**Proof.** (i): By proposition \[6.4.7\] the dimension of \( M \) can be computed as the length of the longest chain \( F_0 \subseteq F_1 \subseteq \cdots \subseteq F_d \) of strict inclusions of faces of \( M_R \). On the other hand, given such a maximal chain, denote by \( r_i \) the dimension of the \( R \)-vector space spanned by \( F_i \); in view proposition \[6.3.8(ii),(iii)\], it is easily seen that \( r_{i+1} - r_i = 1 \) for every \( i = 0, \ldots, d - 1 \). Since \( M_R \cap (-M_R) \) is the minimal face of \( M_R \), we deduce that

\[
\dim M = \dim M^{gp} - \dim M_R \cap (-M_R).
\]

Clearly \( \dim M^{gp} = \text{rk}_Z M^{gp} \); moreover, by proposition \[6.4.7\] the face \( M_R \cap (-M_R) \) is spanned by the image of the face \( M^\times \) of \( M \), whence the assertion.

(ii) is similar: again proposition \[6.3.8(ii),(iii)\] implies that, every face \( F \) of \( M_R \) fits into a maximal strictly ascending chain of faces of \( M_R \), and the length of any such maximal chain is \( \dim M \) by (i).

(iii): Notice that \( \text{rk}_Z M^{gp} > 0 \), by (i). By proposition \[6.4.7(i)\], \( M_R \) is strictly convex, therefore, by proposition \[6.3.21(i)\], we may find a non-zero linear map \( \varphi : M^{gp} \otimes_Z \mathbb{Q} \to \mathbb{Q} \), such that \( M_R \cap \text{Ker } \varphi \otimes_Z \mathbb{R} = \{0\} \) and \( \varphi(M) \subseteq \mathbb{Q}_+ \). A suitable positive integer of \( \varphi \) will do.

(iv): Under the stated assumption, we may regard \( M \) as a submonoid of \( M_R \), and the latter contains no non-zero linear subspaces. By corollary \[6.5.14\] and proposition \[6.3.21(i)\], we may then find \( r \) linearly independent forms \( u_1, \ldots, u_r : M^{gp} \otimes_Z \mathbb{Q} \to \mathbb{Q} \) which are positive on \( M \). It follows that \( u_1 \otimes_Q \mathbb{R}, \ldots, u_r \otimes_Q \mathbb{R} \) generate a polyhedral cone \( \sigma^\vee \subseteq M_R^{\times} \), so its dual cone \( \sigma \subseteq M_R^{gp} \) contains \( M_R \). By construction, \( \sigma \) admits precisely \( r \) extremal rays, say the rays generated by the vectors \( v_1, \ldots, v_r \), which we can pick in \( M_R^{gp} \), in which case they form a basis of the latter \( \mathbb{Q} \)-vector space. Now, every \( x \in M_R \) can be written uniquely in the form \( x = \sum_{i=1}^r a_i v_i \) for certain \( a_1, \ldots, a_r \in \mathbb{Q}_+ \); since \( M \) is finitely generated, we may find an integer \( N > 0 \) independent of \( x \), such that \( Na_i \in \mathbb{N} \) for every \( i = 1, \ldots, r \). In other words, \( M \) is contained in the monoid generated by \( N^{-1}v_1, \ldots, N^{-1}v_r \); the latter is isomorphic to \( \mathbb{N}^{\oplus r} \). \[\square\]

6.4.11. For any monoid \( M \), the dual of \( M \) is the monoid

\[
M^\vee := \text{Hom}_{\text{Mon}}(M, \mathbb{N})
\]

(see \[6.1.1\]). As usual, there is a natural morphism

\[
M \to M^{\vee\vee} : m \mapsto (\varphi \mapsto \varphi(m)) \quad \text{for every } m \in M \text{ and } \varphi \in M^\vee.
\]

We say that \( M \) is reflexive, if this morphism is an isomorphism.

**Proposition 6.4.12.** Let \( M \) be a monoid. We have:

(i) \( M^\vee \) is integral, saturated and sharp.
(ii) If $M$ is finitely generated, $M^\vee$ is fine, and we have a natural identification:

$$(M^\vee)_R \cong (M_R)^\vee$$

(where $(M_R)^\vee$ is defined as in (6.3.1)). Moreover, $\dim M = \dim M^\vee$.

(iii) If $M$ is finitely generated and sharp, we have a natural identification:

$$(M^\vee)^{sp} \cong (M^{sp})^\vee.$$ 

(iv) If $M$ is fine, sharp and saturated, then $M$ is reflexive.

Proof. (i) It is easily seen that the natural group homomorphism

$$(6.4.13) \quad (M^\vee)^{sp} \to (M^{sp})^\vee := \text{Hom}_\mathbb{Z}(M^{sp}, \mathbb{Z})$$

is injective. Now, say that $\varphi \in (M^\vee)^{sp}$ and $N\varphi \in M^\vee$ for some $N \in \mathbb{N}$; we may view $\varphi$ as group homomorphism $\varphi : M^{sp} \to \mathbb{Z}$, and the assumption implies that $\varphi(M) \subset \mathbb{Z} \cap \mathbb{Q}_+ = \mathbb{N}$, whence the contention.

(ii): Indeed, let $x_1, \ldots, x_n$ be a system of generators of $M$. Define a group homomorphism $f : (M^{sp})^\vee \to \mathbb{Z}^{\geq n}$ by the rule: $\varphi \mapsto (\varphi(x_1), \ldots, \varphi(x_n))$ for every $f : M^{sp} \to \mathbb{Z}$. Then $M^\vee = \varphi^{-1}(\mathbb{N}^{\geq n})$, and since $(M^\vee)^{sp}$ is fine, corollary 6.4.2 implies that $M^\vee$ is fine as well. Next, the injectivity of (6.4.13) implies especially that $(M^\vee)^{sp}$ is torsion-free, hence $(6.4.13) \otimes_\mathbb{Z} \mathbb{R}$ is still injective; its restriction to $(M^\vee)_R$ factors therefore through an injective map $f : (M^\vee)_R \to (M^\vee)^{sp}$. The latter map is determined by the image of $M^\vee$, and by inspecting the definitions, we see that $f(\varphi) := \varphi^{sp} \otimes 1$ for every $\varphi \in M^\vee$. To prove that $f$ is an isomorphism, it suffices to show that it has dense image. However, say that $\varphi \in (M^\vee)^{sp}$; then $\varphi : M^{sp} \to \mathbb{R}$ is a group homomorphism such that $\varphi(M) \subset \mathbb{R}_+$. Since $M$ is finitely generated, in any neighborhood of $\varphi$ in $M^{sp}$ we may find some $\varphi' : M^{sp} \to \mathbb{Q}_+$, and then $N\varphi' \in M^\vee$ for some integer $N \in \mathbb{N}$ large enough. It follows that $\varphi$ is in the image of $f$, whence the contention.

The stated equality follows from the chain of identities:

$$\dim M = \dim M_R = \dim (M_R)^\vee = \dim (M^\vee)_R = \dim M^\vee$$

where the first and the last follow from proposition (6.4.7) ii), and the second follows from corollary 6.3.12 ii).

(iii): Let us show first that, under these assumptions, $(6.4.13) \otimes_\mathbb{Z} \mathbb{R}$ is an isomorphism. Indeed, if $M$ is sharp, $(M_R)^\vee$ spans $(M_R^{sp})^\vee$ (corollary 6.3.14 and proposition 6.4.7 i); then the assertion follows from (ii). We deduce that $(M^\vee)^{sp}$ and $(M^{sp})^\vee$ are free abelian groups of the same rank, hence we may find a basis $\varphi_1, \ldots, \varphi_r$ of $(M^\vee)^{sp}$ (resp. $\psi_1, \ldots, \psi_r$ of $(M^{sp})^\vee$), and positive integers $N_1, \ldots, N_r$ such that $(6.4.13)$ is given by the rule: $\varphi_i \mapsto N_i \psi_i$ for every $i = 1, \ldots, r$. But then necessarily we have $N_i = 1$ for every $i \leq r$, and (iii) follows.

(iv): It is easily seen that $M^\vee = (M_R)^\vee \cap (M^{sp})^\vee$ (notation of (6.4.6)). After dualizing again we find: $M^{\vee\vee} = ((M^\vee)_R)^\vee \cap (M^{\vee^{sp}})^\vee$. From (ii) we deduce that $((M^\vee)_R)^\vee = (M_R)^{\vee\vee} = M_R$ (lemma 6.3.2), and from (iii) we get: $(M^{\vee^{sp}})^\vee = (M^{sp})^{\vee\vee} = M^{sp}$. Hence $M^{\vee\vee} = M_R \cap M^{sp} = M$ (proposition 6.3.22 iii)).

\begin{remark}
(i) Let $M$ be a sharp and fine monoid. Proposition 6.4.12 iii) implies that the natural map

$$\text{Hom}_\text{Mnd}(M, \mathbb{Q}_+)^{sp} \to \text{Hom}_\text{Mnd}(M, \mathbb{Q})$$

is an isomorphism. Indeed, it is easily seen that this map is injective. For the surjectivity, one uses the identification $\text{Hom}_\text{Mnd}(M, \mathbb{Q}) \cong (M^\vee)^{sp} \otimes_\mathbb{Z} \mathbb{Q}$, which follows from loc.cit. (Details left to the reader.)

(ii) For $i = 1, 2$, let $N_i \to N$ be two morphisms of monoids. By general nonsense, we have a natural isomorphism:

$$(N_1 \otimes N_2)^\vee \cong N_1^\vee \otimes_{N^\vee} N_2^\vee.$$
(iii) If \( f_i : M_i \to M \) \((i = 1, 2)\) are morphisms of fine, saturated and sharp monoids, there exists a natural surjection:

\[
M_1^\vee \otimes_{M^\vee} M_2^\vee \to (M_1 \times_M M_2)^\vee
\]

whose kernel is the subgroup of invertible elements. Indeed, set \( P := M_1^\vee \otimes_{M^\vee} M_2^\vee \); in view of (ii) and proposition \[6.4.12\](iv), we have a natural identification \([P^\vee] \congto (M_1 \times_M M_2)^\vee\), and the sought map is its composition with the double duality map \( P \to P^\vee\). Moreover, clearly \( P \) is finitely generated, and it is also integral and saturated, since saturation commutes with colimits. Hence – again by proposition \[6.4.12\](iv) – the double duality map induces an isomorphism \( P/P^\times \congto P^\vee\).

(iv) In the situation of (iii), if \( f_i : M_i \to M \) \((i = 1, 2)\) are epimorphisms, then \([6.4.15]\) is an isomorphism. Indeed, in this case the dual morphisms \( f_i^\vee : M^\vee \to M_i^\vee \) are injective, so that \( P \) is sharp (lemma \[6.1.13]\), whence the claim.

**Theorem 6.4.16.** Let \( M \) be a saturated monoid, such that \( M^\sharp \) is fine. We have:

(i) \( M = \bigcap_{\text{ht } p = 1} M_p \) (where the intersection runs over the prime ideals of \( M \) of height one).

(ii) If moreover, \( \dim M = 1 \), then there is an isomorphism of monoids:

\[ M^\times \times \mathbb{N} \congto M. \]

(iii) Suppose that \( M^{gp} \) is a torsion-free abelian group, and let \( R \) be any normal domain. Then the group algebra \( R[M] \) is a normal domain as well.

*Proof.* (i): Pick a decomposition \( M = M^I \times M^\times \) as in lemma \[6.2.10]\] and notice that \( M^I \) is fine, sharp and saturated. The prime ideals of \( M \) are of the form \( \mathfrak{p} = p_0 \times M^\times \), where \( p_0 \) is a prime ideal of \( M^I \). Then it is easily seen that \( M_\mathfrak{p} = M^I_\mathfrak{p}_0 \times M^\times \). Therefore, the sought assertion holds for \( M \) if and only if it holds for \( M^I \), and therefore we may replace \( M \) by \( M^I \), which reduces to the case where \( M \) is sharp, hence the natural morphism \( \varphi : \log M \to M_\mathfrak{p} \) is injective. In such situation, we have \( M = M_{\mathfrak{p}_R} \cap M^{gp} \) and \( M_\mathfrak{p} = M_{\mathfrak{p}_R} \cap M^{gp} \) for every prime ideal \( \mathfrak{p} \subset M \) (proposition \[6.3.22\](iii) and lemma \[6.2.9\](i))). Thus, we are reduced to showing that

\[ M_{\mathfrak{p}_R} = \bigcap_{\text{ht } \mathfrak{p} = 1} M_{\mathfrak{p}_R}. \]

However, set \( \tau := (M \setminus \mathfrak{p})_\mathfrak{p} \); by inspecting the definitions, one sees that \( M_{\mathfrak{p}_R} = M_\mathfrak{p} + (\tau) \), and proposition \[6.4.7\] shows that \( \tau \) is a facet of \( M_{\mathfrak{p}_R} \), hence \( M_{\mathfrak{p}_R} \) is the half-space denoted \( H_\tau \) in \[6.3.10\]. Then the assertion is a rephrasing of proposition \[6.3.11\](ii).

(ii): Arguing as in the proof of (i), we may reduce again to the case where \( M \) is sharp, in which case \( M = M_{\mathfrak{p}_R} \cap M^{gp} \). The foregoing shows that, in case \( \dim M = 1 \), the cone \( M_{\mathfrak{p}_R} \) is a half-space, whose boundary hyperplane is the only non-trivial face \( \sigma \) of \( M_{\mathfrak{p}_R} \). However, \( \sigma \) is generated by the image of the unique non-trivial face of \( M \), i.e. by \( M^\times = \{1\} \) (proposition \[6.4.7\](ii)), hence \( \sigma = \{0\} \), so \( M_{\mathfrak{p}_R} \) is a half-line. Now, let \( u : M^{gp} \to \mathbb{R} \) be a non-zero linear form, such that \( u(M) \geq 0 \), and \( x_1, \ldots, x_n \) a system of non-zero generators for \( M \); say that \( u(x_i) \) is the least of the values \( u(x_i) \), for \( i = 1, \ldots, n \). Since \( M \) is saturated, it follows easily that every value \( u(x_i) \) is an integer multiple of \( u(x_1) \) (proposition \[6.3.22\](iii)), and then \( x_1 \) is a generator for \( M \), so \( M \simeqto \mathbb{N} \).

(iii): To begin with, \( R[M] \subset R[M^{gp}] \), and since \( M^{gp} \) is torsion-free, it is clear that \( [M^{gp}] \) is a domain, hence the same holds for \( R[M] \). Furthermore, from (i) we derive: \( R[M] = \bigcap_{\text{ht } \mathfrak{p} = 1} R[M_\mathfrak{p}] \), hence it suffices to show that \( R[M_\mathfrak{p}] \) is normal whenever \( \mathfrak{p} \) has height one. However, we have \( R[M_\mathfrak{p}] \simeqto R[M^\times_\mathfrak{p}] \otimes R[\mathbb{N}] \) in light of (ii), and since \( M^\times_\mathfrak{p} \) is torsion free, it is a filtered colimit of a family of free abelian groups of finite rank, so everything is clear. \( \square \)
Example 6.4.17. Let $M$ be a fine, sharp and saturated monoid of dimension 2.

(i) By corollary [6.4.10(i)] and example [6.3.16], we see that $M$ admits exactly two facets, which are fine saturated monoids of dimension one; by theorem [6.4.16(ii)] each of these facets is generated by an element, say $e_i$ (for $i = 1, 2$). From proposition [6.3.22(iii)] it follows that $Q_+e_1 \oplus Q_+e_2 = M_Q$. Especially, we may find an integer $N > 0$ large enough, such that:

$$Ne_1 \oplus Ne_2 \subset M \subset \mathbb{N}\frac{e_1}{N} \oplus \mathbb{N}\frac{e_2}{N}.$$

(ii) Moreover, clearly $e_1$ and $e_2$ are unimodular elements of $M^{sp}$ (i.e. they generate direct summands of the latter free abelian group of rank 2). We may then find a basis $f_1, f_2$ of $M^{sp}$ with $e_1 = f_1$, and $e_2 = af_1 + bf_2$, where $a, b \in \mathbb{Z}$ and $(a, b) = 1$. After replacing $f_2$ by some element of the form $cf_2 + df_1$ with $c \in \{1, -1\}$ and $d \in \mathbb{Z}$, we may assume that $b > 0$ and $0 \leq a < b$. Clearly, such a normalized pair $(a, b)$ determines the isomorphism class of $M$, since $M_{R}$ is the strictly convex cone of $M_{R}^{sp}$ whose extremal rays are generated by $e_1$ and $e_2$, and $M = M^{sp} \cap M_{R}$.

(iii) More precisely, suppose that $M'$ is another fine, sharp and saturated monoid of dimension 2, and $\phi : M \rightarrow M'$ an isomorphism. Pick a basis $f'_1, f'_2$ of $M^{sp}$ and a normalized pair $(a', b')$ as in (ii), such that $e'_1 := f_1$ and $e'_2 := af'_1 + bf'_2$ generate the two facets of $M'$. Clearly, $\phi$ must send a facet of $M$ onto a facet of $M'$; we distinguish two possibilities:

- either $\phi(e_1) = e'_1$ and $\phi(e_2) = e'_2$, in which case we get $\phi(f_2) = b^{-1}(a' - a)f'_1 + b^{-1}b'f'_2$;
- or else $\phi(e_1) = e'_2$, and $\phi(e_2) = e'_1$, in which case we get $\phi(f_2) = b^{-1}(1 - aa')f'_1 + b^{-1}b'af_2$.

It follows again that $b' \in \mathbb{Z}$, so $b = b'$, arguing as in the previous case. Moreover, $0 \leq a' < b$, and $1 - aa' \in \mathbb{Z}$. In other words, the class of $a'$ in the group $(\mathbb{Z}/b\mathbb{Z})^\times$ is the inverse of the class of $a$.

Conversely, it is easily seen that if $M'$ is as above, $f'_1, f'_2$ is a basis of $M^{sp}$, and the two facets of $M'$ are generated by $f'_1$ and $a'f'_1 + b'f'_2$, for a pair $(a', b')$ normalized as in (ii), and such that $aa' \equiv 1 \pmod{b}$, then there exists an isomorphism $M \sim M'$ of monoids (details left to the reader). Hence, set $(\mathbb{Z}/b\mathbb{Z})^\times := (\mathbb{Z}/b\mathbb{Z})^\times / \sim$, where $\sim$ denotes the smallest equivalence relation such that $[a] \sim [a]^{-1}$ for every $[a] \in (\mathbb{Z}/b\mathbb{Z})^\times$. We conclude that there exists a natural bijection between the set of isomorphism classes of fine, sharp and saturated monoids of dimension 2, and the set of pairs $(b, [a])$, where $b > 0$ is an integer, and $[a] \in (\mathbb{Z}/b\mathbb{Z})^\times$.

6.4.18. Let $A$ be a ring, $P$ a monoid. Recall that $m_p$ is the maximal (prime) ideal of $P$ (see [6.1.10]). The $m_p$-adic filtration of $P$ is the descending sequence of ideals:

$$\cdots \subset m_p^3 \subset m_p^2 \subset m_p$$

where $m_p^n$ is the $n$-th power of $m$ in the monoid $\mathcal{P}(P)$ (see [6.1.1]). It induces a $m_p$-adic filtration $\text{Fil}_n M$ on any $P$-module $M$ and any $A[P]$-algebra $B$, defined by letting $\text{Fil}_n M := m_p^n M$ and $\text{Fil}_n B := A[m_p^n] \cdot B$, for every $n \in \mathbb{N}$.

Lemma 6.4.19. Suppose that $P$ is finite. We have:

(i) The $m_p$-adic filtration is separated on $P$.

(ii) If $P$ is sharp, $P \setminus m_p^\infty$ is a finite set, for every $n \in \mathbb{N}$.

Proof. (i): Indeed, choose $A$ to be a non-zero noetherian ring, set $J := \cap_{n \geq 0} A[m_p^n]$ and notice that $J$ is generated by $m_p^\infty := \cap_{n \in \mathbb{N}} m_p^n$. On the other hand, $J$ is annihilated by an element of $1 + A[m_p]$ ([100 Th.8.9]). Thus, suppose $x \in m_p^\infty$, and pick $y \in A[m_p]$ such that $(1 - y)x = 0$; we may write $y = a_1 t_1 + \cdots + a_r t_r$ for certain $a_1, \ldots, a_r \in A$ and $t_1, \ldots, t_r \in m_p$. Therefore $x = a_1 x t_1 + \cdots + a_r x t_r$ in $A[P]$, which is absurd, since $P$ is integral.

Assertion (ii) is immediate from the definition.
6.4.20. Keep the assumptions of lemma 6.4.19. It turns out that $P$ can actually be made into a graded monoid, albeit in a non-canonical manner. We proceed as follows. Let $\varepsilon : P \to P^{\text{sat}}$ the inclusion map, $T \subset P^{\text{sat}}$ the torsion subgroup, set $Q := P^{\text{sat}}/T$, and let $\pi : P^{\text{sat}} \to Q$ be the natural surjection. We may regard $\log Q$ as a submonoid of the polyhedral cone $Q_{\mathbb{R}}$, lying in the vector space $Q_{\mathbb{R}}^\ast$, as in (6.4.6). Since $Q_{\mathbb{R}}$ is a rational polyhedral cone, the same holds for $Q_{\mathbb{Q}}$, hence we may find a $\mathbb{Q}$-linear form $\gamma : \log Q^{\text{gp}} \otimes \mathbb{Q} \to \mathbb{Q}$, which is non-negative on $\log Q$, and such that $Q_{\mathbb{R}} \cap \text{Ker} \gamma \otimes \mathbb{R} = 0$, i.e. the $\mathbb{R}$-vector space spanned by the image of $Q^\ast$. If we multiply $\gamma$ by some large positive integer, we may achieve that $(\log P) \subset \mathbb{N}$. We set:

$$\text{gr}_n^\gamma P := (\gamma \circ \pi \circ \varepsilon)^{-1}(n) \quad \text{for every } n \in \mathbb{N}.$$ 

It is clear that $\text{gr}_n^\gamma P \cdot \text{gr}_m^\gamma P \subset \text{gr}_{n+m}^\gamma P$, hence

$$P = \bigsqcup_{n \in \mathbb{N}} \text{gr}_n^\gamma P$$

is a $\mathbb{N}$-graded monoid, and consequently:

$$A[P] = \bigoplus_{n \in \mathbb{N}} A[\text{gr}_n^\gamma P]$$

is a graded $A$-algebra. Moreover, it is easily seen that $\text{gr}_n^\gamma P = P^\times$. More generally, for $x \in P$, let $\mu(x)$ be the maximal $n \in \mathbb{N}$ such that $x \in m_n^\gamma$; then there exists a constant $C \geq 1$ such that:

$$\gamma(x) \geq \mu(x) \geq C^{-1}\gamma(x) \quad \text{for every } x \in P$$

so that the $m_P$-adic filtration and the filtration defined by $\text{gr}_n^\gamma P$, induce the same topology on $P$ and on $A[P]$. As a corollary of these considerations, we may state the following “regularity criterion” for fine monoids:

**Proposition 6.4.21.** Let $P$ be an integral monoid such that $P^\ast$ is fine. Then we have

$$\text{rk}_P m_P/m_P^2 \geq \dim P$$

(notation of example 4.8.18) and the equality holds if and only if $P^\ast$ is a free monoid.

**Proof.** (Notice that $m_P/m_P^2$ is a free pointed $P^\times$-module, since $P^\times$ obviously acts freely on $m_P \setminus m_P^2$. Since $m_P/m_P^2 = (m_P/m_P^2) \otimes_P P^\times$, we may replace $P$ by $P^\times$, and assume from start that $P$ is sharp and fine. Then, the rank of $m_P/m_P^2$ equals the cardinality of the set $\Sigma := \text{m}_P \setminus m_P^2$, which is finite, by lemma 6.4.19. We have a surjective morphism of monoids $\varphi : \mathbb{N}^{(\Sigma)} \to P$, that sends the basis of $\mathbb{N}^{(\Sigma)}$ bijectively onto $\Sigma \subset P$ (corollary 6.1.12). The sought inequality follows immediately, and it is also clear that we have equality, in case $P$ is free. Conversely, if equality holds, $\varphi^{\text{gp}}$ must be a surjective group homomorphism between free abelian group of the same finite rank (corollary 6.4.10(i)), so it is an isomorphism, and then the same holds for $\varphi$. 

**Proposition 6.4.22.** Let $P$ be a fine and sharp monoid, $A$ a noetherian local ring. Set $S_P := 1 + A[m_P]$; then we have:

$$\dim S_P^{-1} A[P] = \dim A + \dim P.$$

**Proof.** To begin with, the assumption that $P$ is sharp implies that $S_P^{-1} A[P]$ is local. Next, notice that $A[P]$ is a free $A$-module, hence the natural map $A \to S_P^{-1} A[P]$ is a flat and local ring homomorphism. Let $k$ be the residue field of $A$; in view of [100 Th.15.1(ii)], we deduce:

$$\dim S_P^{-1} A[P] = \dim A + \dim S_P^{-1} k[P].$$

Hence we are reduced to showing the stated identity for $A = k$. However, clearly $S_P^{-1} k[P] = k[P]_m$, where $m$ is the maximal ideal generated by the image of $m_P$, hence it suffices to apply claim [11.6.36(ii) and corollary 6.4.10(i), to conclude. 

6.4.23. Let $A$ be a ring, and $P$ a fine and sharp monoid. We define:

$$A[[P]] := \lim_{n \in \mathbb{N}} A(P/m_P^n).$$

Alternatively, this is the completion of $A[P]$ for its $A[m_P]$-adic topology. In view of the finiteness properties of the $m_P$-adic filtration (lemma 6.4.19(ii)), one may present $A[[P]]$ as the ring of formal infinite sums $\sum_{\sigma \in P} a_\sigma \cdot \sigma$, with arbitrary coefficients $a_\sigma \in A$, where the multiplication and addition are defined in the obvious way. Moreover, we may use a morphism of monoids $\gamma : \log P \to \mathbb{N}$ as in (6.4.20), to see that:

$$A[[P]] = \prod_{n \in \mathbb{N}} A[\text{gr}_{n}^\gamma P]$$

where $A[\text{gr}_{n}^\gamma P] \cdot A[\text{gr}_{m}^\gamma P] \subseteq A[\text{gr}_{n+m}^\gamma P]$ for every $m, n \in \mathbb{N}$. So any element $x \in A[[P]]$ can be decomposed as an infinite sum

$$x = \sum_{n \in \mathbb{N}} \text{gr}_{n}^\gamma x.$$

The term $\text{gr}_{0}^\gamma x \in \text{gr}_{0}^\gamma A = A$ does not depend on the chosen $\gamma$ : it is the constant term of $x$, i.e. the image of $x$ under the natural projection $A[[P]] \to A$.

**Corollary 6.4.25.** Let $P$ be a fine and sharp monoid, $A$ a noetherian local ring. Then:

(i) For any local morphism $P \to A$ (see (6.1.10)), we have the inequality:

$$\dim A \leq \dim A/m_P A + \dim P.$$

(ii) $\dim A[P] = \dim A[[P]] = \dim A + \dim P$.

**Proof.** (i): Set $A_0 := A/m_P A$, and $B := S^{-1}_P A_0 P$, where $S_P \subset A_0 P$ is the multiplicative subset $1 + A_0 P/m_P P$; if we denote by $\text{gr}_A$ (resp. $\text{gr}_B$) the graded $A_0$-algebra associated to the $m_P$-adic filtration on $A$ (resp. on $B$), we have a natural surjective homomorphism of graded $A_0$-algebras:

$$\text{gr}_B \to \text{gr}_A.$$

Hence $\dim A = \dim \text{gr}_A \leq \dim \text{gr}_B = \dim B$, by [100 Th.15.7]. Then the assertion follows from proposition 6.4.22.

(ii): Set $B := S^{-1}_P A[P]$ and let $m_A$ (resp $m_B$) be the maximal ideal of $A$ (resp. of $B$); notice that $A[[P]]$ is the $(m_P B)$-adic completion of the local noetherian ring $B$, so $A[[P]]$ is a local noetherian ring as well, with maximal ideal $n := m_A[[P]] + A[[m_P]]$, and the $n$-adic completion of $A[[P]]$ is naturally isomorphic to the $m_B$-adic completion $B^\wedge$ of $B$. Hence we get

$$\dim A[[P]] = \dim B^\wedge = \dim B$$

so the second identity follows from proposition 6.4.22. Next, clearly we have $\dim A \geq \dim B$. On the other hand, let $q \subseteq A[P]$ be any prime ideal, set $p := q \cap A$ and denote by $\kappa$ the residue field of the local ring $A_p$; with this notation, [100 Th.15.1(ii)] says that

$$\dim A[P]_q = \dim A_p + \dim A[P]_q \otimes_A \kappa = \dim A_p + \dim \kappa[P]_q \leq \dim A + \dim \kappa[P]$$

so the assertion follows from [11.6.36(ii) and corollary 6.4.10(i)].

\hfill \square

6.4.26. Now we wish to state and prove the combinatorial versions of the Artin-Rees lemma, and of the local flatness criterion (see [100 Th.22.3]). Namely, let $P$ be a pointed monoid, such that $P^d$ is finitely generated; let also $(A, m_A)$ be a local noetherian ring, $N$ a finitely generated $A$-module, and consider a morphism of pointed monoids:

$$\alpha : P \to (A, \cdot)$$

The following is our version of the Artin-Rees lemma:
Lemma 6.4.27. In the situation of (6.4.26), let \( J \subset P \) be an ideal, \( M \) a finitely generated \( P \)-module, \( M_0 \subset M \) a submodule. Then there exists \( c \in \mathbb{N} \) such that:

\[
J^n M \cap M_0 = J^{n-c}(J^c M \cap M_0) \quad \text{for every } n > c.
\]

Proof. Set \( \overline{M} := M/P^\infty \), \( \overline{M}_0 := M_0/P^\infty \) and \( \overline{J} := J/P^\infty \), the set-theoretic quotients for the respective natural \( P^\infty \)-actions. Notice that \( \overline{J} \) is an ideal of \( P^\infty \) and \( \overline{M}_0 \subset \overline{M} \) is an inclusion of \( \overline{P} \)-modules. Moreover, any set of generators of the ideal \( \overline{J} \) (resp. of the \( P^\infty \)-module \( \overline{M}_0 \)) lifts to a set of generators for \( J \) (resp. for the \( P \)-module \( M_0 \)). Furthermore, it is easily seen that (6.4.28) is equivalent to the identity \( \overline{J} \cap \overline{M}_0 = \overline{J}^{n-c}(\overline{J}^c \overline{M} \cap \overline{M}_0) \). Hence, we are reduced to the case where \( P = P^\infty \) is a finitely generated monoid. Then \( \mathbb{Z}[P] \) is noetherian, \( \mathbb{Z}[M] \) is a \( \mathbb{Z}[P] \)-module of finite type, and we notice that:

\[
\mathbb{Z}[J^n M \cap M_0] = J^n \mathbb{Z}[M] \cap \mathbb{Z}[M_0] \quad \text{and} \quad \mathbb{Z}[J^{n-c}(J^c M \cap M_0)] = J^{n-c}(J^c \mathbb{Z}[M] \cap \mathbb{Z}[M_0]).
\]

Thus, the assertion follows from the standard Artin-Rees lemma [100, Th.8.5].

Proposition 6.4.29. In the situation of (6.4.26), suppose moreover that \( P^\infty \) is fine (see remark 4.8.14(vi)), and let \( m_\alpha := \alpha^{-1}m_A \). Then the following conditions are equivalent:

(a) \( N \) is \( \alpha \)-flat (see definition 6.1.35).
(b) \( \text{Tor}^\mathbb{Z}(P)_i(N, \mathbb{Z}(M)) = 0 \) for every \( i > 0 \) and every integral pointed \( P \)-module \( M \).
(c) \( \text{Tor}^\mathbb{Z}(P)_i(N, \mathbb{Z}(P/m_\alpha)) = 0 \).
(d) The natural map:

\[
(m^n_\alpha/m^{n+1}_\alpha) \otimes_P N \to m^n_\alpha N/m^{n+1}_\alpha N
\]

is an isomorphism of \( A \)-modules, for every \( n \in \mathbb{N} \) (notation of (6.1.34)).

Proof. The assertion (a)\( \Rightarrow \)(b) is just a restatement of proposition 6.1.41(i), and holds in greater generality, without any assumption on either \( A \) or the pointed integral monoid \( P \). Also, obviously (b)\( \Rightarrow \)(c). As for the remaining assertions, let \( S := \alpha^{-1}(A^\times) \); since the localization \( P \to S^{-1}P \) is flat, the natural maps:

\[
\text{Tor}^\mathbb{Z}(P)_i(N, \mathbb{Z}(M)) \to \text{Tor}^\mathbb{Z}(S^{-1}P)_i(N, \mathbb{Z}(S^{-1}M))
\]

are isomorphisms, for every \( i \in \mathbb{N} \) and every \( P \)-module \( M \). Also, notice that the two \( P \)-modules appearing in (d) are actually \( S^{-1}P \)-modules (and the natural map is \( \mathbb{Z}(S^{-1}P) \)-linear). Hence, we can replace everywhere \( P \) by \( S^{-1}P \), which allows to assume that \( \alpha \) is local, i.e. \( m_\alpha = m_P \).

(c)\( \Rightarrow \)(d): For every \( n \in \mathbb{N} \), we have a short exact sequence of pointed \( P \)-modules:

\[
0 \to m^n_P/m^{n+1}_P \to P/m^{n+1}_P \to P/m^n_P \to 0.
\]

It is easily seen that \( m^n_P/m^{n+1}_P \) is a free \( P/m_P \)-module (in the category of pointed modules), so the assumption implies that \( \text{Tor}^\mathbb{Z}(P)_i(N, m^n_P/m^{n+1}_P) = 0 \) for every \( n \in \mathbb{N} \). By looking at the induced long Tor-sequences, we deduce that the natural map

\[
\text{Tor}^\mathbb{Z}(P)_i(N, P/m^n_P) \to \text{Tor}^\mathbb{Z}(P)_i(N, P/m^n_P)
\]

is injective for every \( n \in \mathbb{N} \). Then, a simple induction shows that, under assumption (c), all these modules vanish. The latter means that the natural map:

\[
m^n_P \otimes_P N \to m^n_P N
\]

is an isomorphism, for every \( n \in \mathbb{N} \). We consider the commutative ladder with exact rows:

\[
\begin{array}{ccccccc}
m^{n+1}_P \otimes_P N & \longrightarrow & m^n_P \otimes_P N & \longrightarrow & (m^n_P/m^{n+1}_P) \otimes_P N & \longrightarrow & 0 \\
\downarrow & & \downarrow & & \downarrow & & \\
m^{n+1}_P N & \longrightarrow & m^n_P N & \longrightarrow & m^n_P N/m^{n+1}_P N & \longrightarrow & 0.
\end{array}
\]
By the foregoing, the two left-most vertical arrows are isomorphisms, hence the same holds for the right-most, whence (c).

(d)⇒(c): We have to show that the natural map \( u : m_p \otimes_P N \to m_pN \) is an isomorphism. To this aim, we consider the \( m_P \)-adic filtrations on these two modules; for the associated graded modules one gets:

\[
\text{gr}_n(m_pN) = m^n_pN/m^{n+1}_pN \quad \text{gr}_n(m_p \otimes_P N) = (m^n_p/m^{n+1}_p) \otimes_P N
\]

for every \( n \in \mathbb{N} \); whence maps of \( A \)-modules:

\[
\text{gr}_n(m_p \otimes_P N) \xrightarrow{\text{gr}_n u} \text{gr}_n(m_pN).
\]

which are isomorphism by assumption. To conclude, it suffices to show:

**Claim 6.4.30.** For every ideal \( I \subset P \), the the \( A \)-module \( I \otimes_P N \) is \( m_pA \)-adically separated.

**Proof of the claim.** Indeed, notice that the ideal \( I/P^i \subset P^i \) is finitely generated (proposition 6.1.9(ii)), hence the same holds for \( I \), so \( I \otimes_P N \) is a finitely generated \( A \)-module. Then the contention follows from [100, Th.8.10]. □

(c)⇒(b): We argue by induction on \( i \). For \( i = 1 \), suppose first that \( M = P/I \) for some ideal \( I \subset P \) (notice that any such quotient is an integral pointed \( P \)-module); in this case, the assertion to prove is that the natural map \( v : I \otimes_P N \to IN \) is an isomorphism. However, consider the \( m_P \)-adic filtration on \( P/I \); for the associated graded module we have:

\[
\text{gr}_n(P/I) = (m^n_p \cup I)/(m^{n+1} \cup I) \quad \text{for every } n \in \mathbb{N}
\]

and it is easily seen that this is a free pointed \( P^\times \)-module, for every \( n \in \mathbb{N} \). Hence, by inspecting the long exact Tor-sequences associated to the exact sequences

\[
0 \to \text{gr}_n(P/I) \to P/(m^{n+1}_p \cup I) \to P/(m^n_p \cup I) \to 0
\]

our assumption (c), together with a simple induction yields:

\[
(6.4.31) \quad \text{Tor}^\mathbb{Z}(P)_{i-1}(N, \mathbb{Z}\langle P/(m^n_p \cup I) \rangle) \quad \text{for every } n \in \mathbb{N}.
\]

Now, fix \( n \in \mathbb{N} \); in light of lemma 6.4.27 there exists \( k \geq n \) such that \( m^k_p \cap I \subset m^n_pI \). We deduce surjective maps of \( A \)-modules:

\[
I \otimes_P N \to \frac{I}{m^k_p \cap I} \otimes_P N \to \frac{I}{m^k_p} \otimes_P N \to \frac{I}{m^n_p} \otimes_P N.
\]

On the other hand, (6.4.31) says that the natural map \( (m^k_p \cup I) \otimes_P N \to (m^n_p \cup I)N \) is an isomorphism, so the same holds for the induced composed map:

\[
\frac{I}{m^k_p \cap I} \otimes_P N \cong \frac{m^k_p \cup I}{m^k_p} \otimes_P N \to \frac{(m^k_p \cup I)N}{m^n_pN}.
\]

Consequently, the kernel of \( v \) is contained in \( m^k_p(I \otimes_P N) \); since \( n \) is arbitrary, we are reduced to showing that the \( m_P \)-adic filtration is separated on \( I \otimes_P N \), which is claim 6.4.30.

Next, again for \( i = 1 \), let \( M \) be an arbitrary integral \( P \)-module. In view of remark 6.1.28(i), we may assume that \( M \) is finitely generated; moreover, remark 6.1.28(ii), together with an easy induction further reduces to the case where \( M \) is cyclic, in which case, according to remark 6.1.28(iii), \( M \) is of the form \( P/I \) for some ideal \( I \), so the proof is complete in this case.

Finally, suppose \( i > 1 \) and assume that the assertion is already known for \( i - 1 \). We may similarly reduce to the case where \( M = P/I \) for some ideal \( I \) as in the foregoing; to conclude, we observe that:

\[
\text{Tor}^\mathbb{Z}(P)_{i-1}(N, \mathbb{Z}\langle P/I \rangle) \simeq \text{Tor}^\mathbb{Z}(P)_{i-1}(N, \mathbb{Z}\langle I \rangle).
\]

Since obviously \( I \) is an integral \( P \)-module, the contention follows. □
As a corollary, we have the following combinatorial going-down theorem, which is proved in the same way as its commutative algebra counterpart.

**Corollary 6.4.32.** In the situation of (6.4.26), assume that \( P^q \) is fine, and that \( A \) is \( \alpha \)-flat. Let \( p \subset q \) be two prime ideals of \( P \), and \( q' \subset A \) a prime ideal such that \( q = \alpha^{-1}q' \). Then there exists a prime ideal \( p' \subset q' \) such that \( p = \alpha^{-1}p' \).

**Proof.** Let \( \beta : P_q \rightarrow A_{q'} \) be the morphism induced by \( \alpha \); it is easily seen that \( A_{q'} \) is \( \beta \)-flat, and moreover \( (P_q)^2 = (P_{q'})^2 \) is still fine (Lemma 6.1.21(iv)). Hence we may replace \( \alpha \) by \( \beta \), which (in view of (6.1.10)) allows to assume that \( q \) (resp. \( q' \)) is the maximal ideal of \( P \) (resp. of \( A \)). Next, let \( P_0 := P/pA \) and denote by \( \alpha_0 : P_0 \rightarrow A_0 \) the morphism induced from \( \alpha \); it is easily seen that \( A_0 \) is \( \alpha_0 \)-flat : for instance, the natural map \( (m_p^0/m_p^{1+}) \otimes_A A_0 \rightarrow m_{p^0}A_0/m_{p^{1}}A_0 \) is of the type \( f \otimes_A A_0 \), where \( f \) is the map in proposition 6.4.29(c), thus if the latter is bijective, so is the former. Moreover \( P_0^q \) is a quotient of \( P^q \), hence it is again fine. Therefore we may replace \( P \) by \( P_0 \) and \( A \) by \( A_0 \), which allows to further assume that \( p = \{0\} \), and it suffices to show that there exists a prime ideal \( q' \subset A \), such that \( \alpha^{-1}q' = \{0\} \). Set \( \Sigma := P \setminus \{0\} \); it is easily seen that the natural morphism \( P \rightarrow \Sigma^{-1}P \) is injective; moreover, its cokernel \( C \) (in the category of pointed \( P \)-modules) is integral, so that \( \text{Tor}_{1}(\Sigma, \mathbb{Z}(C)) = 0 \) by assumption. It follows that the localization map \( A \rightarrow \Sigma^{-1}A \) is injective, especially \( \Sigma^{-1}A \neq \{0\} \), and therefore it contains a prime ideal \( q'' \). The prime ideal \( q' := q'' \cap A \) will do. \( \square \)

### 6.4.33. Fractional ideals.

Let \( P \) be an integral monoid. A fractional ideal of \( P \) is a \( P \)-submodule \( I \subset P^{\mathbb{P}} \) such that \( I \neq \emptyset \) and \( x \cdot I \subset P \) for some \( x \in P \). Clearly the union and the intersection of finitely many fractional ideals, are again fractional ideals. We may also define the product of two fractional ideals \( I_1, I_2 \subset P^{\mathbb{P}} \); namely, the subset

\[
I_1I_2 := \{ xy \mid x \in I_1, y \in I_2 \} \subset P^{\mathbb{P}}
\]

which is again a fractional ideal, by an easy inspection. If \( I \) is a fractional ideal of \( P \), we say that \( I \) is *finitely generated*, if it is such, when regarded as a \( P \)-module. For any two fractional ideals \( I_1, I_2 \), we let

\[
(I_1 : I_2) := \{ x \in P^{\mathbb{P}} \mid x \cdot I_2 \subset I_1 \}.
\]

It is easily seen that \((I_1 : I_2) \) is a fractional ideal of \( P \) (if \( x \in I_2 \) and \( yI_1 \subset P \), then clearly \( xy(I_1 : I_2) \subset P \)). We set

\[
I^{-1} := (P : I) \quad \text{and} \quad I^* := (I^{-1})^{-1} \quad \text{for every fractional ideal} \ I \subset P^{\mathbb{P}}.
\]

Clearly \( J^{-1} \subset I^{-1} \), whenever \( I \subset J \), and \( I \subset I^* \) for all fractional ideals \( I, J \). We say that \( I \) is *reflexive* if \( I = I^* \). We remark that \( I^{-1} \) is reflexive, for every fractional ideal \( I \subset P^{\mathbb{P}} \). Indeed, we have \( I^{-1} \subset (I^{-1})^* \), and on the other hand \((I^{-1})^* = (I^*)^{-1} \subset I^{-1} \). It follows that \( I^* \) is reflexive, for every fractional ideal \( I \). Moreover, \( I^* \subset J^* \), whenever \( I \subset J \); especially, \( I^* \) is the smallest reflexive fractional ideal containing \( I \). Notice furthermore, that \( aI^{-1} = (a^{-1})I^{-1} \) for every \( a \in P^{\mathbb{P}} \); therefore, \( aI^* = (aI)^* \), for every fractional ideal \( I \) and \( a \in P^{\mathbb{P}} \).

**Lemma 6.4.34.** Let \( P \) be any integral monoid, \( I, J \subset P^{\mathbb{P}} \) two fractional ideals. Then:

(i) \( (IJ)^* = (I^*J^*)^* \).

(ii) \( I^* \) is the intersection of the invertible fractional ideals of \( P \) that contain \( I \) (see definition 4.8.6(iv)).

**Proof.** (i): Since \( IJ \subset I^*J^* \), we have \((IJ)^* \subset (I^*J^*)^* \). To show the converse inclusion, it suffices to check that \( I^*J^* \subset (IJ)^* \), since \((IJ)^* \) is reflexive, and \((I^*J^*)^* \) is the smallest reflexive fractional ideal containing \( I^*J^* \). Now, let \( a \in I \) be any element; we get \( aI^* = (aJ)^* \subset (IJ)^* \), so \( IJ^* \subset (IJ)^* \), and therefore \((IJ)^* \subset (IJ)^* \). Lastly, let \( b \in J^* \) be any element; we get \( bI^* = (bI)^* \subset (IJ)^* \), so \( I^*J^* \subset (IJ)^* \), whence the lemma.
(ii): It suffices to unwind the definitions. Indeed, \( a \in P_{\text{gp}} \) lies in \( I^* \) if and only if \( aI^{-1} \subset P \), if and only if \( ab \in P \), for every \( b \in P_{\text{gp}} \) such that \( bI \subset P \). In other words, \( a \in I^* \) if and only if \( a \in b^{-1}P \) for every \( b \in P_{\text{gp}} \) such that \( I \subset b^{-1}P \), which is the contention. \( \square \)

6.4.35. Let \( P \) be any integral monoid. We denote by \( \text{Div}(P) \) the set of all reflexive fractional ideals of \( P \). We define a composition law on \( \text{Div}(P) \) by the rule:

\[
I \circ J := (IJ)^* \quad \text{for every } I, J \in \text{Div}(P).
\]

It follows easily from lemma 6.4.34(i) that \( \circ \) is an associative law; indeed we may compute:

\[
(I \circ J) \circ K = ((IJ)^* K)^* = (IK)^* = (I(JK))^* = I \circ (J \circ K)
\]

for every \( I, J, K \in \text{Div}(P) \). Clearly \( I \circ J = J \circ I \) and \( P \circ I = I \), for every \( I, J \in \text{Div}(P) \), so \( (\text{Div}(P), \circ) \) is a commutative monoid. Notice as well that if \( I \subset P \), then also \( I^* \subset P \) (lemma 6.4.34(ii)), so the subset of all reflexive fractional ideals contained in \( P \) is a submonoid \( \text{Div}_+(P) \subset \text{Div}(P) \).

Example 6.4.36. Let \( A \) be an integral domain, and \( K \) the field of fractions of \( A \). Classically, one defines the notion of fractional ideal: see e.g. [100, p.80] and [28, Ch.VII, §1, no.1], but notice that the definitions in these two references differ slightly, as the zero ideal is a fractional ideal according to the latter, but not according to the former. Additionally, one has a notion of reflexive fractional ideal of \( A \), which are also called divisorial fractional ideals in [28, Ch.VII, §1, no.1]. In our terminology, these are understood as follows. Set \( A' := A \cap K^\times \), and notice that the monoid \( (A', \cdot) \) is naturally isomorphic to the integral pointed monoid \( A'_0 \). Then a fractional ideal of \( A \) is an \( A'_0 \)-submodule of \( K^\times = K \) of the form \( I_0 \), where \( I \subset K^\times \) is a fractional ideal of \( A' \). Likewise one may define the reflexive fractional ideals of \( A \). The set \( \text{Div}(A) \) of all reflexive fractional ideals of \( A \) is then endowed with the unique monoid structure, such that the map \( \text{Div}(A') \to \text{Div}(A) \) given by the rule \( I \mapsto I_0 \) is an isomorphism of monoids.

Lemma 6.4.37. Let \( P \) be an integral monoid, and \( G \subset P^\times \) a subgroup. We have:

(i) The rule \( I \mapsto I/G \) induces a bijection from the set of fractional ideals of \( P \) to the set of fractional ideals of \( P/G \).

(ii) A fractional ideal \( I \) of \( P \) is reflexive if and only if the same holds for \( I/G \).

(iii) The rule \( I \mapsto I/G \) defines an isomorphism of monoids

\[ \text{Div}(P) \xrightarrow{\sim} \text{Div}(P/G). \]

(iv) If \( P_{\text{eff}} \) is fine, every fractional ideal of \( P \) is finitely generated.

Proof. The first assertion is left to the reader. Next, we remark that \( I^{-1}/G = (I/G)^{-1} \) and \( (IJ)/G = (I/G) \cdot (J/G) \), for every fractional ideals \( I, J \) of \( P \), which imply immediately assertions (ii) and (iii). Lastly, suppose that \( P_{\text{eff}} \) is finitely generated, and let \( I \) be any fractional ideal of \( P \); pick \( x \in I^{-1} \); since \( P \) is integral, \( I \) is finitely generated if and only if the same holds for \( xI \). Hence, in order to show (iv), we may assume that \( I \subset P \), in which case the assertion follows from proposition 6.1.9(ii) and lemma 6.1.17(i.a). \( \square \)

In order to characterize the monoids \( P \) such that \( \text{Div}(P) \) is a group, we make the following:

Definition 6.4.38. Let \( P \) be an integral monoid, and \( a \in P_{\text{gp}} \) any element.

(a) We say that \( a \) is power-bounded, if there exists \( b \in P \) such that \( a^n b \in P \) for all \( n \in \mathbb{N} \).

(b) We say that \( P \) is completely saturated, if all power-bounded elements of \( P_{\text{gp}} \) lie in \( P \).

Example 6.4.39. Let \( (\Gamma, \leq) \) be an ordered abelian group, and set \( \Gamma^+ := \{ \gamma \in \Gamma \mid \gamma \leq 1 \} \). Then \( \Gamma^+ \) is always a saturated monoid, but it is completely saturated if and only if the convex rank of \( \Gamma \) is \( \leq 1 \) (see [59, Def.6.1.20]). The proof shall be left as an exercise for the reader.
Proposition 6.4.40. Let \( P \) be an integral monoid. We have:

(i) \((\text{Div}(P), \odot)\) is an abelian group if and only if \( P \) is completely saturated.

(ii) If \( P \) is fine and saturated, then \( P \) is completely saturated.

(iii) Let \( A \) be a Krull domain, and set \( A' := A \setminus \{0\} \). Then \((A', \cdot)\) is a completely saturated monoid.

Proof. (i): Suppose that \( I \in \text{Div}(I) \) admits an inverse \( J \) in the monoid \((\text{Div}(P), \odot)\), and notice that \( I \odot I^{-1} \subset P \); it follows easily that \( I \odot (J \cup I^{-1})^* = P \), hence \( I^{-1} \subset J \), by the uniqueness of the inverse. On the other hand, if \( J \) strictly contains \( I^{-1} \), then \( IJ \) strictly contains \( P \), which is absurd. Thus, we see that \( \text{Div}(P) \) is a group if and only if \( I \odot I^{-1} = P \) for every \( I \in \text{Div}(P) \).

Now, suppose first that \( P \) is completely saturated. In view of lemma 6.4.34(ii), we are reduced to showing that \( P \) is contained in every invertible fractional ideal containing \( I^{-1} \). Hence, say that \( I^{-1} \subset aP \) for some \( a \in P^{\text{gp}} \); equivalently, we have \( a^{-1}I^{-1} \subset P \), i.e. \( a^{-1}I^{-1} \subset I^{-1} \), and then \( a^{-k}I^{-1} \subset I^{-1} \) for every integer \( k \in \mathbb{N} \). Say that \( b \in I^{-1} \) and \( c \in I^* \); we conclude that \( a^{-k}bc \in P \) for every \( k \in \mathbb{N} \), so \( a^{-1} \in P \), by assumption, and finally \( P \subset aP \), as required.

Conversely, suppose that \( \text{Div}(P) \) is a group, and let \( a \in P^{\text{gp}} \) be any power-bounded element. By definition, this means that the \( P \)-submodule \( I \) of \( P^{\text{gp}} \) generated by \((a^k \mid k \in \mathbb{N})\) is a fractional ideal of \( P \). Then \( I^{-1} \) is a reflexive fractional ideal, and by assumption \( I^{-1} \) admits an inverse, which must be \( I^* \), by definition. On the other hand, by construction we have \( aI \subset I \), hence \( aI^* = (aI)^* \subset I^* \). We deduce that \( aP = a(I^* \odot I^{-1}) = aI^* \odot I^{-1} \subset I^* \odot I^{-1} = P \), i.e. \( a \in P \), as stated.

(ii) is a special case of the following:

Claim 6.4.41. Let \( P \) be any fine and saturated monoid, \( M \subset P^{\text{gp}} \) a non-empty finitely generated \( P \)-submodule, and \( a \in P^{\text{gp}} \) an element such that \( aM \subset M \). Then \( a \in P \).

Proof of the claim. Pick any \( m \in M \), and denote by \( M' \subset M \) the submodule generated by \((a^km \mid k \in \mathbb{N})\). According to proposition 6.1.9(i), there exists \( N \geq 0 \) such that \( M' \) is generated by the finite system \((a^km \mid k = 0, \ldots, N)\). Especially, \( a^{N+1}m \in M' \), and therefore there exist \( x \in P \) and \( i \leq N \) such that \( a^{N+1}m = a^imx \) in \( M \); it follows that \( a^{N+1-i} \in P \), and finally \( a \in P \), since \( P \) is saturated.

(iii): See [100, §12] for the basic generalities on Krull domains. One is immediately reduced to the case where \( A \) is a valuation ring whose value group \( \Gamma \) has rank \( \leq 1 \). Taking into account (i) and lemma 6.4.37, it then suffices to show that the monoid \( A'/A^{\text{gp}} \) is completely saturated. However, the latter is isomorphic to the submonoid \( \Gamma^+ \) of elements \( \leq 1 \) in \( \Gamma \), so the assertion follows from example 6.4.39.

\[ \square \]

6.4.42. Let \( \varphi : P \to Q \) be a morphism of integral monoids, and \( I \) any fractional ideal of \( P \); notice that \( IQ := \varphi^{\text{gp}}(I)Q \subset Q^{\text{gp}} \) is a fractional ideal of \( Q \). Moreover, the identities

\[
(I_1 \cup I_2)Q = I_1Q \cup I_2Q \quad (I_1I_2)Q = (I_1Q) \cdot (I_2Q)
\]

are immediate from the definitions. Likewise, if \( A \) an integral domain and \( \alpha : P \to (A \setminus \{0\}, \cdot) \) a morphism of monoids, then the \( A \)-submodule \( IA := \alpha^{\text{gp}}(I)A \) of the field of fractions of \( A \) is a fractional ideal of the ring \( A \) (in the usual commutative algebraic meaning: see example 6.4.36), and we have corresponding identities:

\[
(I_1 \cup I_2)A = I_1A + I_2A \quad (I_1I_2)A = (I_1A) \cdot (I_2A)
\]

for all fractional ideals \( I_1, I_2 \subset P^{\text{gp}} \).

Lemma 6.4.43. In the situation of 6.4.42., suppose that \( \varphi \) is flat and \( A \) is \( \alpha \)-flat, and let \( I, J, J' \subset P^{\text{gp}} \) be three fractional ideals, with \( I \) finitely generated. Then we have:

(i) \((J : I)Q = (JQ : IQ) \) and \((J : I)A = (J : IA)\).

(ii) Especially, if \( I \) is reflexive, the same holds for \( IQ \) and \( IA \) (see example 6.4.36).
(iii) Suppose furthermore that \( A \) is local, and \( \alpha \) is a local morphism. Then \( JA = J'A \) if and only if \( J = J' \).

(iv) If \( P \) is fine, the rule \( I \mapsto IQ \) and \( I \mapsto IA \) define morphisms of monoids
\[
\text{Div}(\varphi) : \text{Div}(P) \to \text{Div}(Q) \quad \text{Div}(\alpha) : \text{Div}(P) \to \text{Div}(A)
\]
(where \( \text{Div}(A) \) is defined as in example 6.4.36), and \( \text{Div}(\alpha) \) is injective, if \( \alpha \) is local and \( A \) is a local domain.

**Proof.** (i): Say that \( I = a_1P \cup \ldots \cup a_nP \) for elements \( a_1, \ldots, a_n \in P^{gp} \). Then
\[
(J : I) = a_1^{-1}J \cap \ldots \cap a_n^{-1}J \quad \text{and} \quad (JQ : IQ) = a_1^{-1}JQ \cap \ldots \cap a_n^{-1}JQ
\]
and likewise for \( (J : I)A \), hence the assertion follows from an easy induction, and the following

**Claim 6.4.44.** For any two fractional ideals \( J_1, J_2 \subset P \), we have \( (J_1 \cap J_2)Q = J_1Q \cap J_2Q \) and \( (J_1 \cap J_2)A = J_1A \cap J_2A \).

**Proof of the claim.** Pick any \( x \in P \) such that \( xJ_1, xJ_2 \subset P \); since \( P \) is an integral monoid, and \( A \) is an integral domain, it suffices to show that \( x(J_1 \cap J_2)Q = xJ_1Q \cap xJ_2Q \) and likewise for \( x(J_1 \cap J_2)A \), and notice that \( x(J_1 \cap J_2) = xJ_1 \cap xJ_2 \). We may thus assume that \( J_1 \) and \( J_2 \) are ideals of \( P \), in which case the assertion is lemma 6.1.38.

(ii): Suppose that \( I \) is reflexive; from (i) we deduce that \( (\langle IA \rangle)^{-1} = IA \). The assertion is an immediate consequence, once one remarks that, for any fractional ideal \( J \subset A \), there is a natural isomorphism of \( A \)-modules : \( J^{-1} \stackrel{\sim}{\rightarrow} J' : = \text{Hom}_A(J, A) \). Indeed, the isomorphism assigns to any \( x \in J^{-1} \) the map \( \mu_x : J \to A : a \mapsto xa \) for every \( a \in J \) (details left to the reader).

(iii): We may assume that \( JA = J'A \), and we prove that \( J = J' \), and by replacing \( J' \) by \( J \cup J' \), we may assume that \( J \subset J' \). Then the contention follows easily from lemma 6.1.37.

(iv): This is immediate from (i) and (iii).

**Remark 6.4.45.** In the situation of lemma 6.4.43(iv), obviously \( \text{Div}(\varphi) \) restricts to a morphism of submonoids :
\[
\text{Div}_+(\varphi) : \text{Div}_+(P) \to \text{Div}_+(Q).
\]

6.4.46. Next, suppose that \( P \) is fine and saturated, and let \( I \subset P^{gp} \) be any fractional ideal. Then theorem 6.4.16(i) easily implies that :
\[
I^{-1} = \bigcap_{\text{ht } p = 1} (I_p)^{-1}
\]
where the intersection – running over the prime ideals of \( P \) of height one – is taken within \( \text{Hom}_P(I, P^{gp}) \), which naturally contains all the \( (I_p)^{-1} \). The structure of the fractional ideals of \( P_p \) when \( \text{ht } p = 1 \) is very simple : quite generally, theorem 6.4.16(ii) easily implies that if \( \dim P = 1 \), then all fractional ideals are cyclic, and then clearly they are reflexive. On the other hand, \( I \) is finitely generated, by lemma 6.4.37(iv). We deduce that \( I \) is reflexive if and only if :
\[
I = \bigcap_{\text{ht } p = 1} I_p.
\]
Indeed, suppose that (6.4.47) holds; then we have \( I^* = \bigcap_{\text{ht } p = 1} (I_p^{-1})^{-1} = \bigcap_{\text{ht } p = 1} I_p \), since we have just seen that \( I_p \) is a reflexive fractional ideal of \( P_p \), for every prime ideal \( p \) of height one.

**Proposition 6.4.48.** Let \( P \) be a fine and saturated monoid, and denote by \( D \subset \text{Spec } P \) the subset of all prime ideals of height one. Then the mapping :
\[
\mathbb{Z}^\oplus D \to \text{Div}(P) : \sum_{\text{ht } p = 1} n_p[p] \mapsto \bigcap_{\text{ht } p = 1} m_p^{n_p}
\]
is an isomorphism of abelian groups.
Proof. Here $m_{P_p} \subset P_p$ is the maximal ideal, and for $n \geq 0$, the notation $m^n_{P_p}$ means the usual $n$-th power operation in the monoid $\mathcal{P}(P^\text{sp})$, which we extend to all integers $n$, by letting $m^n_{P_p} := m_{P_p}^n$ whenever $n < 0$.

In order to show that (6.4.49) is well defined, set $I := \bigcap_{\text{ht } p = 1} m^n_p$. Pick, for every $p$ such that $n_p < 0$, an element $x_p \in p$, and set $y_p := x_p^{-n_p}$; if $n_p \geq 0$, set $y_p := 1$. Then it is easy to check (using theorem 6.4.16(i)) that $\prod_{\text{ht } p = 1} y_p$ lies in $I^{-1}$, hence $I$ is a fractional ideal. Next, for given $p, p' \in D$, notice that $(P_p)p' = P^\text{sp}$; it follows that

(6.4.50) \[ I_p = m^n_p \quad \text{for every } p \in D \]

therefore $I$ is reflexive. Furthermore, it is easily seen (from theorem 6.4.16(ii)), that every reflexive ideal of $P_p$ is of the form $m^n_p$ for some integer $n$, and moreover $m^n_p = m^n_{P_p}$ if and only if $n = m$. Then (6.4.47) implies that the mapping (6.4.49) is surjective, and the injectivity follows from (6.4.50). It remains to check that (6.4.49) is a group homomorphism, and to this aim we may assume – in view of lemma 6.4.43(iv) – that $\dim P = 1$, in which case the assertion is immediate. \[ \square \]

6.4.51. A morphism $\varphi : I \to J$ of fractional ideals of $P$ is, by definition, a morphism of $P$-modules. Let $x, y \in I$ be any two elements; we may find $a, b \in P$ such that $ax = by$ in $I$, and therefore $a\varphi(x) = \varphi(ax) = \varphi(by) = b\varphi(y)$; thus, $\varphi(y) = (b^{-1}a) \cdot \varphi(x) = (x^{-1}y) \cdot \varphi(x)$. This shows that, for every morphism $\varphi : I \to J$ of fractional ideals, there exists $c \in P^\text{sp}$ such that $\varphi(x) = cx$ for every $x \in I$. Especially, $I \simeq J$ if and only if there exists $a \in P^\text{sp}$ such that $I = aJ$. Likewise one may characterize the morphisms and isomorphisms of fractional ideals of an integral domain. We denote

$\text{Div}(P)$

the set of isomorphism classes of reflexive fractional ideals of $P$. From the foregoing, it is clear that if $I \simeq I'$, we have $I \odot J \simeq I' \odot J$ for every $J \in \text{Div}(P)$; therefore the composition law of $\text{Div}(P)$ descends to a composition law for $\text{Div}(P)$, which makes it into a (commutative) monoid, and if $P$ is completely saturated, then $\text{Div}(P)$ is an abelian group. We also deduce an exact sequence of monoids

(6.4.52) \[ 1 \to P^\times \to P^\text{sp} \xrightarrow{j_P} \text{Div}(P) \to \text{Div}(P) \to 1 \]

where $j_P$ is given by the rule $A : a \mapsto aP$ for every $a \in P$; especially, $j_P$ restricts to a morphism of monoids

$j_P : P \to \text{Div}(P).$

Likewise, we define $\text{Div}(A)$, for any integral domain $A$; see example 6.4.36. Moreover, in the situation of (6.4.42), we see from lemma (6.4.43(iv)) that if $\alpha$ is local, $P$ is fine, $A$ is $\alpha$-flat, and $\varphi$ is flat, then $\text{Div}(\varphi)$ and $\text{Div}(\alpha)$ descend to well defined morphisms of monoids

$\text{Div}(\varphi) : \text{Div}(P) \to \text{Div}(Q) \quad \text{Div}(\alpha) : \text{Div}(P) \to \text{Div}(A).$

**Proposition 6.4.53.** Let $P$ be a fine and saturated monoid, $I, J \subset P^\text{sp}$ two fractional ideals, $A$ a local integral domain, and $\alpha : P \to (A, \cdot)$ a local morphism of monoids. We have:

(i) $(I : I) = P$.

(ii) Suppose that $A$ is $\alpha$-flat. Then $IA \simeq JA$ if and only if $I \simeq J$. Especially, in this case $\text{Div}(\alpha)$ is an injective map.

**Proof.** (i): Clearly it suffices to show that $(I : I) \subset P$. Hence, say that $x \in (I : I)$, and pick any $a \in I$; it follows that $x^n a \in P$ for every $n > 0$; in the additive group $\log P^\text{sp}$ we have therefore the identity $n \cdot \log(x) + \log(a) \in \log P$, so $\log(x) + n^{-1} \log(a) \in (\log P)_\mathbb{R}$ for every $n > 0$. Since $(\log P)_\mathbb{R}$ is a convex polyhedral cone in $(\log P^\text{sp})_\mathbb{R}$, we deduce that $x \in (\log P)_\mathbb{R} \cap (\log P^\text{sp}) = \log P$ (proposition 6.3.22(iii)), as claimed.
(ii): We may assume that $IA$ is isomorphic to $JA$, and we show that $I$ is isomorphic to $J$. Indeed, the assumption means that $a(IA) = JA$ for some $x \in \text{Frac}(A)$; therefore, $a \in (JA : IA)$ and $a^{-1} \in (IA : JA)$, so

$$A = (IA : JA) \cdot (JA : IA) = ((I : J) \cdot (J : I))A$$

by virtue of lemma 6.4.43(i). Since $A$ is local, it follows that there exist $a \in (I : J)$ and $b \in (J : I)$ such that $\alpha(ab) \in A^\times$, whence $ab \in P^\times$, since $\alpha$ is local. It follows easily that $I = aJ$, as asserted. □

**Example 6.4.54.** (i) Let $P$ be a fine and saturated monoid, and $D \subset \text{Spec} P$ the subset of all prime ideals of height one; for every $p \in D$, denote

$$\nu_p : P \to P_p^\sharp \twoheadrightarrow \mathbb{N}$$

the composition of the localization map, and the natural isomorphism resulting from theorem 6.4.16(ii). A simple inspection shows that the isomorphism (6.4.49) identifies the map $j_P$ of (6.4.52) with the morphism of monoids

$$\nu_P : P^\text{gp} \to \mathbb{Z}^{\oplus D} \quad x \mapsto (\nu_p^\text{gp}(x) \mid p \in D).$$

With this notation, the isomorphism (6.4.49) is the map given by the rule:

$$k_\bullet \mapsto \nu_P^{-1}(k_\bullet + \mathbb{N}^{\oplus D}) \quad \text{for every } k_\bullet \in \mathbb{Z}^{\oplus D}.$$

(ii) Suppose now that $P$ is sharp and $\dim P = 2$, in which case $D = \{p_1, p_2\}$ contains exactly two elements. According to example 6.4.17(ii), we may find a basis $f_1, f_2$ of $P^\text{gp}$, such that the two facets $P \setminus p_1$ and $P \setminus p_2$ of $P$ are generated respectively by $e_1 := f_1$ and $e_2 := a f_1 + b f_2$, for some $a, b \in \mathbb{N}$, with $a < b$ and $(a, b) = 1$. It follows easily that $P$ is a submonoid of the free monoid

$$Q := \mathbb{N}e_1' \oplus \mathbb{N}e_2' \quad \text{where } e_1' := b^{-1}e_1 \text{ and } e_2' := b^{-1}e_2$$

and $Q^\text{gp}/P^\text{gp} \simeq \mathbb{Z}/b\mathbb{Z}$ (details left to the reader). The induced map $\text{Spec } Q \to \text{Spec } P$ is a homeomorphism; especially $Q$ admits two prime ideals $q_1, q_2$ of height one, so that $q_i \cap P = p_i$ for $i = 1, 2$, whence − by proposition 6.4.48 − a natural isomorphism

$$s^* : \text{Div}(Q) \twoheadrightarrow \text{Div}(P)$$

and notice that $j_Q : Q^\text{gp} \to \text{Div}(Q)$ is the isomorphism given by the rule: $e_i' \mapsto q_i$ for $i = 1, 2$. Moreover, we have commutative diagrams of monoids:

$$\begin{array}{ccc}
P & \xrightarrow{s} & Q \\
\text{v}_{q_1} \downarrow & & \downarrow \text{v}_{q_2} \\
\mathbb{N} & \xrightarrow{t_i} & \mathbb{N} \\
\end{array} \quad (i = 1, 2).$$

Clearly, $Q \setminus q_i$ is the facet generated by $e_i'$, so $v_{q_i}$ is none else than the projection onto the direct factor $\mathbb{N}e_{i-i}$, for $i = 1, 2$. In order to compute $v_{p_i}$, it then suffices to determine $t_i$, or equivalently $t_i^\text{gp}$. However, set $\tau_i := v_{q_i}^\text{gp} \circ s^\text{gp}$; clearly $\tau_1(f_2) = \tau_1(e_2' - ae_1') = 1$, so $\tau_1$ is surjective. Also, $\tau_2(f_1) = b$ and $\tau_2(f_2) = -a$, so $\tau_2$ is surjective as well; therefore both $t_1$ and $t_2$ are the identity endomorphism of $\mathbb{N}$. Summing up, we find that

$$j_P = s^* \circ j_Q \circ s^\text{gp}$$

and the morphism $\nu_P$ is naturally identified with $s^\text{gp} : P^\text{gp} \to Q^\text{gp}$. Especially, we have obtained a natural isomorphism

$$\overline{\text{Div}}(P) \twoheadrightarrow \mathbb{Z}/b\mathbb{Z}.$$

We may then rephrase in more intrinsic terms the classification of example 6.4.17(iii): namely the isomorphism class of $P$ is completely determined by the datum of $\overline{\text{Div}}(P)$ and the equivalence class of the height one prime ideals of $P$ in the quotient set $\overline{\text{Div}}(P)^{\dagger}$ defined as in loc.cit.
(iii) In the situation of (ii), a simple inspection yields the following explicit description of all reflexive fractional ideals of $P$. Recall that such ideals are of the form

$$I_{k_1,k_2} := m_i^{k_1} \cap m_j^{k_2} = \{ x \in P^{\text{gp}} \mid v_{p_1}(x) \geq k_1, v_{p_2}(x) \geq k_2 \}$$

where $m_i$ is the maximal ideal of $P_{p_i}$, and $k_i \in \mathbb{Z}$, for $i = 1, 2$. Then

$$I_{k_1,k_2} = \{ x_1 e_1 + x_2 e_2 \mid x_1, x_2 \in b^{-1} \mathbb{Z}, x_1 \geq b^{-1} k_2, x_2 \geq b^{-1} k_1 \} \cap P^{\text{gp}}$$

for all $k_1, k_2 \in \mathbb{Z}$.

With this notation, the cyclic reflexive ideals are then those of the form

$$(x_1 f_1 + x_2 f_2) P = I_{x_2 b, x_1 b - x_2 a} \quad \text{with } x_1, x_2 \in \mathbb{Z}.$$ 

Especially, we see that the classes of $p_1 = I_{0,1}$ and $p_2 = I_{1,0}$ are both of order $b$ in $\overline{\text{Div}}(P)$.

**Lemma 6.4.55.** Let $P$ be a finite and saturated monoid of dimension 2, and denote by $b$ the order of the finite cyclic group $\overline{\text{Div}}(P)$. We have :

$$m^{[b/2]}_P \subseteq I \cdot I^{-1} \quad \text{for every } I \in \text{Div}(P)$$

(where $[b/2]$ denotes the largest integer $\leq b/2$).

**Proof.** Notice first that the assertion holds for a given $I \in \text{Div}(P)$, if and only if it holds for $xI$, for any $x \in P^{\text{gp}}$. If $b = 1$, then $P = \mathbb{N}^{\oplus 2}$, in which case $\overline{\text{Div}}(P) = 0$, so every reflexive fractional ideal of $P$ is isomorphic to $P$, and the assertion is clear. Hence, assume that $b > 1$; let $p_1, p_2$ be the two prime ideals of height one of $P$, and define $Q, e_1, e_2$ and $I_{k_1,k_2}$ for every $k_1, k_2 \in \mathbb{Z}$, as in example 6.4.54(ii,iii). With this notation, notice that

$$m_P \setminus m_P^{[b/2]} = \{ e_1, e_2 \} \cup \Sigma \quad \text{where } \Sigma \subseteq \{ x_1 e_1 + x_2 e_2 \mid x_1, x_2 \in b^{-1} \mathbb{Z}, 0 \leq x_1, x_2 < 1 \}.$$ 

It follows easily that, for every $i \in \mathbb{N}$, every element of $m_P$ is of the form $x_1 e_1 + x_2 e_2$ with $x_1, x_2 \in b^{-1} \mathbb{N}$ and $\max(x_1, x_2) \geq b^{-1} i$. Hence, let $I \in \text{Div}(P)$ and $x := x_1 e_1 + x_2 e_2 \in m_P^{[b/2]}$, and say that $bx_1 \geq [b/2]$. According to example 6.4.54(iii), we may assume that $I = p_{b-j}^2 = I_{b-j,0}$ for some $j \in \{0, \ldots, b-1\}$. Moreover, notice that the assertion holds for $I$ if and only if it holds for $I^{-1}$, whose class in $\overline{\text{Div}}(P)$ agrees with the class of $p_{b-j}^{b-j}$. Clearly, either $j \leq [b/2]$ or $b - j \leq [b/2]$; hence, we may assume that $j \in \{0, \ldots, [b/2]\}$. Thus, $P \subset I^{-1}$, and $I \subset I \cdot I^{-1}$, and clearly $x \in I$, so we are done in this case. The case where $bx_2 \geq [b/2]$ is dealt with in the same way, by writing $I = p_j^2$ for some non-negative $j \leq [b/2]$ : the details are left to the reader. \hfill \Box

If $f : P \to Q$ is a general morphism of integral monoids, and $I$ a fractional ideal of $Q$, the $P$-module $f^{\text{gp}}(I)$ is not necessarily a fractional ideal of $P$ (for instance, consider the natural map $P \to P^{\text{gp}}$). One may obtain some positive results, by restricting to the class of morphisms introduced by the following :

**Definition 6.4.56.** Let $f : P \to Q$ be a morphism of monoids. We say that $f$ is of Kummer type, if $f$ is injective, and the induced map $f_Q : P_Q \to Q_Q$ is surjective (notation of (6.3.20)).

**Lemma 6.4.57.** Let $f : P \to Q$ be a morphism of monoids of Kummer type, $S_Q \subset Q$ a submonoid, and set $S_P := f^{-1} S_Q$. We have :

(i) The map $\text{Spec } f : \text{Spec } Q \to \text{Spec } P$ is bijective; especially $\dim P = \dim Q$.

(ii) If $Q^\times$ is a torsion-free abelian group, $P$ is the trivial monoid (resp. is sharp) if and only if the same holds for $Q$.

(iii) The induced morphism $S_P^{-1} P \to S_Q^{-1} Q$ is of Kummer type.

(iv) Suppose that $P$ is integral, the unit of adjunction $P \to P^{\text{sat}}$ is of Kummer type.

(vi) If both $P$ and $Q$ are integral, and $P$ is saturated, then $f$ is exact.
Lemma 6.4.61.\(\phi\) seen that, more generally, \(\text{gr}\) is a reflexive fractional ideal of \(P\).

(ii) and (iv) are trivial, and (iii) is an exercise for the reader.

Proof. Clearly, we may replace \(I\) by \(a^{-1}I\), and reduce to the case where \(a = 1\), in which case we have to check that \(\phi^*\) is a reflexive fractional ideal. However, according to example (6.4.54(i)), we may write \(I = v^{-1}_q(k + N^D)\), where \(D \subset \text{Spec} Q\) is the subset of the height one prime ideals, and \(k \in \mathbb{Z}^D\). Set
\[
k' := ([v^{-1}_q]^D) \mid q \in D \}.
\]
where, for a real number \(x\), we let \([x]\) be the smallest integer \(\geq x\). Since \(\text{Spec} \phi\) is bijective (lemma (6.4.57)(i)), the commutative diagrams (6.4.60) imply that \(\phi^* = v^{-1}_q(k' + N^D)\), whence the contention.

Example 6.4.62. Let \(P\) be as in example (6.4.54(ii)), set \(Q := \text{Div}_+(P)\), and take \(\phi := j_P^+: P \rightarrow Q\) (notation of (6.4.51)). The discussion of loc.cit. shows that \(\phi\) is a morphism of Kummer type, and notice that the \(\varphi\)-grading of \(Q\) is indexed by \(Q^\text{sp}/P^\text{sp} = \text{Div}(P)\). Now,
pick any $x \in Q$, and let $\pi \in \overline{\text{Div}}(P)$ be the equivalence class of $x$; by lemma 6.4.61, the $P$-module $\text{gr}_x Q$ is isomorphic to a reflexive fractional ideal of $P$. We claim that the isomorphism class of $\text{gr}_x Q$ is precisely $\pi^{-1}$ (where the inverse is formed in the commutative group $\overline{\text{Div}}(P)$). Indeed, let $a \in P^{\text{sp}}$ be any element; by definition, we have $a \in \varphi^+(x^{-1}\text{gr}_x Q)$ if and only if $\varphi^+(a) \in x^{-1}\text{gr}_x Q$, if and only if $ax \in Q$, if and only if $a \in x^{-1}$, whence the claim. Thus, the family 

$$(\text{gr}_x \text{Div}_+(P) \mid \gamma \in \overline{\text{Div}}(P))$$

is a complete system of representatives for the isomorphism classes of the reflexive fractional ideals of a fine, sharp and saturated monoid $P$ of dimension 2.

**Remark 6.4.63.** Further results on reflexive fractional ideals for monoids, and their divisor class groups can be found in [38].

6.5. Fans. According to Kato ([89, §9]), a fan is to a monoid what a scheme is to a ring. More prosaically, the theory of fans is a reformulation of the older theory of rational polyhedral decompositions, developed in [92].

**Definition 6.5.1.** (i) A monoidal space is a datum $(T, \mathcal{O}_T)$ consisting of a topological space $T$ and a sheaf of monoids $\mathcal{O}_T$ on $T$.

(ii) A morphism of monoidal spaces is a datum 

$$((f, \log f) : (T, \mathcal{O}_T) \to (S, \mathcal{O}_S)$$

consisting of a continuous map $f : T \to S$, and a morphism $\log f : f^*\mathcal{O}_S \to \mathcal{O}_T$ of sheaves of monoids that is local, i.e. whose stalk $(\log f)_t : \mathcal{O}_{S,f(t)} \to \mathcal{O}_{T,t}$ is a local morphism, for every $t \in T$. The strict locus of $(f, \log f)$ is the subset

$$\text{Str}(f, \log f) \subset T$$

consisting of all $t \in T$ such that $(\log f)_t$ is an isomorphism.

(iii) We say that a monoidal space $(T, \mathcal{O}_T)$ is sharp, (resp. integral, resp. saturated) if $\mathcal{O}_T$ is a sheaf of sharp (resp. integral, resp. integral and saturated) monoids.

(iv) For any monoidal space (resp. integral monoidal space) $(T, \mathcal{O}_T)$, the sharpening (resp. the saturation) of $(T, \mathcal{O}_T)$ is the sharp monoidal space $(T, \mathcal{O}_T)^{\sharp} := (T, \mathcal{O}_T^{\sharp})$ (resp. $(T, \mathcal{O}_T)^{\text{sat}} := (T, \mathcal{O}_T^{\text{sat}})$).

It is easily seen that the rule $(T, \mathcal{O}_T) \mapsto (T, \mathcal{O}_T)^{\sharp}$ extends to a functor from the category of monoidal spaces to the full subcategory of sharp monoidal spaces. This functor is right adjoint to the corresponding fully faithful embedding of categories.

Likewise, the functor $(T, \mathcal{O}_T) \mapsto (T, \mathcal{O}_T)^{\text{sat}}$ is right adjoint to the fully faithful embedding of the category of saturated monoidal spaces, into the category of integral monoidal spaces.

6.5.2. Let $P$ be any monoid; for every $f \in P$, let us set

$$D(f) := \{ p \in \text{Spec } P \mid f \notin p \}.$$ 

Notice that $D(f) \cap D(g) = D(fg)$ for every $f, g \in P$. We endow $\text{Spec } P$ with the topology having a basis consisting of the subsets $D(f)$, for every $f \in P$. Notice that $m_P$ is the only closed point of $\text{Spec } P$ (especially, $\text{Spec } P$ is trivially quasi-compact).

By lemma 6.1.14, the localization map $j_f : P \to P_f$ induces an identification $j_f^* : \text{Spec } P_f \simto D(f)$. It is easily seen that $(j_f)^{-1}D(fg) = D(j(g)) \subset \text{Spec } P_f$; in other words, the topology of $\text{Spec } P_f$ agrees with the topology induced from $\text{Spec } P$, via $j_f^*$.

Next, for every $f \in P$ we set :

$$\mathcal{O}_{\text{Spec } P}(D(f)) := P_f.$$
We claim that $\mathcal{O}_{\text{Spec } P}(D(f))$ depends only on the open subset $D(f)$, up to natural isomorphism (and not on the choice of $f$). More precisely, say that $D(f) \subset D(g)$ for two given elements $f, g \in P$; it follows that the image of $g$ in $P_f$ lies outside the maximal ideal $m_{P_f}$, hence $g \in P_f^\times$, and therefore the localization map $j_f : P \to P_f$ factors uniquely through a morphism of monoids:

$$j_{f,g} : P_g \to P_f.$$ 

Likewise, if $D(g) \subset D(f)$ as well, the localization $j_g : P \to P_g$ factors through a unique map $j_{g,f} : P_f \to P_g$, whence the identities:

$$j_{f,g} \circ j_{g,f} \circ j_f = j_f \quad j_{g,f} \circ j_{f,g} \circ j_g = j_g$$

and since $j_f$ and $j_g$ are epimorphisms, we see that $j_{f,g}$ and $j_{g,f}$ are mutually inverse isomorphisms.

6.5.3. Say that $D(f) \subset D(g) \subset D(h)$ for some $f, g, h \in P$; by direct inspection, it is clear that $j_{f,g} \circ j_{g,h} = j_{f,h}$, so the rule $D(f) \mapsto P_f$ yields a well defined presheaf of monoids on the site $\mathcal{E}_P$ of open subsets of $\text{Spec } P$ of the form $D(f)$ for some $f \in P$. Then $\mathcal{O}_{\text{Spec } P}$ is trivially a sheaf on $\mathcal{E}_P$ (notice that if $D(f) = \bigcup_{i \in I} D(g_i)$ is an open covering of $D(f)$, then $D(g_i) = D(f)$ for some $i \in I$). According to [44, Ch.0, §3.2.2] it follows that $\mathcal{O}_{\text{Spec } P}$ extends uniquely to a well defined sheaf of monoids on $\text{Spec } P$, whence a monoidal space $(\text{Spec } P, \mathcal{O}_{\text{Spec } P})$. By inspecting the construction, we find natural identifications:

$$(\mathcal{O}_{\text{Spec } P})_p \sim \sim P_p \quad \text{for every } p \in \text{Spec } P$$

and moreover:

$$P \sim \sim \Gamma(\text{Spec } P, \mathcal{O}_{\text{Spec } P}).$$

It is also clear that the rule

$$(6.5.5) \quad P \mapsto (\text{Spec } P, \mathcal{O}_{\text{Spec } P})$$

defines a functor from the category $\text{Mnd}^\circ$ to the category of monoidal spaces.

**Proposition 6.5.6.** The functor $(6.5.5)$ is right adjoint to the functor:

$$(T, \mathcal{O}_T) \mapsto \Gamma(T, \mathcal{O}_T)$$

from the category of monoidal spaces, to the category $\text{Mnd}^\circ$.

**Proof.** Let $f : P \to \Gamma(T, \mathcal{O}_T)$ be a map of monoids. We define a morphism

$$\varphi_f := (\varphi_f, \log \varphi_f) : (T, \mathcal{O}_T) \to (\text{Spec } P, \mathcal{O}_{\text{Spec } P})$$

as follows. Given $t \in T$, let $f_t : P \to \mathcal{O}_{T,t}$ be the morphism deduced from $f$, and denote by $m_t \subset \mathcal{O}_{T,t}$ the maximal ideal. We set $\varphi_f(t) := f_t^{-1}(m_t)$. In order to show that $\varphi_f$ is continuous, it suffices to prove that $U_s := \varphi_f^{-1}(D(s))$ is open in $M_T$, for every $s \in P$. However, $U_s = \{ t \in T | f_t(s) \in \mathcal{O}_{T,t}^\times \}$, and it is easily seen that this condition defines an open subset (details left to the reader). Next, we define $\log \varphi_f$ on the basic open subsets $D(s)$. Indeed, let $j_s : \Gamma(T, \mathcal{O}_T) \to \mathcal{O}_T(U_s)$ be the natural map; by construction, $j_s \circ f(s)$ is invertible in $\mathcal{O}_T(U_s)$, hence $j_s \circ f$ extends to a unique map of monoids:

$$P_s = \mathcal{O}_{\text{Spec } P}(D(s)) \to \varphi_f \mathcal{O}_T(D(s)).$$

By [44] Ch.0, §3.2.5, the above rule extends to a unique morphism $\mathcal{O}_{\text{Spec } P} \to \varphi_f \mathcal{O}_T$ of sheaves of monoids, whence – by adjunction – a well defined morphism $\log \varphi_f : \varphi_f \mathcal{O}_{\text{Spec } P} \to \mathcal{O}_T$. In order to show that $(\varphi_f, \log \varphi_f)$ is the sought morphism of monoidal spaces, it remains to check that $(\log \varphi_f)_t : P_{\varphi_f(t)} \to \mathcal{O}_{T,t}$ is a local morphism, for every $t \in T$. However, let $i_t : P \to P_{\varphi_f(t)}$ be the localization map; by construction, we have $(\log \varphi_f)_t \circ i_t = f_t$, and the contention is a straightforward consequence.
Conversely, say that \((\varphi, \log \varphi) : (T, \mathcal{O}_T) \to (\text{Spec } P, \mathcal{O}_{\text{Spec } P})\) is a morphism of monoidal spaces; then \(\log \varphi\) corresponds to a unique morphism \(\psi : \mathcal{O}_{\text{Spec } P} \to \varphi_{*} \mathcal{O}_T\), and we set \(f_{\varphi} := \Gamma(\text{Spec } P, \psi) : P \to \Gamma(T, \mathcal{O}_T)\).

By inspecting the definitions, it is easily seen that \(f_{\varphi} = f\) for every morphism of monoids \(f\) as above. To conclude, it remains only to show that the rule \((\varphi, \log \varphi) \mapsto f_{\varphi}\) is injective. However, for a given morphism of monoidal spaces \((\varphi, \log \varphi)\) as above, and every point \(t \in T\), we have a commutative diagram of monoids:

\[
P \xrightarrow{f_{\varphi}} \Gamma(T, \mathcal{O}_T).
\]

\[
P_{\varphi(t)} \xrightarrow{\log \varphi_{t}} \mathcal{O}_{T,t}
\]

Since \(\log \varphi_{t}\) is local, it follows that \(\varphi(t) = (f_{\varphi} \circ j_{t})^{-1}m_{t}\), especially \(f_{\varphi}\) determines \(\varphi : T \to \text{Spec } P\). Finally, since the map \(P \to P_{\varphi(t)}\) is an epimorphism, we see that \(\log \varphi_{t}\) is determined by \(f_{\varphi}\) as well, and the proposition follows. \(\square\)

**Definition 6.5.7.** Let \((T, \mathcal{O}_T)\) be a sharp monoidal space.

(i) We say that \((T, \mathcal{O}_T)\) is an **affine fan**, if there exist a monoid \(P\) and an isomorphism of sharp monoidal spaces \((\text{Spec } P, \mathcal{O}_{\text{Spec } P}) \xrightarrow{\sim} (T, \mathcal{O}_T)\).

(ii) In the situation of (i), if \(P\) can be chosen to be finitely generated (resp. fine), we say that \((T, \mathcal{O}_T)\) is a **finite (resp. fine) affine fan**.

(iii) We say that \((T, \mathcal{O}_T)\) is a **fan**, if there exists an open covering \(T = \bigcup_{i \in I} U_i\), such that the induced sharp monoidal space \((U_i, \mathcal{O}_{T|U_i})\) is an affine fan, for every \(i \in I\). We denote by \(\text{Fan}\) the full subcategory of the category of monoidal spaces, whose objects are the fans.

(iv) In the situation of (iii), if the covering \((U_i \mid i \in I)\) can be chosen, so that \((U_i, \mathcal{O}_{T|U_i})\) is a finite (resp. fine) affine fan for every \(i \in I\), we say that \((T, \mathcal{O}_T)\) is **locally finite (resp. locally fine)**.

(v) We say that the fan \((T, \mathcal{O}_T)\) is **finite (resp. fine)** if it is locally finite (resp. locally fine) and quasi-compact.

(vi) Let \((T, \mathcal{O}_T)\) be a fan. The **simplicial locus** \(T_{\text{sim}} \subset T\) is the subset of all \(t \in T\) such that \(\mathcal{O}_{T,t}\) is a free monoid of finite rank.

**Remark 6.5.8.** (i) For every monoid \(P\), let \(T_P\) denote the affine fan \((\text{Spec } P)^{\dagger}\). In light of proposition \[6.5.6\], it is easily seen that the functor \(P \mapsto T_P\) is an equivalence from the opposite of the full subcategory of sharp monoids, to the category of affine fans.

(ii) Since the saturation functor commutes with localizations (lemma \[6.2.9\](i)), it is easily seen that the saturation of a fan is a fan, and more precisely, the saturation of an affine fan \(T_P\), is naturally isomorphic to \(T_{P^{\text{sat}}}\).

(iii) Let \(Q_1\) and \(Q_2\) be two monoids; since the product \(P \times Q\) is also the coproduct of \(P\) and \(Q\) in the category \(\text{Mnd}\) (see example \[4.8.30\](i)), we have a natural isomorphism in the category of fans:

\[
T_{P \times Q} \xrightarrow{\sim} T_P \times T_Q.
\]

More generally, suppose that \(P \to Q_i\), for \(i = 1, 2\), are two morphisms of monoids. Then we have a natural isomorphism of fans:

\[
T_{Q_1 \otimes P \otimes Q_2} \xrightarrow{\sim} T_{Q_1} \times_{T_P} T_{Q_2}.
\]

From this, a standard argument shows that fibre products are representable in the category of fans.
(iv) Furthermore, lemma 6.1.7(ii) implies that the natural map:
\[ \pi : \text{Spec} \left( P \times Q \right) \to \text{Spec} P \times \text{Spec} Q \]
is a homeomorphism (where the product of Spec \( P \) and Spec \( Q \) is taken in the category of topological spaces and continuous maps).

(v) Moreover, we have natural isomorphisms of monoids:
\[ \mathcal{O}_{\text{Spec} P, \pi^{-1}(s,t)} \cong \mathcal{O}_{\text{Spec} P, s} \times \mathcal{O}_{\text{Spec} Q, t} \quad \text{for every } s \in \text{Spec} P \text{ and } t \in \text{Spec} Q. \]

(vi) For any fan \( T := (T, \mathcal{O}_T) \), and any monoid \( M \), we shall use the standard notation:
\[ T(M) := \text{Hom}_{\text{fan}}(\text{Spec} M, T). \]
 Especially, if \( T \) is an affine fan, say \( T = (\text{Spec} P)^\ast \), then \( T(M) = \text{Hom}_{\text{Mon}}(P, M^\ast) \); for instance, if \( T \) is affine, \( T(\mathbb{N}) \) is a monoid, and \( T(\mathbb{Q}^+)^\text{gp} \) is a \( \mathbb{Q} \)-vector space. Furthermore, by standard general nonsense we have natural identifications of sets:
\[ (T_1 \times T_2)(M) \cong T_1(M) \times_{T(M)} T_2(M) \]
for any pair of \( T \)-fans \( T_1 \) and \( T_2 \), and every monoid \( M \). If \( T, T_1 \) and \( T_2 \) are affine, this identification is also an isomorphism of monoids.

**Example 6.5.9.** (i) The topological space underlying the affine fan \( (\text{Spec} \mathbb{N}, \mathcal{O}_{\text{Spec} \mathbb{N}})^\ast \) consists of two points: \( \text{Spec} \mathbb{N} = \{ \emptyset, \mathfrak{m} \} \), where \( \mathfrak{m} := \mathbb{N} \setminus \{ 0 \} \) is the closed point. The structure sheaf \( \mathcal{O} := \mathcal{O}_{\text{Spec} \mathbb{N}} \) is determined as follows. The two stalks are \( \mathcal{O}_{\emptyset} = \{ 1 \} \) (the trivial monoid) and \( \mathcal{O}_{\mathfrak{m}} = \mathbb{N} \); the global sections are \( \Gamma(\text{Spec} \mathbb{N}, \mathcal{O}) = \mathbb{N} \).

(ii) Let \( (T, \mathcal{O}_T) \) be any fan, \( P \) any monoid, with maximal ideal \( \mathfrak{m}_P \), and \( \varphi : T_P := (\text{Spec} P, \mathcal{O}_{\text{Spec} P})^\ast \to (T, \mathcal{O}_T) \) a morphism of fans. Say that \( \varphi(\mathfrak{m}_P) \in U \) for some affine open subset \( U \subset F \); then \( \varphi(\text{Spec} P) \subset U \), hence \( \varphi \) factors through a morphism of fans \( T_P \to (U, \mathcal{O}_T|_U) \). In view of proposition 6.5.6, such a morphism corresponds to a unique morphism of monoids \( \varphi^\ast : \mathcal{O}_T(U) \to P^\ast \), and then \( \varphi(\mathfrak{m}_P) = \varphi^\ast(\mathfrak{m}_P) \in \mathcal{O}_T(U) = U. \)

The map on stalks determined by \( \varphi \) is the local morphism
\[ \mathcal{O}_{T, \varphi(\mathfrak{m}_P)} \xrightarrow{\sim} \mathcal{O}_T(U)^\varphi(\mathfrak{m}_P) / \mathcal{O}_T(U)^{\varphi(\mathfrak{m}_P)} \to P^\ast \]
obtained from \( \varphi^\ast \) after localization at the prime ideal \( \varphi^{-1}(\mathfrak{m}_P) \).

(iii) For any two monoids \( M \) and \( N \), denote by \( \text{loc.Hom}_{\text{Mon}}(M, N) \) the set of local morphisms of monoids \( M \to N \). The discussion in (ii) leads to a natural identification:
\[ T(P) \xrightarrow{\sim} \coprod_{t \in T} \text{loc.Hom}_{\text{Mon}}(\mathcal{O}_{T,t}, P^\ast) \]
For any monoid \( P \). The support of a \( P \)-point \( \varphi \in T(P) \) is the unique point \( t \in T \) such that \( \varphi \) corresponds to a local morphism \( \mathcal{O}_{T,t} \to P^\ast \).

**Example 6.5.10.** (i) Let \( P \) be any monoid, \( k > 0 \) any integer, set \( T_P := (\text{Spec} P)^\ast \), and let \( k_P : P \to P \) be the \( k \)-Frobenius map of \( P \) (definition 4.8.40(ii)). Then
\[ k_{T_P} := \text{Spec} k_P : T_P \to T_P \]
is a well defined endomorphism inducing the identity on the underlying topological space.

(ii) More generally, let \( F \) be any fan; for every integer \( k > 0 \) we have the \( k \)-Frobenius endomorphism
\[ k_F : F \to F \]
which induces the identity on the underlying topological space, and whose restriction to any affine open subfan \( U \subset F \) is the endomorphism \( k_U \) defined as in (i).
6.5.11. Let $P$ be a monoid, $M$ a $P$-module, and set $T_P := (\text{Spec } P)^\#$. We define a presheaf $M^\sim$ on the site of basic affine open subsets $D(f) \subset \text{Spec } P$ (for all $f \in P$), by the rule:

$$U \mapsto M^\sim(U) := M \otimes_P \mathcal{O}_{T_P}(U)$$

(and for an inclusion $U' \subset U$ of basic open subsets, the corresponding morphism $M^\sim(U) \to M^\sim(U')$ is deduced from the restriction map $\mathcal{O}_{T_P}(U) \to \mathcal{O}_{T_P}(U')$). It is easily seen that $M^\sim$ is a sheaf, hence it extends to a well defined sheaf of $\mathcal{O}_{T_P}$-modules on $T_P$ ([44] Ch.0, §3.2.5). Clearly $\Gamma(T_P, M^\sim) = M$, and the rule $M \mapsto M^\sim$ yields a well defined functor $\text{P-Mod} \to \mathcal{O}_{T_P}\text{-Mod}$, which is left adjoint to the global section functor on $\mathcal{O}_{T_P}$-modules : $\mathcal{M} \mapsto \Gamma(T_P, \mathcal{M})$ (verification left to the reader).

**Definition 6.5.12.** Let $(T, \mathcal{O}_T)$ be a fan, $\mathcal{M}$ a $\mathcal{O}_{T}$-module. We say that $\mathcal{M}$ is quasi-coherent, if there exist an open covering $T = \bigcup_{i \in I} U_i$ of $T$ by affine open subsets, and for each $i \in I$ an $\mathcal{O}_T(U_i)$-module $M_i$ with an isomorphism of $\mathcal{O}_{T[U_i]}$-modules $\mathcal{M}|_{U_i} \sim M_i^\sim$.

**Remark 6.5.13.** (i) Let $(T, \mathcal{O}_T)$ be a fan, $\mathcal{M}$ a quasi-coherent $\mathcal{O}_{T}$-module, and $U \subset T$ be any open subset, such that $(U, \mathcal{O}_{T[U]})$ is an affine fan (briefly : an affine open subfan of $T$). Then, since $U$ admits a unique closed point $t \in U$, it is easily seen that $\mathcal{M}|_U$ is naturally isomorphic to $\mathcal{M}|_{U_t}^\sim$ as a $\mathcal{O}_{T[U_t]}$-module.

(ii) In the same vein, if $\mathcal{M}$ is an invertible $\mathcal{O}_{T}$-module (see definition 4.8.6(iv)), then the restriction $\mathcal{M}|_U$ of $\mathcal{M}$ to any affine open subset, is isomorphic to $\mathcal{O}_{T[U]}$.

(iii) For any fan $(T, \mathcal{O}_T)$, the sheaf of abelian groups $\mathcal{O}^{\text{gp}}_{T}$ is quasi-coherent (exercise for the reader). Suppose that $T$ is integral; then an $\mathcal{O}_T$-submodule $\mathcal{I} \subset \mathcal{O}^{\text{gp}}_{T}$ is called a fractional ideal (resp. a reflexive fractional ideal) of $\mathcal{O}_T$ if $\mathcal{I}$ is quasi-coherent, and $\mathcal{O}(U)$ is a fractional ideal (resp. a reflexive fractional ideal) of $\mathcal{O}_T(U)$, for every affine open subset $U \subset T$.

(iv) Let $P$ be any integral monoid, $I \subset P^{\text{gp}}$ a fractional ideal of $P$, and set $T_P := (\text{Spec } P)^\#$. It follows easily from lemma 6.4.37(i) that $I^\sim \subset \mathcal{O}^{\text{gp}}_{T_P}$ is a fractional ideal of $\mathcal{O}_{T_P}$, and $I^\sim$ is reflexive if and only if $I$ is a reflexive fractional ideal of $P$ (lemma 6.4.37(ii)).

(v) Suppose that $T$ is locally finite; in this case, it follows easily from proposition 6.1.9(ii) that every quasi-coherent ideal of $\mathcal{O}_T$ is coherent. Likewise, if $T$ is also integral, and $\mathcal{I} \subset \mathcal{O}^{\text{gp}}_{T}$ is a (quasi-coherent) fractional ideal of $\mathcal{O}_T$, then $\mathcal{I}$ is coherent, provided the stalks $\mathcal{I}_t$ are finitely generated $\mathcal{O}_{T,t}$-modules, for every $t \in T$. (Details left to the reader.)

**Remark 6.5.14.** (i) Let $T$ be any integral fan. We define a sheaf $\text{Div}^T$ on $T$, by letting $\text{Div}^T(U)$ be the set of all reflexive fraction ideals of $\mathcal{O}_U$, for every open subset $U \subset T$.

(ii) Now, suppose that $T$ is locally fine; in this case, we can endow $\text{Div}^T$ with a natural structure of $T$-monoid, as follows. First, we define a presheaf of monoids on the site $\mathcal{C}_T$ of affine open subsets of $T$ by the rule:

$$U \mapsto \text{Div}^T(U) := (\text{Div}(\mathcal{O}(U)), \odot)$$

(notation of (6.4.35)) and for an inclusion $U' \subset U$ of affine open subset, the corresponding morphism of monoids $\text{Div}^T(U) \to \text{Div}^T(U')$ is deduced from the flat map $\mathcal{O}(U) \to \mathcal{O}(U')$, by virtue of lemma 6.4.43(iv). Arguing as in (6.5.3), we see that $\text{Div}^T$ is a sheaf on $\mathcal{C}_T$, and then [44] Ch.0, §3.2.2] implies that $\text{Div}^T$ extends uniquely to a sheaf of monoids on $T$. It is then clear that the sheaf of sets underlying this $T$-monoid is (naturally isomorphic to) the sheaf defined in (i).

(iii) In the situation of (ii), we have likewise a $T$-submonoid $\text{Div}^T_T \subset \text{Div}^T$ (remark 6.4.45), and we may also define a $T$-monoid $\text{Div}^T_T$ (see (6.4.51)). Moreover, we have the global version of (6.4.52) : namely, the sequence of $T$-monoids

$$1 \to \mathcal{O}^{\text{gp}}_{T} \xrightarrow{\cdot t} \text{Div}^T \to \text{Div}^T \to 1$$
is exact (recall that \( \mathcal{O}^+_T = 1_T \), the initial \( T \)-monoid), and \( j_T \) restricts to a map of \( T \)-monoids
\[
\mathcal{O}_T \to \mathcal{D}iv^+_T.
\]
Indeed, the assertion can be checked on the stalks over each \( t \in T \), where it reduces to the exact sequence (6.4.52) for \( P := \mathcal{O}_{T,t} \). Lastly, we remark that if \( T \) is locally fine and saturated, then \( \mathcal{D}iv_T \) and \( \mathcal{D}iv^+_T \) are abelian \( T \)-groups (proposition 6.4.40(i,ii)).

6.5.15. If \( f : T' \to T \) is a morphism of fans, and \( \mathcal{M} \) is any \( \mathcal{O}_T \)-module, then we define as usual the \( \mathcal{O}_{T'} \)-module :
\[
f^* \mathcal{M} := f^{-1} \mathcal{M} \otimes_{f^{-1} \mathcal{O}_T} \mathcal{O}_{T'}
\]
where \( f^{-1} \mathcal{M} \) denotes the usual sheaf-theoretic inverse image of \( \mathcal{M} \) (so \( f^{-1} \mathcal{O}_T \) means here what was denoted \( f^* \mathcal{O}_T \) in definition 6.5.1(iii)). The rule \( \mathcal{M} \mapsto f^* \mathcal{M} \) yields a left adjoint to the functor
\[
\mathcal{O}_{T'} \text{-Mod} \to \mathcal{O}_T \text{-Mod} \quad \mathcal{N} \mapsto f_* \mathcal{N}
\]
(verification left to the reader). Notice that if \( \mathcal{M} \) is quasi-coherent, then \( f^* \mathcal{M} \) is a quasi-coherent \( \mathcal{O}_{T'} \)-module. Indeed, the assertion is local on \( T' \), hence we are reduced to the case where \( T' = (\text{Spec } P') \) and \( T = (\text{Spec } P) \) for some monoids \( P \) and \( P' \). In this case, the functor
\[
M \mapsto f^*(M^\sim) : P \text{-Mod} \to \mathcal{O}_{T'} \text{-Mod}
\]
is left adjoint to the functor \( \mathcal{M} \mapsto \Gamma(T', \mathcal{M}) \) on \( \mathcal{O}_{T'} \)-modules. The latter functor also admits the left adjoint given by the rule : \( M \mapsto \Gamma(T', M) \otimes_{P} P' \sim \), whence a natural isomorphism of \( \mathcal{O}_{T'} \)-modules :
\[
f^*(M^\sim) \sim (M \otimes_{P} P')^\sim.
\]

6.5.16. Let \( T := (T, \mathcal{O}_T) \) be a fan, \( t \in T \) any point. The height of \( t \) is :
\[
\text{ht}_T(t) := \dim \mathcal{O}_{T,t} \in \mathbb{N} \cup \{+\infty\}
\]
(see definition 6.1.19) and the dimension of \( T \) is \( \dim T := \sup(\text{ht}_T(t) \mid t \in T) \). (If \( T = \emptyset \) is the empty fan, we let \( \dim T := -\infty \).)

Suppose that \( T \) is locally finite; then it follows from (6.5.4) and lemma 6.1.21(iii),(iv) that the height of any point of \( T \) is an integer. Moreover, let \( \overline{U}(t) \subset T \) denote the subset of all points \( x \in T \) which specialize to \( t \) (i.e. such that the topological closure of \( \{x\} \) in \( T \) contains \( t \)); clearly \( \overline{U}(t) \) is the intersection of all the open neighborhoods of \( t \) in \( T \), and we have a natural homeomorphism :
\[
(6.5.17) \quad \text{Spec } \mathcal{O}_{T,t} \sim (\overline{U}(t), \mathcal{O}_{T,\overline{U}(t)}).
\]
Especially, if \( T \) is locally finite, \( U(t) \) is a finite set, and moreover \( U(t) \) is an open subset : indeed, if \( U \subset T \) is any finite affine open neighborhood of \( t \), we have \( U(t) \subset U \), hence \( U(t) \) can be realized as the intersection of the finitely many open neighborhoods of \( t \) in \( U \). In this case, (6.5.17) induces an isomorphism of fans :
\[
(6.5.18) \quad (\text{Spec } \mathcal{O}_{T,t})^2 \sim (U(t), \mathcal{O}_{T,\overline{U}(t)}).
\]
Therefore, for every \( h \in \mathbb{N} \), let \( T_h \subset T \) be the subset of all points of \( T \) of height \( \leq h \); clearly \( U(t) \subset T_h \) whenever \( t \in T_h \), hence the foregoing shows that – if \( T \) is locally finite – \( T_h \) is an open subset of \( T \) for every \( h \in \mathbb{N} \), and \( T = \bigcup_{h \in \mathbb{N}} T_h \).

Notice also that the simplicial locus of a fan \( T \) is closed under generizations. Therefore, \( T_{\text{sim}} \) is an open subset of \( T \), whenever \( T \) is locally finite.

6.5.19. In the situation of remark 6.5.8(v), suppose additionally that \( P \) and \( Q \) are finitely generated. The natural projection \( P \times Q \to P \) induces a morphism \( j : T_P \to T_{P \times Q} \) of affine fans, and it is easily seen that \( j(t) = \pi^{-1}(t, \emptyset) \) for every \( t \in T_P \). It follows that the restriction of \( j \) is a homeomorphism \( U(t) \sim U(j(t)) \) for every \( t \in T_P \), and moreover \( \log j : j^! \mathcal{O}_{T_{P \times Q}} \to \mathcal{O}_{T_P} \) is an isomorphism. We conclude that \( j \) is an open immersion.
6.5.20. Let $P$ be a fine, sharp and saturated monoid, and set $Q := P^\vee$ (notation of 6.4.11). By proposition 6.4.12(iv), we have a natural identification $P \xrightarrow{\sim} Q^\vee$. By proposition 6.4.7(ii) and corollary 6.3.12(ii), the rule

\[(6.5.21) \quad F \mapsto F^* := F^\vee_R \cap P \]

establishes a natural bijection from the faces of $Q$ to those of $P$. For every face $F$ of $Q$, set $p_F := P \setminus F^*$; there follows a natural bijection $F \mapsto p_F$ between the set of all faces of $Q$ and $\text{Spec } P$, such that

\[F \subset F' \iff p_F \subset p_{F'} .\]

Moreover, set $T_P := (\text{Spec } P)^\partial$; we have natural identifications:

\[F^\vee \xrightarrow{\sim} \partial_{T_P,p_F} \quad \text{for every face } F \text{ of } Q \]

under which, the specialization maps $\partial_{T_P,p_{F'}} \to \partial_{T_P,p_F}$ correspond to the restriction maps $(F')^\vee \to F^\vee : \varphi \mapsto \varphi_{F'}$.

**Definition 6.5.22.** Let $T := (T, \partial_T)$ be a fan.

(i) An integral (resp. a rational) partial subdivision of $T$ is a morphism $f : (T', \partial_{T'}) \to T$ of fans such that, for every $t \in T'$, the group homomorphism

\[\log f : \partial_{T',t}^\text{gp} \to \partial_{T,t}^\text{gp} \quad (\text{resp. the } \mathbb{Q}-\text{linear map } (\log f)^{\partial} \otimes_{\mathbb{Z}} 1_{\mathbb{Q}}) \]

is surjective.

(ii) If $f : T' \to T$ is an integral (resp. rational) partial subdivision, and the induced map

\[T'(\mathbb{N}) \to T(\mathbb{N}) \quad (\text{resp. } T'(\mathbb{Q}_+) \to T(\mathbb{Q}_+)) : \varphi \mapsto f \circ \varphi \]

is bijective, we say that $f$ is an integral (resp. a rational) subdivision of $T$.

(iii) A morphism of fans $f : T' \to T$ is finite (resp. proper), if the fibre $f^{-1}(t)$ is a finite (resp. non-empty) set, for every $t \in T$.

(iv) A subdivision $T' \to T$ of $T$ is simplicial, if $T'_{\text{dim}} = T'$.

**Remark 6.5.23.** (i) Let $T$ be any integral fan. Then the counit of adjunction

\[T^\text{sat} \to T \]

is an integral subdivision. This morphism is also a homeomorphism on the underlying topological spaces, in light of 6.2.9(iv).

(ii) Let $f : T' \to T$ be any integral subdivision. Then $f$ restricts to a bijection $T'_0 \xrightarrow{\sim} T_0$ on the sets of points of height zero. Indeed, notice that if $t' \in T'$ is a point of height zero, then $f(t') \in T_0$ since the map $(\log f)^{\partial}_{t'}$ must be local; moreover $\text{loc. } \text{Hom}_{\text{Mnd}}(\partial_{T,t'}, \mathbb{N})$ consists of precisely one element, namely the unique map $\sigma_t : \mathbb{N} \to \{1\}$, and if $t'_1, t'_2 \in T'_0$ have the same image in $T_0$, the sections $\sigma_{t'_1}$ and $\sigma_{t'_2}$ have the same image in $T(\mathbb{N})$, hence they must coincide, so that $t'_1 = t'_2$, as claimed.

(iii) Let $f : T' \to T$ be an integral subdivision of locally fine and saturated fans. In general, the image of a point $t' \in T'$ of height one may have height strictly greater than one. On the other hand, for any $t \in T$ of height one, and any $t' \in f^{-1}(t)$, the map $\mathbb{Z} \xrightarrow{\sim} \partial_{T,t}^\text{gp} \to \partial_{T',t'}^\text{gp}$ must be surjective (theorem 6.4.16(ii)), therefore $\partial_{T',t'}^\text{gp}$ is a cyclic group; however $\partial_{T,t'}$ is also sharp and saturated, so it must be either the trivial monoid $\{1\}$ or $\mathbb{N}$. The first case is excluded by (ii), so $\text{ht}(t') = 1$, and moreover $(\log f)_{t'}$ is an isomorphism (and there exists a unique such isomorphism). Since the induced map $T'(\mathbb{N}) \to T(\mathbb{N})$ is bijective, it follows easily that $f^{-1}(t)$ consists of exactly one point, and therefore $f$ restricts to an isomorphism $f^{-1}(T_1) \xrightarrow{\sim} T_1$.

**Proposition 6.5.24.** Let $f : T' \to T$ be a morphism of fans, with $T'$ locally finite, and consider the following conditions:

(a) The induced map $T'(\mathbb{N}) \to T(\mathbb{N})$ is injective.
(b) For every integral saturated monoid \( P \), the induced map \( T'(P) \to T(P) \) is injective.

(c) \( f \) is a partial rational subdivision.

Then we have: (a) \( \iff \) (b) \( \Rightarrow \) (c).

**Proof.** Obviously (b) \( \Rightarrow \) (a). Conversely, assume that (a) holds, let \( P \) be a saturated monoid, and suppose we have two sections in \( T'(P) \) whose images in \( T(P) \) agree. In light of example 6.5.9(iii), this means that we may find two points \( t'_1, t'_2 \in T' \), such that \( f(t'_1) = f(t'_2) = t \), and two local morphisms of monoids \( \sigma_i : \mathcal{O}_{T', t'_i} \to P/P^\times \) whose compositions with \( \log f_{t'_i} \) (\( i = 1, 2 \)) yield the same morphism \( \mathcal{O}_{T, t} \to P/P^\times \), and we have to show that these maps are equal. In view of lemma 6.2.9(ii), we may then replace \( P \) by \( P/P^\times \), and assume that \( P \) is sharp. Since the stalks of \( \mathcal{O}_{T'} \) are finitely generated, the morphisms \( \sigma_i \) factor through a finitely generated submonoid \( M \subset P \). We may then replace \( P \) by its submonoid \( M^{\text{sat}} \), which allows to assume additionally that \( P \) is finitely generated (corollary 6.4.11(ii)). In this case, we may find an injective map \( j : P \to \mathbb{N}^{\text{gr}} \) (corollary 6.4.10(iv); notice that \( j \) is trivially a local morphism), hence we may replace \( \sigma_i \) by \( j \circ \sigma_i \) (for \( i = 1, 2 \)), after which we may assume that \( P = \mathbb{N}^{\text{gr}} \) for some \( r \in \mathbb{N} \). Let \( \delta : P \to \mathbb{N} \) be the local morphism given by the rule: \( (x_1, \ldots, x_r) \mapsto x_1 + \cdots + x_r \), for every \( x_1, \ldots, x_r \in \mathbb{N} \); the compositions \( \delta \circ \sigma_i \) (for \( i = 1, 2 \)) are two elements of \( T'(\mathbb{N}) \) whose images agree in \( T(\mathbb{N}) \), hence they must coincide by assumption. This implies already that \( t'_1 = t'_2 \). Next, let \( \pi_k : P \to \mathbb{N} \) (for \( k = 1, \ldots, r \)) be the natural projections, and fix \( k \leq r \); the morphisms \( \pi_k \circ \sigma_i \) for \( i = 1, 2 \) are not necessarily local, but they determine elements of \( T'(\mathbb{N}) \) whose images agree again in \( T(\mathbb{N}) \), hence they must coincide. Since \( k \) is arbitrary, we deduce that \( \sigma_1 = \sigma_2 \), as stated.

Next, we suppose that (b) holds, and we wish to show assertion (c); the latter is local on \( F' \), hence we may assume that both \( F \) and \( F' \) are affine, say \( F = (\text{Spec} \ Q)^2 \) and \( F' = (\text{Spec} \ Q')^2 \), with \( Q' \) finitely generated and sharp, and then we are reduced to checking that the map \( Q^{\text{gp}} \otimes_{\mathbb{Z}} Q \to Q^{\text{gp}} \otimes_{\mathbb{Z}} Q \) induced by \( f \) is surjective, or equivalently, that the dual map:

\[
\text{Hom}_{\text{Mnd}}(Q', Q) \to \text{Hom}_{\text{Mnd}}(Q', Q)
\]

is injective. To this aim, we may further assume that \( Q' \) is integral, in which case, by remark 6.4.14(i) we have \( \text{Hom}_{\text{Mnd}}(Q', Q) = \text{Hom}_{\text{Mnd}}(Q', Q')^{\text{gp}} \); the contention is an easy consequence. \( \square \)

6.5.25. In light of proposition 6.5.24 we may ask whether the surjectivity of the map on \( P \)-points induced by a morphism \( f \) of fans can be similarly characterized. This turns out to be the case, but more assumptions must be made on the morphism \( f \), and also some additional restrictions must be imposed on the type of monoid \( P \). Namely, we shall consider monoids of the form \( \Gamma_+ \), where \( (\Gamma, \leq) \) is any totally ordered abelian group, and \( \Gamma_+ \subset \Gamma \) is the subgroup of all elements \( \leq 1 \) (where \( 1 \in \Gamma \) denotes the neutral element). With this notation, we have the following:

**Proposition 6.5.26.** Let \( f : T' \to T \) be a finite partial integral subdivision, with \( T \) locally finite. The following conditions are equivalent:

(a) The induced map \( T'(\mathbb{N}) \to T(\mathbb{N}) \) is surjective.

(b) For every totally ordered abelian group \( (\Gamma, \geq) \), the induced map \( T'(\Gamma_+) \to T(\Gamma_+) \) is surjective.

**Proof.** Obviously, we need only to show that (a) \( \Rightarrow \) (b). Thus suppose, by way of contradiction, that (a) holds, but nevertheless there exist a totally ordered abelian group \( (\Gamma, \leq) \), and an element of \( T(\Gamma_+) \) which is not in the image of \( T'(\Gamma_+) \). Such element corresponds to a local morphism of monoids \( \varphi : \mathcal{O}_{T, t} \to \Gamma_+ \), for some \( t \in T \), and the assumption means that \( \varphi \) does not factor
through the monoid $\mathcal{O}_{T',s}$, for any $s \in f^{-1}(t)$. Set

$$P := \mathcal{O}_{T,t}^\text{int} \quad Q_s := P^{\text{gp}} \times_{\mathcal{O}_{T,s}^\text{int}} \mathcal{O}_{T',s}^\text{int} \quad \text{for every } s \in f^{-1}(t)$$

Notice that, since the map $P^{\text{gp}} \to \mathcal{O}_{T',s}^\text{int}$ is surjective, we have

$$Q_s/Q_s^\times \cong \mathcal{O}_{T',s}^\text{int}/(\mathcal{O}_{T,s}^\text{int})^\times$$

and there is a natural injective morphism of monoids $g_s : P \to Q_s$, determined by the pair $(i, \log f_s^\text{int})$, where $i : P^\text{int} \to P^{\text{gp}}$ is the natural morphism; moreover, $P^{\text{gp}} = Q_s^{\text{gp}}$ for every $s \in f^{-1}(t)$. Clearly $\varphi$ factors through a morphism $\overline{\varphi} : P \to \Gamma$; since the unit of adjunction $\mathcal{O}_{T,t} \to P$ is surjective, it follows that $P$ is sharp and $\overline{\varphi}$ is local. Moreover, the group homomorphism $\overline{\varphi}^{\text{gp}} : P^{\text{gp}} \to \Gamma$ factors uniquely through each $Q_s^{\text{gp}}$. Our assumption then states that we may find, for each $s \in f^{-1}(t)$, an element $x_s \in Q_s$ whose image in $\Gamma$ lies in the complement of $\Gamma_+$, i.e., the image of $x_s^{-1}$ lies in the maximal ideal $m \subset \Gamma_+$. Let $P' \subset P^{\text{gp}}$ be the submonoid generated by $P$ and by $(x_s^{-1} \mid s \in f^{-1}(t))$. By construction, $P'$ is finitely generated, and the morphism $\overline{\varphi}$ extends uniquely to a morphism $P' \to \Gamma_+$, which maps each $x_s^{-1}$ into $m$. It follows that all the $x_s^{-1}$ lie in the maximal ideal of $P'$. Let us now pick any local morphism $\psi' : P' \to \mathbb{N}$ (corollary 6.4.10(iii)); by restriction, $\psi'$ induces a local morphism $\psi : P \to \mathbb{N}$, which – according to (a) – must factor through a local morphism $\psi_s : Q_s \to \mathbb{N}$, for at least one $s \in f^{-1}(t)$. However, on the one hand we have $\psi^{\text{gp}} = \psi^{\text{gp}} = \psi_s^{\text{gp}}$; on the other hand $\psi'(x_s^{-1}) \neq 0$, hence $\psi_s(x_s) = \psi^{\text{gp}}(x_s) \notin \mathbb{N}$, a contradiction.$\square$

**Example 6.5.27.** Let $T$ be a locally fine fan, $\varphi : F \to T$ an integral subdivision, with $F$ locally fine and saturated, and $k > 0$ an integer. Suppose we have a commutative diagram of fans:

$$\begin{array}{ccc}
F & \xrightarrow{\varphi} & T \\
\downarrow{g} & & \downarrow{k_T} \\
F & \xrightarrow{\varphi} & T,
\end{array}$$

where $k_T$ is the $k$-Frobenius endomorphism (example 6.5.10(ii)). Then we claim that necessarily $g = k_F$. Indeed, suppose that this fails; then we may find a point $t \in T$ such that the composition of $g$ and the open immersion $j_t : U(t) \to F$ is not equal to $j_t \circ k_{U(t)}$. Set $P := \mathcal{O}_{F,t}$; then $g \circ j_t \neq j_t \circ k_{U(t)}$ in $F(P)$. However, an easy computation shows that $\varphi(g \circ j_t) = \varphi(j_t \circ k_{U(t)})$, which contradicts proposition 6.5.24.

6.5.29. Let $P := \bigcap_{n \in \mathbb{N}} P_n$ be a $\mathbb{N}$-graded monoid (see definition 4.8.8); then $P_0$ is a submonoid of $P$, every $P_n$ is a $P_0$-module, and $P_+ := \bigcap_{n > 0} P_n$ is an ideal of $P$. For every $a \in P$, the localization $P_a$ is $\mathbb{Z}$-graded in an obvious way, and we denote by $P_{(a)} \subset P_a$ the submonoid of elements of degree 0. Notice that there is a natural identification of $P_0$-monoids

$$P_{(a^n)} \cong P_{(a)} \quad \text{for every integer } n > 0.\quad (6.5.30)$$

Set as well:

$$D_+(a) := (\text{Spec } P_{(a)})^\bullet$$

and notice that the natural map $P \to P_{(a)}$ induces a morphism of fans $\pi_a : D_+(a) \to T_P := (\text{Spec } P_0)^\bullet$. If $b \in P$ is any other element, in order to determine the fibre product $D_+(a) \times_{T_P} D_+(b)$ we may assume – in light of (6.5.30) – that $a, b \in P_n$ for the same integer $n$, in which case we have natural isomorphisms

$$P_{(a)} \otimes_{P_0} P_{(b)} \cong P_{(ab)} \cong P_{(a)}[b^{-1}a]$$

(see remark 6.1.26(i)) onto the localization of $P_{(a)}$ obtained by inverting its element $a^{-1}b$; this is of course the same as $P_{(b)}[a^{-1}b]$. In other words $D_+(a) \times_{T_P} D_+(b)$ is naturally isomorphic
to $D_+(ab)$, identified to an open subfan in both $D_+(a)$ and $D_+(b)$. We may then glue the fans $D_+(a)$ for $a$ ranging over all the elements of $P$, to obtain a new fan, denoted:

$$\text{Proj } P$$

called the \textit{projective fan} associated with $P$. By inspecting the construction, we see that the morphisms $\pi_a$ assemble to a well defined morphism of fans $\pi_P : \text{Proj } P \to T_P$. Each element $a \in P$ yields an open immersion $j_a : D_+(a) \to \text{Proj } P$, and if $b \in P$ is any other element, $j_{ab}$ factors through an open immersion $D_+(ab) \to D_+(a)$.

6.5.31. Let $\varphi : P \to P'$ be a morphism of $\mathbb{N}$-graded monoids (so $\varphi P_n \subset P'_n$ for every $n \in \mathbb{N}$). Set:

$$G(\varphi) := \bigcup_{a \in P} D_+(\varphi(a)) \subset \text{Proj } P'.$$

Notice that, for every $a \in P$, $\varphi$ induces a morphism $\varphi(a) : P(a) \to P'_a$, whence a morphism of affine fans $(\text{Proj } \varphi)_a : D_+(\varphi(a)) \to D_+(a) \subset \text{Proj } P$. Moreover, if $b \in P$ is any other element, it is easily seen that $(\text{Proj } \varphi)_a$ and $(\text{Proj } \varphi)_b$ agree on $D_+((\varphi(a)) \cap D_+((\varphi(b))$. Therefore, the morphisms $(\text{Proj } \varphi)_a$ glue to a well defined morphism:

$$\text{Proj } \varphi : G(\varphi) \to \text{Proj } P.$$ Notice that $G(\varphi) = \text{Proj } P'$, whenever $\varphi P$ generates the ideal $P'_a$. Moreover, we have

$$\text{(Proj } \varphi)^{-1} D_+(a) = D_+(\varphi(a)) \quad \text{for every } a \in P.$$ Indeed, say that $D_+(b) \subset G(\varphi)$ for some $b \in P'$, and $(\text{Proj } \varphi)D_+(b) \subset D_+(a)$. In order to show that $D_+(b) \subset D((\varphi(a))$, it suffices to check that $D_+(b \varphi(c)) \subset D_+(\varphi(a))$ for every $c \in P$. However, the assumption means that the natural map

$$P_c \to P'_c \to P'_c/(b \varphi(c))$$

factors through the localization $P_c \to P_{ac}$. This is equivalent to saying that $\varphi(c^{-1}a)$ is invertible in $P'_c/(b \varphi(c))$, in which case the localization $P'_c/(b \varphi(c)) \to P'_c/(b \varphi(c))$ factors through the localization $P'_c/(b \varphi(c)) \to P'_c/(\varphi(ac))$. The latter means that the open immersion $D_+(b \varphi(c)) \subset D_+(\varphi(c))$ factors through the open immersion $D_+(\varphi(ac)) \subset D_+(\varphi(c))$, as claimed.

6.5.33. In the situation of (6.5.29), set $Y : = \text{Proj } P$ to ease notation. Let $M$ be a $\mathbb{Z}$-graded $P$-module; for every $a \in P$, let $M(a) \subset M \subset M \otimes P_a$ be the $P_a$-submodule of degree zero elements (for the natural grading on $M$). We deduce a quasi-coherent $\mathscr{O}_{D_+(a)}$-module $\mathcal{M}_a$ (see definition 6.5.12). Moreover, if $b \in P$ is any other element, we have a natural identification

$$\mathcal{M}_{a,b} : M_{a,a} D_+(a) \cap D_+(b) \to M_{b,b} D_+(a) \cap D_+(b).$$

This can be verified as follows. First, in view of (6.5.30), we may assume that $a,b \in P_n$, for some $n \in \mathbb{N}$, in which case we consider the $P$-linear morphism:

$$M_{a,a} \to M_{b,b} \otimes P_{a,b} P(a) [a^{-1}] : \frac{x}{a^m} \mapsto \frac{x}{b^m} \otimes \frac{b^m}{a^m} \quad \text{for every } x \in M_{nm}.$$ It is easily seen that this map is actually $P_a$-linear, hence it extends to a $\mathcal{O}_T(D_+(a) \cap D_+(b))$-linear morphism:

$$\omega_{a,b} : M_{a,a} \otimes P_{a,b} P(a) [a^{-1}] \to M_{b,b} \otimes P_{a,b} P(b) [a^{-1}].$$ Moreover, $\omega_{a,b} \circ \omega_{b,a}$ is the identity map, hence $\omega_{a,b}$ induces the sought isomorphism $\mathcal{M}_{a,b}$. Furthermore, for any $a,b,c \in P$, set $D_+(a,b,c) : = D_+(a) \cap D_+(b) \cap D_+(c)$; we have the identity:

$$\mathcal{M}_{a,c} D_+(a,b,c) = \mathcal{M}_{b,c} D_+(a,b,c) \circ \mathcal{M}_{a,b} D_+(a,b,c)$$
which shows that the locally defined sheaves $M^\sim_n$, glue to a well defined $\mathcal{O}_Y$-module, which we shall denote $M^\sim$. Especially, for every $n \in \mathbb{Z}$, let $P(n)$ be the $\mathbb{Z}$-graded $P$-module such that $P(n)_k := P_{n+k}$ for every $k \in \mathbb{Z}$ (with the convention that $P_n := \emptyset$ if $n < 0$); we set:

$$\mathcal{O}_Y(n) := P(n)^\sim.$$

Every element $a \in P_n$ induces a natural isomorphism:

$$\mathcal{O}_Y(n)_{D_+(a)} \xrightarrow{\sim} \mathcal{O}_{D_+(a)} : x \mapsto f^{-k}x \quad \text{for every local section } x.$$

Hence on the open subset:

$$U_n(P) := \bigcup_{a \in P_n} D_+(a)$$

the sheaf $\mathcal{O}_Y(n)$ restricts to an invertible $\mathcal{O}_{U_n(P)}$-module (see definition 4.8.6(iv)). Especially, if $P_1$ generates $P_+$, the $\mathcal{O}_Y$-modules $\mathcal{O}_Y(n)$ are invertible, for every $n \in \mathbb{Z}$.

6.5.34. In the situation of (6.5.31), let $M$ be a $\mathbb{Z}$-graded $P$-module. Then $M' := M \otimes_P P'$ is a $\mathbb{Z}$-graded $P'$-module, with the grading defined by the rule:

$$M'_n := \bigcup_{j+k=n} \text{Im}(M_j \otimes_{P_0} P'_k \to M').$$

There follows a $P_{(a)}$-linear morphism:

$$M_{(a)} \to M'_{(\varphi(a))} : \frac{x}{a^k} \mapsto \frac{x}{\varphi(a)^k} \quad \text{for every } a \in P$$

and since both localization and tensor product commute with arbitrary colimits, it is easily seen that (6.5.36) extends an injective $P'_{(\varphi(a))}$-linear map

$$M_{(a)} \otimes_{P_{(a)}} P'_{(\varphi(a))} \to M'_{(\varphi(a))}$$

whence a map of $\mathcal{O}_{D_+(\varphi(a))}$-modules $(\text{Proj } \varphi)^*M_{(\varphi(a))} \to (M')_{(\varphi(a))}$, and the system of such maps, for $a$ ranging over the elements of $P$, is compatible with all open immersions $D_+(\varphi(ab)) \subset D_+(a)$, whence a well defined monomorphism of $\mathcal{O}_{G(\varphi)}$-modules

$$\text{(Proj } \varphi)^*M^\sim \to (M')_{(\varphi)}.$$

Moreover, if $a \in P_1$, then for every $m \in M_j$ and $x \in P'_k$, we may write

$$\frac{m \otimes x}{\varphi(a)^{k+j}} = \frac{m}{a^j} \otimes \frac{x}{\varphi(a)^j}$$

so the above map is an isomorphism on $D_+(a)$. Thus, (6.5.37) restricts to an isomorphism on the open subset

$$G_1(\varphi) := \bigcup_{a \in P_1} D_+(\varphi(a)).$$

Especially (6.5.37) is an isomorphism whenever $P_1$ generates $P_+$. Notice as well that $G_1(\varphi) \subset U_1(P') \cap G(\varphi)$, and actually $G_1(\varphi) = U_1(P')$ if $\varphi(P)$ generates $P'_+$.  

6.5.38. Let $P$ be as in (6.5.29), and $f : P_0 \to Q$ a given morphism of monoids. Then $P' := P \otimes_{P_0} Q$ is naturally $\mathbb{N}$-graded, so that the natural map $f_P : P \to P'$ is a morphism of graded monoids. Every element of $P'$ is of the form $a \otimes b = (a \otimes 1) \cdot (1 \otimes b)$, where $a \in P$ and $b \in Q$. Then lemma 4.8.34 yields a natural isomorphism of $Q$-monoids:

$$P(a) \otimes_{P_0} Q[b^{-1}] \cong P'(a \otimes b)$$

whence an isomorphism of affine fans:

$$\beta_{a \otimes b} : D_+(a \otimes b) \cong D_+(a) \times_{T_P} D(b)$$

such that $(\pi_a \times_{T_P} j_b^*) \circ \beta_{a \otimes b} = \pi_{a \otimes b}$, where $j_b^* : D(b) \to T_Q := (\text{Spec } Q)^!$ is the natural open immersion. Especially, it is easily seen that the isomorphisms $\beta_{a \otimes 1}$ assemble to a well defined isomorphism of fans:

$$(\text{Proj } f_P, \pi_{P'}) : \text{Proj } P' \cong \text{Proj } P \times_{T_P} T_Q$$

such that $(\pi_P \times_{T_P} 1_{T_Q}) \circ (\text{Proj } f_P, \pi_{P'}) = \pi_{P'}$. Lastly, if $g : Q \to R$ is another morphism of monoids, $T_R := (\text{Spec } R)^!$, and $P'' := P' \otimes_Q R$, then we have the identity:

$$(\text{Proj } f_P, \pi_{P'}) \times_{T_Q} 1_{T_R} \circ (\text{Proj } g_{P'}, \pi_{P''}) = (\text{Proj } (g \circ f)_P, \pi_{P''}).$$

Moreover, for every $\mathbb{Z}$-graded module $M$, the map $(\text{Proj } f_P)^* M \sim \to (M \otimes_{P_0} Q) \sim_{\text{G}(f_P)}$ of (6.5.37) is an isomorphism, regardless of whether or not $P_1$ generates $P_+$ (verification left to the reader). Especially, we get a natural identification:

$$(\text{Proj } f_P)^* \mathcal{O}_Y(n) \cong \mathcal{O}_{Y'}(n) \quad \text{for every } n \in \mathbb{Z}$$

where $Y := \text{Proj } P$ and $Y' := \text{Proj } P'$.

6.5.40. In the situation of (6.5.38), let $\varphi : R \to P$ be a morphism of $\mathbb{N}$-graded monoids. There follow morphisms of fans:

$$\text{Proj } \varphi : G(\varphi) \to \text{Proj } R \quad \text{Proj}(f_P \circ \varphi) : G(f_P \circ \varphi) \to \text{Proj } R$$

and in view of (6.5.32), it is easily seen that:

$$(\text{Proj } f_P \circ \varphi) = (\text{Proj } f_P)^{-1}(G(\varphi)).$$

6.5.42. Let now $(T, \mathcal{O}_T)$ be any fan. A $\mathbb{N}$-graded $\mathcal{O}_T$-monoid is a $\mathbb{N}$-graded $T$-monoid $\mathcal{P}$, with a morphism $\mathcal{O}_T \to \mathcal{P}$ of $T$-monoids. We say that such a $\mathcal{O}_T$-monoid is quasi-coherent, if it is such, when regarded as a $\mathcal{O}_T$-module. To a quasi-coherent $\mathbb{N}$-graded $\mathcal{O}_T$-monoid $\mathcal{P}$, we attach a morphism of fans:

$$\pi_{\mathcal{P}} : \text{Proj } \mathcal{P} \to T$$

constructed as follows. First, for every affine open subfan $U \subset T$, the monoid $\mathcal{P}(U)$ is $\mathbb{N}$-graded, so we have the projective fan $\text{Proj } \mathcal{P}(U)$, and the morphism of monoids $\mathcal{O}_T(U) \to \mathcal{P}(U)$ induces a morphism of fans $\text{Proj } \mathcal{P}(U) \to U$. Next, say that $U_1, U_2 \subset T$ are two affine open subsets; for any affine open subset $V \subset U_1 \cap U_2$ we have restriction maps $\rho_{V, i} : \mathcal{P}(U_i) \to \mathcal{P}(V)$ inducing isomorphisms of graded $\mathcal{O}_T(V)$-monoids:

$$\mathcal{P}(U_i) \otimes_{\mathcal{O}_T(U_i)} \mathcal{O}_T(V) \cong \mathcal{P}(V).$$

whence isomorphisms of $V$-fans:

$$\text{Proj } \mathcal{P}(V) \cong \text{Proj } \mathcal{P}(U_i) \otimes_{\mathcal{O}_T(U_i)} \mathcal{O}_T(V) \xrightarrow{\text{Proj } \rho_{V, i}} \text{Proj } \mathcal{P}(U_i) \times_{U_i} V$$

which in turn yield natural identifications:

$$\partial_V : \text{Proj } \mathcal{P}(U_i) \times_{U_i} V \cong \text{Proj } \mathcal{P}(U_2) \times_{U_2} V.$$
If $W \subset V$ is a smaller affine open subset, (6.5.39) implies that $\vartheta_V \times_V 1_W = \vartheta_W$, and therefore the isomorphisms $\vartheta_V$ glue to a single isomorphism of $U_1 \cap U_2$-fans:

$$\text{Proj } \mathcal{P}(U_1) \times_{U_1} (U_1 \cap U_2) \overset{\sim}{\rightarrow} \text{Proj } \mathcal{P}(U_2) \times_{U_2} (U_1 \cap U_2)$$

which is furthermore compatible with base change to any triple intersection $U_1 \cap U_2 \cap U_3$ of affine open subsets (details left to the reader). In such situation, we may glue the fans $\text{Proj } \mathcal{P}(U)$ – with $U \subset T$ ranging over all the open affine subsets – along the above isomorphisms, to obtain the sought fan $\text{Proj } \mathcal{P}$; the construction also comes with a well defined morphism to $T$, as required. Then, for every such open affine $U$, the induced morphism $\text{Proj } \mathcal{P}(U) \rightarrow \text{Proj } \mathcal{P}$ is an open immersion; finally a direct inspection shows that, for every smaller affine open subset $V \subset U$ we have:

$$U_n(\mathcal{P}(U)) \cap \text{Proj } \mathcal{P}(V) = U_n(\mathcal{P}(V)) \quad \text{for every } n \in \mathbb{N}$$

(where the intersection is taken in $\text{Proj } \mathcal{P}$). Hence the union of all the open subsets $U_n(\mathcal{P}(U))$ is an open subset $U_n(\mathcal{P}) \subset \text{Proj } \mathcal{P}$, intersecting each $\text{Proj } \mathcal{P}(U)$ in its subset $U_n(\mathcal{P}(U))$.

6.5.43. To ease notation, set $Y := \text{Proj } \mathcal{P}$, and let $\pi : Y \rightarrow T$ be the projection. Let $\mathcal{M}$ be a $\mathbb{Z}$-graded $\mathcal{P}$-module, quasi-coherent as a $\vartheta_T$-module; for every affine open subset $U \subset T$, the graded $\mathcal{P}(U)$-module $\mathcal{M}(U)$ yields a quasi-coherent $\vartheta_{\pi^{-1}U}$-module $\mathcal{M}_{\pi^{-1}U}$, and every inclusion of affine open subset $U' \subset U$ induces a natural isomorphism $\mathcal{M}_{\pi^{-1}U'} \overset{\sim}{\rightarrow} \mathcal{M}_{\pi^{-1}U}$ of $\vartheta_{\pi^{-1}U'}$-modules. Therefore the modules $\mathcal{M}_{\pi^{-1}U}$ glue to a well defined $\vartheta_Y$-module $\mathcal{M}$.

For every $n \in \mathbb{Z}$, denote by $\mathcal{M}(n)$ the $\mathbb{Z}$-graded $\mathcal{P}$-module such that $\mathcal{M}(n)_k := \mathcal{M}(n+k)$ for every $k \in \mathbb{Z}$ (especially, with the convention that $\mathcal{P}(k) := 0$ whenever $k < 0$, we obtain in this way the $\mathcal{P}$-module $\mathcal{P}(n)$). We set:

$$\vartheta_Y(n) := \mathcal{P}(n)\overset{\sim}{\rightarrow} and \mathcal{M}(n) := \mathcal{M} \otimes_{\vartheta_Y} \vartheta_Y(n).$$

Clearly the restriction of $\vartheta_Y(n)$ to $U_n(\mathcal{P})$ is invertible, for every $n \in \mathbb{Z}$.

Moreover, for every $n \in \mathbb{Z}$, the scalar multiplication $\mathcal{P}(n) \otimes_{\vartheta_T} \mathcal{M} \rightarrow \mathcal{M}(n)$ determines a well defined morphism of $\vartheta_Y$-modules:

$$\mathcal{M}(n) \rightarrow \mathcal{M}(n)\overset{\sim}{\rightarrow} and \mathcal{M}(n) \rightarrow \mathcal{M}(n)$$

and arguing as in (6.5.34) we see that the restriction of this map is an isomorphism on $U_1(\mathcal{P})$.

Especially, we have natural morphisms of $\vartheta_Y$-modules:

$$\vartheta_Y(n) \otimes_{\vartheta_Y} \vartheta_Y(m) \rightarrow \vartheta_Y(n + m) \quad \text{for every } n, m \in \mathbb{Z}$$

whose restrictions to $U_1(\mathcal{P})$ are isomorphisms.

**Example 6.5.44.** Let $T$ be a fan, $\mathcal{L}$ an invertible $\vartheta_T$-module, and set $\mathcal{P}(\mathcal{L}) := \text{Sym}^*_{\vartheta_T} \mathcal{L}$ (see example 4.8.10). Then the morphism

$$\pi_{\mathcal{P}(\mathcal{L})} : \mathcal{P}(\mathcal{L}) := \text{Proj } \mathcal{P}(\mathcal{L}) \rightarrow T$$

is an isomorphism. Indeed, the assertion can be checked locally on every affine open subset $U \subset T$, hence say that $U = (\text{Spec } P)^\vartheta$ for some monoid $P$, and $\mathcal{L} \simeq \vartheta_T | U$, in which case the $P$-monoid $\mathcal{P}(\mathcal{L})(U)$ is isomorphic to $P \times \mathbb{N}$ (with its natural morphism $P \rightarrow P \times \mathbb{N} : x \mapsto (x, 0)$ for every $x \in P$), and the sought isomorphism corresponds to the natural identification:

$$(6.5.45) \quad P = (P \times \mathbb{N})_{(1)}$$

where $(1, 1) \in P \times \{1\} = (P \times \mathbb{N})_1$. Likewise, $\vartheta_{\mathcal{P}(\mathcal{L})}(n)$ is the $\vartheta_{\mathcal{P}(\mathcal{L})}$-module associated with the graded $(P \times \mathbb{N})$-module $P \times \mathbb{N}(n) = \mathcal{L} ^{\otimes n}(U) \otimes_P (P \times \mathbb{N})$, so $(6.5.45)$ induces a natural isomorphism

$$\pi_{\mathcal{P}(\mathcal{L})}^* \mathcal{L} ^{\otimes n} \overset{\sim}{\rightarrow} \vartheta_{\mathcal{P}(\mathcal{L})}(n) \quad \text{for every } n \in \mathbb{N}.$$
6.5.46. In the situation of (6.5.42), let \( \varphi : \mathcal{P} \to \mathcal{P}' \) be a morphism of quasi-coherent \( \mathbb{N} \)-graded \( \mathcal{O}_T \)-monoids (defined in the obvious way). By the foregoing, for every affine open subset \( U \subset T \), we have an induced morphism \( \text{Proj} \varphi(U) : G(\varphi(U)) \to \text{Proj} \mathcal{P}(U) \) of \( U \)-fans, where \( G(\varphi(U)) \) is an open subset of \( \text{Proj} \mathcal{P}(U) \). Let \( V \subset U \) be a smaller affine open subset; in light of (6.5.41), we have
\[
G(\varphi(V)) = G(\varphi(U)) \cap \text{Proj} \mathcal{P}(V).
\]

It follows that the union of all the open subsets \( G(\varphi(U)) \) is an open subset \( G(\varphi) \) such that
\[
G(\varphi) \cap \text{Proj} \mathcal{P}(U) = G(\varphi(U)) \quad \text{for every affine open subset } U \subset T
\]
and the morphisms \( \text{Proj} \varphi(U) \) assemble to a well defined morphism
\[
\text{Proj} \varphi : G(\varphi) \to \text{Proj} \mathcal{P}.
\]

Moreover, if \( \mathcal{M} \) is a \( \mathbb{Z} \)-graded quasi-coherent \( \mathcal{P} \)-module, the morphisms (6.5.37) assemble to a well defined morphism of \( \mathcal{O}_{G(\varphi)} \)-modules:
\[
(\text{Proj} \varphi)^* \mathcal{M} \sim (\mathcal{M}')_{G(\varphi)}
\]
where the grading of \( \mathcal{M}' := \mathcal{M} \otimes_{\mathcal{P}} \mathcal{P}' \) is defined as in (6.5.35). Likewise, the union of all open subsets \( G_1(\varphi(U)) \) is an open subset \( G_1(\varphi) \subset U_1(\mathcal{P}) \cap G(\varphi) \), such that the restriction of (6.5.47) to \( G_1(\varphi) \) is an isomorphism. Especially, set \( Y := \text{Proj} \mathcal{P} \) and \( Y' := \text{Proj} \mathcal{P}' \); we have a natural morphism:
\[
(\text{Proj} \varphi)^* \mathcal{O}_Y(n) \sim \mathcal{O}_{Y'}(n)_{G(\varphi)}
\]
which is an isomorphism, if \( \mathcal{P}_1 \) generates \( \mathcal{P}_+ := \bigsqcup_{n>0} \mathcal{P}_n \) locally on \( T \).

6.5.48. On the other hand, let \( f : T' \to T \) be a morphism of fans. The discussion in (6.5.38) implies that \( f \) induces a natural isomorphism of \( T' \)-fans:
\[
\text{Proj} f^* \mathcal{P} \sim \text{Proj} \mathcal{P} \times_T T'.
\]

Moreover, set \( Y := \text{Proj} \mathcal{P}, Y' := \text{Proj} f^* \mathcal{P} \), and let \( \pi_Y : Y' \to Y \) be the projection deduced from (6.5.49); then there follows a natural identification:
\[
\mathcal{O}_{Y'}(n) \sim \pi_Y^* \mathcal{O}_Y(n) \quad \text{for every } n \in \mathbb{Z}.
\]

6.5.50. Keep the notation of (6.5.42), and to ease notation, set \( Y := \text{Proj} \mathcal{P} \). Let \( \mathcal{C} \) be the category whose objects are all the pairs \((\psi : X \to T, \mathcal{L})\), where \( \psi \) is a morphism of fans, and \( \mathcal{L} \) is an invertible \( \mathcal{O}_X \)-module; the morphisms \((\psi : X \to T, \mathcal{L}) \to (\psi' : X' \to T, \mathcal{L}')\) are the pairs \((\beta, h)\), where \( \beta : X \to X' \) is a morphism of \( T \)-fans, and \( h : \beta^* \mathcal{L}' \sim \mathcal{L} \) is an isomorphism of \( \mathcal{O}_X \)-modules (with composition of morphisms defined in the obvious way). Consider the functor
\[
F_{\mathcal{P}} : \mathcal{C} \to \text{Set}
\]
which assigns to any object \((\psi, \mathcal{L})\) of \( \mathcal{C} \), the set consisting of all morphisms of graded \( \mathcal{O}_X \)-monoids
\[
g : \psi^* \mathcal{P} \to \text{Sym}^*_{\mathcal{O}_X} \mathcal{L}
\]
which are epimorphisms on the underlying \( \mathcal{O}_X \)-modules (notation of example 4.8.10). On a morphism \((\beta, h)\) as in the foregoing, and an element \( g' \in F_{\mathcal{P}}(\psi', \mathcal{L}')\), the functor acts by the rule:
\[
F_{\mathcal{P}}(\beta, h) := (\text{Sym}^*_{\mathcal{O}_X} h) \circ \beta^* g'.
\]

**Lemma 6.5.51.** In the situation of (6.5.50), the following holds:

(i) The object \((\pi_{\mathcal{P}|U_1(\mathcal{P})} : U_1(\mathcal{P}) \to T, \mathcal{O}_Y(1)_{U_1(\mathcal{P})})\) represents the functor \( F_{\mathcal{P}} \).
(ii) If $\mathcal{P}$ is an integral $T$-monoid, the $T$-monoid $\mathcal{P}_{sat}$ admits a unique grading such that the unit of adjunction $\mathcal{P} \to \mathcal{P}_{sat}$ is a $\mathbb{N}$-graded morphism, and there is a natural isomorphism of Proj $\mathcal{P}$-fans:

$$\text{Proj} (\mathcal{P}_{sat}) \sim (\text{Proj} \mathcal{P})_{sat}.$$  

**Proof.** (i): The proof is *mutatis mutandis*, the same as that of lemma 10.6.33 (with some minor simplifications). We leave it as an exercise for the reader.

(ii): The first assertion shall be left to the reader. The second assertion is local on Proj $\mathcal{P}$, hence we may assume that $T = (\text{Spec} P_0)$, and $\mathcal{P} = P^\sim$ for some $\mathbb{N}$-graded integral $P_0$-monoid $P$. Let $a \in P_{sat}$ be any element; by definition we have $a^n \in P$ for some $n > 0$, and we know that the open subsets $D_+ (a)$ et $D_+ (a^n)$ coincide in $\text{Proj}(\mathcal{P}_{sat})$; hence we come down to showing that $(P_a)_{sat} = (P_{sat})_a$ for every $a \in P$, which can be left to reader. □

**Definition 6.5.52.** Let $(T, \mathcal{O}_T)$ be a fan (resp. an integral fan), $\mathcal{I} \subset \mathcal{O}_T$ an ideal (resp. a fractional ideal) of $\mathcal{O}_T$.

(i) Let $f : X \to T$ be a morphism of fans (resp. of integral fans); then $f^{-1} \mathcal{I}$ is an ideal (resp. a fractional ideal) of $f^{-1} \mathcal{O}_T$, and we let:

$$\mathcal{I}_X := \log f (f^{-1} \mathcal{I}) \cdot \mathcal{O}_X$$

which is the smallest ideal (resp. fractional ideal) $\mathcal{O}_X$ containing the image of $f^{-1} \mathcal{I}$.

(ii) A blow up of the ideal $\mathcal{I}$ is a morphism of fans (resp. of integral fans) $\varphi : T' \to T$ which enjoys the following universal property. The ideal (resp. fractional ideal) $\mathcal{I}_T$ is invertible, and every morphism of fans (resp. of integral fans) $X \to T$ such that $\mathcal{I}_X$ is invertible, factors uniquely through $\varphi$.

6.5.53. Let $T$ be a fan (resp. an integral fan), $\mathcal{I} \subset \mathcal{O}_T$ a quasi-coherent ideal (resp. fractional ideal), and consider the $\mathbb{N}$-graded $\mathcal{O}_T$-monoid:

$$\mathcal{B}(\mathcal{I}) := \bigoplus_{n \in \mathbb{N}} \mathcal{I}^n$$

where $\mathcal{I}^n \subset \mathcal{O}_T$ is the ideal (resp. fractional ideal) associated with the presheaf $U \mapsto \mathcal{I}(U)^n$ for every open subset $U \subset T$ (notation of 6.1.1), with the convention that $\mathcal{I}^0 := \mathcal{O}_T$ and the multiplication law of $\mathcal{B}(\mathcal{I})$ is defined in the obvious way.

**Proposition 6.5.54.** The natural projection

$$\text{Proj} \mathcal{B}(\mathcal{I}) \to T$$

is a blow up of the ideal $\mathcal{I}$.

**Proof.** We shall consider the case where $T$ is not necessarily integral, and $\mathcal{I} \subset \mathcal{O}_T$; the case of a fractional ideal of an integral fan is proven in the same way. Set $Y := \text{Proj} \mathcal{B}(\mathcal{I})$ to begin with, let us show that $\mathcal{I}_T$ is invertible. The assertion is local on $T$, hence we may assume that $T = (\text{Spec} P)^{\sim}$, and $\mathcal{I} = I^+$ for some ideal $I \subset P$, so $Y = \text{Proj} B(I)$, where $B(I) := \prod_{n \in \mathbb{N}} I^n$. Let $a \in B(I)_1 = I$ be any element; then the restriction of $\mathcal{I}_T$ to $D_+ (a)$ is generated by $1 = a/a \in B(I)_1 (a)$, so clearly $\mathcal{I}_{|D_+ (a)} \simeq \mathcal{O}_Y$; since $U_1 (B(I)) = Y$ (notation of 6.5.33), the contention follows.

Next, let $\varphi : X \to T$ be a morphism of fans, such that $\mathcal{I}_X$ is an invertible ideal. It follows easily that $\mathcal{I}^n \mathcal{O}_X$ is invertible for every $n \in \mathbb{N}$, so the natural map of $\mathbb{N}$-graded $\mathcal{O}_X$-monoids

$$\varphi^* \text{Sym}^*_{\mathcal{O}_T} (\mathcal{I}) \sim \text{Sym}^*_{\mathcal{O}_X} (\mathcal{I}_X) \to \mathcal{B}(\mathcal{I}_X)$$

is an isomorphism. On the other hand, the projection $\text{Proj} \mathcal{B}(\mathcal{I}_X) \to X$ is an isomorphism (example 6.5.44), whence – in view of 6.5.49 – a natural morphism of $T$-fans:

$$X \to \text{Proj} \mathcal{B}(\mathcal{I}).$$
To conclude, it remains to show that \( (6.5.55) \) is the only morphism of \( T \)-fans from \( X \) to \( \text{Proj} \mathcal{A}(\mathcal{F}) \). The latter assertion can be checked again locally on \( T \), so we are reduced as above to the case where \( T \) is the spectrum of \( P \), and \( \mathcal{F} \) is associated with \( I \). We may also assume that \( X = (\text{Spec} Q)^i \), and \( \varphi \) is given by a morphism of monoids \( f : P \rightarrow Q \). Then the hypothesis means that the ideal \( f(I)Q \) is isomorphic to \( Q \) (see remark \( 6.5.13(ii) \)), hence it is generated by an element of the form \( f(a) \), for some \( a \in I \), and the endomorphism \( x \mapsto f(a)x \) of \( f(I)Q \), is an isomorphism. In such situation, it is clear that \( f \) factors uniquely through a morphism of monoids \( P \rightarrow B(I)(a) \); namely, one defines \( g : B(I)(a) \rightarrow Q \) by the rule \( a^{-1}x \mapsto f(a)^{-1}f(x) \) (for every \( x \in I^i \)), which is well defined, by the foregoing observations. The morphism \( (\text{Spec} g)^i : X \rightarrow D_+(a) \) must then agree with \( (6.5.55) \). \( \square \)

**Example 6.5.56.** (i) Let \( P \) be a monoid, \( I \subseteq P \) any finitely generated ideal, \( \{a_1, \ldots, a_n\} \) a finite system of generators of \( I \); set \( T := (\text{Spec} P)^i \), and let \( \varphi : T' \rightarrow T \) be the blow up of the ideal \( I' \subseteq O_T \). Then \( T' \) admits an open covering consisting of the affine fans \( D_+(f_i) \). The latter are the spectra of the monoids \( Q_i \), consisting of all fractions of the form \( a \cdot f_i^{-1} \), for every \( a \in I^n \); we have \( a \cdot f_i^{-1} = b \cdot f_i^{-k} \) in \( Q_i \) if and only if there exists \( k \in \mathbb{N} \) such that \( a \cdot f_i^{k+1} = b \cdot f_i^{1+k} \), if and only if the two fractions are equal in \( P_{f_i} \), in other word, \( Q_i \) is the submonoid of \( P_{f_i} \) generated by \( I \) and \( \{f_j \cdot f_i^{-1} \mid j \leq n\} \), for every \( i = 1, \ldots, n \).

(ii) Consider the special case where \( P \) is fine, and the ideal \( I \subseteq P \) is generated by two elements \( f, g \in P \). Let \( t \in T' \) be any point; up to swapping \( f \) and \( g \), we may assume that \( t \) corresponds to a prime ideal \( p \subseteq P[f/g] \), hence \( \varphi(t) \) corresponds to \( p := j^{-1}p \subseteq P \), where \( j : P \rightarrow P[f/g] \) is the natural map. We have the following two possibilities:

- Either \( f/g \notin p \), in which case the spectra of \( Q_i \) is associated with \( \mathcal{F}' := P[f/g] \setminus p \) any element; writing \( x = y \cdot \frac{f}{g} \) for some \( n \geq 0 \) and \( y \in P \), we deduce that \( n = 0 \), so \( x = y \in F := P \setminus q \), therefore \( F' = j(F) \). Notice as well that in this case \( f/g \) is not invertible in \( P[f/g] \), hence \( P[f/g]^{\times} = P^{\times} \), whence \( \dim P[f/g] = \dim P \), and, by corollary \( 6.4.10(i) \).
- Or else \( f/g \notin p \), in which case the same argument yields \( F' = j(F') \). In this case, \( f/g \) is invertible in \( P[f/g] \) if and only if it is invertible in the face \( F' \), hence \( \text{ht} p = \dim P - \text{rk}_Z F' \geq \dim P - \dim F - 1 \), by corollary \( 6.4.10(i),(ii) \).

In either event, corollary \( 6.4.10(i),(ii) \) implies the inequality:

\[
1 \geq \text{ht}(\varphi(t)) - \text{ht}(t) \geq 0 \quad \text{for every } t \in T'.
\]

6.6. **Special subdivisions.** In this section we explain how to construct – either by geometrical or combinatorial means – useful subdivisions of given fans.

6.6.1. Let \( T \) be any locally fine and saturated fan, and \( t \in T \) any point. By reflexivity (proposition \( 6.4.12(iv) \)), the elements \( s \in \mathcal{O}^{\text{gp}}_{T,t} \otimes_Z \mathbb{Q} \) correspond bijectively to \( \mathbb{Q} \)-linear forms \( \rho_s : U(t)(\mathbb{Q}_+)^{\text{gp}} \rightarrow \mathbb{Q} \), and \( s \in \mathcal{O}^{\text{gp}}_{T,t} \) if and only if \( \rho_s \) restricts to a morphism of monoids \( U(t)(\mathbb{N}) \rightarrow \mathbb{Z} \). Moreover, this bijection is compatible with specialization maps: if \( t' \) is a generalization of \( t \) in \( T \), then the form \( U(t')(\mathbb{Q}_+)^{\text{gp}} \rightarrow \mathbb{Q} \) induced by the image of \( s \) in \( \mathcal{O}^{\text{gp}}_{T,t'} \otimes_Z \mathbb{Q} \) is the restriction of \( \rho_s \) (see \( 6.5.20 \)).

Hence, any global section \( \lambda \in \Gamma(T, \mathcal{O}^{\text{gp}}_T) \) yields a well defined function

\[
\rho_\lambda : T(\mathbb{N}) \rightarrow \mathbb{Z}
\]

whose restriction to \( U(t)(\mathbb{N}) \) is the restriction of a \( \mathbb{Z} \)-linear form on \( U(t)_{(\mathbb{N})}^{\text{gp}} \), for every \( t \in T \); conversely, any such function arises from a unique global section of \( \mathcal{O}^{\text{gp}}_T \). Likewise, we have a natural isomorphism between the \( \mathbb{Q} \)-vector space of global sections \( \lambda \) of \( \mathcal{O}^{\text{gp}}_T \otimes_Z \mathbb{Q} \), and the space of functions \( \rho_\lambda : T(\mathbb{Q}_+) \rightarrow \mathbb{Q} \) with a corresponding linearity property.
Let now \( \rho : T(\mathbb{Q}_+) \rightarrow \mathbb{Q} \) be any function; we may attach to \( \rho \) a sheaf of fractional ideals of \( \mathcal{O}_{T, \mathbb{Q}} \) (notation of 6.3.20), by the rule:
\[
\mathcal{J}_{\rho, \mathbb{Q}}(U) := \{ s \in \mathcal{O}_{T, \mathbb{Q}}(U) \mid \rho_s \geq \rho_{\mathbb{Q}} \}
\]
for every open subset \( U \subset T \).

In this generality, not much can be said concerning \( \mathcal{J}_{\rho, \mathbb{Q}} \); to advance, we restrict our attention to a special class of functions, singled out by the following:

**Definition 6.6.2.** Let \( T \) be a locally fine and saturated fan.

(a) A roof on \( T \) is a function:

\[
\rho : T(\mathbb{Q}_+) \rightarrow \mathbb{Q}
\]

such that, for every \( t \in T \), there exist \( k := k(t) \in \mathbb{N} \) and \( \mathbb{Q} \)-linear forms

\[
\lambda_1, \ldots, \lambda_k : U(t)(\mathbb{Q}_+)^{gp} \rightarrow \mathbb{Q}
\]

with \( \rho(s) = \min(\lambda_i(s) \mid i = 1, \ldots, k) \) for every \( s \in U(t)(\mathbb{Q}_+) \).

(b) An integral roof on \( T \) is a roof \( \rho \) on \( T \) such that \( \rho(s) \in \mathbb{Z} \) for every \( s \in T(\mathbb{N}) \).

6.6.3. The interest of the notion of roof on a fan \( T \), is that it encodes in a geometrical way, an integral subdivision of \( T \), together with a coherent sheaf of fractional ideals of \( \mathcal{O}_T \) (see definition 4.8.6(iii)). This shall be seen in several steps. To begin with, let \( T \) and \( \rho \) be as in definition 6.6.2(a). For any \( t \in T \), pick a system \( \lambda := \{ \lambda_1, \ldots, \lambda_k \} \) of \( \mathbb{Q} \)-linear forms fulfilling condition (b) of the definition; then for every \( i = 1, \ldots, k \) let us set:

\[
U(t, i)(\mathbb{N}) := \{ x \in U(t)(\mathbb{N}) \mid \rho(x) = \lambda_i(x) \}.
\]

Notice that \( U(t)(\mathbb{N}) = \mathcal{O}_{T, \mathbb{H}} \), by proposition 6.4.12(iv). Moreover, say that \( \lambda \) is irredundant for \( t \) if no proper subsystem of \( \lambda \) fulfills condition (b) of definition 6.6.2 relative to \( U(t) \).

**Lemma 6.6.4.** With the notation of (6.6.3), the following holds:

(i) \( U(t, i)(\mathbb{N}) \) is a saturated fine monoid for every \( i \leq k \).

(ii) There is a unique system of \( \mathbb{Q} \)-linear forms which is irredundant for \( t \).

(iii) If \( \lambda \) is irredundant for \( t \), then \( \dim U(t, i)(\mathbb{N}) = \text{ht}_T(t) \) for every \( i = 1, \ldots, k \).

**Proof.** (i): We leave to the reader the verification that \( U(t, i) \) is a saturated monoid. Next, let \( \sigma_i \subset U(t)(\mathbb{R}_+)^{gp} \) be the convex polyhedral cone spanned by the linear forms

\[
((\lambda_j - \lambda_i) \otimes_{\mathbb{Q}} \mathbb{R} \mid j = 1, \ldots, k).
\]

Then \( \sigma_i \) is \( \mathcal{O}_{T, \mathbb{R}}^{gp} \)-rational, so \( \sigma_i^\vee \) is \( \mathcal{O}_{T, \mathbb{R}}^{gp} \)-rational, and \( \sigma_i^\vee \cap \mathcal{O}_{T, \mathbb{R}}^{gp} \) is a fine monoid (propositions 6.3.21(i), and 6.3.22(ii)), therefore the same holds for \( U(t, i)(\mathbb{N}) = \sigma_i^\vee \cap \mathcal{O}_{T, \mathbb{R}} \) (corollary 6.4.2).

(iii): Notice that \( \text{ht}_T(t) = \dim U(t)(\mathbb{N}) \), by proposition 6.4.12(ii) and (6.5.18). In view of corollary 6.4.10(i), it follows already that \( \dim U(t, i) \leq \text{ht}_T(t) \). Now, let \( \lambda_1, \ldots, \lambda_k \) be an irredundant system, and suppose, by contradiction, that \( \dim U(t, i)(\mathbb{N}) < \dim U(t)(\mathbb{N}) \) for some \( i \leq k \). Especially, \( \sigma_i^\vee \cap \mathcal{O}(t)(\mathbb{R}_+) \) does not span the \( \mathbb{R} \)-vector space \( U(t)(\mathbb{R}_+)^{gp} \), and therefore the dual \( \sigma_i^\vee \cap \mathcal{O}(t)(\mathbb{R}_+) \) is not strictly convex (corollary 6.3.14). After relabeling, we may assume that \( i = 1 \). Hence there exist \( a_j, b_j \in \mathbb{R}_+ \) and \( \varphi, \varphi' \in U(t)(\mathbb{R}_+)^{gp} \), and an identity:

\[
\sum_{j=2}^k a_j(\lambda_j - \lambda_1) + \varphi = - \sum_{j=2}^k b_j(\lambda_j - \lambda_1) - \varphi'.
\]

Moreover, \( \sum_{j=2}^k (a_j + b_j) > 0 \). It follows that there exist \( \psi \in U(t)(\mathbb{R}_+)^{gp} \), and non-negative real numbers \( (c_j \mid j = 2, \ldots, k) \) such that

\[
\lambda_i = \sum_{j=2}^k c_j \lambda_j + \psi \quad \text{and} \quad \sum_{j=2}^k c_j = 1.
\]
On the other hand, the irredundancy condition means that there exists \( x \in U(t, 1)(\mathbb{N}) \) such that \( \lambda_j(x) > \lambda_i(x) \) for every \( j > 1 \). Since \( \psi(x) \geq 0 \), we get a contradiction.

(ii): The assertion is clear, if \( ht_T(t) \leq 1 \). Hence suppose that the height of \( t \) is \( \geq 2 \), and let \( \Lambda := \{ \lambda_1, \ldots, \lambda_k \} \) and \( \mu := \{ \mu_1, \ldots, \mu_r \} \) be two irredundant systems for \( t \). Fix \( i \leq k \), and pick \( x \in U(t, i)(\mathbb{N}) \) which does not lie on any proper face of \( U(t, i)(\mathbb{N}) \) (the existence of \( x \) is ensured by (iii) and proposition \( 6.4.7 \)); say that \( \mu_1(x) = \rho(x) \). Since \( i \) is arbitrary, the assertion shall follow, once we have shown that \( \mu_1 \) agrees with \( \lambda_i \) on the whole of \( U(t, i)(\mathbb{N}) \).

However, by definition we have \( \mu_1(y) \geq \lambda_i(y) \) for every \( y \in U(t, i)(\mathbb{N}) \), and then it is easily seen that \( \text{Ker}(\mu_1 - \lambda_i) \cap U(t, i)(\mathbb{N}) \) is a face of \( U(t, i)(\mathbb{N}) \); since \( x \in \text{Ker}(\mu_1 - \lambda_i) \), we deduce that \( \mu_1 - \lambda_i \) vanishes identically on \( U(t, i)(\mathbb{N}) \).

6.6.5. Henceforth, we denote by \( \Lambda(t) := \{ \lambda_1, \ldots, \lambda_k \} \) the irredundant system of \( \mathbb{Q} \)-linear forms for \( t \). Let \( 1 \leq i, j \leq k \); then we claim that \( U(t, i, j)(\mathbb{N}) := U(t, i)(\mathbb{N}) \cap U(t, j)(\mathbb{N}) \) is a face of both \( U(t, i)(\mathbb{N}) \) and \( U(t, j)(\mathbb{N}) \). Indeed say that \( x, x' \in U(t, i)(\mathbb{N}) \) and \( x + x' \in U(t, i, j)(\mathbb{N}) \); these conditions translate the identities:

\[
\lambda_i(x) + \lambda_i(x') = \lambda_j(x) + \lambda_j(x') \quad \lambda_i(x) \leq \lambda_j(x) \quad \lambda_i(x') \leq \lambda_j(x')
\]

whence \( x, x' \in U(t, i, j)(\mathbb{N}) \). Define:

\[
U(t, i) := (\text{Spec} U(t, i)(\mathbb{N}))^\times \quad U(t, i, j) := (\text{Spec} U(t, i, j)(\mathbb{N}))^\times \quad \text{for every } i, j \leq k.
\]

According to \( 6.5.20 \) and \( 6.5.18 \), the inclusion maps \( U(t, i, j)(\mathbb{N}) \to U(t, l)(\mathbb{N}) \) (for \( l = i, j \)) are dual to open immersions

(6.6.6) \[
U(t, i) \leftarrow U(t, i, j) \to U(t, j).
\]

We may then attach to \( t \) and \( U(t, \rho) \) the fan \( U(t, \rho) \) obtained by gluing the affine fans \( U(t, i) \) along their common intersections \( U(t, i, j) \). The duals of the inclusions \( U(t, i)(\mathbb{N}) \to U(t)(\mathbb{N}) \) determine a well defined morphism of locally fine and saturated fans:

(6.6.7) \[
U(t, \rho) \to U(t)
\]

which, by construction, induces a bijection on \( \mathbb{N} \)-points: \( U(t, \rho)(\mathbb{N}) \sim U(t)(\mathbb{N}) \), so it is a rational subdivision, according to proposition \( 6.5.24 \).

6.6.8. Let now \( t' \in T \) be a generalization of \( t \); clearly the system \( \Lambda' := \{ \lambda'_1, \ldots, \lambda'_l \} \) consisting of the restrictions \( \lambda'_i \) of the linear forms \( \lambda_i \) to the \( \mathbb{Q} \)-vector subspace \( U(t')(\mathbb{Q}_+)^{gp} \), fulfills condition (b) of definition \( 6.6.2 \) relative to \( t' \). However, \( \Lambda' \) may fail to be irredundant; after relabeling, we may assume that the subsystem \( \{ \lambda'_1, \ldots, \lambda'_l \} \) is irredundant for \( t' \), for some \( l \leq k \).

With the foregoing notation, we have obvious identities:

\[
U(t', i)(\mathbb{N}) = U(t, i)(\mathbb{N}) \cap U(t')(\mathbb{N}) \quad U(t', i, j)(\mathbb{N}) = U(t, i, j)(\mathbb{N}) \cap U(t')(\mathbb{N})
\]

for every \( i, j \leq l \); whence, in light of remark \( 6.4.14 \) iii), a commutative diagram of fans:

\[
\begin{array}{ccc}
U(t', i) & \leftarrow & U(t', i, j) \to U(t', j) \\
\downarrow & & \downarrow \\
U(t, i) \times_{U(t)} U(t') & \leftarrow & U(t, i, j) \times_{U(t)} U(t') \to U(t, i) \times_{U(t)} U(t')
\end{array}
\]

whose top horizontal arrows are the open immersions \( 6.6.6 \) (with \( t \) replaced by \( t' \)), whose bottom horizontal arrows are the open immersions \( 6.6.6 \times_{U(t)} U(t') \), and whose vertical arrows are natural isomorphisms. Since \( U(t') \) is an open subset of \( U(t) \), we deduce an open immersion

\[
j_{t', t} : U(t', \rho) \to U(t, \rho).
\]
If $t''$ is a generalization of $t'$, it is clear that $j_{t',t''} \circ j_{t,t'} = j_{t,t''}$, hence we may glue the fans $U(t, \rho)$ along these open immersions, to obtain a locally fine and saturated fan $T(\rho)$. Furthermore, the morphisms (6.6.7) glue to a single rational subdivision:

(6.6.9) \[ T(\rho) \to T. \]

**Remark 6.6.10.** (i) In the language of definition 6.3.25, the foregoing lengthy procedure translates as the following simple geometric operation. Given a fan $\Delta$ (consisting of a collection of convex polyhedral cones of a $\mathbb{R}$-vector space $V$), a roof on $\Delta$ is a piecewise linear function $F := \bigcup_{\sigma \in \Delta} \sigma \to \mathbb{R}$, which is concave on each $\sigma \in \Delta$ (and hence it is a roof on each such $\sigma$, in the sense of example 6.3.27). Then, such a roof determines a natural refinement $\Delta'$ of $\Delta$; namely, $\Delta'$ is the coarsest refinement such that, for each $\sigma' \in \Delta'$, the function $\rho_{|\sigma'}$ is the restriction of a $\mathbb{R}$-linear form on $V$. This refinement $\Delta'$ corresponds to the present $T(\rho)$.

(ii) Moreover, let $P$ be a fine, sharp and saturated monoid of dimension $d$, set $T_P := (\text{Spec } P)^\sharp$, and suppose that $f : T \to T_P$ is any integral, fine, proper and saturated subdivision. Then $f$ corresponds to a geometrical subdivision $\Delta$ of the strictly convex polyhedral cone $T_P(\mathbb{R}_+) = P^\vee_P$, and we claim that $\Delta$ can be refined by the subdivision associated with a roof on $T_P$. Namely, let $\Delta_{d-1}$ be the subset of $\Delta$ consisting of all $\sigma$ of dimension $d - 1$; every $\sigma \in \Delta_{d-1}$ is the intersection of a $d$-dimensional element of $\Delta$ and a hyperplane $H_\sigma \subset P^\vee_P$; such hyperplane is the kernel of a linear form $\lambda_\sigma$ on $P^\vee_P$. Let us define

$$\rho(x) := \sum_{\sigma \in \Delta_{d-1}} \min(0, \lambda_\sigma(x)) \quad \text{for every } x \in T_P(\mathbb{R}_+).$$

Then it is easily seen that the subdivision of $T_P(\mathbb{R}_+)$ associated with the roof $\rho$ as in (i), refines the subdivision $\Delta$. In the language of fans, this construction translates as follows. For every point $\sigma \in T$ of height $d - 1$, let $H_\sigma \subset P^{\text{gp}}$ be the kernel of the surjection $P^{\text{gp}} \to \mathcal{O}^{\text{gp}}_{T,\sigma}$ induced by $\log f$; notice that $H_\sigma$ is a free abelian group of rank one, and pick a generator $s_\sigma$ of $H_\sigma$, which – as in (6.6.1) – corresponds to a function $\lambda_\sigma : T_P(\mathbb{N}) \to \mathbb{Z}$, so we may again consider the integral roof $\rho$ on $T$ defined as in the foregoing. Then it is easily seen that the rational subdivision $T(\rho) \to T_P$ associated with $\rho$, factors as the composition of $f$ and a (necessarily unique) integral subdivision $g : T(\rho) \to T$. More precisely, for every mapping $\varepsilon : \{\sigma \in T \mid \text{ht}(\sigma) = d - 1\} \to \{0, 1\}$, let us set

$$\lambda_\varepsilon := \sum_{\text{ht}(\sigma) = d - 1} \varepsilon(\sigma) \cdot \lambda_\sigma \quad \text{and} \quad U(\varepsilon)(\mathbb{N}) := \{x \in T_P(\mathbb{N}) \mid \rho(x) = \lambda_\varepsilon(x)\}.$$ 

Whenever $U(\varepsilon)(\mathbb{N})$ has dimension $d$, let $t_\varepsilon \in T(\rho)$ be the unique point such that $U(\varepsilon)(\mathbb{N})^\vee = \mathcal{O}_{T(\rho),t_\varepsilon}$. As the reader may check, there exists a unique closed point $\tau \in T$, such that $\varepsilon(\sigma) \cdot \lambda_\sigma(x) \leq 0$ for every $x \in U(\tau)(\mathbb{N})$ and every $\sigma \in U(\tau)$ of height $d - 1$. Then we have $g(t_\varepsilon) = \tau$, and the restriction $U(t_\varepsilon) \to U(\tau)$ of $g$ is deduced from the inclusion $U(\varepsilon)(\mathbb{N}) \subset U(\tau)(\mathbb{N})$ of submonoids of $T_P(\mathbb{N})$.

(iii) Furthermore, in the situation of (ii), the roof $\rho$ on $T_P$ can also be viewed as a roof on $T$, and then it is clear from the construction that the morphism $g : T(\rho) \to T$ is also the subdivision of $T$ attached to the roof $\rho$.

We wish now to establish some basic properties of the sheaf of fractional ideals

$$\mathcal{I}_\rho := \mathcal{I}_{\rho,\mathbb{Q}} \cap \mathcal{O}^{\text{gp}}_T$$

attached to a given roof on $T$. First we remark:

**Lemma 6.6.11.** Keep the notation of (6.6.5), and let $s \in \mathcal{O}^{\text{gp}}_{T,j} \otimes_{\mathbb{Z}} \mathbb{Q}$ be any element such that $\rho_s \geq \rho_{|U(t)}$. Then we have:
(i) There exist \( \varphi \in (\mathcal{O}_{T,t})_Q \) (notation of \(6.3.20\)) and \( c_1, \ldots, c_k \in \mathbb{R}_+ \) such that:

\[
\rho_s = \rho_\varphi + \sum_{i=1}^k c_i \lambda_i = \sum_{i=1}^k c_i = 1.
\]

(ii) The stalk \( \mathcal{I}_{\rho,t} \) is a finitely generated \( \mathcal{O}_{T,t} \)-module.

**Proof.** (i) Let \( \sigma \subset U(t)(\mathbb{R}_+)^{\mathbb{R}} \) be the convex polyhedral cone spanned by the linear forms \((\lambda_i - \rho_s) \otimes \mathbb{Q} R | i = 1, \ldots, k)\). Then the assumption on \( s \) means that:

\[
U(t)(\mathbb{R}_+)^{\mathbb{R}} \cap \sigma^\vee = U(t)(\mathbb{R}_+) \cap \operatorname{Ker} \rho_s \otimes \mathbb{Q} R.
\]

Especially \( \sigma^\vee \cap U(t)(\mathbb{R}_+) \) does not span \( U(t)(\mathbb{R}_+)^{\mathbb{R}} \). Then one can repeat the proof of lemma 6.6.4(ii) to derive the assertion.

(ii): By remark 6.4.14(i), we may write \( \lambda_i = \rho_{s_i} - \rho_{s_i'} \), where \( s_i, s_i' \in (\mathcal{O}_{T,t})_Q \) for each \( i \leq k \); pick \( N \in \mathbb{N} \) large enough, so that \( N s_i' \in \mathcal{O}_{T,t} \) for every \( i \leq k \), and set \( \tau := N \sum_{i=1}^k s_i' \). Then \( \tau + \mathcal{I}_{\rho,t} \subset \mathcal{O}_{T,t}^\mathbb{R} \cap (\mathcal{O}_{T,t})_Q = \mathcal{O}_{T,t} \). By proposition 6.1.9(ii), we deduce that \( \tau + \mathcal{I}_{\rho,t} \) is a finitely generated ideal, whence the contention. \( \square \)

**Proposition 6.6.12.** Let \( T \) be a locally fine and saturated fan, \( \rho \) a roof on \( T \). Then the associated fractional ideal \( \mathcal{I}_\rho \) of \( \mathcal{O}_T \) is coherent.

**Proof.** In view of lemma 6.6.11(ii) and remark 6.5.13(v), it suffices to show that \( \mathcal{I}_\rho \) is quasi-coherent, i.e., for every generalization \( t' \) of \( t \), the image of \( \mathcal{I}_{\rho,t'} \) in \( \mathcal{O}_{T,t'} \) generates the \( \mathcal{O}_{T,t'} \)-module \( \mathcal{I}_{\rho,t'} \). Fix such \( t' \); by propositions 6.3.21(i) and 6.4.7(i), there exists \( \lambda \in \mathcal{O}_{T,t} = U(t)(\mathbb{N})^\vee \) such that \( U(t)(\mathbb{N})^{\mathbb{R}} = \operatorname{Ker} \lambda \); especially, we see that \( U(t')(\mathbb{N})^{\mathbb{R}} \) is a direct summand of \( U(t)(\mathbb{N})^{\mathbb{R}} \). Now, let \( s' \in \mathcal{I}_{\rho,t'} \) be any local section; it follows that we may find \( s \in \mathcal{O}_{T,t}^{\mathbb{R}} \) such that \( \rho_s : U(t)(\mathbb{N})^{\mathbb{R}} \to \mathbb{Z} \) is a \( \mathbb{Z} \)-linear extension of the corresponding \( \mathbb{Z} \)-linear form \( \rho_{s'} : U(t')(\mathbb{N})^{\mathbb{R}} \to \mathbb{Z} \). Let also \( \{\lambda_1, \ldots, \lambda_k\} \) be the irredundant system of \( \mathbb{Q} \)-linear forms for \( t \) (relative to the roof \( \rho \)). For every \( i \leq k \) we have the following situation:

\[
\lambda_{i R} := \lambda_i \otimes \mathbb{Q} R \in U(t, i)(\mathbb{R}_+)^{\mathbb{R}} \quad (\rho_s - \lambda_i) \otimes \mathbb{Q} R \in U(t, i)(\mathbb{R}_+)^{\mathbb{R}}.
\]

However, \( U(t', i)(\mathbb{R}_+)^{\mathbb{R}} \supset (U(t, i)(\mathbb{R}_+)^{\mathbb{R}} \cap \operatorname{Ker} \lambda_{i R}) \), hence \( U(t', i)(\mathbb{R}_+)^{\mathbb{R}} = U(t, i)(\mathbb{R}_+)^{\mathbb{R}} + \mathbb{R} \lambda_{i R} \). Especially, there exist \( r_i \in \mathbb{R}_+ \) and \( \varphi \in U(t)(\mathbb{R}_+)^{\mathbb{R}} \) such that \( (\rho_s - \lambda_i) \otimes \mathbb{Q} R = \varphi - r_i \lambda_{i R} \). Let \( N \) be an integer greater than \( \max(r_1, \ldots, r_k) \); it follows that \( s + N \lambda \in \mathcal{I}_{\rho,t} \) and its image in \( \mathcal{I}_{\rho,t'} \) equals \( s' \). \( \square \)

**Proposition 6.6.13.** In the situation of \(6.6.3\) suppose that \( \rho \) is an integral roof on \( T \). Then the morphism \(6.6.9\) is the saturation of a blow up of the fractional ideal \( \mathcal{I}_\rho \).

**Proof.** We have to exhibit an isomorphism \( f : T(\rho) \to X := \operatorname{Proj} \mathcal{B}(\mathcal{I})^{\mathbb{R}} \mathcal{S} \) of \( T \)-fans. We begin with:

**Claim 6.6.14.** (i) The fractional ideal \( \mathcal{I}_\rho \mathcal{O}_{T(\rho)} \) is invertible.

(ii) For every \( n \in \mathbb{N} \), denote by \( n \rho : T(\mathbb{Q}_+) \to \mathbb{Q}_+ \) the function given by the rule \( x \mapsto n \cdot \rho(x) \) for every \( x \in T(\mathbb{Q}_+) \). Then:

\[
\mathcal{B}(\mathcal{I})^{\mathbb{R}} \mathcal{S} = \mathcal{B}' := \prod_{n \in \mathbb{N}} \mathcal{I}_{n \rho}.
\]

**Proof of the claim.** (ii): The assertion is local on \( T \), hence we may assume that \( T = U(t) \) for some \( t \in T \), in which case, denote by \( \Delta := \{\lambda_1, \ldots, \lambda_k\} \) the irredundant system of \( \mathbb{Q} \)-linear forms for \( t \). Let \( n \in \mathbb{N} \), and \( s \in \mathcal{I}_{n \rho}(U(t)) \); it is easily seen that the \( T \)-monoid \( \mathcal{B}' \) is saturated, hence it suffices to show that there exists an integer \( k > 0 \) such that \( k \rho_s = \rho_s' \) for some \( s' \in \mathcal{I}_{\rho}(U(t)) \) (notation of \(6.6.1\)). However, lemma 6.6.11(ii) implies more precisely that we may find such \( k \), so that the corresponding \( s' \) lies in the ideal generated by \( \Delta \).
(i) The assertion is local on $T(\rho)$, hence we consider again $t \in T$ and the corresponding $\lambda\rho$ as in the foregoing. It suffices to show that $\mathcal{I} := \mathcal{I}_\rho\partial_{U(t,i)}$ is invertible for every $i = 1, \ldots, k$ (notation of \ref{6.6.11}). However, by inspecting the constructions it is easily seen that $\mathcal{I}(U(t,i))$ consists of all $s \in (U(t,i)(\mathbb{N})^\vee)^{gp}$ such that $\rho_s(x) \geq \rho(x)$ for every $x \in U(t,i)(\mathbb{Q}_+)$, i.e., $\rho_s(x) \geq \lambda_i(x)$ for every $x \in U(t,i)(\mathbb{Q}_+)$. However, since $\rho$ is integral, we have $\lambda_i \in \partial_{T,i}^g$; if we apply lemma \ref{6.6.11}(i) with $T$ replaced by $U(t,i)$, we conclude that $\mathcal{I}(U(t,i))$ is the fractional ideal generated by $\lambda_i$, whence the contention.

In view of claim \ref{6.6.14}(i) we see that there exists a unique morphism $f$ of $T$-fans from $T(\rho)$ to $X$. It remains to check that $f$ is an isomorphism; the latter assertion is local on $X$, hence we may assume that $T = U(t)$ for some $t \in T$, and then we let again $\lambda$ be the irredundant system for $t$. A direct inspection yields a natural identification of $\partial_{T,i}$-monoids:

$$\mathcal{I}(U(t,i))(\lambda_i) \cong U(t,i)(\mathbb{N})^\vee$$

whence an isomorphism $U(t,i) \cong D_+(\lambda_i) \subset X$, which – by uniqueness – must coincide with the restriction of $f$. On the other hand, the proof of claim \ref{6.6.14}(ii) also shows that $X = D_+(\lambda_1) \cup \cdots \cup D_+(\lambda_k)$, and the proposition follows.

\begin{example} \label{6.6.15} Let $P$ be a fine, sharp and saturated monoid.

(i) The simplest non-trivial roofs on $T_P := (\text{Spec } P)^t$ are the functions $\rho_\lambda$ such that

$$\rho_\lambda(x) := \min(0, \lambda(x))$$

for every $x \in T_P(\mathbb{Q}_+)$. Where $\lambda$ is a given element of $\text{Hom}_Q(T_P(\mathbb{Q}_+)^{gp}, \mathbb{Q}) \cong P^{gp} \otimes \mathbb{Q}$. Such a $\rho_\lambda$ is an integral roof, provided $\lambda \in P^{gp}$. In the latter case, we may write $\lambda = \rho_{s_1} - \rho_{s_2}$, for some $s_1, s_2 \in P$. Set $\rho' := \rho_\lambda + \rho_{s_2}$, i.e. $\rho' = \min(\rho_{s_1}, \rho_{s_2})$.

(ii) More generally, any system $\lambda_1, \ldots, \lambda_k \in \text{Hom}_Q(T_P(\mathbb{Q}_+)^{gp}, \mathbb{Q})$ of $\mathbb{Q}$-linear forms yields a roof $\rho$ on $T_P$, such that $\rho(x) := \sum_{i=1}^k \min(0, \lambda_i(x))$ for every $x \in T_P(\mathbb{Q}_+)$. A simple inspection shows that the corresponding subdivision $T(\rho) \rightarrow T$ of the type considered in (ii), so that $f$ factors as the composition of $g$ and a subdivision $h : T(\rho) \rightarrow T$ which is also of the type (ii). Especially, both $f$ and $h$ can be realized as the composition of finitely many saturated blow up of ideals generated by at most two elements of $P$.

(iii) These subdivisions of $T_P$ ”by hyperplanes” are precisely the ones that occur in remark \ref{6.6.10}(i),(ii), (iii). Summing up, we conclude that every proper integral and saturated subdivision $g : T \rightarrow T_P$ of $T_P$ can be dominated by another subdivision $f : T(\rho) \rightarrow T_P$ of the type considered in (ii), so that $f$ factors as the composition of $g$ and a subdivision $h : T(\rho) \rightarrow T$ which is also of the type (ii).

\end{example}

6.6.16. Let $P$ be a fine, sharp and saturated monoid. A proper, integral, fine and saturated subdivision of

$$T_P := (\text{Spec } P)^t$$

is essentially equivalent to a $(P^{gp})^\vee$-rational subdivision of the polyhedral cone $\sigma := P^t_\mathbb{R}$ (see \ref{6.4.6} and definition \ref{6.3.25}). A standard way to subdivide a polyhedron $\sigma$ consists in choosing a point $x_0 \in \sigma \setminus \{0\}$, and forming all the polyhedra $x \ast F$, where $F$ is any proper face of $\sigma$, and $x \ast F$ denotes the convex span of $x_0$ and $F$. We wish to describe the same operation in terms of the topological language of affine fans.
Namely, pick any non-zero \( \varphi \in T_P(Q_+) \) (\( \varphi \) corresponds to the point \( x_0 \) in the foregoing). Let \( U(\varphi) \subset \text{Spec} \ P \) be the set of all prime ideals \( p \) such that \( \varphi(P \setminus p) \neq \{0\} \); in other words, the complement of \( U(\varphi) \) is the topological closure of the support of \( \varphi \) in \( T_P \), especially, \( U(\varphi) \) is an open subset of \( T_P \). Denote by \( j : P = \Gamma(T_P, \mathcal{O}_{T_P}) \to \Gamma(U(\varphi), \mathcal{O}_{T_P}) \) the restriction map. The morphism of monoids:

\[
P \to \Gamma(U(\varphi), \mathcal{O}_{T_P}) \times Q_+ \quad x \mapsto (j(x), \varphi(x))
\]
determines a cocartesian diagram of fans

\[
\begin{array}{ccc}
U(\varphi) \times (\text{Spec} \ Q_+)^\sharp & \xrightarrow{\beta'} & U(\varphi) \times (\text{Spec} \ N)^\sharp \\
\psi' \downarrow & & \downarrow \psi \\
T_P & \xrightarrow{\beta} & T_{\varphi^{-1}N} := (\text{Spec} \ \varphi^{-1}N)^\sharp
\end{array}
\]

**Lemma 6.6.17.** With the notation of (6.6.16), the morphisms \( \psi \) and \( \psi' \) are proper rational subdivisions, which we call the subdivisions centered at \( \varphi \).

**Proof.** Notice that both \( \beta \) and \( \beta' \) are homeomorphisms on the underlying topological spaces, and moreover both \( \log \beta' \beta \otimes Z 1_Q \) and \( \log \beta' \beta \otimes Z 1_Q \) are isomorphisms. Thus, it suffices to show that \( \psi \) is a proper rational subdivision, hence we may replace \( P \) by \( \varphi^{-1}N \), which allows to assume that \( \varphi \) is a morphism of monoids \( P \to N \), and \( \psi \) is a morphism of fans

\[
T' := U(\varphi) \times (\text{Spec} \ N)^\sharp \to T_P.
\]

In this situation, by inspecting the construction, we find that \( \psi \) restricts to an isomorphism:

\[
\psi^{-1}U(\varphi) \xrightarrow{\sim} U(\varphi)
\]

and the preimage of the closed subset \( T_P \setminus U(\varphi) \) is the preimage of the closed point \( m \in (\text{Spec} \ N)^\sharp \) under the natural projection \( T' \to (\text{Spec} \ N)^\sharp \); in view of the discussion of (6.5.19), this is naturally identified with \( U(\varphi) \times \{m\} \). Moreover, the restriction \( U(\varphi) \times \{m\} \to T_P \setminus U(\varphi) \) of \( \psi \) is the map \( (t, m) \mapsto t \cup \varphi^{-1}m \) (recall that \( t \subset P \) is a prime ideal which does not contain \( \varphi^{-1}m \)). Thus, the assertion will follow from:

**Claim 6.6.18.** The \( Q \)-linear map

\[
\log \psi^{\beta}(t, m) \otimes Z 1_Q : P^{\beta} \otimes Z Q \to (\mathcal{O}_{T_P, t} \times Z) \otimes Z Q
\]
is surjective for every \( t \in U(\varphi) \), and the induced map:

(6.6.19) \[ T'(Q_+) \to T_{\varphi^{-1}N}(Q_+) = T_P(Q_+) \]
is bijective.

**Proof of the claim.** Indeed, let \( F_t \subset P^\varphi \) be the face of \( P^\varphi \) corresponding to the point \( t \in U(\varphi) \), under the bijection (6.5.21); then \( \varphi \not\in F_t \), whence a natural isomorphism of monoids:

\[
(F_t + N\varphi)^\varphi \xrightarrow{\sim} \mathcal{O}_{T_P, t} \times N \quad : \quad \lambda \mapsto (\lambda|_{F_t}, \lambda(\varphi))
\]

whose inverse, composed with \( \log \psi^{\beta}(t, m) \), yields the restriction map \( P \to (F_t + N\varphi)^\varphi \). This interpretation makes evident the surjectivity of \( \log \psi^{\beta}(t, m) \otimes Z 1_Q \). In view of example 6.5.9(iii), the bijectivity of (6.6.19) is also clear, if one remarks that:

\[
P^\varphi = \bigcup_{t \in U(\varphi)} (F_t + N\varphi)_{\mathbb{R}}.
\]

The latter identity is obvious from the geometric interpretation in terms of polyhedral cones. A formal argument runs as follows. Let \( \varphi' \in P^\varphi_{\mathbb{R}} \); since \( P \) spans \( P^{\beta}_{\mathbb{R}} \), the cone \( (P^\varphi)^\varphi \) is strictly convex (corollary 6.3.14), hence the line \( \varphi' + \mathbb{R} \varphi \subset P^\varphi_{\mathbb{R}} \) is not contained in \( P^\varphi_{\mathbb{R}} \), therefore there
exists a largest \( r \in \mathbb{R} \) such that \( \varphi' - r \varphi \in P'_R \), and necessarily \( r \geq 0 \). If \( \varphi' - r \varphi = 0 \), the assertion is clear; otherwise, let \( F \) be the minimal face of \( P' \) such that \( \varphi' - r \varphi \in F_R \), so that \( \varphi' = (\varphi' - r \varphi) + r \varphi \in (F + N \varphi)_R \). Thus, we are reduced to showing that \( \varphi \notin F \). But notice that \( \varphi' - r \varphi \) lies in the relative interior of \( F \); therefore, if \( \varphi \in F \), we may find \( \varepsilon > 0 \) such that \( \varphi' - (r + \varepsilon) \varphi \) still lies in \( F_R \), contradicting the definition of \( r \).

**Lemma 6.6.20.** Lemma 6.6.17 is frequently used to construct subdivisions centered at an interior point of \( T_P \), i.e., a point \( \varphi \in T_P(\mathbb{N}) \) which does not lie on any proper face of \( T_P(\mathbb{N}) \) (equivalently, the support of \( \varphi \) is the closed point \( m_P \) of \( T_P \)). In this case \( U(\varphi) = T_P \setminus \{ m_P \} = (T_P)_{d-1} \), where \( d := \dim P \). By Lemma 6.6.17, the \( \mathbb{N} \)-point \( \varphi \) lifts to a unique \( \mathbb{Q}_+ \)-point \( \bar{\varphi} \) of \( (T_P)_{d-1} \times (\text{Spec } \mathbb{N})^2 \), and by inspecting the definitions, it is easily seen that – under the identification of remark 6.5.8(iii) – the support of \( \bar{\varphi} \) is the point \( (\varnothing, m_N) \), where \( \varnothing \in T_P \) is the generic point. More precisely, we may identify \( (\text{Spec } \mathbb{N})^2(\mathbb{Q}_+) \) with \( \mathbb{Q}_+ \), and \( (T_P)_{d-1}(\mathbb{Q}_+) \) with a cone in the \( \mathbb{Q} \)-vector space \( T_P(\mathbb{Q}_+)_{\mathbb{Q}_+} \); and \( \bar{\varphi} \) corresponds to the point \( (0, 1) \in T_P(\mathbb{Q}_+)_{\mathbb{Q}_+} \).

Suppose now that we have an integral roof

\[ \rho : (T_P)_{d-1}(\mathbb{Q}_+) \to \mathbb{Q} \]

and let \( \pi : T(\rho) \to (T_P)_{d-1} \) be the associated subdivision. Let also \( \psi : (T_P)_{d-1} \times (\text{Spec } \mathbb{N})^2 \to T_P \) be the subdivision centered at \( \varphi \); we deduce a new subdivision:

\[
(6.6.21) \quad T^* := T(\rho) \times (\text{Spec } \mathbb{N})^2 \xrightarrow{\pi \times 1_{(\text{Spec } \mathbb{N})^2}} (T_P)_{d-1} \times (\text{Spec } \mathbb{N})^2 \xrightarrow{\psi} T_P
\]

whose restriction to the preimage of \((T_P)_{d-1}\) is \( T_P \)-isomorphic to \( \pi \).

**Lemma 6.6.22.** In the situation of (6.6.20), there exist an integral roof

\[ \bar{\rho} : T_P(\mathbb{Q}_+) \to \mathbb{Q} \]

whose restriction to \((T_P)_{d-1}(\mathbb{Q}_+)\) agrees with \( \rho \), and a morphism \( T^* \to T(\bar{\rho}) \) of \( T_P \)-monoids, whose underlying continuous map is a homeomorphism.

**Proof.** According to remark 6.5.8(vi), we have a natural identification:

\[ T_P(\mathbb{Q}_+) = T(\rho)(\mathbb{Q}_+) \times (\text{Spec } \mathbb{N})^2(\mathbb{Q}_+) = T(\rho)(\mathbb{Q}_+) \times \mathbb{Q}_+ \subset T_P(\mathbb{Q}_+) \]

mapping the point \( \varphi \) to \((0, 1)\). For a given \( c \in \mathbb{R} \), denote by \( \rho_c : T_P(\mathbb{Q}_+) \to \mathbb{Q} \) the function given by the rule \((x, y) \mapsto \rho(x) + cy\) for every \( x \in T(\rho)(\mathbb{Q}_+) \) and every \( y \in \mathbb{Q}_+ \).

Let \( t \in T(\rho) \) be any point of height \( d - 1 \); by assumption, there exists a \( \mathbb{Q} \)-linear form \( \lambda_t : U(\pi(t))(\mathbb{Q}_+)_{\mathbb{Q}_+} \to \mathbb{Q} \) whose restriction to \( U(t)(\mathbb{Q}_+) \) agrees with the restriction of \( \rho \). Therefore, the restriction of \( \rho_c \) to \( U(t,m_N)(\mathbb{Q}_+) = U(t)(\mathbb{Q}_+) \times \mathbb{Q}_+ \) agrees with the restriction of the \( \mathbb{Q} \)-linear form

\[ \lambda_{t,c} : U(\pi(t))(\mathbb{Q}_+)_{\mathbb{Q}_+} \to \mathbb{Q} = T_P(\mathbb{Q}_+) \]

\((x, y) \mapsto \lambda_t(x) + cy\).

For any two points \( t, t' \in T(\rho) \) of height \( d - 1 \), with \( \pi(t) = \pi(t') \), pick a finite system of generators \( \{ x_1, \ldots, x_n \} \) for \( U(t')(\mathbb{N}) \), and let \( y_1, \ldots, y_n \in U(t)(\mathbb{Q})_{\mathbb{Q}_+} \), \( a_1, \ldots, a_n \in \mathbb{Q} \) such that

\[ x_i = y_i + a_i \varphi \]

in the vector space \( U(\pi(t))(\mathbb{Q}_+) \).

In case \( x_i \in U(t)(\mathbb{N}) \), we shall have \( a_i = 0 \), and otherwise we remark that \( a_i > 0 \). Indeed, if \( a_i < 0 \) we would have \( x_i - a_i \varphi \in U(t)(\mathbb{Q}_+) \cap T_P(\mathbb{Q}_+) \subset U(\pi(t))_{\mathbb{Q}_+} \); however, \( U(\pi(t))_{\mathbb{Q}_+} \) is a proper face of \( T_P(\mathbb{Q}_+) \), hence \( \varphi \notin U(\pi(t))_{\mathbb{Q}_+} \), a contradiction.

We may then find \( c > 0 \) large enough, so that \( \lambda_{t,c}(x_i) < \lambda_{t,c}(x_i) \) for every \( x_i \notin U(t)(\mathbb{N}) \). It follows easily that

\[
(6.6.23) \quad \lambda_{t',c}(x) < \lambda_{t,c}(x) \quad \text{for all } x \in U(t', m_N)(\mathbb{Q}_+) \setminus U(t, m_N)(\mathbb{Q}_+)
\]

Clearly we may choose \( c \) large enough, so that (6.6.23) holds for every pair \( t, t' \) as above, and then it is clear that \( \rho_c \) will be a roof on \( T_P \). Notice that the points of height \( d \) of \( T^* \) are
Then the foregoing shows that we may find a sequence of integers \( S \), rated monoids. We let \( d \) are in natural bijection with those of \( T^* \), and if \( \tau \in T(\rho_\tau) \) corresponds to \( \tau^* \in T^* \) under this bijection, we have an injective mapping \( U(\tau^*)(\mathbb{N}) \to U(\tau)(\mathbb{N}) \), commuting with the induced projections to \( T_P(\mathbb{N}) \). There follows a morphism of \( T_P \)-fans \( U(\tau^*) \to U(\tau) \) inducing a bijection \( U(\tau^*)(\mathbb{Q}_+^* \to U(\tau)(\mathbb{Q}_+^*) \). Since \( T(\rho_\tau) \) (resp. \( T^* \)) is the union of all such \( U(\tau) \) (resp. \( U(\tau^*) \)), we deduce a morphism \( T^* \to T(\rho_\tau) \) inducing a homeomorphism on underlying topological spaces. Lastly, say that \( \tau^* = (t, m) \); then \( U(\tau^*)(\mathbb{N})^{gp} = U(t)(\mathbb{N})^{gp} \oplus \mathbb{Z}_2 \varphi \), and on the other hand \( U(t)(\mathbb{N})^{gp} \) is a direct factor of \( U(\tau)(\mathbb{N})^{gp} \) (since the specialization map \( O_{U(\tau)}^{gp} \to O_{U(t)}^{gp} \) is surjective). It follows easily that we may choose for \( c \) a suitable positive integer, in such a way that the resulting roof \( \tilde{\rho}_c \) will also be integral.

6.6.24. Let \( P \) be a fine, sharp and saturated monoid, and set as usual \( T_P := (\text{Spec} \, P)^\sharp \). There is a canonical choice of a point in \( T_P(\mathbb{N}) \) which does not lie on any proper face of \( T_P(\mathbb{N}) \); namely, one may take the \( \mathbb{N} \)-point \( \varphi_P \) defined as the sum of the generators of the one-dimensional faces of \( T_P(\mathbb{N}) \) (such faces are isomorphic to \( \mathbb{N} \), by theorem 6.4.16(ii)).

Set \( d := \dim P \); if \( \rho \) is a given integral roof for \((T_P)_{d-1} \), and \( c \in \mathbb{N} \) is a sufficiently large, we may then attach to the datum \((\varphi_P, \rho, c)\) an integral roof \( \tilde{\rho} \) of \( T_P \) extending \( \rho \) as in lemma 6.6.22 and such that \( \tilde{\rho}(\varphi_P) = c \). More generally, let \( T \) be a fine and saturated fan of dimension \( d \), and suppose we have a given integral roof \( \rho_{d-1} \) on \((T_{d-1}) \); for every point \( t \in T \) of height \( d \) we have the corresponding canonical point \( \varphi_t \) in the “interior” of \( U(t)(\mathbb{N}) \), and we may then pick an integer \( e_d \) large enough, so that \( \rho_{d-1} \) extends to an integral roof \( \rho_d : T(Q_+^*) \to Q_+^{\ast} \) with \( \rho_d(\varphi_t) = c_d \) for every \( t \in T \) of height \( d \), and such that the associated subdivision is \( T_P \)-homeomorphic to \( T(\rho_{d-1}) \times (\text{Spec} \, \mathbb{N}) \).

This is the basis for the inductive construction of an integral roof on \( T_P \) which is canonical in a certain restricted sense. Indeed, fix an increasing sequence of positive integers \( \underline{c} := (c_2, \ldots, c_d) \); first we define \( \rho_1 : T_1(Q_+^*) \to Q_+^* \) to be the identically zero map. This roof is extended recursively to a function \( \rho_h \) on \( T_h \), for each \( h = 2, \ldots, d \), by the rule given above, in such a way that \( \rho_h(\varphi_t) = c_i \) for every point \( t \) of height \( i \leq h \). By the foregoing we see that the sequence \( \underline{c} \) can be chosen so that \( \rho_d \) shall again be an integral roof.

6.6.25. More generally, let \( \mathscr{F} := \{P_1, \ldots, P_k\} \) be any finite set of fine, sharp and saturated monoids. We let \( \mathscr{F} \)-Fan be the full subcategory of \( \text{Fan} \) whose objects are the fans \( T \) such that, for every \( t \in T \), there exist \( P \in \mathscr{F} \) and an open immersion \( U(t) \subset (\text{Spec} \, P)^\sharp \).

Then the foregoing shows that we may find a sequence of integers \( \underline{c}(\mathscr{F}) := (c_2, \ldots, c_d) \), with \( d := \max(\dim P_i \mid i = 1, \ldots, k) \) such that the following holds. Every object \( T \) of \( \mathscr{F} \)-Fan is endowed with an integral roof \( \rho_T : T(Q_+^*) \to \mathbb{Q}_+^* \) such that:

- \( \rho_T(\varphi_t) = c_i \) whenever \( \text{ht}(t) = i \geq 2 \), and \( \rho_T \) vanishes on \( T_1(Q_+^*) \).
- Every open immersion \( g : T' \to T \) in \( \mathscr{F} \)-Fan determines an open immersion \( \tilde{g} : T'(\rho_{T'}) \to T(\rho_T) \) such that the diagram

\[
\begin{align*}
T'(\rho_{T'}) & \xrightarrow{\tilde{g}} T(\rho_T) \\
\pi_T' & \downarrow \quad \pi_T \\
T' & \xrightarrow{g} T
\end{align*}
\]

commutes (where \( \pi_T \) and \( \pi_{T'} \) are the subdivisions associated to \( \rho_T \) and \( \rho_{T'} \)).

- If \( \dim T = d \), there exists a natural rational subdivision

\[
(6.6.26) \quad T_{d-1}(\rho_{T_{d-1}}) \times (\text{Spec} \, \mathbb{N})^\sharp \to T(\rho_T)
\]

which is a homeomorphism on the underlying topological spaces.
6.6.27. Notice as well that, by construction, \( T_1(\rho_{T_1}) = T_1 \); hence, by composing the morphisms (6.6.26), we obtain a rational subdivision of \( T(\rho_T) : \\
T_1 \times (\text{Spec } \mathbb{N}^{\oplus d-1})^\dagger \to \cdots \to T_{d-2}(\rho_{T_{d-2}} \times (\text{Spec } \mathbb{N}^{\oplus 2})^\dagger \to T_{d-1}(\rho_{T_{d-1}} \times (\text{Spec } \mathbb{N})^\dagger \to T(\rho_T). \\
In view of theorem 6.4.16(ii), it is easily seen that every affine open subset of \( T_1 \) is isomorphic to \( (\text{Spec } \mathbb{N})^\dagger \), and any two such open subsets have either empty intersection, or else intersect in their generic points. In any case, we deduce a natural epimorphism

\[
(Q_+)_T \to O_{T_1, \mathbb{Q}} \\
\text{(notation of 6.5.20)}
\]

from the constant \( T_1 \)-monoid arising from \( Q_+ \); whence an epimorphism :

\[
\vartheta_T : (\mathbb{Q}_+^{\oplus d})_T(\rho_T) \to O_{T(\rho_T), \mathbb{Q}}
\]

which is compatible with open immersions \( g : T' \to T \) in \( \mathcal{F}_{-}\text{-Fan}, \) in the following sense. Set \( d' := \dim T' \); and notice that \( d' \leq d; \) denote by \( \pi_{d'd'} : \mathbb{Q}_+^{\oplus d'} \to \mathbb{Q}_+^{\oplus d} \) the projection on the first \( d' \) direct summands; then the diagram of \( T' \)-monoids :

\[
\begin{array}{ccc}
(\mathbb{Q}_+^{\oplus d})_T(\rho_T) & \xrightarrow{(\pi_{d'd'})_T(\rho_T)} & (\mathbb{Q}_+^{\oplus d'})_T(\rho_T) \\
\downarrow \vartheta_T & & \downarrow \vartheta_{T'} \\
(\mathbb{Q}_+^{\oplus d})_T(\rho_T) & \xrightarrow{\vartheta_T} & O_{T(\rho_T), \mathbb{Q}}
\end{array}
\]

(6.6.28)

commutes.

6.6.29. Let \( f : T' \to T \) be a proper morphism, with \( T' \) locally fine, such that the induced map \( T(Q_+) \to T'(Q_+) \) is injective, and let \( s, t \in T \) be any element. For every \( t \in f^{-1}(s) \), we set

\[
G_t := U(t)(Q_+) \cap U(s)(\mathbb{N})^{\text{gp}} \\
H_t := U(t)(\mathbb{N})^{\text{gp}} \\
\delta_t := (G_t : H_t)
\]

and define \( \delta(f, s) := \max(\delta_t \mid t \in f^{-1}(s)) \).

**Lemma 6.6.30.** For every \( s \in T \) we have :

(i) \( \delta(f, s) \in \mathbb{N} \).

(ii) If \( t, t' \in f^{-1}(s) \), and \( t \) is a specialization of \( t' \) in \( T' \), then \( \delta_t \leq \delta_{t'} \).

(iii) If \( f \) is a rational subdivision, the following conditions are equivalent :

(a) \( \delta(f, s) = 1 \).

(b) \( U(s)(\mathbb{N}) = \bigcup_{t \in f^{-1}(s)} U(t)(\mathbb{N}) \).

**Proof.** (i): Since \( f^{-1}(s) \) is a finite set, the assertion means that \( \delta_t < +\infty \) for every \( t \in f^{-1}(s) \). However, for such a \( t \), let \( P := O_{T,s} \) and \( Q := O_{T', t} \); then

\[
U(t)(Q_+)^{\text{gp}} = \text{Hom}_{\mathbb{Z}}(\mathbb{Q}^{\text{gp}}, \mathbb{Q}) \\
U(t)(\mathbb{N})^{\text{gp}} = \text{Hom}_{\mathbb{Z}}(\mathbb{Q}^{\text{gp}}, \mathbb{Z})
\]

(remark 6.4.14(i) and proposition 6.4.12(iii)). By proposition 6.5.24 we know that the map \( (\log f)|_t^{\text{gp}} \otimes_{\mathbb{Z}} \mathbb{Q} : P^{\text{gp}} \otimes_{\mathbb{Z}} \mathbb{Q} \to \mathbb{Q}^{\text{gp}} \otimes_{\mathbb{Z}} \mathbb{Q} \) is surjective. Since \( Q \) is finitely generated, it follows that the image \( Q' \) of \( P^{\text{gp}} \) in \( \mathbb{Q}^{\text{gp}} \) is a subgroup of finite index, and then it is easily seen that \( \delta_t = (Q^{\text{gp}} : Q') \).

(ii): Under the stated assumptions we have :

\[
G_t = G_t \cap U(t')(Q_+)^{\text{gp}} \\
H_t = H_t \cap U(t')(\mathbb{N})^{\text{gp}}
\]

whence the contention.

(iii): Assume that (b) holds, and let \( \varphi \in U(t)(Q_+)^{\text{gp}} \cap U(s)(\mathbb{N})^{\text{gp}} \) for some \( t \in f^{-1}(s) \). Pick any element \( \varphi_0 \in U(t)(\mathbb{N}) \) which does not lie on any proper face of \( O_{T', t}^{\text{gp}} \); we may then find an integer \( a > 0 \) large enough, so that \( \varphi + a\varphi_0 \in U(t)(Q_+) \). Set \( \varphi_1 := \varphi + a\varphi_0 \) and \( \varphi_2 := a\varphi_0; \) then \( \varphi_1, \varphi_2 \in U(t)(Q_+) \cap U(s)(\mathbb{N}) = U(t)(\mathbb{N}) \), hence \( \varphi = \varphi_1 - \varphi_2 \in U(t)(\mathbb{N})^{\text{gp}}. \) Since \( \varphi \) is arbitrary, we see that \( \delta_t = 1 \), whence (a).
Conversely, suppose that (a) holds, and let \( \varphi \in U(t)(\mathbb{N}) \); then there exists \( t \in f^{-1}(s) \) such that \( \varphi \in U(t)(\mathbb{Q}_+) \). Thus, \( \varphi \in U(t)(\mathbb{N})^{op} \cap U(t)(\mathbb{Q}_+) = U(t)(\mathbb{N}) \), whence (b).

**Theorem 6.6.31.** Every locally fine and saturated fan \( T \) admits an integral, proper, simplicial subdivision \( f : T' \to T \), whose restriction \( f^{-1}T_{\text{sim}} \to T_{\text{sim}} \) is an isomorphism of fans.

**Proof.** Let \( T \) be such a fan. By induction on \( h \in \mathbb{N} \), we shall construct a system of integral, proper simplicial subdivisions \( f_h : S(h) \to T_h \) of the open subsets \( T_h \) (notation of (6.5.16)), such that, for every \( h \in \mathbb{N} \), the restriction \( f_{h+1}^{-1}(T_h) \to T_h \) of \( f_{h+1} \) is isomorphic to \( f_h \), and such that \( f_h^{-1}T_{h,\text{sim}} \to T_{h,\text{sim}} \) is an isomorphism. Then, the colimit of the morphisms \( f_h \) will be the sought subdivision of \( T \).

For \( h \leq 1 \), we may take \( S(h) := T_h \).

Next, suppose that \( h > 1 \), and that \( f_{h-1} : S(h-1) \to T_{h-1} \) has already been given; as a first step, we shall exhibit a rational, proper simplicial subdivision of \( T_h \). Indeed, for every \( t \in T_h \setminus T_{h-1} \), choose a \( \mathbb{N} \)-point \( \varphi_t \in U(t)(\mathbb{N}) \) in the following way. If \( t \in T_{\text{sim}} \), then let \( \varphi_t \) be the (unique) generator of an arbitrarily chosen one-dimensional face of \( U(t)(\mathbb{N}) \); and otherwise take any point \( \varphi_t \) which does not lie on any proper face of \( U(t)(\mathbb{N}) \).

With these choices, notice that \( U(\varphi_t) \times (\text{Spec } \mathbb{N})^2 = U(t) \) in case \( t \in T_{\text{sim}} \), and otherwise \( U(\varphi_t) = U(t)_{h-1} \) (notation of (6.6.16)). By lemma 6.6.17 we obtain corresponding rational subdivisions \( U(\varphi_t) \times (\text{Spec } \mathbb{N})^2 \to U(t) \) of \( U(t) \) centered at \( \varphi_t \). Notice that if \( t \) lies in the simplicial locus, this subdivision is an isomorphism, and in any case, it restricts to an isomorphism on the preimage of \( U(t)_{h-1} \).

By composing with the restriction of \( f_{h-1} \times (\text{Spec } \mathbb{N})^2 \), we get a rational subdivision:

\[
g_t : T'_t := f_{h-1}^{-1}U(\varphi_t) \times (\text{Spec } \mathbb{N})^2 \to U(t)
\]

whose restriction to the preimage of \( U(t)_{h-1} \) is an isomorphism. Moreover, \( g_t \) is an isomorphism if \( t \) lies in \( T_{\text{sim}} \). Also notice that \( g_t \) is simplicial, since the same holds for \( f_{h-1} \).

If \( t, t' \) are any two distinct points of \( T \) of height \( h \), we deduce an isomorphism

\[
g_t^{-1}(U(t) \cap U(t')) \cong g_{t'}^{-1}(U(t) \cap U(t'))
\]

hence we may glue the fans \( T'_t \) and the morphisms \( g_t \) along these isomorphisms, to obtain the sought simplicial rational subdivision \( g : T' \to T_h \).

For the next step, we shall refine \( g \) locally at every point \( s \) of height \( h \); i.e. for such \( s \), we shall find an integral, proper simplicial subdivision \( f_s : T'' \to U(s) \), whose restriction to \( U(s)_{h-1} \) agrees with \( g \), hence with \( f_{h-1} \). Once this is accomplished, we shall be able to build the sought subdivision \( f_h \) by gluing the morphisms \( f_s \) and \( f_{h-1} \) along the open subsets \( U(s)_{h-1} \).

Of course, if \( s \) lies in the simplicial locus of \( T \), we will just take for \( f_s \) the restriction of \( g \), which by construction is already an isomorphism.

Henceforth, we may assume that \( T = U(s) \) is an affine fan of dimension \( h \) with \( s \notin T_{\text{sim}} \), and \( g : T' \to T \) is a given proper rational simplicial subdivision, whose restriction to \( g^{-1}T_{h-1} \) is an integral subdivision. We wish to apply the criterion of lemma 6.6.30(iii), which shows that \( g \) is an integral subdivision if and only if \( \delta(g, s) = 1 \). Thus, let \( t_1, \ldots, t_k \) be the points of \( T' \) such that \( \delta_t = \delta(g, s) \) for every \( i = 1, \ldots, k \). Since \( \delta(g, s) \) is anyway a positive integer (lemma 6.6.30(ii)), a simple descending induction reduces to the following:

**Claim 6.6.32.** Given \( g \) as above, we may find a proper rational simplicial subdivision \( g' : T'' \to T \) such that the following holds:

(i) The restriction of \( g' \) to \( g^{-1}T_{h-1} \) is isomorphic to the restriction of \( g \).

(ii) Let \( t'_1, \ldots, t'_{k'} \in T'' \) be the points such that \( \delta_{t'_i} = \delta(g', s) \) for every \( i = 1, \ldots, k' \). We have \( \delta(g', s) \leq \delta(g, s) \), and if \( \delta(g', s) = \delta(g, s) \) then \( k' < k \).
Proof of the claim. Set $t := t_1$; by definition, there exists $\varphi' \in U(s)(\mathbb{N})$ which lies in $U(t)(\mathbb{Q}_+) \setminus U(t)(\mathbb{N})$; this means that there exists a morphism $\varphi$ fitting into a commutative diagram:

$$\begin{array}{ccc}
\mathcal{O}_{T,s} & \xrightarrow{(\log g)_t} & \mathcal{O}_{T',t} \\
\varphi' \downarrow & & \varphi \\
\mathbb{N} & \xrightarrow{u} & \mathbb{Q}_+. \\
\end{array}$$

Say that $\mathcal{O}_{T',t} \simeq \mathbb{N}^{\oplus r}$, and let $(\pi_1, \ldots, \pi_r)$ be the (essentially unique) basis of $\mathcal{O}_{T,(t),t}$; then $\varphi = a_1\pi_1 + \cdots + a_r\pi_r$, for some $a_1, \ldots, a_r \geq 0$, and after subtracting some positive integer multiple of $\pi$, we may assume that $0 \leq a_i < 1$ for every $i = 1, \ldots, r$. Moreover, the coefficients are all strictly positive if and only if $\varphi$ is a local morphism; more generally, we let $t'$ be the unique generization of $t$ such that $\varphi$ factors through a local morphism $\mathcal{O}_{T',t'} \to \mathbb{N}$. Set $s := \text{ht}(t')$, and denote by $\pi_1, \ldots, \pi_e$ the basis of $\mathcal{O}_{T',t'}$, so that:

$$\varphi = b_1\pi_1 + \cdots + b_e\pi_e$$

for unique rational coefficients $b_1, \ldots, b_e$ such that $0 < b_i < 1$ for every $i = 1, \ldots, e$.

Denote by $Z \subset T'$ the topological closure of $\{t'\}$; for every $u \in Z \cap T'$, the morphism $\varphi$ factors through a morphism $\varphi_u : \mathcal{O}_{T,u} \to \mathbb{Q}_+$, and we may therefore consider the subdivision of $U(u)$ centered at $\varphi_u$ as in (6.6.16), which fits into a commutative diagram of fans:

$$
\begin{array}{ccc}
(U(u) \setminus Z) \times (\text{Spec } \mathbb{Q}_+) & \xrightarrow{\psi_u} & (U(u) \setminus Z) \times (\text{Spec } \mathbb{N})^2 \\
\downarrow & & \downarrow \\
U(u) & \xrightarrow{1} & U'(u) := (\text{Spec } \varphi_u^{-1}\mathbb{N})^2.
\end{array}
$$

We complete the family $(\psi_u | u \in Z)$, by letting $U'(u) := U(u)$ and $\psi_u := 1_{U(u)}$ for every $u \in T' \setminus Z$. Notice then, that the topological spaces underlying $U(u)$ and $U'(u)$ agree for every $u \in T'$, and for every $u_1, u_2 \in T'$, the restrictions of $\psi_{u_i}$ and $\psi_{u_2}$:

$$
\psi_{u_i}^{-1}(U(u_1) \cap U(u_2)) \to U(u_1) \cap U(u_2) \\
(i = 1, 2)
$$

are isomorphic. Furthermore, by construction, each restriction $U(u) \to T$ of $g$ factors uniquely through a morphism $\beta_u : U'(u) \to T$, hence the family $(\beta_u \circ \psi_u | u \in T')$ glues to a well defined morphism of fans $g' : T'' \to T$. By a direct inspection, it is easily seen that $g'$ is a proper rational simplicial subdivision which fulfills condition (i) of the claim.

Moreover, the map of topological spaces underlying $g'$ factors naturally through a continuous map $p : T'' \to T'$, so that $g' = g \circ p$. The restriction $V := p^{-1}(T' \setminus Z) \to T$ of $g'$ is isomorphic to the restriction $T' \setminus Z \to T$ of $g$, hence:

$$
\delta_t = \delta_{p(t)} \quad \text{for every } t \in p^{-1}(T' \setminus Z).
$$

It follows that if $k > 1$ and $T' \setminus Z$ contains at least one of the points $t_2, \ldots, t_k$, then $\delta(g', s) \geq \delta(g, s)$. On the other hand, $p^{-1}(T' \setminus Z)$ contains at most $k - 1$ points $u$ of $T''$ such that $\delta_u = \delta(g, s)$, and for the remaining points $u' \in p^{-1}(T' \setminus Z)$ we have $\delta_{u'} < \delta(g, s)$. Since obviously

$$
\delta(g', s) = \max(\delta(g'_{p^{-1}(T' \setminus Z)}, s), \delta(g'_{p^{-1}(T' \setminus Z)}, s))
$$

we see that condition (ii) holds provided we show:

$$
\delta(g'_{p^{-1}(T' \setminus Z)}, s) = \max(b_1, \ldots, b_e) \cdot \delta(g, s).
$$

Hence, let us fix $u \in Z$, and let $(v, x) \in (\text{Spec } \mathbb{N})^2$ be any point (see (6.5.19)); if $x = \emptyset$, then $(v, x) \notin p^{-1}Z$, so it suffices to consider the points of the form $(v, m)$ (where $m \subset \mathbb{N}$ is the maximal ideal). Moreover, say that $\text{ht}(u) = d$; in view of lemma[6.6.30] (ii), it suffices to consider the points $(v, m)$ such that $\text{ht}(v) = d - 1$. There are exactly $e$ such points, namely the
prime ideals \(v_i := (\pi_i \circ \sigma)^{-1}m\), where \(\pi_1, \ldots, \pi_e\) are as in (6.6.33), and \(\sigma : \mathcal{O}_{T,v} \to \mathcal{O}_{T,v'}\) is the specialization map.

In order to estimate \(\delta_{(v,m)}\) for some \(v := v_i\), we look at the transpose of the map

\[
(\log g')_{(v,m)}^{sp} : \mathcal{O}_{T,v}^{sp} \to \mathcal{O}_{T,v'}^{sp} \times \mathbb{Z} : z \mapsto ((\log g')_{v,m}^{sp}(z), \varphi_{v,m}^{sp}(z)).
\]

Let \((p_1, \ldots, p_d)\) be the basis of \(\mathcal{O}_{T,v'}^{sp}\), ordered in such a way that \(p_i = \pi_i \circ \sigma\) for every \(i = 1, \ldots, e\). By a little abuse of notation, we may then denote \((p_j | \ j \neq i)\) the basis of \(\mathcal{O}_{T,v}^{sp}\), so that the dual group \((\mathcal{O}_{T,v'}^{sp} \times \mathbb{Z})^\vee\) admits the basis \(\{p_j^{sp} | \ j \neq i\} \cup \{q\}\), where \(q\) is the natural projection onto \(\mathbb{Z}\). Set as well \(p'_i := p_i \circ (\log g)^{sp}_{(v,m)}\) for every \(i = 1, \ldots, d\). With this notation, the above transpose is the group homomorphism given by the rule:

\[
p_j \mapsto p'_i \quad \text{for} \ j \neq i \quad \text{and} \quad q \mapsto b_1 p'_1 + \cdots + b_e p'_e
\]

from which we deduce easily that \(\delta_{(v,m)} = b_i \cdot \delta_{u},\) from (6.6.34).

\[\square\]

**Proposition 6.6.35.** Let \((\Gamma, +, 0)\) be a fine monoid, \(M\) a fine \(\Gamma\)-graded monoid. Then:

(i) There exists a finite set of generators \(C := \{\gamma_1, \ldots, \gamma_k\}\) of \(\Gamma\), with the following property. For every \(\gamma \in \Gamma\), we may find \(a_1, \ldots, a_k \in \mathbb{N}\) such that:

\[
\gamma = a_1 \gamma_1 + \cdots + a_k \gamma_k \quad \text{and} \quad M_\gamma = M_{\gamma_1}^{a_1} \cdots M_{\gamma_k}^{a_k}.
\]

(ii) There exists a subgroup \(H \subset \Gamma^{sp}\) of finite index, such that:

\[
M_{a\gamma} = M_a^\gamma \quad \text{for every} \ \gamma \in H \cap \Gamma \ \text{and every integer} \ a > 0.
\]

(In (i) and (ii) we use the multiplication law of \(\mathcal{P}(M)\), as in (6.1.1)).

**Proof.** Obviously we may assume that \(M\) maps surjectively onto \(\Gamma\), in which case \(G := \Gamma^{sp}\) is finitely generated, and its image \(G'\) into \(G_{\mathbb{R}} := G \otimes_{\mathbb{Z}} \mathbb{R}\) is a free abelian group of finite rank. The same holds as well for the image \(L\) of \(\log M^{sp}\) in \(M_{\mathbb{R}}^{sp} := M^{sp} \otimes_{\mathbb{Z}} \mathbb{R}\). Let \(p : G \to G'\) be the natural projection. According to proposition 6.3.22(iii), we have:

\[
(6.6.36) \quad M_Q = M_R \cap M_Q^{sp}
\]

(notation of (6.3.20)). Let \(f_R^{sp} : M_R^{sp} \to G_R\) be the induced \(\mathbb{R}\)-linear map, and denote by \(f_R : M_R \to G_R\) the restriction of \(f_R^{sp}\). By proposition 6.3.28(ii), we may find a \(G'\)-rational subdivision \(\Delta\) of \(f_R(M_R)\) such that:

\[
(6.6.37) \quad f_R^{-1}(a + b) = f_R^{-1}(a) + f_R^{-1}(b)
\]

for every \(\sigma \in \Delta\) and every \(a, b \in \sigma\). After choosing a refinement, we may assume that \(\Delta\) is a simplicial cone (theorem 6.6.31). Let \(\tau \in \Delta\) be any cone; by proposition 6.3.22(i), the monoid \(N := \tau \cap G'\) is finitely generated, and then the same holds for \(M \times_{G'} N\), by corollary 6.4.2. However, the latter is just \(M' := \bigoplus_{\gamma \in p^{-1}N} M_\gamma\) (lemma 4.8.29(iii)). Set \(\Gamma' := \Gamma \cap p^{-1}N\).

**Claim 6.6.38.** \(p(\Gamma')\) generates \(\tau\).

**Proof of the claim.** Clearly the \(\Gamma\)-grading of \(M\) induces a surjection \(M_Q \to \Gamma_Q\) (notation of (6.3.20)). By proposition 6.3.22(iii), we have \(\Gamma_Q = f_R(M_R) \cap G_Q\), hence \(N \subset \tau \cap G_Q \subset \Gamma_Q\). Thus, for every \(n \in N\) we may find \(a \in \mathbb{N}\) such that \(a \cdot n \in p(\Gamma)\), hence \(a \cdot n \in p(\Gamma')\). On the other hand, \(N\) generates \(\tau\), since the latter is \(G'\)-rational. The claim follows.

In view of claim 6.6.38, we may replace \(M\) by \(M'\), and \(\Gamma\) by \(\Gamma'\), which allows to assume that \(f_R(M_R)\) is a simplicial cone, and (6.6.37) holds for every \(a, b \in f_R(M_R)\). Next, let \(S := \{e_1, \ldots, e_n\} \subset p(\Gamma)\) be a set of generators of the cone \(f_R(M_R)\); from the discussion in (6.3.13) we see that, up to replacing \(S\) by a subset, the rays \(\mathbb{R}_+ \cdot e_i\) (with \(i = 1, \ldots, n\)) are precisely the extremal rays of \(f_R(M_R)\), especially, the vectors \(e_1, \ldots, e_n\) are \(\mathbb{R}\)-linearly independent. Choose
According to corollary 6.4.3, there exist finite subsets $\Sigma_1, \ldots, \Sigma_n \subset M$, such that:

$$M_{\Sigma_i} = M_0 \cdot \Sigma_i$$

for every $i = 1, \ldots, n$.

Claim 6.6.39. $(M_0)_Q = f^{-1}_R(0) \cap M_{SP}^Q$.

Proof of the claim. To begin with, we may write $f^{-1}_R(0) = (f_{SP}^{-1})^{-1}(0) \cap M_R$, hence $f^{-1}_R(0) \cap M_{SP}^Q = (f_{Q}^{-1})^{-1}(0) \cap M_Q$, by (6.6.36). Now, suppose $x \in (f_{Q}^{-1})^{-1}(0) \cap M_Q$; then we may find an integer $a > 0$ such that $ax = m \otimes 1$ for some $m \in \log M$. Say that $m \in \log M_\Sigma$; then $f_{Q}^{-1}(\gamma) = 0$, therefore $\gamma$ is a torsion element of $G'$, and consequently $bm \in \log M_\Sigma$ for an integer $b > 0$ large enough. We conclude that $x = (bm) \otimes (ba)^{-1} \in (M_0)_Q$, as claimed. 

On the other hand, since $\mathbb{R} + e_i$ is a $G'$-rational polyhedral cone, $f^{-1}_R(\mathbb{R} + e_i)$ is an $L$-rational polyhedral cone (proposition 6.3.21 ii,i,iii), hence it admits a finite set of generators $S_i \subset L$. Up to replacing the elements of $S_i$ by some positive rational multiples, we may assume that $f_R(s)$ is either 0 or $e_i$, for every $s \in S_i$. In this case, it follows easily that

$$(6.6.40) f^{-1}_R(e_i) = f^{-1}_R(0) + T_i$$

where:

$$T_i := \left\{ \sum_{s \in S_i} t_s \cdot s \mid t_s \in \mathbb{R}^+, \sum_{s \in S_i} t_s = 1 \right\}$$

is the convex hull of $S_i$ (and as usual, the addition of sets in (6.6.40) refers to the addition law of $\mathcal{P}(M_{SP}^Q)$, see (6.1.1)). Next, notice that $S_i \subset M_Q$, by (6.6.36); thus, we may find an integer $a > 0$ such that $a \cdot s$ lies in the image of $\log M$, for every $s \in S_i$. After replacing $e_i$ by $a \cdot e_i$ and $S_i$ by $\{ a \cdot s \mid s \in S_i \}$, we may then achieve that (6.6.40) holds, and furthermore $S_i$ lies in the image of $\log M$, therefore in the image of $\log M_{\Sigma_i}$. It follows easily that (6.6.40) still holds with $S_i$ replaced by the set $\Sigma_i \otimes 1 := \{ m \otimes 1 \mid m \in \Sigma_i \}$. Let $\Sigma_0 \subset \log M$ be a finite set of generators for the monoid $M_0$; claim 6.6.39 implies that $\Sigma_0$ is also a set of generators for the $L$-rational polyhedral cone $f^{-1}_R(0)$. Let $P \subset M$ be the submonoid generated by $\Sigma := \Sigma_0 \cup \Sigma_1 \cup \cdots \cup \Sigma_n$, and $\Delta \subset \Gamma$ the submonoid generated by $g_1, \ldots, g_n$; clearly the $\Gamma$-grading of $M$ restricts to a $\Delta$-grading on $P$. Notice that $g_1 \otimes 1, \ldots, g_n \otimes 1$ are linearly independent in $G_Q$, since the same holds for $e_1, \ldots, e_n$; especially, $\Delta \simeq \mathbb{N}^n$.

Claim 6.6.41. (i) The set $\Sigma \otimes 1 := \{ s \otimes 1 \mid s \in \Sigma \}$ generates the cone $M_\Sigma$.

(ii) $P_{a+b} = P_a \cdot P_b$ for every $a, b \in \Delta$.

(iii) There exists a finite set $A \subset M$ such that $M = A \cdot P$.

Proof of the claim. By (6.6.40) and the foregoing discussion, we know that $(\Sigma_0 \cup \Sigma_1) \otimes 1$ generate $f^{-1}_R(\mathbb{R} + e_i)$, for every $i = 1, \ldots, n$. Since the additivity property (6.6.37) holds for every $a, b \in f_R(M_\Sigma)$, assertion (i) follows. (ii) is a straightforward consequence of the definitions. Next, from (i) and proposition 6.3.22 iii, we deduce that $M_{\Sigma} = P_{\Sigma}$. Thus, let $m_1, \ldots, m_r$ be a system of generators for the monoid $M$; it follows that there are integers $k_1, \ldots, k_r > 0$, such that $m_1^{k_1}, \ldots, m_r^{k_r} \in P$, and therefore the subset $A := \{ \prod_{i=1}^{r} m_i^{k_i} \mid 0 \leq t_i < k_i \}$ fulfills the condition of (iii).

We introduce a partial ordering on $G$, by declaring that $a \leq b$ for two elements $a, b \in G$, if and only if $b - a \in \Delta$. Now, let $a \in G$ be any element; we set

$$G(a) := \{ g \in G \mid g \leq a \}.$$

The subset $G(a)$ inherits a partial ordering from $G$, and $a$ is the maximum of the elements of $G(a)$; moreover, notice that every finite subset $S \subset G(a)$ admits a supremum $\sup S \in G(a)$. Indeed, it suffices to show the assertion for a set of two elements $S = \{ b_1, b_2 \}$; we may then write $a - b_i = \sum_{j=1}^{n} k_{ij}g_j$ for certain $k_{ij} \in \mathbb{N}$, and then $\sup(b_1, b_2) = a - \sum_{j=1}^{n} \min(k_{1j}, k_{2j}) \cdot g_j$. 
Let $A$ be as in claim 6.6.41(iii), and denote by $B \subset \Gamma$ the image of $A$; then
$$M = M_0 \cdot M_B$$
where $M_B := \bigoplus_{b \in B} \log M_b$.

For every $a \in G$, let also $B(a) := B \cap G(a)$; invoking several times claim 6.6.41(ii), we get:

$$M_a = \bigcup_{b \in B(a)} M_b \cdot P_{a-b}$$
$$= \bigcup_{b \in B(a)} M_b \cdot P_{\sup B(a)-b} \cdot P_{a-\sup B(a)}$$
$$\subset M_{\sup B(a)} \cdot P_{a-\sup B(a)}.$$  

Finally, say that $a - \sup B(a) = \sum_{i=1}^n t_i g_i$ for certain $t_1, \ldots, t_n \in \mathbb{N}$; applying once more claim 6.6.41(ii), we conclude that:

$$M_a \subset M_{\sup B(a)} \cdot \prod_{i=1}^n M_{g_i}^{t_i}.$$  

The converse inclusion is clear, and therefore the set $C := \{g_1, \ldots, g_n\} \cup \{\sup B(a) \mid a \in G\}$ fulfills condition (i) of the proposition.

(ii): For $h \in \Delta^{\mathrm{gp}}$, say $h = \sum_{i=1}^n a_i g_i$, with integers $a_1, \ldots, a_n$, we let $|h| := \sum_{i=1}^n |a_i| g_i \in \Delta$. Choose any positive integer $\alpha$ such that:

$$|b| \leq \alpha \cdot \sum_{i=1}^n g_i$$

for every $b \in B \cap \Delta^{\mathrm{gp}}$ and let $H \subset \Delta^{\mathrm{gp}}$ be the subgroup generated by $\alpha g_1, \ldots, \alpha g_n$.

Claim 6.6.43. $B(h) = B(\alpha h)$ for every $h \in H$ and every integer $k > 0$.

Proof of the claim. Let $h := \sum_{i=1}^n a_i g_i \in H$, and suppose that $b \in B(\alpha h)$ for some $k > 0$; therefore $k \alpha - b \in \Delta$, hence $b \in \Delta^{\mathrm{gp}}$, and we can write $b = \sum_{i=1}^n \beta_i g_i$ for integers $\beta_1, \ldots, \beta_n$, such that $k \alpha_i - \beta_i \geq 0$ for every $i = 1, \ldots, n$. In this case, (6.6.42) implies that $\alpha_i \geq 0$ for every $i \leq n$, and $\alpha_i \geq \alpha \geq \beta_i$ whenever $\beta_i > 0$. It follows easily that $k' h - b \in \Delta$ for every integer $k' > 0$, whence the claim.

Using claims 6.6.41(ii) and 6.6.43, and arguing as in the foregoing, we may compute:

$$M_{ah} = M_{\sup B(ah)} \cdot P_{ah-\sup B(ah)}$$
$$= M_{\sup B(h)} \cdot P_{ah-\sup B(h)}$$
$$= M_{\sup B(h)} \cdot P_{h-\sup B(h)} \cdot P_{h}^{a-1}$$
$$\subset M_h^a.$$  

The converse inclusion is clear, so (ii) holds.  \end{proof}

6.6.44. Let $M$ be an integral monoid, and $w \in \log M^{\mathrm{gp}}$ any element. For $\varepsilon \in \{1, -1\}$ we have a natural inclusion

$$j_\varepsilon : \log M \to M(\varepsilon) := \log M + \varepsilon Nw$$

(i.e. $M(\varepsilon)$ is the submonoid of $M^{\mathrm{gp}}$ generated by $M$ and $w^\varepsilon$). Let us write $w := b^{-1} a$ for some $a, b \in M$; then the induced morphisms of affine schemes $\iota_\varepsilon := \mathrm{Spec} \ Z[j_\varepsilon]$ have a natural geometric interpretation. Namely, let $f : X \to \mathrm{Spec} \ Z[M]$ be the blow up of the ideal $I \subset Z[M]$ generated by $a$ and $b$; we have $X = U_1 \cup U_1$, where $U_1$, for $\varepsilon = \pm 1$, is the largest open subscheme of $X$ such that $w^\varepsilon \in \mathcal{O}_X(U_1)$. Then $\iota_\varepsilon$ is naturally identified with the restriction $U_\varepsilon \to \mathrm{Spec} \ Z[M]$ of the blow up $f$. More generally, by adding to $M$ any finite number of elements of $M^{\mathrm{gp}}$, we may construct in a combinatorial fashion, the standard affine charts of $X$.  \end{proof}
Theorem 6.6.45. Let \( j : M \to N \) be an inclusion of fine monoids. Then there exist a finite set \( \Sigma \subset \log M^{\text{fp}} \), and an integer \( k > 0 \) such that the following holds:

(i) For every mapping \( \varepsilon : \Sigma \to \{ \pm 1 \} \), the induced inclusion:

\[
M(\varepsilon) := \log M + \sum_{\sigma \in \Sigma} \varepsilon(\sigma)N\sigma \to N(\varepsilon) := \log N + \sum_{\sigma \in \Sigma} \varepsilon(\sigma)N\sigma
\]

is a flat morphism of fine monoids.

(ii) Suppose that \( j \) is a flat morphism, and let \( \iota : M \to M^{\text{sat}} \) be the natural inclusion. Denote by \( Q \) the push-out of the diagram

\[
N \xrightarrow{\iota \circ k_M} M^{\text{sat}} \to Q^{\text{sat}} \text{ (where } k_M \text{ is the } k\text{-Frobenius). Then the natural map } M^{\text{sat}} \to Q^{\text{sat}} \text{ is flat and saturated.}
\]

Proof. (i): (Notice that \( \log M \), \( \log N \) and \( P(\varepsilon) := \sum_{\sigma \in \Sigma} \varepsilon(\sigma)N\sigma \) may be regarded as submonoids of \( \log N^{\text{fp}} \), and then the above sum is taken in the monoid \( (\mathcal{P}(\log N^{\text{fp}}),+) \) defined as in (6.11).) Set \( G := N^{\text{fp}}/M^{\text{fp}} \), and let \( N^{\text{fp}} = \bigoplus_{\gamma \in G} N^{\text{fp}}_{\gamma} \) be the \( j \)-grading of \( N^{\text{fp}} \) (remark 6.2.5(iii)); notice that this grading restricts to \( j \)-gradings for \( N \) and \( N(\varepsilon) \). Let also \( \Gamma := \{ \gamma \in G \mid N_\gamma \neq \emptyset \} \), and choose a finite generating set \( \{ \gamma_1, \ldots, \gamma_r \} \) of \( \Gamma \) with the properties of proposition 6.6.35(i). According to corollary 6.4.3, for every \( i \leq r \) there exists a finite subset \( \Sigma_i := \{ t_{i1}, \ldots, t_{im_i} \} \subset M \) such that \( N_{\gamma_i} = N_0 \cdot \Sigma_i \). Moreover, \( N_0 \) is a finitely generated monoid, by corollary 6.4.2. Let \( \Sigma_0 \) be a finite system of generators for \( N_0 \), and for every \( i \leq r \) define \( \Sigma'_i := \{ t_{ij} - t_{il} \mid 1 \leq j < l \leq n_i \} \). We claim that the subset \( \Sigma := \Sigma_0 \cup \Sigma'_1 \cup \cdots \cup \Sigma'_r \) will do. Indeed, first of all notice that \( \Sigma \subset \log M^{\text{fp}} \). We shall apply the flatness criterion of remark 6.2.5(iv). Thus, we have to show that, for every \( g \in \Gamma \), the \( M(\varepsilon) \)-module \( N(\varepsilon)_{\gamma} \) is a filtered union of cosets \( \{ m \} + M(\varepsilon) \) (for certain \( m \in N_{\gamma} \)). Hence, let \( x_1, x_2 \in N(\varepsilon)_{\gamma} \); we may write \( x_i = m_i + p_i \) for some \( m_i \in \log N \) and \( p_i \in P(\varepsilon) (i = 1, 2) \); since \( \{ x_i \} + M(\varepsilon) \subset \{ m_i \} + M(\varepsilon) \), we may then assume that \( p_1 = p_2 = 0 \), hence \( x_1, x_2 \in N_\gamma \). Thus, it suffices to show that \( N_0 \) is contained in a filtered union of cosets as above. However, by assumption there exist \( a_1, \ldots, a_r \in N_\gamma \) such that \( g = \sum_{i=1}^r a_\gamma_i \) and \( N_\gamma = N_{\gamma_1} \cdots N_{\gamma_r} \); we are then easily reduced to the case where \( g = \gamma_i \) for some \( i \leq r \). Therefore, \( x_j = a_j + b_j \), where \( a_j \in \Sigma_i \) and \( b_j \in N_0 \), for \( j = 1, 2 \). Notice that \( P(\varepsilon) \) contains either \( \sigma_1 - \sigma_2 \), or \( \sigma_2 - \sigma_1 \) (or both); in the first occurrence, set \( \sigma := \sigma_2 \), and otherwise, let \( \sigma := \sigma_1 \). Likewise, say that \( \Sigma_0 = \{ y_1, \ldots, y_n \} \), so that \( b_j = \sum_{s=1}^{n} a_{js} y_s \) for certain \( a_{js} \in \mathbb{N} \) \((j = 1, 2) \); for every \( s \leq n \), we set \( a^*_s := \min(a_{1s}, a_{2s}) \) if \( y_s \in P(\varepsilon) \), and otherwise we set \( a^*_s := \max(a_{1s}, a_{2s}) \). One sees easily that \( x_1, x_2 \in \sigma + \sum_{s=1}^{n} a^*_s y_s + M(\varepsilon) \), whence the contention.

(ii): By proposition 6.6.35(ii), there exists a subgroup \( H \subset G \) of finite index, such that:

\[
\pi^{-1}(h^n) = \pi^{-1}(h)^n
\]

for every integer \( n > 0 \) and every \( h \in H \). Let \( k := (G : H) \), and define \( N' \) as the fibre product in the cartesian diagram:

\[
\begin{align*}
N' & \xrightarrow{\pi'} G \\
N & \xrightarrow{\pi} G
\end{align*}
\]

The trivial morphism \( 0_M : M \to G \) (i.e. the unique one that factors through \( \{ 1 \} \)) and the inclusion \( j \) satisfy the identity: \( k_G \circ 0_M = \pi \circ j \), hence they determine a well-defined map \( \varphi : M \to N' \).

Claim 6.6.47. \( \varphi \) is flat and saturated.
Proof of the claim. For the flatness, we shall apply the criterion of remark 6.2.3(iv). First, \( \varphi \) is injective, since \( \mu \circ \varphi = j \). Next, notice that the sequence of abelian groups:

\[
0 \to M^{gp} \xrightarrow{\varphi^{gp}} (N')^{gp} \xrightarrow{(\pi')^{gp}} G \to 0
\]

is short exact; indeed, this is none else than the pullback \( \mathcal{E} \ast k_G^{gp} \) along the morphism \( k_G \), of the short exact sequence

\[
(6.6.50)
\]

It follows that \( \varphi \) is flat if and only if, for every \( x \in \pi'(N') \), the preimage \( (\pi')^{-1}(x) \) is a filtered union of cosets of the form \( \{n\} \cdot \varphi(M') \). However, the induced map \( (\pi')^{-1}(g) \to (\pi')^{-1}(g^k) \) is a bijection for every \( g \in G \), and the flatness of \( j \) implies that \( \pi^{-1}(x^k) \) is a filtered union of cosets, whence the contention. Notice also that \( \operatorname{Im} k_G \subset H \); hence, by the same token, we derive that \( (\pi')^{-1}(g^n) = (\pi')^{-1}(g)^n \) for every \( g \in G \), therefore \( \varphi \) is quasi-saturated, by proposition 6.2.31. Since we know already that \( j \) is integral (theorem 6.2.3), the claim follows.

Next, we wish to consider the commutative diagram of monoids:

\[
(6.6.51)
\]

such that \( \psi \) is the map determined by the pair of morphisms \( (f, k_M) \). Let \( P \) be the push-out of the maps \( j \) and \( k_M \); the maps \( \varphi \) and \( \psi \) determine a morphism \( \tau : P \to N' \).

Claim 6.6.50. (i) The diagram \((6.6.46)^{gp}\) of associated abelian groups, is cartesian.

(ii) The diagram of abelian groups \((6.6.49)^{gp}\) is cocartesian (i.e. \( \tau^{gp} \) is an isomorphism).

(iii) There exists a morphism \( \lambda : N' \to P \) such that \( \lambda \circ \tau = k_P \) and \( \tau \circ \lambda = k_{N'} \).

Proof of the claim. (i): Suppose that \( x \in (N')^{gp} \) is any element such that \( (\pi')^{gp}(x) = 1 \) and \( \mu^{gp}(x) = 1 \); we may write \( x = b^{-1}a \) for some \( a, b \in N' \), since the forgetful functor \( \text{Mnd} \to \text{Set} \) commutes with fibre products. Thus \( x = 1 \). On the other hand, suppose that \( \pi^{gp}(b^{-1}a) = x^k \) for some \( a, b \in N \) and \( x \in G \); therefore, \( \pi(b^{-1}a) = (bx)^k \), so there exists \( c \in N' \) such that \( \mu(c) = b^{-1}a \) and \( \pi'(c) = bx \). Likewise, there exists \( d \in N' \) with \( \mu(d) = b^k \) and \( \pi'(d) = b \). Consequently, \( \pi^{gp}(d^{-1}c) = x \) and \( \mu(d^{-1}c) = b^{-1}a \). The assertion follows.

(ii): Quite generally, let \( E := (0 \to A \to B \to C \to 0) \) be a short exact sequence of objects in an abelian category \( \mathcal{C} \), and for every object \( X \) of \( \mathcal{C} \), let \( k_X := k \cdot 1_X : X \to X \). Then one has a natural map of complexes \( \alpha_E : E \ast k_C \to E \) (resp. \( \beta_E : E \to k_A \ast E \)) from \( E \) to the pullback of \( E \) along \( k_C \) (resp. from the push-out of \( E \) along \( k_A \) to \( E \)), and a natural isomorphism \( \omega_E : k_A \ast E \xrightarrow{\sim} E \ast k_C \) in the category \( \text{Ext}_\mathcal{C}(C, A) \) of extensions of \( C \) by \( A \) (this is the category whose objects are all short exact sequences in \( \mathcal{C} \) of the form \( 0 \to A \to X \to C \to 0 \), and whose morphisms are the maps of complexes which are the identity on \( A \) and \( C \)). These maps are related by the identities:

\[
(6.6.51) \quad \beta_E \circ \alpha_E \circ \omega_E = k \cdot 1_{k_A \ast E} \quad \omega_E \circ \beta_E \circ \alpha_E = k \cdot 1_{E \ast k_C}.
\]

We leave to the reader the construction of \( \omega_E \). In the case at hand, we obtain a natural isomorphism \( \omega_{\mathcal{E}} : k_{A_{\mathcal{E}}} \ast \mathcal{E} \xrightarrow{\sim} \mathcal{E} \ast k_G \), where \( \mathcal{E} \) is the short exact sequence of \( (6.6.48) \). An inspection of the construction shows that the map \( \tau^{gp} \) is precisely the isomorphism defined by \( \omega_{\mathcal{E}} \).

(iii): Let \( \mu' : N \to P \) be the natural map, and set \( \lambda := \mu' \circ \mu \). By inspecting the constructions, one checks easily that \( \lambda^{gp} \) is the map defined by \( \beta_{\mathcal{E}} \circ \alpha_{\mathcal{E}} \). Then the assertion follows from \((6.6.51)\).  \( \diamond \)
Let \( P' \) be the push-out of the diagram \( N' \llap{\overset{\tau}{\longrightarrow}} M \llap{\xrightarrow{\tau}} M_{\text{sat}} \); from claim 6.6.47, lemma 6.2.2(i) and corollary 6.2.25(iii), we deduce that the natural map \( M_{\text{sat}} \to P' \) is flat and saturated, hence \( P' \) is saturated. On the other hand, directly from the definitions we get a cocartesian diagram

\[
P \longrightarrow Q \\
\tau \downarrow \quad \downarrow \tau' \\
N' \longrightarrow P'.
\]

(6.6.52)

The induced diagram \( (6.6.52)_{\text{sat}} \) of saturated monoids is still cocartesian (remark 4.8.41(v)); however, claim 6.6.50(iii) implies easily that \( \tau_{\text{sat}} \) is an isomorphism, therefore the same holds for \( (\tau')_{\text{sat}} \), and assertion (ii) follows. \( \square \)

7. Homological algebra

This chapter lays the foundations of homological and homotopical algebra that shall be needed in the rest of the treatise. For some standard facts that we do not repeat here, we use the book [125] as a quick reference.

7.1. Complexes in an additive category. Let \( \mathcal{A} \) be any additive category. We denote by \( \mathsf{C}(\mathcal{A}) \) the category of (cochain) complexes of objects of \( \mathcal{A} \). Hence, an object of \( \mathsf{C}(\mathcal{A}) \) is a pair

\[
K^\bullet := (K^\bullet, d_K^\bullet)
\]

consisting of a system of objects \( (K^n | n \in \mathbb{Z}) \) and morphisms \( (d_K^n : K^n \to K^{n+1} | n \in \mathbb{Z}) \) of \( \mathcal{A} \), called the differentials of the complex \( K^\bullet \), such that

\[
d_K^{n+1} \circ d_K^n = 0 \quad \text{for every } n \in \mathbb{Z}.
\]

The morphisms \( \varphi^\bullet : K^\bullet \to L^\bullet \) in \( \mathsf{C}(\mathcal{A}) \) are the systems of morphisms \( (\varphi^n : K^n \to L^n | n \in \mathbb{Z}) \) of \( \mathcal{A} \) such that

\[
\varphi^{n+1} \circ d_K^n = d_L^{n+1} \circ \varphi^n \quad \text{for every } n \in \mathbb{Z}.
\]

We will usually omit the subscript when referring to the differentials of a complex, unless there is a danger of confusion. Also, let \( I \subseteq \mathbb{Z} \) be any (bounded or unbounded) interval, \( i.e. I \) is either of the form \( [a, +\infty[, \text{or } [\mathbb{Z}\cap [-\infty, \mathbb{Z}], b] \) (for some \( a, b \in \mathbb{Z} \)), or the intersection of any of these two. We shall denote by

\[
\mathsf{C}^I(\mathcal{A})
\]

the full subcategory of \( \mathsf{C}(\mathcal{A}) \) whose objects are the complexes \( K^\bullet \) such that \( K^i = 0 \) whenever \( i \notin I \) (where we fix a zero object \( 0 \) of \( \mathcal{A} \)). For instance, if \( I = \mathbb{Z} \cap [a, +\infty[ \), then \( \mathsf{C}^I(\mathcal{A}) \) is also denoted \( \mathsf{C}^{\geq a}(\mathcal{A}) \), and likewise for the case of an upper bounded interval. Moreover, we set

\[
\mathsf{C}^{\leq n}(\mathcal{A}) := \bigcup_{n \in \mathbb{Z}} \mathsf{C}^{\leq n}(\mathcal{A}) \quad \mathsf{C}^+(\mathcal{A}) := \bigcup_{n \in \mathbb{Z}} \mathsf{C}^{\geq n}(\mathcal{A}) \quad \mathsf{C}^b(\mathcal{A}) := \bigcup_{n \in \mathbb{Z}} \mathsf{C}^{[-n,n]}(\mathcal{A})
\]

so \( \mathsf{C}^{\leq n}(\mathcal{A}) \) (resp. \( \mathsf{C}^+(\mathcal{A}) \), resp. \( \mathsf{C}^b(\mathcal{A}) \)) is the full subcategory of \( \mathsf{C}(\mathcal{A}) \) whose objects are the bounded above (resp. bounded below, resp. bounded) complexes of \( \mathcal{A} \).

7.1.1. For every \( a \in \mathbb{Z} \), the inclusion functor

\[
(7.1.2) \quad \mathsf{C}^{\geq a}(\mathcal{A}) \to \mathsf{C}(\mathcal{A}) \quad \text{(resp. } \mathsf{C}^{\leq a}(\mathcal{A}) \to \mathsf{C}(\mathcal{A}) \text{ )}
\]

admits a right (resp. left) adjoint called the brutal truncation functor, and denoted

\[
t^{\geq a} : \mathsf{C}(\mathcal{A}) \to \mathsf{C}^{\geq a}(\mathcal{A}) \quad \text{(resp. } t^{\leq a} : \mathsf{C}(\mathcal{A}) \to \mathsf{C}^{\leq a}(\mathcal{A}) \text{ ).}
\]

Namely, for any complex \( K^\bullet \), let \( t^{\geq a}(K^\bullet) \) be the unique object of \( \mathsf{C}^{\geq a}(\mathcal{A}) \) that agrees with \( K^\bullet \) in all degrees \( \geq a \), and with the same differentials as \( K^\bullet \), in this range of degrees (and likewise for \( t^{\leq a}(K^\bullet) \)). If \( \varphi^\bullet : K^\bullet \to L^\bullet \) is any morphism in \( \mathsf{C}(\mathcal{A}) \), then \( t^{\geq a}\varphi^\bullet \) is the unique morphism \( t^{\geq a}K^\bullet \to t^{\geq a}L^\bullet \) which agrees with \( \varphi^\bullet \) in all degrees \( \geq a \) (and likewise for \( t^{\leq a}\varphi^\bullet \)).
Moreover, if $\mathcal{A}$ is an abelian category, (7.1.2) also admits a left (resp. a right) adjoint
\[ \tau^{\leq a} : C(\mathcal{A}) \to C^{\leq a}(\mathcal{A}) \quad \text{(resp. } \tau^{\geq a} : C(\mathcal{A}) \to C^{\geq a}(\mathcal{A})) \]
called the normalized truncation functor (or just the truncation functor). Namely, we fix representatives for all kernels and cokernels of $\mathcal{A}$, and for any complex $K^*$, we let $\tau^{\leq a}(K^*)$ be the unique object of $C^{\leq a}(\mathcal{A})$ whose term in degree $a$ equals $\text{Coker } d^{n-1}_K$, and which agrees with $K^*$ in all degrees $> a$, with the same differentials as $K^*$, in this range of degrees; the differential in degree $a$ is the unique morphism $\text{Coker } d^{n-1}_K \to K^{a+1}$ whose composition with the natural map $K^a \to \text{Coker } d^{n-1}_K$ equals $d^n_K$. If $\phi^* : K^* \to L^*$ is any morphism in $C(\mathcal{A})$, then $\tau^{\leq a} \phi^*$ is the unique morphism $\tau^{\leq a} K^* \to \tau^{\leq a} L^*$ which agrees with $\phi^*$ in all degrees $> a$, and which, in degree $a$, is the morphism $\text{Coker } d^n_K \to \text{Coker } d^n_L$ induced by $\phi^0$.

Likewise, $\tau^{\geq a}(K^*)$ is the unique complex of $C^{\geq a}(\mathcal{A})$ whose term in degree $a$ equals $\text{Ker } d^n_K$, and which agrees with $K^*$ in all degrees $< a$, with the same differentials as $K^*$, in all degrees $< a - 1$; the differential in degree $a - 1$ is the restriction of $d^{n-1}_K$. Again, for $\phi^*$ as above, $\tau^{\geq a} \phi^*$ agrees with $\phi^*$ in degrees $< a$, and is the restriction $\text{Ker } d^n_K \to \text{Ker } d^n_L$ of $\phi^0$ in degree $a$.

7.1.3. There is an obvious functor
\[ \mathcal{A} \to C(\mathcal{A}) : \ A \mapsto A[0] \]
that sends any object $A$ of $\mathcal{A}$ to the complex with $A$ placed in degree zero, i.e. such that $A[0]^i$ equals $A$ if $i = 0$, and equals 0 otherwise (clearly, there is a unique such complex). On the other hand, the shift operator is the functor
\[ C(\mathcal{A}) \to C(\mathcal{A}) : \ K^* \mapsto K^*[1] \]
given by the rule:
\[ K^*[1]^n := K^{n+1} \quad d^n_{K[1]} := -d^{n+1}_K \quad \text{for every } n \in \mathbb{Z}. \]

Clearly the shift operator is an automorphism of $C(\mathcal{A})$, and one defines the operator $K^* \mapsto K^*[n]$, for every $n \in \mathbb{Z}$, as the $n$-th power of the shift operator (in the automorphism group of $C(\mathcal{A})$). Then, we can combine the two previous operators, to define the complex
\[ A[n] := (A[0])[n] \quad \text{for every } n \in \mathbb{Z} \text{ and every } A \in \text{Ob}(\mathcal{A}). \]
Furthermore, notice that the shift operator restricts to functors
\[ C^+_*(\mathcal{A}) \to C^+_*(\mathcal{A}) \quad C^-_*(\mathcal{A}) \to C^-_*(\mathcal{A}) \quad C^b(\mathcal{A}) \to C^b(\mathcal{A}). \]

**Definition 7.1.4.** Let $\mathcal{A}$ be an additive category, $\phi^*, \psi^* : K^* \to L^*$ two morphisms in $C(\mathcal{A})$.

(i) A (chain) homotopy from $\phi^*$ to $\psi^*$ is the datum $(s^n : K^n \to L^{n-1} \mid n \in \mathbb{Z})$ of a system of morphisms in $\mathcal{A}$ such that
\[ \phi^n - \psi^n = s^{n+1} \circ d^n_K + d^{n-1}_L \circ s^n \quad \text{for every } n \in \mathbb{Z}. \]

(ii) We say that $\phi^*$ and $\psi^*$ as in (i) are chain homotopic if there is a chain homotopy between them. It is easily seen that this defines an equivalence relation $\sim$ on the set $\text{Hom}_C(\mathcal{A})(K^*, L^*)$, which is preserved by composition of morphisms: if $\phi^* \sim \psi^*$ and $\alpha^* : K^* \to K^*$, $\beta^* : L^* \to L^*$ are any two morphisms, then $\phi^* \circ \alpha^* \sim \psi^* \circ \alpha^*$ and $\beta^* \circ \phi^* \sim \beta^* \circ \psi^*$. It follows that, for every interval $I \subset \mathbb{Z}$ there exists a well defined homotopy category
\[ \text{Hot}^I(\mathcal{A}) \]
whose objects are the same as those of $C^I(\mathcal{A})$, and whose morphisms are the homotopy classes of morphisms of complexes, and a natural functor
\[ (7.1.5) \quad C^I(\mathcal{A}) \to \text{Hot}^I(\mathcal{A}) \]
which is the identity on objects, and the quotient map on \( \text{Hom}\)-sets. If \( I = \mathbb{Z} \), we write \( \text{Hot}(\mathcal{A}) \) instead of \( \text{Hot}^\mathbb{Z}(\mathcal{A}) \), and we denote

\[
\text{Hot}_{\mathcal{A}}(K^\bullet, L^\bullet)
\]

the set of morphisms \( K^\bullet \to L^\bullet \) in \( \text{Hot}(\mathcal{A}) \). We may also define the subcategories \( \text{Hot}^+(\mathcal{A}) \), \( \text{Hot}^-(\mathcal{A}) \) and \( \text{Hot}^b(\mathcal{A}) \) as in (7.1).

(iii) We also say that a morphism \( \varphi : K^\bullet \to L^\bullet \) is a \emph{homotopy equivalence}, if the class \( \varphi^* \) is an isomorphism in \( \text{Hom}(\mathcal{A}) \), i.e. if there exists a morphism \( \psi^* : L^\bullet \to K^\bullet \) such that \( \psi^* \circ \varphi^* \sim 1_{K^\bullet} \) and \( \varphi^* \circ \psi^* \sim 1_{L^\bullet} \). We say that \( \varphi^* \) is \emph{null-homotopic} if it is chain homotopic to the zero morphism \( K^\bullet \to L^\bullet \). We say that a complex \( K^\bullet \) is \emph{homotopically trivial}, if the zero endomorphism \( 0 \cdot 1_{K^\bullet} \) is a homotopy equivalence.

**Remark 7.1.6.** Let \( \mathcal{A} \) and \( \mathcal{A}' \) be any two additive categories.

(i) If \( F : \mathcal{A} \to \mathcal{A}' \) is any additive functor, we get induced functors

\[
C(F) : C(\mathcal{A}) \to C(\mathcal{A}') \quad \text{Hot}(F) : \text{Hot}(\mathcal{A}) \to \text{Hot}(\mathcal{A}')
\]

by the rule:

\[
F(K^\bullet)^n := F(K^n) \quad \text{and} \quad d^n_{F(K)} := F(d^n_K) \quad \text{for every} \ n \in \mathbb{Z} \ \text{and every} \ K^\bullet \in \text{Ob}(C(\mathcal{A})).
\]

More generally, we get induced functors \( C^I(F), \text{Hot}^I(F) \) for any interval \( I \subset \mathbb{Z} \), as well as \( C^+(F), C^-(F) \) and \( C^b(F) \) (and the corresponding homotopy category variants), in the obvious fashion. Also, notice that the shift operators descend to a functor on the homotopy category:

\[
\text{Hot}(\mathcal{A}) \to \text{Hot}(\mathcal{A}) \quad A^\bullet \mapsto A^\bullet[n] \quad \text{for every} \ n \in \mathbb{Z}
\]

and the latter restrict to endofunctors of the subcategories \( \text{Hot}^+(\mathcal{A}) \), \( \text{Hot}^-(\mathcal{A}) \) and \( \text{Hot}^b(\mathcal{A}) \).

(ii) The category \( C(\mathcal{A}) \) is additive. Namely, if \( K^\bullet, L^\bullet \) are any two complexes of \( \mathcal{A} \), and \( \varphi^*, \psi^* : K^\bullet \to L^\bullet \) any two morphisms, we define

\[
(\varphi + \psi)^i := \varphi^i + \psi^i \quad \text{for every} \ i \in \mathbb{Z}
\]

and it is clear that this rule yields a natural abelian group structure on \( \text{Hom}_{\mathcal{A}}(K^\bullet, L^\bullet) \), such that composition of morphisms is a bilinear operation. The zero object is the (unique) complex \( 0 \) which has the zero object of \( \mathcal{A} \) in each degree, and biproducts in \( C(\mathcal{A}) \) admit natural representatives, defined by the rule:

\[
(A \oplus B)^i := A^i \oplus B^i \quad \text{for every} \ A^\bullet, B^\bullet \in \text{Ob}(C(\mathcal{A})) \ \text{and every} \ i \in \mathbb{Z}.
\]

Moreover, it is clear that if \( \varphi_1^*, \varphi_2^* : K^\bullet \to L^\bullet \) are any two morphisms in \( C(\mathcal{A}) \) such that \( \varphi_1^* \sim \varphi_2^* \), we have \( \varphi_1^* + \psi^* \sim \varphi_2^* + \psi^* \) for every other morphism \( \psi^* : K^\bullet \to L^\bullet \); hence there is a unique abelian group structure on \( \text{Hot}_{\mathcal{A}}(K^\bullet, L^\bullet) \) for every \( K^\bullet, L^\bullet \in \text{Ob}(C(\mathcal{A})) \), that makes \( \text{Hot}(\mathcal{A}) \) into an additive category, such that (7.1.5) is an additive functor.

Furthermore, if \( \mathcal{A} \) is abelian, the same holds for \( C(\mathcal{A}) \). Indeed, we can take

\[
\text{(Ker } \varphi)^i := \text{Ker } \varphi^i \quad \text{(Coker } \varphi)^i := \text{Coker } \varphi^i \quad \text{for every morphism } \varphi^* \text{ of } C(\mathcal{A})
\]

and it is clear that the resulting morphism \( \beta_\varphi^* \) as in (3.6.33) is an isomorphism. It is then also clear that, for any additive functor \( F \) as in (i), the induced functors \( C(F) \) and \( \text{Hot}(F) \) are additive, and the same holds as well for the shift operators on \( C(\mathcal{A}) \) and \( \text{Hot}(\mathcal{A}) \).

All these considerations extend more generally to the full subcategories \( C^I(\mathcal{A}) \) (for any interval \( I \subset \mathbb{Z} \)), \( C^-(\mathcal{A}) \), \( C^+(\mathcal{A}) \) and \( C^b(\mathcal{A}) \), as well as their homotopy category variants: the detailed verifications shall be left to the reader.

(iii) Taking into account remark 3.6.37(i), we get a natural identification

\[
C(\mathcal{A})^o \simeq C(\mathcal{A}^o) \quad K^\bullet \mapsto (K^\circ)^\bullet
\]
where
\[ (K^o)^i := (K^{-i})^o \quad \text{and} \quad d^o_K := (-1)^{i+1} \cdot (d^{-i-1})^o \]
for every \( i \in \mathbb{Z} \) and every \( K^\bullet \in \text{Ob}(C(\mathcal{A})) \). If \( \varphi^\bullet : K^\bullet \to L^\bullet \) is any morphism in \( C(\mathcal{A}) \), then \( (\varphi^o)^i := \varphi^{-i} \) for every \( i \in \mathbb{Z} \). Also, if \( s^\bullet \) is a homotopy between morphisms \( f^\bullet, g^\bullet : K^\bullet \to L^\bullet \), then the system
\[ (s^o)^i := ((-1)^i \cdot (s^{-i})^o \mid i \in \mathbb{Z}) \]
is a homotopy between \( (f^o)^\bullet, (g^o)^\bullet : (L^o)^\bullet \to (K^o)^\bullet \), whence an isomorphism of categories:
\[ \text{Hot}(\mathcal{A})^o \cong \text{Hot}(\mathcal{A}^o). \]

One may wonder about the reason for inserting apparently artificial signs in the above formulas; the point is that this sign convention makes the foregoing natural identifications behave slightly better in connection with additive contravariant functors (and their extensions to complexes: see e.g. the construction of the \( \text{Hom}^\bullet \) functor in example 7.1.7). On the other hand, there is a drawback as well: indeed, notice that by applying twice our natural isomorphism, we do not get the identity automorphism of \( C(\mathcal{A})^oo = C(\mathcal{A}) \); rather
\[ d^o_{Koo} = -d^o_K \quad \text{and} \quad (s^oo)^i = s^i \]
for every object \( K^\bullet \) and every homotopy \( s^\bullet \) of \( C(\mathcal{A}) \) (details left to the reader).

(iv) The indexing notation that makes use of superscript to denote the degrees in a complex, is known traditionally as \textit{cohomological degree notation}. Sometimes it is more natural to switch to the \textit{homological degree notation}, that makes use of subscript indexing; namely, one associates with any cochain complex \( K^\bullet \), the \textit{chain complex} \( K^\bullet \) given by the rule:
\[ K_n := K^{-n} \quad \text{and} \quad d_n := d^{−n} : K_n \to K_{n−1} \quad \text{for every} \ n \in \mathbb{Z}. \]

(v) If \( \mathcal{A} \) is complete (resp. cocomplete) then the same holds for \( C^I(\mathcal{A}) \), for any interval \( I \subset \mathbb{Z} \). Indeed, we may regard these categories as full subcategories of the category \( \text{Fun}(\mathbb{Z}, \mathcal{A}) \), where the ordered set \( \mathbb{Z} \) (endowed with its standard ordering) is viewed as a category as explained in example 1.1.6(iii), and therefore the assertion follows from corollary 1.4.1(ii,iv), which shows more precisely that the limits and colimits in \( C^I(\mathcal{A}) \) are formed degree-wise.

(vi) If \( \mathcal{A} \) is complete (resp. cocomplete), then all products (resp. coproducts) of \( \text{Hot}^I(\mathcal{A}) \) are representable, for every interval \( I \subset \mathbb{Z} \). Indeed, let \( K^\bullet := (K^\bullet_j \mid j \in J) \) be any family of objects of \( \text{Hot}^I(\mathcal{A}) \) indexed by a small set \( J \); we claim that the product \( K^\bullet \) in the category \( C^I(\mathcal{A}) \) of the family \( K^\bullet \) also represents the product of the same family in \( \text{Hot}^I(\mathcal{A}) \). Indeed, let \( M^\bullet \) be any other object of \( \text{Hot}^I(\mathcal{A}) \), and \( \pi^\bullet_j : K^\bullet \to K^\bullet_j \) the canonical projection, for every \( j \in J \); from any morphism \( \varphi^\bullet : M^\bullet \to K^\bullet \) we obtain a system \( (\varphi^\bullet_j := \varphi^{−j} \circ \varphi^\bullet : M^\bullet \to K^\bullet_j \mid j \in J) \) of morphisms in \( \text{Hot}^I(\mathcal{A}) \). Conversely, given such a system of morphisms, for every \( j \in J \) pick arbitrarily a morphism of complexes \( \tilde{\varphi}^\bullet_j : M^\bullet \to K^\bullet_j \) in the class of \( \varphi^\bullet_j \); the system \( (\tilde{\varphi}^\bullet_j \mid j \in J) \) yields by (v) a unique morphism of complexes \( \tilde{\varphi}^\bullet : M^\bullet \to K^\bullet \) and we let \( \varphi^\bullet \) be the homotopy class of \( \tilde{\varphi}^\bullet \). We need to show that \( \varphi^\bullet \) does not depend on the choices of representatives \( \tilde{\varphi}^\bullet_j \), to this aim, we come down to checking that if each \( \tilde{\varphi}^\bullet_j \) is null-homotopic, then the same holds for \( \tilde{\varphi}^\bullet \). Hence, pick for every \( j \in J \) a homotopy \( s^\bullet_j \) from \( \tilde{\varphi}^\bullet_j \) to the zero morphism. Since the products are computed degree-wise in \( C^I(\mathcal{A}) \), the system \( (s^\bullet_j : M^n \to K^{n−1} \mid j \in J) \) corresponds, for every \( n \in I \), to a unique morphism \( s^n : M^n \to K^{n−1} \) of \( \mathcal{A} \), and it is easily seen that the system \( (s^n \mid n \in I) \) yields a well defined homotopy from \( \tilde{\varphi}^\bullet \) to the zero morphism \( M^\bullet \to K^\bullet \). By applying the same argument to the opposite category \( \mathcal{A}^o \) and invoking (iii) we get the assertion for coproducts.

\textbf{Example 7.1.7.} Denote by \( \text{Z-Mod}_{\text{fg}} \) the additive category of free abelian groups of finite rank.
We have a natural isomorphism of categories:
\[ \text{Z-Mod}_{\text{fg}}^o \cong \text{Z-Mod}_{\text{fg}} : \ P \mapsto P^\vee := \text{Hom}_\mathbb{Z}(P, \mathbb{Z}) \]
that sends any \(\mathbb{Z}\)-linear map \(f : P \to Q\) to its transpose \(f' : Q' \to P'\). In view of remark 7.1.6(iii) there follow natural isomorphisms of categories

\[
\mathcal{C}(\mathcal{Z}\text{-}\mathcal{M}od_{\mathfrak{m}})^{\circ} \simeq \mathcal{C}(\mathcal{Z}\text{-}\mathcal{M}od_{\mathfrak{m}}) \quad \text{Hot}(\mathcal{Z}\text{-}\mathcal{M}od_{\mathfrak{m}})^{\circ} \simeq \text{Hot}(\mathcal{Z}\text{-}\mathcal{M}od_{\mathfrak{m}}) \quad K^* \mapsto K'^*.
\]

**Definition 7.1.8.** Let \(\mathcal{A}\) be an abelian category, \(K^*\) any object of \(\mathcal{C}(\mathcal{A})\), and \(i \in \mathbb{Z}\) any integer.

(i) The **cohomology of \(K^*\) in degree \(i\)** is the object of \(\mathcal{A}\):

\[
H^i K^* := \text{Ker} d^{i}/\text{Im} d^{i-1}.
\]

(ii) We say that \(K^*\) is **acyclic in degree \(i\)** (resp. **acyclic**) if \(H^i K^* = 0\) (resp. if \(H^i K^* = 0\) for every \(j \in \mathbb{Z}\)).

**Remark 7.1.9.** (i) Clearly, for every \(i \in \mathbb{Z}\), the rule \(K^* \mapsto H^i K^*\) extends to a functor

\[
H^i : \mathcal{C}(\mathcal{A}) \to \mathcal{A}.
\]

(ii) Moreover, if \(\varphi^*, \psi^* : K^* \to L^*\) are chain homotopic morphisms in \(\mathcal{C}(\mathcal{A})\), then it is easily seen that, for every \(i \in \mathbb{Z}\), the induced morphisms in cohomology

\[
H^i \varphi^*, H^i \psi^* : H^i K^* \to H^i L^*
\]

coincide. Hence, the cohomology functor \(H^i\) factors (uniquely) through a functor

\[
H^i : \text{Hot}(\mathcal{A}) \to \mathcal{A} \quad \text{for every } i \in \mathbb{Z}.
\]

(iii) Notice as well that the cohomology is a **self-dual** operation : namely, we have an essentially commutative diagram of functors

\[
\begin{array}{ccc}
\mathcal{C}(\mathcal{A})^{\circ} & \xrightarrow{\sim} & \mathcal{C}(\mathcal{A}^{\circ}) \\
(H^i)^{\circ} \downarrow & & \downarrow H^{-i} \\
\mathcal{A}^{\circ} & \xrightarrow{\sim} & \mathcal{A}
\end{array}
\]

whose top horizontal arrow is the isomorphism of remark 7.1.6(iii). Indeed, if \(K^*\) is any complex of \(\mathcal{A}\), the morphism \(d_{K}^{i-1}\) factors uniquely through a morphism \(e_{K}^{i-1} : K^{i-1} \to \text{Ker} d_{K}^{i}\), and we have a natural isomorphism \(H^i K^* \sim \text{Coker} e_{K}^{i-1}\). On the other hand, the morphism \(d_{K}^i\) factors uniquely through a morphism \(f_{K}^{i} : \text{Coker} d_{K}^{i-1} \to K^{i}\) and we have also the natural isomorphism \(H^i K^* \sim \text{Ker} f_{K}^{i}\), so the assertion follows from remark 3.6.37(i).

(iv) Just like in remark 7.1.6(iv), it is sometimes convenient to switch to a subscript notation; thus, for any chain complex \(K^*\) one sets

\[
H_{n} K^* := H^{-n} K_n \quad \text{for every } n \in \mathbb{Z}
\]

and calls this object of \(\mathcal{A}\) the **homology of \(K^*\)** in degree \(n\).

**7.1.10.** A **double complex** of \(\mathcal{A}\) is an object of

\[
\mathcal{C}_2(\mathcal{A}) := \mathcal{C}(\mathcal{C}(\mathcal{A}))
\]

(and likewise for a morphism of double complexes); i.e. a double complex is a triple

\[
K^{**} := (K^{**}, d_{h}^{**}, d_{v}^{**})
\]

consisting of a system \((K^{pq} \mid p, q \in \mathbb{Z})\) of objects of \(\mathcal{A}\), and morphisms \(d_{h}^{pq}, d_{v}^{pq}\) called respectively the **horizontal** and **vertical** differentials, fitting into a commutative diagram

\[
\begin{array}{ccc}
K^{pq} & \xrightarrow{d_{h}^{pq}} & K^{p+1,q} \\
\downarrow d_{v}^{pq} & & \downarrow d_{h}^{p+1,q} \\
K^{p,q+1} & \xrightarrow{d_{h}^{pq}} & K^{p+1,q+1}
\end{array}
\]

for every \(p, q \in \mathbb{Z}\).
and such that
\[ d^{p+1,q}_h \circ d^{pq}_h = 0 \quad d^{p,q+1}_v \circ d^{pq}_v = 0 \quad \text{for every } p, q \in \mathbb{Z}. \]

7.1.11. There are natural functors
\[ C_2(\mathcal{A}) \to C_2(\mathcal{A}) : K^{**} \mapsto fl_{\mathcal{A}}(K^{**}) \quad C_2(\mathcal{A}) \to C(\mathcal{A}) : K^{**} \mapsto (K^{**})^\Delta \]
where:
- The flip \( fl_{\mathcal{A}}(K^{**}) \) of \( K^{**} \) is the double complex \( F^{**} \) such that \( F^{pq} := K^{qp} \) for every \( p, q \in \mathbb{Z} \), with differentials deduced from those of \( K^{**} \), in the obvious way.
- The diagonal \( (K^{**})^\Delta \) is the complex \( D^* \) such that \( D^p := K^{pp} \) for every \( p \in \mathbb{Z} \) and with differentials
\[ d^{p+1,q}_v \circ d^{pq}_v : D^p \to D^{p+1} \quad \text{for every } p \in \mathbb{Z}. \]
Suppose that all coproducts (resp. all products) are representable in \( \mathcal{A} \). Then there are two other natural functors
\[ \text{Tot}^\oplus : C_2(\mathcal{A}) \to C(\mathcal{A}) \quad (\text{resp. } \text{Tot}^\prod : C_2(\mathcal{A}) \to C(\mathcal{A})) \]
defined as follows. The total complex \( \text{Tot}^\oplus_{\mathcal{A}}(K^{**}) \) (resp. \( \text{Tot}^\prod_{\mathcal{A}}(K^{**}) \)) is the complex \( T^* \) with
\[ T^n := \bigoplus_{p+q=n} K^{pq} \quad (\text{resp. } T^n := \prod_{p+q=n} K^{pq}) \]
and with differentials \( T^n \to T^{n+1} \) given by the sum (resp. the product) of the morphisms
\[ d^{pq}_h + (-1)^p \cdot d^{pq}_v : K^{pq} \to K^{p+q+1} \oplus K^{p+1,q} \quad \text{for all } p, q \in \mathbb{Z} \text{ such that } p + q = n. \]
We usually drop the subscript \( \mathcal{A} \), unless the omission would be a source of ambiguities, and we often omit as well the superscript \( \oplus \) when dealing with the total complex functor; to avoid confusion, we stipulate that the notation \( \text{Tot} \) shall always refer to the functor \( \text{Tot}^\oplus \), so if we need to use the other total complex functor, we shall denote it explicitly by \( \text{Tot}^\prod \). Notice that we have natural isomorphisms
\[ \text{Tot}(K^{**}) \cong \text{Tot}(fl_{\mathcal{A}}(K^{**})) \quad (\text{resp. } \text{Tot}^\prod(K^{**}) \cong \text{Tot}^\prod(fl_{\mathcal{A}}(K^{**}))) \]
given, in each degree \( n \in \mathbb{Z} \), by the direct sum (resp. the direct product) of the morphisms
\( (-1)^p \cdot 1_{K^{pq}} \) for every \( p, q \in \mathbb{Z} \) such that \( p + q = n. \)

7.1.12. The category of triple complexes of \( \mathcal{A} \) can be realized in two equivalent ways: namely, we have natural identifications:
\[ C_2(C(\mathcal{A})) \cong C(C_2(\mathcal{A})) \]
and we denote either of these categories by \( C_3(\mathcal{A}) \). In other words, a triple complex is a system
\[ (K^{ijk}, d_1^{ijk}, d_2^{ijk}, d_3^{ijk} | i, j, k \in \mathbb{Z}) \]
such that, for every fixed \( p \in \mathbb{Z} \), the subsystems
\[ (K^{p,**}, d_2^{p,**}, d_3^{p,**}) \quad (K^{**,*}, d_1^{**,*}, d_3^{**,*}) \quad (K^{***,*}, d_1^{***,*}, d_2^{***,*}) \]
are double complexes of \( \mathcal{A} \). Corresponding to the two interpretations of \( C_3(\mathcal{A}) \), we have two different way of forming total complexes out of triple complexes; namely, if \( \mathcal{A} \) is cocomplete we have the functors
\[ \text{Tot}_{\mathcal{A}} \circ \text{Tot}_{C(\mathcal{A})}, \text{Tot}_{\mathcal{A}} \circ C(\text{Tot}_{\mathcal{A}}) : C_3(\mathcal{A}) \to C(\mathcal{A}). \]
and likewise for the \( \text{Tot}^\Pi \) variant, if \( \mathcal{A} \) is complete. However, a simple computation shows that these two functors agree under the natural identification (7.1.13)\footnote{due to the naturality of the functors}, namely, both functors yield a complex whose differential is the direct sum (resp. direct product) of the morphisms

\[
d^{ij}_{k} = (-1)^{i} \cdot d^i_{2k} + (-1)^{i+j} \cdot d^j_{3k} : K^{i,j}_{k} \to K^{i+1,j,k} \oplus K^{i,j+1,k} \oplus K^{i,j,k+1}.
\]

We shall therefore denote these functors indifferently by \( \text{Tot} \) (resp. by \( \text{Tot}^\Pi \)), just as for double complexes.

7.1.14. Let \( \mathcal{A}, \mathcal{A}', \mathcal{A}'' \) be three additive categories, and

\[
B : \mathcal{A} \times \mathcal{A}' \to \mathcal{A}'
\]

a biadditive functor, i.e. such that, for every \( A \in \text{Ob}(\mathcal{A}) \) and every \( A' \in \text{Ob}(\mathcal{A}') \), both functors

\[
B(A, -) : \mathcal{A} \to \mathcal{A}' \quad B(-, A') : \mathcal{A}' \to \mathcal{A}'
\]

are additive. The functor \( B \) induces a biadditive functor

\[
B^{\bullet} : C(\mathcal{A}) \times C(\mathcal{A}') \to C_2(A')
\]

by the rule

\[
B^{ij}(K^\bullet, L^\bullet) := B(K^i, L^j) \quad \text{for every } K^\bullet \in \text{Ob}(C(\mathcal{A})) \text{ and } L^\bullet \in \text{Ob}(C(\mathcal{A}')).
\]

The differentials of \( B^{\bullet\bullet}(K^\bullet, L^\bullet) \) in degree \( (p, q) \) are respectively \( B(d^p_K, 1_{L^n}) \) and \( B(1_{K^p}, d^q_L) \). Suppose that \( \mathcal{A}'' \) is cocomplete (resp. complete); then, by composing with the functor \( \text{Tot}^\Pi \) (resp. with \( \text{Tot} \)), we deduce a biadditive functor

\[
B^\bullet_+: C^-(\mathcal{A}) \times C^-(\mathcal{A}') \to C^-(\mathcal{A}'') \quad \text{resp. } B^\bullet_+ : C^+(\mathcal{A}) \times C^+(\mathcal{A}') \to C^+(\mathcal{A}'').
\]

For a general additive category \( \mathcal{A}'' \), the foregoing functors are still well defined at least on bounded above or bounded below complexes, i.e. we have functors

\[
B^\bullet_- : C^-(\mathcal{A}) \times C^-(\mathcal{A}') \to C^-(\mathcal{A}'') \quad B^\bullet_- : C^+(\mathcal{A}) \times C^+(\mathcal{A}') \to C^+(\mathcal{A}'').
\]

Example 7.1.15. (i) If \( \mathcal{A} \) is any additive category, the construction of (7.1.14) extends the biadditive functor

\[
\text{Hom}_\mathcal{A}(-, -) : \mathcal{A}^\bullet \times \mathcal{A}^\bullet \to \mathbb{Z}\text{-Mod}
\]

to a functor \( \text{Hom}_\mathcal{A}^\bullet : C(\mathcal{A}) \times C(\mathcal{A}) \to C(\mathbb{Z}\text{-Mod}) \) (notice the swapping of the two factors, that is required in order to conform with established sign conventions) and combining with the natural identification of remark 7.1.6(iii), we obtain a biadditive functor

\[
\text{Hom}_\mathcal{A}^\bullet(-, -) : C(\mathcal{A}) \times C(\mathcal{A}) \to C(\mathbb{Z}\text{-Mod}) : (L^\bullet, K^\bullet) \to \text{Hom}_\mathcal{A}^\bullet((K^\bullet)^\bullet, L^\bullet).
\]

We shall denote by \( d^p_{K,L} \) the differential of the complex \( \text{Hom}_\mathcal{A}^\bullet(K^\bullet, L^\bullet) \), for every \( K^\bullet, L^\bullet \in \text{Ob}(C(\mathcal{A}')) \). Let \( n \in \mathbb{Z} \) be any integer; with this notation, a simple inspection shows that:

- \( d^p_{K,L} \) is the product, for every \( j \in \mathbb{Z} \), of the maps

\[
\text{Hom}_\mathcal{A}((K^{j-n}, L^j) \to \text{Hom}_\mathcal{A}((K^{j-n}, L^{j+1}) \oplus \text{Hom}_\mathcal{A}((K^{j-n-1}, L^j)
\]

given by the rule \( (\varphi : K^{j-n} \to L^j) \mapsto d^p_L \circ \varphi - (-1)^n \cdot \varphi \circ d^{p-1}_L \).

- \( \text{Hom}_\mathcal{A}(K^\bullet, L^\bullet[n]) = \text{Ker} d^p_{K,L} \).

- Let \( \varphi^\bullet, \psi^\bullet : K^\bullet \to L^\bullet[n] \) be any two morphisms; then the set of homotopies from \( \varphi^\bullet \) to \( \psi^\bullet \) is naturally identified with the subset

\[
\{ s^\bullet \in \text{Hom}_\mathcal{A}^{-1-n}(K^\bullet, L^\bullet) | d^{1-n}_{K,L}(s^\bullet) = \psi^\bullet - \varphi^\bullet \}.
\]

- Consequently, we have a natural identification:

\[
\text{Hot}_\mathcal{A}^n(K^\bullet, L^\bullet[n]) \overset{\sim}{\to} H^n(\text{Hom}_\mathcal{A}^\bullet(K^\bullet, L^\bullet)).
\]
(ii) The constructions of (i) can be used to endow $\mathcal{C}(\mathscr{A})$ with a natural 2-category structure, whose 2-cells are given by homotopies of complexes. Indeed, let us write
\[ s^* : \varphi^* \Rightarrow \psi^* \]
if $s^* := (s^n | n \in \mathbb{N})$ is a homotopy from $\varphi^*$ to $\psi^*$. Then, if $\lambda^* : K^* \to L^*$ is another morphism, and $t^* : \psi^* \Rightarrow \lambda^*$ another homotopy, we define a composition law by setting
\[ s^* \circ t^* := (s^n + t^n | n \in \mathbb{N}) \]
and it is immediate that $s^* \circ t^*$ is a homotopy $\varphi^* \Rightarrow \lambda^*$. Moreover, if $\beta^*, \gamma^* : L^* \to P^*$ are two other morphisms in $\mathcal{C}(\mathscr{A})$, and $u : \beta^* \Rightarrow \gamma^*$ another homotopy, we have a Godement composition law by the rule
\[ u^* \circ s^* := (\beta^{n+1} \circ s^n + u^n \circ \psi^n | n \in \mathbb{N}) : \beta^* \circ \varphi^* \Rightarrow \gamma^* \circ \psi^*. \]
The associativity of the laws $\ast$ and $\circ$ thus defined are easily checked by direct computation.

Now, suppose that $\delta^* : L^* \to P^*$ is yet another morphism, and $v : \gamma \Rightarrow \delta$ another homotopy. A direct calculation yields the identity
\[ (u^* \circ s^*) \circ (v^* \circ t^*) = (u^* \circ v^*) \circ (s^* \circ t^*) + c^* \]
where $c^n := d^{n-2}_P \circ u^{n-1} \circ t^n - u^n \circ t^{n+1} \circ d^1_K$ for every $n \in \mathbb{Z}$, which can be rewritten as
\[ c^* = d^{2}_L \circ (u \circ t) \]
where $(u \circ t)^n := u^{n-1} \circ t^n$ for every $n \in \mathbb{Z}$.

Summing up, we conclude that $\mathcal{C}(\mathscr{A})$ carries a 2-category structure, whose 2-cells $\varphi \Rightarrow \psi$ (for any two 1-cells $\varphi, \psi : K^* \to L^*$) are the classes
\[ \bar{s} \in \text{Hom}^{-1}_{\mathcal{C}}(K^*, L^*)/\text{Im}(d^2_{K,L}) \quad \text{such that} \quad d^1_{K,L}(\bar{s}) = \psi^* - \varphi^*. \]

(iii) Moreover, if $F$ is any additive functor as in remark 7.1.6(i), the induced functor $\mathcal{C}(F)$ extends to a pseudo-functor for the 2-category structures given by (ii); indeed, if $s^* : K^* \Rightarrow L^*$ is a homotopy, obviously the system $(F s^n | n \in \mathbb{N})$ is a homotopy $F s^* : F(K^*) \Rightarrow F(L^*)$.

**Example 7.1.6.** (i) Suppose that $(\mathscr{A}, \otimes, \Phi, \Psi)$ is a tensor abelian category, and set
\[ B(A, A') := A \otimes A' \quad \text{for every} \ A, A' \in \text{Ob}(\mathscr{A}). \]
Following (7.1.14), we get a corresponding functor $B^{***}_{\mathcal{A}}$, for which we use the notation
\[ - \boxtimes - : \mathcal{C}(\mathscr{A}) \times \mathcal{C}(\mathscr{A}) \to \mathcal{C}(\mathcal{A}). \]
If all coproducts are representables in $\mathscr{A}$, we get as well the functor $B^{\circ}_{\mathcal{A}}$, which we denote :
\[ K^* \boxtimes L^* := \text{Tot}(K^* \boxtimes L^*). \]

If $\mathscr{A}$ is not cocomplete, $K^* \boxtimes L^*$ is still well defined, provided $K^*$ and $L^*$ are both bounded below or if they are both bounded above. The commutativity constraints for $(\mathscr{A}, \otimes)$ yield natural isomorphisms $K^* \boxtimes L^* \cong \mathcal{A}(L^* \boxtimes K^*)$, as well as
\[ (7.1.17) \quad \Psi^*_{K,L} : K^* \boxtimes L^* \cong L^* \boxtimes K^*. \]
Namely, one takes the direct sum of the maps $(-1)^{pq} \cdot \Psi^*_{K^p,L^q}$, for every $p, q \in \mathbb{Z}$.

(ii) Likewise, if $P^*$ is another complex of $\mathscr{A}$, the associativity constraints of $\mathscr{A}$ assemble to an isomorphism of triple complexes
\[ (\Phi^*_{K^i,L^j,p}) | i,j,k : (K^* \boxtimes L^*) \boxtimes P^* \cong K^* \boxtimes (L^* \boxtimes P^*) \]
whence, taking into account the discussion of (7.1.12), a natural isomorphism in $\mathcal{C}(\mathscr{A})$ :
\[ \Phi^*_{K,L,P} : K^* \boxtimes (L^* \boxtimes P^*) \cong (K^* \boxtimes L^*) \boxtimes P^*. \]
With these natural isomorphisms, $C(\mathscr{A})$ is then a tensor abelian category as well.
(iii) In the situation of (i), notice that the natural morphism $K^i \otimes L^j \to (K^* \otimes L^*)^{i+j}$ induces morphisms

$$\text{Ker } (d^i_K) \otimes \text{Ker } (d^j_L) \to \text{Ker } (d^{i+j}_{K \otimes L})$$

$$(\text{Ker } (d^i_K) \otimes \text{Im } (d^{-1}_L)) \oplus (\text{Im } (d^{-1}_K) \otimes \text{Ker } (d^j_L)) \to \text{Im } (d^{i+j}_{K \otimes L})$$

so, the induced map $\text{Ker } (d^i_K) \otimes \text{Ker } (d^j_L) \to H^{i+j}(K^* \otimes L^*)$ factors through a natural pairing:

$$H^i(K^*) \otimes H^j(L^*) \to H^{i+j}(K^* \otimes L^*) \quad \text{for every } i, j \in \mathbb{Z}.$$  

(iv) Moreover, if $P^*$ is a third complex, in view of (ii) we get a commutative diagram

$$
\begin{align*}
H^i(K^*) \otimes (H^j L^* \otimes H^k P^*) &\xrightarrow{\alpha} (H^i K^* \otimes H^j L^*) \otimes H^k P^* \\
&\xrightarrow{\beta} H^{i+j}(K^* \otimes L^*) \otimes H^k P^* \\
&\xrightarrow{\delta} H^i K^* \otimes H^{i+j+k}(L^* \otimes P^*)
\end{align*}
$$

where $\alpha$ is the associativity constraint, $\beta, \gamma, \delta$ and $\lambda$ are given by the above pairing, and $\sigma$ is deduced from $\Phi_{K,L,P}$.

(v) If $\mathcal{A}$ also admits an internal Hom functor, we may define as well a functor

$$\mathcal{H}om^{\bullet, \bullet} : C(\mathcal{A}) \times C(\mathcal{A}) \to C_2(\mathcal{A})$$

following the trace of example 7.1.15(i); namely, we set

$$\mathcal{H}om^{p,q}(K^*, L^*) := \mathcal{H}om(K^{-p}, L^q)$$

for every $p, q \in \mathbb{Z}$.

with differentials

$$d^p_{h, q} := \mathcal{H}om(1_{K^{-p}}, d^q_{L^q}) \\
d^p_{v} := (-1)^{p+1} \cdot \mathcal{H}om(d^{-p-1}_{K^{-p}} 1_{L^q})$$

for every $p, q \in \mathbb{Z}$. If all products are representable in $\mathcal{A}$, we may then define

$$\mathcal{H}om^{\bullet, \bullet}(K^*, L^*) := \text{Tot}^\Pi \mathcal{H}om^{\bullet, \bullet}(K^*, L^*).$$

(vi) Suppose that $\mathcal{A}$ is both complete and cocomplete, and $P^*$ is any other complex; to ease notation, set $H^* := \mathcal{H}om^{\bullet, \bullet}(K^*, L^*)$ and $N^* := P^* \otimes K^*$. We have natural isomorphisms

$$\text{Hom}_{\mathcal{A}}(P^*, H^*) \xrightarrow{\sim} \text{Equal} \left( \text{Hom}_{\mathcal{A}}^{0,0}(P^*, H^*) \xrightarrow{d_v} \text{Hom}_{\mathcal{A}}^{1,1}(P^*, H^*) \right)$$

where

$$d_h := \prod_{n \in \mathbb{Z}} \text{Hom}_{\mathcal{A}}(P^n, d^h_{L^n})$$

and

$$d_v := \prod_{n \in \mathbb{Z}} \text{Hom}_{\mathcal{A}}(d^v_{P^n}, H^{n+1})$$

(see example 7.1.15(i)). However, notice that

$$\text{Hom}_{\mathcal{A}}^{n,0}(P^*, H^*) = \prod_{n \in \mathbb{Z}} \text{Hom}_{\mathcal{A}}(P^n, \text{Hom}(K^{-p}, L^q))$$

$$= \prod_{n \in \mathbb{Z}} \prod_{p+q = n+a} \text{Hom}_{\mathcal{A}}(P^n, \text{Hom}(K^{-p}, L^q))$$

$$= \prod_{n \in \mathbb{Z}} \prod_{p+q = n+a} \text{Hom}_{\mathcal{A}}(P^n \otimes K^{-p}, L^q)$$

$$= \prod_{q \in \mathbb{Z}} \left( \bigoplus_{n-p = q-a} P^n \otimes K^{-p}, L^q \right)$$
for every \( n, a \in \mathbb{Z} \), whence

\[
\text{Hom}_{C(\mathcal{A})}(P^\bullet, H^\bullet) \xrightarrow{\sim} \text{Equal} \left( \text{Hom}_{\mathcal{A}}^0(N^\bullet, L^\bullet) \xrightarrow{d_a^0} \text{Hom}_{\mathcal{A}}^1(N^\bullet, L^\bullet) \right)
\]

where

\[
d_a^h := \prod_{n \in \mathbb{Z}} \text{Hom}_{\mathcal{A}}(d_N^h, L^0) \quad \text{and} \quad d_a'^v := \prod_{n \in \mathbb{Z}} \text{Hom}_{\mathcal{A}}(N^q, d_L^v)
\]

so finally:

\[
\text{Hom}_{C(\mathcal{A})}(P^\bullet, \mathcal{H} \text{om}^\bullet(K^\bullet, L^\bullet)) \xrightarrow{\sim} \text{Hom}_{C(\mathcal{A})}(P^\bullet \otimes K^\bullet, L^\bullet)
\]

which says that \( \mathcal{H} \text{om}^\bullet \) is an internal Hom functor for \( C(\mathcal{A}) \).

7.1.18. Suppose that \( \mathcal{A} \) is an additive category with small Hom-sets, and let \( (G^\bullet, d_G^\bullet) \) be any complex of free abelian groups of finite rank; with the notation of (3.6.47), we obtain an object \( (G^\bullet, d_G^\bullet) \) of \( C(\mathcal{A}) \); on the other hand, if \( (K^\bullet, d_K^\bullet) \) is any object of \( C(\mathcal{A}) \), we may also consider the object \( h^i_K := (h^i_{Kn}, h^i_{Kn}| n \in \mathbb{N}) \) of \( C(\mathcal{A}) \), and since \( \mathcal{A} \) is an abelian tensor category, we may form the tensor product

\[
G^\bullet \boxtimes_Z K^\bullet := \mathcal{H} \text{om}^{\bullet\bullet}(G^\bullet, h^1_K)
\]

according to example 7.1.16(v). Arguing as in (3.6.47), we see that this object of \( C_2(\mathcal{A}) \) is isomorphic to an object of \( C_2(\mathcal{A}) \), and after choosing representing objects, we get a functor

\[
C(\mathbb{Z}-\text{Mod}_{\mathbb{R}}) \times C(\mathcal{A}) \to C_2(\mathcal{A}) \quad (G^\bullet, K^\bullet) \mapsto G^\bullet \boxtimes_Z K^\bullet
\]

which is additive in both arguments. If all direct sums are representable in \( \mathcal{A} \), or else, if \( G^\bullet \) is a bounded complex, it then natural to define

\[
G^\bullet \boxtimes_Z K^\bullet := \text{Tot} \ G^\bullet \boxtimes_Z K^\bullet \quad \text{for every } G^\bullet \text{ and } K^\bullet \text{ as above.}
\]

Likewise, we set \( K^\bullet \boxtimes_Z G^\bullet := \text{fl}_{\mathcal{A}}(G^\bullet \boxtimes_Z K^\bullet) \) and \( K^\bullet \boxtimes_G G^\bullet := \text{Tot}(K^\bullet \boxtimes_Z G^\bullet) \).

Remark 7.1.19. (i) With the notation of (7.1.18), notice the natural isomorphism

\[
K^\bullet[1] \xrightarrow{\sim} Z[1] \otimes_Z K^\bullet \quad \text{for every } K^\bullet \in \text{Ob}(C(\mathcal{A}))
\]

which explains the sign convention in the definition of the shift operator in (7.1.3).

(ii) Moreover, denote by \( \mathbb{K}\langle 1 \rangle^1 \in \text{Ob}(C^{-1,0}(\mathbb{Z}-\text{Mod})) \) the object such that

\[
\mathbb{K}\langle 1 \rangle^{-1} := \mathbb{Z} \quad \mathbb{K}\langle 1 \rangle^0 := \mathbb{Z} \oplus \mathbb{Z}
\]

and with differential \( d^{-1} \) given by the rule: \( n \mapsto (n, -n) \) for every \( n \in \mathbb{Z} \). Let \( e_0 := (0, 1) \) and \( e_1 := (1, 0) \) be the canonical basis of \( \mathbb{K}\langle 1 \rangle^0 \); we have two morphisms

\[
i^i : Z[0] \to \mathbb{K}\langle 1 \rangle^i \quad \text{for } i = 0, 1
\]

given, in degree zero, by the rule: \( n \mapsto n \cdot e_i \) for every \( n \in \mathbb{N} \). For any pair of morphisms \( \varphi^\bullet, \psi^\bullet : L^\bullet \to M^\bullet \) in \( C(\mathcal{A}) \), and any homotopy \( s^\bullet := (s^n | n \in \mathbb{Z}) \) from \( \varphi^\bullet \) to \( \psi^\bullet \), we obtain a morphism of complexes

\[
\sigma^\bullet : \mathbb{K}\langle 1 \rangle^\bullet \otimes_Z L^\bullet \to M^\bullet
\]
as follows. For every \( n \in \mathbb{Z} \), the morphism \( \sigma^n : L^n \oplus L^n \oplus L^{n+1} \rightarrow M^n \) restricts to \( \varphi^n \) (resp. \( \psi^n \), resp. \( s^n \)) on the first (resp. second, resp. third) summand. Clearly

\[
(7.1.20) \quad \varphi^* = \sigma^* \circ (i_0^* \otimes_Z L^*) \quad \psi^* = \sigma^* \circ (i_1^* \otimes_Z L^*).}

Conversely, the datum of a morphism \( \sigma^* : \mathbb{K}(1)^* \otimes_Z L^* \rightarrow M^* \) yields a homomorphism from \( \sigma^* \circ (i_1^* \otimes_Z L^*) \) to \( \sigma^* \circ (i_0^* \otimes_Z L^*) \).

(iii) If \( \mathcal{A} \) is abelian, the functor \(- \otimes_Z -\) extends to the category \( \mathcal{C}(\mathbb{Z}-\text{Mod}_{\mathcal{A}}) \times \mathcal{C}(\mathcal{A}) \), and if \( \mathcal{A} \) is also cocomplete, we can even extend it to the whole of \( \mathcal{C}(\mathbb{Z}-\text{Mod}) \times \mathcal{C}(\mathcal{A}) \) and we have as well a corresponding functor \(- \otimes_Z -\) on this category (see (3.6.47) and remark 3.6.49(ii)).

(iv) Let \( M^* \) and \( N^* \) be any two complexes of abelian groups, and \( f_0^*, f_1^* : M^* \rightarrow N^* \) two homotopy equivalent morphisms. If \( K^* \) is any object of \( \mathcal{C}(\mathcal{A}) \) and the tensor product \( M^* \otimes_Z K^* \), \( N^* \otimes_Z K^* \) are both representable in \( \mathcal{C}(\mathcal{A}) \), then the induced morphisms \( f_0^* \otimes_Z K^* \) and \( f_1^* \otimes_Z K^* \) are homotopy equivalent. Indeed, by (ii), we have a morphism \( \tau^* : \mathbb{K}(1)^* \otimes_Z M^* \rightarrow N^* \) such that \( \tau^* \circ (i_1^* \otimes_Z 1_M) = f_i^* \) for \( i = 0, 1 \); by example 7.1.16(ii) the tensor product \( \tau^* \otimes_Z K^* \) is naturally identified with a morphism \( \tau_K^* : \mathbb{K}(1)^* \otimes_Z (M^* \otimes_Z K^*) \rightarrow N^* \otimes_Z K^* \) such that \( \tau_K^* \circ (i_1^* \otimes_Z 1_{M \otimes_Z K}) = f_i^* \otimes_Z K^* \) for \( i = 0, 1 \), whence the claim, again by (ii).

(v) Let \( P^* \) be any bounded complex of free abelian groups of finite rank. Notice the natural identification

\[
(P^* \otimes_Z K^*)^0 \xrightarrow{\sim} P^{0*} \otimes_Z (K^0)^* \quad \text{in} \ \mathcal{C}(\mathcal{A}^0)
\]
deduced from example 7.1.7 and remark 7.1.6(iii).

**Proposition 7.1.21.** Let \( \mathcal{A} \) be any additive category, and \( F : \mathcal{C}(\mathcal{A}) \rightarrow \mathcal{B} \) any functor. The following conditions are equivalent:

1. \( F \) factors uniquely through the natural functor \( \mathcal{C}(\mathcal{A}) \rightarrow \text{Hot}(\mathcal{A}) \).
2. \( F \varphi^* \) is an isomorphism, for every homotopy equivalence \( \varphi^* \) in \( \mathcal{C}(\mathcal{A}) \).

**Proof.** Clearly (a) \( \Rightarrow \) (b), hence, suppose that (b) holds, consider two chain homotopic morphisms \( \varphi^*, \psi^* : L^* \rightarrow M^* \) in \( \mathcal{C}(\mathcal{A}) \), and define \( \sigma^* \) as in remark 7.1.19(ii); in view of (7.1.20), assertion (a) will follow, once we know that

\[
F(i_0^* \otimes_Z L^*) = F(i_1^* \otimes_Z L^*).}

To show the latter identity, consider the morphism

\[
p^* : \mathbb{K}(1)^* \rightarrow \mathbb{Z}[0]
\]
such that \( p_0 : \mathbb{Z} \oplus \mathbb{Z} \rightarrow \mathbb{Z} \) is the addition map : \( (a, b) \mapsto a + b \) for every \( a, b \in \mathbb{Z} \). Clearly

\[
p^* \circ i_0^* = 1_{\mathbb{Z}[0]} = p^* \circ i_1^*
\]
so we are easily reduced to showing that \( F(p^* \otimes_Z L^*) \) is an isomorphism in \( \mathcal{B} \). By assumption (b), the latter in turn will follow, once we have shown that \( p^* \otimes_Z L^* \) is a homotopy equivalence. Thus, it suffices to exhibit a morphism \( j^* : \mathbb{Z}[0] \rightarrow \mathbb{K}(1)^* \) such that

\[
(7.1.22) \quad p^* \circ j^* = 1_{\mathbb{Z}[0]}
\]
and \( (j^* \circ p^*) \otimes_Z L^* \) is homotopy equivalent to \( 1_{\mathbb{K}(1)^* \otimes_Z L^*} \). Set \( \mathbb{K}(1, 1)^* := \mathbb{K}(1)^* \otimes_Z \mathbb{K}(1)^* \); by remark 7.1.19(ii), the datum of a homotopy from \( (j^* \circ p^*) \otimes_Z L^* \) to \( 1_{\mathbb{K}(1)^* \otimes_Z L^*} \) is equivalent to that of a morphism

\[
\tau^* : \mathbb{K}(1, 1)^* \otimes_Z L^* \rightarrow \mathbb{K}(1)^* \otimes_Z L^*
\]
such that

\[
\tau^* \circ (i_0^* \otimes_Z \mathbb{K}(1)^* \otimes_Z L^*) = (j^* \circ p^*) \otimes_Z L^* \quad \text{and} \quad \tau^* \circ (i_1^* \otimes_Z \mathbb{K}(1)^* \otimes_Z L^*) = 1_{\mathbb{K}(1)^* \otimes_Z L^*}.
\]
Notice that (7.1.22) is fulfilled with \( j^* := i_0^* \); we are then further reduced to showing the existence of a morphism

\[
t^* : \mathbb{K}(1, 1)^* \rightarrow \mathbb{K}(1)^*
\]
such that
\[ t^* \circ (i_1^* \otimes_{\mathbb{K}(1)} \mathbb{K}(1)^*) = i_0^* \circ p^* \quad \text{and} \quad t^* \circ (i_1^* \otimes_{\mathbb{K}(1)} \mathbb{K}(1)^*) = 1_{\mathbb{K}(1)}. \]

To this aim, let \( e_0, e_1 \) be the canonical basis of \( \mathbb{K}(1)^0 \), so that \( d^{-1}(1) = e_0 - e_1 \). Then:

\[ \mathbb{K}(1,1)^k \text{ is spanned by } \begin{cases} 
1 \otimes 1 & \text{for } k = -2 \\
(e \otimes e_i, e_i \otimes e_i & \text{for } k = -1 \\
e_i \otimes e_j & \text{for } k = 0 
\end{cases} \]

with differentials given by the rules:
\[
\begin{align*}
d^{-2}(1 \otimes 1) &= (e_0 - e_1) \otimes 1 - 1 \otimes (e_0 - e_1) \\
d^{-1}(1 \otimes e_i) &= (e_0 - e_1) \otimes e_i \\
d^{-1}(e_i \otimes 1) &= e_i \otimes (e_0 - e_1).
\end{align*}
\]

We define a morphism \( t^* \) as sought, by the rules:
\[
\begin{align*}
t^{-2}(1 \otimes 1) &= 0 \\
t^{-1}(1 \otimes e_0) &= t^{-1}(e_0 \otimes 1) = 0 \\
t^{-1}(e_i \otimes 1) &= t^{-1}(1 \otimes e_i) = 1 \\
t^0(e_i \otimes e_0) &= e_0 \quad (i = 0, 1) \\
t^0(e_i \otimes e_1) &= e_i \quad (i = 0, 1).
\end{align*}
\]

A direct inspection shows that \( t^* \) satisfies the required identities, and concludes the proof. \( \Box \)

7.1.23. In the situation of (7.1.14), let \( A \in \text{Ob}(\mathcal{A}), A' \in \text{Ob}(\mathcal{A}') \) and let \( P \) be any free abelian group of finite rank. With the notation of (5.6.47), it is easily seen that there exist natural isomorphisms in \( \mathcal{A}' \):

\[ (7.1.24) \quad B(P \otimes_{\mathbb{K}} A, A') \overset{\sim}{\rightarrow} P \otimes_{\mathbb{K}} B(A, A') \overset{\sim}{\rightarrow} B(A, P \otimes_{\mathbb{K}} A'). \]

Now, let "\( \oplus \)" be either \( + \) or \( - \), and \( K^* \) (resp. \( L^* \)) any object of \( C^i(\mathcal{A}) \) (resp. of \( C^i(\mathcal{A}') \)); let also \( P^* \) be any bounded complex of free abelian groups of finite rank. The maps (7.1.24) assemble to a natural isomorphism of triple complexes

\[ \omega^{ijk} : B(P^i \otimes_{\mathbb{K}} K^j, L^k) \overset{\sim}{\rightarrow} P^i \otimes_{\mathbb{K}} B(K^j, L^k) \quad i, j, k \in \mathbb{Z} \]

whence, taking into account the discussion of (7.1.12), an isomorphism of total complexes

\[ \omega^{*}_{K,L,P} : B^*_i(P^* \otimes_{\mathbb{K}} K^*, L^*) \overset{\sim}{\rightarrow} P^* \otimes_{\mathbb{K}} B^*_i(K^*, L^*) \]

(notation of (7.1.18)). Likewise, we get a natural isomorphism

\[ \sigma^{*}_{P,K,L} : B^*_i(K^*, P^* \otimes_{\mathbb{K}} L^*) \overset{\sim}{\rightarrow} P^* \otimes_{\mathbb{K}} B^*_i(K^*, L^*). \]

(Notice that \( \sigma^{*}_{P,K,L} \) involves composition with the flip operator \( C(\text{fl}_{\mathcal{A}}) : C_3(\mathcal{A}) \overset{\sim}{\rightarrow} C_3(\mathcal{A}) \), hence, in each degree \( p \in \mathbb{Z} \), it is the direct sum of morphisms \((-1)^{ij} \sigma^{ijk}\), for all \( i, j, k \in \mathbb{Z} \) such that \( i + j + k = p \), and where \( \sigma^{ijk} \) is a natural isomorphism as in (7.1.24).

Especially, take \( P^* := \mathbb{K}(1)^* \); it is easily seen that \( \omega^{*}_{K,L,K(1)} \) identifies the morphism

\[ B^*_i(i_1^* \otimes_{\mathbb{K}} 1_K, L^*) : B^*_i(K^*, L^*) \rightarrow B^*_i(\mathbb{K}(1)^* \otimes_{\mathbb{K}} K^*, L^*) \]

with the morphism

\[ i_1^* \otimes_{\mathbb{K}} B^*_i(K^*, L^*) : B^*_i(K^*, L^*) \rightarrow \mathbb{K}(1)^* \otimes_{\mathbb{K}} B^*_i(K^*, L^*). \]
Hence, suppose that \( \varphi_0^\bullet, \varphi_1^\bullet : L^\bullet \to M^\bullet \) are two homotopy equivalent morphisms in \( C^2(\mathcal{A}') \); taking into account remark 7.1.19(ii), we deduce that the induced morphisms \( B_i^\bullet(K^\bullet, \varphi_i^\bullet) \) (for \( i = 0, 1 \)) are also homotopy equivalent. A similar argument shows that the functor

\[
C^1(\mathcal{A}) \to C^2(\mathcal{A}'') : K^\bullet \mapsto B_i^\bullet(K^\bullet, L^\bullet)
\]

likewise preserves homotopy equivalences. We conclude that the functor \( B_i^\bullet \) descends to the homotopy category, to give a functor

\[
B_i^\bullet : \text{Hot}^2(\mathcal{A}) \times \text{Hot}^2(\mathcal{A}') \to \text{Hot}^2(\mathcal{A}'')
\]

which, in case \( \mathcal{A}'' \) is cocomplete (resp. complete), can even be extended to a functor

\[
B_i^\bullet : \text{Hot}(\mathcal{A}) \times \text{Hot}(\mathcal{A}') \to \text{Hot}(\mathcal{A}'') \quad \text{(resp. } B_i^\bullet : \text{Hot}(\mathcal{A}) \times \text{Hot}(\mathcal{A}') \to \text{Hot}(\mathcal{A}''))
\]

**Example 7.1.25.** (i) Consider any abelian tensor category \( (\mathcal{A}, \otimes, \Phi, \Psi) \). Following (7.1.23), the tensor product of example 7.1.16(i) descends to a biadditive functor

\[
\otimes : \text{Hot}(\mathcal{A}) \times \text{Hot}(\mathcal{A}') \to \text{Hot}(\mathcal{A}')
\]

for “?” equal to either + or −. If \( \mathcal{A} \) is cocomplete, this functor is even defined on the whole of \( \text{Hot}(\mathcal{A}) \).

(ii) The constructions of (7.1.23) can also be applied to the functor \( \text{Hom}_\mathcal{A}^\bullet \) of example 7.1.15(i) : taking into account remark 7.1.6(iii), we deduce that the functor \( \text{Hom}_\mathcal{A}^\bullet \) descends to a biadditive functor :

\[
\text{Hot}_\mathcal{A}^\bullet : \text{Hot}(\mathcal{A}) \times \text{Hot}(\mathcal{A})' \to \text{Hot}(\mathcal{Z}_{-\text{Mod}}) : (L^\bullet, K^\bullet) \mapsto \text{Hom}_\mathcal{A}^\bullet(K^\bullet, L^\bullet).
\]

**7.2. Filtered complexes and spectral sequences.** Let \( \mathcal{A} \) be any abelian category; a filtered object of \( \mathcal{A} \) is a datum

\[(A, \text{Fil}^\bullet A)\]

consisting of an object \( A \) of \( \mathcal{A} \) and a system of subobjects \( (\text{Fil}^p A \mid p \in \mathbb{Z}) \) of \( A \), with

\[\text{Fil}^{p+1} A \subset \text{Fil}^p A \quad \text{for every } p \in \mathbb{Z}.
\]

If \((B, \text{Fil}^\bullet B)\) is any other filtered object of \( \mathcal{A} \), a morphism of filtered objects

\[
(A, \text{Fil}^\bullet A) \to (B, \text{Fil}^\bullet B)
\]

is just a morphism \( u : A \to B \) in \( \mathcal{A} \) which restricts to a morphism

\[\text{Fil}^p u : \text{Fil}^p A \to \text{Fil}^p B \quad \text{for every } p \in \mathbb{Z}.
\]

With these morphisms, clearly the filtered objects of \( \mathcal{A} \) form a category

\[\text{Fil}_{\mathcal{A}}.
\]

Moreover, any functor \( F : \mathcal{A} \to \mathcal{B} \) induces a functor

\[\text{Fil}.F : \text{Fil}_{\mathcal{A}} \to \text{Fil}_{\mathcal{B}}
\]

that assigns to any filtered object \((A, \text{Fil}^\bullet A)\) of \( \mathcal{A} \) the filtered object \((FA, \text{Fil}^\bullet FA)\) such that \( \text{Fil}^k FA := \text{Im}(F(\text{Fil}^k A) \to FA) \) for every \( k \in \mathbb{Z} \).
7.2.2. To any object \((A, \text{Fil}^* A)\) of \(\mathcal{A}\) we attach its associated graded object, which is the system of objects of \(\mathcal{A}\):

\[
(\text{gr}^n A \mid n \in \mathbb{Z}) \quad \text{where} \quad \text{gr}^n A := \text{Fil}^n A / \text{Fil}^{n+1} A \quad \text{for every } n \in \mathbb{Z}.
\]

Notice that any morphism \(u(A, \text{Fil}^*) \to (B, \text{Fil}^*)\) of filtered objects of \(\mathcal{A}\) induces a system of morphisms in \(\mathcal{A}\):

\[
\text{gr}^p u : \text{gr}^p A \to \text{gr}^p B \quad \text{for every } p \in \mathbb{Z}.
\]

We say that the filtration \(\text{Fil}^* A\) of a filtered object \((A, \text{Fil}^* A)\) is bounded above (resp. bounded below) if there exists \(N \in \mathbb{Z}\) such that \(\text{Fil}^N A = A\) (resp. such that \(\text{Fil}^N A = 0\)). We say that the filtration \(\text{Fil}^*\) is finite if it is bounded above and below. Clearly, if \(\text{Fil}^* A\) is bounded above (resp. below), then \(\text{gr}^n A = 0\) whenever \(-n\) (resp. \(n\)) is sufficiently large.

**Definition 7.2.3.** Let \(\mathcal{A}\) be an abelian category, and \(r_0 \in \mathbb{N}\) any integer.

(i) A (cohomological) \(r_0\)-spectral sequence in \(\mathcal{A}\) is a datum

\[
((E^p_{pq}, \partial^p_{pq}, \beta^p_{pq}) \mid p, q, r \in \mathbb{Z}, \quad r \geq r_0)
\]

consisting of:

- objects \(E^p_{pq}\) of \(\mathcal{A}\) and morphisms \(\partial^p_{pq} : E^p_{pq} \to E^{p+r,q-r+1}_{r}\) in \(\mathcal{A}\), such that:

\[
d^{p+r,q-r+1}_{r} \circ \partial^p_{pq} = 0 \quad \text{for every } p, q, r \in \mathbb{Z} \text{ with } r \geq r_0.
\]

- isomorphisms

\[
\beta^p_{pq} : \text{Ker} \partial^p_{pq} / \text{Im} \partial^{p-r,q+r-1}_{r} \xrightarrow{\sim} E^{p+1}_{r} \quad \text{for every } p, q, r \in \mathbb{Z} \text{ with } r \geq r_0.
\]

(ii) Let \((E^*, E^*, \beta^p_{pq})\) and \((F^*, F^*, \beta^p_{pq})\) be two \(r_0\)-spectral sequences in \(\mathcal{A}\). A morphism of \(r_0\)-spectral sequences

\[
u^* : E^* \to F^*
\]

is a system \((\nu^p_{pq} : E^p_{pq} \to F^p_{pq} \mid p, q, r \in \mathbb{Z}, \quad r \geq r_0)\) of morphisms of \(\mathcal{A}\), such that the diagrams

\[
\begin{array}{ccc}
E^p_{r} & \xrightarrow{d^p_{E,r}} & E^{p+r,q-r+1}_{r} \\
\downarrow \quad \nu^p_{pq} & & \downarrow \quad \nu^p_{pq} \\
F^p_{r} & \xrightarrow{d^p_{F,r}} & F^{p+r,q-r+1}_{r}
\end{array}
\]

\[
\begin{array}{ccc}
\text{Ker} \partial^p_{E,r} & \xleftarrow{d^p_{E,r}} & \text{Ker} \partial^p_{E,r} / \text{Im} \partial^{p-r,q+r-1}_{r} \\
\downarrow \quad \nu^p_{pq} & & \downarrow \quad \nu^p_{pq} \\
\text{Ker} \partial^p_{F,r} & \xleftarrow{d^p_{F,r}} & \text{Ker} \partial^p_{F,r} / \text{Im} \partial^{p-r,q+r-1}_{r}
\end{array}
\]

commute for every \(p, q, r \in \mathbb{Z}\) with \(r \geq r_0\) (where the unmarked arrows are the natural monomorphisms and epimorphisms). Obviously, the \(r_0\)-spectral sequences of \(\mathcal{A}\) and their morphisms form a category, which we denote by

\[
\text{Sp.Seq}_{r_0}(\mathcal{A})
\]

7.2.5. Let \(r \in \mathbb{N}\) be any integer. Clearly, for every integer \(s \geq r\) there is a natural functor

\[
\text{Sp.Seq}_r(\mathcal{A}) \to \text{Sp.Seq}_s(\mathcal{A})
\]

that simply forgets the terms \(E^p_{pq}\) with \(r \leq k < s\). One may also define a natural functor form \(s\)-spectral sequences to \(r\)-spectral sequences. Namely, let \(E^*_{s}\) be any \((r+1)\)-spectral sequence of \(\mathcal{A}\). The décalage of \(E^*_{s}\) is the \(s\)-spectral sequence \((\text{Déc}(E)^*, \beta^p_{\text{Déc}(E)}\)) given by the rule

\[
\text{Déc}(E)^{p,q-p}_{s} := E^{p+q-p}_{s+1}, \quad \beta^p_{\text{Déc}(E)} := d^p_{E,s+1} \quad \text{for every } p, q, s \in \mathbb{Z} \text{ with } s \geq r
\]

and whose isomorphisms \(\beta^p_{\text{Déc}(E)}\) are deduced from the corresponding isomorphisms for \(E^*\), in the obvious way. Clearly, this rule extends to a natural functor

\[
\text{Déc} : \text{Sp.Seq}_{r+1}(\mathcal{A}) \to \text{Sp.Seq}_r(\mathcal{A}).
\]
7.2.6. Let $E_{r}^{p,q}$ be any $r_0$-spectral sequence; with the notation of definition 7.2.3 we define, by induction on $k-r$, two systems of subobjects

$$(Z_k(E_{r}^{p,q}), B_k(E_{r}^{p,q}) \subset E_{r}^{p,q} \ | \ p, q, k \in \mathbb{Z}, \ k > r \geq r_0)$$

as follows. First, we set

$$Z_{r+1}(E_{r}^{p,q}) := \text{Ker} \ d_{r}^{p,q} \quad B_{r+1}(E_{r}^{p,q}) := \text{Im} \ d_{r}^{p-r,q+r-1} \quad \text{for every } p, q, r \in \mathbb{Z} \text{ with } r \geq r_0.$$

Next, say that $i \geq 2$ is any integer, and suppose that both $Z_k(E_{r}^{p,q})$ and $B_k(E_{r}^{p,q})$ have already been defined, for every $p, q, r \in \mathbb{Z}$ with $k > r \geq r_0$ and $k-r < i$; we let

$$Z_{r+i}(E_{r}^{p,q}) := \pi_{rq}^{-1} Z_{r+i-1}(E_{r}^{p,q}) \quad B_{r+i}(E_{r}^{p,q}) := \pi_{pqr}^{-1} B_{r+i-1}(E_{r}^{p,q})$$

where $\pi_{pqr}$ is the composition

$$Z_{r+1}(E_{r}^{p,q}) \to Z_{r+1}(E_{r}^{p,q})/B_{r+1}(E_{r}^{p,q}) \xrightarrow{\beta_{r}^{p,q}} E_{r+1}^{p,q}.$$

Then it is clear that the system $(\beta_{r}^{p,q} \ | \ p, q, r \in \mathbb{Z}, \ r \geq r_0)$ induces isomorphisms

$$\beta_{r}^{p,q} : Z_{k}(E_{r}^{p,q})/B_{k}(E_{r}^{p,q}) \cong E_{k}^{p,q} \quad \text{for every } p, q, r, k \in \mathbb{Z} \text{ with } k > r \geq r_0$$

and for every $p, q, r, k, n \in \mathbb{Z}$ with $k > n > r \geq r_0$ we have inclusions

$$B_k(E_{r}^{p,q}) \subset B_{k+1}(E_{r}^{p,q}) \subset Z_{n+1}(E_{r}^{p,q}) \subset Z_n(E_{r}^{p,q}) \subset E_{r}^{p,q}.$$  

**Definition 7.2.7.** In the situation of (7.2.6), we define:

(i) an *abutment for the spectral sequence* $E_{r}^{p,q}$ to be a datum consisting of

- a system of subobjects $(B_{\infty}(E_{r}^{p,q}), Z_{\infty}(E_{r}^{p,q}) \subset E_{r}^{p,q} \ | \ p, q \in \mathbb{Z})$ such that $B_k(E_{r}^{p,q}) \subset B_{\infty}(E_{r}^{p,q}) \subset Z_{\infty}(E_{r}^{p,q}) \subset Z_k(E_{r}^{p,q})$ for every $p, q, k \in \mathbb{Z}$ with $k > r_0$
- a system of filtered objects $((E_{\infty}^n, \text{Fil}^n E_{\infty}^n) \ | \ n \in \mathbb{Z})$ of $\mathcal{A}$
- a system of isomorphisms in $\mathcal{A}$

$$\beta_{\infty}^{p,q} : E_{\infty}^{p,q} := Z_{\infty}(E_{r_0}^{p,q})/B_{\infty}(E_{r_0}^{p,q}) \cong \text{gr}^p E_{\infty}^{p+q} \quad \text{for every } p, q \in \mathbb{Z}.$$

We summarize these conditions via the traditional notation:

$$E_{r}^{p,q} \Rightarrow E_{\infty}^{p+q}.$$  

For any $n \in \mathbb{Z}$, we say that $E_{r}^{p,q}$ is *convergent in degree* $n$, if for every $p, q \in \mathbb{Z}$ with $p + q = n$ there exists $k \in \mathbb{N}$ such that $B_k(E_{r_0}^{p,q}) = B_{\infty}(E_{r_0}^{p,q})$ and $Z_k(E_{r_0}^{p,q}) = Z_{\infty}(E_{r_0}^{p,q})$. We say that $E_{r}^{p,q}$ is *convergent*, if it is convergent in all degrees.

(iii) Let $(E_{r}^{p,q}, B_{r}(E_{r}^{p,q}), Z_{r}(E_{r}^{p,q}), E_{\infty}, \beta_{E,\infty})$ and $(F_{r}^{p,q}, B_{r}(F_{r}^{p,q}), Z_{r}(F_{r}^{p,q}), F_{\infty}, \beta_{F,\infty})$ be two $r_0$-spectral sequences in $\mathcal{A}$ with abutments. A *morphism of $r_0$-spectral sequences with abutments* is a pair

$$u_{r}^{p,q} : E_{r}^{p,q} \to F_{r}^{p,q} \quad (v_{r}^{n} : (E_{\infty}^n, \text{Fil}^n E_{\infty}^n) \to (F_{\infty}^n, \text{Fil}^n F_{\infty}^n) \ | \ n \in \mathbb{Z})$$

such that:

- $u_{r}^{p,q}$ is a morphism of $r_0$-spectral sequences,
- $v_{r}^{n}$ is a morphism of filtered objects of $\mathcal{A}$, for every $n \in \mathbb{Z}$,
- $u_{r_0}^{p,q}(B_{\infty}(E_{r_0}^{p,q})) \subset B_{\infty}(F_{r_0}^{p,q})$ and $u_{r_0}^{p,q}(Z_{\infty}(E_{r_0}^{p,q})) \subset Z_{\infty}(F_{r_0}^{p,q})$ for every $p, q \in \mathbb{Z}$,
- The following diagrams commute, for every $p, q \in \mathbb{Z}$:

$$\begin{array}{ccc}
E_{r}^{p,q} & \xrightarrow{\beta_{r}^{p,q}} & E_{\infty}^{p,q} \\
\downarrow u_{r_0}^{p,q} & & \downarrow \text{gr}^p E_{\infty}^{p+q} \\
F_{r_0}^{p,q} & \xrightarrow{\beta_{r}^{p,q}} & \text{gr}^p F_{\infty}^{p+q}
\end{array}$$

(where the unmarked arrows are the natural epimorphisms and monomorphisms).
7.2.8. For every $r \in \mathbb{N}$, we denote by
\[
\text{Sp.Seq}_{\infty}^{r}(\mathcal{A})
\]
the category of $r$-spectral sequences with abutments (and their morphisms, as in definition 7.2.7(ii)). For every integer $s > r$ there is an obvious functor
\[
\text{Sp.Seq}_{\infty}^{r}(\mathcal{A}) \to \text{Sp.Seq}_{\infty}^{s}(\mathcal{A})
\]
that simply forgets the terms $E_{r}^{pq}$ with $r \leq k < s$, and replaces the terms $B_{\infty}(E_{r}^{pq})$, $Z_{\infty}(E_{r}^{pq})$ with their images $\beta_{r,s}^{pq}(B_{\infty}(E_{r}^{pq}))$, $\beta_{r,s}^{pq}(Z_{\infty}(E_{r}^{pq}))$ in $E_{s}^{pq}$.

Remark 7.2.9. Let $r_{0} \in \mathbb{N}$, $n \in \mathbb{Z}$ and $E_{\bullet}$ any $r_{0}$-spectral sequence of $\mathcal{A}$.

(i) Notice that if $E_{r}^{pq} = 0$ for some $p, q \in \mathbb{Z}$ and $r \geq r_{0}$, then $E_{r}^{pq} = 0$ for every $s \geq r$.

(ii) We say $E_{\bullet}$ is bounded above (resp. bounded below) in degree $n$, if there exist $r, N \in \mathbb{N}$ with $r \geq r_{0}$, such that
\[
E_{r}^{pq} = 0 \quad \text{for all } p, q \in \mathbb{Z} \text{ such that } r \geq N \text{ (resp. } p \geq N)\]

If $E_{\bullet}$ is bounded above in degree $n + 1$ and bounded below in degree $n - 1$, notice that for every $p, q \in \mathbb{Z}$ with $p + q = n$ there exists an integer $r \geq r_{0}$ such that both $d_{r}^{p,q}$ and $d_{r}^{q-s,q+s-1}$ are zero morphisms for every $s \geq r$, in which case $\beta_{r,s}^{pq}$ is an isomorphism $E_{s+1}^{pq} \cong E_{s}^{pq}$, for every $s \geq r$, and for every $p, q, s, k \in \mathbb{Z}$ with $k > s \geq r$ and $p + q = n$ we have :
\[
Z_{k}(E_{s+1}^{pq}) = Z_{s+1}(E_{s}^{pq}) = B_{k}(E_{s}^{pq}) = B_{s+1}(E_{s}^{pq}).
\]

Definition 7.2.10. Let $\mathcal{A}$ be any abelian category, and $n \in \mathbb{Z}$.

(i) A filtered complex $(K^{\bullet}, \text{Fil}^{\bullet} K^{\bullet})$ of $\mathcal{A}$ is just an object of the category Fil.C(\mathcal{A}).

(ii) We say that $\text{Fil}^{\bullet} K^{\bullet}$ is bounded above (resp. bounded below, resp. finite) in degree $n$, if the filtration $\text{Fil}^{n} K^{n}$ on the object $K^{n}$ of $\mathcal{A}$ is bounded above (resp. bounded below, resp. finite). We say that $\text{Fil}^{\bullet} K^{\bullet}$ is bounded, if it is finite in all degrees (see (7.2.2)).

Remark 7.2.11. Likewise, we may define a filtered double complex as an object of the category Fil.C_{2}(\mathcal{A}). Then, the flip and diagonal functors of (7.1.11) can be upgraded to functors
\[
\text{Fil.C}_{2}(\mathcal{A}) \rightarrow \text{Fil.C}_{2}(\mathcal{A}) \quad \text{Fil.C}_{2}(\mathcal{A}) \rightarrow \text{Fil.C}(\mathcal{A})
\]
If all coproducts (resp. all products) are representable in $\mathcal{A}$, the total complex functor $\text{Tot}^{\oplus}$ (resp. $\text{Tot}^{\prod}$) induces a corresponding functor
\[
\text{Fil.Tot}^{\oplus} : \text{Fil.C}_{2}(\mathcal{A}) \rightarrow \text{Fil.C}(\mathcal{A}) \quad \text{Fil.C}_{2}(\mathcal{A}) \rightarrow \text{Fil.C}(\mathcal{A})
\]
(see (7.2)) which we shall often denote just by Tot (resp. by Tot^{\prod}).

7.2.12. Any filtered complex of $\mathcal{A}$ determines a spectral sequence of $\mathcal{A}$, whose terms are defined as follows. For every $p, q \in \mathbb{Z}$ and $r \in \mathbb{N}$, set
\[
Z(K)_{r}^{pq} := \text{Ker} \left( \overline{d} : (\text{Fil}^{p} K^{\bullet})^{p+q} \rightarrow (\text{Fil}^{p+r} K^{\bullet})^{p+q+1} / (\text{Fil}^{p+r} K^{\bullet})^{p+q+1} \right)
\]
\[
D(K)_{r}^{pq} := (\text{Fil}^{p+1} K^{\bullet})^{p+q} + d_{K}^{p+q-1}( (\text{Fil}^{p-r+1} K^{\bullet})^{p+q-1} ) \subset (\text{Fil}^{p-r+1} K^{\bullet})^{p+q}
\]
\[
B(K)_{r}^{pq} := D(K)_{r}^{pq} \cap Z(K)_{r}^{pq}
\]
\[
E(K)_{r}^{pq} := Z(K)_{r}^{pq} / B(K)_{r}^{pq}
\]
where $\overline{d}$ is the morphism in $\mathcal{A}$ induced by the differential
\[
d_{\text{Fil}^{p} K^{\bullet}}^{p+q} : (\text{Fil}^{p} K^{\bullet})^{p+q} \rightarrow (\text{Fil}^{p} K^{\bullet})^{p+q+1}
\]
of the complex $\text{Fil}^{p} K^{\bullet}$. Notice that
\[
(\text{Fil}^{p+r} K^{\bullet})^{p+q} \subset Z(K)_{r}^{pq} \subset (\text{Fil}^{p} K^{\bullet})^{p+q} \quad \text{for every } p, q \in \mathbb{Z} \text{ and } r \in \mathbb{N}.
\]
Lemma 7.2.13. With the notation of (7.2.12), we have:

\[ B(K)_{pq} = Z(K)_{r}^{p+1,q-1} + d_{K}^{p+q-1}(Z(K)_{r-1}^{p-r+1,q+r-2}) \quad \text{for every } p, q \in \mathbb{Z} \text{ and } r \geq 1. \]

Proof. Notice first that

\[ D(K)_{pq} \cap (\text{Fil}^{p}K^{\bullet})^{p+q} = (\text{Fil}^{p+1}K^{\bullet})^{p+q} + (\text{Im } d_{\text{Fil}^{p+1}K}^{p+q-1} \cap (\text{Fil}^{p}K^{\bullet})^{p+q}) \]

and

\[ \text{Im } d_{\text{Fil}^{p+1}K}^{p+q-1} \cap (\text{Fil}^{p}K^{\bullet})^{p+q} = d_{K}^{p+q-1}(Z(K)_{r-1}^{p-r+1,q+r-2}). \]

On the other hand, we have:

\[ d_{K}^{p+q}(D(K)_{pq}) \cap (\text{Fil}^{p+r}K^{\bullet})^{p+q+1} = \text{Im } d_{\text{Fil}^{p+1}K}^{p+q} \cap (\text{Fil}^{p+r}K^{\bullet})^{p+q+1} = d_{K}^{p+q}(Z(K)_{r}^{p+1,q-1}). \]

The lemma follows easily, by comparing these identities. \qed

7.2.14. It is easily seen that \( d_{\text{Fil}^{p}K}^{p+q} \) restricts to a morphism

\[ (7.2.15) \quad D(K)_{pq} + Z(K)_{r} \rightarrow Z(K)_{r}^{p+r,q-r+1} \]

which sends \( D(K)_{pq} \) into \( B(K)_{r}^{p+r,q-r+1} \), and therefore induces a morphism

\[ d(K)_{pq}: E(K)_{pq} \rightarrow E(K)_{r}^{p+r,q-r+1} \quad \text{for every } p, q \in \mathbb{Z} \text{ and } r \in \mathbb{N}. \]

Clearly \( d(K)_{pq}^{p+r,q-r+1} \circ d(K)_{pq} = 0 \). Furthermore, a simple inspection shows that

\[ \text{Ker } d(K)_{pq} = (Z(K)_{r+1}^{pq} \cap D(K)_{pq}) \quad \text{Im } d(K)_{pq}^{p+r,q-r+1} = D(K)_{pq}^{r+1}/D(K)_{pq}^{r} \]

whence a natural isomorphism

\[ E(K)_{pq}^{r+1} \cong \text{Ker } d(K)_{pq}^{p+r,q-r+1} \quad \text{for every } p, q \in \mathbb{Z} \text{ and } r \in \mathbb{N} \]

so the system \( (E(K)_{pq}^{\bullet}, d(K)_{pq}^{\bullet}) \) is indeed a spectral sequence.

Remark 7.2.16. (i) A simple inspection shows that

\[ E(K)_{pq}^{0} = \text{gr}^{p}K^{p+q} \quad \text{and} \quad d(K)_{pq}^{0} = d_{\text{gr}^{p}K}^{p+q} \quad \text{for every } p, q \in \mathbb{Z} \]

so the resulting complex \( (E(K)_{pq}^{\bullet}, d(K)_{pq}^{\bullet}) \) is just \( \text{gr}^{p}K^{\bullet}[q] \), for every \( p, q \in \mathbb{Z} \).

(ii) In view of (i), we have a natural isomorphism

\[ E(K)_{pq}^{1} \cong H^{p+q}(\text{gr}^{p}K^{\bullet}) \quad \text{for every } p, q \in \mathbb{Z} \]

which identifies \( d(K)_{pq}^{1} \) with a morphism

\[ H^{p+q}(\text{gr}^{p}K^{\bullet}) \rightarrow H^{p+q+1}(\text{gr}^{p+1}K^{\bullet}). \]

A direct inspection shows that the latter is the boundary morphism in degree \( p + q \) arising (by the snake lemma) from the short exact of complexes

\[ 0 \rightarrow \text{gr}^{p+1}K^{\bullet} \rightarrow \text{Fil}^{p}K^{\bullet}/\text{Fil}^{p+2}K^{\bullet} \rightarrow \text{gr}^{p}K^{\bullet} \rightarrow 0. \]

7.2.17. With the notation of (7.2.6) and (7.2.12), it is easily seen that

\[ Z_{k}(E(K)_{pq}^{k}) = \text{Im } (Z(K)_{k}^{pq} \rightarrow E(K)_{k}^{pq}) \]

\[ B_{k}(E(K)_{pq}^{k}) = \text{Im } (B(K)_{k}^{pq} \rightarrow E(K)_{k}^{pq}) \]

for every \( p, q, r, k \in \mathbb{Z} \) with \( k > r \geq 0 \). We may then define a natural abutment for \( E(K)_{pq}^{\bullet} \), as follows. For every \( p, q, r, k \in \mathbb{Z} \) we set

\[ Z_{\infty}(E(K)_{pq}^{0}) := \text{Im } (\text{Ker } d_{\text{Fil}^{p}K}^{p+q} \rightarrow E(K)_{0}^{pq}) \]

\[ B_{\infty}(E(K)_{pq}^{0}) := \text{Im } ((\text{Fil}^{p}K^{p+q} \cap \text{Im } d_{K}^{p+q-1}) \rightarrow E(K)_{0}^{pq}) \]

as well as

\[ E(K)_{\infty}^{n} := H^{n}K^{\bullet} \quad \text{Fil}^{p}E(K)_{\infty}^{n} := \text{Im } (H^{n}(\text{Fil}^{p}K^{\bullet}) \rightarrow H^{n}(K^{\bullet})) \quad \text{for every } p, n \in \mathbb{Z}. \]
By inspecting the definitions we find natural isomorphisms
\[ \beta(K)^p_q : E(K)^p_q := Z_\infty(E(K)^p_q)/B_\infty(E(K)^p_q) \xrightarrow{\sim} gr^p E(K)^{p+q} \]
and the datum \( A(K)^{\bullet}_\infty := (B_\infty(E(K)^p_q), Z_\infty(E(K)^p_q)), \beta(K)^p_q \) is the sought abutment. Summing up, we get a well defined functor
\[ \text{Fil.C}(\mathscr{A}) \rightarrow \text{Sp.Seq}^\infty(\mathscr{A}) \quad (K^\bullet, \text{Fil}^\bullet K^\bullet) \mapsto (E(K)^{\bullet}_\infty, A(K)^{\bullet}_\infty). \]
Clearly, if \( \text{Fil}^\bullet K^\bullet \) is bounded in degree \( n \), then \( \text{Fil}^n E(K)^{n}_\infty \) is a finite filtration.

**Proposition 7.2.18.** (i) Let \( (K^\bullet, \text{Fil}^\bullet K^\bullet) \) be a filtered complex in \( \mathscr{A} \), and \( N \in \mathbb{N} \) such that:
\[ H^{n-1}(K^\bullet/\text{Fil}^{-p} K^\bullet) = 0 \quad \text{and} \quad H^{n+1}(\text{Fil}^p K^\bullet) = 0 \quad \text{for every} \quad p \geq N. \]
Then the 1-spectral sequence with abutment \( (E(K)^{\bullet}_\infty, A(K)^{\bullet}_\infty) \) is convergent in degree \( n \).

(ii) Especially, the conclusion of (i) holds if \( \text{Fil}^\bullet K^\bullet \) is bounded above in degree \( n-1 \) and bounded below in degree \( n+1 \).

**Proof.** Obviously (i)⇒(ii). Hence, let us assume that the condition of (i) holds, and consider, for every \( r \in \mathbb{N} \) and every \( p, q \in \mathbb{Z} \) with \( p + q = n \), the composition
\[ H^n(\text{gr}^p K^\bullet) \xrightarrow{\delta} H^{n+1}(\text{Fil}^p K^\bullet) \xrightarrow{H^{n+1}(\pi_r)} H^{n+1}(\text{Fil}^{p+1} K^\bullet/\text{Fil}^{p+r} K^\bullet) \]
where \( \delta \) is the boundary morphism attached by the snake lemma to the short exact sequence of complexes \( 0 \rightarrow \text{Fil}^{p+r} K^\bullet \rightarrow \text{Fil}^{p+1} K^\bullet \rightarrow \text{Fil}^{p+1} K^\bullet/\text{Fil}^{p+r} K^\bullet \rightarrow 0 \), and \( \pi_r : \text{Fil}^{p+1} K^\bullet \rightarrow \text{Fil}^{p+1} K^\bullet/\text{Fil}^{p+r} K^\bullet \) is the projection. By direct inspection, we see that:
\[ \text{Ker}(H^{n+1}(\pi_r) \circ \delta) = Z_r(E^{pq}_1) \quad \text{and} \quad \text{Ker} \delta = Z_\infty(E^{pq}_1). \]
On the other hand, the long exact cohomology sequence attached to the short exact sequence of complexes \( 0 \rightarrow \text{Fil}^{p+r} K^\bullet \rightarrow \text{Fil}^{p+1} K^\bullet \rightarrow \text{Fil}^{p+1} K^\bullet/\text{Fil}^{p+r} K^\bullet \rightarrow 0 \) shows that \( \text{Ker} H^{n+1}(\pi_r) \) is a quotient of \( H^{n+1}(\text{Fil}^{p+r} K^\bullet) \). Thus, \( H^{n+1}(\pi_r) \) is a monomorphism for every \( r \in \mathbb{N} \) such that \( p + r \geq N \), and in that case we get \( Z_r(E^{pq}_1) = Z_\infty(E^{pq}_1) \). Likewise, consider the composition:
\[ H^{n-1}(\text{Fil}^{p-r+1} K^\bullet/\text{Fil}^p K^\bullet) \xrightarrow{H^{n-1}(j_r)} H^{n-1}(K^\bullet/\text{Fil}^p K^\bullet) \xrightarrow{\delta'} H^n(\text{gr}^p K^\bullet) \]
where \( \delta' \) is the boundary morphism attached by the snake lemma to the short exact sequence \( 0 \rightarrow \text{Fil}^p K^\bullet \rightarrow K^\bullet \rightarrow \text{Fil}^p K^\bullet \rightarrow 0 \), and \( j_r : \text{Fil}^{p-r+1} K^\bullet/\text{Fil}^p K^\bullet \rightarrow K^\bullet/\text{Fil}^p K^\bullet \) is the natural inclusion. By direct inspection we see that:
\[ \text{Im}(\delta' \circ H^{n-1}(j_r)) = B_r(E^{pq}_1) \quad \text{and} \quad \text{Im} \delta' = B_\infty(E^{pq}_1). \]
On the other hand, the long exact cohomology sequence attached to the short exact sequence \( 0 \rightarrow \text{Fil}^{p-r+1} K^\bullet/\text{Fil}^p K^\bullet \rightarrow K^\bullet/\text{Fil}^p K^\bullet \rightarrow K^\bullet/\text{Fil}^{p+r+1} K^\bullet \rightarrow 0 \) shows that \( \text{Coker} H^{n-1}(j_r) \) is a subobject of \( H^{n-1}(K^\bullet/\text{Fil}^{p+r+1} K^\bullet) \). Especially, \( H^{n-1}(j_r) \) is an epimorphism whenever \( p - r + 1 \leq -N \), and in that case we get \( B_r(E^{pq}_1) = B_\infty(E^{pq}_1) \).

7.2.19. The constructions of examples [7.1.15](i), [7.1.16](i) admit filtered counterparts. Namely, suppose that \( (\mathscr{A}, \otimes, \Phi, \Psi) \) is a tensor abelian category, and let \( (A, \text{Fil}^\bullet A) \) and \( (B, \text{Fil}^\bullet B) \) be any two objects of \( \text{Fil.}\mathscr{A} \). Suppose that:
- at least one of the filtrations \( \text{Fil}^\bullet A \) and \( \text{Fil}^\bullet B \) is bounded
- or else, \( \mathscr{A} \) is cocomplete.

In this situation we define a filtration \( \text{Fil}^\bullet (A \otimes B) \) on \( A \otimes B \), by ruling that:
\[ \text{Fil}^p(A \otimes B) := \sum_{k \in \mathbb{Z}} \text{Im}(\text{Fil}^k A \otimes \text{Fil}^{p-k} B \rightarrow A \otimes B) \quad \text{for every} \quad p \in \mathbb{Z}. \]

In case \( \mathscr{A} \) is cocomplete, clearly, this rule yields a functor:
\[ \text{Fil.}\mathscr{A} \times \text{Fil.}\mathscr{A} \rightarrow \text{Fil.}\mathscr{A}. \]
Next, suppose that \( \mathcal{A} \) is cocomplete, and let \((K^\bullet, \text{Fil}^\bullet K^\bullet)\) and \((L^\bullet, \text{Fil}^\bullet L^\bullet)\) be any two filtered complexes of \( \mathcal{A} \); we get an induced filtration \( \text{Fil}^\bullet K^\bullet \otimes L^\bullet \) on the double complex \( K^\bullet \otimes L^\bullet \), and applying the functor \( \text{Tot} \) of remark \( \ref{7.2.11} \) we obtain a filtration on \( K^\bullet \otimes L^\bullet \), whence a functor

\[
\text{Fil}.C(\mathcal{A}) \times \text{Fil}.C(\mathcal{A}) \to \text{Fil}.C(\mathcal{A}) \quad (\text{Fil}^\bullet K, \text{Fil}^\bullet L) \mapsto \text{Fil}^\bullet K^\bullet \otimes L^\bullet.
\]

Notice that if \( \mathcal{A} \) is not cocomplete, the filtered double complex \( \text{Fil}^\bullet K^\bullet \otimes L^\bullet \) is still well defined, provided at least one of the filtrations \( \text{Fil}^\bullet K^\bullet \) and \( \text{Fil}^\bullet L^\bullet \) is bounded. If moreover both \( K^\bullet \) and \( L^\bullet \) lie in \( C^- (\mathcal{A}) \) or \( C^+ (\mathcal{A}) \), then also \( \text{Fil}^\bullet K^\bullet \otimes L^\bullet \) is well defined.

7.2.20. Let \((A, \text{Fil}^\bullet A)\) and \((B, \text{Fil}^\bullet B)\) be any two objects of \( \text{Fil}.\mathcal{A} \). We define a filtration \( \text{Fil}^\bullet \text{Hom}_{\mathcal{A}}(A, B) \) on the abelian group \( \text{Hom}_{\mathcal{A}}(A, B) \), by ruling that

\[
\text{Fil}^p \text{Hom}_{\mathcal{A}}(A, B) := \{ f : A \to B \mid f(\text{Fil}^k A) \subset \text{Fil}^{p+k} B \text{ for every } k \in \mathbb{Z} \}
\]

for every \( p \in \mathbb{Z} \). Clearly this rule yields a functor

\[
(7.2.21) \quad \text{Fil}.\mathcal{A} \times (\text{Fil}.\mathcal{A})^0 \to \text{Fil}.\mathbb{Z}-\text{Mod}.
\]

Let now \((K^\bullet, \text{Fil}^\bullet K^\bullet)\) and \((L^\bullet, \text{Fil}^\bullet L^\bullet)\) be any two filtered complexes of \( \mathcal{A} \); we define a filtration \( \text{Fil}^p \text{Hom}_{\mathcal{A}}^\bullet(K^\bullet, L^\bullet) \) on the double complex of abelian groups \( \text{Hom}_{\mathcal{A}}^\bullet(K^\bullet, L^\bullet) \) (see example \( \ref{7.1.15} \)(i)), by ruling that

\[
\text{Fil}^p \text{Hom}_{\mathcal{A}}^p(K^\bullet, L^\bullet) := \text{Fil}^p \text{Hom}_{\mathcal{A}}(K^{-p}, L^q) \quad \text{for every } p, q, k \in \mathbb{Z}
\]

(where the right-hand side is the filtered abelian group obtained by applying the functor \( (7.2.21) \) to the filtered objects \((K^{-p}, \text{Fil}^\bullet K^{-p})\) and \((L^q, \text{Fil}^\bullet L^q)\) of \( \mathcal{A} \)). After applying the functor \( \text{Tot} \) of remark \( \ref{7.2.11} \) we deduce a filtration on \( \text{Hom}_{\mathcal{A}}^\bullet(K^\bullet, L^\bullet) \), whence a functor

\[
\text{Fil}.C(\mathcal{A}) \times (\text{Fil}.\mathcal{A})^0 \to \text{Fil}.C(\mathbb{Z}-\text{Mod}) \quad (\text{Fil}^\bullet L^\bullet, \text{Fil}^\bullet K^\bullet) \mapsto \text{Fil}^\bullet \text{Hom}_{\mathcal{A}}^\bullet(K^\bullet, L^\bullet).
\]

Taking into account remark \( \ref{7.1.15} \)(i), we also see that

\[
\text{Hom}_{\text{Fil}.C(\mathcal{A})}(K^\bullet, L^\bullet) = \text{Fil}^0 \text{Hom}_{\mathcal{A}}(K^\bullet, L^\bullet) \cap \ker d_{K,L}^0.
\]

**Definition 7.2.22.** Let \( \mathcal{A} \) be any abelian category, \( k \in \mathbb{Z} \) any integer, \( \varphi^\bullet, \psi^\bullet : (K^\bullet, \text{Fil}^\bullet K^\bullet) \to (L^\bullet, \text{Fil}^\bullet L^\bullet) \) any two morphisms of filtered complexes of \( \mathcal{A} \).

(i) A homotopy of order \( k \) from \( \varphi^\bullet \) to \( \psi^\bullet \) is an element \( s^\bullet \in \text{Fil}^k \text{Hom}_{\mathcal{A}}^{-1}(K^\bullet, L^\bullet) \) such that \( d_{K,L}^1(s^\bullet) = \psi^\bullet - \varphi^\bullet \) (notation of example \( \ref{7.1.15} \)(i)).

(ii) We write \( \varphi^\bullet \sim_k \psi^\bullet \) if there exists a homotopy of order \( k \) from \( \psi^\bullet \) to \( \varphi^\bullet \). It is easily seen that if this is the case, and \( \alpha^\bullet : K^\bullet \to K^\bullet, \beta^\bullet : L^\bullet \to L^\bullet \) are any two morphisms, then \( \varphi^\bullet \circ \alpha^\bullet \sim_k \psi^\bullet \circ \alpha^\bullet \) and \( \beta^\bullet \circ \varphi^\bullet \sim_k \beta^\bullet \circ \psi^\bullet \). Moreover, \( \sim_k \) is an equivalence relation on \( \text{Hom}_{\text{Fil}.C(\mathcal{A})}(K^\bullet, L^\bullet) \). It follows that there exists a well defined filtered homotopy category of order \( k \)

\[
\text{Fil}.\text{Hot}(\mathcal{A}, k)
\]

whose objects are the same as those of \( \text{Fil}.C(\mathcal{A}) \), and whose morphisms are the order \( k \) homotopy classes of morphisms of complexes. Furthermore, we have a natural functor

\[
\text{Fil}.C(\mathcal{A}) \to \text{Fil}.\text{Hot}(\mathcal{A}, k)
\]

which is the identity on objects, and the quotient map on \( \text{Hom}-\text{sets} \).
7.2.23. With the notation of definition 7.2.22, suppose that $k \geq 0$, and consider any element $s^\bullet \in \Fil^k \Hom^\bullet(K^\bullet, L^\bullet)$; then $\sigma := d_{KL}^{-1}(s^\bullet) : (K^\bullet, \Fil^s K^\bullet) \to (L^\bullet, \Fil^s L^\bullet)$ is a morphism of filtered complexes, and a simple inspection shows that

$$
\sigma_{p+q}(Z(K)_r^{pq}) \subset \Ker d_{KL}^{p+q}
$$

for every $p, q, r \in \mathbb{Z}$ with $r \geq k$

so the induced map $E(\sigma)^{pq} : E(K)_r^{pq} \to E(L)_r^{pq}$ vanishes for every $p, q, r \in \mathbb{Z}$ with $r \geq k$.

Consequently, we obtain a commutative diagram of functors

\[
\begin{array}{ccc}
\Fil \C(\mathcal{A}) & \longrightarrow & \Sp \Seq_0^\infty(\mathcal{A}) \\
\downarrow & & \downarrow \\
\Fil \Hot(\mathcal{A}, k) & \longrightarrow & \Sp \Seq_k^\infty(\mathcal{A})
\end{array}
\]

for every $k \geq 0$

whose top horizontal arrow is the functor of (7.2.17), and whose left (resp. right) vertical arrow is the functor of definition 7.2.22(ii) (resp. the forgetful functor of (7.2.8)).

7.2.24. We show next, how to lift the décalage functor of (7.2.5), to a functor on complexes

$$
\Dec : \Fil \C(\mathcal{A}) \to \Fil \C(\mathcal{A}).
$$

Namely, given $(K^\bullet, \Fil^s K^\bullet)$ as in (7.2.12), we set

$$
D^\bullet := K^\bullet \quad \text{and} \quad \Fil^p D^n := Z(K)_1^{p+n,-p}
$$

for every $p, n \in \mathbb{Z}$.

It follows straightforwardly from (7.2.15), that the differential $d_K^s$ of $K^\bullet$ restricts to a morphism \(\Fil^p D^n \to \Fil^p D^{n+1}\) for every $p, n \in \mathbb{Z}$, so $(D^\bullet, \Fil^s D^\bullet)$ is an object of $\Fil \C(\mathcal{A})$, and we let

$$
\Dec(K^\bullet, \Fil^s K^\bullet) := (D^\bullet, \Fil^s D^\bullet).
$$

Every morphism (7.2.1) induces in the obvious fashion a morphism

$$
\Dec(K^\bullet, \Fil^s K^\bullet) \to \Dec(L^\bullet, \Fil^s L^\bullet)
$$

so \(\Dec\) is a functor as sought. Moreover, it is easily seen that if $\Fil^s K^\bullet$ is a bounded filtration, the same holds for the filtration of $\Dec(K^\bullet, \Fil^s K^\bullet)$.

7.2.25. We wish next to compare the spectral sequences

$$
E(K)^{\bullet\bullet} \quad \text{and} \quad E(\Dec K)^{\bullet\bullet}
$$

attached, as in (7.2.12), to $(K^\bullet, \Fil^s)$ and respectively to $\Dec(K^\bullet, \Fil^s K^\bullet)$. To this aim, notice that

$$
Z(\Dec K)_0^{p+n-p} = Z(K)_1^{p+n,-p} \quad \text{and} \quad D(\Dec K)_0^{p+n-p} = Z(K)_1^{p+1+n,-p-1}
$$

and we have

$$
Z(K)_1^{p+1+n,-p-1} \subset (\Fil^p + 1 + n K^\bullet)^n \subset D(K)_1^{p+n,-p} \subset Z(K)_1^{p+n,-p}
$$

whence a natural epimorphism

$$
u_{p+n-p} : E(\Dec K)_0^{p+n-p} \to \Dec(E(K))_0^{p+n-p}
$$

for every $p, n \in \mathbb{Z}$.

With this notation, we have:

**Proposition 7.2.26.** With the notation of (7.2.24), the following holds:

(i) The system $(\nu_{p+n-p} | p, n \in \mathbb{Z})$ extends to an epimorphism in $\Sp \Seq_0(\mathcal{A})$

$$
\nu_{\bullet\bullet} : E(\Dec K)^{\bullet\bullet} \to \Dec(E(K))^{\bullet\bullet}.
$$

(ii) The morphism $\nu_{\bullet}$ induces isomorphisms in $\Sp \Seq_1(\mathcal{A})$

$$
(E(\Dec K)_r^{\bullet\bullet} | r \geq 1) \xrightarrow{\sim} (\Dec(E(K))_r^{\bullet\bullet} | r \geq 1).
$$
Proof. For any filtered complex \((L^\bullet, \text{Fil}^\bullet L^\bullet)\) of \(\mathscr{A}\), let
\[
L^\bullet := L^\bullet, \quad (\text{Fil}^p L^\bullet)^n := (\text{Fil}^{p-n} L^\bullet)^n \quad \text{for every } p, n \in \mathbb{Z}.
\]
It is easily seen that
\[
(L^\bullet, \text{Fil}^\bullet L^\bullet) := (L^\bullet, \text{Fil}^\bullet L^\bullet)
\]
is a filtered complex of \(\mathscr{A}\), and a direct inspection of the definitions yields the identities
\[
E(L)^{p,n-p} = E(L')^{r+1,n,r-p} = d(L)^{p,n-p} = d(L')^{r+1,p,n-r-p} \quad \text{for every } p, n \in \mathbb{Z} \text{ and } r \in \mathbb{N}
\]
which add up to an identity in \(\text{Sp.Sequential}(\mathscr{A})\):
\[
(\text{Sp.Sequential})_r = \text{Dec}(E(L')^{r+1,n} \mid r \geq 0).
\]
Especially, set \((M^\bullet, \text{Fil}^\bullet M^\bullet) := (\text{Dec} (K^\bullet, \text{Fil}^\bullet K^\bullet))'\). Explicitly, we have
\[
M^\bullet = K^\bullet, \quad (\text{Fil}^p M^\bullet)^n = Z(K)^{p,n-p} \subset (\text{Fil}^p K^\bullet)^n \quad \text{for every } p, n \in \mathbb{Z}
\]
so that the identity morphism \(1_K : M^\bullet \to K^\bullet\) is a morphism
\[
(M^\bullet, \text{Fil}^\bullet M^\bullet) \to (K^\bullet, \text{Fil}^\bullet K^\bullet) \quad \text{in } \text{Fil.C}(\mathscr{A})
\]
which in turns yields a morphism in \(\text{Sp.Sequential}(\mathscr{A})\):
\[
E(M)^\bullet \to E(K)^\bullet.
\]
Combining with \((7.2.27)\), we get a natural morphism
\[
v^\bullet : E(\text{Dec} K)^\bullet \to \text{Dec}(E(K))^\bullet
\]
and a direct inspection shows that \(v^\bullet = v^\bullet\), whence (i). To check (ii), we remark that
\[
Z(M)_r = \text{Ker}(\bar{d} : Z(K)^{q+1}_1 \to Z(K)^{q+1}_1/Z(K)^{q+1}_1) = Z(K)^{p,q}_r \quad \text{for every } r \geq 1
\]
whence :
\[
B(M)_r = B(K)_r \quad \text{for every } r \geq 1
\]
due to lemma \((7.2.13)\). \(\square\)

7.3. Derived categories and derived functors. Let \(\mathscr{A}\) be any additive category. With the notation of remark \(7.1.19\)(ii), set
\[
\mathbb{C}^\bullet := \text{Coker}(i^\bullet : \mathbb{Z}[0] \to \mathbb{K}(1)^\bullet).
\]
Explicitly, \(\mathbb{C}^\bullet\) is the object of \(\mathbb{C}(-1,0)_{\text{Z-Mod}}\) such that \(\mathbb{C}^{-1} = \mathbb{C}^0 = \mathbb{Z}\) and with \(c^{-1} = 1_z\). The morphism \(i^\bullet\) induces a short exact sequence of complexes of abelian groups :
\[
0 \to \mathbb{Z}[0] \xrightarrow{i^\bullet} \mathbb{C}^\bullet \xrightarrow{e^\bullet} \mathbb{Z}[1] \to 0.
\]
Now, let \(\varphi^\bullet : K^\bullet \to L^\bullet\) be any morphism in \(\mathbb{C}(\mathscr{A})\). We define the cone of \(\varphi^\bullet\) as the push-out in the cocartesian diagram of \(\mathbb{C}(\mathscr{A})\) :
\[
\begin{array}{ccc}
K^\bullet & \xrightarrow{i^\bullet \otimes 1_K} & \mathbb{C}^\bullet \otimes_{\mathbb{Z}} K^\bullet \\
\varphi^\bullet \downarrow & & \downarrow \beta^\bullet \\
L^\bullet & \xrightarrow{\psi^\bullet} & (\text{Cone } \varphi)^\bullet.
\end{array}
\]
Let also \(\gamma^\bullet : \mathbb{K}(1)^\bullet \to \mathbb{C}^\bullet\) be the natural projection; by remark \(7.1.19\)(ii), the composition
\[
\beta^\bullet \circ (\gamma^\bullet \otimes_{\mathbb{Z}} K^\bullet) : \mathbb{K}(1)^\bullet \otimes_{\mathbb{Z}} K^\bullet \to (\text{Cone } \varphi)^\bullet
\]
corresponds to a homotopy from \(\psi^\bullet \circ \varphi^\bullet\) to \(\beta^\bullet \circ (\gamma^\bullet \circ i^\bullet) \otimes_{\mathbb{Z}} K^\bullet\), and the latter is obviously the zero endomorphism of \(K^\bullet\). Moreover, we get a natural identification
\[
(7.3.1) \quad \text{Coker } \psi^\bullet \xrightarrow{\sim} \text{Coker } (i^\bullet \otimes_{\mathbb{Z}} K^\bullet) \xrightarrow{\sim} K^\bullet[1]
\]
and we let \( \partial^* \) be the unique morphism of complexes which fits in the commutative diagram

\[
\begin{array}{c}
\text{Coker } \psi^* \\
\downarrow \pi^* \\
K^*[1]
\end{array}
\]

whose horizontal arrow is the identification \((7.3.1)\), and where \( \pi^* \) is the natural projection. Summing up, we have attached to \( \varphi^* \) a natural sequence of morphisms of complexes

\[
\Theta(\varphi^*) : K^* \xrightarrow{\varphi^*} L^* \xrightarrow{\psi^*} (\text{Cone } \varphi)^* \xrightarrow{\partial^*} K^*[1]
\]

such that \( \psi^* \circ \varphi^* \) is homotopically trivial, and the induced sequence of morphisms in \( \mathcal{A} \)

\[
0 \to L^i \xrightarrow{\psi^i} (\text{Cone } \varphi)^i \xrightarrow{\partial^i} K^{i+1} \to 0
\]

is split exact for every \( i \in \mathbb{Z} \), i.e. such that \( (\text{Cone } \varphi)^i = L^i \oplus K^{i+1} \), and \( \psi_i \) (resp. \( -\partial^i \)) is the natural monomorphism (resp. epimorphism) induced by this direct sum decomposition. A direct inspection shows that the differential

\[
d_{\text{Cone } \varphi}^{i-1} : L^{i-1} \oplus K^i \to L^i \oplus K^{i+1}
\]

is given by the matrix

\[
\begin{bmatrix}
d_{L}^{i-1} & \varphi_i \\
0 & -d_{K}^{i}
\end{bmatrix}.
\]

Moreover, it is easily seen that every morphism \( \beta^* : \varphi_1^* \to \varphi_2^* \) in \( \text{Morph}(\mathcal{C}(\mathcal{A})) \) induces a natural commutative diagram in \( \mathcal{C}(\mathcal{A}) \):

\[
\begin{array}{c}
\Theta(\varphi_1^*) & \xrightarrow{K_1} & \xrightarrow{\varphi_1^*} & \xrightarrow{L_1} & \xrightarrow{\varphi_1^*} & \xrightarrow{(\text{Cone } \varphi_1)^*} & \xrightarrow{\partial_1^*} & \xrightarrow{K_1^*[1]} \\
\Theta(\varphi_2^*) & \xrightarrow{K_2} & \xrightarrow{\varphi_2^*} & \xrightarrow{L_2} & \xrightarrow{\varphi_2^*} & \xrightarrow{(\text{Cone } \varphi_2)^*} & \xrightarrow{\partial_2^*} & \xrightarrow{K_2^*[1]}
\end{array}
\]

\((7.3.2)\)

where \( \psi_1^* \) and \( \psi_2^* \) are the natural morphisms, as in the foregoing (details left to the reader).

**Definition 7.3.3.** Let \( \mathcal{A} \) be any additive category, and denote by \( T(\mathcal{A}) \) either of the categories \( \mathcal{C}(\mathcal{A}) \) or \( \text{Hot}(\mathcal{A}) \). With the notation of \((7.3)\):

(i) We call \( \Theta(\varphi^*) \) the **true triangle** associated to the morphism \( \varphi^* \), and \( \partial^* \) is the **boundary morphism** of \( \Theta(\varphi^*) \).

(ii) A **triangle** of \( T(\mathcal{A}) \) is any sequence of morphisms of \( T(\mathcal{A}) \):

\[
A^* \xrightarrow{\alpha^*} B^* \xrightarrow{\beta^*} C^* \xrightarrow{\gamma^*} A^*[1].
\]

\((7.3.4)\)

(iii) Let \( \Theta_i := (A_i^* \xrightarrow{\alpha_i^*} B_i^* \xrightarrow{\beta_i^*} C_i^* \xrightarrow{\gamma_i^*} A_i^*[1]) \) for \( i = 1, 2 \) be two triangles of \( T(\mathcal{A}) \). A **morphism of triangles** \( \Theta_1 \to \Theta_2 \) is a commutative diagram of morphisms of \( T(\mathcal{A}) \):

\[
\begin{array}{c}
A_1^* \xrightarrow{\alpha_1^*} B_1^* \xrightarrow{\beta_1^*} C_1^* \xrightarrow{\gamma_1^*} A_1^*[1] \\
\downarrow \gamma_1^* \downarrow \gamma_1^* \\
A_2^* \xrightarrow{\alpha_2^*} B_2^* \xrightarrow{\beta_2^*} C_2^* \xrightarrow{\gamma_2^*} A_2^*[1].
\end{array}
\]

Morphisms of triangles can be composed in the obvious fashion, and clearly the system of all triangles of \( T(\mathcal{A}) \) and their morphisms, forms a category.
(iv) A distinguished triangle of \( T(\mathcal{A}) \) is a triangle of \( T(\mathcal{A}) \) that is isomorphic to a true triangle. We denote by

\[
\Theta.T(\mathcal{A})
\]

the full subcategory of the category of triangles of \( T(\mathcal{A}) \) whose objects are the distinguished triangles.

(v) Let \( \mathcal{B} \) be any other additive category. A triangulated functor from \( T(\mathcal{A}) \) to \( T(\mathcal{B}) \) is a pair \((F, \tau)\) consisting of a functor \( F : T(\mathcal{A}) \to T(\mathcal{B}) \) and a natural isomorphism

\[
\tau_K : F(K^[1]) \cong (FK^*)[1]
\]

for every \( K \in \text{Ob}(T(\mathcal{A})) \) such that, for every distinguished triangle \((7.3.4)\) of \( T(\mathcal{A}) \), the triangle

\[
FA^\bullet \xrightarrow{FA^*} FB^\bullet \xrightarrow{FB^*} FC^\bullet \xrightarrow{\tau_K \circ F^*} FA^*[1]
\]

is distinguished in \( T(\mathcal{B}) \). We also say that \( F \) is triangulated if there exists a natural isomorphism \( \tau \) as above, such that \((F, \tau)\) is a triangulated functor.

**Remark 7.3.5.** (i) With the terminology of definition \([7.3.3]\) we may say that diagram \((7.3.2)\) is a morphism of distinguished triangles, and clearly the rules: \( \varphi^* \mapsto \Theta(\varphi^*) \) for any morphism \( \varphi^* \in \text{C}(\mathcal{A}) \) and \( \beta^* \mapsto \Theta(\beta^*) \) for any morphism \( \beta^* \in \text{Morph}(\text{C}(\mathcal{A})) \) amount to a functor

\[
\Theta : \text{C}(\mathcal{A}) \to \Theta.\text{C}(\mathcal{A})
\]

Moreover, if \( \varphi^* \) is a morphism of \( \text{C}^+ (\mathcal{A}) \) (resp. \( \text{C}^- (\mathcal{A}) \), resp. \( \text{C}^b (\mathcal{A}) \)), then clearly \((\text{Cone} \varphi)^*\) lies in the same subcategory of \( \Theta.\text{C}(\mathcal{A}) \), so \((7.3.6)\) restricts to functors

\[
\text{Morph}(\text{C}^+ (\mathcal{A})) \to \Theta.\text{C}^+ (\mathcal{A})
\]

with “?” equal to either +, −, or \( b \)

with obvious notation.

(ii) Let \( F : \mathcal{A} \to \mathcal{B} \) be any additive functor between additive categories. Directly from the definitions, it is clear that the induced functors \( \text{C}(F) \) and \( \text{Hot}(F) \) are both triangulated.

(iii) Suppose now that \( \mathcal{A} \) is an abelian category, so that the same holds for \( \text{C}(\mathcal{A}) \), and the discussion of \([7.3]\) yields a short exact sequence

\[
0 \to L^* \xrightarrow{\varphi^*} (\text{Cone} \varphi^*) \xrightarrow{\partial^*} K^*[1] \to 0 \quad \text{in} \quad \text{C}(\mathcal{A})
\]

such that the boundary map in degree \( i \) of the induced long exact cohomology sequence is none else than \( \varphi^{i+1} \), so we get a natural acyclic complex

\[
\cdots \to H^{i-1}L^* \xrightarrow{\varphi^*} H^{i-1}(\text{Cone} \varphi^*) \xrightarrow{\partial^{i-1}} H^iK^* \xrightarrow{\varphi^i} H^iL^* \to \cdots
\]

for every morphism \( \varphi^* \) in \( \text{C}(\mathcal{A}) \). However, one of the subtleties of distinguished triangles, is that they provide a language for expressing certain exactness and cohomological assertions, that remains available even for general additive but not necessarily abelian categories. For instance, let us show the following:

**Proposition 7.3.7.** Let \( \mathcal{A} \) be any additive category. For any complex \( L^* \) of \( \mathcal{A} \), the functors

\[
\begin{align*}
\text{C}(\mathcal{A}) & \to \text{C}(\text{Z-Mod}) & K^* & \mapsto \text{Hom}^*_\mathcal{A}(L^*, K^*) \\
\text{Hot}(\mathcal{A}) & \to \text{Hot}(\text{Z-Mod}) & K^* & \mapsto \text{Hot}^*_\mathcal{A}(L^*, K^*)
\end{align*}
\]

are triangulated (notation of example \([7.1.25]\)).

**Proof.** Let \( \varphi^* : K_1^* \to K_2^* \) be any morphism of complexes of \( \mathcal{A} \). The universal properties of the push-out and of the cokernel yield a unique commutative diagram

\[
\begin{array}{cccc}
\text{Hom}^*_\mathcal{A}(L^*, \Theta(\varphi^*)) & \to & \text{Hom}^*_\mathcal{A}(L^*, K_2^*) & \to & \text{Hom}^*_\mathcal{A}(L^*, (\text{Cone} \varphi^*)) & \to & \text{Hom}^*_\mathcal{A}(L^*, K_1^*[1]) \\
\downarrow & & \downarrow & & \downarrow & & \downarrow \\
\Theta(\text{Hom}^*_\mathcal{A}(L^*, \varphi^*)) & \to & \text{Cone} \text{Hom}^*_\mathcal{A}(L^*, \varphi^*) & \to & \text{Hom}^*_\mathcal{A}(L^*, K_1^*) & \to & \text{Hom}^*_\mathcal{A}(L^*, K_1^*[1]).
\end{array}
\]
Now, since the sequence $0 \to K_i^j \to (\text{Cone } \varphi)^i \to K_i^{j+1} \to 0$ is split exact in each degree $i \in \mathbb{Z}$, it is easily seen that the same holds for the induced sequence

$$0 \to \text{Hom}_\mathcal{A}(L^i, K_i^j) \to \text{Hom}_\mathcal{A}(L^i, (\text{Cone } \varphi)^i) \to \text{Hom}_\mathcal{A}(L^i, K_i^{j+1}) \to 0.$$ 

It follows that $\gamma^i$ is the obvious natural identification and $\beta^i$ is the direct product of the natural identifications

$$\text{Hom}_\mathcal{A}(L_i^i, \varphi^i \oplus \varphi^{i+1}) \cong \text{Hom}_\mathcal{A}(L_i^i, \varphi^i) \oplus \text{Hom}(L_i^{i+1}, \varphi^{i+1}) \quad \text{for every } i, j \in \mathbb{Z}$$

whence the assertion for the functor $\text{Hom}_\mathcal{A}$. The assertion for $\text{Hot}_\mathcal{A}$ follows immediately. □

**Remark 7.3.8.** Resume the situation of (7.1.23). It is easily seen that, *mutatis mutandis*, the proof of proposition 7.3.7 shows also the following. For every $K^i \in \text{Ob}(\text{Hot}(\mathcal{A}))$ the functor

$$\text{Hot}^{-}(\mathcal{A}') \to \text{Hot}^{-}(\mathcal{A}'') \quad L^i \mapsto B^i(K^i, L^i)$$

is triangulated. Likewise, the same holds for the functor

$$\text{Hot}^{-}(\mathcal{A}') \to \text{Hot}^{-}(\mathcal{A}'') \quad K^i \mapsto B^i(K^i, L^i)$$

for every $L^i \in \text{Ob}(\text{Hot}(\mathcal{A}''))$: details left to the reader.

**Lemma 7.3.9.** With the notation of (7.3), let $\varphi_1^i, \varphi_2^i : K^i \to L^i$ be any two morphisms in $\mathcal{C}(\mathcal{A})$. The following holds:

(i) Any homotopy $s^i$ from $\varphi_1^i$ to $\varphi_2^i$ induces a natural isomorphism

$$\gamma^i : (\text{Cone } \varphi_1^i)^i \cong (\text{Cone } \varphi_2^i)^i \quad \text{in } \mathcal{C}(\mathcal{A})$$

fitting into a commutative diagram

$$\begin{array}{ccc}
K^i & \xrightarrow{\varphi_1^i} & L^i \\
\downarrow \gamma^i & & \downarrow \gamma^i \\
K^i & \xrightarrow{\varphi_2^i} & L^i
\end{array}$$

whose top (resp. bottom) row is $\Theta(\varphi_1^i)$ (resp. $\Theta(\varphi_2^i)$).

(ii) There is a natural isomorphism

$$\omega^i : (\text{Cone } \psi_1^i)^i \cong K^i[1] \oplus (C^i \otimes Z L^i) \quad \text{in } \mathcal{C}(\mathcal{A})$$

fitting into a commutative diagram

$$\begin{array}{ccc}
K^i[1] & \xrightarrow{-p_1^i} & K^i[1] \oplus (C^i \otimes Z L^i) \\
\downarrow \omega^i & & \downarrow p_2^i \\
L^i[1] & \xrightarrow{\varphi_1^i \circ \psi_1^i} & L^i[1]
\end{array}$$

whose top row is $\Theta(\psi_1^i)$, and where $p_1^i$ is the natural projection, and $p_2^i$ is the morphism given by the matrix

$$\begin{bmatrix}
0 & \varphi_1^{i+1} \\
-1 & -L^i \end{bmatrix} : L^i \oplus K^{i+1} \oplus L^{i+1} \to L^{i+1} \quad \text{for every } i \in \mathbb{Z}.$$ 

**Proof.** (i): By assumption, $\varphi_1^i = \varphi_2^i + d^{i-1}s^i + s^{i+1}d^i$ for every $i \in \mathbb{Z}$. We let $\gamma_1^i$ be the automorphism of $L^i \oplus K^{i+1}$ given by the matrix

$$\begin{bmatrix}
1 & s^{i+1} \\
0 & 1
\end{bmatrix} \quad \text{for every } i \in \mathbb{Z}.$$
A direct computation shows that the system \((\gamma^i | i \in \mathbb{Z})\) is the sought isomorphism, and the commutativity of the resulting diagram as in (i) follows by a simple inspection.

(ii): Set \(\sigma^\bullet := (e^\bullet \otimes \mathbb{Z} 1_L) \circ \varphi_1^\bullet\). By definition, we have a natural identification
\[
(\text{Cone } \sigma)^\bullet = (\text{Cone } \psi_1)^\bullet
\]
as well as a commutative diagram
\[
\begin{array}{cccccc}
K^\bullet & \xrightarrow{\varphi_1^\bullet} & L^\bullet & \xrightarrow{e^\bullet \otimes \mathbb{Z} 1_L} & \mathbb{C}^\bullet \otimes \mathbb{Z} L^\bullet \\
\downarrow i^\bullet \otimes 1_K & & \downarrow \psi_1^\bullet & & \downarrow \\
\mathbb{C}^\bullet \otimes \mathbb{Z} K^\bullet & \xrightarrow{(\text{Cone } \varphi_1)^\bullet} & (\text{Cone } \psi_1)^\bullet
\end{array}
\]
whose two square subdiagrams on the top ladder are cocartesian. Notice that \(\mathbb{C}^\bullet\) is homotopically trivial (details left to the reader); by remark [7.1.19](iv), the same then holds for \(\mathbb{C}^\bullet \otimes \mathbb{Z} L^\bullet\). Thus, \(\sigma^\bullet\) is null-homotopic. In light of (i) and (7.3.1), we deduce an isomorphism as sought, fitting into a commutative diagram
\[
\begin{array}{cccccc}
K^\bullet & \xrightarrow{\varphi_1^\bullet} & L^\bullet & \xrightarrow{e^\bullet \otimes \mathbb{Z} 1_L} & \mathbb{C}^\bullet \otimes \mathbb{Z} L^\bullet & \xrightarrow{\partial_2^\bullet} & K^\bullet[1] \\
\downarrow i^\bullet \otimes 1_K & & \downarrow \psi_1^\bullet & & \downarrow & & \downarrow \\
\mathbb{C}^\bullet \otimes \mathbb{Z} K^\bullet & \xrightarrow{(\text{Cone } \varphi_1)^\bullet} & (\text{Cone } \psi_1)^\bullet & \xrightarrow{\partial_1^\bullet} & K^\bullet[1] & \xrightarrow{\partial_0^\bullet} & K^\bullet[1] \\
\end{array}
\]
whose bottom row is the true triangle associated to the zero morphism \(K^\bullet \to \mathbb{C}^\bullet \otimes \mathbb{Z} L^\bullet\). Explicitly, the differentials
\[
d^i_{(\text{Cone } \psi_1), \text{(Cone } \psi_1)} : L^i \oplus K^{i+1} \oplus L^{i+1} \to L^{i+1} \oplus K^{i+2} \oplus L^{i+2}
\]
given by the matrices
\[
\begin{bmatrix}
0 & 1_{L^{i+1}} \\
-1_{K^i} & 0 \\
0 & -d_{L^i}^{i+1}
\end{bmatrix}
\]
and then the commutativity of the right square subdiagram of (ii) is immediate. Lastly, it is easily seen that \(\partial^\bullet_0 = -p^\bullet_1\), therefore
\[
-\varphi_1^\bullet \circ \omega^\bullet \circ \tau^\bullet = \partial^\bullet_{\varphi_1} \circ \tau^\bullet = \partial^\bullet_{\varphi_1}
\]
which shows the commutativity of the left square subdiagram of (ii).

\[\square\]

**Remark 7.3.10.** (i) In the situation of lemma [7.3.9](i) notice that the diagram
\[
\begin{array}{cccccc}
K^\bullet & \xrightarrow{\varphi_1^\bullet} & L^\bullet & \xrightarrow{\psi_1} & (\text{Cone } \varphi_1)^\bullet & \xrightarrow{\partial_2^\bullet} & K^\bullet[1] \\
\downarrow \varphi_2^\bullet & & \downarrow & & \downarrow \gamma_1^\bullet & & \downarrow \\
K^\bullet & \xrightarrow{\varphi_2^\bullet} & L^\bullet & \xrightarrow{\psi_2} & (\text{Cone } \varphi_2)^\bullet & \xrightarrow{\partial_2^\bullet} & K^\bullet[1]
\end{array}
\]
commutes in $\text{Hot}(\mathcal{A})$, and amounts to a natural isomorphism

$$\Theta(\varphi^\bullet) \xrightarrow{\sim} \Theta(\varphi^\bullet_2) \quad \text{in } \Theta.\text{Hot}(\mathcal{A}).$$

(ii) Let $\Theta := (A^\bullet \xrightarrow{\alpha^\bullet} B^\bullet \xrightarrow{\beta^\bullet} C^\bullet \xrightarrow{\gamma^\bullet} A^\bullet[1])$ be any triangle of $\text{C}(\mathcal{A})$ or $\text{Hot}(\mathcal{A})$. We obtain a new triangle by setting

$$\Theta[1] := (B^\bullet \xrightarrow{\beta^\bullet} C^\bullet \xrightarrow{\gamma^\bullet} A^\bullet[1] \xrightarrow{-\alpha^\bullet[1]} B^\bullet[1])$$

and clearly, the rule $\Theta \mapsto \Theta[1]$ yields an endofunctor of the category of triangles. The change of sign on the last arrow is needed to ensure that this operator restricts to an endofunctor of the subcategory of distinguished triangles, at least up to homotopy. Indeed, we may state:

**Proposition 7.3.11.** With the notation of remark [7.3.10](ii), suppose that $\Theta$ is a distinguished triangle of $\text{Hot}(\mathcal{A})$. Then the same holds for $\Theta[1]$, so we have an automorphism

$$\Theta.\text{Hot}(\mathcal{A}) \xrightarrow{\sim} \Theta.\text{Hot}(\mathcal{A}) \quad \Theta \mapsto \Theta[1].$$

**Proof.** We may assume that $\Theta = \Theta(\alpha^\bullet)$ for some morphism $\alpha^\bullet : A^\bullet \rightarrow B^\bullet$ of complexes of $\mathcal{A}$, in which case $C^\bullet = (\text{Cone } \alpha^\bullet)^\bullet$, and it suffices to show the more precise:

**Claim 7.3.12.** There is a natural isomorphism

$$\Theta(\beta^\bullet) \xrightarrow{\sim} \Theta(\alpha^\bullet)[1] \quad \text{in } \Theta.\text{Hot}(\mathcal{A}).$$

**Proof of the claim.** Indeed, notice that the natural projection $p^\bullet_1 : A^\bullet[1] \oplus (C^\bullet \otimes_\mathbb{Z} B^\bullet) \rightarrow A^\bullet[1]$ represents an isomorphism in $\text{Hot}(\mathcal{A})$, whose inverse is the class of the natural monomorphism $e^\bullet : A^\bullet[1] \rightarrow A^\bullet[1] \oplus (C^\bullet \otimes_\mathbb{Z} B^\bullet)$. Taking into account lemma [7.3.9](ii), we then get the commutative diagram in $\text{Hot}(\mathcal{A})$:

$$\begin{array}{ccc}
B^\bullet & \xrightarrow{\beta^\bullet} & (\text{Cone } \alpha^\bullet)^\bullet & \xrightarrow{\partial^\bullet_0} & B^\bullet[1] \\
\downarrow & & \downarrow & & \downarrow \\
B^\bullet & \xrightarrow{\beta^\bullet} & (\text{Cone } \alpha^\bullet)^\bullet & \xrightarrow{\partial^\bullet_1} & A^\bullet[1] & \xrightarrow{-\alpha^\bullet} & B^\bullet[1]
\end{array}$$

where $\omega^\bullet : (\text{Cone } \beta^\bullet)^\bullet \xrightarrow{\sim} A^\bullet[1] \oplus (C^\bullet \otimes_\mathbb{Z} B^\bullet)$ is the isomorphism provided by lemma [7.3.9](ii). The claim follows. \(\square\)

**Definition 7.3.13.** Let $\mathcal{A}$ be any abelian category.

(i) A **quasi-isomorphism** is a morphism $\varphi^\bullet : K^\bullet \rightarrow L^\bullet$ in $\text{C}(\mathcal{A})$ such that $H^i\varphi^\bullet$ is an isomorphism for every $i \in \mathbb{Z}$.

(ii) With the notation of (7.3), we let $\Sigma$ be the subset of $\text{Morph}(\text{C}(\mathcal{A}))$ consisting of all quasi-isomorphisms. We set

$$D(\mathcal{A}) := \text{C}(\mathcal{A})[\Sigma^{-1}]$$

(see remark [1.6.10](i)) and we call this category the **derived category of $\mathcal{A}$**.

(iii) More generally, if $I \subset \mathbb{Z}$ is any interval as in (7.1), and $a \in \mathbb{Z}$ is any integer, we denote

$$D^I(\mathcal{A}) \quad D^{\geq a}(\mathcal{A}) \quad D^{\leq a}(\mathcal{A}) \quad D^+(\mathcal{A}) \quad D^-(\mathcal{A}) \quad D^b(\mathcal{A})$$

the essential image in $D(\mathcal{A})$ of the categories $C^I(\mathcal{A})$, respectively $C^{\geq a}(\mathcal{A})$, $C^{\leq a}(\mathcal{A})$, $C^+(\mathcal{A})$, $C^-(\mathcal{A})$, $C^b(\mathcal{A})$.

**Remark 7.3.14.** (i) Notice that, if $\varphi^\bullet$ is a quasi-isomorphism in $\text{C}(\mathcal{A})$, and $\psi^\bullet$ is any other morphism that is homotopy equivalent to $\varphi^\bullet$, then $\psi^\bullet$ is a quasi-isomorphism as well (remark [7.1.9](iii)). We may then say that a morphism $\varphi^\bullet$ in $\text{Hot}(\mathcal{A})$ is a **quasi-isomorphism**, if it admits a representative in $\text{C}(\mathcal{A})$ which is a quasi-isomorphism; by the foregoing, this property can be checked on any representative for the homotopy class $\varphi^\bullet$. 

(ii) In the same vein, notice that, by virtue of proposition 7.1.21, the localization functor $C^i(\mathcal{A}) \to D^i(\mathcal{A})$ factors uniquely through a functor

$\text{Hot}^i(\mathcal{A}) \to D^i(\mathcal{A})$

whenever "?" equals either +, −, b, or any interval $I \subset \mathbb{Z}$.

(iii) In light of remark 7.1.9 (iii), we see that the isomorphism of remark 7.1.9 (iv) identifies the subset $\Sigma^\circ \subset \text{Ob}(C(\mathcal{A})^\circ)$ with the system of quasi-isomorphisms of $C(\mathcal{A}^\circ)$. Combining with remark 1.6.10 (ii) we get natural isomorphisms of categories:

$$D^i(\mathcal{A})^\circ \cong D^{-i}(\mathcal{A}^\circ) \quad D^+(\mathcal{A})^\circ \cong D^-(\mathcal{A}^\circ) \quad D^i(\mathcal{A})^\circ \cong D^i(\mathcal{A}^\circ)$$

where $I \subset \mathbb{Z}$ is any interval, and we set $-I := \{-a \mid a \in I\}$.

(iv) Notice that the brutal truncation functors of (7.1.1) do not transform quasi-isomorphism into quasi-isomorphisms, hence they do not descend to the derived category. On the other hand, the normalized truncation functors do preserve quasi-isomorphisms, so they yield functors

$$\tau_{\geq a} : D(\mathcal{A}) \to D_{\geq a}(\mathcal{A}) \quad \text{and} \quad \tau_{\leq a} : D(\mathcal{A}) \to D_{\leq a}(\mathcal{A}).$$

for every $a \in \mathbb{Z}$.

Moreover, let $i_{\geq a} : C_{\geq a}(\mathcal{A}) \to C(\mathcal{A})$ and $j_{\geq a} : D_{\geq a}(\mathcal{A}) \to D(\mathcal{A})$ be the inclusion functors; so the counit of the adjoint pair $(\tau_{\geq a}, i_{\geq a})$ is just the identity endofunctor $1_{C_{\geq a}(\mathcal{A})}$, and it is easily seen that the unit of adjunction $1_{D(\mathcal{A})} \to i_{\geq a} \circ \tau_{\geq a}$ induces a natural transformation $\eta : 1_{D(\mathcal{A})} \to j_{\geq a} \circ \tau_{\geq a}$. Then, the triangular identities for the adjunction $(\tau_{\geq a}, i_{\geq a})$ imply corresponding triangular identities for $\eta$ and the identity endofunctor $1_{D_{\geq a}(\mathcal{A})}$; by proposition 1.1.15 (i), we conclude that $\tau_{\geq a}$ is left adjoint to $j_{\geq a}$. Likewise, $\tau_{\leq a}$ is right adjoint to the inclusion functor $D_{\leq a}(\mathcal{A}) \to D(\mathcal{A})$.

(v) Directly from the definition (and the universal property of localization), we see that, for every $i \in \mathbb{Z}$, the cohomology functor in degree $i$ factors uniquely through a functor

$$H^i : D(\mathcal{A}) \to \mathcal{A}.$$  

**Theorem 7.3.16.** Let $\mathcal{A}$ be any abelian category, and denote by

$$\Sigma_? \subset \text{Morph}(\text{Hot}^3(\mathcal{A}))$$

with "?" equal to either +, −, b, or any interval $I \subset \mathbb{Z}$

the subset of all quasi-isomorphisms. We have:

(i) The functor (7.3.15) factors uniquely through an equivalence:

$$\text{Hot}^3(\mathcal{A})[\Sigma_?^{-1}] \cong D^3(\mathcal{A}).$$

(ii) The set $\Sigma_?$ admits both a right and a left calculus of fractions.

**Proof.** To begin with, we point out:

**Claim 7.3.17.** For any abelian category $\mathcal{A}$, the following holds:

(iii) Let $K^\bullet, L^\bullet$ be any two complexes of $\mathcal{A}$, with $L^\bullet \in \text{Ob}(C_{\leq a}(\mathcal{A}))$. If there exists a quasi-isomorphism $K^\bullet \to L^\bullet$, then the counit of adjunction $\tau_{\leq a} K^\bullet \to K^\bullet$ is a quasi-isomorphism.

(iv) In order to prove the theorem, it suffices to show that $\Sigma$ admits a right calculus of fractions.

**Proof of the claim.** (iii) follows immediately from remark 7.3.14 (iv) (details left to the reader).

(iv): Indeed, suppose that $\Sigma$ admits a right calculus of fraction; in view of remark 7.3.14 (iii) it follows that $\Sigma$ admits as well a left calculus of fraction. Next, in case "?" equals $\mathbb{Z}$, assertion (i) says that the induced functor $\text{Hot}(\mathcal{A})[\Sigma^{-1}] \to D(\mathcal{A})$ is an equivalence; the latter follows immediately by comparing the respective universal properties: details left to the reader. So, the theorem is completely proven, for "?" equal to $\mathbb{Z}$.
Next, from (iii), the case "?" = \(\mathbb{Z}\) of the theorem, and proposition 1.6.21 we get assertion (i) of the theorem for "?" equal to \([-\infty, a]\], and we also deduce that \(\Sigma_{[-\infty, a]}\) admits a right calculus of fractions. We check directly that \(\Sigma_{[-\infty, a]}\) admits also a left calculus of fractions. Indeed, (the duals of) axioms (CF1) and (CF2) are obviously fulfilled. For (CF3), let us consider any pair of morphisms \(f^\bullet : B^\bullet \to A^\bullet\) and \(s^\bullet : B^\bullet \to C^\bullet\) in \(\text{Hot}^{[-\infty, a]}(\mathcal{A})\), with \(s^\bullet\) a quasi-isomorphism; since (the dual of) (CF3) is already known to hold for \(\Sigma\), we may find morphisms \(t : A \to D\) and \(g : C \to D\) in \(\text{Hot}(\mathcal{A})\), such that \(t \circ f = g \circ s\), and where \(t\) is a quasi-isomorphism. But then, by remark 7.3.14(iv), we may replace \(D\) (resp. \(t\), resp. \(g\)) by \(\tau_{\geq a}D\) (resp. by \(\tau_{\geq a}t\), resp. by \(\tau_{\geq a}g\)), after which we may assume that \(t \in \Sigma_{[-\infty, a]}\), whence (CF3). The proof of (CF4) is similar, and shall be left to the reader.

Dualizing the foregoing case, and taking into account remark 7.3.14(iii), we then get both assertions (i) and (ii) of the theorem also for "?" equal to \([a, +\infty]\], so the proof of theorem is complete for the case when "?" equals any unbounded interval \(I \subset \mathbb{Z}\). One argues likewise to show the theorem in case "?" equals either \(+\infty\) or \(-\infty\) (details left to the reader). Lastly, for "?" equal to either \(b\) or an interval \([a, b]\), it suffices to apply proposition 1.6.21 and (iii) to the fully faithful inclusion functors

\[
\text{Hot}^{[a, b]}(\mathcal{A}) \to \text{Hot}^{\geq a}(\mathcal{A}) \quad \text{Hot}^{b}(\mathcal{A}) \to \text{Hot}^{+}(\mathcal{A})
\]

and argue as in the foregoing cases to complete the proof of the claim.

By claim 7.3.17(ii), it remains only to show that \(\Sigma\) admits a right calculus of fractions. To this aim, we check the conditions of definition 1.6.14 (CF1) and (CF2) are obvious. Next, consider two morphisms \(\varphi^\bullet : A^\bullet \to B^\bullet\) and \(\psi^\bullet : C^\bullet \to B^\bullet\) in \(\mathcal{C}(\mathcal{A})\), with \(\varphi^\bullet\) a quasi-isomorphism. Let \(\beta^\bullet : B^\bullet \to (\text{Cone } \psi)^\bullet\) be the natural morphism; with the notation of (7.3.2), we have an induced commutative diagram

\[
\begin{array}{ccc}
A^\bullet & \longrightarrow & (\text{Cone } \psi)^\bullet \\
\downarrow_{\varphi^\bullet} & & \downarrow_{(\text{Cone } \beta \circ \varphi)^\bullet} \\
B^\bullet & \longrightarrow & (\text{Cone } \psi)^\bullet \\
\downarrow_{\beta^\bullet} & & \downarrow_{(\text{Cone } \beta)^\bullet} \\
B^\bullet[1] & \longrightarrow & B^\bullet[1]
\end{array}
\]

where \(\gamma^\bullet := (\text{Cone } (\varphi^\bullet, 1)^\bullet\), and by the 5-lemma, it follows that \(\gamma^\bullet\) is a quasi-isomorphism. However, lemma 7.3.9(ii) identifies \(\gamma^\bullet\) with a morphism \((\text{Cone } \beta \circ \varphi)^\bullet \to C^\bullet[1] \oplus (C^\bullet \otimes_{\mathbb{Z}} B^\bullet)\), whence a commutative diagram

\[
\begin{array}{ccc}
(\text{Cone } \beta \circ \varphi)^\bullet & \longrightarrow & A^\bullet[1] \\
\downarrow_{\pi^\bullet \circ \varphi^\bullet} & & \downarrow_{\varphi^\bullet[1]} \\
C^\bullet[1] & \longrightarrow & B^\bullet[1]
\end{array}
\]

where \(\pi^\bullet : C^\bullet[1] \oplus (C^\bullet \otimes_{\mathbb{Z}} B^\bullet) \to C^\bullet[1]\) is the natural projection. Since \(C^\bullet \otimes_{\mathbb{Z}} B^\bullet\) is homotopically trivial (see the proof of lemma 7.3.9(ii)), we see that \(\pi^\bullet\) is also a quasi-isomorphism, which shows (CF3). Lastly, let \(f^\bullet, g^\bullet : X^\bullet \to Y^\bullet\) be any two morphisms in \(\text{Hot}^2(\mathcal{A})\), and \(s^\bullet : Y^\bullet \to Z^\bullet\) a quasi-isomorphism such that \(s^\bullet \circ f^\bullet = s^\bullet \circ g^\bullet\) in \(\text{Hot}^2(\mathcal{A})\). We rewrite the latter condition as \(s^\bullet \circ (f^\bullet - g^\bullet) = 0\), and we notice the exact sequence

\[
H^{-1}\text{Hot}^\ast_{\mathcal{A}}(X^\bullet, (\text{Cone } s^\bullet)) \to H^0\text{Hot}^\ast_{\mathcal{A}}(X^\bullet, Y^\bullet) \to H^0\text{Hot}^\ast_{\mathcal{A}}(X^\bullet, Z^\bullet)
\]

induced, via remark 7.3.3(ii), by the distinguished triangle \(\text{Hot}^\ast_{\mathcal{A}}(X^\bullet, \Theta(s^\bullet))\) provided by proposition 7.3.7. Taking into account example 7.1.15(i), we deduce that there exists a morphism

\[
h^\bullet : X^\bullet \to (\text{Cone } s^\bullet)[-1] \quad \text{such that } \delta^\bullet s[-1] \circ h^\bullet = f^\bullet - g^\bullet \quad \text{in } \text{Hot}^2(\mathcal{A})
\]
where \( \partial_s^* : (\text{Cone } s)^* \to Y^*[1] \) is the boundary morphism of the true triangle \( \Theta(s^*) \). Let now \( \partial_h^* : (\text{Cone } h)^* \to X^*[1] \) be the boundary morphism of \( \Theta(h^*) \); from proposition 7.3.11 it follows easily that
\[
\partial_h^* \circ \partial_h^*[-1] = 0 \quad \text{in } \text{Hot}^+(\mathcal{A})
\]
whence \( (f^* - g^*) \circ \partial_h^*[-1] = 0 \), and to deduce (CF4), it suffices to remark:

**Claim 7.3.18.** \( \partial_h^* \) is a quasi-isomorphism.

**Proof of the claim.** By assumption, \( s^* \) is a quasi-isomorphism; in light of the long exact sequence of remark 7.3.5(i), it follows easily that \( H^i(\text{Cone } s)^* = 0 \) for every \( i \in \mathbb{Z} \). By the same token, we see that \( H^i\partial_h^* \) is an isomorphism for every \( i \in \mathbb{Z} \), which is the claim. \( \square \)

7.3.19. Let now \( \mathcal{A} \) be an abelian category, \( \mathcal{B} \) an additive subcategory of \( \mathcal{A} \), and set
\[
\Sigma_{\mathcal{B},+} := \Sigma \cap \text{Morph}(\text{Hot}^+(\mathcal{B})) \quad \Sigma_{\mathcal{B},-} := \Sigma \cap \text{Morph}(\text{Hot}^-(\mathcal{B}))
\]
where \( \Sigma \subseteq \text{Morph}(\text{Hot}(\mathcal{A})) \) is the set of all quasi-isomorphisms. We may define the categories
\[
\text{D}^+_{\mathcal{B}}(\mathcal{A}) := \text{Hot}^+(\mathcal{B})[\Sigma_{\mathcal{B},+}^{-1}] \quad \text{D}^-_{\mathcal{B}}(\mathcal{A}) := \text{Hot}^-(\mathcal{B})[\Sigma_{\mathcal{B},-}^{-1}]
\]
and clearly the inclusion functor \( \mathcal{B} \to \mathcal{A} \) induces natural functors
\[
i^+ : \text{D}^+_{\mathcal{B}}(\mathcal{A}) \to \text{D}^+(\mathcal{A}) \quad i^- : \text{D}^-_{\mathcal{B}}(\mathcal{A}) \to \text{D}^-(\mathcal{A})
\]

**Proposition 7.3.20.** In the situation of (7.3.19), suppose additionally that the following holds :

(a) \( \mathcal{B} \) is a full subcategory of \( \mathcal{A} \).

(b) For every \( A \in \text{Ob}(\mathcal{A}) \), there exists \( B \in \text{Ob}(\mathcal{B}) \) with a monomorphism \( A \to B \) in \( \mathcal{A} \).

Then the functor \( i^- \) is an equivalence, and \( \Sigma_{\mathcal{B},+} \) admits a left calculus of fractions.

**Proof.** Set \( \Sigma_+ := \Sigma \cap \text{Morph}(\text{Hot}^+(\mathcal{A})) \). By theorem 7.3.16(i), it suffices to show that the induced functor
\[
\text{Hot}^+(\mathcal{B})[\Sigma_{\mathcal{B},+}^{-1}] \to \text{Hot}^+(\mathcal{A})[\Sigma_+^{-1}]
\]
is an equivalence. In light of remark 1.6.24 and theorem 7.3.16(ii), we are then reduced to checking:

**Claim 7.3.21.** Suppose that conditions (a) and (b) of the proposition hold. Then, for every \( K^* \in \text{C}^+(\mathcal{A}) \) there exists \( L^* \in \text{C}^+(\mathcal{B}) \) with a quasi-isomorphism \( K^* \to L^* \).

**Proof of the claim.** Say that \( K^* \in \text{C}^+(\mathcal{A}) \) for some \( a \in \mathbb{Z} \); we shall construct first a double complex \( A^{p,q} \in \text{C}^{\mathbb{Z}}(\text{C}^+(\mathcal{A})) \) such that

- \( A^{p,-1} = K^p \) and \( d^{p-1,-1}_K = d^{p-1}_K \) for every \( p \in \mathbb{Z} \).
- \( A^{pq} \in \text{Ob}(\mathcal{B}) \) for every \( p \in \mathbb{Z} \) and every \( q \geq 0 \).
- For every \( p \in \mathbb{Z} \), the cohomology of the complex \( (A^{p,*}, d^{p,*}_A) \) vanishes in every degree.

To this aim, we proceed by induction on \( p \). Hence, we let \( A^{pq} = 0 \) for every \( p < a \) and every \( q \in \mathbb{Z} \). Suppose that \( p \geq a \), and that \( A^{ij} \) is already defined for every \( i < a \) and every \( j \in \mathbb{Z} \), as well as all the differentials \( d^{i,j}_B \) and \( d^{i-1,j}_K \) for every \( i < a \) and every \( j \in \mathbb{Z} \). Then we construct \( A^{pq} \) and the differentials \( d^{p,j-1}_B \) and \( d^{p-1,j}_K \) by induction on \( j \in \mathbb{Z} \). Namely, for \( j < -1 \) we set \( A^{pq} = 0 \), and for \( j = -1 \) we set \( A^{p,-1} = K^p \) and \( d^{p-1,-1}_K = d^{p-1}_K \). Thus, suppose that \( j \geq 0 \), and \( A^{p,j-1} \) is already given, as well as \( d^{p-1,j-1}_K \) and \( d^{p,j-2}_A \); we define the object \( B^{pq} \) of \( \mathcal{A} \) as the coproduct in the push-out diagram

\[
\begin{array}{ccc}
A^{p-1,j} & \xrightarrow{g} & B^{pq} \\
\pi_a \downarrow & & \downarrow f \\
\text{Coker } d^{p-1,j-2} & \xrightarrow{\pi_b} & \text{Coker } d^{p,j-2}
\end{array}
\]
where $\varphi_v$ and $\varphi_h$ are induced by $d_{h_i}^{p-1,j-1}$ and respectively $d_{h_i}^{p-1,j-1}$. Notice that, by inductive assumption, $\varphi_v$ is a monomorphism, so the same holds for $f$ (details left to the reader). By assumption (b), we may find a monomorphism $h : B'^i \to C$ for some $C \in \text{Ob}(B)$, and we set $A'^i := C$, $d'^{p-1,j} := h \circ g$ and $d_{h'}^{p-1,j} := h \circ f \circ p$, where $p : A'^{p,j-1} \to \text{Coker} d_{h'}^{p,j-2}$ is the natural projection. Then it is easily seen that $d_{h'}^{p-1,j} \circ d_{h'}^{p-1,j-1} = d_{h'}^{p-1,j-1} \circ d_{h'}^{p-1,j-1}$, and moreover

$$\text{Ker} d_{h'}^{p-1,j} / \text{Im} d_{h'}^{p-1,j} = 0$$

as required. Now, let $i^\geq : C_2(\mathcal{A}) \to C(C_2^\geq(\mathcal{A}))$ be the brutal truncation functor, and set

$$E'^{\bullet \bullet} := i^\geq A'^{\bullet \bullet} \quad C'^{\bullet \bullet} := K'^[0] \quad L'^{\bullet} := \text{Tot} B'^{\bullet \bullet}.$$

(Hence, $C'^{\bullet \bullet}$ is the double complex whose rows $C'^i$ are the zero complex, except for $q = 0$, where it agrees with $K'^i$). The differentials $d'^{p,i-1} \circ A'^{\bullet \bullet}$ induce a morphism $f^\bullet : K'^\bullet \to L'^\bullet$, and it remains only to check that $f^\bullet$ is a quasi-isomorphism. To this aim, notice that the differentials $d'^{p,i-1}$ also induce a morphism of double complexes

$$g'^{\bullet \bullet} : C'^{\bullet \bullet} \to B'^{\bullet \bullet}$$

such that $\text{Tot} g'^{\bullet \bullet} = f^\bullet$. Moreover, we have standard convergent spectral sequences

$$E'^2_2 := H^q(C'^{\bullet \bullet}) \Rightarrow H^{p+q}\text{Tot} C'^{\bullet \bullet} \quad F'^2_2 := H^q(B'^{\bullet \bullet}) \Rightarrow H^{p+q}\text{Tot} B'^{\bullet \bullet}$$

and by construction, $g'^{\bullet \bullet}$ induces an isomorphism of spectral sequences $E'^2_2 \sim F'^2_2$, whence the claim. \hfill \Box

**Remark 7.3.22.** (i) In view of remark [7.3.14](iii), we see that the dual of proposition [7.3.20](a) also holds. Namely, in the situation of (7.3.19), suppose that

(a) $\mathcal{B}$ is a full subcategory of $\mathcal{A}$.

(b) For every $A \in \text{Ob}(\mathcal{A})$, there exists $B \in \text{Ob}(\mathcal{B})$ with an epimorphism $B \to A$ in $\mathcal{A}$.

Then the functor $i^\bullet$ is an equivalence, and $\Sigma_{\mathcal{B}}$ admits a right calculus of fractions.

(ii) Two special cases of proposition [7.3.20](a) (and its dual) are especially important. Namely, let $\mathcal{J}$ (resp. $\mathcal{P}$) be the full subcategory of $\mathcal{A}$ whose objects are the injective (resp. projective) objects of $\mathcal{A}$. We say that $\mathcal{A}$ has enough injectives (resp. enough projectives) if $\mathcal{J}$ (resp. $\mathcal{P}$) satisfies condition (b) of proposition [7.3.20](a) (resp. condition (b) of (i)). When this holds, proposition [7.3.20](a) (and its dual) can be further sharpened; namely, we have :

**Theorem 7.3.23.** Let $\mathcal{A}$ be any abelian category, and define the subcategories $\mathcal{J}$ and $\mathcal{P}$ of $\mathcal{A}$ as in remark [7.3.22](ii). Then the following holds :

(i) Let $I'^\bullet$ be any object of $\text{C}^+(\mathcal{J})$. Let also $L'^\bullet$ be any object of $\text{C}(\mathcal{A})$, and $\alpha'^\bullet : I'^\bullet \to L'^\bullet$ any quasi-isomorphism. Then there exists a morphism $\beta'^\bullet : L'^\bullet \to I'^\bullet$ in $\text{C}(\mathcal{A})$ such that

$$\beta'^\bullet \circ \alpha'^\bullet = 1_{I'^\bullet} \quad \text{in} \ \text{Hot}(\mathcal{A}).$$

(ii) If $\mathcal{A}$ has enough injectives, the inclusion functor $\mathcal{J} \to \mathcal{A}$ induces an equivalence

$$\text{Hot}^+(\mathcal{J}) \sim \text{D}^+(\mathcal{A}).$$

(iii) Dually, if $\mathcal{A}$ has enough projectives, the inclusion $\mathcal{P} \to \mathcal{A}$ induces an equivalence

$$\text{Hot}^-(\mathcal{P}) \sim \text{D}^-(\mathcal{A}).$$

**Proof.** (i): To begin with, we remark :

**Claim 7.3.24.** In the situation of (i), let also $K'^\bullet$ be any acyclic complex of $\mathcal{A}$, and $\varphi'^\bullet : K'^\bullet \to I'^\bullet$ any morphism in $\text{C}(\mathcal{A})$. Then $\varphi'^\bullet$ is null-homotopic.
Proof of the claim. We need to exhibit a system of morphisms \((s^n : K^n \to I^{n-1} \mid n \in \mathbb{Z})\) with (7.3.25) 
\[
\varphi^n = d^{n-1}_I \circ s^n + s^{n+1} \circ d_K^n
\]
for every \(n \in \mathbb{Z}\). To this aim, say that \(I^* \in \text{Ob}(\mathbb{C}^{\leq n}(\mathcal{A}))\) for some \(n \in \mathbb{Z}\); then we let \(s^j\) be the zero morphism for every \(j \leq a\). Next, suppose that \(j \geq a\), and that \(s^j\) has already been given, so that (7.3.25) holds for \(n = j - 1\). We compute:
\[
(\varphi^j - d^{j-1}_I \circ s^j) \circ d^{j-1}_K = d^{j-1}_I \circ \varphi^{j-1} - d^{j-1}_I \circ s^j \circ d^{j-1}_K
\]
\[
= d^{j-1}_I \circ (\varphi^{j-1} - s^j \circ d^{j-1}_K)
\]
\[
= d^{j-1}_I \circ d^{j-2}_I \circ s^{j-1} = 0.
\]

Since \(\text{Im} \ d^{j-1}_K = \text{Ker} \ d^j_I\), it follows that \(\varphi^j - d^{j-1}_I \circ s^j\) factors through a morphism \(\text{Im} \ d^{j-1}_K \to I^j\), and since \(I^j\) is injective, the latter can be extended to a morphism \(s^{j+1} : K^{j+1} \to I^j\). By construction, (7.3.25) holds for \(n = j\), with this choice of \(s^{j+1}\), whence the claim. 
\(\square\)

Now, under the condition of (i), the complex \(\text{Cone} \alpha^*\) is acyclic (remark 7.3.5(iii)), so the boundary morphism \(\partial^* : \text{Cone} \alpha^* \to \text{Cone} [\alpha^*][1]\) is null-homotopic, by claim 7.3.24(ii). Let us then fix a homotopy \(s^*\) from the zero morphism to \(\partial^*\); in each degree \(j \in \mathbb{Z}\), the morphism \(s^j\) is the sum of a morphism \(s^j_L : L^j \to I^j\) and a morphism \(s^j_I : I^{j+1} \to I^j\), and the relation
\[
-\partial^j = d^{j-1}_I \circ s^j + s^{j+1} \circ d^j_{\text{Cone} \varphi}
\]
translates as the pair of identities:
\[
-d^j_I \circ s^j_L + s^{j+1}_L \circ d^j_I = 0
\]
\[
-d^j_I \circ s^j_I + s^{j+1}_I \circ d^j_I + s^{j+1}_I \circ d^{j+1}_I = 1_{I^{j+1}}
\]
the first of which says that the system \((s^j_L \mid j \in \mathbb{Z})\) amounts to a morphism of complexes \(s^*_L : L^* \to I^*\), and the second says that the system \((s^*_I \mid j \in \mathbb{Z})\) yields a homotopy from \(1_I\) to \(s^*_I \circ \alpha^*\). In other words, the morphism \(\beta^* := s^*_I\) will do.

(ii): By proposition 7.3.20, it suffices to check that every quasi-isomorphism in \(\text{Hot}^+ (\mathcal{I})\) is an isomorphism. But this follows immediately from (i).

(iii): Clearly the subcategory of injective objects of \(\mathcal{A}^\alpha\) is \(\mathcal{P}^\alpha\), so the assertion follows from (ii) and remark 7.3.14(iii).
\(\square\)

Corollary 7.3.26. With the notation of theorem 7.3.23, the natural map
\[
\text{Hot}_\alpha (K^*, I^*) \to \text{Hom}_D(\mathcal{A})(K^*, I^*)
\]
is an isomorphism, for every \(K^* \in \text{Ob}(\mathbb{C}(\mathcal{A}))\) and every \(I^* \in \text{Ob}(\mathbb{C}^+ (\mathcal{I}))\).

Proof. By virtue of theorem 7.3.16, every morphism \(g^* : K^* \to I^*\) in \(D(\mathcal{A})\) is represented by a fraction \((f^*, \alpha^*)\), where \(f^* : K^* \to L^*\) is any morphism in \(\text{Hot}(\mathcal{A})\), and \(\alpha^* : I^* \to L^*\) is a quasi-isomorphism. Then, by theorem 7.3.23(i) we may find a morphism \(\beta^* : L^* \to I^*\) in \(\text{Hot}(\mathcal{A})\) such that \(\beta^* \circ \alpha^* = 1_{I^*};\) clearly \(\beta^*\) is also a quasi-isomorphism, and \(g^* = \beta^* \circ f^*\) in \(D(\mathcal{A})\), so the map of the corollary is surjective. For the injectivity, suppose that \(f^*_{1}, f^*_{2} : K^* \to I^*\) are any two morphisms in \(\text{Hot}(\mathcal{A})\) whose images agree in \(D(\mathcal{A})\); invoking again theorem 7.3.16 we then find a quasi-isomorphism \(\alpha^* : I^* \to L^*\) in \(\text{Hot}(\mathcal{A})\) such that \(\alpha^* \circ f^*_{1} = \alpha^* \circ f^*_{2}\) in \(\text{Hot}(\mathcal{A})\). Then pick again \(\beta^*\) as in the foregoing; we deduce that
\[
f^*_{1} = \beta^* \circ \alpha^* \circ f^*_{1} = \beta^* \circ \alpha^* \circ f^*_{2} = f^*_{2}
\]
in \(\text{Hot}(\mathcal{A})\) whence the assertion. 
\(\square\)

Definition 7.3.27. Let \(\mathcal{A}\) and \(\mathcal{B}\) be two abelian categories, and \(F : \mathbb{C}^+ (\mathcal{A}) \to D(\mathcal{B})\) a functor. Denote \(\omega^+_{\mathcal{A}} : \mathbb{C}^+ (\mathcal{A}) \to D^+ (\mathcal{A})\) and \(\omega^-_{\mathcal{A}} : \mathbb{C}^- (\mathcal{A}) \to D^- (\mathcal{A})\) the localization functors.
(i) A right derived functor of \( F \) is a pair \((RF, \mu)\) consisting of a functor
\[
RF : \text{D}^+(\mathcal{A}) \to \text{D}(\mathcal{B})
\]
and a natural transformation
\[
\mu : F \Rightarrow RF \circ \omega^+_\mathcal{A}
\]
which satisfies the following universal property. For every other pair \((G, \zeta)\) consisting of a functor \( G : \text{D}^+(\mathcal{A}) \to \text{D}(\mathcal{B}) \) and a natural transformation \( \zeta : F \Rightarrow G \circ \omega^+_\mathcal{A} \), there exists a unique natural transformation \( \xi : RF \Rightarrow G \) such that
\[
(7.3.28) \quad \zeta = (\xi \ast \omega^+_\mathcal{A}) \circ \mu.
\]
(ii) Dually, if \( F : \text{C}^-(\mathcal{A}) \to \text{D}(\mathcal{B}) \) is any functor, a left derived functor of \( F \) is a pair \((LF, \mu)\) consisting of a functor
\[
LF : \text{D}^-(\mathcal{A}) \to \text{D}(\mathcal{B})
\]
and a natural transformation
\[
\mu : F \Rightarrow LF \circ \omega^-\mathcal{A}
\]
such that \(((LF)^0, \mu^0)\) is a right derived functor of \( F^0 \), under the natural identifications of remark 7.3.14(iii).

(iii) Especially, let \( \varphi : \mathcal{A} \to \mathcal{B} \) be any additive functor, and for “?” equal to + or −, let \( \omega^+\mathcal{A} : \text{C}^+(\mathcal{B}) \to \text{D}^+(\mathcal{B}) \) be the localization functor. Then a right (resp. left) derived functor of \( \omega^+\mathcal{A} \circ \text{C}^+(\varphi) \) (resp. \( \omega^-\mathcal{A} \circ \text{C}^-(\varphi) \)) shall just be called a right (resp. left) derived functor of \( \varphi \), and we shall just write \( R\varphi \) (resp. \( L\varphi \)) to denote this functor.

Remark 7.3.29. Keep the situation of definition 7.3.27

(i) As usual, if the right derived functor of \( F \) exists, it is unique up to isomorphism. More precisely, let \((RF, \mu)\) be any pair as in definition 7.3.27(i); if \((G, \zeta)\) is any other such pair fulfilling the same universal condition, there exists a unique isomorphism of functors \( \xi : RF \cong G \) such that (7.3.28) holds. Likewise one characterizes left functors up to isomorphism.

(ii) For \( F \) as in definition 7.3.27(i) (resp. definition 7.3.27(ii)), we shall use, for every \( p \in \mathbb{Z} \) and every object \( K^\bullet \) of \( \text{D}^+(\mathcal{A}) \) (resp. of \( \text{D}^-(\mathcal{A}) \)), the standard notation:
\[
R^pFK^\bullet := H^p(RFK^\bullet) \quad (\text{resp. } L^pFK^\bullet := H^p(LFK^\bullet)).
\]
Also, if \( \varphi \) is as in definition 7.3.27(iii), and the right (resp. left) derived functor of \( \varphi \) exists, then we have a natural transformation
\[
\varphi A \to R^0\varphi A[0] \quad (\text{resp. } L^0\varphi A[0] \to \varphi A) \quad \text{for every } A \in \text{Ob}(\mathcal{A})
\]
and it is easily seen that this transformation is an isomorphism of functors if and only if \( \varphi \) is left exact (resp. right exact: details left to the reader).

(iii) Suppose that \( \mathcal{A} \) has enough injectives (see remark 7.3.22(ii)), and \( F : \text{C}^+(\mathcal{A}) \to \text{D}(\mathcal{B}) \) is a functor that factors through \( \text{Hot}^+(\mathcal{A}) \) (via the natural functor (7.1.5)). Then the right derived functor of \( F \) exists, and can be constructed as follows. First, say that \( f^\bullet : I^\bullet \to J^\bullet \) is a quasi-isomorphism, with \( I^\bullet, J^\bullet \in \text{Ob}(\text{C}^+(\mathcal{A})) \) (where \( \mathcal{A} \) is as in remark 7.3.22(ii)). By theorem 7.3.25(i), it follows that \( f^\bullet \) is a homotopy equivalence, so \( Ff^\bullet \) is an isomorphism by assumption, and therefore \( F \) induces a functor
\[
RF_f : \text{D}^+_\mathcal{A} \to \text{D}^+(\mathcal{B})
\]
(note of (7.3.19)). However, according to proposition 7.3.20, the natural functor \( i^+ : \text{D}^+_\mathcal{A} \to \text{D}^+(\mathcal{A}) \) admits a quasi-inverse \( j^+ : \text{D}^+(\mathcal{A}) \to \text{D}^+_\mathcal{A} \); in view of claim 7.3.21 the functor \( j^+ \) can be described by choosing, for every object \( K^\bullet \) of \( \text{C}^+(\mathcal{A}) \), a quasi-isomorphism
\[
\tau^\bullet_K : K^\bullet \to I^\bullet_K \quad \text{with } I^\bullet_K \in \text{Ob}(\text{C}^+(\mathcal{A})).
\]
With this notation, we let
\[ RF := R F_{\gamma} \circ j^+ \]
and we define a natural transformation \( \mu : F \Rightarrow RF \circ \omega^+_\gamma \), by the rule:
\[ K^\bullet \mapsto F(\tau^\bullet_K) \quad \text{for every} \ K^\bullet \in \text{Ob}(C^+(\mathcal{A})). \]

Now, suppose that \( G : D^+(\mathcal{A}) \to D(\mathcal{B}) \) is another functor, with a natural transformation \( \zeta : F \Rightarrow G \circ \omega^+_\gamma \). There follows a commutative diagram in \( D(\mathcal{B}) \)
\[
\begin{array}{ccc}
FK^\bullet & \xrightarrow{\xi_K} & GK^\bullet \\
\downarrow F\tau_K & & \downarrow G\tau_K \\
FI_K & \xrightarrow{\zeta_K} & GI_K
\end{array}
\]
in which \( G\tau^\bullet_K \) is an isomorphism. It follows that \( (7.3.28) \) holds if and only if \( \xi_K = (G\tau^\bullet_K)^{-1} \circ \zeta^\bullet_K \) for every \( K^\bullet \in \text{Ob}(C^+(\mathcal{A})) \), and therefore \( (RF, \mu) \) is a derived functor of \( F \), as stated. This is essentially the original construction of the right derived functor proposed by Grothendieck in \([67]\), which predates the invention of derived categories. Dually, one obtains likewise a left derived functor of \( F \), in case \( \mathcal{A} \) has enough projectives: in this case, one starts by fixing, for every bounded above complex \( K^\bullet \) of \( \mathcal{A} \), a quasi-isomorphism \( P^\bullet_K \to K^\bullet \) with \( P^\bullet \) in \( C^+(\mathcal{P}) \).

(iv) From \([67, Lemme 3.3.1]\) one can also extract a construction which works only for additive functors \( F : \mathcal{A} \to \mathcal{B} \), but which requires only that \( \mathcal{A} \) has enough \( F \)-acyclic objects. Namely, let us suppose that \( \mathcal{A} \) contains a full subcategory \( \mathcal{M} \) with the following properties:

(a) For every \( A \in \text{Ob}(\mathcal{A}) \), there exists a monomorphism \( A \to M \), with \( M \in \text{Ob}(\mathcal{M}) \).
(b) For every \( M, M' \in \text{Ob}(\mathcal{M}) \) and every short exact sequence in \( \mathcal{A} \)

\[ \Sigma : 0 \to M' \to M \to M'' \to 0 \]

the object \( M'' \) is also in \( \mathcal{M} \), and \( \Sigma \) induces a short exact sequence

\[ F(\Sigma) : 0 \to F(M') \to F(M) \to F(M'') \to 0. \]

Then we obtain a right derived functor of \( F \) as follows. First, let \( (M^\bullet, d^\bullet_M) \) be any acyclic object of \( C^+(\mathcal{M}) \); an easy induction shows that the induced sequences

\[ \Sigma^i : 0 \to \text{Im} d^i \to M'^{i+1} \to \text{Im} d^{i+1} \to 0 \]

are short exact and \( \text{Im} d^i \in \text{Ob}(\mathcal{M}) \) for every \( i \in \mathbb{Z} \). By assumption, the sequences \( F(\Sigma^i) \) are then also short exact, and therefore \( FM^\bullet \) is still acyclic. Next, let \( f^\bullet : M^\bullet \to N^\bullet \) be any quasi-isomorphism in \( C^+(\mathcal{M}) \); then \( \text{Cone} f^\bullet \) is acyclic, so the same holds for \( F(\text{Cone} f^\bullet) \), by the foregoing, and since \( C^+(F) \) is a triangulated functor, we conclude that \( Ff^\bullet \) is still a quasi-isomorphism. Thus, \( C^+(F) \) induces a functor

\[ RF_{\mathcal{M}} : D^+_\mathcal{M}(\mathcal{A}) \to D^+(\mathcal{B}). \]

On the other hand, proposition \([7.3.20]\) says that the natural functor \( i^+ : D^+_\mathcal{M}(\mathcal{A}) \to D^+(\mathcal{A}) \) admits a quasi-inverse \( j^+ : D^+(\mathcal{A}) \to D^+_\mathcal{M}(\mathcal{A}) \), so we may set again

\[ RF := RF_{\mathcal{M}} \circ j^+ \]

and one obtains as in (iii) a natural transformation \( \mu \), such that the pair \( (RF, \mu) \) fulfills the required universal property: details left to the reader.

(v) Notice that any short exact sequence \( 0 \to I' \to I \to I'' \to 0 \) in \( \mathcal{A} \) with \( I' \) injective, is split, and \( I'' \) is injective if and only if the same holds for \( I \). Hence, if \( \mathcal{A} \) has enough injectives, the category \( \mathcal{M} := \mathcal{A} \) fulfills the conditions of (iv) for every additive functor \( F \). Conversely, suppose that \( \mathcal{M} \) fulfills the conditions of (iv), and moreover, every \( A \in \text{Ob}(\mathcal{A}) \) isomorphic to a direct factor of an object of \( \mathcal{M} \), is an object of \( \mathcal{M} \). Then \( \mathcal{M} \) contains every injective object
Remark 7.3.33. In the situation of example 7.3.30, our methods do not allow us to extend the functor \( L \) factors through \( \text{Hot}(\mathcal{A}) \times \text{Hot}(\mathcal{A})^o \) (see example 7.1.25); hence, after fixing an equivalence \( f^+ : D^+(\mathcal{A}) \to D^+_J(\mathcal{A}) \) and arguing as in remark 7.3.29(iii), we deduce a functor

\[
R\text{Hom}_\mathcal{A} : D^+(\mathcal{A}) \times \text{Hot}(\mathcal{A})^o \to D(\mathbb{Z}\text{-Mod})
\]

such that, for every \( K^* \in \text{Ob}(\text{Hot}(\mathcal{A})) \), the restriction

\[
D^+(\mathcal{A}) \to D(\mathbb{Z}\text{-Mod}) : L^* \mapsto R\text{Hom}_\mathcal{A}(K^*, L^*)
\]

is the derived functor of the functor \( \text{Hom}_\mathcal{A}(K^*, -) : C^+(\mathcal{A}) \to D(\mathbb{Z}\text{-Mod}) \). Moreover, (7.3.31) is triangulated, by proposition 7.3.7. Furthermore, let \( \varphi^* : K^n_2 \to K^n_2 \) be any quasi-isomorphism in \( \text{Hot}(\mathcal{A}) \); we claim that \( R\text{Hom}_\mathcal{A}(\varphi^*, L^*) \) is a quasi-isomorphism, for every \( L^* \in \text{Ob}(D^+(\mathcal{A})) \). Indeed, let \( I^n_2 := j^+L^n \); by example 7.1.15(i) and corollary 7.3.26 we have natural isomorphisms of abelian groups

\[
H^n R\text{Hom}_\mathcal{A}(\varphi^*, L^*) \cong \text{Hot}_\mathcal{A}(\varphi^*, I^n_2[n]) \cong \text{Hom}_\mathcal{A}(\varphi^*, I^n_2[n])
\]

whence the contention. It follows that \( R\text{Hom}_\mathcal{A} \) descends to an additive functor

\[
R\text{Hom}_\mathcal{A} : D^+(\mathcal{A}) \times D(\mathbb{Z}\text{-Mod})^o \to D(\mathbb{Z}\text{-Mod})
\]

with a natural isomorphism of abelian groups, for every \( K^* \in D(\mathcal{A}) \) and every \( L^* \in D^+(\mathcal{A}) : (7.3.32)

\[
R^n\text{Hom}_\mathcal{A}(K^*, L^*) \cong \text{Hom}_\mathcal{A}(K^*, L^*[n]).
\]

Remark 7.3.33. In the situation of example 7.3.30 our methods do not allow us to extend the functor \( R\text{Hom}_\mathcal{A} \) to unbounded complexes in both arguments, but still we can show that every \( L^* \in D(\mathcal{A}) \) and every distinguished triangle of \( D(\mathcal{A})\)

\[
\Theta : K^* \to K''^* \to K^*[1]
\]

induce a long exact Ext-sequence:

\[
\text{Hom}_{D(\mathcal{A})}(L^*, K^*) \to \text{Hom}_{D(\mathcal{A})}(L^*, K''^*) \to \text{Hom}_{D(\mathcal{A})}(L^*, K^*[1]) \to \cdots
\]

Indeed, let \( L^* \to L^* \) be any quasi-isomorphism; we may assume that \( \Theta \) is already a distinguished triangle of \( \text{Hot}(\mathcal{A}) \), and due to proposition 7.3.7 and remark 7.3.5(iii), we get the long exact sequence

\[
\text{Hot}_{\mathcal{A}}(L^*, K^*) \to \text{Hot}_{\mathcal{A}}(L^*, K''^*) \to \text{Hot}_{\mathcal{A}}(L^*, K^*[1]) \to \cdots
\]

and on the other hand, theorem 7.3.16(ii) implies that \( \text{Hom}_{D(\mathcal{A})}(L^*, K^*) \) is isomorphic to the colimit of the system \( \text{Hot}_{\mathcal{A}}(L^*, K^*) \to L^* \to L^* \) indexed by the filtered set of all such quasi-isomorphisms (proposition 1.6.16(i)). Since all filtered colimits are exact in the category of abelian groups, the assertion follows. Likewise, from \( \Theta \) and any \( L^* \in \text{Ob}(D(\mathcal{A})) \) we get as well the long exact Ext-sequence:

\[
\text{Hom}_{D(\mathcal{A})}(K'^*[1], L^*) \to \text{Hom}_{D(\mathcal{A})}(K''^*, L^*) \to \text{Hom}_{D(\mathcal{A})}(K^*, L^*) \to \cdots
\]
**Example 7.3.34.** (i) Remark [7.3.29](iv) can be adapted to biaxitive functors. Namely, in the situation of (7.1.23), let us say that an object $A$ of $\mathcal{A}$ (resp. $A'$ of $\mathcal{A}'$) is left $B$-flat (resp. right $B$-flat) if the additive functor $B(A, -)$ (resp. $B(-, A')$) is exact. We assume that:

- $\mathcal{A}$ has enough left $B$-flat objects and $\mathcal{A}'$ has enough right $B$-flat objects; i.e. for every $M \in \text{Ob}(\mathcal{A})$ (resp. $M' \in \text{Ob}(\mathcal{A}')$) there exists an epimorphism $A \to M$ (resp. $A' \to M'$), where $A$ (resp. $A'$) is a left (resp. right) $B$-flat object of $\mathcal{A}$ (resp. of $\mathcal{A}'$).

Let us denote by $\mathcal{F}$ (resp. $\mathcal{F}'$) the full subcategory of $\mathcal{A}$ (resp. of $\mathcal{A}'$) whose objects are the left $B$-flat (resp. right $B$-flat) objects of $\mathcal{A}$ (of $\mathcal{A}'$). By remark [7.3.22](i), the natural functors

\[ D^{-}\mathcal{F}(\mathcal{A}) \rightarrow D^{-}(\mathcal{A}) \quad D^{-}\mathcal{F}'(\mathcal{A}') \rightarrow D^{-}(\mathcal{A}') \]

are equivalences. On the other hand, let $P^*$ be any object of $C^{-}(\mathcal{F})$, and $f^* : K^* \to L^*$ any quasi-isomorphism in $C^{-}(\mathcal{A}')$; we wish to show that the induced morphism $B^*_*(P^*, f^*)$ is a quasi-isomorphism as well. By remark [7.3.8] it suffices to check that $B^*_*(P^*, \text{Cone } f^*)$ is acyclic. However, the double complex $B^*(P^*, \text{Cone } f^*)$ yields a convergent spectral sequence

\[ E^{i,j}_1 := H^iB(P^*, \text{Cone } f^*) \Rightarrow H^{i+j}B^*_*(P^*, \text{Cone } f^*) \]

and since $P^j$ is left $B$-flat and $\text{Cone } f^*$ is acyclic, we get $E^{i,j}_1 = 0$ for every $i, j \in \mathbb{Z}$, whence the claim. Likewise, we see that $B^*(g^*, Q^*)$ is a quasi-isomorphism, whenever $Q^* \in \text{Ob}(C^{-}(\mathcal{F}'))$ and $g^*$ is any quasi-isomorphism in $C^{-}(\mathcal{A})$. Then, as in remark [7.3.29](iv), after fixing quasi-inverse functors for the equivalences (7.3.35), we obtain a functor

\[ LB^*_* : D^{-}(\mathcal{A}) \times D^{-}(\mathcal{A}') \rightarrow D^{-}(\mathcal{A}'') \]

with a natural transformation

\[ \mu : LB^*_* \circ (\omega_{\mathcal{A}} \times \omega_{\mathcal{A}'}) \rightarrow \omega_{\mathcal{A}''} \circ B^*_* \]

such that, for every $K^* \in \text{Ob}(C^{-}(\mathcal{A}))$, the induced functor

\[ D^{-}(\mathcal{A}') \rightarrow D^{-}(\mathcal{A}'') : X^* \mapsto LB^*_*(K^*, X^*) \]

together with the corresponding restriction of $\mu$, is a left derived functor of $B^*_*(K^*, -)$. Symmetrically, for every $K^* \in \text{Ob}(C^{-}(\mathcal{A}''))$, the functor $LB^*_*(-, K^*)$ provides a left derived functor of $B^*_*(-, K^*)$; details left to the reader.

(ii) By remark [7.3.29](ii), the following conditions are equivalent:

(a) The induced morphism

\[ B^* : \mathcal{A} \times \mathcal{A}' \rightarrow \mathcal{A}'' \]

is an isomorphism for every $A \in \text{Ob}(\mathcal{A})$ and every $A' \in \text{Ob}(\mathcal{A}')$.

(b) The functor $B : \mathcal{A} \rightarrow \mathcal{A}''$ is right exact for every $A \in \text{Ob}(\mathcal{A})$.

(c) The functor $B : \mathcal{A} \rightarrow \mathcal{A}''$ is right exact for every $A' \in \text{Ob}(\mathcal{A}')$.

Moreover, $B^*$ is obviously another biadditive functor $\mathcal{A} \times \mathcal{A}' \rightarrow \mathcal{A}''$, and every right (resp. left) $B^*$-flat object of $\mathcal{A}$ (of $\mathcal{A}'$) is also a right (resp. left) $B^*$-flat object. Thus, $\mathcal{A}$ has enough right $B^*$-flat objects and $\mathcal{A}'$ has enough left $B^*$-flat objects, so we may define as well the left derived functor $LB^*_{\mathcal{A}}$ of $B^*$. Furthermore, a simple inspection shows that the functors $B^* : \mathcal{A} \rightarrow \mathcal{A}$ and $B^*(-, A')$ are right exact, for every $A \in \text{Ob}(\mathcal{A})$ and $A' \in \text{Ob}(\mathcal{A}')$, and the induced morphism

\[ LB^* : \mathcal{A} \rightarrow \mathcal{A} \]

is an isomorphism of functors. Lastly, an object $P$ of $\mathcal{A}$ (resp. $P'$ of $\mathcal{A}'$) is right (resp. left) $B^*$-flat if and only if $L^1B(P, -)$ (resp. $L^1B(-, P')$) is the (constant) zero functor. The detailed verifications of all these assertions shall be left as exercises for the reader.
7.3.36. Let \((\mathcal{A}, \otimes, \Phi, \Psi)\) be any abelian tensor category; example 7.3.34 applies especially to the functor \(\otimes\). In this case, it is clear that an object of \(\mathcal{A}\) is left \(\otimes\)-flat if and only if it is right \(\otimes\)-flat, and such objects shall therefore be called simply \(\otimes\)-flat. Thus, suppose that \(\mathcal{A}\) has enough \(\otimes\)-flat objects; we conclude that the induced tensor functor for complexes of \(\mathcal{A}\) (see example 7.1.16) admits a left derived functor
\[
- \otimes^L : D^-(\mathcal{A}) \times D^-(\mathcal{A}) \to D^-(\mathcal{A})
\]
called the \textit{derived tensor product}. Explicitly, this is defined as follows: for every bounded above complex \(K^*\) we fix a quasi-isomorphism \(\rho_K^* : P_K^* \to K^*\) with \(P_K^*\) a bounded above complex of \(\otimes\)-flat objects, and we set
\[
K^* \otimes^L L^* := P_K^* \otimes P_L^*.
\]
By inspecting the construction, we also see that \(K^* \otimes^L L^*\) is naturally isomorphic – via \(\rho_K^*\) and \(\rho_L^*\) – to both \(K^* \otimes P_L^*\) and \(P_K^* \otimes L^*\). Moreover, if \(A\) is any object of \(\mathcal{A}\), clearly the functor \(A \otimes - : \mathcal{A} \to \mathcal{A}\) is right exact if and only if the same holds for the functor \(- \otimes A : \mathcal{A} \to \mathcal{A}\), and remark 7.3.29(ii) implies that the latter condition holds if and only if the induced morphism
\[
H^0(A[0] \otimes B[0]) \to A \otimes B
\]
is an isomorphism for every \(B \in \text{Ob}(\mathcal{A})\). We also let
\[
\text{Tor}^\mathcal{A}_i(K^*, L^*) := H_i(K^* \otimes^L L^*) \quad \text{for every } i \in \mathbb{Z}.
\]
In case \(\mathcal{A} = A\text{-Mod}\) for some ring \(A\), it is customary to denote this functor by \(- \otimes_A -\), and then one also writes \(\text{Tor}^A_i\) instead of \(\text{Tor}^\mathcal{A}_i\).

\textbf{Remark 7.3.37.} (i) Using the commutativity and associativity constraints for the tensor product in \(\mathcal{A}\), we deduce – in light of example 7.1.16(i,ii) – natural associativity isomorphisms
\[
K^* \otimes^L (L^* \otimes^L Q^*) \cong (K^* \otimes^L L^*) \otimes^L Q^* \quad \text{in } D^-(\mathcal{A})
\]
as well as commutativity isomorphisms
\[
K^* \otimes^L L^* \cong L^* \otimes^L K^* \quad \text{in } D^-(\mathcal{A})
\]
for any bounded above complexes \(K^*, L^*,\) and \(Q^*\).

(ii) In the situation of (7.3.36), take \(\mathcal{A} = A\text{-Mod}\) for some ring \(A\), and suppose furthermore that \(\varphi : A \to B\) is a ring homomorphism, \(K^*\) a bounded above complex of \(A\)-modules, and \(L^*\) a complex of \(B\)-modules. Notice that \(P_K^* \otimes_A L^*\) is naturally a complex of \(B\)-modules; also, if \(L^* \to Q^*\) is any morphism of complexes of \(B\)-modules, then the induced map \(P_K^* \otimes_A L^* \to P_K^* \otimes_A Q^*\) is \(B\)-linear. It follows easily that the derived tensor product yields a functor
\[
D^-(A\text{-Mod}) \times D^-(B\text{-Mod}) \to D^-(B\text{-Mod}) \quad (K^*, L^*) \mapsto K^* \otimes_A L^*
\]
such that, denoting \(\varphi^* : D^-(B\text{-Mod}) \to D^-(A\text{-Mod})\) the “forgetful” functor, we have a natural isomorphism
\[
K^* \otimes_A \varphi^* L^* \cong \varphi^*(K^* \otimes_A L^*) \quad \text{in } D^-(A\text{-Mod}).
\]
Let now $M_1^\bullet, M_2^\bullet, N_1^\bullet, N_2^\bullet$ be any four objects of $\mathcal{C}^-(\mathscr{A})$, and to ease notation, set

$$M_{12}^\bullet := M_1^\bullet \otimes M_2^\bullet \quad N_{12}^\bullet := N_1^\bullet \otimes N_2^\bullet \quad P_{12}^\bullet := P_{M_{12}}^\bullet \quad \rho_{12}^\bullet := \rho_{M_{12}}^\bullet$$

as well as $P_i^\bullet := P_{M_i}^\bullet$ and $\rho_i^\bullet := \rho_{M_i}^\bullet$ for $i = 1, 2$. There is a commutative diagram in $D^-(\mathscr{A})$

$$
\begin{array}{ccc}
P_1^\bullet \otimes P_2^\bullet & \xrightarrow{\varphi_{12}} & P_{12}^\bullet \\
\rho_1^\bullet \otimes \rho_2^\bullet & & \varphi_{12} \\
M_{12}^\bullet & & \rho_{12}^\bullet
\end{array}
$$

where $\rho_{12}^\bullet$ is an isomorphism, so $\varphi_{12}$ is uniquely determined, whence a map

$$(M_1^\bullet \otimes N_1^\bullet) \otimes (M_2^\bullet \otimes N_2^\bullet) \xrightarrow{\varphi_{12} \otimes N_{12}^\bullet} P_{12}^\bullet \otimes N_{12}^\bullet \xrightarrow{\varphi_{12} \otimes N_{12}^\bullet} M_{12}^\bullet \otimes N_{12}^\bullet.
$$

Taking into account example 7.1.16(iii) and remark 7.3.14(v), we deduce a bilinear pairing

$$\text{Tor}_{ij}^f(M_1^\bullet, N_1^\bullet) \otimes \text{Tor}_{ij}^f(M_2^\bullet, N_2^\bullet) \to \text{Tor}_{ij}^{f_j}(M_{12}^\bullet, N_{12}^\bullet) \quad \text{for every } i, j \in \mathbb{Z}.
$$

Moreover, suppose that $M_3^\bullet$ and $N_3^\bullet$ are two other bounded above complexes of $\mathscr{A}$; by inspecting the constructions, we find a commutative diagram

$$
\begin{array}{ccc}
P_1^\bullet \otimes (P_2^\bullet \otimes P_3^\bullet) & \xrightarrow{\varphi_{12} \otimes \varphi_{23}} & P_1^\bullet \otimes P_{23}^\bullet \\
\rho_1^\bullet \otimes \rho_2^\bullet \otimes \rho_3^\bullet & & \rho_1^\bullet \otimes \rho_{23}^\bullet \\
(M_1^\bullet \otimes P_2^\bullet) \otimes P_3^\bullet & & \varphi_{12} \otimes P_3^\bullet \\
\Phi_P^\bullet & & \varphi_{12} \otimes P_3^\bullet \\
(P_1^\bullet \otimes P_2^\bullet) \otimes P_3^\bullet & & P_2^\bullet \otimes P_3^\bullet \\
\Phi_M^\bullet & & \Phi_{M_P}^\bullet \\
M_{123}^\bullet & & P_{123}^\bullet
\end{array}
$$

where $M_{123}^\bullet := M_{12}^\bullet \otimes M_3^\bullet, M_{23}^\bullet := M_2^\bullet \otimes M_3^\bullet, M_{123}^\bullet := M_1^\bullet \otimes M_{23}^\bullet$, and likewise for $P_{123}^\bullet, P_{23}^\bullet$, and $P_{123}^\bullet$ and the morphism $\varphi_{23}, \varphi_{123}, \varphi_{123}, \rho_{23}, \rho_{123}, \rho_{123}$. Here $\Phi_M^\bullet$ and $\Phi_P^\bullet$ are the associativity constraints.

Therefore, set $T_{ij}^k := \text{Tor}_{ij}^f(M_{jk}^\bullet, N_{jk}^\bullet)$ for every $i, j, k \in \mathbb{Z}$ and also

$$T_{ij}^k := \text{Tor}_{ij}^f(M_{jk}^\bullet, N_{jk}^\bullet) \quad T_{i}^{1,23} := \text{Tor}_{i}^f(M_{12}^\bullet, N_{12}^\bullet) \quad T_{i}^{12,3} := \text{Tor}_{i}^f(M_{12}^\bullet, N_{12}^\bullet)$$

for every $i \in \mathbb{Z}$, with $j = 1, 2$ and $k = j + 1$; in light of example 7.1.16(iv), we deduce a commutative diagram in $\mathscr{A}$:

$$
\begin{array}{cccc}
T_{i}^1 \otimes (T_{j}^2 \otimes T_{k}^3) & \xrightarrow{T_{i}^1 \otimes T_{j}^{23}} & T_{i}^1 \otimes T_{j}^{23+}j+k & \xrightarrow{T_{i}^{1,23}} & T_{i}^{1,23+}j+k \\
\downarrow & & \downarrow & & \downarrow \\
(T_{i}^1 \otimes T_{j}^2) \otimes T_{k}^3 & \xrightarrow{T_{i}^{12} \otimes T_{k}^3} & T_{i}^{12} \otimes T_{k}^3 & \xrightarrow{T_{i}^{12,3}} & T_{i}^{12,3+}j+k
\end{array}
$$

whose horizontal arrows are given by the above bilinear pairing, and whose left (resp. right) vertical arrow is the associativity constraint (resp. is induced by the associativity constraint $\Phi_{M_P}^\bullet$).

The following lemma is borrowed from [16 Exp.VII,Prop.1.8(ii)]:

**Lemma 7.3.40.** Let $\mathscr{A}$ be any abelian category and $a, b \in \mathbb{Z}$ any two integers. We have:
Proposition 7.3.43. \(\text{Let } K^\bullet \in \text{Ob}(\mathcal{D}^{\leq b}(\mathcal{A})) \) and \( L^\bullet \in \text{Ob}(\mathcal{D}^{\geq a}(\mathcal{A})) \) be any two complexes, and suppose that \( \mathcal{A} \) has enough injectives. Then the complex \( R\text{Hom}_A^l(K^\bullet, L^\bullet) \) lies in \( \mathcal{D}^{\geq a-b}(\mathcal{A}) \).

(ii) Suppose that \( (\mathcal{A}, \otimes, \Phi, \Psi) \) is an abelian tensor category with enough \( \otimes \)-flat objects, and let \( K^\bullet \in \text{Ob}(\mathcal{D}^{\leq a}(\mathcal{A})) \) and \( L^\bullet \in \text{Ob}(\mathcal{D}^{\leq b}(\mathcal{A})) \). Then \( K^\bullet \otimes L^\bullet \in \text{Ob}(\mathcal{D}^{\leq a+b}(\mathcal{A})) \).

Proof. (i) follows easily from (7.3.32) and remark 7.3.14(iv); details left to the reader. Assertion (ii) follows immediately from the construction of the derived tensor product.

\[ \square \]

7.3.41. Complexes of modules over a ring. We conclude this section with a discussion of a few special features of the category of complexes of modules over a ring and of its derived category.

7.3.42. Let \( A \) be any ring; to ease notation we set
\[ C(A) := C(A, \text{-Mod}) \quad \text{Hot}(A) := \text{Hot}(A, \text{-Mod}) \quad D(A) := D(A, \text{-Mod}) \]
and likewise we define \( C^I(A), \text{Hot}^I(A) \) and \( D^I(A) \) for any interval \( I \subset \mathbb{Z} \).

**Proposition 7.3.43.** With the notation of (7.3.42), the following holds:

(i) The localization functor \( j^1 : C^I(A) \to D^I(A) \) commutes with direct sums and direct products.

(ii) Let \( (K_n^\bullet, \varphi_n^\bullet : K_n^\bullet \to K_{n+1}^\bullet \mid n \in \mathbb{N}) \) be any direct system of objects of \( C^I(A) \), and \( L^\bullet \) its colimit in the category \( C^I(A) \). Then \( L^\bullet \) represents also the colimit of the system \( j^1(K_n^\bullet), j^1(\varphi_n^\bullet) \mid n \in \mathbb{N} \) in the category \( D^I(A) \).

(iii) Let \( (K_n^\bullet, \varphi_n^\bullet : K_n^\bullet \to K_{n+1}^\bullet \mid n \in \mathbb{N}) \) be any inverse system of complexes of \( A \)-modules, and \( L^\bullet \) its limit in the category \( C(A) \). Suppose that for every \( i \in \mathbb{Z} \) the inverse system \( (K_n^i, \varphi_n^i \mid n \in \mathbb{N}) \) satisfies the Mittag-Leffler condition. Then for every object \( C^\bullet \) of \( D(A) \) we have a short exact sequence
\[ 0 \to \lim_{n \in \mathbb{N}}^1 \text{Hom}_{D(A)}(C^\bullet, K_n^\bullet[-1]) \to \text{Hom}_{D(A)}(C^\bullet, L^\bullet) \to \lim_{n \in \mathbb{N}} \text{Hom}_{D(A)}(C^\bullet, K_n^\bullet) \to 0. \]

Proof. (i): In light of remark 7.1.6(vi), it suffices to check that the localization functor
\[ \text{Hot}^I(A) \to D^I(A) \]
commutes with direct sums and direct products. Hence, consider any family \( (K_j^\bullet \mid j \in J) \) of objects of \( \text{Hot}^I(A) \) indexed by a small set \( J \), set \( K^\bullet := \prod_{j \in J} K_j^\bullet \), the direct product in the category \( C^I(A) \), and denote by \( \pi_j^\bullet : K^\bullet \to K_j^\bullet \) the canonical projection, for every \( j \in J \); we know that \( K^\bullet \) represents also the direct product of the family \( K_j^\bullet \) in \( \text{Hot}^I(A) \). Hence, let \( L^\bullet \) be any other object of \( \text{Hot}^I(A) \); from any morphism \( \varphi^\bullet : L^\bullet \to K^\bullet \) in \( D^I(A) \) we obtain the system \( (\varphi_j^\bullet := \pi_j^\bullet \circ \varphi^\bullet : K_j^\bullet \to L^\bullet \mid j \in J) \) of morphisms in \( D^I(A) \). Conversely, given such a system of morphisms, we know by theorem 7.3.16(ii) that there exist for every \( j \in J \) a quasi-isomorphism \( \psi_j^\bullet : K_j^\bullet \to K^\bullet \) and a morphism \( \varphi_j^\bullet : K^\bullet \to L^\bullet \) in \( C^I(A) \) representing the class of \( \varphi^\bullet \) in \( \text{Hot}^I(A) \). The systems \( \{K_j^\bullet \mid j \in J\} \) and \( \{\psi_j^\bullet \mid j \in J\} \) yield morphisms \( \varphi^\bullet : K^\bullet := \prod_{j \in J} K_j^\bullet \to L^\bullet \) and \( \psi^\bullet : K^\bullet \to K^\bullet \), and we come down to checking that \( \psi^\bullet \) is a quasi-isomorphism. However, we have \( H^rK^\bullet = \prod_{j \in J} H^rK_j^\bullet \) and likewise for \( H^rK^\bullet \), for every \( r \in \mathbb{Z} \), and under this identification the map \( H^r\psi^\bullet \) equals \( \prod_{j \in J} H^r\psi_j^\bullet \), whence the contention. A similar argument proves the assertion for direct sums.

(ii): We have commutative diagrams in \( C(A) \):

\[
\begin{array}{ccc}
K_i^\bullet & \xrightarrow{\psi_i^\bullet} & K_i^\bullet \oplus K_{i+1}^\bullet \\
\downarrow & & \downarrow \\
0 & \xrightarrow{\oplus_{n \in \mathbb{N}} K_n^\bullet} & \oplus_{n \in \mathbb{N}} K_n^\bullet \xrightarrow{\psi^\bullet} L^\bullet \xrightarrow{} 0
\end{array}
\]

for every \( i \in \mathbb{N} \).
whose bottom rows are the same short exact sequence for every \( i \in \mathbb{N} \), and with \( \psi_i(x) := (x, -\varphi^*_i(x)) \) for every \( i \in \mathbb{N} \), every \( r \in \mathbb{Z} \) and every \( x \in K^r_i \). For every object \( C^* \) of \( D(A) \) set

\[
P(k) := \prod_{n \in \mathbb{N}} \text{Hom}_{D(A)}(K^*_n, C^*[k]) \quad \tilde{\psi}(k) := \text{Hom}_{D(A)}(\psi^*, C^*[k]) \quad \text{for every } k \in \mathbb{Z}.
\]

By (i) and remark \([7,3,33]\) there follows a long exact sequence:

\[
\text{Hom}_{D(A)}(L^*, C^*[k]) \rightarrow P(k) \xrightarrow{\tilde{\psi}(k)} P(k) \rightarrow \text{Hom}_{D(A)}(L^*, C^*[k + 1]) \rightarrow \cdots
\]

and commutative diagrams for every \( i \in \mathbb{N} \) and \( k \in \mathbb{Z} \):

\[
\begin{array}{ccc}
P(k) & \xrightarrow{T(k)} & P(k) \\
\downarrow & & \downarrow \\
\text{Hom}_{D(A)}(K^*_i \oplus K^*_{i+1}, C^*[k]) & \longrightarrow & \text{Hom}_{D(A)}(K^*_i, C^*[k])
\end{array}
\]

(7.3.44)

whose bottom rows are induced by \( \psi^*_i \). Thus, \( \text{Ker} \tilde{\psi}(0) \) consists of the systems of morphisms \((\beta^*_n : K^*_n \rightarrow C^* \mid n \in \mathbb{N})\) such that \( \beta^*_{n+1} \circ \varphi^*_n = \beta^*_n \) for every \( n \in \mathbb{N} \). In other words, \( \text{Ker} \tilde{\psi}(0) \) is naturally identified with the set of cocones with basis \((K^*_n \mid n \in \mathbb{N})\) and vertex \( C^* \) in the category \( D(A) \). Moreover, considering (7.3.44) with \( k = -1 \), a simple induction on \( i \) shows that \( \tilde{\psi}(-1) \) is surjective (details left to the reader); summing up, we have a natural identification

\[
\text{Hom}_{D(A)}(L^*, C^*) \rightarrow \text{Hom}_{D(A)}(\text{colim}_{n \in \mathbb{N}} j_i^*(K^*_n), C^*)
\]

whence the assertion.

(iii): We argue similarly, considering the commutative diagram in \( C(A) \):

\[
\begin{array}{ccc}
0 & \longrightarrow & L^* \\
\longrightarrow & & \longrightarrow \\
\prod_{n \in \mathbb{N}} K^*_n & \xrightarrow{\mu^*} & \prod_{n \in \mathbb{N}} K^*_n \\
\downarrow & & \downarrow \\
K^*_i \oplus K^*_{i+1} & \xrightarrow{\mu^*} & K^*_i \\
& & \downarrow
\end{array}
\]

for every \( i \in \mathbb{N} \)

whose top row is independent of \( i \) and with \( \mu_i^*(x, y) := x - \varphi^*_i(y) \) for every \( i \in \mathbb{N} \), every \( r \in \mathbb{Z} \) and every \( (x, y) \in K^r_i \oplus K^r_{i+1} \). Notice that the top row is a short exact sequence in \( C(A) \), since the system \((K^*_n \mid n \in \mathbb{N})\) satisfies the Mittag-Leffler condition for every \( r \in \mathbb{Z} \). For every \( k \in \mathbb{Z} \) and any \( C^* \in \text{Ob}(D(A)) \) set

\[
Q(k) := \prod_{n \in \mathbb{N}} \text{Hom}_{D(A)}(C^*, K^*_n[k]) \quad \tilde{\mu}(k) := \text{Hom}_{D(A)}(C^*, \mu^*[k]).
\]

By (i) and remark \([7,3,33]\) there follows a long exact sequence

\[
\text{Hom}_{D(A)}(C^*, L^*[k]) \rightarrow Q(k) \xrightarrow{\tilde{\mu}(k)} Q(k) \rightarrow \text{Hom}_{D(A)}(C^*, L^*[k + 1]) \rightarrow \cdots
\]

as well as commutative diagrams as in (7.3.44). Then, a simple inspection yields a natural identification of \( \text{Ker} \tilde{\mu}(0) \) with the set of cones in \( D(A) \) with basis \((K^*_n \mid n \in \mathbb{N})\) and vertex \( C^* \). Lastly, \( \text{Coker} \tilde{\mu}(-1) \) is naturally identified with \( \lim_{n \in \mathbb{N}} \text{Hom}_{D(A)}(C^*, K^*_n[-1]) \), whence the contention. □
7.3.45. Minimal resolutions. Let $A$ be a local ring, $k$ its residue field, and:

$$\cdots \xto{d_3} L_2 \xto{d_2} L_1 \xto{d_1} L_0 \xto{\varepsilon} M$$

a resolution of an $A$-module $M$ of finite type. We say that $(L_\bullet, d_\bullet, \varepsilon)$ is a finite-free resolution if each $L_i$ is a free $A$-module of finite rank. We say that $(L_\bullet, d_\bullet, \varepsilon)$ is a minimal free resolution of $M$ if it is a finite-free resolution, and moreover the induced maps $k \otimes_A L_i \to k \otimes_A \text{Im} d_i$ are isomorphisms for all $i \in \mathbb{N}$ (where we let $d_0 := \varepsilon$). One verifies easily that if $A$ is a coherent ring, then every finitely presented $A$-module admits a minimal resolution.

7.3.46. Let $L := (L_\bullet, d_\bullet, \varepsilon)$ and $L' := (L'_\bullet, d'_\bullet, \varepsilon')$ be two free resolutions of $M$. A morphism of resolutions $L \to L'$ is a map of complexes $\varphi_\bullet : (L_\bullet, d_\bullet) \to (L'_\bullet, d'_\bullet)$ that extends to a commutative diagram

$$
\begin{array}{c}
L_\bullet \xto{\varphi} M \\
\downarrow \quad \downarrow \\
L'_\bullet \xto{\varepsilon'} M
\end{array}
$$

**Lemma 7.3.47.** Let $L := (L_\bullet, d_\bullet, \varepsilon)$ be a minimal free resolution of an $A$-module $M$ of finite type, $L' := (L'_\bullet, d'_\bullet, \varepsilon')$ any other finite-free resolution, $\varphi : (L_\bullet, d_\bullet) \to (L'_\bullet, d'_\bullet)$ that extends to a commutative diagram.

**Proof.** Suppose first that $L = L'$. We set $d_0 := \varepsilon$, $L_{-1} := M$, $\varphi_{-1} := 1_M$ and we show by induction on $n$ that $\varphi_n$ is an isomorphism. Indeed, this holds for $n = -1$ by definition. Suppose that $n \geq 0$ and that the assertion is known for all $j < n$; by a little diagram chasing (or the five lemma) we deduce that $\varphi_{n-1}$ induces an automorphism $\text{Im} d_n \cong \text{Im} d_n$, therefore $\varphi_n \otimes_A 1_k : k \otimes_A L_n \to k \otimes_A L_n$ is an automorphism (by minimality of $L$), so the same holds for $\varphi_n$ (e.g. by looking at the determinant of $\varphi_n$).

For the general case, by standard arguments we construct a morphism of resolutions $\psi_\bullet : L \to L'$. By the foregoing case, $\varphi_\bullet \circ \psi_\bullet$ is an automorphism of $L$, so $\varphi_\bullet$ is necessarily an epimorphism, and $L'$ decomposes as claimed. Finally, it is also clear that $\text{Ker} \varphi_\bullet$ is an acyclic bounded above complex of free $A$-modules, hence it is null homotopic. \(\square\)

**Remark 7.3.48.** (i) Suppose that $A$ is a coherent local ring, and let $L := (L_\bullet, d_\bullet, \varepsilon)$ and $L' := (L'_\bullet, d'_\bullet, \varepsilon')$ be two minimal resolutions of the finitely presented $A$-module $M$. It follows easily from lemma 7.3.47 that $L$ and $L'$ are isomorphic as resolutions of $M$.

(ii) Moreover, any two isomorphisms $L \to L'$ are homotopic, hence the rule: $M \mapsto L_\bullet$ extends to a functor

$$A\text{-Mod}_{\text{coh}} \to \text{Hot}(A\text{-Mod})$$

from the category of finitely presented $A$-modules to the homotopy category of complexes of $A$-modules.

(iii) The sequence of $A$-modules $(\text{Syz}_A^i M) := \text{Im} d_i \mid i > 0$ is determined uniquely by $M$ (up to non-unique isomorphism). The graded module $\text{Syz}_A^\bullet M$ is sometimes called the syzygy of the module $M$. Moreover, if $L''$ is any other finite free resolution of $M$, then we can choose a morphism of resolutions $L'' \to L$, which will be a split epimorphism by lemma 7.3.47 and the submodule $d_\bullet(L''_n) \subset L_n$ decomposes as a direct sum of $\text{Syz}_A^\bullet M$ and a free $A$-module of finite rank.

**Lemma 7.3.49.** Let $A \to B$ a faithfully flat homomorphism of coherent local rings, $M$ a finitely presented $A$-module. Then there exists an isomorphism of graded $B$-modules:

$$B \otimes_A \text{Syz}_A^\bullet M \cong \text{Syz}_B^\bullet (B \otimes_A M).$$
**Proof.** Left to the reader. □

**Proposition 7.3.50.** Let \( A \to B \) be a flat and essentially finitely presented local ring homomorphism of local rings, \( M \) an \( A \)-flat finitely presented \( B \)-module. Then the \( B \)-module \( M \) admits a minimal free resolution

\[
\Sigma_* : \cdots \to d_3 L_2 \xrightarrow{d_2} L_1 \xrightarrow{d_1} L_0 \xrightarrow{d_{-1}} L_{-1} = M.
\]

Moreover, \( \Sigma \) is universally \( A \)-exact, i.e. for every \( A \)-module \( N \), the complex \( \Sigma_* \otimes_A N \) is still exact.

**Proof.** To start out, let us notice:

**Claim 7.3.51.** In order to prove the proposition, it suffices to show that, for every \( A \)-flat finitely presented \( B \)-module \( N \), and every \( B \)-linear surjective map \( d : L \to N \), from a free \( B \)-module \( L \) of finite rank, \( \ker d \) is also an \( A \)-flat finitely presented \( B \)-module.

**Proof of the claim.** Indeed, in that case, we can build inductively a minimal resolution \( \Sigma_* \) of \( M \), such that \( N_i := \ker(d_i : L_i \to L_{i-1}) \) is an \( A \)-flat finitely presented \( B \)-module for every \( i \in \mathbb{N} \). Namely, suppose that a complex \( \Sigma^{(i)}_* \) with these properties has already been constructed, up to degree \( i \), and let \( \kappa_B \) be the residue field of \( B \); by Nakayama’s lemma, we may find a surjection \( d_{i+1} : L_{i+1} \to N_i \), where \( L_{i+1} \) is a free \( B \)-module of rank \( \dim \, \kappa_B (N_i \otimes_B \kappa_B) \). Under the assumption of the claim, the resulting complex \( \Sigma^{(i+1)}_* : (L_{i+1} \to L_i \to L_{i-1} \to \cdots \to M) \) fulfills the sought conditions, up to degree \( i + 1 \).

It is easily seen that the complex \( \Sigma_* \) thus obtained shall be universally \( A \)-exact.

Let us write \( A \) as the union of the filtered family \( (A_\lambda \mid \lambda \in \Lambda) \) of its noetherian subalgebras. Say that \( B = C_p \), for some finitely presented \( A \)-algebra \( C \), and a prime ideal \( p \subset C \), and \( M = N_p \) for some finitely presented \( C \)-module \( N \). We may find \( \lambda \in \Lambda \), a finitely generated \( A_\lambda \)-algebra \( C_\lambda \) and a \( C_\lambda \)-module \( N_\lambda \) such that \( C = C_\lambda \otimes_{A_\lambda} A \), and \( N = N_\lambda \otimes_{A_\lambda} A \); for every \( \mu \geq \lambda \), let \( C_\mu := A_\mu \otimes_{A_\lambda} C_\lambda \) and \( N_\mu := A_\mu \otimes_{A_\lambda} N_\lambda \); also, denote by \( p_\mu \) the preimage of \( p \) in \( C_\mu \), and set \( B_\mu := (C_\mu/\mu p_\mu, M_\mu := (N_\mu/\mu p_\mu. According to [50, Cor.11.2.6.1(ii)], we may assume that \( M_\mu \) is a flat \( A_\mu \)-module, for every \( \mu \geq \lambda \). Moreover, suppose that \( d : L \to M \) is a \( B \)-linear surjection from a free \( B \)-module \( L \) of rank \( r \); then we may find \( \mu \in \Lambda \) such that \( d \) descends to a \( B_\mu \)-linear surjection \( d_\mu : L_\mu \to M_\mu \) from a free \( B_\mu \)-module \( L_\mu \) of rank \( r \). It follows easily that \( K_\mu := \ker d_\mu \) is a flat \( A_\mu \)-module, for every \( \mu \geq \lambda \), and the induced map \( K_\mu \otimes_{B_\mu} B \to K := \ker d \) is a surjection, whose kernel is a quotient of \( \text{Tor}_1^{A_\mu}(A, M_\mu)_p \); the latter vanishes, since \( M_\mu \) is \( A_\mu \)-flat. Hence, \( K \) is \( A \)-flat; furthermore, \( K_\mu \) is clearly a finitely generated \( B_\mu \)-module, hence \( K \) is a finitely presented \( B \)-module. Then the proposition follows from claim [7.3.51]. □

### 9.4. Simplicial objects

In this section, we introduce the simplicial formalism, which provides the language for the homotopical algebra of section 7.10.

**Definition 7.4.1.** Let \( \mathcal{C} \) be any category, and \( k \in \mathbb{N} \) any integer.

(i) We denote by \( \Delta \) the simplicial category, whose objects are the finite ordered sets:

\[
[n] := \{0 < 1 < \cdots < n\} \quad \text{for every } n \in \mathbb{N}
\]

and whose morphisms are the non-decreasing functions.

(ii) \( \Delta \) is a full subcategory of the augmented simplicial category \( \Delta^\wedge \), whose set of objects is \( \text{Ob}(\Delta) \cup \{\emptyset\} \), with \( \text{Hom}_{\Delta^\wedge}(\emptyset, [n]) \) consisting of the unique mapping of sets \( \emptyset \to [n] \), for every \( n \in \mathbb{N} \). It is convenient to set \( [-1] := \emptyset \).

(iii) The augmented \( k \)-truncated simplicial category \( \Delta^\wedge_k \), is the full subcategory of \( \Delta^\wedge \) whose objects are the elements of \( \text{Ob}(\Delta^\wedge) \) of cardinality \( \leq k + 1 \). The \( k \)-truncated simplicial category is the full subcategory \( \Delta_k \) of \( \Delta^\wedge_k \) whose set of objects is \( \text{Ob}(\Delta^\wedge_k) \setminus \{\emptyset\} \).
A simplicial object (resp. an augmented simplicial object, resp. a k-truncated simplicial object, resp. a k-truncated augmented simplicial object) of \( \mathcal{C} \) is a functor \( \Delta^o \rightarrow \mathcal{C} \) (resp. \( (\Delta^\wedge)^o \rightarrow \mathcal{C} \), resp. \( \Delta_k^o \rightarrow \mathcal{C} \), resp. \( (\Delta_k^\wedge)^o \)). The morphisms of simplicial objects of \( \mathcal{C} \) are just the natural transformations (and likewise for the truncated or augmented variants). Clearly, these objects form a category, and we use the notation
\[
\begin{align*}
\text{s.}\mathcal{C} & := \text{Fun}(\Delta^o, \mathcal{C}) \\
\text{s}_k\mathcal{C} & := \text{Fun}(\Delta_k^o, \mathcal{C})
\end{align*}
\]
\( \hat{s}_k\mathcal{C} := \text{Fun}(\Delta_k^\wedge, \mathcal{C}) \).

Dually, a cosimplicial object \( F^* \) of \( \mathcal{C} \) is a functor \( F : \Delta \rightarrow \mathcal{C} \), or which is the same – a simplicial object in \( \mathcal{C}^o \). Likewise one defines the truncated or augmented cosimplicial variants, and we set
\[
\begin{align*}
\text{c.}\mathcal{C} & := \text{Fun}(\Delta, \mathcal{C}) \\
\text{c}_k\mathcal{C} & := \text{Fun}(\Delta_k, \mathcal{C})
\end{align*}
\]
\( \hat{c}_k\mathcal{C} := \text{Fun}(\Delta_k^\wedge, \mathcal{C}) \).

Notice the front-to-back involution:
\[
\Delta \rightarrow \Delta : (\alpha : [n] \rightarrow [m]) \mapsto (\alpha^\vee : [n] \rightarrow [m]) \quad \text{for every } n, m \in \mathbb{N}
\]
defined as the endofunctor which induces the identity on \( \text{Ob}(\Delta) \), and such that:
\[
\alpha^\vee(i) := m - \alpha(n - i) \quad \text{for every } \alpha \in \text{Hom}_\Delta([n], [m]) \text{ and every } i \in [n].
\]

Another construction of interest is the endofunctor
\[ \gamma : \Delta \rightarrow \Delta \]
given by the rule : \( [n] \mapsto [n+1] \) for every \( n \in \mathbb{N} \), and which takes any morphism \( \alpha : [n] \rightarrow [m] \) of \( \Delta \), to the morphism \( \gamma(\alpha) : [n+1] \rightarrow [m+1] \) which is the unique extension of \( \alpha \) such that \( \gamma(\alpha)(n+1) := m+1 \). Notice that \( \gamma \) restricts to functors \( \gamma_k : \Delta_{k+1} \rightarrow \Delta_k \) for every \( k \in \mathbb{N} \).

- Given a simplicial object \( F \) of \( \mathcal{C} \), one gets a cosimplicial object \( F^o \) of \( \mathcal{C} \), by the (obvious) rule : \( (F^o)[n] := F[n] \) for every \( n \in \mathbb{N} \), and \( F^o(\alpha) := F(\alpha)^o \) for every morphism \( \alpha \) in \( \Delta \).
- Moreover, by composing a simplicial (resp. cosimplicial) object \( F \) (resp. \( G \)) with the involution (7.4.3), one obtains a simplicial (resp. cosimplicial) object \( F^\vee \) (resp. \( G^\vee \)). Likewise, given a morphism \( \alpha : F_1 \rightarrow F_2 \), the Godement product \( \alpha^\vee := \alpha \ast (7.4.3) \) is a morphism \( F_1^\vee \rightarrow F_2^\vee \).
- For \( F \) and \( G \) as above, we may also consider the simplicial (resp. cosimplicial) object \( \gamma F := F \circ \gamma^o \) (resp. \( \gamma G := G \circ \gamma \)), and this definition extends again to morphisms, by taking Godement products. The object \( \gamma F \) (resp. \( \gamma G \)) is called the path space of \( F \) (resp. of \( G \)). If \( F \) is a \((k+1)\)-truncated simplicial object, then we can consider \( \gamma_k F := F \circ \gamma_k^o \), which is a \( k \)-truncated simplicial object (and likewise for truncated cosimplicial objects).

There is an obvious fully faithful functor:
\[ \mathcal{C} \rightarrow \text{s.}\mathcal{C} : A \\rightarrow sA \quad (\text{resp. } \mathcal{C} \rightarrow \text{s}_k\mathcal{C} : A \\rightarrow s_kA) \]

that assigns to each object \( A \) of \( \mathcal{C} \) the constant simplicial object \( sA \) (resp. constant truncated simplicial object \( s_kA \) ) such that \( sA[n] := A \) for every \( n \in \mathbb{N} \) (resp. for every \( n \leq k \)), and \( sA(\alpha) := 1_A \) for every morphism \( \alpha \) of \( \Delta \) (resp. of \( \Delta_k \)). Of course, we have as well augmented variants \( \hat{s}_A \) and \( \hat{s}_kA \), and cosimplicial versions \( \text{c.}\mathcal{C} \). Likewise, \( \hat{c}_A \), \( \hat{c}_kA \), and \( \hat{c}_k\mathcal{C} \).

Moreover, we have, for every integer \( k \in \mathbb{N} \), the \( k \)-truncation functor
\[ \text{s.trunc}_k : \text{s.}\mathcal{C} \rightarrow \text{s}_k\mathcal{C} \quad (\text{resp. } \hat{\text{s}}.\text{trunc}_k : \hat{s}_k\mathcal{C} \rightarrow \hat{s}_k\mathcal{C}) \]

that assigns to any simplicial (resp. augmented simplicial) object \( F : \Delta^o \rightarrow \mathcal{C} \) (resp. \( F : (\Delta^\wedge)^o \rightarrow \mathcal{C} \)) its composition with the inclusion functor \( \Delta_k^o \rightarrow \Delta^o \) (resp. \( (\Delta_k^\wedge)^o \rightarrow (\Delta^\wedge)^o \)).
Again, we have as well the corresponding cosimplicial versions \( c.\text{trunc}_k \) and \( c.\text{trunc}_k \). Also, for every \( n \in \mathbb{N} \), we have the functor

\[
\bullet[n] : s.\mathcal{A} \to \mathcal{A} \quad \quad A \mapsto A[n],
\]

Lastly, any functor \( \varphi : \mathcal{B} \to \mathcal{C} \) induces functors

\[
s.\varphi : s.\mathcal{B} \to s.\mathcal{C} \quad s_k.\varphi : s_k.\mathcal{B} \to s_k.\mathcal{C} : F \mapsto \varphi \circ F
\]

and there are of course augmented variants \( \hat{\mathcal{S}}.\varphi \) and \( \hat{s}_k.\varphi \), as well as the corresponding cosimplicial versions.

**Example 7.4.5.** (i) For every integer \( k \geq -1 \), we denote by \( \Delta_k \) the simplicial set represented by \([k]\). Explicitly, \( \Delta_k \) is given by the rule

\[
\Delta_k[n] := \text{Hom}_\Delta([n],[k]) \quad \text{and} \quad \Delta_k[\varphi] := \text{Hom}_\Delta(\varphi,[k])
\]

for every \( n \in \mathbb{N} \) and every morphism \( \varphi \) in \( \Delta \). For instance, \( \Delta_{-1} \) (resp. \( \Delta_0 \)) is the constant simplicial set associated to the empty set (resp. to the set with one element); this is also the initial (resp. final) object for \( s.\text{Set} \).

(ii) Any morphism \( \varphi : [k] \to [n] \) in \( \Delta^\wedge \) induces a morphism which we shall denote

\[
\Delta_\varphi := \text{Hom}_{\Delta^\wedge}(-,\varphi) : \Delta_k \to \Delta_n
\]

given by left composition with \( \varphi \) on \( \Delta_k[i] \), for every \( i \in \mathbb{N} \).

**7.4.6.** For given \( n \in \mathbb{N} \), and every \( i = 0, \ldots, n \), let

\[
\varepsilon_i : [n-1] \to [n] \quad \text{(resp. } \eta_i : [n+1] \to [n])
\]

be the unique injective map in \( \Delta^\wedge \) whose image misses \( i \) (resp. the unique surjective map in \( \Delta \) with two elements mapping to \( i \)). The morphisms \( \varepsilon_i \) (resp. \( \eta_i \)) are called face maps (resp. degeneracy maps). By direct inspection, one checks that they fulfill the identities:

\[
\begin{align*}
\varepsilon_j \circ \varepsilon_i &= \varepsilon_i \circ \varepsilon_{j-1} & \text{if } i < j \\
\eta_j \circ \eta_i &= \eta_i \circ \eta_{j+1} & \text{if } i \leq j \\
\eta_j \circ \varepsilon_i &= \begin{cases} 
\varepsilon_i \circ \eta_{j-1} & \text{if } i < j \\
1 & \text{if } i = j \text{ or } i = j+1 \\
\varepsilon_{i-1} \circ \eta_j & \text{if } i > j+1.
\end{cases}
\end{align*}
\]

**Example 7.4.7.** (i) For instance, notice the identities:

\[
\varepsilon_i^\vee = \varepsilon_{n-i} \quad \eta_i^\vee = \eta_{n-i} \quad \text{for every } n \in \mathbb{N} \text{ and every } i = 0, \ldots, n.
\]

(ii) For every \( r, s, i \in \mathbb{N} \) with \( i \leq r \), we set

\[
\varepsilon_{r,i}^\vee := \varepsilon_i \circ \cdots \circ \varepsilon_i : [r] \to [r+s].
\]

This is the injective mapping whose image is \( \{0, \ldots, i-1, s+i, \ldots, r+s\} \); for instance, the front-to-back dual

\[
\varepsilon_{r,0}^\vee := \varepsilon_{r+s} \circ \cdots \circ \varepsilon_{r+1} : [r] \to [r+s]
\]

is just the natural inclusion map. We shall also use the notation

\[
\varepsilon_{s,0}^\vee : [-1] \to [s] \quad \text{for every } s \in \mathbb{N}
\]

for the unique morphism \( \emptyset \to [s] \) in \( \Delta^\wedge \); of course, we have \( \varepsilon_{s,0}^\vee = \varepsilon_{s,0}^\vee \) for every \( s \in \mathbb{N} \).
7.4.8. It is easily seen that every morphism \( \alpha : [n] \to [m] \) in \( \Delta \) admits a unique factorization \( \alpha = \varepsilon \circ \eta \), where the monomorphism \( \varepsilon \) is uniquely a composition of faces:

\[
\varepsilon = \varepsilon_{i_1} \circ \cdots \circ \varepsilon_{i_s} \quad \text{with} \quad 0 \leq i_s \leq \cdots \leq i_1 \leq m
\]
and the epimorphism \( \eta \) is uniquely a composition of degeneracy maps:

\[
\eta = \eta_{j_1} \circ \cdots \circ \eta_{j_t} \quad \text{with} \quad 0 \leq j_t \leq \cdots \leq j_1 \leq m
\]
(see [125, Lemma 8.1.2]). It follows that, to give a simplicial object \( A[\bullet] \) of a category \( \mathcal{C} \), it suffices to give a sequence of objects \( (A[n] \mid n \in \mathbb{N}) \) of \( \mathcal{C} \), together with face operators

\[
\partial_i := A[\varepsilon_i] : A[n] \to A[n-1] \quad i = 0, \ldots, n
\]
for every integer \( n > 0 \) and degeneracy operators

\[
\sigma_i := A[\eta_i] : A[n] \to A[n+1] \quad i = 0, \ldots, n
\]
for every \( n \in \mathbb{N} \), satisfying the following simplicial identities:

\[
\partial_i \circ \partial_j = \partial_{j-1} \circ \partial_i \quad \text{if} \quad i < j
\]
\[
\sigma_i \circ \sigma_j = \sigma_{j+1} \circ \sigma_i \quad \text{if} \quad i \leq j
\]

(7.4.9)

Under this correspondence we have \( \partial_i = A(\varepsilon_i) \) and \( \sigma_i = A(\eta_i) \) ([125, Prop.8.1.3]). Likewise, a \( k \)-truncated simplicial object of \( \mathcal{C} \) is the same as the datum of a sequence \( (A[n] \mid n = 0, \ldots, k) \) of objects of \( \mathcal{C} \), and of a system of face and degeneracy operators restricted to this sequence of objects, and fulfilling the same identities (7.4.9).

Dually, a cosimplicial object \( A[\bullet] \) of \( \mathcal{C} \) is the same as the datum of a sequence \( (A[n] \mid n \in \mathbb{N}) \) of objects of \( \mathcal{C} \), together with coface operators

\[
\partial^i : A[n-1] \to A[n] \quad i = 0, \ldots, n
\]
and codegeneracy operators

\[
\sigma^i : A[n+1] \to A[n] \quad i = 0, \ldots, n
\]
which satisfy the cosimplicial identities:

\[
\partial^i \circ \partial^j = \partial^i \circ \partial^{j-1} \quad \text{if} \quad i < j
\]
\[
\sigma^i \circ \sigma^j = \sigma^i \circ \sigma^{j+1} \quad \text{if} \quad i \leq j
\]

(7.4.10)

and likewise for \( k \)-truncated cosimplicial objects.

7.4.11. An augmented simplicial object of a category \( \mathcal{C} \) can be viewed as the datum of a simplicial object \( A[\bullet] \) of \( \mathcal{C} \), together with an object \( A[-1] \in \text{Ob}(\mathcal{C}) \), and a morphism \( \varepsilon : A[0] \to A[-1] \), which is an augmentation, i.e. such that:

\[
\varepsilon \circ \partial_0 = \varepsilon \circ \partial_1.
\]
Dually, an augmented cosimplicial object of \( \mathcal{C} \) can be viewed as a cosimplicial object \( A[\bullet] \), together with a morphism \( \eta : A[-1] \to A[0] \) in \( \mathcal{C} \), such that \( \eta^0 \) is an augmentation for \( A^0[\bullet] \). We say that \( \eta \) is an augmentation for \( A[\bullet] \).
Remark 7.4.12. Let $A$ be a simplicial object of the category $\mathcal{C}$.

(i) For every $n \in \mathbb{N}$ we have $\gamma A[n] := A[n+1]$ (notation of (7.4.2)), and the face operators $\gamma A[i_1] : \gamma A[n+1] \to \gamma A[n]$ for $i \leq n+1$ (resp. degeneracy operators $\gamma A[i_n] : \gamma A[n] \to \gamma A[n+1]$ for $i \leq n$) of $\gamma A$ are $\partial_i : A[n+2] \to A[n+1]$ (resp. $\sigma_i : A[n+1] \to A[n+2]$); i.e. we drop $\partial_{n+2}$ and $\sigma_{n+1}$. Likewise for the truncated variants.

(ii) The discarded faces $\partial_{n+2}$ and degeneracies $\sigma_{n+1}$ can be used to produce natural morphisms

$$s.A[0] \xrightarrow{f_A} \gamma A \xrightarrow{g_A} A.$$ 

Namely, we set

$$f_A[n] := \sigma_n \circ \cdots \circ \sigma_1 \quad g_A[n] := \partial_{n+1} \quad \text{for every } n \in \mathbb{N}.$$

For every $k \in \mathbb{N}$, the same operation on an object $A \in \text{Ob}(s_{k+1}.\mathcal{C})$ yields natural morphisms

$$s.\text{trunc}_k A \xrightarrow{f_A} \gamma_k A \xrightarrow{g_A} s.\text{trunc}_k A.$$

(iii) Since there is a unique morphism $\sigma_{n,0} : [n] \to [0]$ in $\Delta$ for every $n \in \mathbb{N}$, it is easily seen that the system $(A[\sigma_{n,0}] : A[0] \to A[n])$ defines a natural morphism

$$s.A[0] \to A \quad \text{in } s.\mathcal{C}.$$ 

(iv) Likewise, suppose $\varepsilon : A[0] \to A[-1]$ is an augmentation for $A$; since there is exactly one morphism $\varepsilon_{n+1,0} : \emptyset \to [n]$ in $\Delta$ for every $n \in \mathbb{N}$, we see that the system $(A[\varepsilon_{n+1,0}] | n \in \mathbb{N})$ defines a natural morphism

$$A \to s.A[-1] \quad \text{in } s.\mathcal{C}.$$ 

Definition 7.4.13. Let $\mathcal{C}$ be any category. Denote by

$$e_i : \Delta^o \to [1]/\Delta^o \quad i = 0, 1$$

the functor that assigns to each $[n] \in \text{Ob}(\Delta)$ the unique morphism $[n] \to [1]$ of $\Delta$ whose image is $\{i\}$. Let also $t : [1]/\Delta^o \to \Delta^o$ be the target functor (see (1.1.24)). Let $A$ and $B$ be two simplicial objects of $\mathcal{C}$, and $f, g : A \to B$ two morphisms.

(i) A homotopy from $f$ to $g$ is the datum of a natural transformation

$$u : A \circ t \Rightarrow B \circ t$$

such that $u \ast e_0 = f$ and $u \ast e_1 = g$.

(ii) If $A[\bullet]$ is an augmented simplicial object of $\mathcal{C}$, with augmentation given by a morphism $\varphi : A \to s.A[-1]$ in $s.\mathcal{C}$, then we say that $A$ is homotopically trivial, if there exist a morphism $\psi : s.A[-1] \to A$ and homotopies $u$ and $v$, respectively from $1_{s.A[-1]}$ to $\varphi \circ \psi$, and from $1_A$ to $\psi \circ \varphi$.

(iii) Dually, if $C$ and $D$ are cosimplicial objects of $\mathcal{C}$, and $p, q : C \to D$ any two morphisms in $\mathcal{C}$, then a homotopy from $p$ to $q$ is a homotopy from $p^o$ to $q^o$ in $s.\mathcal{C}^o$. Likewise we define homotopically trivial cosimplicial objects.

Remark 7.4.14. (i) In the situation of definition 7.4.13, suppose that $p : A' \to A$ and $q : B \to B'$ are any two morphisms in $s.\mathcal{C}$; then the natural transformation

$$(q \ast t) \circ u \circ (p \ast t) : A' \circ t \Rightarrow B' \circ t$$

is a homotopy from $f \circ p$ to $q \circ g$. Moreover, if $F : \mathcal{C} \to \mathcal{D}$ is any functor, then

$$F \ast u : FA \ast t \Rightarrow FB \ast t$$

is a homotopy from $Ff$ to $Fg$.

(ii) However, unlike the case for chain homotopies, simplicial homotopies cannot be composed in this generality; hence, the simplicial category $s.\mathcal{C}$ cannot be made into a 2-category, by taking the homotopies as 2-cells.
(iii) In the same vein, for a general category \( \mathcal{C} \), the relation “there exists a homotopy from \( f \) to \( g \)” on morphisms of \( s.\mathcal{C} \) is neither symmetric nor transitive (though it will follow from \( \text{Theorem 7.4.59} \) that this is an equivalence relation, in case \( \mathcal{C} \) is abelian).

7.4.15. Notice that there are exactly \( n + 1 \) morphisms \( \varphi : [n] \to [1] \) for every \( [u] \in \text{Ob}(\Delta) \), and they can be labeled by the cardinality of \( \varphi^{-1}(0) \) for every \( n \in \mathbb{N} \) and every \( k \leq n + 1 \), we shall write \( \varphi_{n,k} : [n] \to [1] \) for the unique morphism such that \( \varphi_{n,k}^{-1}(0) \) has cardinality \( k \). With this notation, notice that

\[
\varphi_{n,k} \circ \varepsilon_i = \begin{cases} 
\varphi_{n-1,k} & \text{if } i \geq k \\
\varphi_{n-1,k-1} & \text{if } i < k
\end{cases}
\quad\text{and}\quad
\varphi_{n,k} \circ \eta_i = \begin{cases} 
\varphi_{n+1,k} & \text{if } i \geq k \\
\varphi_{n+1,k+1} & \text{if } i < k.
\end{cases}
\]

Hence, a homotopy \( u \) from \( f \) to \( g \) as in \( \text{Definition 7.4.13} \) is the same as a system of morphisms

\[
u_{n,k} : A[n] \to B[n] \quad \text{for every } n \in \mathbb{N} \text{ and every } k \leq n + 1
\]
such that \( u_{n,n+1} = f[n] \) and \( u_{n,0} = g[n] \) for every \( n \in \mathbb{N} \), and the diagrams

\[
\begin{array}{ccc}
A[n] & \xrightarrow{u_{n,k}} & B[n] \\
\downarrow \partial_k & & \downarrow \partial_k \\
A[n-1] & \xrightarrow{u_{n-1,k-1}} & B[n-1]
\end{array}
\quad
\begin{array}{ccc}
A[n] & \xrightarrow{u_{n,k}} & B[n] \\
\downarrow \sigma_i & & \downarrow \sigma_i \\
A[n+1] & \xrightarrow{u_{n+1,k+1}} & B[n+1]
\end{array}
\]

commute for every \( n \in \mathbb{N} \) and every \( k \leq n + 1 \), where \( a := 0 \) if \( i \geq k \), and \( a := 1 \) if \( i < k \).

7.4.16. A \textit{bisimplicial object} in a category \( \mathcal{C} \) is an object of the category \( s.(s.\mathcal{C}) \). The latter can also be regarded as the category of all bisimplicial objects \( \Delta^0 \times \Delta^0 \to \mathcal{C} \); it follows that a bisimplicial object of \( \mathcal{C} \) is the same as a system \((A[p, q] \mid (p, q) \in \mathbb{N} \times \mathbb{N})\) of objects of \( \mathcal{C} \), together with morphisms

\[
A[\alpha, \beta] : A[p, q] \to A[p', q'] \quad \text{for all morphisms } \alpha : [p'] \to [p], \beta : [q'] \to [q] \text{ of } \Delta
\]

compatible with compositions of morphisms in \( \Delta \), in the obvious way. More generally, we may define inductively the category of \( n \)-simplicial objects \( s^n.\mathcal{A} \), for every \( n \in \mathbb{N} \), by letting \( s^0.\mathcal{A} := \mathcal{A} \), and \( s^n.\mathcal{A} := s.(s^{n-1.\mathcal{A}}) \), for every \( n > 0 \). The \textit{diagonal functor}

\[
\Delta \to \Delta \times \Delta \quad [n] \mapsto ([n], [n]) \quad \alpha \mapsto (\alpha, \alpha)
\]

induces a functor

\[
\Delta^\Delta : s^2.\mathcal{C} \to s.\mathcal{C} \quad A \mapsto A^\Delta
\]

Especially, we have \( A^\Delta[n] : A[n, n] \) for every \( n \in \mathbb{N} \), and the face operators \( \partial_i \) on \( A^\Delta[n] \) are of the form \( A[\varepsilon_i, \varepsilon_i] \), for every \( i = 0, \ldots, n \) (and likewise for the degeneracies). Also, the \textit{flip functor}

\[
\Delta \times \Delta \to \Delta \times \Delta \quad ([m], [n]) \mapsto ([n], [m])
\]

induces an endofunctor

\[
\text{fl} : s^2.\mathcal{A} \to s^2.\mathcal{A}
\]
in the obvious way. Furthermore, the endofunctors

\[
\Delta \times \Delta \xrightarrow{\gamma \times 1_\Delta} \Delta \times \Delta \xleftarrow{1_\Delta \times \gamma} \Delta \times \Delta
\]

induce functors

\[
s^2.\mathcal{A} \xleftarrow{\gamma} s^2.\mathcal{A} \xrightarrow{s_2} s^2.\mathcal{A}
\]

that admit descriptions as in \( \text{Remark 7.4.12(i)} \). Correspondingly, we get natural morphisms

\[
g_A^{(i)} : \gamma_i A \to A \quad \text{for } i = 1, 2 \text{ and every } A \in \text{Ob}(s^2.\mathcal{A})
\]
as in \( \text{Remark 7.4.12(ii)} \).
**Remark 7.4.17.** (i) Let $\mathcal{C}$ be a category whose finite coproducts are representable. Let also $f:\text{Set}$ be the category of finite sets. To every object $S$ of $\text{Set}$ and every $X \in \text{Ob}(f: \mathcal{C})$, we attach a bisimplicial object $S \boxtimes X$ of $\mathcal{C}$ as follows. For every $n, m \in \mathbb{N}$, we let $S \boxtimes X[n, m]$ be the coproduct of finitely many copies of $X[m]$, indexed by the elements of $S[n]$; hence, for every $a \in S[n]$ we have a natural morphism $i_a : X[m] \to S \boxtimes X[n, m]$. If $\varphi : [n] \to [n']$ and $\psi : [m] \to [m']$ are any morphisms in $\Delta$, we let $S \boxtimes X[\varphi, \psi] : S \boxtimes X[n, m] \to S \boxtimes X[n', m']$ be the unique morphism such that $S \boxtimes X[\varphi, \psi] \circ i_a = i_{S[\varphi](a)} \circ X[\psi]$ for every $a \in S[n]$. Clearly, this rules extends to a well defined functor

$$s.f:\text{Set} \times s.\mathcal{C} \to s^2.\mathcal{C} \quad (S, X) \mapsto S \boxtimes X.$$

Likewise, we define $X \boxtimes S := \text{fl}(S \boxtimes X)$ (notation of (7.4.16)). If all coproducts of $\mathcal{C}$ are representable, we may even extend the above construction to arbitrary simplicial sets.

(ii) In the same vein, let $\mathcal{A}$ be any abelian category, and $M$ any object of $s.\mathcal{Z}\text{-Mod}_{f_3}$ (notation of (3.6.47)). For any $A \in \text{Ob}(s.\mathcal{A})$, we may define a bisimplicial object $M \boxtimes_{\mathcal{A}} A$ of $\mathcal{A}$, by the rule : $[n, m] \mapsto M[n] \boxtimes_{\mathcal{A}} A[n]$ for every $n, m \in \mathbb{N}$ and $[\varphi, \psi] \mapsto M[\varphi] \boxtimes_{\mathcal{A}} A[\psi]$ for all morphisms $\varphi, \psi$ of $\Delta$ (where these mixed tensor products are as defined in (3.6.47)). Clearly, these rules yield a well defined functor

$$s.\mathcal{Z}\text{-Mod}_{f_3} \times s.\mathcal{A} \to s^2.\mathcal{A} \quad (M, A) \mapsto M \boxtimes_{\mathcal{A}} A.$$

Likewise, we set $A \boxtimes_{\mathcal{A}} M := \text{fl}(M \boxtimes_{\mathcal{A}} A)$.

(iii) Furthermore, if $(\mathcal{C}, \otimes)$ is any tensor category, and $X, Y$ any two simplicial objects of $\mathcal{C}$, we may define a bisimplicial object $X \boxtimes Y$, by the same rule as in (ii). This yields a functor

$$s.\mathcal{C} \times s.\mathcal{C} \to s^2.\mathcal{C} \quad (X, Y) \mapsto X \boxtimes Y.$$

In this situation (resp. in the situation of (i), resp. of (ii)), we shall let also

$$X \otimes Y := (X \boxtimes Y)^\Delta \quad (\text{resp. } S \otimes X := (S \boxtimes X)^\Delta, \text{ resp. } M \otimes_{\mathcal{A}} A := (M \boxtimes_{\mathcal{A}} A)^\Delta)$$

which we shall call the *tensor product* of $X$ and $Y$ (resp. of $S$ and $X$, resp. of $M$ and $A$).

Notice the natural identifications

$$S \boxtimes A \sim (S \otimes s.\mathcal{Z}) \boxtimes_{\mathcal{A}} A \quad \text{for every } S \in \text{Ob}(s.f:\text{Set}) \text{ and every } A \in \text{Ob}(s.\mathcal{A}).$$

Likewise, if $U$ is any unit object for $(\mathcal{C}, \otimes)$, we get natural identifications

$$S \boxtimes X \sim (S \otimes s.\mathcal{U}) \boxtimes_{\mathcal{C}} X \quad \text{for every } S \in \text{Ob}(s.f:\text{Set}) \text{ and every } X \in \text{Ob}(s.\mathcal{C})$$

via the isomorphisms $u_X : X \sim U \otimes X$ provided by proposition (3.6.6). In the same vein, we have a natural identification $\Delta_0 \otimes X \sim X \text{ for every } X \in \text{Ob}(\mathcal{C})$ (notation of example (7.4.5(i))).

(iv) Notice also that if $f, g : S \to T$ are any two morphisms of simplicial finite sets, then

- in light of remark (7.4.14(i)) – any homotopy $u$ from $f$ to $g$ induces a homotopy $u \otimes X$ from $f \otimes X$ to $g \otimes X$.

(v) Let $f, g : A \to B$ be as in definition (7.4.13). Notice that the datum of a homotopy $u$ from $f$ to $g$ is the same as that of a morphism

$$\tilde{u} : \Delta_1 \otimes A \to B \quad \text{such that } \tilde{u} \circ (\Delta_{e_0} \otimes 1_A) = f \text{ and } \tilde{u} \circ (\Delta_{e_1} \otimes 1_A) = g$$

(where $e_0, e_1 : [0] \to [1]$ are the face maps : notation of example (7.4.5(ii))). Indeed, given $u$, we construct $\tilde{u}$ as follows. For every $n \in \mathbb{N}$ and every $\varphi \in \Delta_1[n]$, let $\widetilde{u}[n]$ be the unique morphism such that $\widetilde{u}[n] \circ i_{\varphi} = u[\varphi]$. The naturality of $u$ easily implies that this rule amounts to a morphism $\tilde{u}$ as sought. Conversely, given $\tilde{u}$, we can construct a natural transformation $u$ by reversing the foregoing rule.
Remark 7.4.18. (i) Let \((\mathcal{C}, \otimes)\) be a tensor category with internal \(\text{Hom}\) functor \(\mathcal{H}om\), and unit object \(U\). To every two objects \(X, Y\) of \(s.\mathcal{C}\), we may attach the object of \(\mathcal{C}\)

\[
\mathcal{H}om_{s.\mathcal{C}}(X, Y) := \text{Equal}(\prod_{n \in \mathbb{N}} \mathcal{H}om(X[n], Y[n]))
\]

where the second product ranges over the morphisms \(\varphi\) of \(\Delta\), and where

\[
d_0 := \prod_{\varphi : [n] \to [m]} \mathcal{H}om(X[\varphi], Y[n]) \quad \text{and} \quad d_1 := \prod_{\varphi : [n] \to [m]} \mathcal{H}om(X[m], Y[\varphi]).
\]

Arguing as in example 7.1.16(vi), it is easily seen that there are natural isomorphisms

\[
\text{Hom}_{\mathcal{C}}(Z, \mathcal{H}om_{s.\mathcal{C}}(X, Y)) \xrightarrow{\sim} \text{Hom}_{s.\mathcal{C}}(s.Z \otimes X, Y)
\]

for every \(Z \in \text{Ob}(\mathcal{C})\) and every \(X, Y \in \text{Ob}(s.\mathcal{C})\).

(ii) Suppose additionally, that all finite coproducts of \(\mathcal{C}\) are representable. For every \(Z \in \text{Ob}(\mathcal{C})\), and every \(X \in \text{Ob}(s.\mathcal{C})\), consider the simplicial set

\[
\text{Hom}_{\mathcal{C}}(Z, X)
\]

such that \(\text{Hom}_{\mathcal{C}}(Z, X)[n] := \text{Hom}_{\mathcal{C}}(Z, X[n])\) for every \(n \in \mathbb{N}\), with face and degeneracies deduced from those of \(X\), in the obvious way. For any \(k \in \mathbb{N}\), let also \(\Delta_k\) be the simplicial set defined in example 7.4.5(i); we have natural isomorphisms

\[
\text{Hom}_{\mathcal{C}}(Z, \mathcal{H}om_{s.\mathcal{C}}(\Delta_k \otimes s.U, X)) \xrightarrow{\sim} \text{Hom}_{s.\mathcal{C}}(\Delta_k \otimes s.Z, X)
\]

\[
\xrightarrow{\sim} \text{Hom}_{s.\mathcal{Set}}(\Delta_k, \text{Hom}_{\mathcal{C}}(Z, X))
\]

\[
\xrightarrow{\sim} \text{Hom}_{\mathcal{C}}(Z, X)[k]
\]

where the last isomorphism follows from Yoneda’s lemma (proposition 1.2.6(ii); details left to the reader). Applying again Yoneda’s lemma, we deduce a natural isomorphism

\[
\mathcal{H}om_{s.\mathcal{C}}(\Delta_k \otimes s.U, X) \xrightarrow{\sim} X[k] \quad \text{for every} \quad k \in \mathbb{N}.
\]

(iii) Notice that \(\Delta_{\varphi} \circ \Delta_{\psi} = \Delta_{\varphi \circ \psi}\) for every two morphisms \(\varphi : [k] \to [k']\) and \(\psi : [k'] \to [k'']\) of \(\Delta^\sim\) (notation of example 7.4.5(ii)). Hence, the system \((\Delta_i)\) \(i \in \mathbb{N}\)) amounts to an object of \(c.s.\text{Set}\). Moreover, since the Yoneda isomorphisms are natural in both \(X\) and \(\Delta_k\), we get a commutative diagram

\[
\begin{array}{ccc}
\mathcal{H}om_{s.\mathcal{C}}(\Delta_k \otimes s.U, X) & \xrightarrow{\sim} & X[k'] \\
\mathcal{H}om_{s.\mathcal{C}}(\Delta_{\varphi} \otimes s.U, X) \downarrow & & \downarrow X[\varphi] \\
\mathcal{H}om_{s.\mathcal{C}}(\Delta_k \otimes s.U, X) & \xrightarrow{\sim} & X[k]
\end{array}
\]

for every morphism \(\varphi\) as above.

(iv) Notice as well that the considerations of (ii) and (iii) can be repeated, \textit{mutatis mutandis}, for truncated simplicial objects: if \(X\) and \(Y\) are objects of \(s_n.\mathcal{C}\) and \(Z\) is an object of \(\mathcal{C}\), then \(\mathcal{H}om_{s_n.\mathcal{C}}(X, Y)\) (resp. \(\text{Hom}_{\mathcal{C}}(Z, X)\)) shall be an object of \(\mathcal{C}\) (resp. of \(s_k.\text{Set}\)), and we shall have natural isomorphisms

\[
\mathcal{H}om_{s_n.\mathcal{C}}(s.\text{trunc}_n(\Delta_k \otimes s.U), X) \xrightarrow{\sim} X[k] \quad \text{for every} \quad k \leq n
\]

and similarly for the commutative diagrams of (iii) (details left to the reader).
7.4.19. Let \( \mathcal{C} \) be a finitely cocomplete category. Theorem 1.3.4 say that, for every integer \( k \in \mathbb{N} \), the \( k \)-truncation functor on \( s.\mathcal{C} \) admits a left adjoint

\[
\text{sk}_k : s_k \mathcal{C} \to s.\mathcal{C}
\]

which is called the \emph{k-th skeleton functor}. By inspecting the proof of \emph{loc.cit.} we see that, for every \( k \)-truncated simplicial object \( F \), this adjoint is calculated by the rule:

\[
(7.4.20) \quad \text{sk}_k A[n] := \operatorname{colim}_{\varphi : [i] \to [n]} F[i]
\]

where \( i \) ranges over all the integers \( \leq k \), and \( \varphi \) over all the morphisms \( [i] \to [n] \) in \( \Delta^o \), and the transition maps \( F[i] \to F[j] \) in the colimit are the morphisms \( F[\psi] \) given by all commutative triangles

\[
(7.4.21) \quad [i] \xrightarrow{\psi} [j] \xleftarrow{\varphi} [n] \quad \text{in} \ \Delta^o.
\]

A morphism \( \alpha : [n] \to [m] \) in \( \Delta^o \) induces a morphism \( \text{sk}_k F[\alpha] : \text{sk}_k A[n] \to \text{sk}_k A[m] \); namely, for every \( \varphi : [i] \to [m] \) one has a natural morphism \( j_\varphi : F[i] \to \text{sk}_k F[m] \), and \( \text{sk}_k F[\alpha] \) is the colimit of the system of morphisms

\[
\text{sk}_k F[i] \xrightarrow{j_{\alpha \psi}} \text{sk}_k A[m]
\]

for all \( \psi : [i] \to [n] \).

It is clear that, for every \( n, m \leq k \) and every \( \alpha : [n] \to [m] \), the colimit (7.4.20) is realized by \( F[n] \), and under this identification, \( \text{sk}_k A[\alpha] \) agrees with \( F[\alpha] \), so the unit of adjunction

\[
F \to s.\text{trunc}_k \circ \text{sk}_k F
\]

is an isomorphism. Dually, if all finite limits are representable in \( \mathcal{C} \), the truncation functor admits a right adjoint

\[
\text{cosk}_k : s_k \mathcal{C} \to s.\mathcal{C}
\]

called the \emph{k-th coskeleton functor}, and a simple inspection of the proof of \emph{loc.cit.} yields the rule:

\[
(7.4.22) \quad \text{cosk}_k F[n] := \operatorname{lim}_{\varphi : [n] \to [i]} F[i]
\]

where \( i \) ranges over the integers \( \leq k \), and \( \varphi : [n] \to [i] \) over the morphisms in \( \Delta^o \), and the transition maps are as in the foregoing (except that the downwards arrows in the commutative triangles (7.4.21) are reversed). Especially, we easily deduce that the counit of adjunction

\[
\text{trunc}_k \circ \text{cosk}_k F \to F
\]

is an isomorphism. Moreover, if \( \mathcal{B} \) is another category with small Hom-sets, whose finite colimits (resp. finite limits) are all representable, and \( \varphi : \mathcal{B} \to \mathcal{C} \) is any functor, then for any \( F \in \operatorname{Ob}(s_k \mathcal{B}) \) there is a natural transformation

\[
\text{sk}_k(s_k \varphi F) \to s.\varphi(\text{sk}_k F) \quad \text{(resp.} \ s.\varphi(\text{cosk}_k F) \to \text{cosk}_k(s_k \varphi F) \text{)}
\]

which is an isomorphism, if \( \varphi \) is right exact (resp. if \( \varphi \) is left exact).
7.4.22. Let \( \mathcal{A} \) be an abelian category, and \( A \) any object of \( s.\mathcal{A} \). For every \( n > 0 \), set

\[
d_n := \sum_{i=0}^{n} (-1)^i \cdot \partial_i \quad A[n] \to A[n-1].
\]

Directly from the simplicial identities \( (7.4.9) \) we may compute

\[
d_n \circ d_{n+1} = \sum_{i=0}^{n} \sum_{j=0}^{n+1} (-1)^{i+j} \cdot \partial_i \circ \partial_j
\]

\[
= \sum_{i=0}^{n} \sum_{j>i}^{n+1} (-1)^{i+j} \cdot \partial_{j-1} \circ \partial_i + \sum_{i=0}^{n} \partial_i \circ \partial_i + \sum_{i=0}^{n} \sum_{j<i}^{n} (-1)^{i+j} \cdot \partial_i \circ \partial_j
\]

\[
= \sum_{i=0}^{n} \sum_{j>1}^{n+1} (-1)^{i+j} \cdot \partial_{j-1} \circ \partial_i + \sum_{i=0}^{n} \sum_{j<i}^{n} (-1)^{i+j} \cdot \partial_i \circ \partial_j = 0
\]

for every \( n \in \mathbb{N} \), so we are led to the following:

**Definition 7.4.23.** Let \( \mathcal{A} \) be an abelian category, and \( k \in \mathbb{N} \) any integer.

(i) If \( A[\bullet] \) is any simplicial object of \( \mathcal{A} \), with face operators \( \partial_i \), the *unnormalized complex associated to \( A[\bullet] \)* is the complex \( (A_{\bullet}, d_{\bullet}) \in \text{Ob}(C^{\leq 0}(\mathcal{A})) \) such that \( A_n := A[n] \) for every \( n \in \mathbb{N} \), and \( d_n \) is defined as in \( (7.4.22) \), for every \( n > 0 \).

(ii) If \( A[\bullet] \) is a \( k \)-truncated simplicial object of \( \mathcal{A} \), the *unnormalized complex associated to \( A[\bullet] \)* is the complex \( (A_{\bullet}, d_{\bullet}) \) where \( A_n \) and \( d_n \) are defined as in (i) for every \( n \leq k \), and \( A_n := 0, d_n := 0 \) for every \( n > k \).

(iii) If \( A[\bullet] \) is as in (i) (resp. as in (ii)), the *normalized complex associated to \( A[\bullet] \)* is the subcomplex \( N_{\bullet}A \) of \( A_{\bullet} \) such that

\[
N_0 A := A[0] \quad \text{and} \quad N_n A := \bigcap_{i=1}^{n} \text{Ker} \partial_i \quad \text{for every} \quad n > 0 \quad \text{(resp. for} \quad 0 < n \leq k).
\]

So, the differential \( N_n A \to N_{n-1} A \) equals \( \partial_0 \), for every \( n \in \mathbb{N} \) (resp. for every \( n \leq k \)).

(iv) If \( A[\bullet] \) is as in (i) or (ii), the *homology of \( A \) in degree \( n \) is

\[
H_n A := H_n A_{\bullet} \quad \text{for every} \quad n \in \mathbb{N}.
\]

(v) Let \( \varepsilon : A \to A_{-1} \) be an augmentation for \( A[\bullet] \). One says that the augmented simplicial object \( (A, \varepsilon) \) is *aspherical*, if \( H_n A = 0 \) for every \( n > 0 \), and \( \varepsilon \) induces an isomorphism \( H_0 A \cong A_{-1} \).

7.4.24. Let \( \mathcal{A} \) be an abelian category, and recall that \( s^n \mathcal{A} \) and \( s_k \mathcal{A} \) are both abelian categories as well, for every \( n, k \in \mathbb{N} \) (remark \( 3.6.37 \) ii)); also, clearly the rule of definition \( 7.4.23 \) (iii) yields natural additive functors

\[
N_{\mathcal{A}} : s.\mathcal{A} \to C^{\leq 0}(\mathcal{A}) \quad N_{\mathcal{A},k} : s_k \mathcal{A} \to C^{\leq 0}(\mathcal{A}) \quad A[\bullet] \to A_{\bullet}A \quad \text{for every} \quad k \in \mathbb{N}
\]

and the rules of definition \( 7.4.23 \) (i,ii) yield additive functors

\[
\begin{array}{ll}
N_{\mathcal{A}} : s.\mathcal{A} \to C^{\leq 0}(\mathcal{A}) & U_{\mathcal{A},k} : s_k \mathcal{A} \to C^{\leq 0}(\mathcal{A}) \quad A[\bullet] \to A_{\bullet} \quad \text{for every} \quad k \in \mathbb{N}.
\end{array}
\]

**Remark 7.4.25.** Let \( \mathcal{A} \) and \( A \) be as in \( (7.4.22) \); directly from the simplicial identities \( (7.4.9) \) we may compute

\[
d_n \circ \sigma_k = \sum_{i=0}^{k-1} (-1)^i \cdot \sigma_{k-1} \circ \partial_i + \sum_{i=k+2}^{n} (-1)^i \cdot \sigma_k \circ \partial_{i-1}.
\]
Especially, if we let
\[
D_0 := 0 \quad \text{and} \quad D_n A := \sum_{i=0}^{n-1} \text{Im} (\sigma_i : A[n-1] \to A[n]) \quad \text{for every } n > 0
\]
we see that \(d_n\) restricts to a morphism \(d'_n : D_n A \to D_{n-1} A\) for every \(n > 0\), hence \((D_* A, d'_* A)\) is a subcomplex of \(A_*\), called the degenerate subcomplex, and clearly we obtain an additive functor
\[
D_{\mathcal{A}} : \mathcal{S} \mathcal{A} \to \mathcal{C}(\mathcal{A}) \quad A \mapsto D_* A.
\]

**Proposition 7.4.26.** The natural injections induce a decomposition
\[
A_* = N_* A \oplus D_* A \quad \text{in } \mathcal{C}(\mathcal{A}).
\]

**Proof.** First, we notice that \(N_n A \cap D_n A = 0\) for every \(n \in \mathbb{N}\). Indeed, it suffices to check that \(N_n A \cap \text{Im}(\sigma_i) = 0\) for every \(i = 0, \ldots, n-1\), but the latter follows easily from the identity \(\partial_{i+1} \circ \sigma_i = 1_{A[n-1]}\). To conclude the proof, it suffices to show that \(N_n A + D_n A = A_n\) for every \(n \in \mathbb{N}\). Indeed, set \(K_0 := A_n\) and define inductively \(K_i := K_{i-1} \cap \text{Ker} \partial_i\) for every \(i = 1, \ldots, n\); to prove the latter assertion, it suffices to check that
\[
(7.4.27) \quad (1_{A_n} - \sigma_i \cdot \partial_i)(K_i) \subset K_{i+1} \quad \text{for every } i = 0, \ldots, n.
\]
However, we have:
\[
\partial_j \circ (1_{A_n} - \sigma_i \cdot \partial_i) = \partial_j - \sigma_{i-1} \circ \partial_i - \partial_j \quad \text{whenever } j < i
\]
and \(\partial_i \circ (1_{A_n} - \sigma_i \cdot \partial_i) = \partial_i - \partial_i = 0\), whence (7.4.27). \(\square\)

**Example 7.4.28.** (i) Let \(S\) be any simplicial set, and set \(\mathbb{Z}^S := S \otimes s.\mathbb{Z}\) (notation of remark 7.4.17(iii)); we wish to give an explicit description of the complex \(N_* \mathbb{Z}^S\). To begin with, notice that \(\mathbb{Z}^S[n]\) is the free abelian group with basis indexed by \(S[n]\), for every \(n \in \mathbb{N}\), and for every \(x \in S[n]\) denote by \(e_x \in \mathbb{Z}^S[n]\) the corresponding basis element. Next, set
\[
D_n S := \bigcup_{i=0}^{n-1} \text{Im} (\sigma_i : S[n-1] \to S[n]) \quad \text{and} \quad N_n S := S[n] \setminus D_n S \quad \text{for every } n \in \mathbb{N}.
\]
From proposition 7.4.26, we see that \(N_n \mathbb{Z}^S\) can be naturally identified with the direct summand of \(\mathbb{Z}^S[n]\) generated by the system \(\{e_x \mid x \in N_n S\}\), for every \(n \in \mathbb{N}\). In order to describe the differential \(d_n\), let us define \(\tau_x := e_x\) if \(x \in N_n S\), and \(\tau_x := 0\) if \(x \in D_n S\). Then we may write
\[
d_n(\tau_x) = \sum_{i=0}^{n} (-1)^i \cdot \tau_{\partial_i x} \quad \text{for every } n \in \mathbb{N} \text{ and every } x \in N_n S.
\]
The verifications are straightforward, and shall be left to the reader.

(ii) For instance, for any \(i \in \mathbb{N}\) consider the simplicial set \(\Delta_i\) of example 7.4.5(i), and set
\[
\mathbb{K}(i)_* := N_* \mathbb{Z}^{\Delta_i}
\]
where \(\mathbb{Z}^{\Delta_i}\) is defined as in (i). Notice that this notation agrees with that of remark 7.1.19(ii). It is easily seen that a morphism \([n] \to [i]\) of \(\Delta\) lies in \(D_n \Delta_i\) if and only if it is not injective; hence \(N_n \Delta_i\) is the set of all injective maps \(\varphi : [n] \to [i]\) of \(\Delta\). We deduce a natural isomorphism
\[
\mathbb{K}(i)_n \simeq \Lambda_{2^{i+1}}^{\mathbb{Z}^{\Delta_i+1}} \quad \text{for every } i, n \in \mathbb{N}.
\]
Namely, to any map \(\varphi\) as above, we assign the exterior product \(e_{\varphi(0)} \wedge \cdots \wedge e_{\varphi(n)}\), where \(e_0, \ldots, e_i\) denotes the canonical basis of \(\mathbb{Z}^{\Delta_i+1}\). Under this isomorphism, the differential of \(\mathbb{K}(i)_*\) gets identified with the differential of the Koszul complex attached to the sequence
\[
\cdots \to \mathbb{Z}^{\Delta_i+1} \xrightarrow{\partial_{i+1}} \mathbb{Z}^{\Delta_i} \xrightarrow{\partial_i} \mathbb{Z}^{\Delta_{i-1}} \to \cdots
\]
$1_{i+1} := (1, \ldots, 1) \in \mathbb{Z}^{\oplus i+1}$, that will be introduced in \(\text{(7.3)}\). Summing up, we obtain natural short exact sequences

$$0 \to \mathbb{K}(i) \cdot [1] \to \mathbb{K}(1_{i+1}) \to \mathbb{Z}[0] \to 0 \quad \text{for every } i \in \mathbb{N}$$

where \([1]\) denotes the shift operator, and \(\mathbb{Z}[0]\) is the complex with \(\mathbb{Z}\) in degree zero : see \((7.1.3)\).

(iii) Let \(\mathcal{A}\) be any abelian category, \(A \in \text{Ob}(\mathcal{A})\) and \(Z \in \text{Ob}(\mathcal{A})\). Notice that the simplicial set \(\text{Hom}_{\mathcal{A}}(Z, A)\) of remark \((7.4.18)\) is actually a simplicial abelian group, and a direct inspection of the arguments of \textit{loc.cit.} yields a natural isomorphism of abelian groups

$$\text{Hom}_{s.\text{-Mod}}(Z^\Delta, \text{Hom}_{\mathcal{A}}(Z, A)) \cong \text{Hom}_{\mathcal{A}}(Z, A[i]) \quad \text{for every } i \in \mathbb{N}.$$

7.4.29. Keep the notation of remark \((7.4.25)\) and let

$$j^A_* : N_\mathcal{A}A \to A_* \quad q^A_* : A_* \to N_\mathcal{A}A$$

be respectively the injection and the projection with kernel \(D_\mathcal{A}A\). Then the rules : \(A \mapsto j^A_*\) and \(A \mapsto q^A_*\) define natural transformations

$$j_* : N_{\mathcal{A}*} \Rightarrow U_{\mathcal{A}*} \quad q_* : U_{\mathcal{A}*} \Rightarrow N_{\mathcal{A}*}.$$

With this notation, we may state :

**Theorem 7.4.30.** With the notation of remark \((7.4.29)\), we have :

(i) The injection \(j^A_*\) is a homotopy equivalence, and \(D_\mathcal{A}A\) is homotopically trivial.

(ii) More precisely, there exist natural modifications

$$j_* \circ q_* \rightsquigarrow 1_{U_{\mathcal{A}*}} \quad q_* \circ j_* \rightsquigarrow 1_{N_{\mathcal{A}*}}$$

on the 2-category \(\mathcal{C}(\mathcal{A})\) as in example \((7.1.15)\) (see definition \(2.2.9)\).

(iii) Especially, the natural map

$$H_i N_* A \to H_i A$$

is an isomorphism, for every \(i \in \mathbb{N}\).

**Proof.** Clearly (ii)\Rightarrow (i), and (i)\Rightarrow (iii), by virtue of remark \((7.1.9)\). To show (ii), set \(\varphi^A_* := 1_{A_0}\) and \(\varphi^A_n := 1_{A[n]} - \sigma_{n-1} \circ \partial^n : A_n \to A_n\) for every \(n > 0\). We notice :

**Claim 7.4.31.** The system \((\varphi^A_n \mid n \in \mathbb{N})\) defines an endomorphism of \(A_*\), which is homotopically equivalent to \(1_{A_*}\).

**Proof of the claim.** Indeed, let \(s_n := (-1)^n \cdot \sigma_n : A_n \to A_{n+1}\) for every \(n \in \mathbb{N}\), and define \(s_n := 0\) for every \(n < 0\). Using the simplicial identities \((7.4.9)\) we compute :

$$s_{n-1} \circ d_n + d_{n+1} \circ s_n = (-1)^{n-1} \cdot \sum_{j=0}^n (-1)^j \cdot (\sigma_{n-1} \circ \partial_j - \partial_j \circ \sigma_n)$$

$$= \varphi^A_n - 1_{A[n]} + (-1)^{n-1} \cdot \sum_{j=0}^{n-1} (-1)^j \cdot (\sigma_{n-1} \circ \partial_j - \sigma_{n-1} \circ \partial_j - \sigma_{n-1} \circ \partial_j)$$

for every \(n > 0\), and for \(n = 0\) we have as well \(s_{-1} \circ d_0 + d_1 \circ s_0 = 0\), whence the claim. \(\diamondsuit\)

Notice that the homotopy exhibited in the proof of claim \((7.4.31)\) is natural in \(A\), so it already yields the first sought modification. Next, for every simplicial object \(B\) of \(\mathcal{A}\), let \(\gamma B\) and \(g_B : \gamma B \to B\) be as in remark \((7.4.12)\)(i,ii), and define inductively

$$\beta^0 A := A \quad \text{and} \quad \beta^{n+1} A := \text{Ker } g_{\beta^n A} \quad \text{for every } n \in \mathbb{N}.$$
A simple inspection shows that
\[ N_{n+1} A \subset \beta^n A[i] \quad \text{and} \quad \beta^n A[0] = N_n A \quad \text{for every} \ i, n \in \mathbb{N}. \]
Hence, we may define a subcomplex \( B^{(n)}_\bullet \) of \( A_\bullet \) for every \( n \in \mathbb{N} \), as follows. For \( i = 0, \ldots, n \) we let \( B^{(n)}_i := N_i A \), and for \( i > n \) we let \( B^{(n)}_i := (\beta^n A)[n + i] \) (notation of \((7.1.3))\). The differential of \( B^{(n)}_\bullet \) is of course just the restriction of that of \( A_\bullet \). By construction, \( N_n A \) is a subcomplex of \( B^{(n)}_\bullet \), for all \( n \in \mathbb{N} \). Next, we define an endomorphism \( f^{(n)}_\bullet \) of \( B^{(n)}_\bullet \), by setting
\[ f^{(n)}_i := 1_{B^{(n)}_i} \quad \text{for every} \ i \leq n, \quad \text{and} \quad f^{(n)}_i := \varphi^{nA}_i \quad \text{for} \ i > n. \]
Notice that the restriction of \( f^{(n)}_\bullet \) to the subcomplex \( N_n A \) is just the inclusion map \( N_n A \to B^{(n)}_\bullet \).

Clearly \( B^{(n+1)}_\bullet \subset B^{(n)}_\bullet \) for every \( n \in \mathbb{N} \), and we remark that \( f^{(n)}_\bullet \) factors through the inclusion map \( B^{(n+1)}_\bullet \subset B^{(n)}_\bullet \). Indeed, since \( B^{(n)}_i = B^{(n+1)}_i \) for every \( i \leq n \), the assertion is obvious for this range of degrees; so we have only to check that \( \varphi^{nA}_i \) factors through \( \beta^{n+1} A_\bullet \) for every \( n \in \mathbb{N} \), and an easy induction reduces to checking that \( \varphi^{nA}_i \) factors through \( B^{(1)}_\bullet \). But the latter assertion comes down to the identity \( \partial_i \circ \varphi^{nA}_i = 0 \) for every \( i > 0 \), which follows easily from the simplicial identities \((7.4.9))\).

If \( (s_i \mid i \in \mathbb{N}) \) is the homotopy between \( 1^{\beta A}_\bullet \) and \( \varphi^{nA}_\bullet \) supplied by claim \(7.4.31\), then we obtain a homotopy \((t^{(n)}_i \mid i \in \mathbb{N})\) between \( 1_{B^{(n)}_\bullet} \) and \( f^{(n)}_\bullet \), by setting
\[ t^{(n)}_i := 0 \quad \text{for every} \ i < n, \quad \text{and} \quad t^{(n)}_i := s_{i-n} \quad \text{for} \ i \geq n. \]
Notice that \( \text{Im} \ t^{(n)}_i \subset D_{i+1} A \) for every \( i, n \in \mathbb{N} \). Thus, for every \( n \in \mathbb{N} \), let \( h^{(n)}_\bullet : B^{(n)}_\bullet \to B^{(n+1)}_\bullet \) be the morphism of complexes deduced from \( f^{(n)}_\bullet \) and \( j^{(n)}_\bullet : B^{(n)}_\bullet \to A_\bullet \) the inclusion map, and set \( q^{(n)}_\bullet := h^{(n)}_\bullet \circ \cdots \circ h^{(0)}_\bullet \); it follows easily that the composition
\[ p^{(n)}_\bullet := j^{(n+1)}_\bullet \circ q^{(n)}_\bullet : A_\bullet \to A_\bullet \]
is homotopically equivalent to \( 1_{A_\bullet} \), for every \( n \in \mathbb{N} \). More precisely, a direct inspection shows that the system of morphisms
\[ \tau^{(n)}_i := \sum_{k=0}^{n-1} j^{(k+1)}_\bullet \circ t^{(k+1)}_i \circ q^{(k)}_\bullet \quad \text{for every} \ i \in \mathbb{N} \]
provides a homotopy between \( 1_{A_\bullet} \) and \( p^{(n)}_\bullet \). Furthermore, it is clear that
\[ p^{(n)}_i = p^{(m)}_i \quad \text{and} \quad \tau^{(n)}_i = \tau^{(m)}_i \quad \text{for every} \ m \geq n \text{ and} \ i \leq n \]
so, we finally get an endomorphism \( p_\bullet : A_\bullet \to A_\bullet \) by setting \( p_i := p^{(i)}_i \) for every \( i \in \mathbb{N} \), and a homotopy \( \tau_\bullet \) between \( p_\bullet \) and \( 1_{A_\bullet} \), with \( \tau_i := \tau^{(i)}_i \) for every \( i \in \mathbb{N} \). By construction, \( p_\bullet \) factors through \( j_{A_\bullet}^A \), and moreover, the restriction of \( p_\bullet \) to the subcomplex \( N_n A \) is just \( j^A \), so \( j_{A_\bullet}^A \) is a homotopy equivalence, via natural homotopies, as stated.

Lastly, notice that \( \text{Im} \ \tau_i \subset D_{i+1} A \) for every \( i \in \mathbb{N} \), from which it follows easily that \( p_i(D_i A) \subset D_i A \) for every \( i \in \mathbb{N} \), and then the foregoing implies that \( \text{Ker} \ p_\bullet = D_\bullet A \). We conclude that \( D_\bullet A \) is homotopically trivial, as stated.

**7.4.32.** By iterating \( U \), we get a functor from bisimplicial objects to double complexes
\[ U^C_{\mathcal{A}} : s^2 \mathcal{A} \xrightarrow{sU_{\mathcal{A}}} s(\mathcal{C}(\mathcal{A})) \xrightarrow{U(\mathcal{C}(\mathcal{A}))} \mathcal{C}(\mathcal{C}(\mathcal{A})) \quad A[\bullet, \bullet] \mapsto A_{\bullet \bullet} \]
and notice that this functor is naturally isomorphic to the functor
\[ s^2 \mathcal{A} \xrightarrow{U_{\mathcal{A}}} \mathcal{C}(s \mathcal{A}) \xrightarrow{C(\mathcal{U}_{\mathcal{A}})} \mathcal{C}(\mathcal{C}(\mathcal{A})). \]
In the same vein, theorem 7.4.30 yields natural decompositions of additive functors:
\[ U^2_{\mathcal{A}} = (C(N_{\mathcal{A}}) \oplus C(D_{\mathcal{A}})) \circ (N_{s,\mathcal{A}} \oplus D_{s,\mathcal{A}}) \]
and if we let
\[ N^2_{\mathcal{A}} := C(N_{\mathcal{A}}) \circ N_{s,\mathcal{A}} : s^2 \mathcal{A} \to C(C(\mathcal{A})) \quad A \mapsto N_{\bullet} A \]
the natural morphism
\[ i_{\bullet} : \text{Tot } N_{\bullet} A \to \text{Tot } A_{\bullet} \]
is a homotopy equivalence.

7.4.34. We wish next to exhibit two natural transformations
\[ A^\Delta \xrightarrow{\text{AW}_n^A} \text{Tot } A_{\bullet} \xrightarrow{\text{Sh}_n^A} A^\Delta \quad \text{for every } A \in \text{Ob}(s^2 \mathcal{A}). \]
Namely, for every \( n \in \mathbb{N} \), define:
- \( \text{Sh}_n^A \) as the sum, for all \( p, q \in \mathbb{N} \) such that \( p + q = n \), of the shuffle maps
  \[ \text{Sh}_{p,q}^A := \sum_{\mu, \nu} \varepsilon_{\mu, \nu} \cdot A[\eta_{n_1} \circ \cdots \circ \eta_{n_p}, \eta_{n_1} \circ \cdots \circ \eta_{n_q}] : A_{p,q} \to A_{n,n} \]
  where the sum ranges over the shuffle permutations \( (\mu, \nu) \) of type \( (p, q) \) of the set \( \{0, \ldots, p + q - 1\} \) (these are the permutations described in [59, §4.3.15]), and \( \varepsilon_{\mu, \nu} \) is the sign of the permutation \( (\mu, \nu) \)
- \( \text{AW}_n^A \) as the sum, for all \( p, q \in \mathbb{N} \) such that \( p + q = n \), of the Alexander-Whitney maps
  \[ \text{AW}_{p,q}^A := A[\varepsilon_{p,0}^q, \varepsilon_{q,0}^p] : A_{n,n} \to A_{p,q} \]
  (notation of example 7.4.7(ii)). Clearly, for every \( p, q \in \mathbb{N} \) the rule \( A \mapsto A_{p,q} \) defines a functor
  \[ \bullet[p, q] : s^2 \mathcal{A} \to \mathcal{A} \]
and the maps \( \text{Sh}_{p,q}^A \) and \( \text{AW}_{p,q}^A \) yield natural transformations
\[ \text{Sh}_{p,q} : \bullet[p, q] \Rightarrow \bullet[p + q, p + q] \quad \text{AW}_{p,q} : \bullet[p + q, p + q] \Rightarrow \bullet[p, q]. \]

Proposition 7.4.35. With the notation of (7.4.24), the sequence \( (\text{Sh}_n^A \mid n \in \mathbb{N}) \) defines a morphism of chain complexes
\[ \text{Sh}_n^A : \text{Tot } A_{\bullet} \to A^\Delta \quad \text{for every } A \in \text{Ob}(s^2 \mathcal{A}). \]

Proof. For any bisimplicial object \( A \) of \( \mathcal{A} \), set \( A_{-1,1} = A_{p,-1} := 0 \) for every \( p, q \in \mathbb{Z} \), and let
\[ A[\varepsilon_0, 1_{[q]}] : A_{0,q} \to A_{-1,1} \quad A[1_{[p]}, \varepsilon_0] : A_{p,0} \to A_{-1,1} \quad A[\varepsilon_0, \varepsilon_0] : A_{0,0} \to A_{-1,1} \]
be the zero maps; likewise, let \( \text{Sh}_{-1,1}^A : A_{-1,1} \to A_{-1,1} \) and \( \text{Sh}_{p,-1}^A : A_{p,-1} \to A_{p,-1} \) be the zero maps, and notice that also \( \text{Sh}_{0,0}^A \) is the zero map. We define
\[ d^{A,h}_{p,q} := \sum_{i=0}^p (-1)^i \cdot A[\varepsilon_i, 1_{[q]}] : A_{p,q} \to A_{p-1,q} \quad d^{A,v}_{p,q} := \sum_{i=0}^q (-1)^i \cdot A[1_{[p]}, \varepsilon_i] : A_{p,q} \to A_{p,q-1} \]
so, for every \( n \in \mathbb{N} \) the differential \( d_n \) in degree \( n \) of \( \text{Tot } A_{\bullet} \) is the sum of the maps
\[ d_{p,q}^{A,h} + (-1)^p \cdot d_{p,q}^{A,v} : A_{p,q} \to A_{p-1,q} \oplus A_{p,q-1} \quad \text{for all } p, q \in \mathbb{N} \text{ such that } p + q = n \]
whereas the differential of \( A^\Delta \) is the morphism
\[ d_n^A := \sum_{i=1}^n A[\varepsilon_i, \varepsilon_i] : A_{n,n} \to A_{n-1,n-1} \]
and we have to check the identity
\[ (7.4.36) \quad d_{p+q}^A \circ \text{Sh}_{p,q}^A = \text{Sh}_{p-1,q}^A \circ d_{p,q}^{A,h} + (-1)^p \cdot \text{Sh}_{p,q-1}^A \circ d_{p,q}^{A,v} \quad \text{for all } p, q \in \mathbb{N}. \]
Now, we set \( B := \gamma_1 A, \ C := \gamma_2 A, \ D := \gamma_2 B \) (notation of \((7.4.16)\)), but for the purpose of this proof, we shall modify the differentials of the double complexes \( B_{\bullet \bullet} \) and \( C_{\bullet \bullet} \) in certain low degrees; namely, we define
\[
delta_{0, q}^{B, h} := A[\varepsilon_0, 1[q]] \quad \quad \delta_{p, 0}^{C, v} := A[1[p], \varepsilon_0] \quad \text{for every } p, q \in \mathbb{N}.
\]

**Claim 7.4.37.** With the foregoing notation, the following holds:

(i) \( \text{Sh}_p^A = (-1)^q \cdot \text{Sh}_p^D \circ A[1[p], \eta_q] + \text{Sh}_{p-1}^D \circ A[\eta_p, 1[q]] \) for every \( p, q \in \mathbb{N} \).

(ii) \( A[\varepsilon_{p+1}, \varepsilon_{p+1}] \circ \text{Sh}_{p-1}^D = \text{Sh}_{p-1}^D \circ A[\varepsilon_p, \varepsilon_q] \) for every \( p > 0 \).

(iii) \( A[\varepsilon_{p+q}, \varepsilon_{p+q}] \circ \text{Sh}_p^A = (-1)^q \cdot \text{Sh}_{p-1}^A \circ A[\varepsilon_q, 1[q]] + \text{Sh}_p^A \circ A[1[p], \varepsilon_q] \) for every \( p, q \in \mathbb{N} \).

**Proof of the claim.** (i): First, we notice the identities:
\[
A[1[p+q], \eta_{p+q}] \circ \text{Sh}_{p+q}^A = \text{Sh}_{p+q}^C \circ A[1[p], \eta_q] \quad \quad \text{for every } p, q \in \mathbb{N},
\]
\[
A[\eta_{p+q}, 1[p+q]] \circ \text{Sh}_{p+q}^A = \text{Sh}_{p+q}^B \circ A[\eta_p, 1[q]].
\]

That are deduced from the identities
\[
\eta_{p1} \circ \cdots \circ \eta_{p1} \circ \eta_{p+q} = \eta_q \circ \eta_{p1} \circ \cdots \circ \eta_{p1}
\]
\[
\eta_{\nu1} \circ \cdots \circ \eta_{\nu1} \circ \eta_{p+q} = \eta_p \circ \eta_{\nu1} \circ \cdots \circ \eta_{\nu1}
\]

which in turn follow from the simplicial identities for degeneracy maps. By applying the first (resp. second) identity \((7.4.38)\) with \( A \) replaced by \( B \) (resp. by \( C \)) and \( p \) replaced by \( p-1 \) (resp. with \( q \) replaced by \( q-1 \)) we get:
\[
A[1[p+q], \eta_{p+q-1}] \circ \text{Sh}_{p-1}^B = \text{Sh}_{p-1}^D \circ A[1[p], \eta_q] \quad \quad \text{for every } p, q \in \mathbb{N},
\]
\[
A[\eta_{p+q-1}, 1[p+q]] \circ \text{Sh}_{p+q-1}^B = \text{Sh}_{p+q-1}^D \circ A[\eta_p, 1[q]]\].

Now, suppose first that \( p, q > 0 \), and let \((\mu, \nu)\) be any \((p, q)\)-shuffling of \(\{0, \ldots, p+q-1\}\); then either \(\mu_p = p+q-1\) or \(\nu_q = p+q-1\). In the first (resp. second) case, after removing \(\mu_p\) (resp. \(\nu_q\)) we get a \((p-1, q)\)-shuffling (resp. a \((p, q-1)\)-shuffling) \((\bar{\mu}, \bar{\nu})\) with
\[
\varepsilon_{\bar{\mu} \bar{\nu}} = (-1)^q \cdot \varepsilon_{\mu \nu} \quad \quad \text{(resp. } \varepsilon_{\bar{\mu} \bar{\nu}} = \varepsilon_{\mu \nu}).
\]

However, the first (resp. second) left-hand side of \((7.4.39)\) contains precisely all the terms of the first (resp. second) type occurring in the definition of \(\text{Sh}_{p,q}^A\), so we get (i) in this case. The cases where either \(p = 0\) or \(q = 0\) can be dealt with by a similar, but simpler, argument.

(ii) follows by naturality of \(\text{Sh}_{p-1, q-1}^B\), applied to the morphism \(g_{A}^{(1)} \circ g_{B}^{(2)} : D \rightarrow A\) from \((7.4.16)\).

(iii): The case where \( p = q = 0 \) is obvious, and the other cases follow by composing both sides of (i) with \( A[\varepsilon_{p+q}, \varepsilon_{p+q}] \), applying (ii), and recalling that \( \eta_q \circ \varepsilon_q = 1[q] \) : details left to the reader. \(\diamondsuit\)

Now, a simple inspection shows that \((7.4.36)\) follows from claim 7.4.37(iii) and the following

**Claim 7.4.40.** \( d_{p+q-1}^D \circ \text{Sh}_{p,q}^A = \text{Sh}_{p-1,q}^A \circ d_{p-1,q}^{B,h} + (-1)^p \cdot \text{Sh}_{p-1,q}^A \circ d_{p,q-1}^{C,v} \) for every \( p, q \in \mathbb{N} \).

**Proof of the claim.** Consider first the case where \( p = 0 \). If \( q \leq 1 \), it is easily seen that both sides of the stated identity vanish; if \( q \geq 2 \), the left-hand side is
\[
d_{q-1}^D \circ A[\eta_0 \circ \cdots \circ \eta_{q-1}, 1[q]] = \sum_{i=0}^{q-1} (-1)^i \cdot A[\eta_0 \circ \cdots \circ \eta_{q-1} \circ \varepsilon_i, \varepsilon_i]
\]
and the right-hand side is
\[
A[\eta_0 \circ \cdots \circ \eta_{q-2}, 1[q]] \circ d_{0,q-1}^{C,v} = \sum_{i=0}^{q-1} (-1)^i \cdot A[\eta_0 \circ \cdots \circ \eta_{q-2}, \varepsilon_i]
\]
We prove now, by induction on $p$, that also (7.4.36) holds for these values of $(p, q)$, and for every bisimplicial object $A$ of $\mathcal{A}$; especially, we get
\[
d^q_d \circ Sh^D_{0,q} = Sh^D_{0,q-1} \circ d^D_{0,q} \quad \text{for every } q \in \mathbb{N}.
\]
Next, for $p = q = 1$, a direct computation shows that both sides equal
\[
A[\varepsilon_0 \circ \eta_0, 1]_1 - A[1_1, \varepsilon_0 \circ \eta_0] : A_{1,1} \rightarrow A_{1,1}.
\]
We prove now, by induction on $q$, that the assertion holds for $p = 1$. This is already known for $q \leq 1$, so suppose that $r > 1$, and that the assertion holds for $p = 1$ and every $q < r$. The latter implies that also (7.4.36) holds for these values of $(p, q)$, and for every bisimplicial object $A$ of $\mathcal{A}$; especially, we get
\[
d^D_d \circ Sh^A_{1,r-1} = Sh^D_{0,r-1} \circ d^D_{1,r-1} - Sh^D_{1,r-2} \circ d_{1,r-1}.
\]
On the other hand, claim (7.4.37(i)) says that
\[
d^D_d \circ Sh^A_{1,r} = (-1)^r \cdot d^D_d \circ Sh^D_{0,r} \circ A[1_1, \eta_r] + d^D_d \circ Sh^D_{1,r-1} \circ A[\eta_1, 1_r].
\]
Combining with (7.4.41) and (7.4.42) we obtain
\[
d^D_d \circ Sh^A_{1,r} = (-1)^r \cdot Sh^D_{0,r-1} \circ d^D_{1,r-1} + (Sh^D_{0,r-1} \circ d^D_{1,r-1} - Sh^D_{1,r-2} \circ d_{1,r-1}) \circ A[\eta_1, 1_r].
\]
However, we have
\[
d^D_{1,r-1} \circ A[\eta_1, 1_r] = A[\eta_1 \circ \varepsilon_0, 1_r] - A[1_1, 1_r] = A[\varepsilon_0 \circ \eta_0, 1_r] - A[1, 1_r]
\]
so we can rewrite $d^D_d \circ Sh^A_{1,r} = \varphi_1 + \varphi_2 - \varphi_3$, where
\[
\begin{align*}
\varphi_1 &:= Sh^D_{0,r-1} \circ ((-1)^r \cdot d^D_{1,r-1} - Sh^D_{1,r-2} \circ d_{1,r-1}) \circ A[\eta_1, 1_r] = (-1)^r \cdot Sh^D_{0,r-1} \circ A[1_1, \eta_r-1] \circ d_{1,r-1}, \\
\varphi_2 &:= Sh^D_{1,r-1} \circ A[\varepsilon_0 \circ \eta_0, 1_r], \\
\varphi_3 &:= Sh^D_{1,r-2} \circ d^D_{1,r-1} \circ A[\eta_1, 1_r].
\end{align*}
\]
On the other hand, using claim (7.4.37(i)), we can compute
\[
Sh^A_{1,r} \circ d^B_{1,r-1} = Sh^D_{0,r-1} \circ A[\eta_0, 1_r] \circ d^B_{1,r-1} = \varphi_2
\]
\[
Sh^A_{1,r-1} \circ d^C_{1,r-1} = ((-1)^{r-1} \cdot Sh^D_{0,r-1} \circ A[1_1, \eta_r-1] + Sh^D_{1,r-2} \circ A[\eta_1, 1_{r-1}]) \circ d_{1,r-1} \circ A[\eta_1, 1_r] = \varphi_3 - \varphi_1
\]
which shows that the claim holds for $p = 1$ and $q = r$, and concludes the induction.

Lastly, we prove the claim for every $p, q \in \mathbb{N}$, by induction on $p + q$; notice that the foregoing already shows that the assertion holds whenever $p + q \leq 2$. Thus, let $r > 2$, and suppose that the claim is already known for every pair $(p, q)$ such that $p + q < r$; then also (7.4.36) holds for such values of $p$ and $q$, and especially we get
\[
d^D_{p+q} \circ Sh^D_{p,q} = Sh^D_{p-1,q} \circ d^D_{p,q} + (-1)^p \cdot Sh^D_{p,q-1} \circ d^D_{p,q} \quad \text{whenever } p + q < r.
\]
Let $(p', q')$ be a pair such that $p' + q' = r$; combining (7.4.43) with claim (7.4.37(i)), we get
\[
d^D_{p'+q'-1} \circ Sh^A_{p', q'} = (-1)^{p'} \cdot (Sh^D_{p'-2,q'} \circ d^D_{p'-1,q}' - (1)^{p'} \cdot Sh^D_{p'-1,q'-1} \circ d^D_{p'-1,q}' - A[1[p'], \eta_{q'}] + (Sh^D_{p'-1,q'-1} \circ d^D_{p'-1,q}' + (1)^{p'} \cdot Sh^D_{p'-2,q'} \circ d^D_{p'-2,q'} \circ A[\eta_{p'}, 1_{q'}].
\]
On the other hand, after noticing that
\[
\begin{align*}
d^D_{p', q'-1} \circ A[\eta_{p'}, 1_{q'}] = (-1)^{p'} \cdot A[\eta_{p'-1}, 1_{q'}] &\circ d_{p'-1, q'} \\
d^D_{p'-1, q'} \circ A[1[p'], \eta_{q'}] = (-1)^{q'} \cdot A[1[p'], \eta_{q'-1}] &\circ d_{p'-1, q'}
\end{align*}
\]
we may apply claim \[7.4.37\text{(i)},\] to compute
\[
\text{Sh}_{p',q'-1}^A \circ d_{p',q'-1}^{B,h} = ((-1)^{q'} \cdot \text{Sh}_{p'-1,q'}^D \circ A[1_{|p'-1|}, \eta_{q'}] + \text{Sh}_{p'-1,q'-1}^D \circ A[\eta_{p'-1}, 1_{|q'|}]) \circ d_{p'-1,q'}^{B,h}
\]
\[
= (-1)^{q'} \cdot \text{Sh}_{p'-2,q'}^D \circ d_{p'-2,q'-1}^{B,h} \circ A[1_{|p'|}, \eta_{q'}] - (-1)^{q'} \cdot \text{Sh}_{p'-1,q'-1}^D
\]
\[
+ \text{Sh}_{p'-1,q'-1}^D \circ d_{p',q'-1}^{B,h} \circ A[\eta_{p'}, 1_{|q'|}]
\]
and
\[
\text{Sh}_{p',q'-1}^A \circ d_{p',q'-1}^{C,v} = ((-1)^{-q'} \cdot \text{Sh}_{p'-1,q'-1}^D \circ A[1_{|p'|}, \eta_{q'-1}]
\]
\[
+ \text{Sh}_{p',q'-2} \circ A[\eta_{p'}, 1_{|q'-1|}]) \circ d_{p',q'-1}^{C,v}
\]
\[
= (-1)^{-q'} \cdot \text{Sh}_{p'-1,q'-1}^D \circ d_{p',q'-1}^{D,v} \circ A[1_{|p'|}, \eta_{q'}] + \text{Sh}_{p'-1,q'-1}^D
\]
\[
+ \text{Sh}_{p',q'-2} \circ d_{p',q'-1}^{D,v} \circ A[\eta_{p'}, 1_{|q'|}]
\]
Finally, the sought identity for the pair \((p', q')\) follows by comparing the last two identities with the previous one for \(d_{p',q'-1}^D \circ \text{Sh}_{p',q'}^A\), and this concludes the proof of the inductive step. \(\square\)

**Proposition 7.4.44.** With the notation of \((7.4.24)\), the sequence \((\text{AW}_n^A \mid n \in \mathbb{N})\) defines a morphism of chain complexes
\[
\text{AW}_n^A : A^\bullet \to \text{Tot}A^\bullet \quad \text{for every } A \in \text{Ob}(s^2.A).
\]

**Proof.** Denote by \(d^T\) the differential of \(\text{Tot}A^\bullet\), and keep the notation of the proof of proposition \[7.4.35\] we have to check the identity
\[
(7.4.45) \quad \text{AW}_{n-1} \circ d_n^A = d^T_n \circ \text{AW}_n \quad \text{for every } n \in \mathbb{N}.
\]
However, say that \(p, q \in \mathbb{N}\) and \(p + q = n\); the projection of the right-hand side of \((7.4.45)\) on the direct summand \(A_{p-1,q}\) of \((\text{Tot}A^\bullet)_{n-1}\) equals
\[
(7.4.46) \quad d_{p,q}^{A,h} \circ \text{AW}_{p,q} + (-1)^{p-1} \cdot d_{p-1,q+1}^{A,v} \circ \text{AW}_{p-1,q+1}.
\]
Unwinding the definition, \((7.4.46)\) is found to be
\[
\sum_{i=0}^{p} (-1)^{i} \cdot A[\varepsilon_{p,0}^q \circ \varepsilon_i, \varepsilon_{p,0}^q] - (-1)^{p} \cdot \sum_{i=0}^{q+1} (-1)^{i} \cdot A[\varepsilon_{p+1,0}^q \circ \varepsilon_{p+1,0}^q, \varepsilon_{p+1,0}^q \circ \varepsilon_{i-1}]
\]
which we may rewrite as
\[
(7.4.47) \quad \sum_{i=0}^{p-1} (-1)^{i} \cdot A[\varepsilon_i^q, \varepsilon_{i}^q] + \sum_{i=p}^{p+q} (-1)^{i} \cdot A[\varepsilon_i^q, \varepsilon_{i}^q, \varepsilon_{i-1}]
\]
On the other hand, the projection of the left-hand side of \((7.4.45)\) onto \(A_{p-1,q}\) equals
\[
\sum_{i=0}^{n} (-1)^{i} \cdot A[\varepsilon_i \circ \varepsilon_{p-1,0}, \varepsilon_i \circ \varepsilon_{p-1,0}^q]
\]
To compare the latter with \((7.4.47)\), it suffices to remark that
\[
\varepsilon_i \circ \varepsilon_{p-1,0}^q = \begin{cases} \varepsilon_{p,0}^q \circ \varepsilon_i & \text{if } i < p \\ \varepsilon_{p+1,0}^q \circ \varepsilon_{p-1,0}^q \circ \varepsilon_i & \text{if } i \geq p \end{cases} \quad \text{and} \quad \varepsilon_i \circ \varepsilon_{p-1,0} = \begin{cases} \varepsilon_{p,0}^q \circ \varepsilon_i & \text{if } i < p \\ \varepsilon_{p-1,0}^q \circ \varepsilon_i & \text{if } i \geq p \end{cases}
\]
which are all deduced from the simplicial identities for the \(\varepsilon_i\). The proposition follows. \(\square\)
7.4.48. Propositions 7.4.35 and 7.4.44 yield natural transformations of functors

\[
\text{Tot } U^2_{\omega} \xrightarrow{\text{Sh}_*} AW_* \xrightarrow{h_{\omega}} U_\omega \circ \Delta_\omega.
\]

Now, denote by \( h_{\omega} : C(\omega) \to \text{Hot}(\omega) \) the natural functor (this induces the identity on the objects, and the projection on the group of morphisms); there follow natural transformations

\[
h_{\omega} \circ \text{Tot } U^2_{\omega} \xrightarrow{h_{\omega} \ast \text{Sh}_*} h_{\omega} \circ U_\omega \circ \Delta_\omega.
\]

between functors \( s^2 : \omega \to \text{Hot}(\omega) \).

**Theorem 7.4.49** (Eilenberg-Zilber-Cartier). With the notation of (7.4.48), we have:

(i) \( h_{\omega} \ast AW_* \) and \( h_{\omega} \ast \text{Sh}_* \) are mutually inverse isomorphisms of functors.

(ii) More precisely, there exist natural modifications (see definition 2.2.9)

\[
AW_* \circ \text{Sh}_* \sim 1_{\text{Tot } U^2_{\omega}} \quad \text{Sh}_* \circ AW_* \sim 1_{U_\omega \circ \Delta_\omega}.
\]

**Proof.** Let \( p^A_n : \text{Tot } A_n \to \text{Tot } N_n A \) be the projection whose kernel is the sum of the remaining three direct summands in the decomposition \( \text{Tot } (7.4.33) \); explicitly, in each degree \( n \in \mathbb{N} \), this kernel is the sum of the subobjects \( \text{Im } A[\eta_1, 1[q]] \) and \( \text{Im } A[1[p], \eta_1] \) of \( A_{p,q} \), for every \( i = 0, \ldots, p - 1, j = 0, \ldots, q - 1 \), and every \( p, q \in \mathbb{N} \) such that \( p + q = n \). Likewise, let \( j^A_n : N_n A^A \to A^A_n \) and \( q^A_n : A^A_n \to N_n A^A \) be as in (7.4.29); theorem 7.4.30 and the discussion of (7.4.32) show that the pairs \( (p^A_n, j^A_n) \) and \( (j^A_n, q^A_n) \) induce mutually inverse isomorphisms in \( \text{Hom}(\omega, \omega) \), so it suffices to check that the same holds for the compositions

\[
\text{Sh}^A_n := q_n^A \circ \text{Sh}^A_n \circ j^A_n : \text{Tot } N_n A \to N_n A^A \quad \text{AW}^A_n := p_n^A \circ \text{AW}^A_n \circ j^A_n : N_n A^A \to \text{Tot } N_n A
\]

for every bisimplicial object \( A \) of \( \omega \). However, we have

**Claim 7.4.50.** \( p^A_n \circ \text{AW}^A_n \circ \text{Sh}^A_n \circ j^A_n = 1_{\text{Tot } N_n A} \).

**Proof of the claim.** More precisely, say that \( p + q = n \), consider the composition

\[
f_{p,q} : A_{p,q} \xrightarrow{\text{Sh}^A_{p,q}} A_{p+q,p+q} \xrightarrow{\text{AW}^A_n} (\text{Tot } A_*)_n
\]

and let \( g_{p,q} : A_{p,q} \to (\text{Tot } A_*)_n \) be the inclusion map; we shall show that \( f_{p,q} - g_{p,q} \subset \text{Ker } p^A_n \).

Indeed, we have

\[
f_{p,q} = \sum_{i=0}^{n} \sum_{(\mu, \nu)} \epsilon_{\mu \nu} \cdot A[\eta_{\mu_1} \circ \cdots \circ \eta_{\nu_q} \circ \epsilon_{i,0}^{n-i}, \eta_{\mu_1} \circ \cdots \circ \eta_{\nu_p} \circ \epsilon^{i}_{n-i,0}]
\]

(note the notation of (7.4.34), and \( \epsilon^{i}_{n-i,0} \) is defined as in the proof of proposition 7.4.44). However, if \( i < p \), then \( \eta_{\mu_1} \circ \cdots \circ \eta_{\mu_p} \circ \epsilon^{i}_{n-i,0} \) is of the form \( \tau \circ \eta_{\mu_p} \) for some \( \tau : [p + q - i - 1] \to [q] \), so the corresponding term does lie in \( \text{Ker } p^A_n \). If \( i > p \), then \( \eta_{\mu_1} \circ \cdots \circ \eta_{\nu_q} \circ \epsilon^{i-1}_{n-i,0} \) is of the form \( \tau \circ \eta_{\mu} \) for some \( k \leq \nu_q \) and some \( \tau : [i - 1] \to [p] \), so this term likewise lies in \( \text{Ker } p^A_n \). It remains to consider the terms with \( i = p \); however, a simple inspection shows that \( \eta_{\mu_1} \circ \cdots \circ \eta_{\nu_q} \circ \epsilon^{p-1}_{n-p,0} \) is of the same form as above, unless \( \nu_q \) is either \( p - 1 \) or \( p \) (details left to the reader); furthermore, if \( \nu_1 = p - 1 \), then \( \mu_p \geq p \), in which case \( \eta_{\mu_1} \circ \cdots \circ \eta_{\nu_p} \circ \epsilon^{i}_{n-i,0} \) is of the form described above.

In all these cases, the corresponding term again lies in \( \text{Ker } p^A_n \). So, it remains only to consider the single case where \( (\mu, \nu) \) is the identity permutation, whose sign equals 1; in this case, the corresponding term is none else than \( A[1[p], 1[q]] \), whence the claim.

**Claim 7.4.50** and theorem 7.4.30(ii) already yield the existence of the sought modification \( AW_* \circ \text{Sh}_* \sim 1_{\text{Tot } U^2_{\omega}} \). Next we define, for every \( n \in \mathbb{N} \), a natural transformation

\[
s_n : \bullet[n] \circ \Delta_\omega \Rightarrow \bullet[n+1] \circ \Delta_\omega.
\]
(notation of (7.4.4); so $s^n$ is a morphism $A[n, n] \to A[n + 1, n + 1]$ for every object $A$ of $s^2\mathcal{A}$). The construction is by induction on $n$: for $n = 0$ we let $s_0^A : A[0, 0] \to A[1, 1]$ be the zero morphism; for $n > 0$ we set

$$s_n^A := Sh_n^A \circ AW_n^A \circ A[\eta_0, \eta_0] - s_{n-1}^A$$

where $A' := (\gamma_2 \circ \gamma_1(A^V))^V$ (notation of (7.4.16) and (7.4.2): explicitly, we have $A'[p, q] := A[p + 1, q + 1]$ for every $p, q \in \mathbb{N}$, and $A'[\varepsilon_i, \varepsilon_j] := A[\varepsilon_{i+1}, \varepsilon_{j+1}]$, and likewise for $A'[\eta_i, \eta_j], A'[\eta_i, \eta_j]$ and $A'[\eta_i, \eta_j]$, for every face and degeneracy map of $\Delta$). We have

**Claim 7.4.51.** The system $(q_{n+1}^A \circ s_n^A \circ j^n_n | n \in \mathbb{N})$ is a homotopy $q_n^A \circ Sh_n^A \circ AW_n^A \circ j_n^A : 1_{N_n^A} \to A$.

**Proof of the claim.** Denote by $d_A^*$ the differential of $A^*_\bullet$, and let $d_0^A : A_0^A \to 0$ and $s_{-1}^A : 0 \to A_0^A$ be the zero morphisms. We check, more precisely, that

$$q_n^A \circ (d_{n+1}^A \circ s_n^A + s_{n-1}^A \circ d_n^A) = q_n^A \circ Sh_n^A \circ AW_n^A - q_n^A$$

for every $n \in \mathbb{N}$.

We argue by induction on $n$, and the assertion is clear for $n = 0$. For $n = 1$, notice that

$$Sh_1^A \circ AW_1^A = A[\varepsilon_1 \circ \eta_0, 1[1]] + A[1[1], \varepsilon_0 \circ \eta_0] : A_{1, 1} \to A_{1, 1}.$$

It follows that

$$s_1^A = Sh_1^A \circ AW_1^A \circ A[\varepsilon_0 \circ \eta_0, \eta_0] = (A[\varepsilon_1 \circ \eta_0 \circ \eta_0, \eta_0] + A[\eta_0, \eta_1])$$

whence

$$d_1^A \circ s_1^A = Sh_1^A \circ AW_1^A - 1_{A[1, 1]} + A[\varepsilon \circ \varepsilon \circ \eta_0, \varepsilon \circ \varepsilon \circ \eta_0]$$

(details left to the reader). Since $\text{Im} \ A[\eta_0, \eta_0] \subset \text{Ker} \ q_1^A$, the assertion follows in this case. Next, suppose that $r > 1$, and that the sought identity is already known for every $n < r$, and every bisimplicial object $A$; especially, it holds for $A'$, so if we let $d_r^A$ be the differential of $A'_{\bullet}$, we get

$$(7.4.52) \quad q_{r-1}^A \circ (d_r^A \circ s_{r-1}^A + s_{r-2}^A \circ d_{r-1}^A) = q_{r-1}^A \circ Sh_{r-1}^A \circ AW_{r-1}^A - q_{r-1}^A.$$

On the other hand, after noticing that

$$d_r^A \circ A[\eta_0, \eta_0] = 1_{A[r, r]} - A[\eta_0, \eta_0] \circ d_r^A$$

we may compute

$$d_r^A \circ s_r^A = d_r^A \circ Sh_r^A \circ AW_r^A \circ A[\eta_0, \eta_0] - d_r^A \circ s_{r-1}^A = Sh_r^A \circ AW_r^A \circ A[\eta_0, \eta_0] - d_r^A \circ s_{r-1}^A = Sh_r^A \circ AW_r^A - Sh_r^A \circ AW_r^A \circ A[\eta_0, \eta_0] \circ d_{r-1}^A - d_r^A \circ s_{r-1}^A - d_r^A \circ s_{r-1}^A$$

which, combined with (7.4.52), implies

$$(7.4.53) \quad q_{r-1}^A \circ (d_r^A \circ s_{r-1}^A + s_{r-2}^A \circ d_{r-1}^A) = -q_{r-1}^A.$$

Furthermore, notice the natural morphism in $s^2\mathcal{A}$

$$(g_1^{(1)} \circ g_2^{(2)})^V : A' \to A$$

supplied by (7.4.16); explicitly, for every $p, q \in \mathbb{N}$, this morphism is given by the discarded face operator $A[\varepsilon_0, \varepsilon_0] : A[p + 1, q + 1] \to A[p, q]$. Then, the naturality of $s_{\bullet}, Sh_{\bullet}$ and $AW_{\bullet}$ implies

$$A[\varepsilon_0, \varepsilon_0] \circ s_r^A = A[\varepsilon_0, \varepsilon_0] \circ Sh_r^A \circ AW_r^A \circ A[\eta_0, \eta_0] - A[\varepsilon_0, \varepsilon_0] \circ s_{r-1}^A = Sh_r^A \circ AW_r^A \circ A[\eta_0, \eta_0] \circ \varepsilon_0 \circ \varepsilon_0 - s_{r-1}^A \circ A[\varepsilon_0, \varepsilon_0] = Sh_r^A \circ AW_r^A - s_{r-1}^A \circ A[\varepsilon_0, \varepsilon_0].$$

Lastly, recalling that $d_r^A = A[\varepsilon_0, \varepsilon_0] - d_r^A$, the latter identity can be added to (7.4.53), to deduce

$$q_{r-1}^A \circ (d_{r+1}^A \circ s_{r-1}^A + s_{r-2}^A \circ d_{r-1}^A) = q_{r-1}^A \circ Sh_r^A \circ AW_r^A - q_{r-1}^A.$$
Now, to prove the assertion in degree $r$, it suffices to observe that $q^A_i$ factors through $q^A_{r-1}$. \hfill \triangleleft

Claim \[7.4.51\] and theorem \[7.4.30\](ii) supply the second sought modification, and conclude the proof of the theorem. \hfill \square

7.4.54. Let $(\mathcal{A}, \otimes)$ be an abelian tensor category, $A[\bullet]$ and $B[\bullet]$ two objects of $s\mathcal{A}$, and define the bisimplicial objects $A \otimes B$ and $B \otimes A$ of $\mathcal{A}$ as in remark \[7.4.17\](iii). Notice that the system of commutativity constraints $(\Psi_{A[n],B[n]} \mid n \in \mathbb{N})$ amounts to an isomorphism

$$\Psi_{A \otimes B} : A \otimes B \sim B \otimes A \quad \text{in } s\mathcal{A}$$

whence an isomorphism $\Psi_{(A \otimes B)[\bullet]} : (A \otimes B)[\bullet] \sim (B \otimes A)[\bullet]$ on the respective unnormalized complexes.

**Proposition 7.4.55.** With the notation of \[7.4.54\], the diagram of chain complexes

$$\begin{array}{ccc}
\text{Tot}(A \boxtimes B)[\bullet] & \xrightarrow{\Psi_{(A \otimes B)[\bullet]}} & \text{Tot}(B \boxtimes A)[\bullet] \\
\text{Sh}_{A \boxtimes B}[\bullet] & \downarrow & \text{Sh}_{B \boxtimes A}[\bullet] \\
(A \otimes B)[\bullet] & \xrightarrow{\Psi_{(A \otimes B)[\bullet]}} & (B \otimes A)[\bullet]
\end{array}$$

commutes, where $\Psi_{(A \otimes B)[\bullet]}$ is the commutativity constraint for the unnormalized chain complexes $A[\bullet]$ and $B[\bullet]$ as in \[7.1.17\].

**Proof.** The assertion boils down to the identity

$$(-1)^{pq} \cdot \text{Sh}_{B[p,q]}[\bullet] \circ \Psi_{A[p],B[q]} = \Psi_{A[n],B[n]} \circ \text{Sh}_{B[p,q]}[\bullet]$$

for every $p, q \in \mathbb{N}$ with $p + q = n$. For the latter, suppose first that $p = 0$, in which case

$$\text{Sh}_{B[p,q]}[\bullet] = A[\eta_0] \otimes \cdots \otimes \eta_{q-1} \otimes 1_{B[q]}$$

and

$$\text{Sh}_{B[p,q]}[\bullet] = 1_{B[q]} \otimes A[\eta_0] \otimes \cdots \otimes \eta_{q-1}$$

from which we derive \[7.4.56\], using the naturality of $\Psi$ (details left to the reader). Likewise we argue for the case where $q = 0$. For the general case, we proceed by induction on $n$. The cases $n = 0, 1$ have already been dealt with, so suppose $r \geq 2$, and that the sought identity is already known for every pair of integers whose sum is $< n$, and every objects $A, B$ of $s\mathcal{A}$. By the foregoing, we may also assume that both $p, q > 0$, and then claim \[7.4.37\](i) implies that

$$\text{Sh}_{B[p,q]}[\bullet] = (-1)^q \cdot \text{Sh}_{p-1,q}^\gamma \circ (A[p] \otimes B[\eta_q]) + \text{Sh}_{B[p,q]}^\gamma \circ (A[\eta_p] \otimes 1_{B[q]})$$

However, it follows easily from remark \[7.4.34\](iii) that $\Psi$ is an additive functor in both of its arguments; combining with the inductive assumption, we deduce that

$$\Psi_{A[n],B[n]} \circ \text{Sh}_{p,q}^\gamma = (-1)^{pq} \cdot \text{Sh}_{p-1,q}^\gamma \circ (A[p] \otimes B[\eta_q]) + (-1)^{pq} \cdot \text{Sh}_{p,q-1}^\gamma \circ (A[p] \otimes B[\eta_q]) + (A[p] \otimes B[\eta_q])$$

where the last equality follows again from claim \[7.4.37\](i) and the additivity of $\Psi$. \hfill \square
7.4.57. The shuffle map is also associative, in the following sense. Let

\[ A := (A[p, q, r] \mid p, q, r \in \mathbb{N}) \]

be any triple simplicial object of the abelian category \( \mathcal{A} \), and denote by \( A^{(1,2)} \) (resp. \( A^{(2,3)} \)) the diagonal bisimplicial object of \( \mathcal{A} \) extracted from \( A \) by the rule

\[ A^{(1,2)}[p, q] := A[p, p, q] \quad \text{(resp. } A^{(2,3)}[p, q] := A[p, q, q] \text{)} \quad \text{for every } p, q \in \mathbb{N}. \]

Let also \( A_{\bullet \bullet \bullet} \) be the triple chain complex associated to \( A \), and \( A_{\bullet \bullet \bullet}^{\Delta} \) the diagonal chain complex extracted from \( A_{\bullet \bullet \bullet} \). Moreover, denote by \( A'_{\bullet \bullet \bullet} \) (resp. \( A''_{\bullet \bullet \bullet} \)) the bisimplicial object of \( s.\mathcal{A} \) given by the rule:

\[ [p, q] \mapsto A[p, q, \bullet] \quad \text{(resp. } [p, q] \mapsto A[\bullet, p, q] \text{)} \quad \text{for every } p, q \in \mathbb{N}. \]

**Proposition 7.4.58.** With the notation of (7.4.57), we have a commutative diagram in \( C(\mathcal{A}) \)

\[
\begin{array}{ccc}
\text{Tot}(A_{\bullet \bullet \bullet}) & \xrightarrow{\text{Sh}_{\mathcal{A}}^{A^{(1,2)}}} & \text{Tot}(A^{(1,2)}) \\
\downarrow & & \downarrow \text{Sh}_{\mathcal{A}}^{A^{(1,2)}} \\
\text{Tot}(A^{(2,3)}) & \xrightarrow{\text{Sh}_{\mathcal{A}}^{A^{(2,3)}}} & A_{\bullet \bullet \bullet}^{\Delta}
\end{array}
\]

whose top horizontal (resp. left vertical) arrow is obtained as the composition of \( \text{Sh}_{\mathcal{A}}^{A'} \) (resp. \( \text{Sh}_{\mathcal{A}}^{A''} \)) with the functor \( \text{Tot} \circ C(U_{\mathcal{A}}) : C(s.\mathcal{A}) \to C(C(\mathcal{A})) \to C(\mathcal{A}) \).

**Proof.** For every \( p, q, r \in \mathbb{N} \), denote by

\[
\begin{align*}
\text{Sh}_{A'}^{A^{(1,2)}}[r] : A[p, q, r] & \to A[p + q, p + q, r] = A^{(1,2)}[p + q, r] \\
\text{Sh}_{A''}^{A^{(2,3)}}[p] : A[p, q, r] & \to A^{(2,3)}[p, q + r]
\end{align*}
\]

respectively the \([r]\)-component of \( \text{Sh}_{A'}^{A'} \) and the \([p]\)-component of \( \text{Sh}_{A''}^{A''} \). The assertion boils down to the identity:

\[ \text{Sh}_{A'}^{A^{(1,2)}} \circ \text{Sh}_{A'}^{A'}[r] = \text{Sh}_{A''}^{A^{(2,3)}} \circ \text{Sh}_{A''}^{A''}[p] \quad \text{for every } p, q, r \in \mathbb{N}. \]

To check the latter, set

\[ D' := \gamma_2 \circ \gamma_1 A' \quad D^{(1,2)} := \gamma_2 \circ \gamma_1 (A^{(1,2)}) \]

and define likewise \( D'' \) and \( D^{(2,3)} \) (notation of (7.4.16)). Also, let \( A[p, q, r] := 0 \) whenever one of the indices \( p, q, r \) is \(< 0 \), and define \( \text{Sh}_{A'}^{A'} \) to be the zero map, when either \( p \) or \( q \) is strictly negative (cp. the proof of proposition 7.4.35). We argue by induction on \( n := p + q + r \); the case \( n = 0 \) is trivial, so suppose that \( n > 0 \), and that the assertion is already known for all indices whose sum is \(< n \), and all triple simplicial objects of \( \mathcal{A} \). Notice as well that the assertion trivially holds as well if any of the indices \( p, q, r \) is strictly negative, since in this case both sides are the zero map. Hence, we may assume that \( p, q, r \in \mathbb{N} \); in this case, by applying
claim \(7.4.37(i)\), first to \(A^{(1,2)}\) and then to \(A'\), we compute

\[
\text{Sh}_{p+q,r}^{A^{(1,2)}} \circ \text{Sh}_{p,q}^{A'[r]} = (-1)^r \cdot \text{Sh}_{p+q-1,r}^{D^{(1,2)}} \circ A[1_{[p+q]}, 1_{[p+q]}, \eta_r] \circ \text{Sh}_{p,q}^{A'[r]}
\]

\[
+ \text{Sh}_{p+q,r-1}^{D^{(1,2)}} \circ A[\eta_{p+q}, \eta_{p+q}, 1_{[r]]}] \circ \text{Sh}_{p,q}^{A'[r]}
\]

\[
= (-1)^r \cdot \text{Sh}_{p+q-1,r}^{D^{(1,2)}} \circ \text{Sh}_{p,q}^{A'[r] + 1} \circ A[1_{[p]}, 1_{[q]}, \eta_r]
\]

\[
+ \text{Sh}_{p+q,r-1}^{D^{(1,2)}} \circ \text{Sh}_{p,q}^{A'[r]} \circ A[\eta_{p}, \eta_{q}, 1_{[r]}]
\]

(\text{by } (7.4.38))

where the last identity holds by inductive assumption. On the other hand, by applying claim \(7.4.37(i)\) to \(A^{(2,3)}\) we get

\[
\text{Sh}_{p,q+r}^{A^{(2,3)}} \circ \text{Sh}_{q,r}^{A'[p]} = (-1)^{q+r} \cdot \text{Sh}_{p-1,q+r}^{D^{(2,3)}} \circ A[1_{[p]}, \eta_q, \eta_{q+r}] \circ \text{Sh}_{q,r}^{A'[p]}
\]

\[
+ \text{Sh}_{p,q+r-1}^{D^{(2,3)}} \circ A[\eta_{p}, 1_{[q+r]}, 1_{[q+r]}] \circ \text{Sh}_{q,r}^{A'[p]}
\]

\[
= (-1)^{q+r} \cdot \text{Sh}_{p-1,q+r}^{D^{(2,3)}} \circ \text{Sh}_{q,r}^{A'[p] + 1} \circ A[1_{[p]}, \eta_q, \eta_r]
\]

\[
+ \text{Sh}_{p,q+r-1}^{D^{(2,3)}} \circ \text{Sh}_{q,r}^{A'[p] + 1} \circ A[\eta_{p}, 1_{[q]}, 1_{[r]}]
\]

(\text{by } (7.4.38))

and after applying again claim \(7.4.37(i)\) to \(A''\) and comparing with the foregoing expression for \(\text{Sh}_{p,q+r}^{A^{(1,2)}} \circ \text{Sh}_{p,q}^{A'[r]}\), we obtain the sought identity.

\[\text{Theorem 7.4.59 (Dold-Puppe-Kan). For any abelian category } \mathcal{A}, \text{ and any } k \in \mathbb{N}, \text{ we have :}\]

\[(i) \text{ The functors } N_{\mathcal{A}} \text{ and } N_{\mathcal{A},k}, \text{ are equivalences.}\]

\[(ii) \text{ If } f, g \text{ are any two morphisms in } s.A, \text{ then there exists a simplicial homotopy from } f \text{ to } g \text{ if and only if there exists a chain homotopy from } N_f \text{ to } N_g.\]

\[\text{Proof. We easily reduce to the case where } \mathcal{A} \text{ is small, and then there exists a fully faithful embedding } \mathcal{A} \rightarrow \mathcal{B}, \text{ where } \mathcal{B} \text{ is a complete and cocomplete abelian tensor category, with internal Hom functor (lemma } 3.6.46)\]

\[(i) \text{ We first construct an explicit quasi-inverse for the functors } N_{\mathcal{B}} \text{ and } N_{\mathcal{A},k}, \text{ as follows. For every } i \in \mathbb{N}, \text{ consider the cochain complex } \mathbb{K}(i)_*, \text{ defined in example } 7.4.28(ii); \text{ notice that every morphism } \varphi : [i] \rightarrow [i'] \text{ in } \Delta \text{ induces a morphism}\]

\[\mathbb{K}(\varphi)_* := N_* \mathbb{K}(\varphi)_* : \mathbb{K}(i)_* \rightarrow \mathbb{K}(i')_*\]

(\text{notation of remark } 7.4.18(iii)). \text{ Hence, the system } \mathbb{K}(i)_* \mid i \in \mathbb{N} \text{ amounts to a cosimplicial object of } C^{\leq 0}(\mathcal{Z}-\text{Mod}). \text{ Now, let } U \text{ be a unit of the tensor category } \mathcal{B}, \text{ for any object } C_* \text{ of } C^{\leq 0}(\mathcal{B}) \text{ (resp. of } C^{[-k,0]}(\mathcal{B})), \text{ we set}\]

\[K_C[i] := \text{Hom}_C(\mathcal{B})(\mathbb{K}(i)_* \otimes_Z U[0], C_*) \text{ for every } i \in \mathbb{N} \text{ (resp. for every } i \leq k)\]

where \(\text{Hom}_C(\mathcal{B})\) is the functor constructed in example 7.1.16(vii), and the mixed tensor product is defined as in (7.1.18). \text{ By the foregoing, it is clear that the system } \{K_C[i] \mid i \in \mathbb{N}\} \text{ amounts to}\]
an object of \(s\mathcal{B}\) (resp. of \(s_k\mathcal{B}\)). In order to compute \(N_\bullet K_C\), let us set
\[
\mathbb{K}^i := \sum_{n=1}^i \text{Im} (\mathbb{Z}^{\Delta n} : \mathbb{Z}^{\Delta i} \to \mathbb{Z}^{\Delta i}) \quad \mathbb{Z}^\Delta_i := \mathbb{Z}^{\Delta i} / \mathbb{Z}^\Delta_i \quad \mathbb{K}(i)_\bullet := N_\bullet \mathbb{Z}^\Delta_i
\]
for every \(i > 0\), as well as \(\mathbb{Z}^\Delta_0 := \mathbb{Z}^\Delta_0\) and \(\mathbb{K}(0)_\bullet := \mathbb{K}(0)_\bullet\); thus, \(\mathbb{K}(i)_\bullet\) is also the quotient of \(\mathbb{K}(i)_\bullet\) by the sum of the images of the morphisms \(\mathbb{K}(\varepsilon_n)\), for \(n = 1, \ldots, i\). With this notation, a simple inspection of the definition shows that
\[
N_i K_C = \mathcal{H}om_{\mathcal{C}(\mathcal{B})}(\mathbb{K}(i)_\bullet \otimes \mathbb{Z} U[0], \mathcal{C}_\bullet) \quad \text{for every } i \in \mathbb{N} \text{ (resp. for every } i \leq k).\]
On the other hand, using the explicit description of example 7.4.28(ii), it is easily seen that
\[
\mathbb{K}(i)_n \sim \begin{cases} 
\mathbb{Z} & \text{if } n = i \text{ or } n = i - 1 \geq 0 \\
0 & \text{otherwise.}
\end{cases}
\]
More precisely, \(\mathbb{K}(i)_i\) (resp. \(\mathbb{K}(i)_{i-1}\)) is generated by the basis element \(e_1\) of \(\mathbb{K}(i)_i\) (resp. \(e_{i_0}\) of \(\mathbb{K}(i)_{i-1}\)) corresponding to the identity map \(1_{[i]}\) (resp. corresponding to \(\varepsilon_0 : [i - 1] \to [i]\)). Furthermore, example 7.4.28(i) shows that the differential \(\mathbb{K}(i)_i \to \mathbb{K}(i)_{i-1}\) maps \(e_1\) to \(e_{i_0}\), so it corresponds to the identity map \(\mathbb{Z} \to \mathbb{Z}\), under the foregoing identification. Taking into account remark 3.6.12(iv), we deduce that \(N_i K_C\) is the kernel of the morphism
\[
(7.4.60) \quad C_i \oplus C_{i-1} \to C_{i-1} \oplus C_{i-2}
\]
given by the matrix
\[
\begin{pmatrix}
(-1)^i \cdot d_i^C & 1 & 0 \\
0 & (-1)^{i+1} \cdot d_{i-1}^C
\end{pmatrix}
\]
and since \(d_{i-1}^C \cdot d_i^C = 0\), the latter is just \(C_i\); more precisely, \(C_i\) is identified with this kernel, via the monomorphism
\[
(7.4.61) \quad (1_{C_i}, (-1)^{i+1} \cdot d_i^C) : C_i \to C_i \oplus C_{i-1}.
\]
This identification \(N_i K_C \sim C_i\) can also be described as follows. For every \(Z \in \text{Ob} (\mathcal{B})\), let
\[
\text{Hom}_{\mathcal{B}}(Z, \mathcal{C}_\bullet)
\]
be the cochain complex such that \(\text{Hom}_{\mathcal{B}}(Z, \mathcal{C}_n) := \text{Hom}_{\mathcal{B}}(Z, \mathcal{C}_n)\) for every \(n \in \mathbb{Z}\), with differentials induced by those of \(\mathcal{C}_\bullet\), in the obvious way; then we have natural identifications
\[
\text{Hom}_{\mathcal{C}(\mathcal{ZMod})}(\mathbb{K}(i)_\bullet, \text{Hom}_{\mathcal{B}}(Z, \mathcal{C}_\bullet)) \sim \text{Hom}_{\mathcal{C}(\mathcal{B})}(\mathbb{K}(i)_\bullet \otimes \mathbb{Z} \mathbb{Z}[0], \mathcal{C}_\bullet) \sim \text{Hom}_{\mathcal{B}}(Z, N_i K_C)
\]
(see example 7.1.16(vii)) whose composition with the induced isomorphism
\[
\text{Hom}_{\mathcal{B}}(Z, N_i K_C) \sim \text{Hom}_{\mathcal{B}}(Z, C_i)
\]
is given by the rule:
\[
(7.4.62) \quad (\varphi_\bullet : \mathbb{K}(i)_\bullet \to \text{Hom}_{\mathcal{B}}(Z, \mathcal{C}_\bullet)) \mapsto (\varphi_1(\varepsilon_1) : Z \to C_i).
\]
It remains to determine the differential \(d_{i+1}^N : N_{i+1} K_C \to N_i K_C\); by definition, the latter is induced by the morphism \(\mathbb{K}(\varepsilon_0)_{i+1} : \mathbb{K}(i)_{i+1} \to \mathbb{K}(i+1)_\bullet\). In turn, the foregoing description says that \(\mathbb{K}(\varepsilon_0)_{i+1}\) is naturally identified with the morphism of \(C(\mathcal{ZMod})\)
\[
\begin{array}{c}
\mathbb{K}(i)_\bullet \\
\downarrow \\
\mathbb{K}(i + 1)_\bullet
\end{array} \quad \begin{array}{c}
\begin{array}{c}
\begin{array}{c}
0 \rightarrow 0 \\
\mathbb{Z} \rightarrow \mathbb{Z} \rightarrow 0
\end{array}
\end{array} \\
\downarrow 1_\mathbb{Z} \\
\begin{array}{c}
\begin{array}{c}
\begin{array}{c}
\begin{array}{c}
0 \rightarrow \mathbb{Z} \rightarrow \mathbb{Z} \rightarrow 0
\end{array}
\end{array}
\end{array}
\end{array}
\end{array}
In view of example 7.1.16(vii) and remark 7.4.18(ii), we deduce a natural transformation

\[
\begin{array}{ccccccccc}
0 & \longrightarrow & C_{i+1} & \oplus & C_i & \longrightarrow & C_i & \oplus & C_{i-1} & \longrightarrow & 0 & \longrightarrow & 0 \\
\downarrow & & \downarrow & & 1 & & \downarrow & & \downarrow & & \downarrow & & \\
0 & \longrightarrow & 0 & \longrightarrow & C_i & \oplus & C_{i-1} & \longrightarrow & C_{i-1} & \oplus & C_{i-2} & \longrightarrow & 0 \\
\end{array}
\]

whose rows are given by the morphisms (7.4.60). Therefore, via the identification (7.4.61), the morphism \(d_{i+1}^N\) becomes none other than \((-1)^{i+1} \cdot d_i^C\), i.e. we have obtained a natural isomorphism

\[
\omega^C : N_*K_C \xrightarrow{\sim} C_*
\]

for every complex in \(C^{\leq 0}(\mathcal{B})\) (resp. in \(C^{[-k,0]}(\mathcal{B})\)).

Conversely, let \(B[\bullet]\) be any object of \(s\mathcal{B}\), and \(Z\) any object of \(\mathcal{B}\); clearly

\[
N_* (\Delta_k \otimes s.Z) = \mathbb{K}(i)_* \otimes_{\mathbb{Z}} Z[0] \quad \text{for every } i \in \mathbb{N}.
\]

In view of example 7.1.16(vii) and remark 7.4.18(ii), we deduce a natural transformation

\[
\text{Hom}_{\mathcal{B}}(Z, B[i]) \xrightarrow{a} \text{Hom}_{s\mathcal{B}}(\Delta_i \otimes s.Z, B)
\]

(7.4.63)

\[
\text{Hom}_{\mathcal{B}}(Z, K_{N_*B}[i]) \xleftarrow{b} \text{Hom}_{C(\mathcal{B})}(\mathbb{K}(i)_* \otimes_{\mathbb{Z}} Z[0], N_*B)
\]

which, by Yoneda’s lemma, comes from a unique morphism in \(\mathcal{B}\)

\[
\psi^B_i : B[i] \to K_{N_*B}[i] \quad \text{for every } i \in \mathbb{N}.
\]

The same construction applies, in case \(B\) is an object of \(s_k\mathcal{B}\): we need only replace the group \(\text{Hom}_{s\mathcal{B}}(\Delta_i \otimes s.Z, B)\) by \(\text{Hom}_{s\mathcal{B}}(s_{\text{trunc}}(\Delta_i \otimes s.Z), B)\) in (7.4.63): see remark 7.4.18(iv). Moreover, remark 7.4.18(iii) implies that the system \(\psi^B := (\psi^B_i | i \in \mathbb{N})\) amounts to a morphism \(B \to K_{N_*B}\) in \(s\mathcal{B}\) (resp. in \(s_k\mathcal{B}\)). By the same token, the \(\mathbb{Z}\)-linear isomorphism \(a\) maps the abelian subgroup \(\text{Hom}_{\mathcal{B}}(Z, N_*B)\) isomorphically onto the subgroup

\[
\text{Hom}_{s\mathcal{B}}(Z_0^{\Delta_i} \otimes s.Z, B) \xrightarrow{\sim} \text{Hom}_{s\mathcal{Z}\text{-Mod}}(Z_0^{\Delta_i}, \text{Hom}_{\mathcal{B}}(Z, B))
\]

for every \(Z \in \text{Ob}(\mathcal{B})\) and every \(i \in \mathbb{N}\), where \(\text{Hom}_{\mathcal{B}}(Z, B)\) is the simplicial abelian group as in example 7.4.28(iii). Explicitly, if \(\beta : Z \to N_*B\) is any morphism, then \(a(\beta)\) is the unique morphism \(Z_0^{\Delta_i} \to \text{Hom}_{\mathcal{B}}(Z, B)\) of simplicial abelian groups such that \(a(\beta)(e_1) = \beta\), where \(e_1 \in \mathbb{K}(i)_i \subset Z_0^{\Delta_i}[i]\) is the basis element described in the foregoing. Likewise, we have natural identifications

\[
\text{Hom}_{\mathcal{Z}\text{-Mod}}(\mathbb{K}(i)_*, \text{Hom}_{\mathcal{B}}(Z, N_*B)) \xrightarrow{\sim} \text{Hom}_{\mathcal{B}}(\mathbb{K}(i)_* \otimes_{\mathbb{Z}} Z[0], N_*B)
\]

and \(b\) restricts to a map

\[
\text{Hom}_{s\mathcal{Z}\text{-Mod}}(Z_0^{\Delta_i}, \text{Hom}_{\mathcal{B}}(Z, B)) \to \text{Hom}_{\mathcal{Z}\text{-Mod}}(\mathbb{K}(i)_*, \text{Hom}_{\mathcal{B}}(Z, N_*B)) \quad \varphi \mapsto N_* \varphi.
\]

Again, the same applies to an object of \(s_k\mathcal{B}\), by taking suitable truncated variants of the above constructions. Taking into account (7.4.62), we conclude that \(\psi^B\) induces an isomorphism

\[
N_* \psi^B : N_* B \xrightarrow{\sim} N_* K_{N_* B}
\]

which is inverse to \(\omega^{N_* B}\). To finish the proof of assertion (i) for the category \(\mathcal{B}\), it then suffices to remark:

**Claim 7.4.64.** The functors \(N_{\mathcal{B}}\) and \(N_{\mathcal{B},k}\) are conservative.
**Proof of the claim.** We show, by induction on \( n \), that if a morphism \( h \) in \( s.B \) or \( s_k.B \) (for any \( k \in \mathbb{N} \)) induces an isomorphism \( N_i h \), then \( h[n] \) is an isomorphism for every \( n \in \mathbb{N} \) (resp. for every \( n \leq k \)). The assertion is obvious for \( n = 0 \), hence suppose that \( n > 0 \), and that \( h[n-1] \) is known to be an isomorphism whenever \( h \) is a morphism in \( s.B \) or in \( s_k.B \) (for arbitrary \( k \in \mathbb{N} \)) such that \( N_i h \) is an isomorphism. Let \( h : A \to B \) be any such morphism in \( s.B \) or in \( s_k.B \). If \( h \) is a morphism in \( s_0.B \), we are done, hence we may suppose that either \( h \) is a morphism in \( s.B \) or \( k > 0 \). Set

\[
A' := \text{Ker}(g_A : \gamma A \to A) \quad \text{(resp. } A' := \text{Ker}(g_A : \gamma_{k-1}A \to s.trunc_{k-1}A) \text{)}
\]

as well as \( B' := \text{Ker}(g_B) \) (notation of remark \[7.4.12\](ii)). Notice that \( g_A \) is an epimorphism, since \( \partial_{n+2} \) admits the section \( \sigma_{n+1} \), for every \( n \in \mathbb{N} \) (resp. for every \( n \leq k \)). Therefore, we have a commutative diagram in \( s.B \) with exact rows

\[
\begin{array}{cccccc}
0 & \longrightarrow & A' & \longrightarrow & \gamma A & \longrightarrow & A & \longrightarrow & 0 \\
& & h' & \downarrow & h & \downarrow & & \ & & \\
0 & \longrightarrow & A' & \longrightarrow & \gamma A & \longrightarrow & A & \longrightarrow & 0
\end{array}
\]

(resp. a corresponding diagram in \( s_{k-1}.B \)). By inspecting the definitions, it is easily seen that \( N_i A' = (N_i A)[-1] \), \( N_i A' = (N_i A)[-1] \), and \( N_i h' = (N_i h)[-1] \); especially, \( N_i h' \) is an isomorphism, so \( h'[n-1] \) is an isomorphism, by inductive assumption. The same holds also for \( h[n-1] \), and we conclude that \( \gamma h[n] \) is an isomorphism. But \( \gamma h[n] = h[n+1] \), so we are done.

Lastly, in order to prove assertion (i) for the original category \( \mathcal{A} \), it suffices to notice:

**Claim 7.4.65.** Let \( C_\bullet \) be any object of \( C(\mathcal{A}) \) (resp. of \( C(k,0)(\mathcal{A}) \)), and regard \( C_\bullet \) as an object of \( C(B) \) (resp. of \( C(k,0)(B) \)), via the fully faithful embedding \( \mathcal{A} \to B \). Then \( K_C \) is isomorphic to an object of \( s.\mathcal{A} \) (resp. \( s_k.\mathcal{A} \)), regarded as a full subcategory of \( s.B \) (resp. of \( s_k.B \)), via the same embedding.

**Proof of the claim.** This follows easily, by remarking that \( \mathbb{K}(i)_\bullet \) lies in \( C(k,0)(\mathbb{Z}\text{-Mod}) \) for every \( i \in \mathbb{N} \), and \( \mathbb{K}(i)_j \) is a finitely generated abelian group for every \( i, j \in \mathbb{N} \); details left to the reader.

(ii): First, let \( f, g : A \to B \) be two morphisms in \( s.\mathcal{A} \), and \( u : \Delta_1 \otimes A \to B \) a homotopy from \( f \) to \( g \) (see remark \[7.4.17\](v)); especially,

\[
u \circ (\Delta_{e_1} \otimes A) = f \quad \text{and} \quad u \circ (\Delta_{e_0} \otimes A) = g.
\]

Notice that

\[
\mathbb{Z}_{\Delta}^1 \otimes_{\mathbb{Z}} A_\bullet = \text{Tot}(\Delta_1 \otimes A)_\bullet
\]

(notation of remark \[7.4.17\](iii) and example \[7.4.28\](i)); there follows a morphism in \( C(\mathcal{A}) \)

\[
\tilde{u}_\bullet : \mathbb{Z}_{\Delta}^1 \otimes_{\mathbb{Z}} A_\bullet \xrightarrow{Sh_\bullet} (\Delta_1 \otimes A)_\bullet \xrightarrow{q_\bullet} N_\bullet (\Delta_1 \otimes A) \xrightarrow{N_\bullet u} N_\bullet B
\]

where \( Sh_\bullet \) denotes the shuffle map for the bisimplicial object \( A \otimes \Delta_1 \), and \( q_\bullet \) is the projection defined in \[7.4.29\]. Moreover, the maps \( \Delta_{e_i}[0] : \Delta_0[0] \to \Delta_1[0] \) \((i = 0, 1)\) induce morphisms

\[
\tilde{e}_{i,n} : \mathbb{Z}_{\Delta}^{1}[0] \otimes_{\mathbb{Z}} A_n : A_n \to \mathbb{Z}_{\Delta}^{1}[0] \otimes_{\mathbb{Z}} A_n \subset (\mathbb{Z}_{\Delta}^{1} \otimes_{\mathbb{Z}} A_\bullet)_n
\]

that amount to morphisms of cochain complexes \( \tilde{e}_{i,\bullet} : A_\bullet \to \mathbb{Z}_{\Delta}^{1} \otimes_{\mathbb{Z}} A_\bullet \) \((i = 0, 1)\), and a simple inspection of the definitions shows that

\[
Sh_\bullet \circ \tilde{e}_{i,\bullet} = (\Delta_{e_i} \otimes A)_\bullet \quad \text{for } i = 0, 1
\]

whence

\[
\tilde{u}_\bullet \circ \tilde{e}_{1,\bullet} = f_\bullet \quad \text{and} \quad \tilde{u}_\bullet \circ \tilde{e}_{0,\bullet} = g_\bullet.
\]
The construction makes it clear that $\bar{\epsilon}_i$ restricts to a morphism $N_\bullet A \to K(1)_\bullet \otimes Z N_\bullet A$, and the latter is none else than the map $\iota_i \otimes Z N_\bullet A$, with the notation of remark 7.1.19(ii). We conclude that the morphism

$$v_\bullet : K(1)_\bullet \otimes Z N_\bullet A \to Z^{\Delta_1} \otimes Z A_\bullet \xrightarrow{\bar{\pi}} N_\bullet B$$

is a homotopy from $N_\bullet f$ to $N_\bullet g$ (notation of (7.4.29)).

Conversely, suppose that $v_\bullet : K(1)_\bullet \otimes Z N_\bullet A \to N_\bullet B$ is a homotopy from $N_\bullet f$ to $N_\bullet g$. Since $K(1)_\bullet$ is a direct summand of $Z^{\Delta_1}$ and $N_\bullet A$ is a direct summand of $A_\bullet$, we may extend $v_\bullet$ to a morphism

$$\tilde{v}_\bullet : Z^{\Delta_1} \otimes Z A_\bullet \to N_\bullet B$$

such that $\tilde{v}_\bullet$ is the zero morphism on the direct summands other than $K(1)_\bullet \otimes Z N_\bullet A$. Next, consider the composition

$$v_\bullet : N_\bullet (\Delta_1 \otimes A) \xrightarrow{j_\bullet} (\Delta_1 \otimes A)_\bullet \xrightarrow{AW_\bullet} A_\bullet \otimes Z Z^{\Delta_1} \xrightarrow{\Psi_\bullet} Z^{\Delta_1} \otimes Z A_\bullet \xrightarrow{\tilde{v}_\bullet} N_\bullet B$$

where $j_\bullet$ is the natural injection (see (7.4.29)), $AW_\bullet$ is the Alexander-Whitney map for the bisimplicial object $A \boxtimes \Delta_1$ (notice that $\Delta_1 \otimes A = (A \boxtimes \Delta_1)^\Delta$), and $\Psi_\bullet$ is the commutativity constraint (see example 7.1.16(i)). By (i), the morphism $v_\bullet$ comes from a unique morphism

$$v : \Delta_1 \otimes A \to B$$

in $\mathcal{A}$. On the other hand, since $N_{p+q}A$ is contained in the kernel of $A[-^{qV}_p]$ for every $p, q \in \mathbb{N}$, it is easily seen that the diagram

$$\begin{array}{ccc}
N_\bullet A & \xrightarrow{\iota_i \otimes Z N_\bullet A} & K(1)_\bullet \otimes Z N_\bullet A \\
\downarrow & & \downarrow \\
N_\bullet (\Delta_1 \otimes A) & \xrightarrow{\Psi_\bullet \circ AW_\bullet \circ j_\bullet} & Z^{\Delta_1} \otimes Z A_\bullet
\end{array}$$

commutes for $i = 0, 1$. We conclude that $v$ is a homotopy from $f$ to $g$. □

**Corollary 7.4.66.** Let $\mathcal{A}$ be any abelian category. We have:

(i) If $k \in \mathbb{N}$ is any integer, and $A$ any $k$-truncated simplicial object of $\mathcal{A}$, then

$$H_i(\cosk_k A) = 0 \quad \text{for every } i \geq k.$$  

(ii) Every homotopically trivial augmented simplicial object of $\mathcal{A}$ is aspherical.

**Proof.** (i): Denote by $t_{\leq k} : C^{\leq 0}(\mathcal{A}) \to C^{[-k,0]}(\mathcal{A})$ the brutal truncation functor (see (7.1.1)). In light of theorem 7.4.59 we see that $t_{\leq k}$ admits a right adjoint $v_k : C^{[-k,0]}(\mathcal{A}) \to C^{\leq 0}(\mathcal{A})$, and clearly there are natural isomorphisms

$$N_\bullet \cosk_k A \xrightarrow{\sim} v_k N_\bullet A \quad \text{for every } A \in \text{Ob}(s_k, \mathcal{A}).$$

Taking into account theorem 7.4.30(iii), we are then reduced to showing

**Claim 7.4.67.** $H_i(v_k K_\bullet) = 0$ for every $(K_\bullet, d_\bullet) \in \text{Ob}(C^{[-k,0]})$ and every $i \geq k$.

**Proof of the claim.** Indeed it is easily seen that:

$$(v_k K_\bullet)_i = \begin{cases} 
K_i & \text{for } i \leq k \\
\ker d_k & \text{for } i = k + 1 \\
0 & \text{for } i > k + 1
\end{cases}$$

and the differential of $v_k K_\bullet$ in degree $\leq k$ agrees with that of $K_\bullet$, whereas in degree $k + 1$ it is the natural inclusion map (details left to the reader). The claim follows immediately. ◇

(ii) follows directly from theorems 7.4.59(ii) and 7.4.30(iii), and remark 7.1.9(ii). □
7.5. **Simplicial sets.** This section, which complements the previous one, collects some classical material pertaining to the homotopy theory of the category of simplicial sets. The presentation is borrowed from [63] and [85], where much more may be found.

7.5.1. To begin with, notice that the category $s.Set$ of simplicial sets is none else than the category of presheaves on the category $\Delta$, so $s.Set$ is complete and cocomplete, and all limits and colimits in $s.Set$ are computed argumentwise (see (4.1)); also, all colimits and monomorphisms are universal, and all epimorphisms are universal effective.

**Example 7.5.2.** (i) We have already introduced in example 7.4.5 the simplicial set $\Delta_k$ (for any $k \in \mathbb{N}$), which is just the image of $[k]$ under the Yoneda embedding

$$h : \Delta \to s.Set.$$ 

To ease notation, for any morphism $\varphi : [n] \to [m]$ in $\Delta$, we shall usually write $\varphi : \Delta_n \to \Delta_m$ instead of $\Delta_\varphi$. By Yoneda’s lemma (proposition [1.2.6]), we have natural identifications

$$(7.5.3) \quad A[n] \xrightarrow{\sim} \text{Hom}_{s.Set}(\Delta_n, A) \quad \text{for every } A \in \text{Ob}(s.Set) \text{ and every } n \in \mathbb{N}.$$ 

(ii) More generally, the category of simplicial sets contains all the products $\Delta_n \times \Delta_m$ (for every $m, n \in \mathbb{N}$). Furthermore, if $S$ is any set and $A$ any simplicial set, we may form the product $s.S \times A$ (notation of (7.4.4)), which we shall denote simply by $S \times A$. Explicitly, we have

$$(S \times A)[n] := S \times A[n] \quad \text{for every } n \in \mathbb{N}$$

and the faces and degeneracies of $S \times A$ are derived from those of $A$, in the obvious fashion.

(iii) Moreover, lemma [1.4.8] yields a natural presentation

$$A \xrightarrow{\sim} \text{colim}_{h_{s.Set} \circ i_A}$$

for every simplicial set $A$. By inspecting the definitions, we see that the latter amounts to the following description of $A$. Notice the natural identification $\Delta_j[i] \xrightarrow{\sim} \text{Hom}_{s.Set}(\Delta_i, \Delta_j)$ provided by (7.5.3); we have a natural diagram in $s.Set$

$$(7.5.4) \quad \coprod_{i,j \in \mathbb{N}} (A[i] \times \Delta_j[j]) \times \Delta_j \xrightarrow{p_* \circ t_*} \coprod_{n \in \mathbb{N}} A[n] \times \Delta_n \xrightarrow{t_*} A$$

where $p_*$ are $c_*$ are the (unique) morphisms which restrict respectively to morphisms

$$\{a\} \times \Delta_j \xleftarrow{\varphi} \{(a, \varphi)\} \times \Delta_j \xrightarrow{\text{1}_\Delta} \{A[\varphi](a)\} \times \Delta_i$$

for every $i, j \in \mathbb{N}$ and every $(a, \varphi) \in A[i] \times \Delta_j[i]$, and where $t_*$ is the (unique) morphism whose restriction to $\{b\} \times \Delta_n \to A$ is the morphism corresponding to $b \in A[n]$ under the identification (7.5.3), for every $b \in A[n]$. Then $t_*$ is an epimorphism, and (7.5.4) naturally identifies $A$ with the coequalizer of $p_*$ and $c_*$.

(iv) Another useful simplicial set is the **boundary** of $\Delta_k$, denoted

$$\partial \Delta_k \quad \text{for every integer } k > 0$$

which is defined as the smallest subobject of $\Delta_k$ containing the images of all the face morphisms $\varepsilon_i : \Delta_{k-1} \to \Delta_k$, for $i = 0, \ldots, k$ (see (7.4.6)). Thus, we have a natural epimorphism in $s.Set$

$$(7.5.5) \quad [k] \times \Delta_{k-1} \to \partial \Delta_k \quad \text{for every } k > 0$$

whose restriction to the subobject $\{i\} \times \Delta_{k-1}$ agrees with $\varepsilon_i$, for every $i = 0, \ldots, k$. 
Notice that the simplicial identities yield a cartesian diagram in $\Delta^\wedge$
\[
\begin{array}{ccc}
[k-2] & \xrightarrow{\varepsilon_{j-1}} & [k-1] \\
\varepsilon_i \downarrow & & \downarrow \varepsilon_i \\
[k-1] & \xrightarrow{\varepsilon_j} & [k]
\end{array}
\]
whenever $0 \leq i < j \leq k$.

Since the Yoneda embedding commutes with representable limits (corollary [1.4.3](vi)), there follows a cartesian diagram in $sSet$
\[
\begin{array}{ccc}
\Delta_{k-2} & \xrightarrow{\varepsilon_{j-1}} & \Delta_{k-1} \\
\varepsilon_i \downarrow & & \downarrow \varepsilon_i \\
\Delta_{k-1} & \xrightarrow{\varepsilon_j} & \Delta_k
\end{array}
\]
(details left to the reader). Now, denote by $S_k \subset [k] \times [k]$ the subset of all pairs $(i, j)$ with $i < j$; since (7.5.5) is effective (by (7.5.1)), we deduce a commutative diagram
\[
S_k \times \Delta_{k-2} \xrightarrow{\varepsilon'_j} [k] \times \Delta_{k-1} \longrightarrow \partial \Delta_k \quad \text{in } sSet
\]
which presents $\partial \Delta_k$ as the coequalizer of $\varepsilon'_i$ and $\varepsilon''_i$, where $\varepsilon'_i$ (resp. $\varepsilon''_i$) is the morphism whose restriction to $\{(i, j)\} \times \Delta_{k-2}$ agrees with $\varepsilon_i : \{(i, j)\} \times \Delta_{k-2} \rightarrow \{i\} \times \Delta_{k-1}$ (resp. with $\varepsilon_{j-1} : \{(i, j)\} \times \Delta_{k-2} \rightarrow \{j\} \times \Delta_{k-1}$) for every $(i, j) \in S_k$. As an immediate corollary, we see that if $A$ is any simplicial set, a morphism $\partial \Delta_k \rightarrow A$ is the same as the datum of an ordered sequence $x_0, \ldots, x_k$ of $k+1$ elements of $A[k-1]$, such that
\[
\partial_j x_j = \partial_{j-1} x_i \quad \text{whenever } 0 \leq i < j \leq k.
\]
Moreover, if $x \in A[n]$ is any element, we may regard $x$ as a morphism $\overline{x} : \Delta_n \rightarrow A$ via the natural identification (7.5.3), and then we shall often denote by
\[
\partial x : \partial \Delta_n \rightarrow A
\]
the restriction of $\overline{x}$ to the subobject $\partial \Delta_n$. Lastly, we set $\partial \Delta_0 := s.\emptyset$.

(v) Another important simplicial set is $\Lambda^n_k$, which is defined for every $k, n \in \mathbb{N}$ such that $k > 0$ and $n = 0, \ldots, k$; namely, it is the smallest subobject of $\Delta_k$ that contains the images of all the face morphisms $\varepsilon_i : \Delta_{k-1} \rightarrow \Delta_k$, except for the face $\varepsilon_n$. Thus, for every such $k$ and $n$ we have a natural monomorphism
\[
\iota^n_k : \Lambda_k^n \rightarrow \Delta_k.
\]
The same argument as in (iv) yields a presentation of $\Lambda_k^n$ as the coequalizer of two morphisms :
\[
S_k^n \times \Delta_{k-2} \xrightarrow{\varepsilon'_j} ([k] \setminus \{n\}) \times \Delta_{k-1} \longrightarrow \Lambda_k^n
\]
where $S_k^n \subset S_k$ is the subset of all pairs $(i, j)$ with $i, j \neq n$, and $\varepsilon'_i, \varepsilon''_i$ are the restrictions of the morphisms with the same name appearing in (iii).

(vi) Let $\psi : X \rightarrow Y$ be any morphism of simplicial sets, $y \in Y[0]$ any element, and $j_y : \Delta_0 \rightarrow Y$ the corresponding morphism of simplicial sets; the resulting fibre product
\[
\psi^{-1}(y) := \Delta_0 \times_Y X
\]
is called the fibre of $\psi$ over $y$. Explicitly, set $\{y_n\} := \text{Im } j_y[n]$ for every $n \in \mathbb{N}$. Then
\[
\psi^{-1}(y)[n] = \psi[n]^{-1}(y_n) \quad \text{for every } n \in \mathbb{N}
\]
and the faces and degeneracies of $\psi^{-1}(y)$ are the restrictions of the corresponding maps for $X$. 
Remark 7.5.6. (i) From the simplicial identities of (7.4.6) we also get a commutative diagram

\[
\begin{array}{c}
\Delta_{n+1} \\
\eta_{j+1} \downarrow \quad \eta_j \\
\Delta_n \quad \eta_i \downarrow \\
\Delta_{n-1}
\end{array}
\]

for every integer \(n > 0\) and every \(i, j \leq n - 1\) with \(i \leq j\). We claim that this diagram is cocartesian in \(s\text{-Set}\). Indeed, let \(X\) be any simplicial set, and \(f, g : \Delta_n \to X\) any two morphisms such that \(f \circ \eta_i = g \circ \eta_{j+1}\). We set \(h := f \circ \varepsilon_{j+1} : \Delta_{n-1} \to X\), and we notice that

\[h = f \circ \eta_i \circ \varepsilon_i \circ \varepsilon_{j+1} = g \circ \eta_{j+1} \circ \varepsilon_i \circ \varepsilon_{j+1} = g \circ \eta_{j+1} \circ \varepsilon_{j+2} \circ \varepsilon_i = g \circ \varepsilon_i.\]

Therefore:

\[h \circ \eta_j = g \circ \varepsilon_i \circ \eta_j = g \circ \eta_{j+1} \circ \varepsilon_i = f \circ \eta_i \circ \varepsilon_i = f\]

\[h \circ \eta_i = f \circ \varepsilon_{j+1} \circ \eta_i = f \circ \eta_i \circ \varepsilon_{j+2} = g \circ \eta_{j+1} \circ \varepsilon_{j+2} = g.\]

Lastly, since both \(\eta_i\) and \(\eta_j\) are epimorphisms, \(h\) is uniquely determined by either of the identities \(h \circ \eta_j = f\) and \(h \circ \eta_i = g\), whence the assertion.

(ii) We point out that also the diagram

\[
\begin{array}{c}
\Delta_{n+1} \\
\eta_i \downarrow \quad 1_{\Delta_n} \\
\Delta_n \rightarrow \Delta_n
\end{array}
\]

is trivially cocartesian for every \(n \in \mathbb{N}\) and every \(i \leq n\), since \(\eta_i\) is an epimorphism.

(iii) Let \(k \in \mathbb{N}\) be any integer. The categories \(\text{Set}\) of all small sets and \(f\text{-Set}\) of finite sets, both satisfy the conditions of (7.4.19), so we get left and right adjoints

\[\text{sk}_k, \cosk_k : s\text{-Set} \to f\text{-Set}\quad \text{sk}_k, \cosk_k : s\text{-Set} \to f\text{-Set}\]

for the respective \(k\)-truncation functors.

(iv) For any simplicial set \(X\) and any integer \(r > 0\), let us say that an element \(x \in X[r]\) is a degenerate simplex, if \(x = \sigma_i y\) for some \(i = 0, \ldots, r - 1\) and some \(y \in X[r - 1]\). We claim that, for any \(k\)-truncated simplicial \(Y\), and every \(r > k\), every element of \(\text{sk}_k Y[r]\) is a degenerate simplex. Indeed, let \(\alpha : [k] \to [r]\) be any morphism in \(\Delta^n\); notice first that, under the identification \(Y[k] \to \text{sk}_k Y[k]\) given by the unit of adjunction, the map \(\text{sk}_k Y[\alpha] : \text{sk}_k Y[k] \to \text{sk}_k Y[r]\) corresponds to the natural map \(j_\alpha : F[k] \to \text{sk}_k Y[r]\). But \(\text{sk}_k Y[r]\) is the union of the images of all such maps (see example [1.2.23](i)), and on the other hand, any such map factors through some degeneracy map \(\sigma_i\), whence the assertion.

(v) For any simplicial set \(X\) and every \(k, n \in \mathbb{N}\) with \(n \geq k\), the counits of adjunction give a natural commutative diagram

\[
\begin{array}{ccc}
sk_k(s\text{-trunc}_k X) & \xrightarrow{\varepsilon_X^{(k,n)}} & sk_n(s\text{-trunc}_n X) \\
\varepsilon_X^{(k)} \downarrow & & \varepsilon_X^{(n)} \downarrow \\
X & \xrightarrow{\varepsilon_X^{(n)}} & \text{sk}_n(s\text{-trunc}_n X)
\end{array}
\]

amounting to a cocone with vertex \(X\), and it follows easily from the discussion of (7.4.19) that \(s\text{-trunc}_k(\varepsilon_X^{(k,n)})\) is an isomorphism for every such \(k, n \in \mathbb{N}\), and the resulting morphism

\[\text{colim}_{n \in \mathbb{N}} \text{sk}_n(s\text{-trunc}_n X) \to X\]

is an isomorphism. We define the \(n\text{-th skeleton of } X\) as the simplicial subset

\[\text{sk}_n X := \text{Im} \varepsilon_X^{(n)}\quad \text{for every } n \in \mathbb{N}.\]
Lemma 7.5.7. Let $X$ be any simplicial set, $r > 0$ any integer, and $x, y \in X[r]$ be any two degenerate simplices (see remark 7.5.6 iii). The following holds:

(i) If $\partial x = \partial y$, then $x = y$.

(ii) There exists a unique pair $(p, z)$ where $p : [r] \rightarrow [n]$ is an epimorphism and $z \in X[n]$ is a non-degenerate simplex such that $x = X[p](z)$.

(iii) The natural morphism $\text{sk}_n(s.\text{trunc}_n X) \rightarrow \text{Sk}_n X$ is an isomorphism for every $n \in \mathbb{N}$.

Proof. (i): Say that $x = \sigma_m z$ and $y = \sigma_n w$ for some $z, w \in X[r - 1]$. If $m = n$, we have

$$z = \partial_m \sigma_m z = \partial_m x = \partial_m y = \partial_m \sigma_m w = w$$

whence the assertion. Hence, we may assume that $m < n$, in which case we get:

$$z = \partial_m x = \partial_m \sigma_n w = \sigma_{n-m} \partial_m w$$

so that $x = \sigma_m \sigma_{n-m} \partial_m w = \sigma_{n-m} \partial_m w$. Thus, we may replace $z$ by $\sigma_m \partial_m w$ and $m$ by $n$, and reduce to the foregoing case, so the proof is complete.

(ii): The existence of such a pair $(p, z)$ is obvious. Next, suppose that $(p', [r] \rightarrow [n'], z')$ is another such pair; from remark 7.5.6 it follows easily that there exists a cocartesian diagram of the form

$$\begin{array}{ccc}
\Delta_r & \xrightarrow{\Delta_p} & \Delta_n \\
\downarrow & & \downarrow \\
\Delta_{n'} & \xrightarrow{\Delta_{q'}} & \Delta_k
\end{array}$$

for a suitable $k \leq n, n'$ and epimorphisms $q : [n] \rightarrow [k]$ and $q' : [n'] \rightarrow [k]$ (details left to the reader). Regarding $z$ and $z'$ as morphisms $x : \Delta_n \rightarrow X$ and respectively $x' : \Delta_{n'} \rightarrow X$, our assumption gives the identity:

$$z \circ \Delta_p = z' \circ \Delta_{q'}$$

whence a unique $w \in X[k]$ such that $X[q'](w) = z$ and $X[q](w) = z'$. Since $z$ and $z'$ are non-degenerate, it follows that $n = k = n'$ and $q = q' = 1_{\Delta_k}$, whence $z = z'$, as stated.

(iii): Set $Y := \text{sk}_n(s.\text{trunc}_n X)$ for every $n \in \mathbb{N}$; the natural map $f[k] : Y[k] \rightarrow \text{Sk}_n[k]$ is surjective for every $k \in \mathbb{N}$, and is bijective for every $k \leq n$, so it suffices to check that $f[k]$ is injective for every $k > n$. Thus, fix $k > N$, and let $y, y' \in Y[k]$ be any two simplices such that $f[k](y) = f[k](y')$. Remark 7.5.6(iv) tells us that $y$ and $y'$ are degenerate, say $y = Y[p](z)$ and $y' = Y[p'](z')$ for epimorphisms $p : [k] \rightarrow [m]$ and $p' : [k] \rightarrow [m']$, and non-degenerate simplices $z \in Y[m]$, $z' \in Y[m']$. We must then have $m, m' \leq n$, and therefore $x := f[m](z)$ and $x' := f[m'](z')$ are two non-degenerate simplices of $\text{Sk}_n X$, such that

$$\text{Sk}_n[p](x) = f[k](y) = f[k](y') = \text{Sk}_n[p'](x').$$

By (ii), we deduce that $p = p'$ and $x = x'$, whence $y = y'$, as required. \qed

Remark 7.5.8. Let $X$ be any simplicial set and $n \in \mathbb{N}$ any integer.

(i) Clearly, $\text{Sk}_n X \subset \text{Sk}_{n+1} X$, and we have

$$X = \bigcup_{r \in \mathbb{N}} \text{Sk}_r X.$$  

(7.5.9)

We say that $X$ has dimension $\leq n$, if $X = \text{Sk}_n X$. Let $s.\text{Set} \leq n$ be the full subcategory of $s.\text{Set}$ whose objects are the simplicial set of dimension $\leq n$; it follows easily from lemma 7.5.7(iii) that the adjunction $(\text{sk}_n, \text{trunc}_n)$ establishes an equivalence

$$s.\text{Set} \leq n \xrightarrow{\sim} s_k.\text{Set}.$$
(ii) Moreover, SkₙX can be obtained by “attaching n-cells” to Skₙ₋₁X, if n > 0. Namely, let Eⁿₓ ⊂ X[n] denote the set of non-degenerate n-simplices of X; we get a commutative diagram

\[
\begin{array}{ccc}
E^n_X \times \partial \Delta_n & \xrightarrow{E^n_X \times i_n} & E^n_X \times \Delta_n \\
\downarrow & & \downarrow c \\
\text{Sk}_{n-1}X & \xrightarrow{c} & \text{Sk}_nX
\end{array}
\]

where iₙ : ∂Δₙ → Δₙ and the bottom horizontal arrow are the natural inclusion maps, and c is the unique morphism whose restriction to the factor \( \{x\} \times \Delta_n \) is the morphism \( \varphi : \Delta_n \to X \) corresponding to \( x \), for every \( x \in E^n_X \). We claim that \( \mathcal{D} \) is a cartesian diagram. For the proof, notice that all the simplicial sets in \( \mathcal{D} \) have dimension \( \leq n \); by (i), it then suffices to check that \( \text{trunc}_n \mathcal{D} \) is cartesian, i.e., that the diagram of sets \( \mathcal{D}[k] \) is cartesian, for every \( k \leq n \) (see (7.5.1)). The latter assertion is clear for \( k < n \), since in this case both horizontal arrows of \( \mathcal{D}[k] \) are isomorphisms. For \( k = n \), notice that the complement \( S \) of \( E^n_X \times \partial \Delta_n[n] \) in \( E^n_X \) is naturally identified with \( E^n_X \), which is also the complement of \( \text{Sk}_{n-1}X[n] \) in \( \text{Sk}_nX[n] \); it then suffices to remark that, under these natural bijections, the restriction of \( c[n] \) to \( S \) is identified with the identity map \( E^n_X \xrightarrow{\sim} E^n_X \) (details left to the reader).

**Definition 7.5.10.** Let \( \varphi : A \to B \) and \( \psi : X \to Y \) be two morphisms of simplicial sets.

(i) We say that \( \psi \) has the right lifting property with respect to \( \varphi \), if for every commutative diagram

\[
\begin{array}{ccc}
A & \xrightarrow{\alpha} & X \\
\varphi \downarrow & & \downarrow \psi \\
B & \xrightarrow{\beta} & Y
\end{array}
\]

in \( \text{s.Set} \) there exists a morphism \( \gamma : B \to X \) such that \( \gamma \circ \varphi = \alpha \) and \( \psi \circ \gamma = \beta \).

(ii) We say that \( \psi : X \to Y \) is a Kan fibration (or briefly, that \( \psi \) is a fibration), if \( \psi \) has the right lifting property with respect to all the monomorphisms \( \iota^k_k : \Delta^n_k \to \Delta_k \), for every \( k, n \in \mathbb{N} \) with \( k > 0 \) and \( n \leq k \) (notation of example 7.5.2(iv,v)).

(iii) We say that \( \varphi \) is a retract of \( \psi \) if there exists a commutative diagram of simplicial sets

\[
\begin{array}{ccc}
A & \xrightarrow{1_A} & A \\
\varphi \downarrow & & \downarrow \varphi \\
B & \xrightarrow{1_B} & B
\end{array}
\]

(iv) We say that a simplicial set \( A \) is fibrant if the (unique) morphism \( A \to \Delta_0 \) is a fibration.

**Remark 7.5.11.** In light of example 7.5.2(iv,v), it is clear that a simplicial set \( A \) is fibrant if and only if the following Kan extension condition holds. For every \( n, k \in \mathbb{N} \) with \( 0 \leq k \leq n + 1 \), and every sequence \( x_0, \ldots, x_{k-1}, x_{k+1}, \ldots, x_{n+1} \) of elements of \( A[n] \) such that

\[
\partial_i x_j = \partial_{i-1} x_i \quad \text{whenever } 0 \leq i < j \leq n + 1 \text{ and } i, j \neq k
\]

there exists an element \( x \in A[n + 1] \) such that

\[
\partial_i x = x_i \quad \text{for every } i = 0, \ldots, k - 1, k + 1, \ldots, n + 1.
\]

**Example 7.5.12.** Let \( A \) be any simplicial group, i.e., an object of \( \text{s.Grp} \), where \( \text{Grp} \) denotes the category of groups. Then the simplicial set underlying \( A \) is fibrant. Indeed, suppose that \( n, k \) and \( x_0, \ldots, x_{n+1} \) are as in remark 7.5.11. We construct by induction on \( i = -1, \ldots, n + 1 \)
an element \( y_i \in A[n+1] \) such that \( \partial_j y_i = x_j \) whenever \( 0 \leq j \leq i, j \neq k \). Indeed, the condition is fulfilled trivially for \( i = -1 \), by setting \( y_{-1} := 1 \), the neutral element of the group \( A[n+1] \). Suppose that \( i \geq 0 \), and \( y_{i-1} \) has already been exhibited as required; if \( i = k \), we set \( y_i := y_{i-1} \), which again trivially fulfills the stated condition. Otherwise, consider the element

\[
\partial_j u = (\partial_j x_i^{-1}) \cdot (\partial_j \partial_i y_{i-1}) = (\partial_j x_i^{-1}) \cdot (\partial_{i-1} \partial_j y_{i-1}) = (\partial_j x_i^{-1}) \cdot (\partial_{i-1} x_j) = 1
\]

for every \( j = 0, \ldots, i-1 \) with \( j \neq k \). Hence, set \( y_i := y_{i-1} \cdot (\sigma_i u)^{-1} \); we have

\[
\partial_j y_i = (\partial_j y_{i-1}) \cdot (\partial_j \sigma_i u)^{-1} = x_i \cdot (\sigma_{i-1} \partial_j u) = x_i \quad \text{whenever } 0 \leq j < i.
\]

Likewise:

\[
\partial_i y_i = (\partial_i y_{i-1}) \cdot (\partial_i \sigma_i u)^{-1} = (\partial_i y_{i-1}) \cdot (\partial_i \sigma_i \partial_i y_{i-1}) \cdot (\partial_i \sigma_i x_i) = x_i
\]

as needed. Thus, the element \( x := y_{n+1} \) fulfills the condition of remark \( 7.5.11 \).

For any given morphism \( \psi \) of \( s.\text{Set} \), the set of all morphisms \( \varphi \) such that \( \psi \) has the right lifting property with respect to \( \varphi \) is closed under certain elementary operations, that are singled out in the following:

**Definition 7.5.13.** Let \( \Sigma \) be a set of monomorphisms of \( s.\text{Set} \).

(i) We say that \( \Sigma \) is saturated if the following conditions hold:

(a) All isomorphisms of \( s.\text{Set} \) lie in \( \Sigma \).

(b) For every countable system of morphisms in \( s.\text{Set} \)

\[
A_0 \xrightarrow{\varphi_0} A_1 \xrightarrow{\varphi_1} A_2 \to \cdots
\]

such that \( \varphi_n \in \Sigma \) for every \( n \in \mathbb{N} \), also the induced morphism

\[
A_0 \to \operatorname{colim}_{n \in \mathbb{N}} A_n
\]

lies in \( \Sigma \).

(c) For any cocartesian diagram of simplicial sets:

\[
A \xrightarrow{\varphi} A', \quad B \xrightarrow{\varphi'} B \coprod_A A'
\]

such that \( \varphi \in \Sigma \), we have \( \varphi' \in \Sigma \).

(d) If \( (\varphi_i : A_i \to B_i \mid i \in I) \) is an arbitrary family of elements of \( \Sigma \), then also

\[
\coprod_{i \in I} \varphi_i : \coprod_{i \in I} A_i \to \coprod_{i \in I} B_i
\]

lies in \( \Sigma \).

(e) Any retract of any element of \( \Sigma \) lies also in \( \Sigma \) (see definition \( 7.5.10(iii) \)).

(ii) The saturation of \( \Sigma \) is the intersection of all saturated sets of monomorphisms of \( s.\text{Set} \) containing \( \Sigma \).

7.5.14. With this terminology, for any morphism \( \psi \) of \( s.\text{Set} \), let \( \Sigma(\psi) \) be the set of monomorphisms \( \varphi \) of \( s.\text{Set} \) such that \( \psi \) has the right lifting property with respect to \( \varphi \). We point out the following simple observation:

**Lemma 7.5.15.** With the notation of \( 7.5.14 \), the following holds:

(i) \( \Sigma(\psi) \) is saturated, for any morphism \( \psi \) of \( s.\text{Set} \).
(ii) For any cartesian square of simplicial sets

\[
\begin{array}{ccc}
  X' & \longrightarrow & X \\
  \downarrow^\psi & & \downarrow^\psi \\
  Y' & \longrightarrow & Y
\end{array}
\]

we have \(\Sigma(\psi) \subset \Sigma(\psi')\).

(iii) If \(\psi'\) is any retract of \(\psi\), then \(\Sigma(\psi) \subset \Sigma(\psi')\) (see definition \[7.5.10\](iii)).

(iv) Especially, in both (ii) and (iii), if \(\psi\) is a fibration, the same holds for \(\psi'\), and for any \(y \in Y[0]\), the fibre \(\psi^{-1}(y)\) is a fibrant simplicial set (see example \[7.5.2\](vi)).

Proof. Left to the reader. \(\square\)

7.5.16. The Kan extension condition isolates a class of simplicial sets on which the standard constructions of homotopy theory can be carried out. Many of these constructions come down to exhibiting certain morphisms from a product of the type \(\Delta_k \times \Delta_1\) (for variable \(k \in \mathbb{N}\)) to given simplicial sets. To manipulate with ease such basic products, it will be useful to have at our disposal presentations for them, in the vein of example \[7.5.2\](iv,v).

To this aim, notice that \(\Delta\) is a full subcategory of the category \(\text{POSet}\) of partially ordered sets (notation of example \[1.1.6\](iii)). We may then extend the Yoneda embedding of \(\Delta\) into \(s.\text{Set}\) to a well defined functor

(7.5.17) \[\text{POSet} \to s.\text{Set} \quad (P, \leq) \mapsto \Delta_P.\]

Namely, for every partially ordered set \((P, \leq)\), let \(h_P : \text{POSet}^{\Delta^\circ} \to \text{Set}\) be the image of \(P\) under the Yoneda embedding of the category \(\text{POSet}\); then \(\Delta_P\) is the restriction of \(h_P\) to the subcategory \(\Delta^\circ\). We notice :

**Lemma 7.5.18.** The functor \(\text{(7.5.17)}\) is fully faithful and commutes with all limits.

Proof. The Yoneda embedding commutes with representable limits (corollary \[1.4.3\](vi)), and the same holds for the restriction functor \(\text{POSet}^{\Delta^\circ} \to s.\text{Set}\), since limits are computed argumentwise in both of these categories (corollary \[1.4.3\](ii)). To see that \(\text{(7.5.17)}\) is faithful, it suffices to remark that there is a natural isomorphism

(7.5.19) \[\Delta_P[0] \sim \widehat{P}\]

for every partially ordered set \((P, \leq)\) which induces a natural identification \(\Delta_\varphi = \varphi\), for every morphism \(\varphi : (P, \leq) \to (Q, \leq)\) of partially ordered sets. To check that \(\text{(7.5.17)}\) is full, let \((P, \leq)\) and \((Q, \leq)\) be any two objects of \(\text{POSet}\), and \(f : \Delta_P \to \Delta_Q\) a morphism of simplicial sets. The natural identification \(\text{(7.5.19)}\) yields a map \(\varphi := f[0] : P \to Q\), and it suffices to check that \(\varphi\) is a map of ordered sets such that \(\Delta_\varphi = f\). Thus, let \(x_0, x_1 \in P\) be any two elements with \(x < y\); there follows a unique morphism \(\psi : \Delta_1 \to P\) of partially ordered sets such that \(\psi(i) = x_i\) for \(i = 0, 1\). Then \(\psi \in \Delta_P[1]\), and we may set

\[
\psi' := f[1](\psi) \in \Delta_Q[1] \quad y_i := \Delta_Q[\varepsilon_{i-1}](\psi') \quad \text{for } i = 0, 1
\]

(notation of \(\text{(7.4.8)}\)). Tracing back the definitions, we see that \(\varphi(x_i) = y_i\) for \(i = 0, 1\), and the existence of \(\psi'\) tells us that \(y_0 \leq y_1\), i.e. \(\varphi\) is a morphism in \(\text{POSet}\), as required. It remains only to show that \(\Delta_\varphi[n] = f[n]\) for every \(n \in \mathbb{N}\). However, let \(x : [n] \to P\) be any element of \(\Delta_P[n]\) and set \(y := f[n](x)\), so the image of \(x\) (resp. \(y\)) is a totally ordered sequence \((x_0, \ldots, x_n)\) of elements of \(P\) (resp. \((y_0, \ldots, y_n)\) of \(Q\)); we have to check that \(\varphi(x_k) = y_k\) for every \(k = 0, \ldots, n\). Now, for any such \(k \leq n\), let \(\beta_k : [0] \to [n]\) be the unique map such that \(\beta_k(0) = k\); the correspondence \(\text{(7.5.19)}\) identifies \(x_k\) with \(\Delta_P[\beta_k](x)\) and \(y_k\) with \(\Delta_Q[\beta_k](y)\), whence the contention (details left to the reader). \(\square\)
7.5.20. The category of partially ordered sets is complete; especially, all finite products

\[ [k_0] \times \cdots \times [k_n] \]

are representable in \( \text{POSet} \): explicitly, the partial ordering on such a product is defined by declaring that

\[ a := (a_0, \ldots, a_n) \leq b := (b_0, \ldots, b_n) \quad \text{if and only if} \quad a_i \leq b_i \quad \text{for every} \quad i = 0, \ldots, n \]

for every pair of elements \( a, b \in [k_0] \times \cdots \times [k_n] \). Now, for any \( k, r \in \mathbb{N} \) with \( r \leq k \), consider the morphism in \( \text{POSet} \)

\[ \varphi_{k,r} : [k + 1] \to [k] \times [1] \quad \text{such that} \quad \varphi_{k,r}(i) = \begin{cases} (0, i) & \text{for} \quad i = 0, \ldots, r \\ (1, i - 1) & \text{for} \quad i = r + 1, \ldots, k + 1. \end{cases} \]

It is easily seen that every morphism \( [t] \to [k] \times [1] \) in \( \text{POSet} \) (for any \( t \in \mathbb{N} \)) factors through some \( \varphi_{k,r} \), so we get an epimorphism of simplicial sets

\[ \varphi_k : [k] \times \Delta_{k+1} \to \Delta_k \times \Delta_1 \]

whose restriction to each subobject \( \{r\} \times \Delta_{k+1} \) is the morphism \( \Delta_{\varphi_{k,r}} \) (notation of (7.5.17)). Now, let \( r, s \) be any two integers such that \( 0 \leq r < s \leq k \); obviously, the intersection of the images of \( \varphi_{k,r} \) and \( \varphi_{k,s} \) is the subset

\[ \{(0,0), \ldots, (0,r), (1,s), \ldots, (1,k)\} \]

so we get a cartesian diagram in \( \text{POSet} \)

\[
\begin{array}{ccc}
[t] & \xrightarrow{\varepsilon_{t,r+1}^{s-r}} & [k + 1] \\
\varepsilon_{t,r+1}^{s-r} & \downarrow \varphi_{k,r} & \leftarrow [k + 1] \xrightarrow{\varphi_{k,s}} [k] \times [1] \\
\end{array}
\]

(notation of example (7.4.7)(ii)). Since (7.5.17) commutes with fibre products, and \( \varphi_k \) is an effective epimorphism (by (7.5.1)), we conclude that the diagram

\[
\bigcup_{0 \leq r < s \leq k} \{(r, s)\} \times \Delta_{k+1-s+r} \xrightarrow{\varepsilon_{t,r+1}^{s-r}} [k] \times \Delta_{k+1} \xrightarrow{\varphi_k} \Delta_k \times \Delta_1
\]

identifies \( \Delta_k \times \Delta_1 \) with the coequalizer of \( \varepsilon' \) and \( \varepsilon'' \), where \( \varepsilon' \) (resp. \( \varepsilon'' \)) is the morphism whose restrictions to each subobject \( \{(r, s)\} \times \Delta_i \) agrees with \( \varepsilon_{t,r+1}^{s-r} : \{(r, s)\} \times \Delta_i \to \{r\} \times \Delta_{k+1} \) (resp. with \( \varepsilon_{t,r+1}^{s-r} : \{(r, s)\} \times \Delta_i \to \{s\} \times \Delta_{k+1} \)).

However, (7.5.21) can be simplified as follows. Notice that if \( i_1, \ldots, i_r \) is any sequence of non-negative integers such that \( 1 \geq i_{n+1} - i_n \geq 0 \) for every \( n = 0, \ldots, r - 1 \), then

\[ \varepsilon_{i_r} \circ \cdots \circ \varepsilon_{i_1} = \varepsilon'_{t,i_1} \quad \text{for every} \quad t \in \mathbb{N}. \]

From this observation, it is easily seen that the terms \( \{(r, s)\} \times \Delta_{k+1-s-r} \) in (7.5.21) with \( s > r + 1 \) are redundant; so we arrive at the presentation

\[
\begin{array}{ccc}
[k - 1] \times \Delta_k & \xrightarrow{\varepsilon'_{t,k+1}} & [k] \times \Delta_{k+1} \xrightarrow{\varphi_k} \Delta_k \times \Delta_1 \\
\end{array}
\]

where each term \( \{r\} \times \Delta_k \) corresponds to the term \( \{(r, r + 1)\} \times \Delta_k \) of (7.5.21), and the morphisms \( \varepsilon', \varepsilon'' \) are redefined accordingly.
7.5.23. We consider now the following sets of monomorphisms of $s.$ Set:

- $\Sigma_1$ is the set of all morphisms $i^n_k : \Delta^n_k \to \Delta_k$, for every $k, n \in \mathbb{N}$ with $k \geq n$.
- $\Sigma_2$ is the set of all morphisms $i^j_k : (\partial \Delta_k \times \Delta_1) \cup (\Delta_k \times \Lambda^j_1) \to \Delta_k \times \Delta_1$ for every $k \in \mathbb{N}$ and $j = 0, 1$.
- $\Sigma_3$ is the set of all monomorphisms of the form $i^j_{K,L} : (K \times \Delta_1) \cup (L \times \Lambda^j_1) \to L \times \Delta_1$

where $K \to L$ is an arbitrary monomorphism of $s.$ Set, and $j = 0, 1$.

With this notation, we may now state:

**Proposition 7.5.24.** The sets $\Sigma_1$, $\Sigma_2$ and $\Sigma_3$ have the same saturation.

**Proof.** In order to check that the saturation of $\Sigma_1$ contains $\Sigma_2$, fix $k \in \mathbb{N}$; if $j = 0$ (resp. if $j = 1$), for every $r = 0, \ldots, k + 1$, denote by $A_r \subset \Delta_k \times \Delta_1$ the image of the restriction of $\varphi_k$ to the subobject $\{0, \ldots, r\} \times \Delta_{k+1}$ (resp. the subobject $\{k + 1 - r, \ldots, k + 1\} \times \Delta_{k+1}$), and define $B_r$ as the fibre product in the cartesian diagram

$$
\begin{array}{ccc}
B_r & \longrightarrow & (\partial \Delta_k \times \Delta_1) \cup (\Delta_k \times \Lambda^j_1) \\
\downarrow & & \downarrow i^j_k \\
A_r & \longrightarrow & \Delta_k \times \Delta_1.
\end{array}
$$

Set also $A_{-1} := s.\emptyset$ (the initial object of $s.$ Set). Now, a straightforward induction reduces to checking that the natural morphisms

$$
B_k \amalg_{B_r} A_r \to B_k \amalg_{B_{r+1}} A_{r+1}
$$

lie in the saturation of $\Sigma_1$. To this aim, it suffices to show that the same holds for the natural morphisms

$$
\tau_r : B_{r+1} \amalg_{B_r} A_r \to A_{r+1}
$$

for $r = -1, \ldots, k - 1$.

This, in turns, follows immediately from:

**Claim 7.5.25.** (i) The natural isomorphism $\{0\} \times \Delta_{k+1} \xrightarrow{\sim} A_0$ identifies $B_0$ with $\{0\} \times \Lambda^1_{k+1}$.

(ii) For every $r = 0, \ldots, k - 1$ there is a commutative diagram in $s.$ Set

$$
\begin{array}{ccc}
\Delta_k & \xrightarrow{\varepsilon_{r+1}} & \Lambda^2_{k+1} \xrightarrow{i^2_{k+1}} \Delta_{k+1} \\
\downarrow & & \downarrow \varepsilon_{k+1} \\
A_r & \xrightarrow{\tau_r} & B_{r+1} \amalg_{B_r} A_r \xrightarrow{\tau_r} A_{r+1}
\end{array}
$$

whose two square subdiagrams are cocartesian.

**Proof of the claim.** To ease notation, we shall identify $\{r\} \times \Delta_k$ with its image under $\varphi_k$, which is a subobject of $\Delta_k \times \Delta_1$, for every $r = 0, \ldots, k$. Notice that $B_{r+1} \amalg_{B_r} A_r$ is the smallest subobject of $\Delta_k \times \Delta_1$ that contains $A_r$ and $Z_{r+1} := (\{r + 1\} \times \Delta_{k+1}) \cap B_k$. However, a morphism $[t] : B_k$ is the same as an increasing sequence of elements of $[k] \times [1]$

$$
(a_n, b_n) \quad n = 0, \ldots, t
$$

such that:

(a) either the cardinality of the set $\{a_0, \ldots, a_t\}$ is strictly less than $k + 1$

(b) or else $b_n \neq j$ for every $n = 0, \ldots, t$. 

(7.5.26)
On the other hand, recall that the inclusion \( \{ r + 1 \} \times \Delta_{k+1} \subset \Delta_k \times \Delta_1 \) corresponds to the inclusion map of partially ordered sets \( \varphi_{k,r+1} \) (notation of (7.5.20)). It follows that an injective morphism \( \Delta_i \to Z_{r+1} \) corresponds to a strictly increasing sequence (7.5.26) contained in

\[
\{(0,0),\ldots,(0,r+1),(1,r+1),\ldots,(1,k)\}
\]

and fulfilling either of the foregoing conditions (a) or (b). Taking \( r = -1 \), we already see that (i) holds. If \( r \geq 0 \), take \( t := k \), and notice that no such sequence can have \( a_r \neq r + 1 \), so we see that of all the \( k + 2 \) monomorphisms

\[
1_{\{r+1\}} \times e_j : \{r+1\} \times \Delta_k \to \{r+1\} \times \Delta_{k+1}
\]

only those with \( j \neq r + 1, r + 2 \) factor through \( Z_{r+1} \). On the other hand, from the presentation (7.5.22) we see that the intersection of \( \{ r + 1 \} \times \Delta_{k+1} \) is the image of \( \{ r \} \times \Delta_k \), which maps to both of them via the morphism \( \varepsilon_{r+1} \). From this, we conclude already that the left square subdiagram of (ii) is indeed cocartesian, if we let the central vertical arrow to be the morphism that naturally identifies \( \Delta_{k+1} \) with \( \{ r + 1 \} \times \Delta_{k+1} \). By the same token, it is clear the right square subdiagram is likewise cocartesian, provided we let the right-most vertical arrow to be the morphism that naturally identifies \( \Delta_{k+1} \) with \( \{ r + 1 \} \times \Delta_{k+1} \).

Next, let us check that the saturation of \( \Sigma_2 \) contains \( \Sigma_3 \). Indeed, let \( \mu : K \to L \) be any monomorphism of \( s.Set \), and fix \( j \in \{0,1\} \); according to example 7.5.2(iii), there exist:

- A countable system of monomorphisms

\[
K_{-1} := K \xrightarrow{\mu_{-1}} K_0 \xrightarrow{} \cdots \xrightarrow{} K_n \xrightarrow{\mu_n} K_{n+1} \xrightarrow{} \cdots
\]

such that \( \mu \) is isomorphic to the induced morphism

\[
K \twoheadrightarrow \operatorname{colim}_{n \in \mathbb{N}} K_n.
\]

- For every \( n \in \mathbb{N} \), a set \( I_n \) and an epimorphism \( K_{n-1} \amalg (I_n \times \Delta_n) \to K_n \) whose restriction to \( K_{n-1} \) agrees with \( \mu_{n-1} \).

There follows, for every integer \( n \in \mathbb{N} \), a cocartesian diagram

\[
\begin{array}{ccc}
(K_{n-1} \times \Delta_1) \cup (K_n \times \Delta_1^i) & \xrightarrow{i_{K_{n-1} \amalg K_n}^i} & (K_{n-1} \times \Delta_1) \cup (L \times \Delta_1^i) \\
\downarrow & & \downarrow \varphi_n \\
K_n \times \Delta_1 & \xrightarrow{} & (K_n \times \Delta_1) \cup (L \times \Delta_1^i)
\end{array}
\]

and the system \( \{\varphi_n \mid n \in \mathbb{N}\} \) induces a morphism

\[
(K \times \Delta_1) \cup (L \times \Delta_1^i) \to \operatorname{colim}_{n \in \mathbb{N}} (K_n \times \Delta_1) \cup (L \times \Delta_1^i) = L \times \Delta_1
\]

which is isomorphic to \( i_{K,L}^i \). Thus, we may assume that there exist a set \( I \) and an epimorphism \( K \amalg (I \times \Delta_n) \to L \) for some \( n \in \mathbb{N} \), and we shall argue by induction on \( n \). Set \( Q := (I \times \Delta_n) \times_L K \) and notice that \( Q \) is a subobject of \( I \times \Delta_n \). Also, since all epimorphisms are effective, the induced commutative diagram

\[
\begin{array}{ccc}
Q & \xrightarrow{} & K \\
\downarrow & & \downarrow \\
I \times \Delta_n & \xrightarrow{} & L
\end{array}
\]

is cocartesian. Furthermore, since all colimits are universal in \( s.Set \), we deduce that

\[
Q = \coprod_{i \in I_n} Q_i \quad \text{where} \quad Q_i := (\{i\} \times \Delta_n) \cap Q \quad \text{for every} \ i \in I.
\]
We are then reduced to the case where \( L = \Delta_n \). If \( n = 0 \), then clearly \( K \) is either \( \Delta_0 \) or \( \Delta_{-1} \), and in either case we have \( i_{K,L}^i \in \Sigma_2 \).

Next, suppose that \( n > 0 \), and that the assertion is already known for every integer \( k < n \). If \( K = \Delta_n \), we are done; otherwise, it is easily seen that the inclusion \( K \to \Delta_n \) factors through \( \partial \Delta_n \), and arguing as in the foregoing, we are reduced to considering the morphisms \( i_{K,\partial \Delta_n}^i \) and \( i_{\partial \Delta_n, \Delta_n}^i \). The latter lies in \( \Sigma_2 \), and from example \( 7.5.24 \)(iv) it is clear that there is an epimorphism \( K \amalg ([n] \times \Delta_{n-1}) \to \partial \Delta_n \), so \( i_{K,\partial \Delta_n}^i \) lies in the saturation of \( \Sigma_2 \), by inductive assumption.

Lastly, we show that the saturation of \( \Sigma_3 \) contains \( \Sigma_1 \). To this aim, it suffices to construct a commutative diagram

\[
\begin{array}{ccc}
\Lambda_k^r & \longrightarrow & (\Lambda_k^r \times \Delta_1) \cup (\Delta_k \times \Lambda_1^r) \longrightarrow \Lambda_k^r \\
\downarrow i' & & \downarrow i' \\
\Delta_k & \longrightarrow & \Delta_k \times \Delta_k \\
\end{array}
\]

for every \( n, r \in \mathbb{N} \) with \( r \leq k \), such that \( p \circ i = 1_{\Delta_k} \). However, notice that a morphism \( [t] \to (\Lambda_k^r \times \Delta_1) \cup (\Delta_k \times \Lambda_1^r) \) (for any \( t \in \mathbb{N} \)) is the same as an increasing sequence \( 7.5.26 \) of elements of \( [k] \times [1] \) such that

(a) either \( b_n \neq j \) for every \( n = 0, \ldots, t \)

(b) or else, the cardinality of of the set \( \{a_0, \ldots, a_t\} \cup \{r\} \) is strictly less than \( k + 1 \).

Now, any such \( p \) and \( i \) shall be the images, under the functor \( 7.5.17 \), of corresponding maps of ordered sets

\[
[k] \xrightarrow{i^r} [k] \times [1] \xrightarrow{p^r} [k] \quad \text{such that } p^r \circ i^r = 1_{[k]}.
\]

We obtain a suitable \( j \in \{0, 1\} \) and suitable \( p^*, i^* \) by the following rule. If \( r < k \), we let \( j := 1 \), and define \( p^* \) and \( i^* \) as the maps such that

\[
i^*(a) = (a, 1) \quad \text{for every } a = 0, \ldots, k
\]

\[
p^*(a, b) = \begin{cases} 
a & \text{if } b = 1 \text{ or } a \leq r \\r & \text{otherwise.}
\end{cases}
\]

If \( r = k \), we let \( j := 0 \), and set

\[
i^*(a) := (a, 0) \quad \text{for every } a = 0, \ldots, k
\]

\[
p^*(a, b) = \begin{cases} 
a & \text{if } b = 0 \\r & \text{otherwise.}
\end{cases}
\]

The reader may easily check that the resulting maps \( i \) and \( p \) will do. \( \square \)

**Definition 7.5.27.** A monomorphism in \( s.Set \) is an **anodyne extension**, if it lies in the saturation of the set \( \Sigma_1 \).

In view of lemma \( 7.5.15 \)(i), we see that a fibration has the right lifting property with respect to every anodyne extension. We also notice:

**Corollary 7.5.28.** Let \( K \to L \) be any anodyne extension, and \( A \to B \) any monomorphism. Then the induced monomorphism

\[
(K \times B) \cup (L \times A) \to L \times B
\]

is an anodyne extension.

**Proof.** Let \( \Sigma \) be the set of monomorphisms \( K' \to L' \) such that the induced morphism

\[
(K' \times B) \cup (L' \times A) \to L' \times B
\]

is an anodyne extension. It is easily seen that \( \Sigma \) is saturated (details left to the reader; cp. the proof of proposition \( 7.5.24 \)); taking into account proposition \( 7.5.24 \), it then suffices to check
that $\Sigma$ contains the morphisms $i^j_{X,Y}$, where $f : X \to Y$ is an arbitrary monomorphism (notation of (7.5.23)). However, for any such $f$ we have a commutative diagram

$$(((X \times \Delta_1) \cup (Y \times \Lambda^1_1)) \times B) \cup ((Y \times \Delta_1) \times A) \xrightarrow{\delta_{(X \times B) \cup (Y \times A) \times B}} (Y \times B) \times \Delta_1$$

whose vertical arrows are isomorphisms. Then the contention follows by appealing again to proposition 7.5.24. $\square$

**Theorem 7.5.29.** For every morphism $f : X \to Y$ of simplicial sets there exists a commutative diagram

$$\begin{array}{ccc}
X & \xrightarrow{i_f} & E_f \\
\downarrow f & & \downarrow p_f \\
Y & \xrightarrow{p_f} & \text{in } s.\text{Set}
\end{array}$$

such that $i_f$ is an anodyne extension, and $p_f$ is a fibration.

**Proof.** For every $k, n \in \mathbb{N}$ with $k \geq \min(1, n)$, consider the set $\mathcal{L}_k^n$ of all commutative diagrams

$$\begin{array}{ccc}
\Lambda_k^n & \xrightarrow{\eta_k} & X \\
\downarrow f & & \downarrow f \\
\Delta_k & \xrightarrow{p_f} & Y
\end{array}$$

and set

$$\Lambda_f := \coprod_{n \in \mathbb{N}} \coprod_{k \geq \min(1, n)} \mathcal{L}_k^n \times \Lambda_k^n \quad \text{and} \quad L_f := \coprod_{n \in \mathbb{N}} \coprod_{k \geq \min(1, n)} \mathcal{L}_k^n \times \Delta_k.$$ 

There follows a natural morphism

$$\begin{array}{ccc}
\Lambda_f & \xrightarrow{\iota} & X \\
\downarrow \iota & & \downarrow f \\
L_f & \xrightarrow{\iota} & Y
\end{array}$$

with $\iota$ an anodyne extension. Define $E_f^0$ as the push-out in the induced cocartesian diagram

$$\begin{array}{ccc}
\Lambda_f & \xrightarrow{\iota} & X \\
\downarrow \iota & & \downarrow i_f^0 \\
L_f & \xrightarrow{\iota} & E_f^0
\end{array}$$

so that $i_f^0$ is anodyne as well, and we have a commutative diagram

$$\begin{array}{ccc}
X & \xrightarrow{\iota} & E_f^0 \\
\downarrow f & & \downarrow p_f^0 \\
Y & \xrightarrow{p_f^0} & \text{in } s.\text{Set}
\end{array}$$

Clearly, the rule $(X, f) \mapsto (E_f^0, p_f^0)$ extends to a well defined functor

$$E^0 : s.\text{Set}/Y \to s.\text{Set}/Y$$
and the rule \((X, f) \mapsto t^0_{(X, f)}\) yields a natural transformation
\[ t^0 : 1_{s.\text{Set}}/Y \to E^0. \]
Thus, we may define inductively:
\[ E^n(X, f) := E^0(E^{n-1}(X, f)) \quad \text{for every integer } n \geq 1 \]
so \(E^n(X, f)\) is a pair \((E^n_f, p^n_f)\), and we get as well as a natural transformation
\[ t^n_{(X, f)} := t^0_{E^{n-1}(X, f)} : E^{n-1}_f \to E^n_f \quad \text{for every integer } n \geq 1 \]
which is again an anodyne extension. We set
\[ E_f := \colim_{n \in \mathbb{N}} E^n_f \]
where the transition maps in the colimit are given by the system of morphisms \((t^n_f | n \in \mathbb{N})\). The colimit of the system of morphism \((p^n_f | n \in \mathbb{N})\) is then a morphism \(p_f : E_f \to Y\); moreover, the induced morphism \(t_f : X \to E_f\) is anodyne, and obviously \(p_f \circ t_f = f\). To conclude the proof, it suffices to show that \(p_f\) is a fibration. Thus, consider any commutative diagram
\[
\begin{array}{ccc}
\Lambda^n_k & \xrightarrow{g} & E_f \\
\downarrow c^n_k & & \downarrow p_f \\
\Delta_k & \xrightarrow{h} & Y.
\end{array}
\]
It follows easily from example 7.5.2(v) that – for \(r \in \mathbb{N}\) large enough – \(g\) factors through a morphism \(g_r : \Lambda^n_k \to E^r_f\) and the natural morphism \(E^r_f \to E_f\), whence a commutative diagram
\[
\begin{array}{ccc}
\Lambda^n_k & \xrightarrow{g_r} & E^r_f \\
\downarrow c^n_k & & \downarrow p_f \\
\Delta_k & \xrightarrow{h} & Y.
\end{array}
\]
But then, by construction of \(E^{r+1}_f\), we see that \(h\) lifts to a morphism \(h' : \Delta_k \to E^{r+1}_f\) such that \(p^{r+1}_f \circ h' = h\) and \(h' \circ c^n_k = i^{r+1}_f \circ g_r\). The composition of \(h'\) with the natural morphism \(E^{r+1}_f \to E_f\) is a morphism \(h'' : \Delta_k \to E_f\) such that \(p_f \circ h'' = h\) and \(h'' \circ i^n_k = g\), as required. ∎

A useful way to produce new fibrant simplicial sets out of old ones is provided by the general construction introduced in the following:

**Definition 7.5.30.** Let \(A\) and \(B\) be any two simplicial sets; the function complex
\[ s.\text{Hom}(A, B) \]
associated with \(A\) and \(B\) is the simplicial set given by the rule:
\[ n \mapsto \text{Hom}_{s.\text{Set}}(\Delta_n \times A, B) \quad \varphi \mapsto \text{Hom}_{s.\text{Set}}(\Delta_\varphi \times 1_A, B) \]
for every \(n \in \mathbb{N}\) and every morphism \(\varphi\) of \(\Delta\).

**Remark 7.5.31.** (i) Notice that the system of isomorphisms \(A[n] \xrightarrow{\sim} \text{Hom}_{s.\text{Set}}(\Delta_n, A)\) given by Yoneda’s lemma for every \(n \in \mathbb{N}\), amounts to a natural identification
\[ t_A : A \xrightarrow{\sim} s.\text{Hom}(\Delta_0, A) \quad \text{for every } A \in \text{Ob}(s.\text{Set}). \]
(ii) Also, if \(A, B\) and \(C\) are any three simplicial sets, there is a natural transformation
\[ \tau_{A,B,C} : s.\text{Hom}(A, B) \to s.\text{Hom}(A \times C, B \times C) \]
which, to any \( n \in \mathbb{N} \), assigns the map
\[
\text{Hom}_{s\cdot\text{Set}}(\Delta_n \times A, B) \to \text{Hom}_{s\cdot\text{Set}}(\Delta_n \times A \times C, B \times C) \quad \varphi \mapsto \varphi \times 1_C.
\]

(iii) There is a natural evaluation morphism
\[
ev_{A,B} : A \times s\cdot\text{Hom}(A, B) \to B \quad \text{for every } A, B \in \text{Ob}(s\cdot\text{Set})
\]
which, to every \( n \in \mathbb{N} \), assigns the map
\[
A[n] \times \text{Hom}_{s\cdot\text{Set}}(\Delta_n \times A, B) \to B[n] \quad (a, f) \mapsto f[n](1_{\Delta_n}, a).
\]
Indeed, for any morphism \( \varphi : [k] \to [n] \) in \( \Delta \), and \( (a, f) \) any element of \( (A \times \text{Hom}(A, B))[n] \) we may compute
\[
B[\varphi] \circ \ev_{A,B}[n](a, f) = B[\varphi] \circ f[n](1_{\Delta_n}, a)
= f[k] \circ (\Delta_n[\varphi] \times A[\varphi])(1_{\Delta_n}, a)
= f[k](\varphi, A[\varphi](a))
= f[k] \circ (\varphi \times 1_A)[k](1_{\Delta_k}, A[\varphi](a))
= (f \circ (\varphi \times 1_A))[k](1_{\Delta_k}, A[\varphi](a))
= ev_{A,B}[k](A[\varphi](a), f \circ (\varphi \times 1_A))
= ev_{A,B}[k] \circ (A \times \text{Hom}(A, B))[\varphi](a, f)
\]
which shows that \( \ev_{A,B} \) is a morphism of simplicial sets.

(iv) Clearly \( s\cdot\text{Set} \) is a tensor category, with tensor product given by the product of simplicial sets, and with \( \Delta_0 \) as unit object. We claim that the functor
\[
s\cdot\text{Hom} : (s\cdot\text{Set})^\circ \times s\cdot\text{Set} \to s\cdot\text{Set}
\]
is an internal Hom functor for \( (s\cdot\text{Set}, \times, \Delta_0) \). Indeed, given \( A, B, C \in \text{Ob}(s\cdot\text{Set}) \) and any morphism \( f : A \times B \to C \), we obtain a morphism
\[
A \overset{\cdot\Delta}{\to} s\cdot\text{Hom}(\Delta_0, A) \overset{\tau_{A,B,C}}{\to} s\cdot\text{Hom}(B, A \times B) \overset{\text{Hom}(B,f)}{\to} s\cdot\text{Hom}(B, C).
\]
Conversely, given a morphism \( g : A \to \text{Hom}(B, C) \), we get a morphism
\[
A \times B \overset{g \times 1_B}{\to} s\cdot\text{Hom}(B, C) \times B \overset{\sim}{\to} B \times s\cdot\text{Hom}(B, C) \overset{\ev_{B,C}}{\to} C.
\]
It is easily seen that these two rules yield mutually inverse natural bijections, as required (details left to the reader).

7.5.32. Let \( f : A \to B \) and \( g : C \to D \) be morphisms of simplicial sets. We have a commutative diagram
\[
\begin{array}{ccc}
s\cdot\text{Hom}(D, A) & \xrightarrow{s\cdot\text{Hom}(D,f)} & s\cdot\text{Hom}(D, B) \\
\downarrow s\cdot\text{Hom}(g,A) & & \downarrow s\cdot\text{Hom}(g,B) \\
s\cdot\text{Hom}(C, A) & \xrightarrow{s\cdot\text{Hom}(C,f)} & s\cdot\text{Hom}(C, B)
\end{array}
\]
whence an induced morphism in \( s\cdot\text{Set} \)
\[
(7.5.33) \quad s\cdot\text{Hom}(D, A) \to s\cdot\text{Hom}(D, B) \times_{s\cdot\text{Hom}(C,B)} s\cdot\text{Hom}(C, A).
\]

**Proposition 7.5.34.** In the situation of (7.5.32), suppose that \( f \) is a fibration and \( g \) a monomorphism. Then (7.5.33) is a fibration as well.
Proof. The datum of a commutative diagram

$$\begin{array}{ccc}
\Lambda_k & \rightarrow & s.\text{Hom}(D, A) \\
\downarrow \quad i_k & & \downarrow \\
\Delta_k & \rightarrow & s.\text{Hom}(D, B) \times_{s.\text{Hom}(C, B)} s.\text{Hom}(C, A)
\end{array}$$

is equivalent, by remark 7.5.31(iv), to that of a commutative diagram

$$\begin{array}{cccc}
(\Lambda_k \times D) \cup (\Delta_k \times C) & \rightarrow & A \\
\downarrow g & & \downarrow f \\
\Delta_k \times D & \rightarrow & B.
\end{array}$$

On the other hand, $f$ has the right lifting property with respect to $g$ (corollary 7.5.28); it follows easily that (7.5.33) has the right lifting property with respect to $i_k^1$, as stated. □

Corollary 7.5.35. Let $A$ be any fibrant simplicial set. We have :

(i) $s.\text{Hom}(D, A)$ is fibrant, for any simplicial set $D$.

(ii) Any monomorphism $D \rightarrow D'$ of simplicial sets induces a fibrant morphism $s.\text{Hom}(D', A) \rightarrow s.\text{Hom}(D, A)$.

Proof. (i): Take $B := \Delta_0$, $C := \Delta_{-1}$, and let $f : A \rightarrow B$, $g : C \rightarrow D$ be the unique morphisms of simplicial sets. In view of proposition 7.5.34, it suffices to notice the natural identifications $s.\text{Hom}(D, \Delta_0) \rightarrow s.\text{Hom}((\Delta_{-1}, D)$ for every simplicial set $A$. The proof of (ii) is similar : details left to the reader. □

7.5.36. Let $f, g : X \rightarrow Y$ be two morphisms of simplicial sets. Recall (see remark 7.4.17(v)) that a homotopy $u$ from $f$ to $g$ is the datum of a commutative diagram of simplicial sets :

$$\begin{array}{cccc}
X \times \Delta_0 & \rightarrow & X \times \Delta_1 & \leftarrow X \times \Delta_0 \\
\downarrow f & & \downarrow u & & \downarrow g \\
X & \rightarrow & Y & \rightarrow X.
\end{array}$$

Definition 7.5.37. In the situation of (7.5.36), suppose that $i : X' \rightarrow X$ is a monomorphism of simplicial sets, such that $f \circ i = g \circ i$. We say that $u$ is a homotopy from $f$ to $g$ relative to $X'$, if $u$ is a homotopy from $f$ to $g$, and the following diagram commutes :

$$\begin{array}{ccc}
X' \times \Delta_1 & \rightarrow & X' \\
\downarrow i \times 1_{\Delta_1} & & \downarrow f \circ i \\
X \times \Delta_1 & \rightarrow & Y
\end{array}$$

where the top horizontal arrow is the natural projection.

Remark 7.5.38. Let $f, g : X \rightarrow Y$ be any two morphisms of simplicial sets.

(i) Of course, a homotopy from $f$ to $g$ can be viewed as a homotopy relative to the sub-object $\Delta_{-1} \subset X$, so definition 7.5.37 generalizes the previous notion. Notice also that to $f$ one may attach a constant homotopy

$$\begin{array}{ccc}
X \times \Delta_1 & \rightarrow & X \\
\downarrow 1_{X} \times \eta_0 & & \downarrow f \\
X & \rightarrow & Y
\end{array}$$

(ii) Let $u$ be any homotopy from $f$ to $g$ relative to a subobject $X'$ of $X$, and $h : Y \rightarrow Z$ any morphism of simplicial sets. Then clearly $h \circ u$ is a homotopy from $h \circ f$ to $h \circ g$ relative to $X'$. Likewise, if $t : Z \rightarrow X$ is any other morphism, then $u \circ (t \times \Delta_1)$ is a homotopy from $f \circ t$ to $g \circ t$ relative to $Z \times_X X'$. 
7.5.39. Let $A$ be any simplicial set; on the set $\text{Hom}_{s\text{-Set}}(\Delta_0, A) \simeq A[0]$ we consider the binary relation $\sim$ such that

$$a \sim b \iff \text{there exists a homotopy from } a \text{ to } b.$$ 

**Lemma 7.5.40.** With the notation of (7.5.39), suppose that $A$ is fibrant. Then $\sim$ is an equivalence relation on $A[0]$.

**Proof.** Clearly $a \sim b$ if and only if there exists a morphism $u : \Delta_1 \to X$ such that $u \circ \varepsilon_0 = a$ and $u \circ \varepsilon_1 = b$. Taking $u := a \circ \sigma_0$, where $\sigma_0 : \Delta_1 \to \Delta_0$ is the unique morphism, and $a \in A[0]$ any element, we obtain the reflexivity of $\sim$. Next, suppose that $a \sim b$ and $b \sim c$ for some $a, b, c \in A[0]$, and pick $u, v : \Delta_1 \to A$ that give a homotopy from $a$ to $b$, and respectively from $b$ to $c$. Then it is easily seen that the datum of $u$ and $v$ determines a unique morphism $s : \Delta_2 \to A$ such that $s \circ \varepsilon_0 = u$ and $s \circ \varepsilon_1 = v$. By assumption, $s$ extends to a morphism $\Lambda_2 \to A$, and then $s \circ \varepsilon_1$ is a homotopy from $a$ to $c$, whence the transitivity of $\sim$.

Lastly, let $u : \Delta_1 \to A$ be a homotopy from $a$ to $b$, for some $a, b \in A[0]$; we let $t : \Lambda_2 \to A$ be the unique morphism such that $t \circ \varepsilon_0 = u$ and $t \circ \varepsilon_1 = b \circ \sigma_0$. By assumption $t$ extends to a morphism $s : \Delta_2 \to A$, and it is easily seen that $s \circ \varepsilon_0$ is a homotopy from $b$ to $a$, which shows that $\sim$ is also symmetric. \[\square\]

7.5.41. More generally, if $i : K \to X$ is any monomorphism in $s\text{-Set}$, and $Y$ is any simplicial set, we consider on $\text{Hom}_{s\text{-Set}}(X, Y)$ the binary relation

$$f \sim_K g \iff \text{there exists a homotopy from } f \text{ to } g \text{ relative to } K.$$ 

In case $K = s\emptyset$, we simply write $f \sim g$ instead of $f \sim_{s\emptyset} g$.

**Theorem 7.5.42.** With the notation of (7.5.41), suppose that $Y$ is fibrant. Then $\sim_K$ is an equivalence relation.

**Proof.** The fibres of the map of sets

$$\text{Hom}_{s\text{-Set}}(X, Y) \to \text{Hom}_{s\text{-Set}}(K, Y), \quad f \mapsto f \circ i$$

give a partition of $\text{Hom}_{s\text{-Set}}(X, Y)$, and if $f \sim_K g$, then $f$ and $g$ lie in the same fibre of (7.5.43).

Hence, we may restrict attention to a single fibre of (7.5.43), say the fibre over the morphism $h : K \to Y$. Now, $h$ corresponds to a morphism $h^* : \Delta_0 \to s\text{Hom}(K, Y)$ in $s\text{-Set}$, and likewise, the datum of a pair of morphisms $f, g : X \to Y$ such that $f \circ i = h = g \circ i$ corresponds to that of a pair of morphisms $f^*, g^* : \Delta_0 \to s\text{Hom}(X, Y)$ with $i^* \circ f^* = h^* = i^* \circ g^*$, where

$$i^* : s\text{Hom}(X, Y) \to s\text{Hom}(K, Y)$$

is the morphism deduced from $i$. Furthermore, a homotopy from $f$ to $g$ relative to $K$ is the same as a morphism $t : \Delta_1 \to s\text{Hom}(X, Y)$ such that $i^* \circ t$ factors through $h^*$ and such that

$$t \circ \varepsilon_0 = f^* \quad t \circ \varepsilon_1 = g^*.$$ 

Set $A := i^{*-1}(h^*)$ (notation of example 7.5.2 vi)). We conclude that $t$ corresponds to a homotopy between the elements of $A[0]$ induced by $f^*$ and $g^*$. However, $A$ is fibrant by corollary 7.5.35 ii) and lemma 7.5.15 iv), so the assertion follows from lemma 7.5.40. \[\square\]

7.5.44. Let $A$ be any simplicial set, $\xi \in A[0]$ any element, and denote also by $\xi : \Delta_0 \to A$ the corresponding morphism of simplicial sets. We shall frequently abuse notation, and denote indifferently by $\xi$ the unique element of $A[n]$ that lies in the image of the map $\xi[n]$. We call the pair $(A, \xi)$ a pointed simplicial set. With this terminology, we have:

**Definition 7.5.45.** Let $(A, \xi)$ be a pointed simplicial set, such that $A$ is fibrant.
(i) For every integer \( n \in \mathbb{N} \), let \( A(\xi, n) \) be the set of all \( a \in A[n] \) such that \( \partial a \) factors through \( \xi \) (notation of example 7.5.2(iv)). We set
\[
\pi_n(A, \xi) := A(\xi, n)/\sim_{\partial \Delta_n}
\]
(where \( \sim_{\partial \Delta_n} \) is the homotopy equivalence relation defined in 7.5.41), and for every \( n > 0 \) we call \( \pi_n(A, \xi) \) the \( n \)-th homotopy group of \( A \).

(ii) Notice that \( \pi_0(A, \xi) \) is actually independent of \( \xi \), so we shall usually just denote it \( \pi_0(A) \). We say that \( A \) is connected if the cardinality of \( \pi_0(A) \) equals one.

**Lemma 7.5.46.** In the situation of definition 7.5.45 let \( n \in \mathbb{N} \) be any integer and \( a \in A(\xi, n) \) any simplex. The following conditions are equivalent:

(a) \( a \sim_{\partial \Delta_n} \xi \).

(b) There exists \( b \in A[n+1] \) such that \( \partial_i b = \xi \) for every \( i = 1, \ldots, n+1 \) and \( \partial_0 b = a \).

**Proof.** (a)\(\Rightarrow\)(b): Let \( h : \Delta_n \times \Delta_1 \to A \) be any morphism in \( s.Set \). From the presentation (7.5.22) we see that \( h \) is the same as a system \( x_0, \ldots, x_n \) of elements of \( A[n+1] \) such that
\[
\partial_i x_i = \partial_{i+1} x_{i+1} \quad \text{for } i = 1, \ldots, n.
\]
Namely, \( x_i := h \circ \varphi_{n,i} \) for every \( i = 0, \ldots, n \), where \( \varphi_{n,i} : [n+1] \to [n] \times [1] \) is defined as in 7.5.20. Moreover, recall that the fully faithful functor (7.5.17) associates with any map of partially ordered sets \( f : [n] \to [n] \times [1] \) a morphism \( \Delta_f : \Delta_n \to \Delta_n \times \Delta_1 \), and it is easily seen that \( \Delta_f \) factors through the subobject \( (\partial \Delta_n \times \Delta_1) \cup (\Delta_n \times \partial \Delta_1) \) if and only if \( f \) fulfills the following condition. Set \( f(j) := (r_j, s_j) \) for every \( j \in [n] \); then, for every \( j = 0, \ldots, n-1 \) we have either \( r_j = r_{j+1} \) or \( s_j = s_{j+1} \) (details left to the reader). It follows easily that \( h \) is a homotopy from \( \xi \) to \( a \) relative to \( \partial \Delta_n \), if and only if we have
\[
\partial_0 x_0 = a \quad \text{and} \quad \partial_{i+1} x_i = \xi \quad \text{for } 0 < i \leq n \quad \text{and} \quad j \neq i, i+1.
\]
Consider then the system \( y_* : (y_1, \ldots, y_{n+2}) \) of elements of \( A[n+1] \) such that \( y_{n+2} := \xi \) and \( y_i = x_{i-1} \) for every \( i = 1, \ldots, n+1 \). A direct calculation shows that
\[
\partial_0 y_j = \partial_{j-1} y_i \quad \text{whenever } 1 \leq i < j \leq n+2
\]
so \( y_* \) corresponds to a unique morphism \( \varphi : \Lambda^0_{n+2} \to A \) whose restriction with the \( i \)-th face of \( \Lambda^0_{n+2} \) agrees with \( y_i \), for every \( i = 1, \ldots, n+2 \). Since \( A \) is fibrant, we may then find \( c \in A[n+2] \) such that \( \partial_j c = y_i \) for every \( i = 1, \ldots, n+2 \). Set \( b := \partial_0 c \); then
\[
\partial_i b = \partial_i \partial_0 c = \partial_0 \partial_{i+1} c = \partial_0 x_i \quad \text{for every } i = 0, \ldots, n+1
\]
whence the assertion.

(b)\(\Rightarrow\)(a): Consider the map \( f : [n] \times [1] \to [n+1] \) in the category \( \text{POSet} \) given by the rule:
\[
(i, 0) \mapsto i \quad \text{and} \quad (i, 1) \mapsto n+1 \quad \text{for every } i \in [n]
\]
and let \( \bar{b} : \Delta_{n+1} \to A \) be the morphism in \( s.Set \) corresponding to \( b \); then it is easily seen that \( \bar{b} \circ \Delta_f : \Delta_n \times \Delta_1 \to A \) is a homotopy from \( a \) to \( \xi \) relative to \( \partial \Delta_n \) (details left to the reader).

7.5.47. Let \( (A, \xi) \) be any pointed simplicial set, such that \( A \) is fibrant. To justify the name of \( \pi_n(A, \xi) \), we shall endow it with a natural group structure, for every \( n > 0 \). To this aim, say that \( \alpha, \beta \in \pi_n(A, \xi) \) are any two classes, and pick representatives \( x, y \in A(\xi, n) \) for \( \alpha \) and respectively \( \beta \). Then, obviously the sequence
\[
\xi, \ldots, \xi, x, y
\]
of \( n+1 \) elements of \( A[n] \) satisfies the compatibility condition of remark 7.5.11 with \( k := n \). We may therefore find \( z \in A[n+1] \) such that \( \partial_{n-1} z = x, \partial_{n+1} z = y \), and \( \partial_i z = \xi \) for \( i = 0, \ldots, n-2 \). The first observation is:
Lemma 7.5.48. With the notation of (7.5.47), the class of \( \partial_n z \) in \( \pi_n(A, \xi) \) depends only on \( \alpha \) and \( \beta \) (and not on \( z \), nor the choice of representatives \( x \) and \( y \)).

Proof. Let \( x' \) and \( y' \) be two other elements of \( A(\xi, n) \), and \( h \) (resp. \( h' \)) a homotopy from \( x \) to \( x' \) (resp. from \( y \) to \( y' \)) relative to \( \partial \Delta_n \). Let also \( z \) (resp. \( z' \)) be a morphism \( \Delta_{n+1} \to A \) such that
\[
z \circ \varepsilon_i = \xi = z' \circ \varepsilon_i \quad \text{for } i = 0, \ldots, n-2
\]
and
\[
z \circ \varepsilon_{n-1} = x \quad z' \circ \varepsilon_{n-1} = x' \quad z \circ \varepsilon_{n+1} = y \quad z' \circ \varepsilon_{n+1} = y'.
\]
Then there exists a unique morphism \( \psi : (\Delta_{n+1} \times \partial \Delta_1) \cup (\Delta_{n+1} \times \Delta_1) \to A \) such that
\begin{itemize}
  \item \( \psi \circ (1_{\Delta_{n+1}} \times \varepsilon_0) = z \) and \( \psi \circ (1_{\Delta_{n+1}} \times \varepsilon_1) = z' \).
  \item \( \psi \circ (\varepsilon_i \times 1_{\Delta_1}) \) factors through \( \xi \) for \( i = 0, \ldots, n-2 \).
  \item \( \psi \circ (\varepsilon_{n-1} \times 1_{\Delta_1}) = h \) and \( \psi \circ (\varepsilon_{n+1} \times 1_{\Delta_1}) = h' \)
\end{itemize}
and it is easily seen that \( \psi \circ (\varepsilon_n \times 1_{\Delta_1}) \) is a homotopy from \( \partial_n z \) to \( \partial_n z' \).

7.5.49. Keep the notation of (7.5.47); lemma 7.5.48 says that the rule \( (\alpha, \beta) \mapsto \partial_n z \) yields a well defined pairing
\[\pi_n(A, \xi) \times \pi_n(A, \xi) \to \pi_n(A, \xi) \quad (\alpha, \beta) \mapsto \alpha \cdot \beta \quad \text{for every integer } n > 0.\]

For any \( x \in A(\xi, n) \), we shall write \( [x] \) for the class of \( x \) in \( \pi_n(A, \xi) \).

Theorem 7.5.51. For every integer \( n > 0 \), the pairing (7.5.50) defines a group law on \( \pi_n(A, \xi) \), whose neutral element is the class \([\xi]\).

Proof. Fix \( n > 0 \) and any \( \alpha \in \pi_n(A, \xi) \); to see that \([\xi] \cdot \alpha = \alpha \cdot [\xi] = \alpha\), pick any representative \( x : \Delta_n \to A \) for \( \alpha \), and set \( z := x \circ \eta_n \), \( z' := x \circ \eta_{n+1} \). From the simplicial identities (7.4.6) it is easily seen that \( \partial_i z = \partial_i z' = [\xi] \) for \( i = 0, \ldots, n-2 \), and \( \partial_{n-1} z = \partial_{n+1} z' = x \), so \( \partial_n z \text{ and } \partial_n z' \) represent respectively \([\xi] \cdot \alpha \) and \( \alpha \cdot [\xi] \). But we have \( \partial_n z = \partial_n z' = x \), whence the claim.

Next, we check that the map
\[\pi_n(A, \xi) \to \pi_n(A, \xi) : \beta \mapsto \alpha \cdot \beta\]
is surjective. Indeed, given any \( y \in A(\xi, n) \), there exists a morphism \( \varphi : \Delta_{n+1} \to A \) such that \( \varphi \circ \varepsilon_i = \xi \) for \( i = 0, \ldots, n-2 \), \( \varphi \circ \varepsilon_{n-1} = x \) and \( \varphi \circ \varepsilon_n = y \). We can then extend \( \varphi \) to a morphism \( z : \Delta_n \to A \), and if we denote by \( \beta \) (resp. \( \gamma \)) the class of \( y \) (resp. of \( \partial_{n+1} z \)) in \( \pi_n(A, \xi) \), we see that \( \alpha \cdot \gamma = \beta \).

Likewise, one shows that right multiplication by \( \alpha \) defines a surjection on \( \pi_n(A, \xi) \) (details left to the reader). It remains only to check the associativity of (7.5.50), and to this aim, let \( x, y, z \in A(\xi, n) \) be any three elements, representing respectively \( \alpha, \beta, \gamma \in \pi_n(A, \xi) \). Then there exist \( u_{n-1}, u_{n+1}, u_{n+2} \in A[n+1] \) such that
\[
\partial_i u_{n-1} = \partial_i u_{n+1} = \partial_i u_{n+2} = \xi \quad \text{for every } i = 0, \ldots, n-2
\]
and
\[
\partial_{n-1} u_{n-1} = x \quad \partial_{n+1} u_{n-1} = y
\]
\[
\partial_{n-1} u_{n+1} = \partial_{n} u_{n-1} \quad \partial_{n+1} u_{n+1} = z
\]
\[
\partial_{n-1} u_{n+2} = y \quad \partial_{n+1} u_{n+2} = z.
\]
By remark 7.5.11 we may then find some \( v \in A[n+2] \) such that \( \partial_i v \) equals \( \xi \) for \( i = 0, \ldots, n-2 \), and equals \( u_i \) for \( i = n-1, n+1, n+2 \). It follows that
\[
\partial_{n-1} \partial_i v = x \quad \partial_{n+1} \partial_i v = \partial_{n} u_{n+2} \quad \text{and} \quad \partial_i \partial_n v = \xi \quad \text{for } i = 0, \ldots, n-2
\]
We may then compute:

\[ (\alpha \cdot \beta) \cdot \gamma = [\partial_n u_{n-1}] \cdot \gamma \]

\[ = [\partial_n u_{n+1}] \]

\[ = [\partial_n \partial_{n+1} v] \]

\[ = [\partial_n v] \]

\[ = \alpha \cdot (\beta \cdot \gamma) \]

as required. \(\square\)

**Remark 7.5.52.** (i) Let us denote

\(s.\text{Set}_o^f\)

the category of *fibrant pointed simplicial sets*, whose objects are all the pairs \((A, \xi)\) consisting of a simplicial set \(A\) and an element \(\xi \in A[0]\). A morphism \(f : (A, \xi) \to (A', \xi')\) in \(s.\text{Set}_o^f\) is a morphism \(f : A \to A'\) of simplicial sets such that \(f[0](\xi) = \xi'\). It follows easily from remark \[7.5.38\](ii) that, for every integer \(n > 0\) (resp. for \(n = 0\)), the rule \((A, \xi) \mapsto \pi_n(A, \xi)\) (resp. \((A, \xi) \mapsto \pi_0(A)\)) yields a functor

\[ \pi_n : s.\text{Set}_o^f \to \text{Grp} \quad (\text{resp. } \pi_0 : s.\text{Set}_o^f \to \text{Set}_o) \]

with values in the category of groups (resp. of pointed sets). Namely, if \(f\) is a morphism in \(s.\text{Set}_o^f\) as in the foregoing, and \(x \in A(\xi, n)\) (resp. \(x \in A[0]\)) is any element, we let \(\pi_n(f, \xi)[x]\) (resp. \(\pi_0(f)[x]\)) be the class of \(f[n](x)\) in \(\pi_n(A', \xi')\) (resp. in \(\pi_0(A')\)). A simple inspection shows that this rule is well defined and does yield a group homomorphism \(\pi_n(A, \xi) \to \pi_n(A', \xi')\), whenever \(n > 0\).

(ii) Let \(X\) and \(Y\) be two fibrant simplicial sets, \(\xi \in X[0]\) any element, and denote also by \(\xi\) the image of the corresponding morphism \(\Delta_0 \to X\), which is therefore a simplicial subset of \(X\). Let \(f, g : X \to Y\) be two morphisms of simplicial sets such that \(f[0](\xi) = g[0](\xi)\) and \(f \sim_\xi g\). Then we claim that

\[ \pi_n(f) = \pi_0(g) \quad \text{and} \quad \pi_n(f, \xi) = \pi_n(g, \xi) \quad \text{for every } n > 0. \]

Indeed, let \(u\) be a homotopy from \(f\) to \(g\) relative to \(\xi\); if \(x \in X(\xi, n)\), denote also by \(x : \Delta_n \to X\) the corresponding morphism, and notice that \(u \circ (x \times 1_{\Delta_1}) : \Delta_n \times \Delta_1 \to Y\) is a homotopy from \(f[n](x)\) to \(g[n](x)\) relative to \(\partial \Delta_n\), whence the contention.

**7.5.53.** Let \(p : X \to Y\) be a fibration between fibrant simplicial sets \(X\) and \(Y\). Let also \(\xi \in X[0]\) be any vertex, and set \(\xi' := p[0](\xi)\) and \(F := p^{-1}(\xi')\) (notation of example \[7.5.2\](vi)), so that \(F\) is fibrant as well, by lemma \[7.5.15\](iv). For any \(n \in \mathbb{N}\) and any \(a \in Y(\xi', n)\), we get a commutative diagram

\[
\begin{array}{ccc}
\Lambda^0_n & \overset{c}{\longrightarrow} & X \\
\downarrow & & \downarrow p \\
\Delta_n & \overset{a}{\longrightarrow} & Y
\end{array}
\]

where \(c\) is the unique morphism in \(s.\text{Set}\) that factors through \(\xi : \Delta_0 \to X\). We may then find \(b \in X[n]\) such that \(p[n](b) = a\) and \(\partial_i b = \xi\) for every \(i = 1, \ldots, n\).

**Lemma 7.5.54.** In the situation of \(7.5.53\), we have \(\partial_0 b \in F(\xi, n - 1)\), and the class \([\partial_0 b] \in \pi_{n-1}(F, \xi)\) depends only on \([a] \in \pi_n(Y, \xi')\) (and is independent of the representative \(a\) for \([a]\) and of the simplex \(b\)).

**Proof.** We have \(\partial_i \partial_0 b = \partial_0 \partial_{i+1} b = \xi\) for every \(i = 0, \ldots, n - 1\), whence the first assertion. Next, suppose that \(a' \in Y(\xi', n)\) is another simplex such that \(a' \sim_\partial \Delta_n a\), and pick any homotopy
Let $a$ to $a'$ relative to $\partial \Delta_n$. Let also $b' \in X[n]$ be any simplex such that $p(b') = a'$ and $\partial_i b' = \xi$ for $i = 1, \ldots, n$. We obtain a commutative diagram

$$
(\Delta_n \times \partial \Delta_1) \cup (\Delta_n^0 \times \Delta_1) \xrightarrow{c'} X \\
\Delta_n \times \Delta_1 \xrightarrow{h} Y
$$

where $c'$ is the unique morphism whose restriction to $\Delta_n \times \Delta^0$ (resp. to $\Delta_n \times \Delta_1$) agrees with $b$ (resp. with $b'$) and whose restriction to $\Delta^0_n \times \Delta_1$ is the unique morphism that factors through $\xi : \Delta^0_n \to X$. Since $p$ is a fibration, we may then find a morphism $h' : \Delta_n \times \Delta_1 \to X$ which extends $c'$, and such that $p \circ h' = h$ (corollary 7.5.28). Set $h'' := h' \circ (\varepsilon_0 \times 1_{\Delta_1}) : \Delta_{n-1} \times \Delta_1 \to X$. It is easily seen that $h''$ is a homotopy from $\partial_0 b$ to $\partial_0 b'$ relative $\partial \Delta_{n-1}$, whence the lemma.

7.5.55. Keep the situation of (7.5.53); it follows from lemma 7.5.4 that the rule $[a] \mapsto [\partial_0 b]$ yields a well defined map

$$
\delta_n : \pi_n(Y, \xi') \to \pi_{n-1}(F, \xi) \quad \text{for every } n > 0
$$

and it is easily seen that $\delta_n[\xi] = [\xi']$, i.e. $\delta_n$ is a map of pointed sets. Let also $i : F \to X$ be the natural monomorphism; there follows, for every $n \in \mathbb{N}$, a natural sequence of pointed sets

$$
\pi_{n+1}(X, \xi') \xrightarrow{\pi_{n+1}(p, \xi)} \pi_{n+1}(Y, \xi') \xrightarrow{\delta_{n+1}} \pi_n(F, \xi) \xrightarrow{\pi_n(i, \xi)} \pi_n(X, \xi) \xrightarrow{\pi_n(p, \xi)} \pi_n(Y, \xi')
$$

called the homotopy sequence in degree $n$ attached to the fibration $p$ (and the vertex $\xi$). Let $1$ denote the monoid with one element (the initial object in the category of monoids); noticed that the category $\text{Set}_o$ can also be regarded naturally as the category of pointed (left) $1$-modules (see 4.8.13), and therefore the homotopy sequence in every degree is naturally a sequence of pointed $1$-modules.

**Theorem 7.5.56.** With the notation of (7.5.55), the following holds:

(i) The homotopy sequence attached to $p$ is exact in every degree $n \in \mathbb{N}$, i.e. we have

$$
\text{Im } \pi_{n+1}(p, \xi) = \ker \delta_{n+1} \quad \text{Im } \delta_{n+1} = \ker \pi_n(i, \xi) \quad \text{Im } \pi_n(i, \xi) = \ker \pi_n(p, \xi).
$$

(ii) $\delta_n$ is a group homomorphism for every $n > 1$.

**Proof.** (See remark 4.8.17(iii) for the notion of kernel of a morphism of pointed 1-modules.)

(ii): Let $a_{n-1}, a_n, a_{n+1} \in Y(\xi', n)$ be three elements, $b_{n-1}, b_n, b_{n+1} \in X[n]$ and $\varphi \in Y[n+1]$ four simplices such that

- $p(b_i) = a_i$ and $\partial_i b_i = \xi$ for every $i = n - 1, n, n + 1$ and $j = 1, \ldots, n$
- $\partial_i \varphi = \xi'$ for $i = 0, \ldots, n - 2$ and $\partial_i \varphi = a_i$ for $i = n - 1, n, n + 1$.

We deduce a commutative diagram

$$
\begin{array}{ccc}
\Lambda^0_{n+1} & \xrightarrow{c} & X \\
\downarrow & & \downarrow p \\
\Delta^0_{n+1} & \xrightarrow{\varphi} & Y
\end{array}
$$

where $c$ is the unique morphism whose restriction to the $i$-th face of $\Lambda^0_{n+1}$ factors through $\xi$ if $i = 1, \ldots, n - 2$, and equals $b_i$ for $i = n - 1, n, n + 1$. Since $p$ is a fibration, we may then find $\psi : \Delta^0_{n+1} \to X$ whose restriction to $\Lambda^0_{n+1}$ agrees with $c$, and such that $p \circ \psi = \varphi$. Set $t := \partial_0 \psi \in X[n]$; then $p[n](t) = \partial_0(p[n+1](\psi)) = \partial_0 \varphi = \xi$, so that $t \in F[n]$. Moreover,
\[ \partial_t = \partial_0 \partial_{i+1} \psi \] for every \( i = 0, \ldots, n \), hence \( \partial_t = \xi \) for \( i < n - 2 \) and \( \partial_t = \partial_0 \partial_{i+1} \) for \( i = n - 2, n - 1, n \). This means that
\[ [\partial_0 b_n] = [\partial_0 b_{n-1}] \cdot [\partial_0 b_{n+1}] \quad \text{in} \quad \pi_{n-1}(F, \xi) \]
and on the other hand we have \([a_n] = [a_{n-1}] \cdot [a_{n+1}]\) in \( \pi_n(Y, \xi') \), whence the assertion.

(i): The inclusion \( \text{Im} \, \{i, \xi\} \subset \text{Ker} \, \{p, \xi\} \) is immediate, and the identity \( \text{Im} \, \{p, \xi\} = \text{Ker} \, \{p, \xi\} \) follows easily from lemma \[ \text{7.5.46} \], by inspection of the definition of \( \delta_{n+1} \). The inclusion \( \text{Im} \, \{p, \xi\} \subset \text{Ker} \, \delta_{n+1} \) is likewise immediate, from the definition of \( \delta_{n+1} \) (details left to the reader).

- Next, let us show that \( \text{Ker} \, \delta_{n+1} \subset \text{Im} \, \{p, \xi\} \). Indeed, let \( a \in Y(\xi', n + 1) \), pick \( b \in X[n + 1] \) such that \( p[n + 1](b) = a \) and \( \partial_i b = \xi \) for every \( i = 1, \ldots, n + 1 \), and suppose that \( \partial_0 b \sim_{\partial \Delta_n} \xi \). Let \( h : \Delta_n \times \Delta_1 \to F \) be a homotopy from \( \partial_0 b \) to \( \xi \) relative to \( \partial \Delta_n \). Then we get a unique morphism
\[ t : (\Delta_{n+1} \times \Delta_1^1) \cup (\partial \Delta_{n+1} \times \Delta_1^0) \to X \]
whose restriction to \( \Delta_{n+1} \times \Delta_1^1 \) agrees with \( b \), whose restriction to \( \Lambda_{n+1}^0 \times \Delta_1^1 \) factors through \( \xi \), and whose restriction to \((\text{Im} \, \{\varepsilon_0\}) \times \Delta_1^1 \subset \partial \Delta_{n+1} \times \Delta_1^1 \) agrees with \( h \). Since \( X \) is fibrant, \( t \) extends to a morphism \( t' : \Delta_{n+1} \times \Delta_1 \to X \), and we denote by \( x \in X[n + 1] \) the restriction of \( t' \) to \( \Delta_{n+1} \times \Delta_1^0 \). Then it is easily seen that \( x \in X(\xi, n + 1) \), and \( p \circ t' \) is a homotopy relative to \( \partial \Delta_n \) from \( a \) to \( p(x) \), whence the assertion.

- Lastly, let \( b \in X(\xi, n) \) be any simplex such that \([p(b)] = [\xi'] \in \pi_n(Y, \xi')\), and pick any homotopy \( h : \Delta_n \times \Delta_1 \to Y \) from \([p(b)] \) to \([\xi'] \) relative to \( \partial \Delta_n \). We get a commutative diagram
\[ \begin{array}{ccc}
(\Delta_n \times \Lambda_1^0) \cup (\partial \Delta_n \times \Delta_1) & \xrightarrow{\varphi} & X \\
\downarrow & & \downarrow p \\
\Delta_n \times \Delta_1 & \xrightarrow{h} & Y
\end{array} \]
where \( \varphi \) is the unique morphism whose restriction to \( \partial \Delta_n \times \Delta_1 \) factors through \( \xi \), and whose restriction to \( \Delta_n \times \Lambda_1^0 \) agrees with \( b \). Since \( p \) is a fibration, we may then find a morphism \( h' : \Delta_n \times \Delta_1 \to X \) extending \( \varphi \) and such that \( p \circ h' = h \). Set \( b' := h' \circ (1_{\Delta_n} \times \varepsilon_1) \), so that \( h' \) is a homotopy from \( b \) to \( b' \) relative to \( \partial \Delta_n \); however, notice that \( p(b') = \xi' \), so \( b' \in F(\xi, n) \), therefore \([b] \in \pi_n(i, \xi)\), which concludes the proof of the theorem.

7.5.57. The following device shall be useful for explaining the functorial behaviour of the homotopy groups under change of base points. Let \( A \) be any fibrant simplicial set; we set
\[ \pi(A) := A[1]/\sim_{\partial \Delta_1} \]
Given \( a \in A[1] \), we denote by \([a] \in \pi(A)\) the class of \( a \). Evidently, the vertices \( \partial_i a \in A[0] \) \((i = 0, 1)\) depend only on \([a] \), so we shall also denote them by \( \partial_i[a] \). We use the notation
\[ [a] : x \to y \]
to signal that \( x = \partial_0[a] \) and \( y = \partial_1[a] \). If \([b] : y \to z\) is another class, we define a composition \([b] \circ [a] : x \to z\) as follows. Let \( \varphi : \Lambda_2^1 \to A \) be the unique morphism such that \( \varphi \circ \varepsilon_0 = a \) and \( \varphi \circ \varepsilon_2 = b \); since \( A \) is fibrant, \( \varphi \) extends to a morphism \( c : \Delta_2 \to A \), and we let
\[ [b] \circ [a] := [\partial_1 c] \]
In order to show that this rule is well defined, suppose that \( a', b' \in A[1] \) and \( c' \in A[2] \) are any three other simplices such that \([a] = [a']\), \([b] = [b']\), \( \partial_0 c' = a' \) and \( \partial_2 c' = b' \). Pick a homotopy \( h \) (resp. \( h' \)) from \( a \) to \( a' \) (resp. from \( b \) to \( b' \)) relative to \( \partial \Delta_1 \); there follows a morphism
\[ t : (\Delta_2 \times \partial \Delta_1) \cup (\Lambda_2^1 \times \Delta_1) \to A \]
whose restriction to $\Delta_2 \times \Lambda^0_1$ (resp. to $\Delta_2 \times \Lambda^1_1$) agrees with $c$ (resp. with $c'$) and whose restriction to $(\text{Im } \varepsilon_0) \times \Delta_1$ (resp. to $(\text{Im } \varepsilon_2) \times \Delta_1$) agrees with $h$ (resp. with $h'$). Since $A$ is fibrant, $t$ extends to a morphism $\Delta_2 \times \Delta_1 \to A$, whose restriction to $(\text{Im } \varepsilon_1) \times \Delta_1$ is a homotopy from $\partial_1 c$ to $\partial_1 c'$ relative to $\partial \Delta_1$, whence the claim. Moreover, we claim that this composition law is associative: indeed, the proof is the same as that of the associativity of the group law on $\pi_1(A, \xi)$ (details left to the reader). Furthermore, for every vertex $x \in A[0]$, let $1_x : \Delta_1 \to A$ be the unique morphism which factors through $x$; then $[a] \circ [1_x] = [a]$ for every $y \in A[0]$ and every $[a] : x \to y$, since

$$\partial_0(a \circ \eta_1) = 1_x \quad \partial_1(a \circ \eta_1) = a \quad \partial_2(a \circ \eta_1) = a.$$ 

Likewise, we see that $[1_x] \circ [b] = [b]$ for every $[b] : y \to x, \varepsilon_1$ by considering $\partial(b \circ \eta_0) = b$ (details left to the reader). Lastly, for any $[a] : x \to y$ consider the unique morphism $t : \Lambda^0_2 \to A$ such that $t \circ \varepsilon_1 = 1_x$ and $t \circ \varepsilon_0 = a$; since $A$ is fibrant, $t$ extends to a morphism $c : \Delta_2 \to A$, and it follows that $[\partial_2 c] \circ [a] = 1_x$. Similarly, we see easily that $[a]$ admits a right inverse. We conclude that the datum

$$\pi(A) := (A[0], \pi(A), \circ)$$ 

is a groupoid, i.e. a category all whose morphisms are isomorphisms. It shall be called the fundamental groupoid of $A$.

**Remark 7.5.58.** Let $f : X \to Y$ be any morphism of fibrant simplicial sets. A simple inspection of the definitions shows that $f$ induces a functor

$$\overline{\pi}(f) : \overline{\pi}(X) \to \overline{\pi}(Y).$$

Explicitly, $\overline{\pi}(f)$ is the functor whose map on objects $X[0] \to Y[0]$ is given by $f[0]$, and whose map on morphisms is induced by $f[1]$. It is then clear that the rule $f \mapsto \overline{\pi}(f)$ defines a functor

$$\overline{\pi} : s.\text{Set} \to \text{Gpd}$$

with values in the full subcategory of $\text{Cat}$ whose objects are all (small) groupoids.

**7.5.59.** Now, let $n \in \mathbb{N}$ be any integer, $x \in A[0]$ any vertex, $b : \Delta_n \to A$ any element of $A(x, n)$, and $[\alpha] : x \to y$ any element of $\pi(A)$. We have a unique morphism

$$t : (\partial \Delta_n \times \Delta_1) \cup (\Delta_n \times \Lambda^1_1) \to A$$

such that:

- the restriction of $t$ to $\partial \Delta_n \times \Delta_1$ equals $\alpha \circ p$, where $p : \partial \Delta_n \times \Delta_1 \to \Delta_1$ is the natural projection
- the restriction of $t$ to $\Delta_n \times \Lambda^1_1$ agrees with $b$.

Since $A$ is fibrant, $t$ extends to a morphism $h : \Delta_n \times \Delta_1 \to A$, and we denote by $\partial_1 h \in A[n]$ the restriction of $h$ to $\Delta_n \times \Lambda^1_1$. Notice that $\partial_1 h \in A(y, n)$.

**Lemma 7.5.60.** With the notation of (7.5.59), the class $[\partial_1 h] \in \pi_n(A, y)$ depends only on $[\alpha]$ and $[b] \in \pi_n(A, x)$ (and is independent of $h$ and of the representatives $\alpha$ and $b$ for these classes).

**Proof.** Say that $[\beta] = [\alpha]$ in $\pi(A)$, so we have a homotopy $\gamma : \Delta_1 \times \Delta_1 \to A$ from $\alpha$ to $\beta$ relative to $\partial \Delta_1$. Suppose also that $[b] = [b']$ in $\pi_n(A, x)$, and let $H : \Delta_n \times \Delta_1 \to A$ be a given homotopy from $b$ to $b'$ relative to $\partial \Delta_n$. Pick also a morphism $h' : \Delta_n \times \Delta_1 \to A$ whose restriction to $\partial \Delta_n \times \Delta_1$ (resp. to $\Delta_n \times \Lambda^1_1$) equals $\beta \circ p$ (resp. $b'$). To ease notation, set

$$K := (\Lambda^1_1 \times \Delta_1) \cup (\Delta_1 \times \partial \Delta_1) \quad \text{and} \quad L := \Delta_1 \times \Delta_1$$

and notice that the monomorphism $K \to L$ is anodyne. We then have a unique morphism $u : (\partial \Delta_n \times L) \cup (\Delta_n \times K) \to A$ such that
the restriction of \( u \) to \( \partial \Delta_n \times L \) equals \( q \circ \gamma \), where \( q : \partial \Delta_n \times L \to L \) is the natural projection

- the restriction of \( u \) to \( \Delta_n \times (\Lambda_1^1 \times \Delta_1) \) equals \( H \)

- the restriction of \( u \) to \( \Delta_n \times (\Lambda_1^1 \times \Delta_1) \) (resp. to \( \Delta_n \times (\Lambda_0^1 \times \Delta_1) \)) equals \( h \) (resp. \( h' \)).

By corollary \[7.5.28\] the morphism \( u \) extends to a morphism \( u'' : \Delta_n \times L \to A \), and it is easily seen that the restriction of \( h'' \) to \( \Delta_n \times (\Lambda_1^0 \times \Delta_1) \) is a homotopy from \( \partial_1 h \) to \( \partial_1 h' \) relative to \( \partial \Delta_n \), whence the assertion. \( \square \)

### Proposition 7.5.62

With the notation of \((7.5.61)\), the following holds for every \( n > 0 \):

1. \( \pi_n(A, [\alpha]) \) is a group homomorphism, and \( \pi_n(A, [1_x]) = 1_{\pi_n(A, x)} \) for every \( x \in A[0] \).
2. If \( [\beta] : y \to z \) is any other element of \( \pi(A) \), we have

\[
\pi_n(A, [\beta]) \circ \pi_n(A, [\alpha]) = \pi_n(A, [\beta] \circ [\alpha]).
\]

3. Therefore, the rule

\[
x \mapsto \pi_n(A, x) \quad [\alpha] \mapsto \pi_n(A, [\alpha])
\]

for every \( x \in A[0] \) and every \( [\alpha] \in \pi(A) \)

yields a well defined functor

\[
\pi_n : \pi(A) \to \text{Grp}.
\]

**Proof.**

(i): Let \( b, b' \in A(x, n) \) be any two elements, and pick a morphism \( c : \Delta_{n+1} \to A \) such that \( \partial_i c = x \) for \( i = 0, \ldots, n-2, \partial_{n-1} c = b \) and \( \partial_{n+1} c = b' \). Let also \( [\alpha] : x \to y \) be any element of \( \pi(A) \), and choose morphisms \( h, h' : \Delta_n \times \Delta_1 \to A \) whose restrictions to \( \partial \Delta_n \times \Delta_1 \) equal \( p \circ \alpha \) (where \( p \) is as in \((7.5.59)\)) and whose restrictions to \( \Delta_n \times \Lambda_1^1 \) agree with \( b \) and respectively \( b' \). Then there exists a unique morphism \( T : (\partial \Delta_{n+1} \times \Delta_1) \cup (\Delta_{n+1} \times \Lambda_1^1) \to A \) such that

- for \( i = 0, \ldots, n-2 \), the restriction of \( T \) to \((\text{Im} \varepsilon_i) \times \Delta_1 \) equals \( p' \circ \alpha \), where \( p' : (\text{Im} \varepsilon_i) \times \Delta_1 \to \Delta_1 \) is the projection
- the restriction of \( T \) to \((\text{Im} \varepsilon_{n-1}) \times \Delta_1 \) (resp. to \((\text{Im} \varepsilon_{n-1}) \times \Delta_1 \)) agrees with \( h \) (resp. with \( h' \))
- the restriction of \( T \) to \( \Delta_{n+1} \times \Lambda_1^1 \) agrees with \( c \).

Since \( A \) is fibrant, \( T \) extends to a morphism \( H : \Delta_{n+1} \times \Delta_1 \to A \), and we denote by \( U : \Delta_n \times \Delta_1 \to A \) the restriction of \( H \) to \((\text{Im} \varepsilon_n) \times \Delta_1 \). By inspecting the definition, it is easily seen that \( \partial_1 U \) is a representative for both \( \pi_n(A, [\alpha])((b) \cdot [b']) \) and \( \pi_n(A, [\alpha])((b)) \cdot \pi_n(A, [\alpha])((b')) \), so \( (\pi_n(A, [\alpha]))((b')) \) is a group homomorphism. A simple inspection shows that \( \pi_n(A, [1_x]) \) is the identity map of \( \pi_n(A, x) \).

(ii): Pick any morphism \( \varphi : \Delta_2 \to A \) such that \( \partial_0 \varphi = \alpha \) and \( \partial_2 \varphi = \beta \). Let also \( b \) and \( h \) as in \((7.5.59)\), and choose similarly a morphism \( h' : \Delta_n \times \Delta_1 \to A \) whose restriction to \( \Delta_n \times \Lambda_1^1 \) equals \( \partial_1 h \), and whose restriction to \( \partial \Delta_n \times \Delta_1 \) equals \( p \circ \beta \). Then there exists a unique morphism \( u : (\partial \Delta_n \times \Delta_2) \cup (\Delta_n \times \Lambda_1^2) \to A \) such that

- the restriction of \( u \) to \( \partial \Delta_n \times \Delta_2 \) equals \( q \circ \varphi \), where \( q : \partial \Delta_n \times \Delta_2 \to \Delta_2 \) is the projection
- the restriction of \( u \) to \( \Delta_n \times (\text{Im} \varepsilon_0) \) (resp. to \( \Delta_n \times (\text{Im} \varepsilon_2) \)) equals \( h \) (resp. \( h' \)).
Since $A$ is fibrant, $u$ extends to a morphism $w : \Delta_n \times \Delta_2 \to A$, and we denote by $w_1 : \Delta_n \times \Delta_1 \to A$ the restriction of $w$ to $\Delta_n \times (\text{Im} \varepsilon_1)$. Hence, the restriction of $w_1$ to $\partial \Delta_n \times \Delta_1$ equals $p \circ (\partial_1 \varphi)$, and its restriction $\partial_1 w_1$ to $\Delta_n \times \Lambda^0_1$ (resp. to $\Delta_n \times \Lambda^1_1$) equals $b$ (resp. $\partial_1 h'$).

Unwinding the definitions, we find that

$$\pi_n(A, [\beta]) \circ \pi_n(A, [\alpha])([b]) = \pi_n(A, [\beta])([\partial_1 h])$$

$$= [\partial_1 w_1]$$

$$= \pi_n(A, [\partial_1 \varphi])([b])$$

$$= \pi_n(A, [\beta \circ [\alpha]])([b])$$

whence the contention. Of course, (iii) results by combining (i) and (ii). \hfill \Box

**Remark 7.5.63.** Let $f : X \to Y$ be any morphism of fibrant simplicial sets, $[\alpha] : x \to x'$ a morphism in $\pi(X)$, and set $y := f[0](x), y' := f[0](y')$ and $\beta := f[1](\alpha)$, so that $[\beta] = \pi(f)[\alpha]$ in $\pi(Y)$ (notation of remark 7.5.58). A direct inspection shows that the resulting diagram

$$\begin{array}{ccc}
\pi_n(X, x) & \xrightarrow{\pi_n(X, [\alpha])} & \pi_n(X, x') \\
\pi_n(f, x) \downarrow & & \downarrow \pi_n(f, x') \\
\pi_n(Y, y) & \xrightarrow{\pi_n(Y, [\beta])} & \pi_n(Y, y')
\end{array}$$

commutes (details left to the reader).

**Definition 7.5.64.** Consider any commutative diagram of simplicial sets:

$$\begin{array}{ccc}
X' & \xrightarrow{f} & X \\
p' \downarrow & & \downarrow p \\
Y. & \xleftarrow{g} & \ \\
p' & & p
\end{array}$$

(i) A \textit{p-fibrewise homotopy from $f$ to $g$} is a homotopy $h$ from $f$ to $g$ such that $p \circ h$ is a constant homotopy (see remark [7.5.38]).

(ii) Let also $K \subset X'$ be any simplicial subset. A \textit{p-fibrewise homotopy from $f$ to $g$ relative to $K$} is a p-fibrewise homotopy from $f$ to $g$ which is also a homotopy relative to $K$ (see definition [7.5.37]). We write

$$f \overset{p}{\sim} g \quad \text{(resp. $f \overset{p}{\sim}_K g$)}$$

if there exists a p-fibrewise homotopy from $f$ to $g$ (resp. relative to $K$).

(iii) Recall that, for every $n \in \mathbb{N}$, we may regard any $x \in X[n]$ as a morphism $x : \Delta_n \to X$. Then, we say that $p$ is a \textit{minimal fibration}, if $p$ is a fibration, and

$$a = b \iff a \overset{p}{\sim}_{\partial \Delta_n} b$$

for every $n \in \mathbb{N}$ and every $a, b \in X[n]$ such that $p[n](a) = p[n](b)$.

(iv) A \textit{strong deformation retract} of $p$ is a datum $(i, r, h)$ consisting of a monomorphism $i : X' \to X$, an epimorphism $r : X \to X'$ such that

$$p \circ i \circ r = p \quad \text{and} \quad r \circ i = 1_X,$$

and a p-fibrewise homotopy $h : X \times \Delta_1 \to X$ from $1_X$ to $i \circ r$ relative to $X'$.

(v) We say that $f$ is a \textit{fibrewise homotopy equivalence from $f'$ to $p$}, if there exists a morphism of simplicial sets $f' : X \to X'$ with

$$p' \circ f' = p \quad f' \circ f \overset{p'}{\sim} 1_{X'} \quad f \circ f' \overset{p}{\sim} 1_{X}.$$
(vi) For any simplicial set $A$, let $p_A : A \to \Delta_0$ be the unique morphism of simplicial sets. If $A$ is fibrant, we say that $A$ is minimal, if $p_A$ is a minimal fibration. We say that a morphism of simplicial sets $f : A \to A'$ is a homotopy equivalence, if $f$ is a fibrewise homotopy equivalence from $p_A$ to $p_{A'}$. We say that a monomorphism $i : A' \to A$ is a strong deformation retract of $A$, if there exist a morphism $r : A \to A'$ and a homotopy $h$ from $1_A$ to $i \circ r$, such that $(i, r, h)$ is a strong deformation retract of $p_A$.

Remark 7.5.65. (i) By inspecting the definitions, it is easily seen that a composition of fibrewise homotopy equivalences is a fibrewise homotopy equivalence. Especially, a composition of homotopy equivalences is a homotopy equivalence.

(ii) Let $(i, r, h)$ be any strong deformation retract; then, clearly, both $i$ and $r$ are fibrewise homotopy equivalences.

Lemma 7.5.66. Let $p : X \to Y$ be any fibration, $p' : X' \to Y$ any object of $s\text{-}\text{Set}/Y$, and $i : K \to X'$ any monomorphism. Then:

(i) $\sim_K$ is an equivalence relation on $\text{Hom}_{s\text{-}\text{Set}/Y}(p', p)$.

(ii) More precisely, let $f, f', f'' \in \text{Hom}_{s\text{-}\text{Set}/Y}(p', p)$ be any three elements such that

$$f \sim_K f' \sim_K f''$$

and $h$ a $p$-fibrewise homotopy from $f$ to $f'$. Then there exists a $p$-fibrewise homotopy $h'$ from $f$ to $f''$ such that

$$h' \circ (i \times 1_{\Delta_1}) = h \circ (i \times 1_{\Delta_1}).$$

(iii) Let $f, f'$ be as in (ii), and suppose that $f$ is a fibrewise homotopy equivalence. Then the same holds for $f'$.

Proof. (i): It is a relative variant of the proof of theorem 7.5.42. Namely, consider first the case of $\sim_K$; on the one hand, by proposition 7.5.34, the morphism

$$t : s\text{Hom}(X', X) \to P := s\text{Hom}(X', Y) \times_{s\text{Hom}(K,Y)} s\text{Hom}(K, X)$$

induced by $p$ and $i$ is a fibration. On the other hand, let $f, f' \in \text{Hom}_{s\text{-}\text{Set}/Y}(p', p)$ be any two elements; the datum of a homotopy $h$ from $f$ to $f'$ relative to $K$ is the same as that of a morphism

$$h^* : \Delta_1 \to s\text{Hom}(X', X)$$

such that $s\text{Hom}(i, X) \circ h^*$ factors through a morphism $a : \Delta_0 \to s\text{Hom}(K, X)$ and the unique morphism $\pi : \Delta_1 \to \Delta_0$. Then, $h$ is a $p$-fibrewise homotopy if and only if

$$s\text{Hom}(K, p) \circ a = s\text{Hom}(i, Y) \circ b$$

$$s\text{Hom}(X', p) \circ h^* = b \circ \pi$$

for the unique morphism $b : \Delta_0 \to s\text{Hom}(X', Y)$ corresponding to $p'$. Now, the pair $(a, b)$ determines a unique morphism $(a, b) : \Delta_0 \to P$, and the foregoing conditions tell us that $t \circ h^* = (a, b) \circ \pi$. Thus, set $Q := t^{-1}(a, b)$ (notation of example 7.5.2(vi)); by lemma 7.5.15(iv), the simplicial set $Q$ is fibrant, and we have a natural bijection

$$Q[0] \iso \{ f \in \text{Hom}_{s\text{-}\text{Set}/Y}(p', p) \mid f \circ i = a \}$$

which identifies the restriction of the relation $\sim_K$ with the relation $\sim$ on $Q[0]$. The latter is an equivalence relation, by lemma 7.5.40, whence the contention.

(ii): Let again $b : \Delta_0 \to s\text{Hom}(X', Y)$ be the morphism corresponding to $p'$, and set

$$P_b := q^{-1}(b) \quad Q_b := P_b \times_p s\text{Hom}(X', X)$$

where $q : P \to s\text{Hom}(X', Y)$ is the natural projection. So, the morphism $t$ restricts to a fibration $t_b : Q_b \to P_b$. By assumption, $f'$ and $f''$ can be regarded as morphisms $\Delta_0 \to
s.\text{Hom}(X', X)$ such that $a := s.\text{Hom}(i, X) \circ f' = s.\text{Hom}(i, X) \circ f''$, and there exists a morphism $g : \Delta_1 \to s.\text{Hom}(X', X)$ such that $s.\text{Hom}(i, X) \circ g$ factors through $a$ and $s.\text{Hom}(X', p) \circ g$ factors through $b$, and moreover $g \circ \varepsilon_1 = f'$, $g \circ \varepsilon_0 = f''$. Likewise, the homotopy $h$ can be regarded as a morphism $\Delta_1 \to s.\text{Hom}(X', X)$ such that $s.\text{Hom}(X', p) \circ h$ factors through $b$, and moreover $h \circ \varepsilon_1 = f$, $h \circ \varepsilon_0 = f'$. The pair $(h, g)$ then amounts to a morphism $(h, g) : \Lambda_2 \to Q_b$ fitting into a commutative diagram

\[
\begin{array}{ccc}
\Lambda_2 & \xrightarrow{(h, g)} & Q_b \\
\downarrow{} & & \downarrow{\iota_2} \\
\Delta_2 & \xrightarrow{\eta_0} & \Delta_1 \\
\end{array}
\]

(namely, $(h, g)$ is the unique morphism such that $(h, g) \circ \varepsilon_0 = h$ and $(h, g) \circ \varepsilon_2 = g$). Thus, $(h, g)$ extends to a morphism $u : \Delta_2 \to Q_b$ such that $t_0 \circ u$ factors as well through $\eta_0$; it is easily seen that the morphism $u \circ \varepsilon_1$ yields the sought homotopy $h'$.

(iii): By assumption, there exists a morphism $g : X \to X'$ of $s.\text{Set}/Y$ such that $g \circ f \sim 1_X$, and $f \circ g \sim 1_X$. On the other hand, since $f \sim f'$, remark 7.5.38(ii) implies that $g \circ f' \sim g \circ f'$ and $f \circ g \sim f' \circ g$. Then the assertion follows from (i).

7.5.67. Consider a fibration $p : X \to Y$ of simplicial sets, and two morphisms $f_0, f_1 : A \to Y$, and for $i = 0, 1$ define the simplicial set $X_i$ as the fibre product in the cartesian diagram

\[
\begin{array}{ccc}
X_i & \xrightarrow{p_i} & X \\
p_i & & \downarrow{p} \\
A & \xrightarrow{f_i} & Y \\
\end{array}
\]

**Proposition 7.5.68.** In the situation of (7.5.67), suppose that $f_0 \sim f_1$ (notation of (7.5.41)). Then there exists a fibrewise homotopy equivalence from $p_0$ to $p_1$.

**Proof.** Let $h : A \times \Delta_1 \to Y$ be a homotopy from $f_0$ to $f_1$, and define the simplicial set $H$ as the fibre product in the resulting diagram whose two square subdiagrams are cartesian

\[
\begin{array}{ccc}
X_i & \xrightarrow{j_i} & H \\
p_i & & \downarrow{p_H} \\
A & \xrightarrow{h} & Y \\
\end{array}
\]

for $i = 0, 1$.

Then, $p_H$ is a fibration (lemma 7.5.15(iv)), hence there exist commutative diagrams

\[
\begin{array}{ccc}
X_i \times \Delta_1 & \xrightarrow{p_i \times \Delta_1} & A \times \Delta_1 \\
\downarrow{\delta_i} & & \downarrow{h} \\
X_i \times \Delta_1 & & \xrightarrow{\theta_i} H \\
\end{array}
\]

(proposition 7.5.24) whence two commutative diagrams with cartesian square subdiagrams

\[
\begin{array}{ccc}
X_i \times \Delta_1 & \xrightarrow{p_i \times \Delta_1} & A \times \Delta_1 \\
\downarrow{\omega_i} & & \downarrow{\theta_i} \\
X_i \times \Delta_1 & & \xrightarrow{\theta_i} H \\
\end{array}
\]

for $i = 0, 1$. 

\[
\begin{array}{ccc}
X_i \times \Delta_1 & \xrightarrow{p_i \times \Delta_1} & A \times \Delta_1 \\
\downarrow{\varepsilon_{i-1}} & & \downarrow{\theta_i} \\
X_i \times \Delta_1 & & \xrightarrow{\theta_i} H \\
\end{array}
\]
Notice now that
\[ \vartheta_0 \circ (X_0 \times \varepsilon_1) = j_1 \circ \omega_0 = \vartheta_1 \circ (X_1 \times \varepsilon_1) \circ \omega_0 = \vartheta_1 \circ (\omega_0 \times \Delta_1) \circ (X_0 \times \varepsilon_1) \]
from which we deduce that there exists a commutative diagram
\[
\begin{array}{ccc}
X_0 \times A_0^1 & \xrightarrow{\beta} & H \\
\downarrow \gamma & & \downarrow \rho H \\
X_0 \times \Delta_2 & \xrightarrow{p \circ \eta_1} & A \times \Delta_1
\end{array}
\]
where \( \beta \) is the unique morphism such that
\[ \beta \circ (X_0 \times \varepsilon_1) = \vartheta_0 \quad \text{and} \quad \beta \circ (X_0 \times \varepsilon_2) = \vartheta_1 \circ (\omega_0 \times \Delta_1). \]
Set \( \gamma_0 := \gamma \circ (X_0 \times \varepsilon_0) : X_0 \times \Delta_1 \to H \), and notice that \( \eta_1 \circ \varepsilon_0 : \Delta_1 \to \Delta_1 \) factors through \( \varepsilon_0 : \Delta_0 \to \Delta_1 \); it follows that \( \gamma_0 \) factors through \( j_0 : X_0 \to H \) and a morphism \( \gamma_0 \circ X_0 \times \Delta_1 \to X_0 \). Lastly, notice that
\[
\begin{align*}
\vartheta_0 \circ (X_0 \times \varepsilon_0) &= j_0 \circ (X_0 \times \varepsilon_0) = j_0 \\
\vartheta_0 \circ (X_0 \times \varepsilon_1) &= \vartheta_1 \circ (\omega_0 \times \Delta_1) \circ (X_0 \times \Delta_0) = \vartheta_1 \circ (X_1 \times \varepsilon_0) \circ \omega_0 = j_0 \circ \omega_1 \circ \omega_0
\end{align*}
\]
whence \( \gamma_0 \circ (X_0 \times \varepsilon_0) = 1_{X_0} \) and \( \gamma_0 \circ (X_0 \times \varepsilon_1) = \omega_1 \circ \omega_0 \), so \( \gamma_0 \) is a homotopy from \( 1_{X_0} \) to \( \omega_1 \circ \omega_0 \). A similar construction yields likewise a homotopy from \( 1_{X_1} \) to \( \omega_0 \circ \omega_1 \), whence the proposition (details left to the reader).

**Proposition 7.5.69.** Every fibration \( p : X \to Y \) admits a strong deformation retract \( (j, r, h) \) such that \( p \circ j \) is a minimal fibration.

**Proof.** For every \( k, n \in \mathbb{N} \) with \( n \geq k \), denote by
\[
Sk_k X \xrightarrow{\varepsilon_{X}^{(k,n)}} Sk_n X \xrightarrow{\eta_{X}^{(n)}} X
\]
the inclusion maps (notation of remark 7.5.6(v)) and set \( p^{(n)} := p \circ \eta_{X}^{(n)} \) for every \( n \in \mathbb{N} \).

**Claim 7.5.70.** For every \( n \in \mathbb{N} \) there exist morphisms
\[
\begin{align*}
\varepsilon^{(n)} : Z^{(n)} &\to Sk_n X \\
r^{(n)} : Sk_n X &\to Z^{(n)} \\
h^{(n)} : Sk_n X \times \Delta_1 &\to X
\end{align*}
\]
such that :
\begin{enumerate}
\item \( p^{(n)} \circ \varepsilon^{(n)} = 1_{Z^{(n)}} \) and \( p^{(n)} \circ \varepsilon^{(n)} \circ r^{(n)} = p^{(n)} \).
\item \( h^{(n)} \) is a homotopy from \( \eta_{X}^{(n)} \) to \( \eta_{X}^{(n)} \circ \varepsilon^{(n)} \circ r^{(n)} \).
\item Both \( p \circ h^{(n)} \) and the restriction \( h_{X}^{(k)} : Z^{(n)} \times \Delta_1 \to X \) of \( h^{(n)} \) are constant homotopies.
\item \( \varepsilon^{(k,n)} \) restricts to a morphism \( e^{(k,n)} : Z(k) \to Z^{(n)} \) for every \( k \leq n \).
\item \( s.t trunc_k e^{(k,n)} : s.t trunc_k Z^{(n)} \to s.t trunc_k Z(k) \) is an isomorphism, and \( s.t trunc_k h^{(n)} = s.t trunc_k h^{(k)} \) for every \( k \leq n \).
\item The induced map \( Z^{(n)}[n] \to X[n] / \mathcal{P}_{\partial \Delta_n} \) is injective.
\end{enumerate}

**Proof of the claim.** We construct inductively the sought simplicial sets and morphisms, as follows. First, set \( Z^{(-1)} := s.\partial \). Next, let \( n \in \mathbb{N} \) be any integer such that either \( n = 0 \) or else \( Z^{(n-1)} \subseteq Sk_{n-1} X \), \( r^{(n-1)} \) and \( h^{(n-1)} \) have already been defined. Since \( Z^{(n-1)}[n] \) consists entirely of degenerate simplices (see remark 7.5.6(iv)), lemma 7.5.7(i) implies that the natural projection \( Z^{(n-1)}[n] \to X[n] / \mathcal{P}_{\partial \Delta_n} \) is injective.

Now, for \( n = 0 \), set \( C_0 := X[0] / \mathcal{P}_{\partial \Delta_n} \), and if \( n > 0 \), let \( C_n \subseteq X[n] / \mathcal{P}_{\partial \Delta_n} \) be the subset of all equivalence classes of elements \( x \in X[n] \) such that \( \partial_i x \in Z^{(n-1)}[n-1] \) for every \( i = 0, \ldots, n \) (notice that \( \partial_i x \) depends only on the class of \( x \) in \( X[n] / \mathcal{P}_{\partial \Delta_n} \)). Pick a
representative $x \in X[n]$ for every equivalence class $\equiv \in C_n$ that does not lie in the image of $Z(n^{-1})[n]$, and let $R_n \subset X[n]$ be the subset of all such chosen representatives; we denote by $T(n) \subset s.\text{trunc}_nX$ the $n$-truncated simplicial set such that

$$T(n)[n] = Z(n^{-1})[n] \cup R_n \quad \text{and} \quad T(n)[k] = Z(n^{-1})[k] \quad \text{for every } k < n.$$ 

The inclusion map $T(n) \to s.\text{trunc}_nX$ induces a morphism $s_kT(n) \to Sk_nX$, so we may set

$$Z(n) := \text{Im} (sk_nT(n) \to Sk_nX)$$

and we let $j(n) : Z(n) \to Sk_nX$ be the inclusion map. With this definition, we already see that conditions (d) and (f) are fulfilled, as well the part of condition (e) concerning $Z(n)$. Next, we define the morphism $r(n) : Sk_nX \to Z(n)$. Namely, we set $r(n)[k] := r(n^{-1})[k]$ for every $k < n$, and the map $r(n)[n]$ is constructed as follows. If $n = 0$, we let $r(0)[0] : X[0] \to Z(0)[0] = R_0$ be the map that sends any $x \in X[0]$ to the unique representative of the equivalence class of $x$ in $X[0]/E_{0}D_*$. If $n > 0$, let $x \in Sk_nX[n] = X[n]$ be any element; if $x \notin Z(n)[n]$, we let $r(n)[n](x) := x$, and if $x \in Z(n)[n]$ we let $h_{\partial x} : \partial \Delta_n \times \Delta_1 \to X$ be the composition

$$\partial \Delta_n \times \Delta_1 \xrightarrow{(\partial x) \times 1_{\Delta_1}} Sk_{n-1}X \times \Delta_1 \xrightarrow{j(n-1)} X.$$

The pair $(h_{\partial x}, x)$ amounts to a morphism $\gamma_x$ fitting into a commutative diagram

$$\begin{array}{ccc} (\Delta_n \times \Delta_1) & \xrightarrow{(\partial x) \times 1_{\Delta_1}} & Sk_{n-1}X \times \Delta_1 \xrightarrow{j(n-1)} X \\ \downarrow & & \downarrow \\ \Delta_n \times \Delta_1 & \xrightarrow{\gamma_x} & \Delta_n \xrightarrow{p \circ x} Y \end{array}$$

whose horizontal (resp. vertical) unmarked arrow is the natural projection (resp. the natural inclusion map). Since $p$ is a fibration, proposition [7.5.24] and lemma [7.5.15] imply that $\gamma_x$ extends to a morphism $h_x : \Delta_n \times \Delta_1 \to X$ by which, by inspection, is a $p$-fibrewise homotopy from $x$ to $x' := h_x \circ (1_{\Delta_n} \times \varepsilon_1) : \Delta_n \to X$ (notation of example [7.5.2] iv). Moreover, $\partial x' \in Z(n^{-1})[n-1]$ for every $i = 0, \ldots, n$, so there exists a unique $x'' \in T(n)[n]$ such that $x' \overset{p}{\sim}_{\partial \Delta_n} x''$, and we set

$$r(n)[n](x) := x''.$$ 

We have to check that the resulting system $r(n)[n](x) := (r(n)[k] \mid k = 0, \ldots, n)$ is a morphism

$$s.\text{trunc}_nX \to T(n)$$

of $n$-truncated simplicial sets. If $n = 0$, there is nothing to show. If $n > 0$, since the sub-system $(r(n)[k] \mid k = 0, \ldots, n-1)$ is already, by assumption, a morphism $s.\text{trunc}_{n-1}X \to s.\text{trunc}_{n-1}Z(n^{-1})$, we have only to show that

$$\partial(r(n)[n](x)) = r(n)[n-1] \circ \partial x \quad \text{for every } x \in X[n].$$

If $x \in T(n)[n]$, the identity is obvious, since the face and degeneracies of $T(n)$ are the restrictions of those of $X$. Hence, suppose $x \notin T(n)[n]$; then, by construction, $\partial(r(n)[n](x))$ is the morphism $h_{\partial x} \circ (1_{\partial \Delta_n} \times \varepsilon_1) : \partial \Delta_n \to X$. The latter is the same as

$$(\eta_X^{(n-1)} \circ j^{(n-1)} \circ r^{(n-1)})[n-1] \circ \partial x$$

(because $h^{(n-1)}$ is a homotopy from $\eta_X^{(n-1)}$ to $\eta_Y^{(n-1)} \circ j^{(n-1)} \circ r^{(n-1)}$) whence the contention.

By adjunction, the morphism $r(n)[n](x)$ yields the required morphism

$$r(n) : Sk_nX \to Z(n).$$
Also, again by adjunction, the identities of (a) can be checked on the respective \( n \)-truncations, where they are clear (details left to the reader).

It remains to exhibit the homotopy \( h^{(n)} : Sk_n X \times \Delta_1 \to X \). However, to any given \( x \in Sk_n X[n] \setminus Z^{(n)}[n] \), we have already attached a \( p \)-fibrewise homotopy \( h_x \) from \( x \) to \( x' \), and we have \( x' \mathcal{E}_{\partial_1 X} r^{(n)}[n]|x \); by lemma 7.5.66(ii), it follows that there exists a \( p \)-fibrewise homotopy \( h'_x : \Delta_n \times \Delta_1 \to X \) from \( x \) to \( r^{(n)}[n]|x \) such that

\[
(7.5.71) \quad h'_x \circ (i_n \times 1_{\Delta_1}) = h_x \circ (i_n \times 1_{\Delta_1}) = h_{\partial_1 x}
\]

where \( i_n : \partial_1 \Delta_n \to \Delta_n \) is the inclusion map. If \( x \in Z^{(n)}[n] \), we have \( x = r^{(n)}[n]|x \), so we may take \( h'_x \) to be a constant homotopy. There results a well defined map

\[
\mu : X[n] \to s._{\mathcal{H}om}(\Delta_1, X)[n] \quad x \mapsto h'_x.
\]

On the other hand, by remark 7.5.31(iv), the homotopy \( h^{(n-1)} \) corresponds to a morphism of simplicial sets

\[
\nu^{(n-1)} : Sk_{n-1} X \to s._{\mathcal{H}om}(\Delta_1, X).
\]

We claim that the datum of \( \mu \) and the maps \( (\nu^{(n-1)}[k]) | k = 0, \ldots, n-1 \) amounts to a morphism of \( n \)-truncated simplicial sets

\[
(7.5.72) \quad s._{\text{trunc}_n} X \to s._{\text{trunc}_n}(s._{\mathcal{H}om}(\Delta_1, X)).
\]

The assertion comes down to checking the identity

\[
(7.5.73) \quad \partial_i \circ \mu(x) = \nu^{(n-1)}[n-1] \circ \partial_i(x) \quad \text{for every } x \in X[n] \text{ and every } i = 0, \ldots, n
\]

and recall that the \( i \)-th face operator on \( s._{\mathcal{H}om}(\Delta_1, X)[n] \)

\[
\partial_i : \text{Hom}_{s._{\text{Set}}}(\Delta_n \times \Delta_1, X) \to \text{Hom}_{s._{\text{Set}}}(\Delta_{n-1} \times \Delta_1, X)
\]

is given by the rule \( \varphi \mapsto \varphi \circ (\varepsilon_i \times 1_{\Delta_1}) \) for every morphism \( \varphi : \Delta_n \times \Delta_1 \to X \).

Hence, if \( x \in Z^{(n)}[n] \), the morphism \( \partial_i(h'_x) \) is the constant homotopy from \( \partial_i x \) to itself; since \( h^{(n-1)} \) fulfills condition (c), this is the same as \( \nu^{(n-1)}[n-1]|(\partial_i x) \), so in this case (7.5.73) holds. In case \( x \not\in Z^{(n)}[n] \), identity (7.5.71) says that \( \partial_i(h'_x) = h_{\partial_1 x} \). But a simple inspection shows that \( h_{\partial_1 x} = \nu^{(n-1)}[n-1] \circ \partial_i x \), so (7.5.73) holds also in this case, and we get the sought morphism (7.5.72); by adjunction, the latter corresponds to a morphism

\[
h^{(n)} : Sk_n X \times \Delta_1 \to X
\]

as required, and clearly condition (e) for \( h^{(n)} \) is fulfilled by construction. Moreover, a simple inspection shows that (7.5.72) fits into a commutative diagram

\[
\begin{array}{ccc}
\text{s.trunc}_n X & \xrightarrow{1_{\text{s.trunc}_n X}} & \text{s.trunc}_n X \\
\text{s.trunc}_n X & \xrightarrow{\text{s.trunc}_n(s._{\mathcal{H}om}(\varepsilon_0, X))} & \text{s.trunc}_n(s._{\mathcal{H}om}(\Delta_1, X)) \\
\text{s.trunc}_n X & \xrightarrow{\text{s.trunc}_n(s._{\mathcal{H}om}(\varepsilon_1, X))} & \text{s.trunc}_n X \\
\text{s.trunc}_n X & \xrightarrow{\text{s.trunc}_n(j^{(n)} \circ r^{(n)})} & \text{s.trunc}_n X \\
\end{array}
\]

where we have used the natural identification \( X \xsim{\sim} s._{\mathcal{H}om}(\Delta_0, X) \) for the target of the morphisms \( s._{\mathcal{H}om}(\varepsilon_i, X) \) \((i = 0, 1)\). By adjunction, this diagram translates as our condition (b) for \( h^{(n)} \). To conclude the proof of the claim, it remains to check condition (c). However, in order to prove that \( p \circ h^{(n)} \) is a constant homotopy it suffices – by adjunction – to show that
the morphism \( \nu(n) : Sk_n X \to s.\text{Hom}(\Delta_1, X) \) corresponding to \( h^{(n)} \) fits into a commutative diagram

\[
\begin{array}{ccc}
Sk_n X & \xrightarrow{\nu(n)} & s.\text{Hom}(\Delta_1, X) \\
p^{(n)} \downarrow & & \downarrow s.\text{Hom}(\Delta_1, p) \\
Y = s.\text{Hom}(\Delta_0, Y) & \xrightarrow{s.\text{Hom}(\pi, Y)} & s.\text{Hom}(\Delta_1, Y)
\end{array}
\]

where \( \pi \) is the unique morphism \( \Delta_1 \to \Delta_0 \). Again by adjunction, it then suffices to check that \( s.\text{trunc}_n \mathcal{D} \) commutes; the latter assertion follows easily by inspecting the construction of the morphism \( (7.5.72) \). We argue similarly to show that \( h^{(n)}_Z \) is a constant homotopy: the assertion comes down to checking the commutativity of the diagram

\[
\begin{array}{ccc}
Z^{(n)} & \xrightarrow{\nu(n) \circ j^{(n)}} & s.\text{Hom}(\Delta_1, X) \\
\downarrow & & \downarrow s.\text{Hom}(\Delta_1, s.\text{Hom}(\Delta_0, Z^{(n)})) \\
Z^{(n)} = s.\text{Hom}(\Delta_0, Z^{(n)}) & \xrightarrow{s.\text{Hom}(\pi, Z^{(n)})} & s.\text{Hom}(\Delta_1, Z^{(n)})
\end{array}
\]

and since the counit of adjunction \( \text{sk}_n T^{(n)} \to Z^{(n)} \) is an epimorphism, we are reduced to showing that \( s.\text{trunc}_n \mathcal{D}_Z \) commutes, which again follows by inspecting the construction of \( (7.5.72) \) : details left to the reader. \( \spadesuit \)

Now, if the system \( (Z^{(n)}, j^{(n)}, r^{(n)}, h^{(n)} | n \in \mathbb{N}) \) fulfills conditions (a)–(f) of claim 7.5.70, we let

\[ Z := \text{colim}_{n \in \mathbb{N}} Z^{(n)} \]

where the transition maps \( Z^{(k)} \to Z^{(n)} \) are the morphisms \( e^{(k,n)} \), for every \( k, n \in \mathbb{N} \) with \( k \leq n \). In view of \( (7.5.9) \), the colimit of the system of monomorphisms \( (j^{(n)} | n \in \mathbb{N}) \) (resp. epimorphisms \( (r^{(n)} | n \in \mathbb{N}) \)) is therefore a monomorphism

\[ j : Z \to X \quad \text{(resp. an epimorphism} \ r : X \to Z) \]

such that \( r \circ j = 1_Z \) and \( p \circ j \circ r = p \). It is also clear that there exists a unique homotopy \( h : X \times \Delta_1 \to X \) from \( 1_X \) to \( j \circ r \), such that

\[ s.\text{trunc}_n (h) = s.\text{trunc}_n (h^{(n)}) \quad \text{for every} \ n \in \mathbb{N} \]

and then the resulting datum \( (j, r, h) \) is the sought strong deformation retract. It remains to check that \( p \circ j \) is a minimal fibration. First, it follows from lemma 7.5.15(iv) that \( p \circ j \) is a fibration. Lastly, fix \( n \in \mathbb{N} \), and suppose that \( z, z' \in Z[n] \) are any two elements such that \( z \overset{p}{\to} \Delta_n z' \); then \( j(z) \overset{p}{\to} \Delta_n j(z') \), so \( z = z' \), by condition (f) of claim 7.5.70 \( \square \)

**Proposition 7.5.74.** Consider a commutative diagram of simplicial sets

\[
\begin{array}{ccc}
X' & \xrightarrow{f} & X \\
p' \downarrow & & \downarrow p \\
Y & &
\end{array}
\]

such that \( p \) and \( p' \) are minimal fibrations, and \( f \) is a fibrewise homotopy equivalence. Then \( f \) is an isomorphism of simplicial sets.

**Proof.** The proposition is an immediate consequence of the following more precise:

**Claim 7.5.75.** In the situation of the proposition, suppose that:

(a) \( f' : X' \to X \) is an isomorphism such that \( p \circ f' = p' \) and \( f \overset{p}{\simeq} f' \).
(b) $p$ is a minimal fibration.

Then $f$ is an isomorphism as well.

**Proof of the claim.** We show first that $f[n]$ is injective for every $n \in \mathbb{N}$. We argue by induction on $n \in \mathbb{N}$. For $n = 0$, notice that $\partial \Delta_0 = s \partial_0$; hence, if $a, b \in X'[0]$ and $f[0](a) = f[0](b)$, assumption (a) yields:

$$f'[0](a) \sim_{\partial_0 \Delta_0} f[0](a) \quad f'[0](b) \sim_{\partial_0 \Delta_0} f[0](b)$$

whence $f'[0](a) \sim_{\partial_0 \Delta_0} f'[0](b)$ by virtue of lemma 7.5.66(i); then assumption (b) implies that $f[0](a) = f'[0](b)$, and finally $a = b$, as stated. Next, suppose that $n > 0$ and $f[n-1]$ is already known to be injective, and let $a, b \in X'[n]$ be any two elements with $f[n](a) = f[n](b)$; condition (a) says that there exists a $p$-fibrewise homotopy $h_a$ (resp. $h_b$) : $\Delta_n \times \Delta_1 \to X$ from $f[n](a)$ to $f[n](a)$ (resp. from $f[n](b)$ to $f'[n](b)$), and on the other hand, the inductive assumption implies that $\partial_i a = \partial_i b$, for every $i = 0, \ldots, n$, so the restrictions of $h_a$ and $h_b$ are both equal to the same morphism $w : \partial \Delta_n \times \Delta_1 \to X$. There follows a commutative diagram

$$(\Delta_n \times \Delta_1^2) \cup (\partial \Delta_n \times \Delta_2) \xrightarrow{u} X \quad \xrightarrow{p} \quad \Delta_n \times \Delta_2 \xrightarrow{v} Y$$

such that

$$u \circ (1_{\Delta_n} \times \varepsilon_1) = h_a \quad u \circ (1_{\Delta_n} \times \varepsilon_0) = h_b$$

and the restriction of $u$ to $\partial \Delta_n \times \Delta_2$ equals $w \circ (1_{\partial \Delta_n} \times \eta_0)$. Also, $v$ is the composition of the projection $\Delta_n \times \Delta_2 \to \Delta_n$ and the morphism $(p \circ f)[n](a) : \Delta_n \to Y$. Then there exists a morphism $t : \Delta_n \times \Delta_2 \to X$ that extends $u$ and lifts $v$; it is easily seen that $t \circ (\Delta_n \times \varepsilon_2) : \Delta_n \times \Delta_1 \to X$ is a $p$-fibrewise homotopy from $f'[n](a)$ to $f'[n](b)$ relative to $\partial \Delta_n$, and since $p$ is minimal, we conclude that $f'[n](a) = f'[n](b)$, so finally $a = b$, as required.

Next, we show by induction on $n \in \mathbb{N}$ that $f[k]$ is surjective, for every $k < n$. If $n = 0$, there is nothing to show, hence suppose that $n > 0$, and let $x \in X[n]$ be any element; by inductive assumption, for every $i = 0, \ldots, n$ there exists $a_i \in X'[n-1]$ such that $f[n-1] (a_i) = \partial_i x$. Since the injectivity of $f$ has already been established, we see easily that $\partial_i a_j = \partial_{j-1} a_i$ whenever $0 \leq i < j \leq n$, so the system $(a_0, \ldots, a_n)$ determines a unique morphism

$$w' : \partial \Delta_n \to X'$$

such that $f \circ w'$ is the restriction of $x : \Delta_n \to X$ to $\partial \Delta_n$ (see example 7.5.2(iv)). Now, let $h : X' \times \Delta_1 \to X$ be a $p$-fibrewise homotopy from $f$ to $f'$; we deduce a commutative diagram

$$(\partial \Delta_n \times \Delta_1) \cup (\Delta_n \times \Delta_1^0) \xrightarrow{w'} X \quad \xrightarrow{p} \quad \Delta_n \times \Delta_1 \xrightarrow{v'} Y$$

such that the restriction of $w'$ to $\partial \Delta_n \times \Delta_1$ (resp. to $\Delta_n \times \Delta_1^0$) agrees with $h \circ (w' \times 1_{\Delta_1})$ (resp. with the composition of the projection $\Delta_n \times \Delta_1^0 \to \Delta_n$ and the morphism $x$). Also, $v'$ is a constant homotopy. There follows a morphism $t' : \Delta_n \times \Delta_1 \to X$ that extends $w'$ and lifts $v'$. Let

$$x' : \Delta_n \to X'$$

be the unique morphism such that $f' \circ x' = t' \circ (1_{\Delta_n} \times \varepsilon_1)$. By construction, we have

$$f' \circ x' \circ i_n = f' \circ w'$$
(where \( i_n : \partial \Delta_n \to \Delta_n \) is the natural inclusion); whence \( x' \circ i_n = w' \), and we obtain yet another commutative diagram

\[
\begin{array}{ccc}
(\Delta_n \times \Lambda_0) \cup (\partial \Delta_n \times \Delta_2) & \xrightarrow{u''} & X \\
\downarrow & & \downarrow p \\
\Delta_n \times \Delta_2 & \xrightarrow{v''} & Y
\end{array}
\]

such that

\[
u'' \circ (1_{\Delta_n} \times \varepsilon_1) = t' \quad u'' \circ (1_{\Delta_n} \times \varepsilon_2) = h \circ (x' \times 1_{\Delta_1})
\]

and where \( v'' \) factors through the projection \( \Delta_n \times \Delta_2 \to \Delta_n \). As usual, we find a morphism \( t'' : \Delta_n \times \Delta_2 \to X \) that lifts \( v'' \) and extends \( u'' \), and it is easily seen that \( t'' \circ (\Delta_n \times \varepsilon_0) \) is a \( p \)-fibrewise homotopy from \( x \) to \( f[\text{n}](x') \) relative to \( \partial \Delta_n \). By the minimality of \( p \), it follows that \( x = f[\text{n}](x') \), whence the sought surjectivity of \( f[\text{n}] \).

\[\Box\]

**Definition 7.5.76.** Let \( f : X \to Y \) be any morphism of fibrant simplicial sets. We say that \( f \) is a *weak equivalence*, if the induced map \( \pi_n(f, \xi) \) is an isomorphism, for every \( \xi \in X[0] \) and every \( n \in \mathbb{N} \).

**Proposition 7.5.77.** Let \( f : X \to Y \) and \( g : Y \to Z \) be any two morphisms of fibrant simplicial sets. The following holds:

(i) If \( f \) has the right lifting property with respect to the natural monomorphism \( i_n : \partial \Delta_n \to \Delta_n \) for every \( n \in \mathbb{N} \), then \( f \) is both a fibration and a weak equivalence.

(ii) If \( f \) is a homotopy equivalence, then it is a weak equivalence.

(iii) If any two of the three morphisms \( f, g, g \circ f \) is a weak equivalence, then so is the third.

**Proof.** (i): It follows easily from lemma 7.5.15(ii) and remark 7.5.8 that \( f \) has the right lifting property with respect to every monomorphism of simplicial sets (details left to the reader). Especially, \( f \) is a fibration. It also follows easily that \( f[0] \) is surjective. Moreover, suppose that \( a, b \in X[0] \) and \( [f(a)] = [f(b)] \) in \( \pi_0(Y) \), and pick a homotopy \( h : \Delta_1 \to Y \) from \( f(a) \) to \( f(b) \); there follows a commutative diagram

\[
\begin{array}{ccc}
\partial \Delta_1 & \xrightarrow{c} & X \\
\downarrow & & \downarrow f \\
\Delta_1 & \xrightarrow{h} & Y
\end{array}
\]

such that the restriction of \( c \) to \( \Lambda_0 \) (resp. to \( \Lambda_1 \)) agrees with \( a \) (resp. with \( b \)). By assumption, \( c \) extends to a morphism \( h' : \Delta_1 \to X \) such that \( f \circ h' = h \). We conclude that \( \pi_0(f) \) is bijective. Next, let \( \xi \in X[0] \) be any vertex, and set \( F := f^{-1}(f(\xi)) \). By lemma 7.5.15(ii), the unique morphism \( F \to \Delta_0 \) has the right lifting properties with respect to \( i_n \), for every \( n \in \mathbb{N} \). By the foregoing, we know already that \( \pi_0(F) \) is a set of cardinality one; moreover, we have:

**Claim 7.5.78.** \( \pi_n(F, \xi) = 0 \) for every \( n \geq 1 \).

**Proof of the claim.** Let \( a \in F(\xi, n) \) be any element; then there exists a unique morphism \( b : \partial \Delta_{n+1} \to F \) whose restriction to \( \Lambda_0 \) factors through \( \xi \), and whose composition with \( \varepsilon_0 : \Delta_n \to \partial \Delta_{n+1} \) agrees with \( a \). By assumption, \( b \) extends to a morphism \( c : \Delta_{n+1} \to X \), and then the claim follows from lemma 7.5.46.

\[\Box\]

The proposition now follows easily from theorem 7.5.56 and claim 7.5.78

(ii): Let \( f' : Y \to X \) be a morphism and \( h : X \times \Delta_1 \to X \) a homotopy from \( \gamma_0 := 1_X \) to \( \gamma_1 := f' \circ f \). By adjunction, \( h \) corresponds to a morphism \( \beta : X \to s.\mathcal{H}om(\Delta_1, X) \) fitting
We consider first the case where Theorem 7.5.80 (Whitehead) that \( f \) contains exactly one element, for every \( n \in \mathbb{N} \).

**Proof of the claim.** As for \( \beta \), since \( \gamma_0 \) is an isomorphism, it suffices to show that \( p_0 := s.\text{Hom}(\varepsilon_0, X) \) is a weak equivalence. To this aim, by (i), we are reduced to checking that \( p_0 \) has the right lifting property with respect to the monomorphisms \( i_n \), for every \( n \in \mathbb{N} \). Thus, let \( a : \partial \Delta_n \to s.\text{Hom}(\Delta_1, X) \) be a morphism such that \( p_0 \circ a \) extends to a morphism \( b : \Delta_n \to X \); by adjunction, \( a \) and \( b \) determine a unique morphism \( (\Delta_n \times \Delta_0^1) \cup (\partial \Delta_n \times \Delta_1) \to X \) which, since \( X \) is fibrant, extends to a morphism \( \Delta_n \to s.\text{Hom}(\Delta_1, X) \) which is the sought extension of \( a \).

The same argument shows as well that \( s.\text{Hom}(\varepsilon_1, X) \) is a weak equivalence, and so the same follows for \( \gamma_1 \), as stated.

Now, if \( f \) is a homotopy equivalence, we have also a homotopy \( h^\prime : Y \times \Delta_1 \to Y \) from \( 1_Y \) to \( f \circ f' \). Taking into account claim 7.5.79 we deduce that both

\[
\pi_n(g, f(\xi)) \circ \pi_n(f, \xi') \quad \text{and} \quad \pi_n(f, f'(\xi')) \circ \pi_n(f', \xi')
\]

are bijections, for every \( n \in \mathbb{N} \), every \( \xi \in X[0] \) and every \( \xi' \in Y[0] \). The assertion follows.

(iii): The only non-trivial assertion is that \( g \) is a weak equivalence if both \( f \) and \( g \circ f \) are. However, in this case it is clear that \( \pi_0(g) \) is an isomorphism, so it remains only to check that \( \pi_n(g, y) \) is an isomorphism for every \( y \in Y[0] \). Thus, fix such vertex \( y \); since \( \pi_0(f) \) is a bijection, there exist \( x \in X[0] \) and a morphism \( [\alpha] : y \to y' := f[0](x) \) in \( \pi(Y) \) (notation of 7.5.57). Set \( z := g[0](y), z' := g[0](z') \) and \( \beta := g[1](\alpha) \); there follows a commutative diagram (see remark 7.5.63)

\[
\begin{array}{ccc}
\pi_n(Y, y) & \xrightarrow{\pi_n(Y, [\alpha])} & \pi_n(Y, y') \\
\downarrow \pi_n(g, y) & & \downarrow \pi_n(g, y') \\
\pi_n(Z, z) & \xrightarrow{\pi_n(Z, [\beta])} & \pi_n(Z, z') \\
\end{array}
\]

from which we see first that \( \pi_n(g, y') \) is an isomorphism, and then the assertion follows.

\[ \Box \]

The following is the main result of this section:

**Theorem 7.5.80 (Whitehead).** Every weak equivalence of fibrant simplicial sets is a homotopy equivalence.

**Proof.** We begin with the following special case:

**Claim 7.5.81.** Let \( f : X \to Y \) be any minimal fibration of fibrant simplicial sets, and suppose that \( f \) is a weak equivalence. Then \( f \) is an isomorphism.

**Proof of the claim.** We consider first the case where \( Y = \Delta_0 \) (notice that \( \Delta_0 \) is trivially a fibrant simplicial set), so that \( f \) is the unique morphism \( X \to \Delta_0 \). We show by induction that \( X[n] \) contains exactly one element, for every \( n \in \mathbb{N} \). Say first that \( n = 0 \); since \( \pi_0(\Delta_0) \) is non-empty, we may find a vertex \( \xi \in X[0] \), and we set \( \xi' := f[0](\xi) \). Let \( a \in X[0] \) be any other vertex; since \( f[0](a) = \xi' \), by assumption we may find a homotopy from \( a \) to \( \xi \), and therefore \( a = \xi \), since \( X \) is minimal. Next, suppose that \( n > 0 \), and the assertion is already known for every
integer \( n > 1 \); let \( b \in X[n] \) be any simplex, and notice that \( \partial b \) must factor through \( \xi \), by inductive assumption, so \( b \in X(\xi,n) \). However, obviously \( \pi_n(\Delta_0, \xi') = 0 \), hence \( b \sim_{\partial \Delta_n} \xi \), and finally \( b = \xi \), again by the minimality of \( X \).

Next, consider an arbitrary minimal fibration \( f \), fix \( \xi' \in Y[0] \) and pick any \( \xi \in f[0]^{-1}(\xi') \) (notice that \( Y[0] \) and \( f[0]^{-1}(\xi') \) are non-empty, since \( Y \) is fibrant and \( f \) is a fibration). Set \( F := f^{-1}(\xi') \); theorem \( \ref{thm:anodyne-extension} \) implies that \( \pi_n(F, \xi) \) has cardinality equal to one, for every \( n \in \mathbb{N} \). On the other hand, since \( f \) is minimal, it is easily seen that the same holds for \( F \) (details left to the reader) therefore \( F \cong \Delta_0 \), by the foregoing case. Since \( \xi' \) is arbitrary, the claim follows.

Now, let \( f : X \to Y \) be any weak equivalence, with \( X \) and \( Y \) fibrant simplicial sets. By theorem \( \ref{thm:anodyne-extension} \), there exist an anodyne extension \( i : X \to E \) and a fibration \( p : E \to Y \) such that \( p \circ i = f \). Since \( Y \) is fibrant, the same holds for \( E \).

**Claim 7.5.82.** The morphism \( i \) is a strong deformation retract of \( E \).

**Proof of the claim.** Since \( i \) is anodyne and \( X \) is fibrant, the identity \( 1_X \) extends to a morphism \( r : E \to X \). Next, consider the unique morphism

\[
t : (X \times \Delta_1) \cup (E \times \partial \Delta_1) \to E
\]

whose restriction to \( X \times \Delta_1 \) is the composition of \( i \) with the projection onto \( X \), and whose restriction with \( E \times \Lambda^0_1 \) (resp. \( E \times \Lambda^1_1 \)) agrees with \( 1_E \) (resp. \( i \circ r \)). Since \( E \) is fibrant, \( t \) extends to a morphism \( h : E \times \Delta_1 \to E \) (corollary \( \ref{cor:cell-deformation} \)), and it is easily seen that \((i, r, h)\) is a strong deformation retract for the unique morphism \( E \to \Delta_0 \).

By claim \( \ref{claim:anodyne-extension} \) and remark \( \ref{rem:anodyne-extension} \) we see that \( i \) is a homotopy equivalence, hence it suffices to check that the same holds for \( p \). Moreover, \( i \) is a weak equivalence (proposition \( \ref{prop:anodyne-extension} \)), hence the same holds for \( p \) (proposition \( \ref{prop:anodyne-extension} \)). Hence, we may replace \( X \) by \( E \) and \( f \) by \( p \), and assume from start that \( f \) is also a fibration. We may then find a strong deformation retract \((j : F \to X, r, h)\) of \( f \) such that \( q := f \circ j \) is a minimal fibration. Arguing as in the foregoing, we see that \( j \) is a weak equivalence, and therefore the same holds for \( q \) (again, by proposition \( \ref{prop:anodyne-extension} \)); then claim \( \ref{claim:anodyne-extension} \) says that \( q \) is an isomorphism. Lastly, \( r \) is a homotopy equivalence (remark \( \ref{rem:anodyne-extension} \)), so the same holds for \( f = q \circ r \).

\( \square \)

### 7.6. Graded rings

To motivate the results of this section, let us review briefly the well known correspondence between \( \Gamma \)-gradings on a module \( M \) (for a given commutative group \( \Gamma \)), and actions of the diagonalizable group \( D(\Gamma) \) on \( M \).

**7.6.1. Graded rings.** Let \( S \) be a scheme; on the category \( \text{Sch}/S \) of \( S \)-schemes we have the presheaf of rings:

\[
\mathcal{O}_{\text{Sch}/S} : \text{Sch}/S \to \text{Z-Alg} \quad (X \to S) \mapsto \Gamma(X, \mathcal{O}_X).
\]

Also, let \( M \) be an \( \mathcal{O}_S \)-module; following \( \cite{42} \) Exp.I, Déf.4.6.1], we attach to \( M \) the \( \mathcal{O}_{\text{Sch}/S} \)-module \( \mathcal{M}_M \) given by the rule:

\[
\Gamma(S', \mathcal{H}om_{\mathcal{O}_{\text{Sch}/S}}(\mathcal{M}_M, \mathcal{M}_N)) = \text{Hom}_{\mathcal{O}_S}(M, f_*, \mathcal{O}_{S'} \otimes_{\mathcal{O}_S} N)
\]

(see \( \cite{42} \) Exp.I, Prop.4.6.4] for the details).

Let \( f : G \to S \) be a group \( S \)-scheme, i.e. a group object in the category \( \text{Sch}/S \). If \( f \) is affine, we say that \( G \) is an affine group \( S \)-scheme; in that case, the multiplication law \( G \times_S G \to G \) and the unit section \( S \to G \) correspond respectively to morphisms of \( \mathcal{O}_S \)-algebras:

\[
\Delta_G : f_* \mathcal{O}_G \to f_* \mathcal{O}_G \otimes_{f_* \mathcal{O}_S} f_* \mathcal{O}_G \qquad \varepsilon_G : \mathcal{O}_S \to f_* \mathcal{O}_G
\]
which make commute the diagram:

\[
\begin{array}{cccccc}
 f_* \mathcal{O}_G & \xrightarrow{\Delta_G} & f_* \mathcal{O}_G \otimes \epsilon_S f_* \mathcal{O}_G \\
\downarrow \Delta_G & & \downarrow 1_{f_* \mathcal{O}_G} & & \downarrow \Delta_G \otimes 1_{f_* \mathcal{O}_G} \\
 f_* \mathcal{O}_G \otimes \epsilon_S f_* \mathcal{O}_G & \xrightarrow{\Delta_G \otimes 1_{f_* \mathcal{O}_G}} & f_* \mathcal{O}_G \otimes \epsilon_S f_* \mathcal{O}_G \otimes \epsilon_S f_* \mathcal{O}_G
\end{array}
\]

as well as a similar diagram, which expresses the unit property of $\varepsilon_G$; see [42, Exp.I, §4.2].

**Example 7.6.3.** Let $G$ be any commutative group. The presheaf of groups

\[ D_S(G) : \text{Sch}/S \to \mathbb{Z}\text{-Mod} \quad (X \to S) \mapsto \text{Hom}_{\mathbb{Z}\text{-Mod}}(G, \mathcal{O}_X^\times(X)) \]

is representable by an affine group $S$-scheme $D_S(G)$, called the *diagonalizable group scheme* attached to $G$. Explicitly, if $S = \text{Spec } R$ is an affine scheme, the underlying $S$-scheme of $D_S(G)$ is $\text{Spec } R[G]$, and the group law is given by the map of $R$-algebras

\[ \Delta_G : R[G] \to R[G] \otimes R[G] \xrightarrow{\sim} R[G \times G] \quad g \mapsto (g, g) \quad \text{for every } g \in G \]

with unit $\varepsilon_G : R[G] \to R$ given by the standard augmentation (see [42, Exp.I, §4.4]). For a general scheme $S$, we have $D_S(G) = D_{\text{Spec } \mathbb{Z}}(G) \times_{\text{Spec } \mathbb{Z}} S$ (with the induced group law and unit section).

**Definition 7.6.4.** Let $M$ be an $\mathcal{O}_S$-module, $G$ a group $S$-scheme. A *$G$-module structure* on $M$ is the datum of a morphism of presheaves of groups on $\text{Sch}/S$:

\[ h_G : \mathcal{O}_\text{sch}/S(M) \to \mathfrak{ut}_{\mathcal{O}_\text{sch}/S}(\mathcal{W}_M) \]

(where $h_G$ denotes the Yoneda embedding; see (1.2.4)).

**7.6.5.** Suppose now that $f : G \to S$ is an affine group $S$-scheme, and $M$ a quasi-coherent $\mathcal{O}_S$-module; in view of (7.6.2), a $G$-module structure on $M$ is then the same as a map of $\mathcal{O}_S$-modules

\[ \mu_M : M \to f_* \mathcal{O}_G \otimes \epsilon_S M \]

which makes commute the diagrams:

\[
\begin{array}{cccccc}
 M & \xrightarrow{\mu_M} & f_* \mathcal{O}_G \otimes \epsilon_S M \\
\downarrow \mu_M & & \downarrow \Delta_G \otimes 1_M \\
 f_* \mathcal{O}_G \otimes \epsilon_S M & \xrightarrow{1_{f_* \mathcal{O}_G} \otimes \mu_M} & f_* \mathcal{O}_G \otimes \epsilon_S f_* \mathcal{O}_G \otimes \epsilon_S M
\end{array}
\]

\[
\begin{array}{cccccc}
 M & \xrightarrow{\mu_M} & f_* \mathcal{O}_G \otimes \epsilon_S M \\
\downarrow 1_M & & \downarrow \varepsilon_G \otimes 1_M \\
 M & \xrightarrow{\varepsilon_G \otimes 1_M} & M.
\end{array}
\]

**Example 7.6.6.** Let $\Gamma$ be a commutative group; a $D_{\mathcal{S}}(\Gamma)$-module structure on a quasi-coherent $\mathcal{O}_S$-module $M$ is the datum of a morphism of $\mathcal{O}_S$-modules

\[ \mu_M : M \to \mathcal{O}_S[\Gamma] \otimes \epsilon_S M = \mathbb{Z}[\Gamma] \otimes \mathbb{Z} M \]

which makes commute the diagrams of (7.6.5). If $S = \text{Spec } R$ is affine, $M$ is associated with an $R$-module which we denote also by $M$; in this case, $\mu_M$ is the same as a system $(\mu_M^{(\gamma)} \mid \gamma \in \Gamma)$ of $\mathcal{O}_S$-linear endomorphisms of $M$, such that:

- for every $x \in M$, the subset $\{ \gamma \in \Gamma \mid \mu_M^{(\gamma)}(x) \neq 0 \}$ is finite.
- $\mu_M^{(\gamma)} \circ \mu_M^{(\tau)} = \delta_{\gamma, \tau} \cdot 1_M$ and $\sum_{\gamma \in \Gamma} \mu_M = 1_M$.

In other words, the $\mu_M^{(\gamma)}$ form an orthogonal system of projectors of $M$, summing up to the identity $1_M$. This is the same as the datum of a $\Gamma$-grading on $M$; namely, for a given $D_{\mathcal{S}}(\Gamma)$-module structure $\mu_M$, one lets

\[ \text{gr}_{\gamma} M := \mu_M^{(\gamma)}(M) \quad \text{for every } \gamma \in \Gamma \]
and conversely, given a $\Gamma$-grading $\text{gr}_M$ on $M$, one defines $\mu_M$ as the $R$-linear map given by the rule: $x \mapsto \gamma \otimes x$ for every $\gamma \in \Gamma$ and every $x \in \text{gr}_\gamma M$.

7.6.7. Suppose now that $g : X \to S$ is an affine $S$-scheme, and $f : G \to S$ an affine group $S$-scheme. A $G$-action on $X$ is a morphism of presheaves of groups:

$$h_G : \text{Aut}_{\text{Sch/S}}(h_X).$$

(notation of (1.2.4)); the latter is the same as a morphism of $S$-schemes

$$G \times_S X \to X$$

inducing a $G$-module structure on $g_* \mathcal{O}_X$:

$$g_* \mathcal{O}_X \to f_* \mathcal{O}_G \otimes_{\mathcal{O}_S} g_* \mathcal{O}_X$$

which is also a morphism of $\mathcal{O}_S$-algebras. For instance, if $S = \text{Spec } R$ is affine, and $G = D_S(\Gamma)$ for an abelian group $\Gamma$, we may write $X = \text{Spec } A$ for some $R$-algebra $B$, and in view of example (7.6.6), the $G$-action on $X$ is the same as the datum of a $\Gamma$-graded $R$-algebra structure on $B$, in the sense of the following:

**Definition 7.6.9.** Let $(\Gamma, +)$ be a commutative monoid, $R$ a ring.

(i) A $\Gamma$-graded (associative, unital) $R$-algebra is a pair $B = (B, \text{gr}_B)$ consisting of an associative unital $R$-algebra $B$ and a $\Gamma$-grading $B = \bigoplus_{\gamma \in \Gamma} \text{gr}_\gamma B$ of the $R$-module $B$, such that

$$\text{gr}_\gamma B \cdot \text{gr}_\gamma B \subset \text{gr}_{\gamma + \gamma'} B$$

for every $\gamma, \gamma' \in \Gamma$.

A morphism of $\Gamma$-graded $R$-algebras is a map of $R$-algebras which is compatible with the gradings, in the obvious way.

(ii) Let $B = (B, \text{gr}_B)$ be a $\Gamma$-graded $R$-algebra. A $\Gamma$-graded (left) $B$-module is a datum $M = (M, \text{gr}_M)$ consisting of a $B$-module $M$ and a $\Gamma$-grading $M = \bigoplus_{\gamma \in \Gamma} \text{gr}_\gamma M$ of the $R$-module underlying $M$, such that

$$\text{gr}_\gamma B \cdot \text{gr}_\gamma M \subset \text{gr}_{\gamma + \gamma'} M$$

for every $\gamma, \gamma' \in \Gamma$.

A morphism of $\Gamma$-graded $B$-modules is a map $f : M \to N$ of $B$-modules, such that $f(\text{gr}_\gamma M) \subset \text{gr}_\gamma N$, for every $\gamma \in \Gamma$. Likewise we define $\Gamma$-graded right $B$-modules and $\Gamma$-graded $B$-bimodules, and their respective morphisms.

(iii) A graded ideal of $B$ is a $\Gamma$-graded sub-$B$-bimodule $(I, \text{gr}_I)$ of $B$. Obviously, in this case we must have $\text{gr}_\gamma I = I \cap \text{gr}_\gamma B$ for every $\gamma \in \Gamma$.

(iv) If $f : \Gamma' \to \Gamma$ is any morphism of commutative monoids, and $M$ is any $\Gamma$-graded $R$-module, we define the $\Gamma'$-graded $R$-module $\Gamma' \times_\Gamma M$ by setting

$$\text{gr}_\gamma (\Gamma' \times_\Gamma M) := \text{gr}_{f(\gamma)} M$$

for every $\gamma \in \Gamma'$.

Notice that if $B = (B, \text{gr}_B)$ is a $\Gamma$-graded $R$-algebra, then $\Gamma' \times_\Gamma B$ is a $\Gamma'$-graded $R$-algebra, with multiplication and addition laws induced by those of $B$, in the obvious way. Likewise, if $(M, \text{gr}_M)$ is a $\Gamma$-graded $B$-module, then $\Gamma' \times_\Gamma M$ is naturally a $\Gamma'$-graded $\Gamma' \times_\Gamma B$-module.

(v) Furthermore, if $N$ is any $\Gamma'$-graded $R$-module, we define the $\Gamma$-graded $R$-module $N_{/\Gamma}$ whose underlying $R$-module is the same as $N$, and whose grading is given by the rule

$$\text{gr}_\gamma (N_{/\Gamma}) := \bigoplus_{\gamma' \in f^{-1}(\gamma)} \text{gr}_{\gamma'} N.$$

Just as in (iii), if $C = (C, \text{gr}_C)$ is a $\Gamma'$-graded $R$-algebra, then we get a $\Gamma$-graded $R$-algebra $C_{/\Gamma}$, whose underlying $R$-algebra is the same as $C$. Lastly, if $(N, \text{gr}_N)$ is a $\Gamma'$-graded $C$-module, then $N_{/\Gamma}$ is a $\Gamma$-graded $C_{/\Gamma}$-module.

In this section we will consider only commutative graded algebras, but in the next section (7.7) we will encounter certain special classes of non-commutative graded algebras as well.
Example 7.6.10. (i) For instance, the $R$-algebra $R[\Gamma]$ is naturally a $\Gamma$-graded $R$-algebra, when endowed with the $\Gamma$-grading such that $\text{gr}_\gamma R[\Gamma] := \gamma R$ for every $\gamma \in \Gamma$.

(ii) Suppose that $\Gamma$ is an integral monoid. Then, to a $\Gamma$-graded $R$-algebra $B$, the correspondence described in (7.6.7) attaches a $D_S(\Gamma^{gp})$-action on $\text{Spec} B$ (where $S := \text{Spec} R$), given by the map of $R$-algebras

\[ \vartheta_B : B \to B[\Gamma] \subset B[\Gamma^{gp}] : b \mapsto b \cdot \gamma \quad \text{for every } \gamma \in \Gamma, \text{ and every } b \in \text{gr}_\gamma B. \]

Remark 7.6.11. (i) Let $R$ be a ring; consider a cartesian diagram of monoids

\[
\begin{array}{ccc}
\Gamma_3 & \longrightarrow & \Gamma_1 \\
\downarrow & & \downarrow \\
\Gamma_2 & \longrightarrow & \Gamma_0 \\
\end{array}
\]

and let $B$ be any $\Gamma_1$-graded $R$-algebra. A simple inspection of the definitions yields an identity of $\Gamma_2$-graded $R$-algebras:

\[ \Gamma_2 \times_{\Gamma_0} B/\Gamma_0 = (\Gamma_3 \times_{\Gamma_1} B)/\Gamma_2. \]

(ii) Suppose that $\Gamma$ is a finite abelian group, whose order is invertible in $\mathcal{O}_S$. Then $D_S(\Gamma)$ is an étale $S$-scheme. Indeed, in light of (4.8.52), the assertion is reduced to the case where $\Gamma = \mathbb{Z}/n\mathbb{Z}$ for some integer $n > 0$ which is invertible in $\mathcal{O}_S$. However, $R[\mathbb{Z}/n\mathbb{Z}] \simeq R[T]/(T^n - 1)$, which is an étale $R$-algebra, if $n \in R^\times$.

(iii) More generally, suppose that $\Gamma$ is a finitely generated abelian group, such that the order of its torsion subgroup is invertible in $\mathcal{O}_S$. Then we may write $\Gamma = L \oplus \Gamma_{\text{tor}}$, where $L$ is a free abelian group of finite rank, and $\Gamma_{\text{tor}}$ is a finite abelian group as in (ii). In view of (4.8.52) and (ii), we conclude that $D_S(\Gamma)$ is a smooth $S$-scheme in this case.

(iv) Let $\Gamma$ be as in (iii), and suppose that $X$ is an $S$-scheme with an action of $G := D_S(\Gamma)$. Then the corresponding morphism (7.6.8) and the projection $p_G : G \times_S X \to G$ induce an automorphism of the $G$-scheme $G \times_S X$, whose composition with the projection $p_X : G \times_S X \to X$ equals (7.6.8). We then deduce that both (7.6.8) and $p_X$ are smooth morphisms. This observation, together with the above correspondence between $\Gamma$-graded algebras and $D_S(\Gamma)$-actions, is the basis for a general method, that allows to prove properties of graded rings, provided they can be translated as properties of the corresponding schemes which are well behaved under smooth base changes. We shall present hereafter a few applications of this method.

Proposition 7.6.12. Let $\Gamma$ be an integral monoid, $B$ a $\Gamma$-graded (commutative, unital) ring, and suppose that the order of any torsion element of $\Gamma^{gp}$ is invertible in $B$. Then:

(i) $\text{nil}(B[\Gamma]) = \text{nil}(B) \cdot B[\Gamma]$.

(ii) $\text{nil}(B)$ is a $\Gamma$-graded ideal of $B$.

Proof. (i): Clearly $\text{nil}(B) \cdot B[\Gamma] \subset \text{nil}(B[\Gamma])$. To show the converse inclusion, it suffices to prove that $\text{nil}(B[\Gamma]) \subset pB[\Gamma]$ for every prime ideal $p \subset B$, or equivalently that $B/p[\Gamma]$ is a reduced ring for every such $p$. Since the natural map $\Gamma \to \Gamma^{gp}$ is injective, we may further replace $\Gamma$ by $\Gamma^{gp}$, and assume that $\Gamma$ is an abelian group. In this case, $B/p[\Gamma]$ is the filtered union of the rings $B/p[H]$, where $H$ runs over the finitely generated subgroups of $\Gamma$; it suffices therefore to prove that each $B/p[H]$ is reduced, so we may assume that $\Gamma$ is finitely generated, and the order of its torsion subgroup is invertible in $B$. In this case, $B/p[\Gamma]$ is a smooth $B/p$-algebra (remark 7.6.11(iii)), and the assertion follows from [51, Ch.IV, Prop.17.5.7].

(ii): The assertion to prove is that $\text{nil}(B) = \bigoplus_{\gamma \in \Gamma} \text{nil}(B) \cap \text{gr}_\gamma B$. However, let $\vartheta_B : B \to B[\Gamma]$ be the map defined as in example 7.6.10(ii); now, (i) implies that $\vartheta_B$ restricts to a map $\text{nil}(B) \to \text{nil}(B) \cdot B[\Gamma]$, whence the contention. \qed

Definition 7.6.13. Let $A$ be a ring, $S \subset A$ the multiplicative subset of regular elements of $A$. 
(i) For every ring homomorphism $A \to B$, we denote the integral closure of $A$ in $B$ by:

\[
i.c.(A, B).
\]

(ii) The total ring of fractions of $A$ is the ring:

\[
\text{Frac}(A) := S^{-1}A.
\]

(iii) The normalization $A$ is $A' := i.c.(A, \text{Frac}(A))$. We say that $A$ is normal if $A = A'$.

(iv) We say that a $A$ is nice if either $A = 0$ or $\text{Frac}(A)$ has Krull dimension zero.

**Remark 7.6.14.** Let $A$ be a ring.

(i) Notice that the localization map $A \to \text{Frac}(A)$ is injective, and every regular element of $\text{Frac}(A)$ is invertible: the details are left to the reader.

(ii) If $A$ has Krull dimension zero, then every regular element of $A$ is invertible: indeed, if $a \in A$ is regular and $p \in \text{Spec} A$, the image of $a$ in $A_p$ is still regular, hence $a \notin pA_p$, because $pA_p$ is the nilradical of $A_p$. Thus, $a$ doesn’t lie in any prime ideal of $A$, whence the contention.

(iii) If $A$ is reduced and has finitely many minimal prime ideals, then $A$ is nice. Indeed, in this case $\text{Frac}(A)$ has also finitely many minimal prime ideals $p_1, \ldots, p_k$; now, if $x \in \text{Frac}(A) \setminus (p_1 \cup \cdots \cup p_k)$, and $x$ is not invertible, then $x$ is not regular, by (i). Say that $xy = 0$ for some $y \in \text{Frac}(A) \setminus \{0\}$, it follows that $y \in p_1 \cap \cdots \cap p_k = 0$, a contradiction. So every non-invertible element of $\text{Frac}(A)$ lies in $p_1 \cup \cdots \cup p_k$, whence the contention.

(iv) If $A$ is noetherian and has no embedded prime ideals, then $A$ is nice. Indeed, in this case $\text{Frac}(A)$ fulfills the same conditions; then, take again $x \in \text{Frac}(A)$ in the complement of the finitely many minimal prime ideals. If $x$ is not invertible, it is not regular according to (i), hence it lies in some associated prime ideal of $A$ ([100, Th.6.1(ii)]), a contradiction.

(v) Every flat ring homomorphism $f : A \to B$ maps the regular elements of $A$ to the regular elements of $B$, hence it extends uniquely to a flat ring homomorphism

\[
\text{Frac}(f) : \text{Frac}(A) \to \text{Frac}(B).
\]

Moreover, if $f$ is injective, the same holds for $\text{Frac}(f)$, since the localization map $B \to \text{Frac}(B)$ is injective by (i): details left to the reader.

(vi) Let $f : A \to B$ be a flat ring homomorphism, such that $A$ is nice and $\text{Spec} \kappa(p) \otimes_A B$ is either empty or has Krull dimension zero for every prime ideal $p$ of $A$ (where $\kappa(p)$ denotes the residue field of $p$). Then $B$ is nice and $\text{Frac}(f)$ induces an isomorphism of $B$-algebras:

\[
f' : \text{Frac}(A) \otimes_A B \cong \text{Frac}(B).
\]

Indeed, let $b \in B$ be any regular element; since the induced map $g : B \to \text{Frac}(A) \otimes_A B$ is flat, $g(b)$ is regular in $\text{Frac}(A) \otimes_A B$. On the other hand, by assumption $\text{Spec} \text{Frac}(A)$ and the fibres of $\text{Spec}(f)$ are either empty or have Krull dimension zero, hence $\text{Frac}(A) \otimes_A B$ is either 0 or has Krull dimension zero, so $g(b)$ is invertible, by (ii). This shows that $g$ extends to a ring homomorphism $\text{Frac}(B) \to \text{Frac}(A) \otimes_A B$ which is the inverse of $f'$, whence the contention.

(vii) If $A$ is nice, $(A_p)^\nu = (A')_p$ for every $p \in \text{Spec} A$. Indeed, in light of (vi) we have:

\[
(A_p)^\nu = i.c.(A_p, \text{Frac}(A_p)) = i.c.(A_p, \text{Frac}(A))_p = (A')_p.
\]

(viii) Especially, if $A$ is a nice and reduced ring, then $A$ is normal if and only if $A$ is locally normal, i.e. if and only if $A_p$ is a reduced local normal domain for every $p \in \text{Spec} A$. Indeed, the condition is sufficient, by virtue of (vii). Conversely, suppose that $A$ is nice, reduced and normal. In view of (viii), it suffices to check that $A_p$ is a domain for every $p \in \text{Spec} A$, and since $A_p$ is reduced, this amounts to showing that $A_p$ has a unique minimal prime ideal. However, $A_p$ is nice due to (vi), hence $X := \text{Spec} \text{Frac}(A_p)$ has Krull dimension zero, and especially it is a totally disconnected topological space. Moreover, it follows from (i) that the inclusion map $X \to \text{Spec} A_p$ has dense image, so it must contain every minimal prime ideal of $\text{Spec} A_p$, and then $X$ is precisely the set of minimal prime ideals of $A_p$. Now, if $X$ contains two distinct
points, we may find non-empty open and closed subsets \( U, U' \subset X \) with \( U \cap U' = \emptyset \) and \( U \cup U' = X \); then there is an idempotent \( e \in \text{Frac}(A_p) \) which vanishes exactly on \( U \). Since \( A_p \) is normal by (vii), it follows that \( e \in A_p \), but then \( \text{Spec} A_p \) is the disjoint union of two non-empty open and closed subsets, which is absurd, since it has a unique closed point.

**Proposition 7.6.15.** Let \( (\Gamma, +, 0) \) be an integral monoid, \( f : A \rightarrow B \) a morphism of \( \Gamma \)-graded rings, and suppose that the order of any torsion element of \( \Gamma^{gp} \) is invertible in \( A \). We have:

(i) \( (\text{i.c.}(A, B))[\Gamma^{gp}] = \text{i.c.}(A[\Gamma], B[\Gamma^{gp}]) \).

(ii) The grading of \( B \) restricts to a \( \Gamma \)-grading on the subring \( \text{i.c.}(A, B) \).

(iii) Suppose moreover that \( B \) is reduced. Then for every \( \gamma \in \Gamma \) such that \( \text{gr}_\gamma \text{i.c.}(A, B) \neq 0 \) there exists an integer \( m > 0 \) with \( \text{gr}_{m\gamma} A \neq 0 \).

**Proof.**

(i): We easily reduce to the case where \( \Gamma \) is finitely generated, in which case \( A[\Gamma^{gp}] \) is a smooth \( A \)-algebra (remark [7.6.11(iii)]), and the assertion follows from [49, Ch.IV, Prop.6.14.4].

(ii): Define \( \vartheta_A \) and \( \vartheta_B \) as in example [7.6.10(ii)], and consider the commutative diagram:

\[
\begin{array}{ccc}
A & \xrightarrow{\vartheta_A} & A[\Gamma] \\
\downarrow f & & \downarrow f[\Gamma] \\
B & \xrightarrow{\vartheta_B} & B[\Gamma].
\end{array}
\]

Say that \( b \in \text{i.c.}(A, B) \); then \( \vartheta_B(b) \in \text{i.c.}(A[\Gamma], B[\Gamma^{gp}]) \). In light of (i), we deduce that \( \vartheta_B(b) \in (\text{i.c.}(A, B))[\Gamma^{gp}] \cap B[\Gamma] = (\text{i.c.}(A, B))[\Gamma] \). The claim follows easily.

(iii): Let \( x \) be any non-zero element of \( \text{gr}_\gamma \text{i.c.}(A, B) \). By definition there exist an integer \( n > 0 \) and \( a_1, \ldots, a_n \in A \) such that \( x^n + a_1 x^{n-1} + \cdots + a_n = 0 \) in \( B \). For \( i = 1, \ldots, n \) let \( a'_i \) be the image of \( a_i \) under the projection \( A \rightarrow \text{gr}_{\gamma,i} A \); it is easily seen that \( x^n + a'_1 x^{n-1} + \cdots + a'_n = 0 \). If \( a'_i = 0 \) for every \( i = 1, \ldots, n \), we deduce that \( x^n = 0 \), which is absurd, since \( B \) is reduced. Thus, we have \( a'_m \neq 0 \) for at least one index \( m \leq n \), so \( \text{gr}_{m\gamma} A \neq 0 \). \( \Box \)

**Definition 7.6.16.** Let \( (\Gamma, +, 0) \) be an integral monoid, \( A := (A, \text{gr}_A) \) a \( \Gamma \)-graded \( \mathbb{Z} \)-algebra. Set \( \text{gr}^*_A := \text{gr}_A A \setminus \{0\} \) for every \( \gamma \in \Gamma \), and \( S^* := \bigcup_{\gamma \in \Gamma} \text{gr}^*_\gamma A \).

(i) We say that \( A \) is a \( * \)-domain if we have \( \text{gr}^*_\gamma A \cdot \text{gr}^*_\gamma A \subset \text{gr}^*_{\gamma + \gamma'} A \) for every \( \gamma, \gamma' \in \Gamma \).

(ii) We say that \( A \) is a \( * \)-field if \( A \neq 0 \) and every element of \( S^* \) is invertible in \( A \).

(iii) Notice that if \( A \) is a \( * \)-domain, then every element of \( S^* \) is regular in \( A \), and obviously \( S^* \) is a multiplicative subset of \( A \), so we have a unique \( \Gamma^{gp} \)-grading on

\[
\text{Frac}^*(A) := S^*^{-1} A
\]

such that the localization map \( A \rightarrow \text{Frac}^*(A) \) is a morphism of \( \Gamma^{gp} \)-graded \( \mathbb{Z} \)-algebras.

**Lemma 7.6.17.** Let \( A \) be a \( \Gamma \)-graded \( * \)-field, and \( M := (M, \text{gr}_M) \) a \( \Gamma \)-graded \( A \)-module. Then \( M \) is a free \( A \)-module, and it admits a basis consisting of homogeneous elements of \( M \).

**Proof.** Indeed, notice first that \( \text{gr}_0 A \) is a field, and \( \Gamma_0 := \{ \gamma \in \Gamma \mid \text{gr}^* A \neq 0 \} \) is an abelian group (with the addition law of \( \Gamma \)). Now, let \( \Lambda \subset \Gamma \) be a system of representatives for \( \Gamma/\Gamma_0 \) (say, with \( 0 \in \Lambda \)), and for every \( \lambda \in \Lambda \), pick a basis \( (m_{\lambda,i} \mid i \in I_\lambda) \) for the \( \text{gr}_0 A \)-vector space \( \text{gr}_\lambda M \). Let us show that \( \Sigma := (m_{\lambda,i} \mid \lambda \in \Lambda, i \in I_\lambda) \) is a basis for the \( A \)-module \( M \). To see that \( \Sigma \) is a generating family for \( M \), consider any \( \gamma \in \Gamma \) and any \( m \in \text{gr}_\gamma M \); then there exist \( \lambda \in \Lambda \) and \( \gamma' \in \Gamma_0 \) such that \( \gamma = \lambda + \gamma' \), and for any \( a \in \text{gr}_{\gamma'} A \) we have a \( \text{gr}_0 A \)-linear combination \( a^{-1} m = \sum_{i \in I} a_{\lambda,i} m_{\lambda,i} \) for a finite subset \( J \subset I_\lambda \). Thus \( m = \sum_{i \in I} a_{\lambda,i} m_{\lambda,i} \), whence the contention. Next, say that we have an \( A \)-linear relation of the form:

\[
\sum_{\lambda \in \Lambda} \sum_{i \in I_\lambda} a_{\lambda,i} m_{\lambda,i} = 0 \quad (\text{where } a_{\lambda,i} = 0 \text{ for all but finitely many indices } (\lambda, i))
\]

then it is easily seen that we have already \( a_{\lambda,i} m_{\lambda,i} = 0 \) for every \( \lambda \in \Lambda \). Then it also follows straightforwardly that \( \sum_{i \in I_\lambda} \text{gr}_\gamma (a_{\lambda,i}) m_{\lambda,i} = 0 \) for every \( \gamma \in \Gamma_0 \), where \( \text{gr}_\gamma (a_{\lambda,i}) \) denotes the image of \( a_{\lambda,i} \) under the projection \( A \rightarrow \text{gr}_\gamma A \). For every
such \( \gamma \), pick \( b_\gamma \in \text{gr}_\gamma A \); then we get the \( \text{gr}_{\gamma} A \)-linear relation
\[
\sum_{i \in I} b_\gamma^{-1} \text{gr}_{\gamma} (a_{\lambda,i}) m_{\lambda,i} = 0
\]
in \( \text{gr}_\lambda M \), and therefore \( \text{gr}_{\gamma} (a_{\lambda,i}) = 0 \) for every \( \lambda \in \Lambda \), every \( \gamma \in \Gamma_0 \) and every \( i \in I_\lambda \), i.e. \( a_{\lambda,i} = 0 \) for all such \( \lambda \) and \( i \), as required.

**Remark 7.6.18.** (i) For every \( \Gamma \)-graded \(*\)-domain \( A \), the \( \Gamma^{gp} \)-graded \( \mathbb{Z} \)-algebra \( \text{Frac}(\text{gr}_{\gamma} A) \) is a \(*\)-field, and the natural maps \( A \to \text{Frac}(\text{gr}_{\gamma} A) \to \text{Frac}(A) \) are injective (details left to the reader).

(ii) Let \( A \) and \( B \) be two \( \Gamma \)-graded \(*\)-domains, and \( f: A \to B \) an injective morphism of \( \Gamma \)-graded \( \mathbb{Z} \)-algebras. Then \( f \) extends to a unique morphism of \( \Gamma^{gp} \)-graded \( \mathbb{Z} \)-algebras \( \text{Frac}(\text{gr}_{\gamma} A) \to \text{Frac}(\text{gr}_{\gamma} B) \), and taking into account (i) and lemma 7.6.17, we see that \( \text{Frac}(\text{gr}_{\gamma} f) \) is a flat and injective ring homomorphism, hence it extends in turn uniquely to a flat and injective homomorphism of total rings of fractions \( \text{Frac}(f): \text{Frac}(A) \to \text{Frac}(B) \), by remark 7.6.14(ii).

(iii) Especially, let \( (A_\lambda := (A_\lambda, \text{gr}_{\lambda} A) | \lambda \in \Lambda) \) be a filtered system of \( \Gamma \)-graded \( \mathbb{Z} \)-algebras, with injective transition maps, such that \( A_\lambda \) is a \(*\)-domain for every \( \lambda \in \Lambda \). It follows easily that the colimit \( A \) of the filtered system of underlying rings \( (A_\lambda | \lambda \in \Lambda) \) carries a unique \( \Gamma \)-grading \( \text{gr}_\gamma A \) such that the natural ring homomorphism \( j_\lambda: A_\lambda \to A \) is a morphism of \( \Gamma \)-graded \( \mathbb{Z} \)-algebras \( A_\lambda \to A := (A, \text{gr}_{\gamma} A) \); moreover, \( A \) is also a \(*\)-domain, and the resulting cocone \( (A_\lambda \to A | \lambda \in \Lambda) \) is universal in the category of \( \Gamma \)-graded \( \mathbb{Z} \)-algebras (details left to the reader). Furthermore, according to (ii), for every \( \lambda, \mu \in \Lambda \) with \( \mu \geq \lambda \), the transition map \( A_\mu \to A_\lambda \) extends uniquely to a flat and injective ring homomorphism \( \text{Frac}(A_\lambda) \to \text{Frac}(A_\mu) \); similarly we get a unique flat and injective extension \( \text{Frac}(j_\lambda): \text{Frac}(A_\lambda) \to \text{Frac}(A) \) of \( j_\lambda \), for every \( \lambda \in \Lambda \). Then it is easily seen that the resulting cocone \( (\text{Frac}(j_\lambda) | \lambda \in \Lambda) \) is universal.

(iv) In the situation of (iii), suppose moreover that \( A_\lambda \) is nice for every \( \lambda \in \Lambda \). Then the same holds for \( A \). Indeed, from (iii) we deduce a natural identification of \( \text{Spec} \text{Frac}(A) \) with the inverse limit of the cofiltered system of topological spaces \( \text{Spec} \text{Frac}(A_\lambda) | \lambda \in \Lambda \). But it is easily seen that the limit of a cofiltered system of spectral spaces of dimension zero has dimension zero (details left to the reader), whence the contention.

**Proposition 7.6.19.** Let \( (\Gamma, +, 0) \) be an abelian group, \( A := (A_\lambda, \text{gr}_{\lambda} A) \) a \( \Gamma \)-graded \(*\)-field, \( p \geq 1 \) the characteristic exponent of the field \( \text{gr}_{\gamma} A \), and suppose that \( \Gamma \setminus \{0\} \) has no \( p \)-torsion elements. Then \( A \) is a nice reduced normal ring.

**Proof.** Clearly \( A \) is the filtered colimit of its \( \Gamma \)-graded \( \mathbb{Z} \)-subalgebras \( \Delta \times_\Gamma A \), where \( \Delta \) ranges over the finitely generated subgroups of \( \Gamma \). Moreover, \( A^\nu \) is the filtered union of its subrings \( (\Delta \times_\Gamma A)^\nu \). Taking into account remark 7.6.18(iv), we are thus easily reduced to the case where \( \Gamma \) is finitely generated, say \( \Gamma = \Delta_1 \oplus \cdots \oplus \Delta_k \), for cyclic abelian groups \( \Delta_1, \ldots, \Delta_k \). Furthermore, after replacing \( \Gamma \) by a subgroup, we may assume that \( \text{gr}_{\gamma} A \neq \emptyset \) for every \( \gamma \in \Gamma \), in which case it is easily seen that \( \text{gr}_{\gamma} A \) is a one-dimensional \( \text{gr}_{\gamma} A \)-vector space, for every \( \gamma \in \Gamma \) (details left to the reader), and we deduce an isomorphism of \( \text{gr}_{\gamma} A \)-algebras:
\[
(\Delta_1 \times_\Gamma A) \otimes_{\text{gr}_{\gamma} A} \cdots \otimes_{\text{gr}_{\gamma} A} (\Delta_k \times_\Gamma A) \cong A.
\]
In view of remark 7.6.14(iii) we are then reduced to checking:

**Claim 7.6.20.** If \( \Gamma \) is a cyclic abelian group, \( A \) is a smooth \( \text{gr}_{\gamma} A \)-algebra.

**Proof of the claim.** Let \( \gamma \) be a generator of \( \Gamma \); recall that \( \text{gr}_{\gamma} A \neq \emptyset \), and pick any \( a \in \text{gr}_{\gamma} A \). If \( \Gamma \to \mathbb{Z} \), then it is easily seen that the map \( P(T) \to P(a) \) yields an isomorphism of \( \text{gr}_{\gamma} A \)-algebras \( \text{gr}_{\gamma} A[T, T^{-1}] \cong A \). Lastly, say that \( \Gamma = \mathbb{Z}/n\mathbb{Z} \) for some \( n \in \mathbb{N} \setminus \{0\} \); by assumption \( n \) is invertible in \( \text{gr}_{\gamma} A \), and \( b := a^n \in \text{gr}_{\gamma} A \). Then the same rule yields an isomorphism of \( \text{gr}_{\gamma} A \)-algebras \( \text{gr}_{\gamma} A[T]/(T^n - b) \cong A \).

**Corollary 7.6.21.** Let \( \Gamma \) be a monoid, \( A := (A, \text{gr}_{\gamma} A) \) a \( \Gamma \)-graded \(*\)-domain and suppose that \( \Gamma^{gp} \) is a torsion-free abelian group. Then \( A \) is a domain.
Proof. In view of remark 7.6.18(i) we may replace $A$ by the $\Gamma^{sp}$-graded $\mathbb{Z}$-algebra $\text{Frac}^*(A)$, and assume from start that $\Gamma$ is a torsion-free abelian group, and $A$ is a $*$-field. Then $A$ is the filtered colimit of the system of $\Gamma$-graded $\mathbb{Z}$-subalgebras $\Delta \times \Gamma A$, where $\Delta$ ranges over the finitely generated subgroups of $\Gamma$, and it suffices to prove the assertion for such subalgebras. Thus, we may assume $\Gamma = \mathbb{Z}^{\geq r}$ for some $r \in \mathbb{N}$, and after replacing $\Gamma$ by a subgroup, we may even assume that $\text{gr}^\gamma A \neq \emptyset$ for every $\gamma \in \Gamma$. In this case, the proof of proposition 7.6.19 shows that $A$ is isomorphic to $\text{gr}_0 A[\Gamma^\pm_1, \ldots, \Gamma^\pm_r]$, whence the contention. □

Corollary 7.6.22. Let $\Gamma$ be an integral monoid, $A := (A, \text{gr} A)$ a $\Gamma$-graded $*$-domain, $\Gamma^\nu \subset \Gamma^{sp}$ the saturation of $\Gamma$, and assume that the order of any torsion element of $\Gamma^{sp}$ is invertible in $A$. Then there exists a unique $\Gamma^\nu$-grading $\text{gr}^\nu A^\nu$ on $A^\nu$ such that $(A^\nu, \text{gr}^\nu A^\nu)$ is a $\Gamma^\nu$-graded nice reduced $*$-domain, and the inclusion map $A \to A^\nu$ is a morphism of $\Gamma^\nu$-graded rings.

Proof. From proposition 7.6.19 and remark 7.6.18(i) we see that $A^\nu = \text{i.c.}(A, \text{Frac}^*(A))$. The corollary then follows straightforwardly from proposition 7.6.15 □

Proposition 7.6.23. Suppose that $(\Gamma', +) \to (\Gamma, +)$ is a morphism of fine monoids, $B$ a finitely generated (resp. finitely presented) $\Gamma$-graded $R$-algebra, and $M$ a finitely generated (resp. finitely presented) $\Gamma$-graded $B$-module. We have:

(i) $\Gamma' \times \Gamma B$ is a finitely generated (resp. finitely presented) $R$-algebra.
(ii) $\Gamma' \times \Gamma M$ is a finitely generated (resp. finitely presented) $\Gamma' \times \Gamma B$-module.
(iii) $\text{gr}^\nu M$ is a finitely generated (resp. finitely presented) $\text{gr}^\nu B$-module, for every $\gamma \in \Gamma$.

Proof. Let $B_M$ denote the direct sum $B \oplus M$, endowed with the $R$-algebra structure given by the rule:

$$(b_1, m_1) \cdot (b_2, m_2) = (b_1b_2, b_1m_2 + b_2m_1) \quad \text{for every } b_1, b_2 \in B \text{ and } m_1, m_2 \in M.$$ 

Notice that $B_M$ is characterized as the unique $R$-algebra structure for which $M$ is an ideal with $M^2 = 0$, the natural projection $B_M \to B$ is a map of $R$-algebras, and the $B$-module structure on $M$ induced via $\pi$ agrees with the given $B$-module structure on $M$.

Claim 7.6.24. The following conditions are equivalent:

(a) The $R$-algebra $B_M$ is finitely generated (resp. finitely presented).
(b) $B$ is a finitely generated (resp. finitely presented) $R$-algebra and $M$ is a finitely generated (resp. finitely presented) $B$-module.

Proof of the claim. (b)⇒(a): Suppose first that $B$ is a finitely generated $R$-algebra, and $M$ is a finitely generated $B$-module. Pick a system of generators $\Sigma_B := \{b_1, \ldots, b_s\}$ for $B$ and $\Sigma_M := \{m_1, \ldots, m_k\}$ for $M$. Then it is easily seen that $\Sigma_B \cup \Sigma_M$ generates the $R$-algebra $B_M$.

For the finitely presented case, pick a surjection of $R$-algebras $\varphi : R[T_1, \ldots, T_s] \to B$ and of $B$-module $\psi : B^{\otimes k} \to M$. Let $\Sigma'_B$ be a finite system of generators of the ideal $\text{Ker} \psi$. Pick also a finite system $b_1, \ldots, b_r$ of generators of the $B$-module $\text{Ker} \psi$; we may write $b_i = \sum_{j=1}^k b_{ij}e_j$ for certain $b_{ij} \in B$ (where $e_1, \ldots, e_k$ is the standard basis of $B^{\otimes k}$). For every $i \leq r$ and $j \leq k$, pick $P_{ij} \in \varphi^{-1}(b_{ij})$. It is easily seen that $B_M$ is isomorphic to the $R$-algebra $R[T_1, \ldots, T_s]/I$, where $I$ is generated by $\Sigma'_B \cup \{\sum_{j=1}^k P_{ij}T_{i+j} \mid i = 1, \ldots, r \cup \{T_{i+s}T_{s+j} \mid 0 \leq i, j \leq k\}$.

(a)⇒(b): Suppose that $B_M$ is a finitely generated $R$-algebra, and let $c_1, \ldots, c_n$ be a system of generators. For every $i = 1, \ldots, n$, we may write $c_i = b_i + m_i$ for unique $b_i \in B$ and $m_i \in M$. Since $M^2 = 0$, it is easily seen that $m_1, \ldots, m_n$ is a system of generators for the $B$-module $M$, and clearly $b_1, \ldots, b_r$ is a system of generators for the $R$-algebra $B$.

Next, suppose that $B_M$ is finitely presented over $R$. We may find a system of generators $b_1, \ldots, b_s, m_1, \ldots, m_k$ of $B_M$ with $b_i \in B$ and $m_j \in M$ for every $i \leq s$ and $j \leq k$. We deduce a surjection of $R$-algebras

$$\varphi : R[T_1, \ldots, T_{s+k}]/(T_{i+s}T_{s+j} \mid 0 \leq i, j \leq k) \to B_M$$
such that $T_i \mapsto b_i$ for every $i \leq s$ and $T_{j+s} \mapsto m_j$ for every $j \leq k$. It is easily seen that $\text{Ker } \varphi$ is generated by the classes of finitely many polynomials $P_1, \ldots, P_r$, where

$$P_i = Q_i(T_1, \ldots, T_s) + \sum_{j=1}^k T_{j+s} Q_{ij}(T_1, \ldots, T_s) \quad i = 1, \ldots, r$$

for certain polynomials $Q_i, Q_{ij} \in R[T_1, \ldots, T_s]$. It follows easily that $B = R[T_1, \ldots, T_s]/I$, where $I$ is the ideal generated by $Q_1, \ldots, Q_r$, and $M$ is isomorphic to the $B$-module $B^{\oplus k}/N$, where $N$ is the submodule generated by the system $\{\sum_{j=1}^k Q_{ij}(b_1, \ldots, b_s)e_j \mid i = 1, \ldots, r\}$.

Suppose now that $B$ is a finitely generated $R$-algebra; then $B$ is generated by finitely many homogeneous elements, say $b_1, \ldots, b_s$ of degrees respectively $\gamma_1, \ldots, \gamma_s$. Thus, we may define surjections of monoids

$$(7.6.25) \quad N^{\oplus s} \to \Gamma : e_i \mapsto \gamma_i \quad \text{for } i = 1, \ldots, s$$

(see remark 6.11(i)).

Claim 7.6.26. $P \times_{N^{\oplus s}} C$ is a finitely presented $R$-algebra.

Proof of the claim. Indeed, this $R$-algebra is none else than $R[P]$, hence the assertion follows from corollary 6.4.2 and lemma 6.1.7(i). \hfill \Box

From claim 7.6.26 it follows already that $B'$ is a finitely generated $R$-algebra. Now, suppose that $M$ is a finitely generated $B$-module, and set $M' := \Gamma' \times_B M$; notice that

$$(7.6.27) \quad \Gamma' \times_B (B_M) = B'_M.$$ 

In view of claim 7.6.24, we deduce that $M'$ is a finitely generated $B'$-module. Next, in case $B$ is a finitely presented $R$-algebra, $I$ is a finitely generated ideal of $C/I$; as we have just seen, this implies that $\Gamma' \times_B I$ is a finitely generated $(\Gamma' \times_B C/I)$-module, and then claim 7.6.26 shows that $B'$ is a finitely presented $R$-algebra. This concludes the proof of (i).

Lastly, if moreover $M$ is a finitely presented $B$-module, assertion (ii), together with (7.6.27) and claim 7.6.24 say that $M'$ is a finitely presented $B'$-module; thus, also assertion (ii) is proven.

(iii): For any given $\gamma \in \Gamma$, let us consider the morphism $j : N \to \Gamma$ such that $1 \mapsto \gamma$, and set $B' := N \times_B B$. By (i), the $R$-algebra $B'$ is finitely generated (resp. finitely presented), and the $B'$-module $M' := N \times_B M$ is finitely generated (resp. finitely presented). After replacing $B$ by $B'$ and $M$ by $M'$, we may then assume from start that $\Gamma = N$, and we are reduced to showing that $\text{gr}_B M$ is a finitely generated (resp. finitely presented) $\text{gr}_B B$-module.

Let $m_1, \ldots, m_t$ be a system of generators of $M$ consisting of homogeneous elements of degrees respectively $j_1, \ldots, j_t$. We endow $B^{\oplus t}$ with the $\mathbb{N}$-grading such that

$$\text{gr}_k B^{\oplus t} := \bigoplus_{i=1}^t \text{gr}_{k-j_i} B e_i$$

(where $e_1, \ldots, e_t$ is the standard basis of $B^{\oplus t}$); then the $B$-linear map $B^{\oplus t} \to M$ given by the rule $e_i \mapsto m_i$ for every $i = 1, \ldots, t$ is a morphism of $\mathbb{N}$-graded $B$-modules, and if $M$ is finitely presented, its kernel is generated by finitely many homogeneous elements $b_1, \ldots, b_s$. In the latter case, endow again $B^{\oplus s}$ with the unique $\mathbb{N}$-grading such that the $B$-linear map $\varphi : B^{\oplus s} \to B^{\oplus t}$ given by the rule $e_i \mapsto b_i$ for every $i = 1, \ldots, s$ is a morphism of $\mathbb{N}$-graded
$B$-modules. Now, in order to check that $\text{gr}_1 M$ is a finitely generated $\text{gr}_0 B$-module, it suffices to show that the same holds for $\text{gr}_1 B^{\text{st}}$. The latter is a direct sum of $\text{gr}_0 B$-modules isomorphic to either $\text{gr}_0 B$ or $\text{gr}_1 B$. Likewise, if $M$ is finitely presented, $\text{gr}_1 M = \text{Coker} \text{gr}_1 \varphi$, and again, $\text{gr}_1 B^{\text{st}}$ is a direct sum of $\text{gr}_0 B$-modules isomorphic to either $\text{gr}_0 B$ or $\text{gr}_1 B$; hence in order to check that $\text{gr}_1 M$ is a finitely presented $\text{gr}_0 B$-module, it suffices to show that $\text{gr}_1 B$ is a finitely presented $\text{gr}_0 B$-module. In either event, we are reduced to the case where $\Gamma = \mathbb{N}$ and $M = B$.

However, from (ii) we deduce especially that $\text{gr}_0 B = \{0\} \times \mathbb{N} B$ is a finitely generated (resp. finitely presented) $R$-algebra, hence $B$ is a finitely generated (resp. finitely presented) $B_0$-algebra as well; we may then assume that $R = \text{gr}_0 B$. Let $\Sigma$ be a system of homogeneous generators for the $R$-algebra $B$; we may then also assume that

\begin{equation}
\Sigma \cap \text{gr}_0 B = \emptyset.
\end{equation}

Then it is easily seen that the $R$-module $\text{gr}_1 B$ is generated by $\Sigma \cap \text{gr}_1 B$. Lastly, if $B$ is a finitely presented $R$-algebra, we consider the natural surjection $\psi : R[\Sigma] \to B$ from the free polynomial $R$-algebra generated by the set $\Sigma$, and endow $R[\Sigma]$ with the unique grading for which $\psi$ is a map of $\mathbb{N}$-graded $R$-algebras; then $I := \text{Ker} \psi$ is a finitely generated $\mathbb{N}$-graded ideal with $\text{gr}_0 I = 0$. As usual, we pick a finite system $\Sigma'$ of homogeneous generators for $I$; clearly $B_1$ is isomorphic to $\text{gr}_1 B_0[\Sigma]/\text{gr}_1 I$. On the other hand, \begin{equation}
(7.6.28)
\end{equation} easily implies that $\text{gr}_1 R[\Sigma]$ is a free $R$-module of finite rank, and moreover $\text{gr}_1 I$ is generated by $\Sigma' \cap \text{gr}_1 I$; especially, $\text{gr}_1 B$ is a finitely presented $R$-module in this case, and the proof is complete. \hfill \qed

7.6.29. Let $(\Gamma, +)$ be a monoid, $R$ a ring, $B := (B, \text{gr}_B)$ a $\Gamma$-graded $R$-algebra, and $M$ a $\Gamma$-graded $B$-module. We denote by $M[\gamma]$ the $\Gamma$-graded $B$-module whose underlying $B$-module is $M$, and whose grading is given by the rule:

$$\text{gr}_B M[-\gamma] := \bigoplus_{\delta + \gamma = \beta} \text{gr}_B M \quad \text{for every } \gamma \in \Gamma.$$ 

Remark 7.6.30. (i) In the situation of (7.6.29), pick any system $x := (x_i \mid i \in I)$ of homogeneous generators of $M$, and say that $x_i \in \text{gr}_\gamma M$ for every $i \in I$. Then we may define a surjective map of $\Gamma$-graded $B$-modules

$$L := \bigoplus_{i \in I} B[-\gamma_i] \to M : e_i \mapsto x_i \quad \text{for every } i \in I$$

where $(e_i \mid i \in I)$ denotes the canonical basis of the free $B$-module $L$ (notice that $e_i \in \text{gr}_\gamma L$ for every $i \in I$).

(ii) In case $M$ is a finitely generated $B$-module, we may pick a finite system $x$ as above, and then $L$ shall be a free $B$-module of finite rank.

(iii) Especially, suppose that $B$ is a coherent ring and $M$ is finitely presented as a $B$-module; then, in the situation of (ii), the kernel of the surjection $L \to M$ shall be again a finitely presented $\Gamma$-graded $B$-module, so we can repeat the above construction, and find inductively a resolution

$$\Sigma : \cdots \to L_n \xrightarrow{d_n} L_{n-1} \to \cdots \to L_0 \xrightarrow{d_0} M$$

such that $L_n$ is a free $B$-module of finite rank, and the map $d_n$ is a morphism of $\Gamma$-graded $B$-modules, for every $n \in \mathbb{N}$.

(iv) In the situation of (iii), suppose furthermore that $B$ is a flat $R$-algebra, in which case $\text{gr}_B B$ is a flat $R$-module, for every $\gamma \in \Gamma$. Then it is clear that the resolution $\Sigma$ yields, in each degree $\gamma \in \Gamma$ a flat resolution $\Sigma_\gamma$ of the $R$-module $\text{gr}_\gamma M$. 

7.7. **Differential graded algebras.** The material of this paragraph shall be applied in section 7.10 in order to study certain strictly anti-commutative graded algebras constructed via homotopical algebra. Especially, the graded algebras appearing in this paragraph are usually not commutative, unless it is explicitly said otherwise.

**Definition 7.7.1.** (i) Let $A$ be any ring, and $B := (B, \text{gr}_B)$ a $\mathbb{Z}$-graded (associative, unital) $A$-algebra. We say that $B$ is **strictly anti-commutative** (or alternating), if we have
\[
\begin{align*}
(a) \quad a \cdot b &= (-1)^{pq} \cdot b \cdot a \quad \text{for every } p, q \in \mathbb{Z}, \, a \in \text{gr}_p B, \, \text{and } b \in \text{gr}_q B \\
(b) \quad a \cdot a &= 0 \quad \text{for every } p \in \mathbb{Z} \text{ and every } a \in \text{gr}_{2p+1} B.
\end{align*}
\]
If only condition (a) holds, we say that $B$ is **anti-commutative**.

(ii) Let $M := (M, \text{gr}_M)$ be any $\mathbb{Z}$-graded $B$-bimodule. An $A$-linear graded derivation from $B$ to $M$ is a morphism of graded $A$-modules $\partial: B \to M$ such that
\[
\partial(xy) = \partial(x) \cdot y + x \cdot \partial(y) \quad \text{for every } x, y \in B.
\]

**Remark 7.7.2.** (i) Let $A$-$\text{Alt}$ be the full subcategory of the category of $\mathbb{Z}$-graded $A$-algebras, whose objects are the strictly anti-commutative graded $A$-algebras. Define also the category $A$-$\text{Alg}$-$\text{Mod}$ as in [59, Def.2.5.22]. We have an obvious functor
\[
\text{gr}_{0,1} : A$-$\text{Alt} \to A$-$\text{Alg}$-$\text{Mod} \quad (B, \text{gr}_B) \mapsto (\text{gr}_0 B, \text{gr}_1 B)
\]
and it is easily seen that the functor $\text{gr}_{0,1}$ is right adjoint to the functor
\[
\Lambda^{\bullet} : A$-$\text{Alg}$-$\text{Mod} \to A$-$\text{Alt} \quad (B, M) \mapsto \Lambda^{\bullet}_B M
\]
that assigns to every object $(B, M)$ the graded $A$-algebra of the $B$-linear exterior powers of $M$; the details shall be left to the reader.

(ii) For every pair of graded $A$-algebras $(B, \text{gr}_B), (B', \text{gr}_B')$ we define a tensor product
\[
(B'', \text{gr}_{B''}) := (B, \text{gr}_B) \otimes_A (B', \text{gr}_B')
\]
which is the graded $A$-algebra with $B'' := B \otimes B'$, and $\text{gr}_n B'' := \bigoplus_{i+j=n} \text{gr}_i B \otimes_A \text{gr}_j B'$ for every $n \in \mathbb{Z}$. The multiplication law of $B''$ is the direct sum of the maps
\[
(\text{gr}_i B \otimes A \text{gr}_{i} B') \times (\text{gr}_j B \otimes A \text{gr}_{j} B') \to \text{gr}_{i+j} B \otimes_A \text{gr}_{i+j} B' \quad (b \otimes b', c \otimes c') \mapsto (-1)^{ij} bc \otimes b'c'.
\]
It is easily seen that if $(B, \text{gr}_B)$ and $(B', \text{gr}_B')$ are anti-commutative (resp. alternating), the same holds for their tensor product. Moreover, if $(B, \text{gr}_B)$ and $(B', \text{gr}_B')$ are alternating, then $(B'', \text{gr}_{B''})$ represents the coproduct of $(B, \text{gr}_B)$ and $(B', \text{gr}_B')$ in the category $A$-$\text{Alt}$. Again, we leave the details to the reader.

(iii) Likewise, all finite coproducts are representable in $A$-$\text{Alg}$-$\text{Mod}$: namely, the coproduct of any two objects $(B, M), (B', M')$ is represented by:
\[
(B'', M'') := (B \otimes_A B', (M \otimes A B') \oplus (B \otimes A M'))
\]
with the obvious universal cocone $(B, M) \to (B'', M'') \leftarrow (B', M')$. By (i), (ii), and proposition 1.3.25(iv), we deduce a natural isomorphism of alternating graded $A$-algebras:
\[
\Lambda^{\bullet}_{B''} M'' \cong \Lambda^{\bullet}_B M \otimes_A \Lambda^{\bullet}_{B'} M'.
\]

**Definition 7.7.3.** Let $A$ be any ring.

(i) A **differential graded $A$-algebra** is the datum of
\[
\begin{itemize}
\item a complex $(B^{\bullet}, d^{\bullet}_B)$ of $A$-modules
\item an $A$-linear map $\mu^{pq}: B^p \otimes_A B^q \to B^{p+q}$ for every $p, q \in \mathbb{Z}$
\end{itemize}
\]
such that the following holds:

(a) Set $B := \bigoplus_{p \in \mathbb{Z}} B^p$; then the system of maps $\mu^{\bullet \bullet}$ adds up to a map $\mu : B \otimes_A B \to B$, and one requires that the resulting pair $(B, \mu)$ is an associative unital $\mathbb{Z}$-graded $A$-algebra. Then, one sets $a \cdot b := \mu(a \otimes b)$, for every $a, b \in B$. 

(b) We have the identities
\[ d_B^{p+q}(a \cdot b) = d_B^p(a) \cdot b + (-1)^p \cdot a \cdot d_B^q(b) \]
for every \( p, q \in \mathbb{Z} \) and every \( a \in B^p, b \in B^q \).

We call \( B \) the graded \( A \)-algebra associated to \( B^\bullet \). Then we also say that \( B^\bullet \) is anti-commutative (resp. strictly anti-commutative) if the same holds for \( B \) (definition \[7.7.1\]).

(ii) A morphism \( B^\bullet \to C^\bullet \) of differential graded \( A \)-algebras is a map of complexes of \( A \)-modules such that the induced map of associated graded \( A \)-modules is a map of \( A \)-algebras. We denote the resulting category of differential graded \( A \)-algebras by:
\[
A\text{-dgAlg}.
\]

We shall also consider the full subcategory of \( A\text{-dgAlg} \) denoted
\[
A\text{-dgAlt}
\]
whose objects are the strictly anti-commutative differential graded \( A \)-algebras.

(iii) Let \((B^\bullet, d_B^\bullet)\) be a differential graded \( A \)-algebra, \( B \) its associated graded \( A \)-algebra, and \((M^\bullet, d_M^\bullet)\) a complex of \( A \)-modules.

(a) We say that \( M^\bullet \) is a left \( B^\bullet \)-module if the \( A \)-module \( M := \bigoplus_{p \in \mathbb{Z}} M^p \) is a graded left \( B \)-module (for the natural \( \mathbb{Z} \)-grading on \( M \)), and we have
\[
d_M^{p+q}(b \cdot m) = (d^p_B b) \cdot m + (-1)^p \cdot b \cdot d^q_M(m)
\]
for every \( p, q \in \mathbb{Z} \), every \( b \in B^p \), and every \( m \in M^q \).

(b) We say that \( M^\bullet \) is a right \( B^\bullet \)-module if \( M \) is a graded right \( B \)-module, and we have
\[
d_M^{p+q}(m \cdot a) = d^q_M(m) \cdot a + (-1)^q \cdot m \cdot d^p_B(a)
\]
for every \( p, q \in \mathbb{Z} \), every \( b \in B^p \), and every \( m \in M^q \).

(c) We say that \( M^\bullet \) is a \( B \)-bimodule if it is both a left and right \( B^\bullet \)-module, and with these \( B^\bullet \)-modules structures, the \( A \)-module \( M \) becomes a \( B \)-bimodule (i.e. the left multiplication commutes with the right multiplication).

We call \( M \) the graded \( B \)-module associated to \( M^\bullet \). A morphism \( M^\bullet \to N^\bullet \) of left (resp. right, resp. bi-) \( B^\bullet \)-modules is a map of complexes of \( A \)-modules, such that the induced map of associated graded \( A \)-modules is a map of left (resp. right, resp. bi-) \( B \)-modules.

**Remark 7.7.4.** Let \( B^\bullet \) be any differential graded \( A \)-algebra.

(i) Notice that condition (b) of definition \[7.7.3\] is the same as saying that \( \mu^\bullet \) induces a map of complexes
\[
\mu^\bullet : B^\bullet \otimes_A B^\bullet \to B^\bullet.
\]
Moreover, in light of example \[7.1.16\], we see that \( B^\bullet \) is anti-commutative if and only if the diagram
\[
\begin{array}{ccc}
B^\bullet \otimes_A B^\bullet & \xrightarrow{\sim} & B^\bullet \otimes_A B^\bullet \\
\mu^\bullet & & \mu^\bullet \\
\downarrow & & \downarrow \\
B^\bullet & \xrightarrow{\mu^\bullet} & B^\bullet
\end{array}
\]
commutes, where the horizontal arrow is the isomorphism \[7.1.17\] that swaps the two tensor factors. Hence, in some sense this is actually a commutativity condition.

(ii) Likewise, if \( M^\bullet \) is a complex of \( A \)-modules with a graded left (right) \( B \)-module structure on the associated graded \( A \)-module \( M \), then \( M^\bullet \) is a left (resp. right) \( B^\bullet \)-module if and only if the scalar multiplication of the \( B \)-module \( M \) induces a map of complexes
\[
B^\bullet \otimes_A M^\bullet \to M^\bullet \quad (\text{resp. } M^\bullet \otimes_A B^\bullet \to M^\bullet).
\]

(iii) It is easily seen that the multiplication maps \( \mu^{pq} \) induce \( A \)-linear maps
\[
(H^p B^\bullet) \otimes_A (H^q B^\bullet) \to H^{p+q} B^\bullet \quad \text{for every } p, q \in \mathbb{Z}
\]
and if we let $H^\bullet B^\bullet := \bigoplus_{p\in\mathbb{Z}} H^p B^p$, then the resulting map
\[(H^\bullet B^\bullet) \otimes_A (H^\bullet B^\bullet) \to H^\bullet B^\bullet\]
endows $H^\bullet B^\bullet$ with a structure of $\mathbb{Z}$-graded associative unital $A$-algebra, which shall be strictly anti-commutative whenever the same holds for $B^\bullet$. Likewise, if $M^\bullet$ is any left (resp. right, resp. bi) $B^\bullet$-module, then $H^\bullet M^\bullet$ is naturally a $\mathbb{Z}$-graded left (resp. right, resp. bi) $H^\bullet B^\bullet$-module.

(iv) Let $M^\bullet$ be a left $B^\bullet$-module, and denote by $\mu_{M}^{pq} : B^p \otimes_A M^q \to M^{p+q}$ the $(p, q)$-graded component of the scalar multiplication of $M^\bullet$, for every $p, q \in \mathbb{Z}$. Then $M^\bullet[1]$ is also naturally a left $B^\bullet$-module, with scalar multiplication $\mu^{pq}_{M[1]}$ given by the rule:
\[\mu_{M[1]}^{pq} := (-1)^p \cdot \mu_{M}^{p,q+1}\]
for every $p, q \in \mathbb{Z}$. Likewise, if $N^\bullet$ is a right $B^\bullet$-module, with scalar multiplication $\mu_{N}^{pq}$, then $N^\bullet[1]$ is naturally a right $B^\bullet$-module, with multiplication $\mu_{N[1]}^{pq}$ given by the rule:
\[\mu_{N[1]}^{pq} := \mu_{N}^{p,q+1}\]
for every $p, q \in \mathbb{Z}$.

Lastly, if $P^\bullet$ is a $B^\bullet$-bimodule, then the left and right $B^\bullet$-module structure defined above on $P^\bullet[1]$, amounts to a natural $B$-bimodule structure on $P^\bullet[1]$.

(v) Let $C^\bullet$ be any $\mathbb{Z}$-graded $A$-algebra, $N^\bullet$ any $\mathbb{Z}$-graded left (resp. right, resp. bi-) $B$-module. We let $N[1]^\bullet$ be the graded $A$-module given by the rule $N[1]^p := N^{p+1}$ for every $p \in \mathbb{Z}$. We shall always view $N[1]^\bullet$ as a left (resp. right, resp. bi-) $B$-module, via the scalar multiplications obtained from those of $N^\bullet$, following the rules spelled out in (iv). This ensures that the functor from $B^\bullet$-modules to $H^\bullet B^\bullet$-modules that assigns to any $B^\bullet$-module $M^\bullet$ its homology $H^\bullet M^\bullet$, is compatible with shift operators.

7.7.5. Let $A$ be ring, $(B^\bullet, d_B)$ any differential graded $A$-algebra, and $I^\bullet \subset B^\bullet$ a (graded) two-sided ideal of $B^\bullet$ (i.e. a bi-submodule of the $B^\bullet$-bimodule $B^\bullet$). Let \[\partial : H^\bullet(B^\bullet/I^\bullet) \to H^\bullet I^\bullet[1]\]
denote the natural map induced by the short exact sequence of complexes \[0 \to I^\bullet \to B^\bullet \to B^\bullet/I^\bullet \to 0.\]
We have:

**Lemma 7.7.6.** In the situation of (7.7.5), the map $\partial$ is an $A$-linear graded derivation of the graded $A$-algebra $H^\bullet(B^\bullet/I^\bullet)$.

**Proof.** Indeed, let $a$ and $b$ be any two cycles of the complex $B^\bullet/I^\bullet$ in degree $p$ and $q$, and $\pi, \bar{b}$ the respective classes; lift $a$ and $b$ to some elements $\tilde{a} \in B^p$ and $\tilde{b} \in B^q$, so that $\partial(\tilde{a} \cdot \tilde{b})$ is the class in $H^{p+q+1}I^\bullet$ of $d_B(\tilde{a} \cdot \tilde{b}) = d_B(\tilde{a}) \cdot \tilde{b} + (-1)^p \cdot \tilde{a} \cdot d_B(\tilde{b})$. Since $d_B(\tilde{a})$ (resp. $d_B(\tilde{b})$) represents the class of $\partial(\pi)$ (resp. $\partial(\bar{b})$), the assertion follows from the explicit description of the bimodule structure on $I^\bullet[1]$ provided by remark 7.7.4(iv). \[\square\]

**Remark 7.7.7.** Let $B^\bullet$ and $C^\bullet$ be two differential graded $A$-algebras, and denote by $B$ and $C$ the respective associated graded $A$-algebras. As in remark 7.7.2(ii), we may endow $B \otimes_A C$ with a natural structure of graded $A$-algebra. In terms of morphisms of complexes, the multiplication law of $B \otimes_A C$ then corresponds to the composition
\[(B^\bullet \otimes_A C^\bullet) \otimes_A (B^\bullet \otimes_A C^\bullet) \tilde{\to} (B^\bullet \otimes_A B^\bullet) \otimes_A (C^\bullet \otimes_A C^\bullet) \xrightarrow{\mu_B^\circ \otimes \mu_C^\circ} B^\bullet \otimes_A C^\bullet\]
where the first isomorphism is obtained by composing the associativity isomorphisms of example 7.1.16(ii) and the isomorphisms 7.1.17 that swap the tensor factors. Here $\mu_B^\circ$ and $\mu_C^\circ$ are the multiplication maps of $B^\bullet$ and $C^\bullet$. Thus, we obtain on the complex $B^\bullet \otimes_A C^\bullet$ a natural structure of differential graded $A$-algebra, and taking into account remark 7.7.2(ii) it is easily
seen that if $B^\bullet$ and $C^\bullet$ are strictly anti-commutative, then $B^\bullet \otimes_A C^\bullet$ represents the coproduct of $B^\bullet$ and $C^\bullet$ in $A$-dgAlt.

7.7.8. Suppose now that both $B^\bullet$ and $C^\bullet$ are bounded above complexes; presumably, in this case there is a canonical way to define a differential graded algebra structure as well on (suitable representatives for)

$$D^\bullet := B^\bullet \otimes_A C^\bullet$$

in such a way that this structure is well defined as an object of the derived category of $A$-dgAlg (the latter should be, as usual, the localization of $A$-dgAlg, by the multiplicative system of quasi-isomorphisms). More modestly, we shall endow the graded $A$-module $H_*D^\bullet$ with a natural structure of associative graded $A$-algebra, in such a way that the natural map

$$H_*D^\bullet := \bigoplus_{i \in \mathbb{Z}} \text{Tor}^A_i(B^\bullet, C^\bullet) \to H_*(B^\bullet \otimes_A C^\bullet)$$

is a morphism of graded $A$-algebras. The multiplication of $H^\bullet D^\bullet$ is defined as the composition

$$H_iD^\bullet \otimes_A H_jD^\bullet \xrightarrow{\alpha} \text{Tor}^A_{i+j}(B^\bullet \otimes_A B^\bullet, C^\bullet \otimes_A C^\bullet) \xrightarrow{\mu} H_{i+j}D^\bullet$$

for every $i, j \in \mathbb{Z}$ where $\alpha$ is the bilinear pairing provided by (7.3.38), and with $\mu := \text{Tor}^A_{i+j}(\mu_{B^\bullet}, \mu_{C^\bullet})$.

Let us check first that the foregoing rule does define an associative multiplication on $H_*D^\bullet$. To this aim, set $B^\bullet := B^\bullet \otimes_A B^\bullet$, $B^\bullet := B^\bullet \otimes A B^\bullet$ and define likewise $C^\bullet$ and $C^\bullet$; a little diagram chase, together with (7.3.39), reduces to verifying the commutativity of the diagram

\[
\begin{array}{ccc}
\text{Tor}^A_i(B^2_2, C^2_2) & \otimes_A H_jD^\bullet & \xrightarrow{\mu \otimes_A h_1d^\bullet} H_iD^\bullet \otimes_A H_jD^\bullet \\
\downarrow & & \downarrow \\
\text{Tor}^A_{i+j}(B^2_3, C^2_3) & \xrightarrow{\gamma} & \text{Tor}^A_{i+j}(B^2_2, C^2_2) \\
\downarrow & & \downarrow \\
\text{Tor}^A_{i+j}(B^2_3, C^2_3) & \xrightarrow{\delta} & \text{Tor}^A_{i+j}(B^2_3, C^2_3)
\end{array}
\]

whose vertical arrows are the bilinear pairings of (7.3.38), and with

$$\gamma := \text{Tor}^A_{i+j}(\mu_{B^\bullet} \otimes_A 1_{B^\bullet}, \mu_{C^\bullet} \otimes_A 1_{C^\bullet}) \quad \delta := \text{Tor}^A_{i+j}(1_{B^\bullet} \otimes_A \mu_{B^\bullet}, 1_{C^\bullet} \otimes_A \mu_{C^\bullet}).$$

We show the commutativity of the left subdiagram; the same argument applies to the right one. Unwinding the definitions, we come down to checking the commutativity, in $D(A\text{-Mod})$, of the diagram of complexes

\[
\begin{array}{ccc}
(P^\bullet_2 \otimes_A C^\bullet) & \otimes_A (P^\bullet_2 \otimes_A C^\bullet) & \xrightarrow{\varphi_{12,3} \otimes 1_{C^\bullet}} P^\bullet_3 \otimes_A C^\bullet \\
\downarrow \varphi^\bullet & \downarrow \varphi^\bullet & \downarrow \varphi^\bullet \\
(P^\bullet_2 \otimes_A C^\bullet) & \otimes_A (P^\bullet_2 \otimes_A C^\bullet) & \xrightarrow{\varphi_{12,3} \otimes 1_{C^\bullet}} P^\bullet_3 \otimes_A C^\bullet
\end{array}
\]

(note of (7.3.36), with $\varphi^\bullet := (P^\bullet_2 \otimes_A \mu_{C^\bullet}) \otimes_A 1_{P^\bullet_2 \otimes_A C^\bullet}$ and $\eta^\bullet := P^\bullet_{\mu_B} \otimes_A 1_{P^\bullet_{\mu_{B^\bullet}}} \otimes_A (\mu_{C^\bullet} \otimes_A 1_{C^\bullet})$, and where $\varphi_{12,3}$ and $\varphi_{12,31}$ are as in (7.3.38) (and with the isomorphisms given by compositions of associativity and swapping isomorphisms). A direct inspection shows that this diagram commutes up to homotopy, as required.

Next, we check that (7.7.9) is a map of graded $A$-algebras. Unwinding the definitions, we see that – with the notation of (7.3.38) – the multiplication of $H_*D^\bullet$ is the map on homology induced by the composition

\[
(P^\bullet_2 \otimes_A C^\bullet) \otimes_A (P^\bullet_2 \otimes_A C^\bullet) \xrightarrow{\varphi_{12} \otimes 1_{C^\bullet}} (P^\bullet_2 \otimes_A P^\bullet_2) \otimes_A C^\bullet \xrightarrow{\varphi_{12} \otimes 1_{C^\bullet}} P^\bullet_2 \otimes A C
\]

where the first isomorphism is again a composition of associativity isomorphisms and isomorphisms that swap the factors; the second map is $\varphi_{12} : P^\bullet_2 \otimes A P^\bullet_2 \to P^\bullet_2$ is defined as in (7.3.38). The last map is $P^\bullet_{\mu_B} \otimes A 1_{C^\bullet}$, where $P^\bullet_{\mu_B}$ is given by (7.3.36). Since the
we deduce a natural map of complexes and taking into account propositions 7.4.55 and 7.4.58, it is easily seen that

$$\varphi^{\star}_{12} \circ A \mu_C$$

$$B_2 \otimes_A C_2^\star$$

$$B^\star \otimes_A C^\star$$

$$P^\star_B \otimes_A C^\star$$

The latter is further reduced to the commutativity of

$$\varphi^{\star}_{12}$$

$$\mu_B$$

$$B_2$$

$$B^\star$$

$$\rho_B$$

$$P^\star_B$$

But a simple inspection shows that this diagram indeed commutes up to homotopy.

Lastly, we claim that if $B^\star$ and $C^\star$ are both anti-commutative, then the same holds for $H_\star D^\star$. Indeed, consider the diagram

$$\varphi^{\star}_{12} \circ A \mu_C$$

$$B_2 \otimes_A C_2^\star$$

$$B^\star \otimes_A C^\star$$

$$P^\star_B \otimes_A C^\star$$

(The upper isomorphism is obtained from the automorphism of $P^\star_B \otimes_A P^\star_B$ that swaps the two factors, and from the automorphism of $C_2^\star$ of the same type; likewise for the lower isomorphism.) The assumption on $B^\star$ and $C^\star$ says that the inner triangular subdiagram commutes, and the same holds – up to homotopy – for the upper and the left and right subdiagrams, by a simple inspection. Then also the outer rectangular subdiagram commutes up to homotopy, and the contention follows easily.

Remark 7.7.10. (i) Simplicial $A$-algebras are an important source of differential graded algebras, thanks to the following construction. Let $R$ be any simplicial $A$-algebra, $R_\star$ the associated chain complex of $A$-modules, and denote by $\mu_R : R \otimes_A R \rightarrow R$ the multiplication map of $R$. By considering the shuffle map for the bisimplicial $A$-module $R \boxtimes_A R$ (notation as in (7.4.54)), we deduce a natural map of complexes

$$\mu_R : R_\star \otimes_A R_\star \rightarrow (R \otimes_A R)_\star \rightarrow (\mu_R)_\star \rightarrow R_\star$$

and taking into account propositions 7.4.55 and 7.4.58, it is easily seen that $(R_\star, \mu_R_\star)$ is a strictly anti-commutative differential graded algebra. By remark 7.7.4(iii), we deduce that the graded $A$-module $H_\star R := \bigoplus_{p \in \mathbb{N}} H_p R$ is naturally an $\mathbb{N}$-graded associative unital and strictly anti-commutative $A$-algebra.

(ii) Likewise, if $M$ is any $R$-module, then we obtain on the associated chain complex $M_\star$ a natural structure of $R_\star$-bimodule, so that $H_\star M$ is naturally a graded $H_\star R$-bimodule.
(iii) Clearly, a morphism \( \varphi : R \to S \) of simplicial \( A \)-algebras induces a morphism \( \varphi_* : R_* \to S_* \) of differential graded \( A \)-algebras, and a morphism \( f : M \to N \) of \( R \)-modules induces a morphism \( \varphi_* : M_* \to N_* \) of \( R_* \)-bimodules.

7.8. Koszul algebras and regular sequences. For any ring \( A \), let us consider the category

\[ A\text{-dAlg.Mod} \]

whose objects are the triples \((B, M, \partial)\), where \( B \) is an \( A \)-algebra, \( M \) is a \( B \)-module, and \( \partial : M \to B \) is an \( A \)-linear map. The morphisms \((B, M, \partial) \to (B', M', \partial')\) in \( A\text{-dAlg.Mod} \) are the pairs \((f, g)\) where \( f : B \to B' \) is a map of \( A \)-algebras, and \( g : B' \otimes_B M \to M' \) is a \( B' \)-linear map, such that

\[ f \circ \partial(m) = \partial' \circ g(1 \otimes m) \quad \text{for every } m \in M \]

with the obvious composition law for such morphisms. We have a natural functor:

\[ \text{induces a morphism } \phi \]

Remark 7.8.1. (i) In light of remark [7.7.2]iii), it is easily seen that the coproduct of any two objects \((B, M, \partial)\) and \((B', M', \partial')\) of \( A\text{-dAlg.Mod} \) is representable by the object

\[ (B'' := B \otimes_A B', M'' := (M \otimes_A B') \oplus (B \otimes_A M'), \partial'') \]

where \( \partial'' : M'' \to B'' \) is the \( A \)-linear map such that

\[ \partial''(m \otimes b', b \otimes m') := \partial(m) \otimes b' + b \otimes \partial'(m') \quad \text{for every } m \in M, m' \in M', b \in B, b' \in B'. \]

Combining with remark [7.7.7] and proposition [1.3.25]iv), we deduce a natural isomorphism:

\[ K_*(B'', M'', \partial'') \sim K_*(B, M, \partial) \otimes_A K_*(B', M', \partial') \quad \text{in } A\text{-dgAlt} \]

(ii) Let \( f := (f_1, \ldots, f_r) \) be a finite sequence of elements of \( A \), and \( I \subset A \) the ideal generated by \( f \); let also \( \partial_f : A^{gr} \to A \) be the \( A \)-linear form such that \( \partial_f(a_1, \ldots, a_r) := \sum_{i=1}^r f_i a_i \) for every \( a_1, \ldots, a_r \in A \). The Koszul complex of the sequence \( f \) is the complex:

\[ K_*(f) := K_*(A, A^{gr}, \partial_f) \]

(see [46] Ch.III, §1.1]). Thus, for \( r = 1 \), so that \( f = (f) \) for a single element \( f \in A \), we have

\[ K_*(f) = (0 \to A \xrightarrow{f} A \to 0) \]

concentrated in homological degrees 0 and 1. In the general case, combining with (i) we get a natural isomorphism:

\[ K_*(f) \sim K_*(f_1) \otimes_A \cdots \otimes_A K_*(f_r) \quad \text{in } A\text{-dgAlt} \]

(iii) For every complex of \( A \)-modules \( M^* \), we also use the customary notation:

\[ K_*(f, M^*) := M^* \otimes_A K_*(f) \quad K^*(f, M^*) := \text{Tot}^*(\text{Hom}^*_A(K_*(f), M^*)) \]
and denote by $H_\ast(f, M^\ast)$ (resp. $H^\ast(f, M^\ast)$) the homology of $K_\ast(f, M^\ast)$ (resp. the cohomology of $K^\ast(f, M^\ast)$). Especially, if $M$ is any $A$-module:

$$H_0(f, M) = M/IM \quad H^0(f, M) = \text{Hom}_A(A/I, M) = \text{Ann}_M(I)$$

(where, as usual, we regard $M$ as a complex placed in degree 0).

**Lemma 7.8.2.** With the notation of remark [7.8.1] iii, let $g : A \to B$ be a ring homomorphism, and $M^\ast$ (resp. $N^\ast$) a complex of $A$-modules (resp. $B$-modules). The following holds:

(i) For every $x \in I$, scalar multiplication by $x$ induces the zero endomorphism on the objects $K_\ast(f, M^\ast)$ and $K^\ast(f, M^\ast)$ of $\text{Hot}(A\text{-Mod})$.

(ii) Especially, $H_i(f, M^\ast)$ and $H^i(f, M^\ast)$ are $A/I$-modules, for every $i \in \mathbb{Z}$.

(iii) If $I = A$, the complexes $K_\ast(f, M^\ast)$ and $K^\ast(f, M^\ast)$ are homotopically trivial.

(iv) Denote by $g(f)$ the image in $B$ of the sequence $f$. Then we have natural identifications

$$K_\ast(f, N^\ast) \xrightarrow{\sim} K_\ast(g(f), N^\ast) \quad K^\ast(f, N^\ast) \xrightarrow{\sim} K^\ast(g(f), N^\ast) \quad \text{in } C(B\text{-Mod}).$$

(v) We have a natural isomorphism

$$K^\ast(f, M^\ast) \xrightarrow{\sim} K^\ast(f, M^\ast)[-r] \quad \text{in } C(A\text{-Mod}).$$

**Proof.** (i): It suffices to notice that scalar multiplication by $f$ induces the zero endomorphism of $K_\ast(f)$, for every $f \in A$ : indeed, a homotopy from $f \cdot 1_{K_\ast(f)}$ to the zero endomorphism is given by the system of maps $(s_n | n \in \mathbb{N})$ with $s_n := 0$ for $n \neq 0$, and $s_0 := 1_A$.

(ii) and (iii) are immediate consequences of (i), and (iv) follows directly from the definitions.

(v): Recall that for every free $A$-module $L$ of finite rank and every $A$-module $M$ we have a natural isomorphism of $A$-modules

$$\text{Hom}_A(L, M) \xrightarrow{\sim} L^\vee \otimes_A M \quad \text{where } L^\vee := \text{Hom}_A(L, A).$$

There follows, for every complex $L_\ast$ of free $A$-modules of finite rank, a natural isomorphism

$$\text{Hom}_A^\ast(L_\ast, M^\ast) \xrightarrow{\sim} L_\ast^\vee \otimes_A M^\ast \quad \text{in } C_2(A\text{-Mod})$$

(notation of example [7.1.16] i)). Moreover, for any two free $A$-modules of finite rank $L_1$ and $L_2$ we have as well a natural isomorphism

$$(L_1 \otimes_A L_2)^\vee \xrightarrow{\sim} L_1^\vee \otimes_A L_2^\vee$$

whence, for any complexes $L_1,\ast$ and $L_2,\ast$ of free $A$-modules of finite rank, a natural isomorphism

$$(L_1,\ast \otimes_A L_2,\ast)^\vee \xrightarrow{\sim} L_1,\ast^\vee \otimes_A L_2,\ast^\vee \quad \text{in } C_2(A\text{-Mod}).$$

Summing up, it then suffices to observe that there is a natural isomorphism

$$K_\ast(f) \xrightarrow{\sim} K_\ast(f)^\vee[1] \quad \text{in } C(A\text{-Mod})$$

for every $f \in A$. \qed

7.8.3. Let $A$ be a ring, $f := (f_1, \ldots, f_r)$ a sequence of elements of $A$, and $f' := (f_1, \ldots, f_{r-1})$; let also $I \subset A$ (resp. $I' \subset A$) be the ideal generated by the sequence $f$ (resp. by $f'$). We have a short exact sequence of complexes: $0 \to A[0] \to K_\ast(f_r) \to A[1] \to 0$, and after tensoring with $K_\ast(f')$, in view of remark [7.8.1] ii) we get a distinguished triangle:

$$K_\ast(f') \to K_\ast(f) \to K_\ast(f')[1] \xrightarrow{\partial} K_\ast(f')[1].$$

By inspecting the definitions one checks easily that the boundary map $\partial$ is induced by multiplication by $f_r$. There follow exact sequences:

$$(7.8.4) \quad 0 \to H_0(f_r, H_p(f', M)) \to H_p(f, M) \to H^0(f_r, H_{p-1}(f', M)) \to 0$$

for every $A$-module $M$ and for every $p \in \mathbb{N}$, and together with remark [7.8.1] iii), we deduce:
Lemma 7.8.5. With the notation of (7.8.3), the following conditions are equivalent:

(a) \( H_i(f, M) = 0 \) for every \( i > 0 \).

(b) The scalar multiplication by \( f_r \) is a bijection on \( H_i(f', M) \) for every \( i > 0 \), and is an injection on \( M/f'M \).

Definition 7.8.6. We say that the sequence \( f := (f_1, \ldots, f_r) \) of elements of \( A \) is completely secant on the \( A \)-module \( M \), if we have \( H_i(f, M) = 0 \) for every \( i > 0 \).

The interest of definition 7.8.6 is due to its relation to the notion of regular sequence of elements of \( A \) (see e.g. [29, Ch.X, §9, n.6]). Namely, we have the following criterion:

Proposition 7.8.7. With the notation of (7.8.3), the following conditions are equivalent:

(a) The sequence \( f \) is \( M \)-regular.

(b) For every \( j \leq r \), the sequence \( (f_1, \ldots, f_j) \) is completely secant on \( M \).

Proof. Lemma 7.8.5 shows that (b) implies (a). Conversely, suppose that (a) holds; we show that (b) holds, by induction on \( r \). If \( r = 0 \), there is nothing to prove. Assume that the assertion is already known for all \( j < r \). Since \( f \) is \( M \)-regular by assumption, the same holds for the subsequence \( f' := (f_1, \ldots, f_{r-1}) \), and \( f_r \) is regular on \( M/(f')M \). Hence \( H_p(f', M) = 0 \) for every \( p > 0 \), by inductive assumption. Then lemma 7.8.5 shows that \( H_p(f, M) = 0 \) for every \( p > 0 \), as claimed.

Notice that any permutation of a completely secant sequence is again completely secant, whereas a permutation of a regular sequence is not always regular. As an application of the foregoing, we point out the following:

Corollary 7.8.8. With the notation of (7.8.3), the following holds:

(i) If a sequence \( (f, g) \) of elements of \( A \) is \( M \)-regular, and \( M \) is \( f \)-adically separated, then \( (g, f) \) is \( M \)-regular.

(ii) If \((n_1, \ldots, n_r)\) is any sequence of strictly positive integers, then \( f \) is completely secant on \( M \) (resp. \( M \)-regular) if and only if the same holds for the sequence \((f_{1}^{n_1}, \ldots, f_{r}^{n_r})\).

Proof. (i): According to proposition 7.8.7, we only need to show that the sequence \( (g) \) is completely secant, i.e. that \( g \) is regular on \( M \). Hence, suppose that \( gm = 0 \) for some \( m \in M \); it suffices to show that \( m \in f'M \) for every \( n \in \mathbb{N} \). We argue by induction on \( n \). By assumption \( g \) is regular on \( M/f'M \), hence \( m \in f'M \), which shows the claim for \( n = 1 \). Let \( n > 1 \), and suppose we already know that \( m = f^{n-1}m' \) for some \( m' \in M \). Hence \( 0 = g(f^{n-1}m') \), so \( gm' = 0 \) and the foregoing case shows that \( m' = fm'' \) for some \( m'' \in M \), thus \( m = f^{n}m'' \), as required.

(ii): We deal first with the assertion for completely secant sequences. First, notice that, since every permutation of a completely secant sequence is still completely secant, it suffices to show the assertion for the sequence of integers \((1, 1, \ldots, 1, n_r)\). However, set \( f' := (f_1, \ldots, f_{r-1}) \); by lemma 7.8.5, \( f \) is completely secant if and only if scalar multiplication by \( f_r \) is a bijection on \( H_i(f', M) \) for every \( i > 0 \), and an injection on \( M/(f')M \). But \( f_r \) fulfills the latter conditions if and only if \( f_r^{n_r} \) does, whence the contention. The assertion for \( M \)-regular sequences follows from the foregoing, in view of proposition 7.8.7.

7.8.9. Let \( A \) be a ring, \( f := (f_1, \ldots, f_r) \) a completely secant sequence of elements of \( A \) (see definition 7.8.6); denote by \( J \) the ideal generated by \( f \), and set \( A_0 := A/J \). We may regard the complex \( A_0[0] \) as an (especially simple) differential graded \( A \)-algebra, with multiplication \( p^* \) deduced from that of \( A_0 \), in the obvious way. We may then state:

Proposition 7.8.10. In the situation of (7.8.9), the \( A_0 \)-module \( J/J^2 \) is free of rank \( r \), and there exists a unique isomorphism of strictly anti-commutative graded \( A \)-algebras

\[
\Lambda^*_{A_0}(J/J^2) \xrightarrow{\sim} H_*(A_0[0] \otimes_A A_0[0])
\]

(i) is an isomorphism.

Proof. By assumption, the Koszul complex, with its natural augmentation, yields a resolution
\[ \varepsilon^\bullet : K_* (f) \to A_0 [0] \]
by free \( A \)-modules. Hence, there is a unique isomorphism \( \omega^\bullet : P^\bullet_{A_0} \sim \to K_* (f) \) in \( \mathbb{D} (A - \text{Mod}) \), whose composition with \( \varepsilon^\bullet \) agrees with \( \rho^\bullet_{A_0} \) (notation of (7.3.36)). Then \( \varepsilon^\bullet \) is a map of differential graded \( A \)-algebras, and we easily deduce a commutative diagram in \( \mathbb{D} (A - \text{Mod}) \)
\[
\begin{array}{ccc}
P^\bullet_{A_0} \otimes_A & P^\bullet_{A_0} & P^\bullet_{A_0} \\
\omega^{\bullet \otimes_A} & \downarrow & \downarrow \\
K^\bullet (f) & \to & K^\bullet (f)
\end{array}
\]
whose bottom horizontal arrow is the multiplication map of \( K^\bullet (f) \), and where \( P^\bullet_{A_0} \) is defined as in (7.3.36). We conclude that \( \omega^\bullet \) induces an isomorphism of anti-commutative graded \( A \)-algebras
\[ H_* (A_0 [0] \otimes_A A_0 [0]) \sim \to K_* (f, A_0 [0]) \sim \to H_* ((\Lambda^\bullet_A (A^{\oplus r}), d_{f,*}) \otimes_A A_0). \]
By simple inspection, we see that \( d_{f, i} \otimes_A 1_{A_0} = 0 \) for every \( i \in \mathbb{Z} \), whence an isomorphism of strictly anti-commutative \( A \)-graded algebras:
\[ H_* ((\Lambda^\bullet_A (A^{\oplus r}), d_{f,*}) \otimes_A A_0) \sim A^\bullet_{A_0} (A^{\oplus r}). \]
Combining with (7.8.12), we obtain in degree one a natural isomorphism
\[ \Lambda^1_{A_0} (A^{\oplus r}) = A^{\oplus r} \sim \to \text{Tor}_1^A (A_0, A_0) \sim \to J/J^2 \]
which, finally, delivers the sought isomorphism of differential graded \( A \)-algebras. The uniqueness of (7.8.11) is clear, since the exterior algebra is generated by its degree one summand. \( \square \)

Definition 7.8.13. Let \( A \) be a ring, \( f := (f_1, \ldots, f_r) \) a finite sequence of elements of \( A \), and \( M \) an \( A \)-module. Set also \( R := \mathbb{Z}[T_1, \ldots, T_r] \), let \( I \subset R \) (resp. \( J \subset A \)) be the ideal generated by \( T := (T_1, \ldots, T_r) \) (resp. \( f \)), and denote by \( \text{gr}_R R \) the graded ring associated with the \( I \)-adic filtration of \( R \); we associate with \( f \) the \( R \)-module structure on \( M \) such that \( T_i x := f_i x \) for every \( x \in M \) and every \( i = 1, \ldots, r \), and denote likewise by \( \text{gr}_M M \) the graded \( \text{gr}_R R \)-module associated with the \( J \)-adic filtration on \( M \). We say that \( f \) is \( M \)-quasi-regular, if the natural map
\[ \text{gr}_R R \otimes_{\text{gr}_R R} \text{gr}_M M \to \text{gr}_M M \]
is an isomorphism.

Lemma 7.8.14. (i) With the notation of definition 7.8.13 we have a natural isomorphism:
\[ R/I \otimes_R M \sim \to K_* (f, M) \text{ in } \mathbb{D} (R - \text{Mod}). \]
(ii) If moreover \( f \) is completely secant on \( A \), we have a natural isomorphism:
\[ A/J \otimes_A M \sim \to K_* (f, M) \text{ in } \mathbb{D} (A - \text{Mod}). \]

Proof. (i): Clearly \( T \) is a regular sequence on \( R \), hence \( H_i (T, R) = 0 \) for every \( i > 0 \) (proposition 7.8.7), i.e. \( K_* (T, R) \) is a resolution of \( R/I \) by free \( R \)-modules (remark 7.8.1(iii)). On the other hand, let \( g : R \to A \) be the unique ring homomorphism such that \( g(T_i) := f_i \) for \( i = 1, \ldots, r \); clearly the \( R \)-module structure of \( M \) is obtained by restriction of scalars along \( g \) from its \( A \)-module structure, so we have a natural identification \( K_* (T, M) \sim \to K_* (f, M) \) (lemma 7.8.2(iv)). The assertion follows immediately.
(ii): If \( f \) is completely secant on \( A \), then \( K_\bullet(f) \) is a resolution of \( A/J \) by free \( A \)-modules (remark 7.8.1(iii)), whence the assertion. \( \square \)

The following result summarizes and completes the list of interdependencies found thus far between the properties of finite sequences of elements in a ring that have been introduced at various stages in the text.

**Proposition 7.8.15.** In the situation of definition 7.8.13 consider the following conditions:

(a) The sequence \( f \) is \( M \)-regular.
(b) The sequence \( f \) is completely secant on \( M \).
(c) \( \text{Tor}_1^R(R/I, M) = 0 \).
(d) The sequence \( f \) is \( M \)-quasi-regular.
(e) \( T_1 \) is \( gr_\bullet M \)-regular, and \( f_1 M \cap J^{n+1} M = f_1 J^n M \) for every \( n \in \mathbb{N} \).
(f) \( M \) is \( J \)-adically complete and separated.

Then (a)\( \Rightarrow \)(b)\( \Rightarrow \)(c)\( \Rightarrow \)(d)\( \Rightarrow \)(e), and if (d) holds, then (f)\( \Rightarrow \)(g)\( \Rightarrow \)(a).

*Proof.* (a)\( \Rightarrow \)(b) is already known, by proposition 7.8.7, and (b)\( \Rightarrow \)(c), by lemma 7.8.14(i).

(c)\( \Rightarrow \)(d): The assumption means that the natural map \( I \otimes_R M \to I M \) is bijective. On the other hand, notice that \( gr_n := R/I \) is isomorphic to \( \mathbb{Z} \), and \( gr_n R := I^n/I^{n+1} \) is a free \( \mathbb{Z} \)-module for every \( n \in \mathbb{N} \); consider then for every \( n \in \mathbb{N} \) the commutative diagram:

\[
\begin{array}{ccc}
0 & \longrightarrow & I^{n+1} \otimes_R M \\
\downarrow & & \downarrow \\
0 & \longrightarrow & I^n \otimes_R M \\
\downarrow & & \downarrow \\
0 & \longrightarrow & I^{n+1} M \\
\downarrow & & \downarrow \\
0 & \longrightarrow & I^n M \\
\downarrow & & \downarrow \\
0 & \longrightarrow & gr_n M
\end{array}
\]

all of whose vertical arrows are surjections, and whose horizontal rows are short exact sequences, as \( \text{Tor}_1^R(gr_n R, M) = 0 \). Then, a simple induction shows that all three vertical arrows are isomorphisms for every \( n \in \mathbb{N} \), whence the assertion.

(d)\( \Rightarrow \)(e): It is easily seen that \((I^{n+1} + T_1 I^n)/I^{n+2}\) is a free \( \mathbb{Z} \)-module for every \( n \in \mathbb{N} \), hence we get a short exact sequence

\[
0 \to gr_n R \otimes_{gr_0 R} gr_0 M \xrightarrow{\varphi} gr_{n+1} R \otimes_{gr_0 R} gr_0 M \to ((I^{n+1} + T_1 I^n)/I^{n+2}) \otimes_{gr_0 R} gr_0 M \to 0
\]

for every \( n \in \mathbb{N} \) where \( \varphi \) is induced by scalar multiplication by \( T_1 \) on \( R \), which maps \( I^n \) into \( I^{n+1} \) for every such \( n \). Then (d) implies that \( T_1 \) is regular on the \( gr_\bullet R \)-module \( gr_\bullet M \); moreover

\[
\{ x \in I^n M \mid f_1 x \in I^{n+2} M \} = I^{n+1} M \quad \text{for every } n \in \mathbb{N}
\]

whence \( f_1 I^n M \cap I^{n+2} M = f_1 I^{n+1} M \) for every \( n \in \mathbb{N} \). By a simple induction on \( k \), we deduce that \( f_1 I^{n-k} M \cap I^{n+2} M = f_1 I^{n+1} M \) for \( k = 0, \ldots, n \), whence the sought identity.

(d) and (f)\( \Rightarrow \)(g): We shall argue by induction on the length \( r \) of \( f \). For \( r = 0 \), there is nothing to prove. Next, suppose that \( r \geq 1 \), and the assertion is already known for every \( M \)-quasi-regular sequence of length \( r - 1 \); by the foregoing, (e) holds for \( M \), so that scalar multiplication by \( f_1 \) on the \( A \)-module \( M \) induces an injective map \( gr_n M \to gr_{n+1} M \) for every \( n \in \mathbb{N} \). Since the \( J \)-adic topology is separated on \( M \), we deduce already that \( f_1 \) is \( M \)-regular and the \( J \)-adic topology on \( f_1 M \) agrees with the topology induced by the \( J \)-adic topology of \( M \); since \( f_1 M \) is isomorphic to \( M \), we conclude that \( f_1 M \) is complete for the topology induced by \( M \), and by virtue of proposition 8.2.13(i,v), condition (f) holds therefore as well for \( \overline{M} := M/f_1 M \).

Now, let \( R' := \mathbb{Z}[T_2, \ldots, T_r] \subset R \), set \( I' := I \cap R' \), \( J' := I'A \), and denote by \( gr_\bullet R' \) the graded ring associated with the \( I' \)-adic filtration of \( R' \). The projection \( R \to R/(T_1) \to R' \) induces isomorphisms of rings and respectively graded rings:

\[
gr_0 R \xrightarrow{\sim} gr_0 R' \quad (gr_\bullet R)/(T_1) \xrightarrow{\sim} gr_\bullet R'
\]
where $T_1 \in \text{gr}_1 R$ denotes the class of $T_1$. Let us endow $\overline{M}$ with the $R'$-module structure obtained by restriction of scalars along the inclusion map $R' \to R$, and let $\text{gr}_* \overline{M}$ be the graded $\text{gr}_* R'$-module associated with the $J'$-adic filtration on $\overline{M}$. Then clearly the $J'$-adic topology of $\overline{M}$ coincides with its $J$-adic topology; moreover, notice that $\text{gr}_* R' \otimes_{\text{gr}_* R} \text{gr}_n M = I^n M/(f_1 I^{n-1} M + I^{n+1} M)$, whereas $\text{gr}_n \overline{M} = I^n M/((f_1 M \cap I^n M) + I^{n+1} M)$ for every $n > 0$. Hence, (e) also implies that the projection $\text{gr}_* M \to \text{gr}_* \overline{M}$ induces isomorphisms of $\text{gr}_0 R$-modules and respectively graded $\text{gr}_* R'$-modules:

$$\text{gr}_0 M \xrightarrow{\sim} \text{gr}_0 \overline{M}, \quad \text{gr}_* R' \otimes_{\text{gr}_* R} \text{gr}_* M \xrightarrow{\sim} \text{gr}_* \overline{M}.$$ 

Therefore, the natural map

$$\text{gr}_* R' \otimes_{\text{gr}_* R} \text{gr}_0 \overline{M} \to \text{gr}_* \overline{M}$$

is bijective, i.e. the sequence $f' := (f_2, \ldots, f_n)$ is $\overline{M}$-quasi-regular; by inductive assumption, $\overline{M}/\sum_{i=2}^k f_i M = M/\sum_{i=1}^k f_i M$ is then $J$-adically separated for $k = 1, \ldots, n$, as required.

(d) and (g) $\Rightarrow$ (a): Again, we argue by induction on $r$. If $r = 0$, there is nothing to show; suppose then that $r > 1$, and the assertion is already known for every $A$-module $M$ fulfilling condition (g), relative to any $M$-quasi-regular sequence of length $r - 1$. As in the foregoing, we see that $f_1$ is $M$-regular, and $f'$ is $\overline{M}$-quasi-regular; then by inductive assumption, $f'$ is $\overline{M}$-regular, so $f$ is $M$-regular.  

\textbf{Remark 7.8.16.} (i) Condition (g) of proposition\textbf{[7.8.15]} holds in either of the following cases:

(a) $A$ is noetherian, $M$ is an $A$-module of finite type and $I$ lies in the Jacobson radical of $A$ (\cite[II Th.8.1(ii)]{100}).

(b) For a given fine monoid $P$, the ring $A$ is $P$-graded, $M$ is a $P$-graded $A$-module, and each of $f_1, \ldots, f_r$ are homogeneous elements whose degrees lie in the maximal ideal of $P$; indeed, recall that the $m$-adic filtration is separated on $P$ (\text{lemma\textbf{[6.4.19]}} i).

(ii) In the situation of definition\textbf{[7.8.13]} notice that the sequence $f$ is quasi-regular on $A$ if and only if the following two conditions hold:

(a) $J/J^2$ is a free $A/J$-module of rank $r$

(b) the natural map of graded $A/J$-algebras

$$\text{Sym}_{A/J}(J/J^2) \to \bigoplus_{n \in \mathbb{N}} J^n/J^{n+1}$$

is an isomorphism: the details shall be left to the reader.

\textbf{Lemma 7.8.17.} Let $A$ be a ring, $n \geq 1$ an integer, and $f := (f_0, \ldots, f_n)$ a completely secant sequence of elements of $A$. The following holds:

(i) The sequences $g := (f_0, f_1 - f_0 T_1, \ldots, f_n - f_0 T_n)$ and $g' := (f_1 - f_0 T_1, \ldots, f_n - f_0 T_n)$ are completely secant in the polynomial $A$-algebra $A[T_1, \ldots, T_n]$.

(ii) Let $A[f_1/f_0, \ldots, f_n/f_0] \subset A[1/f_0]$ be the $A$-subalgebra generated by $f_1/f_0, \ldots, f_n/f_0$. Then the kernel of the surjective map of $A$-algebras

$$A[T_1, \ldots, T_n] \to A[f_1/f_0, \ldots, f_n/f_0] \quad T_i \mapsto f_1/f_0 \quad \text{for } i = 1, \ldots, n$$

is the ideal $I \subset A[T_1, \ldots, T_n]$ generated by the sequence $g'$.

\textbf{Proof.} (i): Since the inclusion map $A \to B := A[T_1, \ldots, T_n]$ is flat, it is clear that the sequence $f$ is completely secant in $B$. Define the $B$-linear forms $\partial_{f_0}, \partial_{g} : B^{\oplus n+1} \to B$ as in remark\textbf{[7.8.1]} ii), so that $K_*(f) = K_*(B, B^{\oplus n+1}, \partial_{f})$, and likewise for $K_*(g)$. We have an isomorphism

$$(1_B, \varphi) : (B, B^{\oplus n+1}, \partial_{g}) \xrightarrow{\sim} (B, B^{\oplus n+1}, \partial_{f}) \quad \text{in } A\text{-dAlg.Mod}.$$
with \( \varphi : B^{\oplus n+1} \xrightarrow{\sim} B^{\oplus n+1} \) the \( B \)-linear automorphism such that \( \varphi(e_0) := e_0 \) and \( \varphi(e_i) := e_i - T_j e_0 \) for \( i = 1, \ldots, n \). The assertion for \( g \) is an immediate consequence.

Combining with lemma 7.8.5, we see that the scalar multiplication by \( f_0 \) is injective on \( H_i(g', B) \), for every \( i \in \mathbb{N} \). Hence, the natural map

\[
H_i(g', B) \to H_i(g', B[f_0^{-1}])
\]

is injective for every \( i \in \mathbb{N} \), and in order to show that \( g' \) is completely secant in \( B \), we may then assume that \( f_0 \in A^\times \). To this aim, we consider also the sequence \( T := (T_1, \ldots, T_n) \); we have an isomorphism

\[
(\psi, 1_{B^{\oplus n}}) : (B, B^{\oplus n}, \partial_T) \xrightarrow{\sim} (B, B^{\oplus n}, \partial_{g'}) \quad \text{in } A\text{-dAlg} \text{-Mod}
\]

where \( \psi : B \xrightarrow{\sim} B \) is the ring isomorphism such that \( \psi(T_i) := f_i - f_0 T_i \) for \( i = 1, \ldots, n \). Since the sequence \( T \) is obviously \( B \)-regular, the assertion then follows from proposition 7.8.7.

(ii) We have a commutative diagram of rings:

\[
\begin{array}{ccc}
B/IB & \longrightarrow & A[f_1/f_0, \ldots, f_n/f_0] \\
\downarrow & & \downarrow \\
B/IB[1/f_0] & \longrightarrow & A[1/f_0]
\end{array}
\]

whose vertical arrows are the localizations, and it is easily seen that the bottom horizontal arrow is an isomorphism. On the other hand, from (i) and lemma 7.8.5 we see that the scalar multiplication by \( f_0 \) is injective on \( B/I \); hence the top horizontal arrow is injective, whence the contention. \( \square \)

**Definition 7.8.18.** Let \( \mathcal{A} \) be any additive category, and \( A_\bullet \) any object of \( \text{Fun}(\mathbb{N}^o, \mathcal{A}) \) (where the partially ordered set \( (\mathbb{N}, \leq) \) is regarded as category, as in example 1.1.6(iii)). In other words, \( A_\bullet \) is a datum \((A_\bullet, \varphi_\bullet)\) consisting of a family \((A_p \mid p \in \mathbb{N})\) of objects of \( \mathcal{A} \) and a system of morphisms \( \varphi_{q,p} : A_q \to A_p \) of \( \mathcal{A} \) for every integers \( q \geq p \geq 0 \), such that

\[
\varphi_{q,p} \circ \varphi_{r,q} = \varphi_{r,p} \quad \text{for every } r \geq q \geq p \geq 0.
\]

The objects of \( \text{Fun}(\mathbb{N}^o, \mathcal{A}) \) are called also **inverse systems** of \( \mathcal{A} \) indexed by \( \mathbb{N} \). Then:

(i) We say that \( A_\bullet \) is **essentially zero**, if for every \( p \in \mathbb{N} \) there exists \( q \geq p \) such that \( \varphi_{q,p} \) is the zero morphism.

(ii) We say that \( A_\bullet \) is **uniformly essentially zero**, if there exists \( c \in \mathbb{N} \) such that \( \varphi_{p+c,p} \) is the zero morphism for every \( p \in \mathbb{N} \). In this case, the smallest of such \( c \) is called the **step** of \( A_\bullet \).

Recall that if \( \text{Fun}(\mathbb{N}^o, \mathcal{A}) \) is an additive category, and it is even abelian, if the same holds for \( \mathcal{A} \); moreover, the kernels and cokernels in \( \text{Fun}(\mathbb{N}^o, \mathcal{A}) \) are computed argumentwise: see remark 3.6.37(ii). We notice:

**Lemma 7.8.19.** Let \( \mathcal{A} \) be any abelian category, and consider a short exact sequence

\[
0 \to A'_\bullet \to A_\bullet \to A''_\bullet \to 0 \quad \text{in } \text{Fun}(\mathbb{N}^o, \mathcal{A}).
\]

Then, \( A_\bullet \) is essentially zero (resp. uniformly essentially zero) if and only if the same holds for both \( A'_\bullet \) and \( A''_\bullet \).

**Proof.** Indeed, it is clear that if \( A_n \to A_m \) is the zero morphism for some \( n \geq m \), then the same holds for the morphisms \( A'_n \to A'_m \) and \( A''_n \to A''_m \). Conversely, suppose that \( A'_n \to A'_m \) and \( A''_p \to A''_q \) are the zero morphisms, for some \( p \geq n \geq m \); then it follows easily that the same holds for the morphism \( A_p \to A_m \). \( \square \)
7.8.20. Let \( f := (f_1, \ldots, f_r) \) and \( g := (g_i \mid i = 1, \ldots, r) \) be two finite sequences of elements of a ring \( A \); we set \( fg := (f_ig_i \mid i = 1, \ldots, r) \) and define as follows a map of Koszul complexes

\[
\varphi_g : K_\bullet(fg) \to K_\bullet(f)
\]

(see remark\cite{7.8.1}\(\text{ii})). First, suppose that \( r = 1 \); then \( f = (f) \), \( g = (g) \) and the sought map \( \varphi_g \) is the commutative diagram:

\[
\begin{array}{ccc}
0 & \to & A \\
\downarrow g & & \downarrow f \\
0 & \to & A
\end{array}
\]

For the general case we let:

\[
\varphi_g := \varphi_{g_1} \otimes_A \cdots \otimes_A \varphi_{g_r}.
\]

Especially, for every \( m, n \geq 0 \) we have maps \( \varphi_{fn} : K_\bullet(f^{n+m}) \to K_\bullet(f^m) \), whence maps

\[
\varphi_{fn}^* : K^*(f^m, M) \to K^*(f^{m+n}, M)
\]

and clearly \( \varphi_{fp+q}^* = \varphi_{fp}^* \circ \varphi_{pq}^* \) for every \( m, p, q \geq 0 \).

7.8.21. In the situation of \((7.8.20)\), set \( A_r := \mathbb{Z}[T_1, \ldots, T_r] \), and denote by \( \beta_f : A_r \to A \) the unique ring homomorphism such that \( \beta_f(T_i) := f_i \) for every \( i = 1, \ldots, r \). Let also \( I_r \subset A_r \) be the ideal generated by \((T_1, \ldots, T_r)\), and set \( I := I_r A \). We consider the following conditions:

(a) The inverse system \((\text{Tor}_{i}^A(A_r/I^n, A) \mid n \in \mathbb{N})\) is essentially zero for every \( i > 0 \).

(b) The inverse system \((\text{Tor}_{i}^A(A/I^n, A/I) \mid n \in \mathbb{N})\) is essentially zero for every \( i > 0 \).

(c) The inverse system \((H_i(f, I^n) \mid n \in \mathbb{N})\) is essentially zero for every \( i > 0 \).

(d) The inverse system \((H_i(A, I^n) \mid n \in \mathbb{N})\) is essentially zero for every \( i > 0 \).

(e) The inverse system \((\text{Tor}_{i+1}^A(A/I^n, M) \mid n \in \mathbb{N})\) is essentially zero, for every \( i, k \in \mathbb{N} \) and every \( A/I^k\)-module \( M \).

(f) For every \( i \in \mathbb{Z} \) and every bounded above complex \( C_\bullet \) of flat \( A\)-modules such that for every \( j \in \mathbb{Z} \) the annihilator ideal of \( H_jC_\bullet = 0 \) contains a power of \( I \), the inverse system \((H_i(I^n C_\bullet) \mid n \in \mathbb{N})\) is essentially zero.

Moreover, we shall also consider the conditions \((a)_f^un, \ldots, (f)_f^un\) obtained from \((a)_f, \ldots, (f)_f\) after replacing “essentially zero” by “uniformly essentially zero”.

Remark 7.8.22. Condition \((d)_f\) seems to have been first considered in [66, Lemma 2.4], and in particular, our remark\cite{7.8.45} was already observed in [66, Lemma 2.5 and th.2.8]. The same condition reappears in [68, Exp.II, Lemme 9], as well as in in [1, Lemma 3.1.1], and it is baptised “weak proregularity” in an errata for that paper. A non-commutative extension is proposed in [123]. For motivation, we point out the following lemma, which says that completely secant sequences \( f \) trivially satisfy condition \((a)_f^un\):

Lemma 7.8.23. With the notation of \((7.8.21)\), if \( f \) is completely secant on \( A \), we have

\[
\text{Tor}_{i+1}^A(A_r/I^n, A) = 0 \quad \text{for every} \ n \in \mathbb{N} \ \text{and every} \ i > 0.
\]

Proof. Notice first that \( A_r/I_r = \mathbb{Z} \), and \( I^n/I_r^{n+1} \) is a free \( \mathbb{Z} \)-module, for every \( n \in \mathbb{N} \); using the long Tor-exact sequences arising from the short exact sequences

\[
0 \to I^n/r^n+1 \to A_r/I_r^{n+1} \to A_r/I^n \to 0
\]

a simple induction reduces to the case where \( n = 1 \) (details left to the reader). In this case, the assertion follows from lemma\cite{7.8.14}\(\text{i}).
Lemma 7.8.24. With the notation of (7.8.21), for every $i, p \in \mathbb{N}$ with $i > 0$, and every $A_r/I_r^p$-module $N$, the natural morphism $\text{Tor}_i^{A_r}(A_r/I_r^p, N) \to \text{Tor}_i^{A_r}(A_r/I_r^p, N)$ is the zero map.

Proof. Let $\text{Fil}^*N$ be the $I_*$-adic filtration of $N$, and $\text{gr}^*N$ the associated graded $A_*/I_*$-module; the long exact Tor-sequences arising from the short exact sequences $0 \to \text{Fil}^qN \to \text{Fil}^{q+1}N \to \text{gr}^qN \to 0$ (for every $q \in \mathbb{N}$), and an easy induction argument, reduce to the case where $p = 1$ (details left to the reader), so $N$ is an $A_*/I_*$-module, i.e. a $\mathbb{Z}$-module; we may moreover reduce to the case where $N$ is a finitely generated $\mathbb{Z}$-module, and then we may even assume that $N = \mathbb{Z}/a\mathbb{Z}$ for some $a \in \mathbb{N}$ (details left to the reader). In this situation, set $B := A_r/aA_r$, $J := I_rB_r$, and consider the standard $2$-spectral sequence (125, Th. 5.6.6)

$$E_{pq}^2 := \text{Tor}_q^B(A_r/I_r^n, B) \otimes \mathbb{Z}/a\mathbb{Z} \Rightarrow \text{Tor}_{p+q}^{A_r}(A_r/I_r^n, \mathbb{Z}/a\mathbb{Z})$$

and notice that, on the one hand, the scalar multiplication by $a$ is injective on $A_r/I_r^n$, and on the other hand, the complex $0 \to A_r \to A_r \to 0$ with differential given by $a \cdot 1_{A_r}$ is a free resolution of $B$; we deduce that $E_{pq}^2 = 0$ whenever $q > 0$, whence natural isomorphisms:

$$\text{Tor}_i^B(B/J^n, \mathbb{Z}/a\mathbb{Z}) \sim \text{Tor}_i^{A_r}(A_r/I_r^n, \mathbb{Z}/a\mathbb{Z})$$

for every $i, n \in \mathbb{N}$ and we are reduced to checking that the natural map

$$\text{Tor}_i^B(B/J^{n+1}, \mathbb{Z}/a\mathbb{Z}) \to \text{Tor}_i^B(B/J^n, \mathbb{Z}/a\mathbb{Z})$$

vanishes for every $i > 0$. To this aim, notice that the Koszul complex $K_* := K_*(T_*, B)$ associated with the sequence $T_* := (T_1, \ldots, T_k)$ of elements of $B$, is a resolution of $\mathbb{Z}/a\mathbb{Z}$ consisting of free $B$-modules (proposition 7.8.7), so we have a natural isomorphism

$$B/J^n \otimes_B K_* \sim B/J^n \otimes_B \mathbb{Z}/a\mathbb{Z} \quad \text{in} \ D(B-\text{Mod}).$$

Now, denote by $\text{gr}_*B$ the standard graded $\mathbb{Z}/a\mathbb{Z}$-algebra structure on $B$ such that $\text{gr}_1B$ is generated by $T_1, \ldots, T_k$. For every $i \in \mathbb{N}$ we define a grading on $K_i$ as follows. Let $(e_1, \ldots, e_k)$ be the canonical basis of $B^{\otimes k}$, and $\mathcal{F}$, the set of all strictly increasing maps $\{1, \ldots, i\} \to \{1, \ldots, r\}$; for every $\varphi \in \mathcal{F}$, and every $r \in \mathbb{N}$ set

$$e_{\varphi} := e_{\varphi(1)} \wedge \cdots \wedge e_{\varphi(i)} \quad \text{and} \quad \text{gr}_r K_i := \sum_{\varphi \in \mathcal{F}} e_{\varphi} : \text{gr}_{r-1}B.$$

A simple inspection then shows that the differential of the Koszul complex is, in each degree, a map of graded $\mathbb{Z}/a\mathbb{Z}$-modules, therefore we get a natural decomposition

$$K_* \sim \bigoplus_{r \in \mathbb{N}} \text{gr}_r K_* \quad \text{in} \ C(\mathbb{Z}/a\mathbb{Z}-\text{Mod})$$

and since $J^n = \bigoplus_{r \geq n} \text{gr}_r B$, the complex $K_* \otimes_B B/J^n$ admits a corresponding decomposition, and we have

$$(\text{gr}_r K_* \otimes_B B/J^n)_i = \begin{cases} 
\text{gr}_r K_i & \text{if } r < i + n \\
0 & \text{otherwise}
\end{cases}$$

Since $H_r K_* = 0$ for every $i > 0$, it follows easily that

$$\text{gr}_r H_i(K_* \otimes_B B/J^n) = 0 \quad \text{for every } i, r, n \in \mathbb{N} \text{ such that } r \neq i + n \text{ and } i > 0.$$

Thus, fix $i, n \in \mathbb{N}$ with $i > 0$, and consider any $x \in \text{Tor}_i^B(B/J^{n+1}, \mathbb{Z}/a\mathbb{Z})$; by the foregoing, we have $x \in H_i(\text{gr}_{i+n} K_* \otimes_B B/J^{n+1})$, and $H_i(\text{gr}_{i+n} K_* \otimes_B B/J^n) = 0$, so the image of $x$ vanishes in $\text{Tor}_i^B(B/J^n, \mathbb{Z}/a\mathbb{Z})$, as required. \qed

Proposition 7.8.25. With the notation of (7.8.21), fix $i \in \mathbb{N}$, and let also $g := (g_i \mid i = 1, \ldots, s)$ be another sequence of elements of $A$ that generates an ideal $J$. We have:

(i) $(a)_r \Leftrightarrow (b)_r \Leftrightarrow (c)_r \Leftrightarrow (d)_r \Leftrightarrow (e)_r \Leftrightarrow (f)_r$.

(ii) $(a)^n \Leftrightarrow (b)^n \Leftrightarrow (c)^n \Leftrightarrow (d)^n \Leftrightarrow (e)^n \Leftrightarrow (f)^n$. 
(iii) If the radical of $I$ equals the radical of $J$, then $(a)_f \leftrightarrow (a)_g$.

(iv) If $I = J$, then $(a)_f^u \leftrightarrow (a)_g^u$.

**Proof.** Let us check first that $(a)_f \Rightarrow (b)_f$ and $(a)_f^u \Rightarrow (b)_f^u$. To this aim, we consider the change of ring spectral sequence

$$E(n)^2_{i,j} := \text{Tor}^A_i(\text{Tor}^A_j(A_r/I^n_r, A), A/I) \Rightarrow \text{Tor}^A_{i+j}(A_r/I^n_r, A/I).$$

Notice that the projection $A_r/I^n_m \to A_r/I^n_0$ induces a morphism of spectral sequences (7.8.26)

$$E(m)^\bullet \to E(n)^\bullet$$

for every $m \geq n$.

Then the assertion is the case $p = 0$ of the following:

**Claim 7.8.27.** If condition $(a)_f$ (resp. $(a)_f^u$) holds, then the inverse system $(E(n)^{p+2}_{i+1,0} | n \in \mathbb{N})$ is essentially zero (resp. uniformly essentially zero) for every $i, p \in \mathbb{N}$.

**Proof of the claim.** We fix $i \in \mathbb{N}$, and we argue by descending induction on $p$. Notice first that

$$E(n)^{i+1}_{i,0} = E(n)^{\infty}_{i,0}$$

for every $i, n \in \mathbb{N}$.

Then, lemma 7.8.24 trivially implies that the assertion holds for every $i, p \in \mathbb{N}$ with $p \geq i$. Now, let $0 \leq q \leq i - 1$, and suppose that the assertion is already known for every $p > q$ (with our fixed $i$). We get an exact sequence of inverse systems

$$0 \to (E(n)^{q+2}_{i+1,0} | n \in \mathbb{N}) \to (E(n)^{q+2}_{i+1,0} | n \in \mathbb{N}) \to (E(n)^{q+2}_{i-q-1,q+1} | n \in \mathbb{N})$$

and by inductive assumption the system $(E(n)^{q+3}_{i+1,0} | n \in \mathbb{N})$ is essentially zero (resp. uniformly essentially zero). Moreover, $(a)_f$ (resp. $(a)_f^u$) implies that the same holds for the system $(E(n)^{q+2}_{i-q-1,q+1} | n \in \mathbb{N})$. Then the contention follows from lemma 7.8.19.

• In order to show that $(b)_f \Rightarrow (a)_f$ we remark:

**Claim 7.8.28.** Let $j \in \mathbb{N}$ be any integer. Then:

(i) If $(E(n)^2_{0,j} | n \in \mathbb{N})$ is an essentially zero inverse system, the same holds for the inverse system $(\text{Tor}^A_{2,j}(A_r/I^n_r, A) | n \in \mathbb{N})$.

(ii) If $(\text{Tor}^A_{2,j}(A_r/I^n_r, A) | n \in \mathbb{N})$ is an essentially zero inverse system, the same holds for the inverse system $(E_{0,j}^{p+2} | n \in \mathbb{N})$, for every $i, p \in \mathbb{N}$.

(iii) The inverse system $(E(n)^{p+2}_{0,j} | n \in \mathbb{N})$ is essentially zero.

(iv) $(b)_f$ implies that $(E(n)^{i+2}_{i,0} | n \in \mathbb{N})$ is an essentially zero system for every $i \in \mathbb{N}$.

**Proof of the claim.** (i): Denote by $\varphi_{n,c} : \text{Tor}^A_{2,j}(A_r/I^n_r, A) \to \text{Tor}^A_{2,j}(A_r/I^n_r, A)$ the natural map. The hypothesis means that for every $n \in \mathbb{N}$ there exists $c \in \mathbb{N}$ such that $\varphi_{n,c} \otimes A A/I = 0$, i.e. $\text{Im} \varphi_{n,c} \subset I \cdot \text{Tor}^A_{2,j}(A_r/I^n_r, A)$. By a simple induction we deduce that for every $n, k \in \mathbb{N}$ there exists $d \in \mathbb{N}$ such that $\text{Im} \varphi_{n,c} \subset I^k \cdot \text{Tor}^A_{2,j}(A_r/I^n_r, A)$, and letting $k = n$, the assertion follows.

(ii): Obviously, the assumption implies that $(E_{0,j}^{2} | n \in \mathbb{N})$ is an essentially zero inverse system; the assertion is an immediate consequence.

(iii) is clear, and notice that $E(n)^{j+2}_{0,j} = E(n)^{\infty}_{0,j}$ for every $n \in \mathbb{N}$. In light of lemma 7.8.24 assertion (iii) follows easily as well.

In light of claim 7.8.28(i) it suffices to show that $(E(n)^{2}_{0,j})$ is essentially zero for every $j > 0$. We argue by induction on $j$; for $j = 1$ we consider the exact sequence of inverse systems:

$$(E(n)^{2}_{2,0} | n \in \mathbb{N}) \to (E(n)^{2}_{0,1} | n \in \mathbb{N}) \to (E(n)^{3}_{0,1}) \to 0.$$
Next, let \( j > 1 \), and suppose that the inverse systems \( (E(n)_{0,k}^2 \mid n \in \mathbb{N}) \) are essentially zero for \( 0 < k < j \). By claim \([7.8.28](\text{ii})\) we deduce that \( (E(n)_{i,k}^{p+2} \mid n \in \mathbb{N}) \) is essentially zero for every \( p, i \in \mathbb{N} \) and whenever \( 0 < k < j \). We show, by descending induction on \( p \), that \( (E(n)_{0,k}^{p+2} \mid n \in \mathbb{N}) \) is essentially zero for every \( p \in \mathbb{N} \). First, the assertion holds for \( p \geq j \), by virtue of claim \([7.8.28](\text{iii})\). Suppose then that \( 0 \leq k < j \), and that the assertion is already known for every \( p > k \); we consider the exact sequence of inverse systems

\[
(E(n)_{k,j-k-1}^{k+2} \mid n \in \mathbb{N}) \to (E(n)_{0,j}^{k+2} \mid n \in \mathbb{N}) \to (E(n)_{0,j}^{k+3}) \to 0.
\]

Our inductive assumptions imply that the first and third terms are essentially zero; then the same holds for the middle term (lemma \([7.8.42]\)). The proof is concluded.

- Next, we show that \((\text{b})_f \Rightarrow (\text{e})_f \) and \((\text{b})_{un} \Rightarrow (\text{e})_{un}\). For any \( A/I^k \)-module \( M \), we need to check that the inverse system \((\text{Tor}_i^A(A/I^n) \mid n \in \mathbb{N})\) is essentially zero (resp. uniformly essentially zero); to this aim, we consider the \( I \)-adic filtration \( \text{Fil}_i^M \) on \( M \), and the associated graded \( A/I \)-module \( \text{gr}_i M \). Applying the long exact Tor-sequences arising from the short exact sequences \( 0 \to \text{Fil}_i^M \to \text{Fil}_{i+1} M \to \text{gr}_i M \to 0 \), together with lemma \([7.8.19]\), we reduce to checking that \((\text{Tor}_i^A(A/I^n, \text{gr}_i M) \mid n \in \mathbb{N})\) is an essentially zero (resp. uniformly essentially zero) inverse system. Thus, we may suppose that \( IM = 0 \), in which case we show more precisely:

**Claim 7.8.29.** Let \( p > 0 \) be any integer, and suppose that \((\text{Tor}_i^A(A/I^n, A/I) \mid n \in \mathbb{N})\) is an essentially zero (resp. uniformly essentially zero) inverse system for every \( i = 1, \ldots, p \). Then, for every \( A/I \)-module \( M \) the inverse system \((\text{Tor}_i^A(A/I^n, M) \mid n \in \mathbb{N})\) is essentially zero (resp. uniformly essentially zero).

**Proof of the claim.** We consider the spectral sequence

\[
E(n)_{i,j}^2 := \text{Tor}_i^A(A/I^n, A/I, M) \Rightarrow \text{Tor}_i^A(A/I^n, M)
\]

for every \( n \in \mathbb{N} \) and the corresponding morphisms of spectral sequences as in \([7.8.26]\), induced by the projections \( A/I^m \to A/I^n \). Notice that \( E(n)_{i,0}^2 = 0 \), and therefore \( E(n)_{i,0}^2 = 0 \) for every \( i > 0 \). On the other hand, our assumption implies that the inverse system \((E(n)^2_{i,j} \mid n \in \mathbb{N})\) is essentially zero (resp. uniformly essentially zero) for every \( i, j \in \mathbb{N} \) such that \( j > 0 \) and \( i + j = q \). Summing up, we deduce that the inverse system \((E(n)^\infty_{i,j} \mid n \in \mathbb{N})\) is essentially zero (resp. uniformly essentially zero) for every \( i, j \in \mathbb{N} \) such that \( i + j = p \). Taking into account lemma \([7.8.19]\) the contention now follows by a simple induction.

- We check next that \((\text{e})_f \Rightarrow (\text{f})_f \) and \((\text{e})_{un} \Rightarrow (\text{f})_{un}\). To this aim, notice that \( H_i(I^n C_\bullet) = H_i(I^n[0] \otimes_A C_\bullet) \) for every \( i, n \in \mathbb{Z} \), since \( C_\bullet \) is a complex of flat \( A \)-modules. On the other hand, we have a standard spectral sequence

\[
E(n)_{p,q}^2 := \text{Tor}_p^A(I^n, H_q C_\bullet) \Rightarrow H_{p+q}(I^n[0] \otimes_A C_\bullet).
\]

Since \( E(n)_{p,q}^2 \Rightarrow \text{Tor}_p^A(I^n, H_q C_\bullet) \) for every \( p, q \), condition \((\text{e})_f \) (resp. \((\text{e})_{un}\)) implies that \((E(n)_{p,q}^2 \mid n \in \mathbb{N})\) is an essentially zero (resp. uniformly essentially zero) inverse system for every \( p \in \mathbb{N} \) and every \( q \in \mathbb{Z} \), hence the same holds for the system \((E(n)^{\infty}_{p,q} \mid n \in \mathbb{N})\).

Since \( C_\bullet \) is bounded above, lemma \([7.8.19]\) easily implies that \( H_i(I^n[0] \otimes_A C_\bullet) \) is an essentially zero (resp. uniformly essentially zero) system for every \( i \in \mathbb{Z} \) (details left to the reader), whence the contention.

Clearly \((\text{f})_f \Rightarrow (\text{e})_f \) and \((\text{f})_{un} \Rightarrow (\text{e})_{un}\), since the Koszul complex is a bounded complex of flat \( A \)-modules whose cohomology is an \( A/I \)-module in each degree (lemma \([7.8.2](\text{ii})]\)).

- To show that \((\text{c})_f \Rightarrow (\text{b})_f \) and \((\text{c})_{un} \Rightarrow (\text{b})_{un}\) we consider the spectral sequence

\[
E(n)_{i,j}^2 := \text{Tor}_i^A(I^n, H_j K_\bullet(f)) \Rightarrow H_{i+j}(f, I^n)
\]

for every \( n \in \mathbb{N} \).
and the corresponding system of morphisms of spectral sequences as in (7.8.26). Recalling that $H_0K_\bullet(f_*) = A/I$, as well as the natural isomorphism

\[(7.8.30) \quad \text{Tor}^i_n(I^n, A/I) \cong \text{Tor}^i_{n+1}(A/I^n, A/I) \quad \text{for every } i, n \in \mathbb{N}\]

the assertion will follow from the case $j = p = 0$ of the following more general:

**Claim 7.8.31.** If $(c)_r$ (resp. $(c)^{un}_r$) holds, the inverse system $(E(n)x_{i,j}^{p+2} | n \in \mathbb{N})$ is essentially zero (resp. uniformly essentially zero) for every $i,j,p \in \mathbb{N}$.

**Proof of the claim.** We argue by induction on $i$. For $i = 0$, notice that $E(n)x_{0,0}^2 = E(n)x_{0,0}^\infty$ for every $n \in \mathbb{N}$; condition $(c)_r$ (resp. $(c)^{un}_r$) then yields the claim for the system $(E(n)x_{0,0}^2 | n \in \mathbb{N})$. In light of (7.8.30) and claim 7.8.29 we deduce that $(E(n)x_{0,j}^2 | n \in \mathbb{N})$ is essentially zero (resp. uniformly essentially zero) for every $j \in \mathbb{N}$, and then the same follows for $(E(n)x_{0,j}^{p+2} | n \in \mathbb{N})$, for every $j,p \in \mathbb{N}$.

Next, suppose that $k > 0$, and the claim is already known for every $i < k$ and every $j,p \in \mathbb{N}$. We show, by descending induction on $q$, that $(E(n)x_{k,0}^q | n \in \mathbb{N})$ is an essentially zero (resp. uniformly essentially zero) system for every $q \in \mathbb{N}$; condition $(c)_r$ (resp. $(c)^{un}_r$) then yields the claim for the system $(E(n)x_{k,0}^q | n \in \mathbb{N})$. In light of (7.8.30) and claim 7.8.29 we deduce that the same holds for $(E(n)x_{k,j}^q | n \in \mathbb{N})$, for every $j \in \mathbb{N}$, and finally the same follows for $(E(n)x_{k,j}^{p+2} | n \in \mathbb{N})$, for every $j,p \in \mathbb{N}$. 

Lastly, let us check that $(a)_r \iff (d)_r$. To this aim, set $T_\bullet := (T_1, \ldots, T_r)$, and notice that $H_i(T^n_\bullet, A_r) = 0$ for every $i, n > 0$ (proposition 7.8.7), whence a natural isomorphism

$$\text{Tor}_i^{A_r}(A_r/T^n_rA_r, A) \cong H_i(K_\bullet(T^n_\bullet) \otimes_{A_r} A) \cong H_i(T^n, A) \quad \text{for every } i, n \in \mathbb{N}.$$  

On the other hand, it is clear that for every $n \in \mathbb{N}$ there exists $m \in \mathbb{N}$ such that

$$I^n_r \subseteq T^n_\bullet A_r \subseteq I^n_r$$

whence the contention.

(iv): Set $B_r := A_r \otimes_{\mathbb{Z}} A$, and notice that $\beta_r$ factors as a composition

$$A_r \xrightarrow{\beta_r^l} B_r \xrightarrow{\gamma_r} A_r$$

where $\beta_r^l : A_r \to B_r$ is the ring homomorphism such that $\beta_r^l(T_i) := 1 \otimes f_i$ for $i = 1, \ldots, r$, and $\gamma_r$ is the map of $\mathbb{Z}$-algebras induced by the pair $(\beta_r, 1_A)$. Let us endow $B_r$ with the $A_r$-module structure given by $\beta_r^l$ and $A$ with the $B_r$-module structure given by $\gamma_r$; there follows, for every $n \in \mathbb{N}$ a change of ring spectral sequence

$$E(n)x_{i,j}^q := \text{Tor}^{B_r}_n(\text{Tor}^{A_r}_i(A_r/I^n_r, B_r), A) \Rightarrow \text{Tor}^{A_r}_{i+j}^n(A_r/I^n_r, A).$$

**Claim 7.8.32.** $\text{Tor}^{A_r}_{i+j}^n(A_r/I^n_r, B_r) = 0$ for every $j > 0$.

**Proof of the claim.** We have a change of ring spectral sequence

$$E^{2}_{p,q} := \text{Tor}^{A_r}_{p}(\text{Tor}^{Z}_q(A, A_r), A_r/I^n_r) \Rightarrow \text{Tor}^{Z}_{p+q}(A, A_r/I^n_r)$$

and clearly $E^{2}_{p,q} = 0$ for every $q > 0$, so there follows a natural isomorphism

$$\text{Tor}^{A_r}_p(B_r, A_r/I^n_r) \cong \text{Tor}^{Z}_p(A, A_r/I^n_r) \quad \text{for every } p \in \mathbb{N}.$$
However, \(A_r/I^n_r\) is a free \(\mathbb{Z}\)-module, whence the claim.

In view of claim 7.8.32 we have \(E^2_{i,j} = 0\) for every \(j > 0\), whence a natural isomorphism

\[
\text{Tor}^B_i(B_r/I^n_r, B_r, A) \cong \text{Tor}^{A_r}(A_r/I^n_r, A)
\]

for every \(i \in \mathbb{N}\).

Especially, \((a)_f\) is equivalent to :

\[
(g)_f,\text{ The inverse system } \langle \text{Tor}^B_i(B_r/I^n_r, B_r, A) \mid n \in \mathbb{N} \rangle \text{ is essentially zero for every } i > 0
\]

and \((a)_f^n\) is equivalent to the corresponding condition \((g)_f^n\).

Now, set \((f, g) := (f_1, \ldots, f_r, g_1, \ldots, g_s)\). In light of the foregoing we see that in order to prove the equivalence \((a)_f \iff (a)_g\) it suffices to check that

\[
(g)_f \iff (g)_{(f,g)} \quad \text{and} \quad (g)_g \iff (g)_{(f,g)}
\]

and likewise for the uniformly essentially zero variants, so we may assume from start that \(s > r\) and \(f_i = g_i\) for \(i = 1, \ldots, r\). In this case, an easy induction on \(s - r\) further reduces to the case where \(s = r + 1\). Now, let us say that \(g_s = \sum_{i=1}^r a_i f_i\) for some \(a_1, \ldots, a_r \in A\), and consider the automorphism of \(A\)-algebras \(\omega : B_{r+1} \xrightarrow{\sim} B_{r+1}\) such that \(\omega(T_i) := T_i\) for \(i = 1, \ldots, r\) and \(\omega(T_{r+1}) := T_{r+1} - \sum_{i=1}^r a_i T_i\). Clearly \(\omega(I^n_{r+1} B_{r+1}) = I^n_{r+1} B_{r+1}\) for every \(n \in \mathbb{N}\), and \(\gamma_g \circ \omega(g) = (f, 0) := (f_1, \ldots, f_r, 0)\). It follows easily that \((g)_g \iff (g)_{(t,0)}\) and \((g)_g^n \iff (g)_{(t,0)}^n\), so we may further assume that \(g = (f, 0)\).

Let \(\pi : B_{r+1} \to B_r\) be the map of \(A\)-algebras such that \(\pi(T_i) := T_i\) for \(i = 1, \ldots, r\) and \(\pi(T_{r+1}) := 0\), and notice that \(\gamma_{(t,0)} = \gamma_t \circ \pi\); if we endow \(B_r\) with the \(B_{r+1}\)-module structure given by \(\pi\), there follows, for every \(n \in \mathbb{N}\), a change of ring spectral sequence

\[
E(n)_{i,j} := \text{Tor}^B_i(\text{Tor}^{B_{r+1}}_j(B_r/I^n_{r+1} B_{r+1}, B_r), A) \Rightarrow \text{Tor}^{B_{r+1}}_i(B_r/I^n_{r+1} B_{r+1}, A)
\]

as well as a system of morphisms of spectral sequences as in (7.8.26).

**Claim 7.8.33.** (i) \(\text{Tor}^{B_{r+1}}_j(B_r/I^n_{r+1} B_{r+1}, B_r) = 0\) for every \(j > 1\).

(ii) The projection \(B_{r+1}/I^n_{r+1} B_{r+1} \to B_{r+1}/I^n_{r+1}\) induces the zero map

\[
\text{Tor}^{B_{r+1}}_1(B_r/I^n_{r+1} B_{r+1}, B_r) \to \text{Tor}^{B_{r+1}}_1(B_r/I^n_{r+1} B_{r+1}, B_r)
\]

for every \(n \in \mathbb{N}\).

**Proof of the claim.** The \(B_{r+1}\)-module \(B_r\) admits the free resolution \(B_{r+1} \to B_{r+1} \xrightarrow{\pi} B_r\) given by scalar multiplication by \(T_{r+1}\). Assertion (i) follows immediately, and we also deduce that

\[
\text{Tor}^{B_{r+1}}_1(B_r/I^n_{r+1} B_{r+1}, B_r) \cong \ker(B_{r+1}/I^n_{r+1} B_{r+1} \xrightarrow{T_{r+1}} B_r/I^n_{r+1} B_{r+1}) \subset I^n_{r+1}/I^n_{r+1}.
\]

Moreover, the transition maps in (ii) are induced by the inclusions \(I^n_{r+1} \subset I^{n-1}_{r+1}\) for every \(n > 0\), whence (ii).

From claim 7.8.33 we see that \(E(n)_{i,j}^2 = 0\) for every \(j > 1\), and \((E(n)_{i,j}^2 \mid n \in \mathbb{N})\) is a uniformly essentially zero inverse system. Hence, \((E(n)_{i,j}^\infty)_{i,j}\) is uniformly essentially zero for every \(j > 0\), and \((E(n)_{i,j}^\infty) = E(n)_{i,j}^2\) for every \(n, i \in \mathbb{N}\). Taking into account lemma 7.8.19 we conclude that \((g)_{(f,0)}\) (resp. \((g)_{(t,0)}^n\)) holds if and only if \((E(n)_{i,j}^2 \mid n \in \mathbb{N})\) is essentially zero (resp. uniformly essentially zero) for every \(i > 0\). But \(E(n)_{i,j}^2 = \text{Tor}^B_i(B_r/I^n_r B_r, A)\), so the latter condition is precisely \((g)_f\) (resp. \((g)_f^n\)).

(iii): By assumption, there exists an integer \(k > 0\) such that \(f_i^k \in J\) and \(g_j^k \in I\) for every \(i = 1, \ldots, r\) and every \(j = 1, \ldots, s\). By the foregoing proof of (iv), we deduce that

\[
(a)_f \iff (a)_{(f^k,g)} \quad \text{and} \quad (a)_g \iff (a)_{(f^k,g)}.
\]

Hence, we are reduced to checking that \((a)_{(f^k,g)} \iff (a)_{(f,g)} \iff (a)_{(f^k,g)}\). We show the first equivalence; obviously the same argument will yield the second one. To this aim, for every integers \(n \geq m \geq 0\) let \(\varphi_{\bullet}^{n,m} : K_*^n(f_n^m, g_m^n) \to K_*(f_m^m, g_m^m)\) and \(\psi_{\bullet}^{n,m} : K_*(f_n^m, g_m^n) \to K_*(f_m^m, g_m^m)\).
be the transition morphisms of the inverse systems \((K_\bullet(f^n, g^n) \mid n \in \mathbb{N})\) and \((K_\bullet(f^n, g^{kn}) \mid n \in \mathbb{N})\). Then, for every \(n, k \in \mathbb{N}\) we have morphisms
\[
K_\bullet(f^{kn}, g^{k^2n}) \xrightarrow{\beta'} K_\bullet(f^{kn}, g^{kn}) \xrightarrow{\beta''} K_\bullet(f^n, g^{kn}) \xrightarrow{\beta'''} K_\bullet(f^n, g^n)
\]
such that \(\beta' \circ \beta'' = \psi^{(kn,n)}\) and \(\beta'' \circ \beta''' = \varphi^{(kn,n)}\) (see \((7.8.20)\)), whence the contention. \qed

**Remark 7.8.34.** (i) By carefully tracking the estimates arising in the proof, it is possible to refine proposition \((7.8.25)\) (ii) as follows. For every \(r \in \mathbb{N}\) and every sequence of integers \((c(i) \mid i \in \mathbb{N})\) there exists a sequence of integers \((d(i) \mid i \in \mathbb{N})\), such that the following holds: for \(A\) and \(f\) of length \(r\) as in \((7.8.21)\), suppose that the inverse system \((\text{Tor}^A_{i+1}(A_r/I^n_r, A) \mid n \in \mathbb{N})\) is uniformly essentially zero with step \(\leq c(i)\), for every \(i \in \mathbb{N}\). Then the inverse system \((H_{i+1}(f, I^n) \mid n \in \mathbb{N})\) is uniformly essentially zero of step \(\leq d(i)\), for every \(i \in \mathbb{N}\).

(ii) A shorter alternative proof for the refinement of (i) can be proven as follows. Fix such a sequence \(c_\bullet\), and suppose that the assertion fails; then we may find a system of pairs \(((R_\lambda, f_\lambda) \mid \lambda \in \mathbb{N})\) consisting of a ring \(R_\lambda\) and a sequence \(f_\lambda\) of \(r\) elements of \(R_\lambda\), for every \(\lambda\), such that the following holds. For every \(\lambda \in \mathbb{N}\), denote by \(\beta_\lambda : A_r \to R_\lambda\) the ring homomorphism associated with the sequence \(f_\lambda\), as in \((7.8.21)\); then:

(a) the inverse system \((\text{Tor}^A_{i+1}(A_r/I^n_r, R_\lambda) \mid n \in \mathbb{N})\) is uniformly essentially zero with step \(\leq c(i)\), for every \(i, \lambda \in \mathbb{N}\)

(b) the inverse system \((H_{i+1}(f, I^n) \mid n \in \mathbb{N})\) is uniformly essentially zero of step \(d(i, \lambda)\), for every \(i \in \mathbb{N}\)

(c) the sequence of integers \((d(i_0, \lambda) \mid \lambda \in \mathbb{N})\) is strictly increasing, for some \(i_0 \in \mathbb{N}\).

Now, set \(J := \bigoplus_{\lambda \in \mathbb{N}} R_\lambda, B := A_r \oplus J,\) and endow \(B\) with the unique ring structure such that \((f, b) \cdot (a', b') := (fa', fb + a'b)\) for every \(a, a' \in A_r\) and \(b, b' \in J\). Then \(J\) is an ideal of \(B\) with \(J^2 = 0\), the natural projection induces a ring isomorphism \(\omega : B/J \xrightarrow{\sim} A_r\), and the inclusion map \(\beta : A_r \to B\) is a ring homomorphism; moreover, the \(A_r\)-module structure induced via \(\omega\) on \(J\) agrees with the \(A_r\)-module structure induced by the system of maps \((\beta_\lambda) \mid \lambda \in \mathbb{N}\). We consider the sequence \(t := (T_1, \ldots, T_r)\) of \(A_r\), and its image \(f := \beta(t)\) in \(B\), and we notice the natural isomorphisms of \(A_r\)-modules
\[
\text{Tor}^A_{i+1}(A_r/I^n_r, B) \xrightarrow{\sim} \bigoplus_{\lambda \in \mathbb{N}} \text{Tor}^A_{i+1}(A_r/I^n_r, A_r)\quad\text{for every } i, n \in \mathbb{N}.
\]

In light of condition (a), we deduce that \(B\) satisfies condition \((a)_f\), so it also satisfies \((c)_f\), by virtue of proposition \((7.8.25)\) (ii); on the other hand, clearly we have as well natural isomorphisms
\[
H_i(f, I^n_r B) \xrightarrow{\sim} H_i(t, I^n) \oplus \bigoplus_{\lambda \in \mathbb{N}} H_i(f_\lambda, I^n_r R_\lambda)\quad\text{for every } i, n \in \mathbb{N}
\]
which, in view of our assumption (c), imply that the inverse system \((H_{i_0}(f, I^n) \mid n \in \mathbb{N})\) cannot be uniformly essentially zero, a contradiction.

### 7.8.35

Let \(f := (f_1, \ldots, f_r)\) be a finite sequence of elements of a ring \(A\), and set
\[
I := f_1 A + \cdots + f_r A\quad\text{and}\quad J := \bigcup_{n \in \mathbb{N}} \text{Ann}_A(I^n).
\]
Denote by \(\overline{f} := (\overline{f}_1, \ldots, \overline{f}_r)\) the image of \(f\) in \(\overline{A} := A/J\).

**Proposition 7.8.36.** With the notation of \((7.8.35)\), the following conditions are equivalent:

(a) The ring \(A\) satisfies condition \((a)?\) (resp. \((a)_{\overline{f}}\)) of \((7.8.21)\).

(b) \(\overline{A}\) satisfies condition \((c)_{\overline{f}}\) (resp. \((c)_{\overline{f}}\)) and there exists \(k \in \mathbb{N}\) with \(I^k J = 0\).
Proof. (a)⇒(b): by proposition 7.8.25(i) the ring \( A \) satisfies condition (c)\(_k\), so there exists \( k \in \mathbb{N} \) such that the natural map \( H_i(f, I^k) \to H_i(f, A) \) is the zero morphism. In other words

\[
I^k \cap \text{Ann}_A(I) = 0.
\]

Therefore we have as well \( I^k \cap J = 0 \), and it follows easily that \( J = \text{Ann}_A(I^k) \). If \( A \) satisfies (c)\(_T^m\), notice that for every \( n \geq k \) the natural map \( I^n \to \Gamma^n A \) is then bijective, and thus the same holds for the induced map \( H_i(f, I^n) \to H_i(f, I^n A) \), for every \( i \in \mathbb{N} \), so \( A \) fulfills (c)\(_T^m\).

If \( A \) satisfies (a)\(_T\) (resp. (a)\(_T^m\)), define \( A_r \) and \( \beta_I \) as in 7.8.21, and endow \( A \) and \( J \) with the \( A_r \)-module structure induced by \( \beta_I \); from lemma 7.8.24 we deduce that the inverse system \( T(J, i) =: (\text{Tor}^A_i(A_r/I^n, J) \mid n \in \mathbb{N}) \) is essentially zero for every \( i > 0 \). By assumption, the inverse system \( T(A, i) =: (\text{Tor}^A_i(A_r/I^n, A) \mid n \in \mathbb{N}) \) is essentially zero (resp. uniformly essentially zero); moreover, the short exact sequence \( A_r \)-modules \( 0 \to J \to A \to A \to 0 \) yields exact sequences of inverse systems:

\[
(7.8.37) \quad T(J, i) \to T(A, i) \to T(\overline{A}, i) =: (\text{Tor}^A_i(A_r/I^n, \overline{A}) \mid n \in \mathbb{N}) \to T(J, i - 1).
\]

for every \( i > 0 \). By virtue of lemma 7.8.19 it follows already that \( T(\overline{A}, i) \) is essentially zero (resp. uniformly essentially zero) for every \( i > 1 \). By the same token, the case \( i = 1 \) yields the exact sequence of inverse systems

\[ T(A, 1) \to T(\overline{A}, 1) \to (J/I^n J \mid n \in \mathbb{N}) \xrightarrow{\varphi_n} (A/I^n \mid n \in \mathbb{N}). \]

But the foregoing shows that \( \varphi_n \) is injective for every \( n \geq k \), hence \( \ker \varphi_n \) is uniformly essentially zero, and finally \( T(\overline{A}, 1) \) is essentially zero (resp. uniformly essentially zero, again by lemma 7.8.19). Summing up, this shows that \( \overline{A} \) fulfills condition (a)\(_T\) (resp. (a)\(_T^m\)), as stated.

(b)⇒(a): Suppose first that \( \overline{A} \) satisfies (a)\(_T\) (resp. (a)\(_T^m\)); by assumption, \( J \) is an \( A_r/I_r \)-module, so the inverse system \( T(J, i) \) is uniformly essentially zero for every \( i > 0 \), by lemma 7.8.24 the inverse system \( T(\overline{A}, i) \) is essentially zero (resp. uniformly essentially zero), and thus the same holds also for \( T(A, i) \), in view of (7.8.37) and lemma 7.8.19. Lastly, if \( \overline{A} \) satisfies (c)\(_T^m\), then it also satisfies condition (a)\(_T\), by proposition 7.8.25(i), hence \( A \) satisfies (a)\(_T\), by the foregoing case; but as we have seen, this implies that the natural map \( H_i(f, I^n) \to H_i(f, I^n \overline{A}) \) is bijective for every \( i \in \mathbb{N} \) and sufficiently large \( n \), so \( A \) satisfies (c)\(_T^m\).

7.8.38. Let \( A, I \) and \( f \) be as in (7.8.35), and for every \( n > 0 \) denote by \( I^n(\alpha) \subset A \) the ideal generated by \( f^n := (f^n_i \mid i = 1, \ldots, r) \). For all \( m \geq n > 0 \) we deduce natural commutative diagrams of complexes:

\[
\begin{array}{ccc}
K\ast(f^n) & \longrightarrow & A/I^{\alpha}(\alpha)[0] \\
\varphi_{\alpha mn} \downarrow & & \downarrow \pi_{\alpha mn} \\
K\ast(f^m) & \longrightarrow & A/I^{\alpha}[0] 
\end{array}
\]

(notation of 7.8.20) where \( \pi_{\alpha mn} \) is the natural surjection, whence a compatible system of maps:

\[
(7.8.39) \quad \text{Hom}_{D(A-\text{Mod})}(A/I^{\alpha}[0], M\ast) \to \text{Hom}_{D(A-\text{Mod})}(K\ast(f^n), M\ast).
\]

for every \( n \geq 0 \) and every complex \( M\ast \in D^+(A-\text{Mod}) \). Since \( K\ast(f^n) \) is a complex of free \( A \)-modules, \( 7.8.39 \) translates as a direct system of maps:

\[
(7.8.40) \quad R^n\text{Hom}_A(A/I^{\alpha}, M\ast) \to H^n(f^n, M\ast) \quad \text{for all } n \in \mathbb{N} \text{ and every } i \in \mathbb{Z}.
\]

Notice that \( I^{nr-r+1} \subset I^n \subset I^r \) for every \( n > 0 \), hence the colimit of the system \( 7.8.40 \) is equivalent to a natural map:

\[
(7.8.41) \quad \colim_{n \in \mathbb{N}} R^n\text{Hom}_A(A/I^n, M\ast) \to \colim_{n \in \mathbb{N}} H^n(f^n, M\ast) \quad \text{for every } i \in \mathbb{Z}.
\]
Lemma 7.8.42. With the notation of (7.8.38), the following conditions are equivalent:

(a) The map (7.8.41) is an isomorphism for every \( M^* \in \text{Ob}(D^+(A\text{-Mod})) \) and all \( i \in \mathbb{Z} \).

(b) \( \text{colim}_{n \in \mathbb{N}} H^i(f^n, J) = 0 \) for every \( i > 0 \) and every injective \( A \)-module \( J \).

(c) The ring \( A \) satisfies condition (d) of (7.8.21).

Proof. (a) \( \Rightarrow \) (b) is obvious. Next, if \( J \) is an injective \( A \)-module, we have natural isomorphisms
\[
H^i(f^n, J) \simeq \text{Hom}_A(H_nK_\bullet(f^n), J)
\]
for all \( n \in \mathbb{N} \), which easily implies that (c) \( \Rightarrow \) (b).

(b) \( \Rightarrow \) (c) : Indeed, for any \( p \in \mathbb{N} \) let us choose an injection \( \varphi : H_pK_\bullet(f^n) \to J \) into an injective \( A \)-module \( J \). By (7.8.43) we can regard \( \varphi \) as an element of \( H^i(f^n, J) \); by (b) the image of \( \varphi \) in \( \text{Hom}_A(H_1K_\bullet(f^n), J) \) must vanish if \( q > p \) is large enough. This can happen only if \( H_1K_\bullet(f^n) \to H_1K_\bullet(f^p) \) is the zero map.

(b) \( \Rightarrow \) (a) : Let \( M^* \to J^* \) be an injective resolution of the complex \( M^* \). The double complex \( \text{colim}_{n \in \mathbb{N}} \text{Hom}_A^\bullet(K_\bullet(f^n), J^*) \) determines two spectral sequences:
\[
E_1^{pq} := \text{colim}_{n \in \mathbb{N}} \text{Hom}_A(K_p(f^n), H^qJ^*) \Rightarrow \text{colim}_{n \in \mathbb{N}} R^{p+q}\text{Hom}_A^\bullet(K_\bullet(f^n), M^*)
\]
\[
F_1^{pq} := \text{colim}_{n \in \mathbb{N}} H^p(f^n, J^*) \simeq \text{colim}_{n \in \mathbb{N}} \text{Hom}_A(H_pK_\bullet(f^n), J^*) \Rightarrow \text{colim}_{n \in \mathbb{N}} R^{p+q}\text{Hom}_A^\bullet(K_\bullet(f^n), M^*)
\]
Clearly \( E_1^{pq} = 0 \) whenever \( q > 0 \), and (b) says that \( F_1^{pq} = 0 \) for \( p > 0 \). Hence these two spectral sequences degenerate and we deduce natural isomorphisms:
\[
\text{colim}_{n \in \mathbb{N}} R^q\text{Hom}_A^\bullet(A/I^{(n)}, M^*) \simeq F_2^{q0} \supseteq F_2^{q0} \simeq \text{colim}_{n \in \mathbb{N}} H^q(f^n, M^*)
\]
By inspection, one sees easily that these isomorphisms are the same as the maps (7.8.41).

Lemma 7.8.44. In the situation of (7.8.38), suppose that the following holds. For every finitely presented quotient \( B \) of \( A \) and every \( i = 1, \ldots, r \), there exists \( p \in \mathbb{N} \) such that
\[
\text{Ann}_B(f^p_i) = \text{Ann}_B(f^p) \quad \text{for every} \quad q \geq p.
\]
Then the ring \( A \) satisfies condition (d) of (7.8.21).

Proof. We shall argue by induction on \( r \). If \( r = 1 \), then \( f = (f) \) for a single element \( f \in A \). In this case, our assumption ensures that there exists \( p \in \mathbb{N} \) such that \( \text{Ann}_A(f^p) = \text{Ann}_A(f^p) \) for every \( q \geq p \). It follows easily that \( H_1(\varphi f^p) : H_1K_\bullet(f^{p+k}) \to H_1K_\bullet(f^k) \) is the zero map for every \( k \geq 0 \) (notation of (7.8.20)), whence the claim.

Next, suppose that \( r > 1 \) and that the claim is known for all sequences of less than \( r \) elements. Set \( g := (f_1, \ldots, f_{r-1}) \) and \( f := f_r \). Specializing (7.8.4) to our current situation, we derive short exact sequences:
\[
0 \to H_0(f^n, H_pK_\bullet(g^n)) \to H_0K_\bullet(f^n) \to H_0(f^n, H_{p-1}K_\bullet(g^n)) \to 0
\]
for every \( p > 0 \) and \( n \geq 0 \); for a fixed \( p \), this is an inverse system of exact sequences. By induction, the inverse system \( (H_0K_\bullet(g^n) \mid n \in \mathbb{N}) \) is essentially zero for \( i > 0 \); in light of lemma 7.8.19, we deduce already that the inverse system \( (H_iK_\bullet(f^n) \mid n \in \mathbb{N}) \) is essentially zero for all \( i > 1 \). To conclude, we are thus reduced to showing that the inverse system \( (T_n := H^0(f^n, H_0K_\bullet(g^n)) \mid n \in \mathbb{N}) \) is essentially zero. However \( A_n := H_0K_\bullet(g^n) = A/(g_1^n, \ldots, g_{r-1}^n) \) is a finitely presented quotient of \( A \) for any fixed \( n \in \mathbb{N} \), hence the foregoing case \( r = 1 \) shows that the inverse system \( (T_{mn} := \text{Ann}_{A_n}(f^m) \mid m \in \mathbb{N}) \) is essentially zero. Let \( m \geq n \) be chosen so that \( T_{mn} \to T_{nn} \) is the zero map; then the composition \( T_m = T_{mn} \to T_{mn} \to T_{nn} \) is zero as well.

Remark 7.8.45. Notice that the condition of lemma 7.8.44 is verified when \( A \) is noetherian. Combining with lemma 7.8.42, we conclude that if \( A \) is noetherian, the map (7.8.41) is an isomorphism, for every finite system \( f \) of elements of \( A \), and every \( i \in \mathbb{N} \).
7.9. Filtered rings and Rees algebras. Some of the following material is borrowed from Appendix III], where much more can be found.

**Definition 7.9.1.** Let $R$ be a ring, $A$ an $R$-algebra.

(i) An *$R$-algebra filtration on $A$* is an increasing exhaustive filtration $\Fil_{\bullet} A$ indexed by $\mathbb{Z}$ and consisting of $R$-submodules of $A$, such that:

\[
1 \in \Fil_0 A \quad \text{and} \quad \Fil_i A \cdot \Fil_j A \subset \Fil_{i+j} A \quad \text{for every } i, j \in \mathbb{Z}.
\]

The pair $\mathcal{A} := (A, \Fil_{\bullet} A)$ is called a filtered $R$-algebra.

(ii) Let $M$ be an $A$-module. An *$A$-filtration* on $M$ is an increasing exhaustive filtration $\Fil_{\bullet} M$ consisting of $R$-submodules, and such that:

\[
\Fil_i A \cdot \Fil_j M \subset \Fil_{i+j} M \quad \text{for every } i, j \in \mathbb{Z}.
\]

The pair $\mathcal{M} := (M, \Fil_{\bullet} M)$ is called a filtered $A$-module.

(iii) Let $U$ be an indeterminate. The *Rees algebra* of $\mathcal{A}$ is the $\mathbb{Z}$-graded subring of $A[U, U^{-1}]$

\[
R(\mathcal{A})_{\bullet} := \bigoplus_{i \in \mathbb{Z}} U^i \cdot \Fil_i A.
\]

(iv) Let $\mathcal{M} := (M, \Fil_{\bullet} M)$ be a filtered $A$-module. The *Rees module* of $\mathcal{M}$ is the graded $R(\mathcal{A})_{\bullet}$-module:

\[
R(\mathcal{M})_{\bullet} := \bigoplus_{i \in \mathbb{Z}} U^i \cdot \Fil_i M.
\]

**Lemma 7.9.2.** Let $R$ be a ring, $\mathcal{A} := (A, \Fil_{\bullet} A)$ a filtered $R$-algebra, $\gr_{\bullet} A$ the associated graded $R$-algebra, $R(\mathcal{A})_{\bullet} \subset A[U, U^{-1}]$ the Rees algebra of $\mathcal{A}$. Then there are natural isomorphisms of graded $R$-algebras:

\[
R(\mathcal{A})_{\bullet}/UR(\mathcal{A})_{\bullet} \simeq \gr_{\bullet} A \quad R(\mathcal{A})_{\bullet}[U^{-1}] \simeq A[U, U^{-1}]
\]

and of $R$-algebras:

\[
R(\mathcal{A})_{\bullet}/(1 - U)R(\mathcal{A})_{\bullet} \simeq A.
\]

**Proof.** The isomorphisms with $\gr_{\bullet} A$ and with $A[U, U^{-1}]$ follow directly from the definitions. For the third isomorphism, it suffices to remark that $A[U, U^{-1}]/(1 - U) \simeq A$. \qed

**Example 7.9.3.** Let $A$ be any ring, $I \subset A$ any ideal, and endow $A$ with its $I$-adic filtration $\Fil_{\bullet} A$, so that $\Fil_i A := I^i$ for every $i \in \mathbb{N}$ and $\Fil_i A = A$ for every $i > 0$. The pair $\mathcal{A} := (A, \Fil_{\bullet} A)$ is obviously a filtered $A$-algebra, and we denote by $R(\mathcal{A}, I)_{\bullet}$ its Rees algebra.

**Definition 7.9.4.** Let $R$ be a ring, $\mathcal{A} := (A, \Fil_{\bullet} A)$ a filtered $R$-algebra.

(i) Suppose that $A$ is of finite type over $R$, let $\mathbf{x} := (x_1, \ldots, x_n)$ be a finite set of generators for $A$ as an $R$-algebra, and $\mathbf{k} := (k_1, \ldots, k_n)$ a sequence of $n$ integers; the *good filtration* $\Fil_{\bullet} A$ attached to the pair $(\mathbf{x}, \mathbf{k})$ is the $R$-algebra filtration such that $\Fil_i A$ is the $R$-submodule generated by all the elements of the form

\[
\prod_{j=1}^n x_j^{a_j} \quad \text{where } \sum_{j=1}^n a_j k_j \leq i \quad \text{and} \quad a_1, \ldots, a_n \geq 0
\]

for every $i \in \mathbb{Z}$. A filtration $\Fil_{\bullet} A$ on $A$ is said to be *good* if it is the good filtration attached to some system of generators $\mathbf{x}$ and some sequence of integers $\mathbf{k}$.

(ii) The filtration $\Fil_{\bullet} A$ is said to be *positive* if it is the good filtration associated with a pair $(\mathbf{x}, \mathbf{k})$ as in (i), such that moreover $k_i > 0$ for every $i = 1, \ldots, n$.

(iii) Let $M$ be a finitely generated $A$-module. An $A$-filtration $\Fil_{\bullet} M$ is called a *good filtration* if $R(M, \Fil_{\bullet} M)_{\bullet}$ is a finitely generated $R(\mathcal{A})_{\bullet}$-module.
Example 7.9.5. Let \( A := R[t_1, \ldots, t_n] \) be the free \( R \)-algebra in \( n \) indeterminates. Choose any sequence \( \mathbf{k} := (k_1, \ldots, k_n) \) of integers, and denote by \( \text{Fil}_\mathbf{k} A \) the good filtration associated with \( t := (t_1, \ldots, t_n) \) and \( \mathbf{k} \). Then \( R(A, \text{Fil}_\mathbf{k} A) \) is isomorphic, as a graded \( R \)-algebra, to the free polynomial algebra \( A[U] = R[U, t_1, \ldots, t_n] \), endowed with the grading such that \( U \in \text{gr}_1 A[U] \) and \( t_j \in \text{gr}_{k_j} A[U] \) for every \( j \leq n \). Indeed, a graded isomorphism can be defined by the rule: \( U \mapsto U \) and \( t_j \mapsto U^{k_j} \cdot t_j \) for every \( j \leq n \). The easy verification shall be left to the reader.

7.9.6. Let \( A \) and \( M \) be as in definition [7.9.4 (iii)]; suppose that \( \mathfrak{m} := (m_1, \ldots, m_n) \) is a finite system of generators of \( M \), and let \( \mathbf{k} := (k_1, \ldots, k_n) \) be an arbitrary sequence of \( n \) integers. To the pair \( (\mathfrak{m}, \mathbf{k}) \) we attach a filtered \( A \)-module \( M := (M, \text{Fil}_\mathbf{k} M) \), by declaring that:

\[
\text{Fil}_i M := m_1 \cdot \text{Fil}_{i-k_1} A + \cdots + m_n \cdot \text{Fil}_{i-k_n} A \quad \text{for every } i \in \mathbb{Z}.
\]

Notice that the homogeneous elements \( m_1 \cdot U^{k_1}, \ldots, m_n \cdot U^{k_n} \) generate the graded Rees module \( R(\mathfrak{m})_\mathbf{k} \), hence \( \text{Fil}_\mathbf{k} M \) is a good \( A \)-filtration. Conversely:

Lemma 7.9.8. For every good filtration \( \text{Fil}_\mathbf{k} M \) on \( M \), there exist a sequence \( \mathfrak{m} \) of generators of \( M \) and a sequence of integers \( \mathbf{k} \), such that \( \text{Fil}_\mathbf{k} M \) is of the form (7.9.7).

Proof. Suppose that \( \text{Fil}_\mathbf{k} M \) is a good filtration; then \( R(\mathfrak{m})_\mathbf{k} \) is generated by finitely many homogeneous elements \( m_1 \cdot U^{k_1}, \ldots, m_n \cdot U^{k_n} \). Thus,

\[
R(\mathfrak{m})_i := U^i \cdot \text{Fil}_\mathbf{k} M = m_1 \cdot U^{k_1} \cdot A_{i-k_1} + \cdots + m_n \cdot U^{k_n} \cdot A_{i-k_n} \quad \text{for every } i \in \mathbb{Z}
\]

which means that the sequences \( \mathfrak{m} := (m_1, \ldots, m_n) \) and \( \mathbf{k} := (k_1, \ldots, k_n) \) will do. \( \square \)

7.9.9. Let \( A \to B \) and \( A \to C \) be maps of noetherian rings, and suppose that either \( B \) or \( C \) is an \( A \)-algebra of finite type; let also \( M \) be a finitely generated \( B \)-module, \( N \) a finitely generated \( C \)-module, and \( I \subset B \) any ideal. Then the \( A \)-modules

\[
T_i := \text{Tor}_i^A(M, N)
\]

inherit natural \( B \otimes_A C \)-module structures, and we remark:

Lemma 7.9.10. In the situation of (7.9.9), the \( B \otimes_A C \)-module \( T_i \) is finitely generated for every \( i \in \mathbb{N} \).

Proof. Say that \( B \) is an \( A \)-algebra of finite type; the same argument will apply also to the case where \( C \) is an \( A \)-algebra of finite type. Then, we have \( B = D/J \) for some free polynomial \( A \)-algebra \( D \) of finite type, and some ideal \( J \subset D \). Hence, \( M \) is also a \( D \)-module of finite type; then \( D \) is a noetherian ring, so we may find a resolution \( L_\bullet \to M \) consisting of free \( D \)-modules of finite type, and since \( D \) is a free \( A \)-module, we get natural \( A \)-linear isomorphisms \( \omega_i : T_i \isom H_i(L_\bullet \otimes_A N) \) for every \( i \in \mathbb{N} \). Moreover, \( L_i \otimes_A N \) is naturally a complex of \( D \otimes_A C \)-modules of finite type, so \( T_i \) inherits via \( \omega_i \) a structure of \( D \otimes_A C \)-module of finite type. Lastly, a simple inspection shows that the latter \( D \otimes_A C \)-module structure on \( T_i \) agrees with the one induced from the natural \( B \otimes_A C \)-module structure, via the surjection \( D \otimes_A C \to B \otimes_A C \), whence the contention. \( \square \)

We endow \( B \) (resp. \( B \otimes_A C \)) with its \( I \)-adic (resp. \( I \cdot (B \otimes_A C) \)-adic) filtration as in example [7.9.3] and denote by \( \widehat{B} \) (resp. \( \widehat{B} \otimes_A C \)) the resulting filtered ring. Also, set \( \text{Fil}_n M := \text{Fil}_n B \cdot M \) for every \( n \in \mathbb{Z} \); we define a \( \widehat{B} \otimes_A C \)-filtration on \( T_i \), by the rule:

\[
\text{Fil}_n T_i := \text{Im}(\text{Tor}_i^A(\text{Fil}_n M, N) \to T_i) \quad \text{for every } i \in \mathbb{N} \text{ and } n \in \mathbb{Z}.
\]

Proposition 7.9.11. The \( \widehat{B} \otimes_A C \)-filtration \( \text{Fil}_\mathbf{k} T_i \) is good, for every \( i \in \mathbb{N} \).
Proof. Pick a finite set of generators $f_1, \ldots, f_r$ for $I$, and consider the surjective map of graded $B$-algebras

$$B[U, t_1, \ldots, t_r] \to R(B)_* : U \mapsto U \in R(B)_1 \quad t_i \mapsto f_i \quad \text{for } i = 1, \ldots, r$$

(for the grading of $B[U, t_1, \ldots, t_r]$ that places the indeterminates $t_1, \ldots, t_r$ in degree $-1$, and $U$ in degree 1). The $B \otimes_A C$-module

$$P_i := \bigoplus_{n \in \mathbb{Z}} \text{Tor}^A_i(\text{Fil}_n M, N)$$

carries a natural structure of graded $R(B)_* \otimes_A C$-module, whence a graded $B \otimes_A C[U, t_1, \ldots, t_r]$-module structure as well, via (7.9.12), and it suffices to show:

**Claim 7.9.14.** $P_i$ is a finitely generated $B \otimes_A C[U, t_1, \ldots, t_r]$-module, for every $i \in \mathbb{N}$.

**Proof of the claim.** Notice that $R(M, \text{Fil}_n M)_*$ is a finitely generated $R(B)_*$-module; *a fortiori*, it is a finitely generated graded $B[U, t_1, \ldots, t_r]$-module. By remark 7.6.30(iv), we may then find a resolution

$$\cdots \to L_n \xrightarrow{d_n} L_{n-1} \to \cdots \to L_0 \xrightarrow{d_0} R(M, \text{Fil}_n M)_*$$

where each $L_n$ is a free $B[U, t_1, \ldots, t_r]$-module of finite rank, each $d_n$ is a morphism of graded $B[U, t_1, \ldots, t_r]$-modules, and the restriction of the resolution to the summands of degree $i$ is a flat resolution of the $B$-module $I^i M$, for every $i \in \mathbb{N}$. There follows a natural isomorphism of graded $B \otimes_A C$-modules

$$P_i \xrightarrow{\sim} H_i(L_\bullet \otimes_A N) \quad \text{for every } i \in \mathbb{N}$$

and a simple inspection shows that the $B \otimes_A C[U, t_1, \ldots, t_r]$-module structure on $P_i$ deduced via (7.9.15) agrees with the foregoing one, so the assertion follows.

**7.9.16.** In the situation of (7.9.9), set $B_n := B/I^n$ for every $n \in \mathbb{N}$. We deduce, for every $i \in \mathbb{N}$, a morphism of projective systems of $B \otimes_A C$-modules

$$X^i_\bullet := (B_n \otimes_B \text{Tor}^A_i(M, N) \mid n \in \mathbb{N}) \xrightarrow{\varphi_i} Y^i_\bullet := (\text{Tor}^A_i(B_n \otimes_B M, N) \mid n \in \mathbb{N})$$

where the transition maps of $X^i_\bullet$ and $Y^i_\bullet$ are induced by the projections $B_{n+1} \to B_n$, for every $n \in \mathbb{N}$, and the morphisms $\varphi_{i,n}$ are induced by the projections $M \to B_n \otimes_B M$.

**Corollary 7.9.17.** With the notation of (7.9.16), we have:

(i) The morphism $\varphi_i$ is an isomorphism of pro-$B \otimes_A C$-modules, for every $i \in \mathbb{N}$.

(ii) The morphism $\varphi_i$ induces an isomorphism of $B \otimes_A C$-modules:

$$\lim_{n \in \mathbb{N}} B_n \otimes_B \text{Tor}^A_i(M, N) \xrightarrow{\sim} \lim_{n \in \mathbb{N}} \text{Tor}^A_i(B_n \otimes_B M, N) \quad \text{for every } i \in \mathbb{N}.$$

**Proof.** (i): The assertion means that the systems $(\text{Ker } \varphi_{i,n} \mid n \in \mathbb{N})$ and $(\text{Coker } \varphi_{i,n} \mid n \in \mathbb{N})$ are essentially zero, for every $i \in \mathbb{N}$. We shall prove the more precise:

**Claim 7.9.18.** For every $i \in \mathbb{N}$ the systems $(\text{Ker } \varphi_{i,n} \mid n \in \mathbb{N})$ and $(\text{Coker } \varphi_{i,n} \mid n \in \mathbb{N})$ are uniformly essentially zero (see definition 7.8.18(ii)).

**Proof of the claim.** The long exact $\text{Tor}^A_i(-, N)$-sequence arising from the short exact sequence

$$0 \to I^n M \to M \to M/I^n M \to 0$$

yields a natural identification

$$\text{Coker } \varphi_{i,n} = \text{Ker } (U^n : P_{i-1,-n} \to P_{i-1,0})$$
whose transition maps are given by multiplication by $B$. Whence the sought vanishing for the maps between kernels. Lastly, since every $\ker(\varphi_{i,n} | n \in \mathbb{N})$ becomes a direct summand of the system of $B \otimes_A C$-modules (7.9.19)

$$\ker(U^n : P_{i-1,\bullet} \to P_{i-1,\bullet} | n \in \mathbb{N})$$

whose transition maps are given by multiplication by $U$. By the same token, the inverse system $(\ker(\varphi_{i,n} | n \in \mathbb{N})$ is naturally identified with the inverse system $(\ker(U^{c+n} = \ker(U^c)$ for every $n \in \mathbb{N}$. Therefore the transition map $\ker(U^{c+n} \to \ker(U^n)$ vanishes for every $n \in \mathbb{N}$, and the proof of the claim is complete.

(ii) is a standard consequence of (i) : see [125, Prop.3.5.7].

**Corollary 7.9.20.** In the situation of (7.8.21), endow $A$ with its $I$-adic filtration $\Fil_{\bullet} A$, and set $B_\bullet := R(A, \Fil_{\bullet} A)$. Denote also by $\bar{f}_0$ the image in $B_0$ of the sequence $f$. Then we have:

(i) $B_\bullet$ satisfies condition $(c)_{\bar{f}_0}$ if and only if $B_\bullet$ satisfies condition $(c)_{\bar{f}_0}^\un$, if and only if $A$ satisfies condition $(c)_{\bar{f}_0}^\un$.

(ii) $B_\bullet$ satisfies condition $(a)_{\bar{f}_0}^\un$ if and only if $A$ satisfies condition $(a)_{\bar{f}_0}^\un$.

(iii) If $A$ is noetherian, then $A$ satisfies condition $(a)_{\bar{f}_0}^\un$.

**Proof.** (iii): It suffices to apply claim 7.9.18 with $A$ (resp. $I$, resp. $B$, resp. $C$) replaced by $A_r$ (resp. by $I_r$, resp. by $B_r$, resp. by $A_r$).

(i): Indeed, if condition $(c)_{\bar{f}_0}$ holds, for every $i \in \mathbb{N}$ there exists $k \in \mathbb{N}$ such that the natural map $H_i(f_0, I^k B_\bullet) \to H_i(f_0, B)$ is the zero map. However, clearly the latter is the direct sum of the natural maps

$$H_i(f, I^{n+k}) \to H_i(f, I^n) \quad \text{for every } n \in \mathbb{N}$$

whence $(c)_{\bar{f}_0}^\un$. By the same token, we immediately see that $(c)_{\bar{f}_0}^\un \Rightarrow (c)_{\bar{f}_0}^\un$.

(ii): Define $A_r$, $I_r$, $\beta_r : A_r \to A$ and $\beta_{\bar{f}_0} : A_r \to B_\bullet$ as in (7.8.21), endow $A_r$ with its $I_r$-adic filtration $\Fil_{\bullet} A_r$, and set

$$B_{r,\bullet} := R(A_r, \Fil_{\bullet} A_r) \quad C_r := B_{r,\bullet} \otimes_A A.$$ 

Let also $t$ be the sequence $(T_1, \ldots, T_r)$ of homogenous elements of degree zero in $B_{r,\bullet}$, and $g$ the image of $t$ under the natural map $B_{r,\bullet} \to C_r$; since the ring $B_{r,\bullet}$ is noetherian, (iii) tells us that it satisfies condition $(a)_{\bar{f}_0}^\un$, which means that we have uniformly essentially zero inverse systems

$$K_{r,\bullet} := (\ker(I^n_0 \otimes_{A_r} B_{r,\bullet} \to I^n_B B_{r,\bullet} | n \in \mathbb{N})$$

and

$$T_{r,\bullet} := (\Tor^{A_r}_{\bar{f}_0}(I^n_r, B_{r,\bullet} | n \in \mathbb{N})$$

for every $i > 0$. Suppose now that $(a)_{\bar{f}_0}^\un$ holds; this means that also the inverse systems

$$K_r := (\ker(I^n_0 \otimes_{A_r} A \to I^n) | n \in \mathbb{N})$$

and

$$T_r := (\Tor^{A_r}_{\bar{f}_0}(I^n_r, A | n \in \mathbb{N})$$

for every $i > 0$ are uniformly essentially zero; in this case, we notice:

**Claim 7.9.21.** For every $i > 0$ there exists $c \in \mathbb{N}$ such that $I^c \cdot T^n_r = 0$ for every $n \in \mathbb{N}$.

**Proof of the claim.** By assumption, for every $i \in \mathbb{N}$ there exists $c \in \mathbb{N}$ such that the transition map $\varphi_{n+c}^i : T^n_{n+c} \to T^n_n$ is the zero morphism for every $n \in \mathbb{N}$. Now, if $a \in I^c$, the scalar multiplication by $a$ on $I^n$ factors as the composition of an $A$-linear map $I^n \to I^{n+c}$ and the inclusion map $I^{n+c} \to I^n$. It follows that scalar multiplication by $a$ on $T^n_r$ factors as the composition of an $A$-linear map $T^n_n \to T^n_{n+c}$ and $\varphi_{n+c,n}$, whence the claim.

\(\diamondsuit\)
Claim 7.9.22. If $C_\bullet$ satisfies condition \((a)_{g}^{\text{un}}\), then $B_\bullet$ satisfies condition \((a)_{g}^{\text{un}}\).

Proof of the claim. We have a natural surjective homomorphism $f_\bullet : C_\bullet \to B_\bullet$ of graded rings, such that $\text{Ker} \ f_\bullet = \bigoplus_{n \in \mathbb{N}} K_n$, and arguing as in the proof of claim 7.9.21 we see that there exists $c \in \mathbb{N}$ such that $I^c \cdot K_n = 0$ for every $n \in \mathbb{N}$. Set

$$J_C := \bigcup_{n \in \mathbb{N}} \text{Ann}_{C_\bullet}(I^n) \quad J_B := \bigcup_{n \in \mathbb{N}} \text{Ann}_{B_\bullet}(I^n)$$

and $\overline{C} := C_\bullet/J_C$; it follows that the projection $C_\bullet \to \overline{C}_\bullet$ factors through a surjective ring homomorphism $B_\bullet \to \overline{C}_\bullet$ whose kernel equals $J_B$, so that $f_\bullet(J_C) = J_B$. Suppose now that $C_\bullet$ satisfies condition \((a)_{g}^{\text{un}}\), and let $g$ be the image of $g$ in $\overline{C}_\bullet$; then there exists $k \in \mathbb{N}$ such that $I^k J_C = 0$, and $\overline{C}_\bullet$ satisfies condition \((a)_{g}^{\text{un}}\) (proposition 7.8.36). Hence $I^k J_B = 0$, and the assertion follows, again by proposition 7.8.36. $\diamond$

In view of claim 7.9.22, we are reduced to checking that for every $i > 0$ the inverse systems

$$K'_\bullet := (\text{Ker}(I^n_\bullet \otimes_A C_\bullet \to I^n_\bullet C_\bullet) \mid n \in \mathbb{N}) \quad \text{and} \quad T'^i_\bullet := (\text{Tor}^A_r(I^n_\bullet, C_\bullet) \mid n \in \mathbb{N})$$

are uniformly essentially zero. However, notice that the natural map

$$K_r \otimes_A A \to K'_\bullet$$

is an epimorphism of inverse systems, so we get already the assertion for $K'_\bullet$. Next, we remark:

Claim 7.9.23. The inverse system $(H_i(A \otimes A_r B_\bullet \otimes A_r I^n_r) \mid n \in \mathbb{N})$ is uniformly essentially zero for every $i > 0$.

Proof of the claim. We have a spectral sequence:

$$E(n)_{pq}^2 := \text{Tor}^A_p(A, \text{Tor}^A_r(B_\bullet, I^n_r)) \Rightarrow H_{p+q}(A \otimes A_r B_\bullet \otimes A_r I^n_r) \quad \text{for every } n \in \mathbb{N}$$

hence it suffices to check that the inverse system $(E(n)_{pq}^2 \mid n \in \mathbb{N})$ is uniformly essentially zero for every $p, q \in \mathbb{N}$ such that $p + q > 0$. The latter assertion is already known for every $q > 0$, since the system $T'^i_\bullet$ is uniformly essentially zero. For $q = 0$, we consider the short exact sequence of inverse systems

$$0 \to K_{r,\bullet} \to (B_{r,\bullet} \otimes_A A, I^n_\bullet) \to (I^n_\bullet B_{r,\bullet} \mid n \in \mathbb{N}) \to 0$$

whence, for every $p \in \mathbb{N}$ an exact sequence of inverse systems

$$X^p_r := \text{Tor}^A_p(A, K_{r,n} \mid n \in \mathbb{N}) \to (E(n)_{pq}^{20} \mid n \in \mathbb{N}) \to Y^p_r := (\text{Tor}^A_p(A, I^n_r B_{r,\bullet}) \mid n \in \mathbb{N}).$$

Now, the system $X^p_r$ is uniformly essentially zero for every $p \in \mathbb{N}$, since the same holds for $K_{r,\bullet}$; moreover, $Y^p_r$ is uniformly essentially zero for $p > 0$, since the same holds for $T'^i_\bullet$. Hence, $(E(n)_{pq}^{20} \mid n \in \mathbb{N})$ is uniformly essentially zero for $p > 0$, and the proof is concluded. $\diamond$

Lastly, for every $n \in \mathbb{N}$ let us consider the spectral sequence

$$E(n)_{pq}^{2} := \text{Tor}^A_p(\text{Tor}^A_q(A, B_{r,\bullet}), I^n_r) \Rightarrow H_{p+q}(A \otimes A_r B_{r,\bullet} \otimes A_r I^n_r)$$

and notice that $(E(n)_{pq}^{20} \mid n \in \mathbb{N}) = T'^p_r$ for every $p \in \mathbb{N}$. To conclude, it suffices therefore to show:

Claim 7.9.24. The inverse system $(E(n)_{pq}^k \mid n \in \mathbb{N})$ is uniformly essentially zero, for every $k \geq 2$ and every $p > 0$. 
Proof of the claim. We fix $p > 0$ and argue by descending induction on $k$. Notice that $E(n)_{j,k}^{p+1} = E(n)_{j,k}^{\infty}$ for every $n \in \mathbb{N}$, so claim 7.9.23 implies that the assertion holds whenever $k \geq p + 1$. Next, let $2 \leq i \leq p$ and suppose that the assertion is known for every $k > i$; we have an exact sequence of inverse systems

$$(E(n)_{j,k}^{i+1} | n \in \mathbb{N}) \to (E(n)_{j,k}^{i} | n \in \mathbb{N}) \to (E(n)_{j,k}^{i-1} | n \in \mathbb{N}).$$

In view of our inductive assumption (and of lemma 7.8.19), we are therefore reduced to showing that the inverse system $(E(n)_{j,k}^{i} | n \in \mathbb{N})$ is uniformly essentially zero. However, by claim 7.9.21 there exists $c \in \mathbb{N}$ such that $I_{c}^{i} \cdot \text{Tor}_{r-1}^{A}(A,B_{r,\bullet}) = 0$, and then the contention follows from lemma 7.8.24.

Conversely, if $(a)^{\infty}$ holds for $B_{\bullet}$, then we get immediately condition $(a)^{\infty}$ for $A$, since the latter is a direct summand of the $A_{r}$-module $B_{\bullet}$.

Remark 7.9.25. By carefully tracking the estimates in the proof, it is easily seen that for every sequence of integers $(c(i) | i \in \mathbb{N})$ there exists a sequence of integers $(d(i) | i \in \mathbb{N})$ such that the following refinement holds. Suppose that for every $i \in \mathbb{N}$ the inverse system $(\text{Tor}_{r}^{A}(A_{i}/I_{n}^{i}, A) | n \in \mathbb{N})$ is uniformly essentially zero with step $\leq c(i)$; then the inverse system $(\text{Tor}_{r}^{A}(A_{i}/I_{n}^{i}, B_{\bullet}) | n \in \mathbb{N})$ is uniformly essentially zero with step $\leq d(i)$.

7.9.26. Let $(A, \text{Fil}_{\bullet}A)$ be a filtered ring, i.e. a filtered $\mathbb{Z}$-algebra, in the sense of definition 7.9.11, and denote by $\text{gr}_{\bullet}A$ the associated graded ring. Suppose that the filtration $\text{Fil}_{\bullet}A$ is exhaustive and separated, that is

$$\bigcup_{n \in \mathbb{Z}} \text{Fil}_{n}A = A \quad \text{and} \quad \bigcap_{n \in \mathbb{Z}} \text{Fil}_{n}A = 0.$$

The filtration $\text{Fil}_{\bullet}A$ defines a linear topology $\mathcal{T}$ on the $\mathbb{Z}$-module $A$, and we suppose moreover that $\mathcal{T}$ is complete (and notice that $\mathcal{T}$ is obviously separated). Furthermore, let $f := (f_{1}, \ldots, f_{r})$ be a finite sequence of elements of $A$; for every $i = 1, \ldots, r$, pick $n_{i} \in \mathbb{Z}$ such that $f_{i} \in \text{Fil}_{n_{i}}A$, denote by $\overline{f}_{i} \in \text{gr}_{n_{i}}A$ the image of $f_{i}$, and let $\overline{f} := (\overline{f}_{1}, \ldots, \overline{f}_{r})$ be the resulting sequence of elements of $\text{gr}_{\bullet}A$.

Proposition 7.9.27. In the situation of (7.9.26), suppose that the sequence $\overline{f}$ is completely secant (see definition 7.8.6). Then the same holds for the sequence $f$.

Proof. We define as follows a filtration on the Koszul complex $K_{\bullet}(f) = K_{\bullet}(f,A)$, i.e. a compatible system of filtrations on the exterior powers $\Lambda^{i}_{A}(A^{\oplus r})$ for $i = 1, \ldots, r$. To this aim, for every $i \leq r$ denote by $S_{i}$ the set of all strictly increasing maps $\{1, \ldots, i\} \to \{1, \ldots, r\}$; for every $\varphi \in S_{i}$ set

$$e_{\varphi} := e_{\varphi(1)} \wedge \cdots \wedge e_{\varphi(i)} \quad \text{and} \quad n_{\varphi} := n_{\varphi(1)} + \cdots + n_{\varphi(i)}.$$

We let $\text{Fil}_{\bullet}A_{i}(A^{\oplus r})$ be the good filtration associated, as in (7.9.6), with the basis $(e_{\varphi} | \varphi \in S_{i})$ and the sequence of integers $(n_{\varphi} | \varphi \in S_{i})$. The explicit description in (7.8) shows that the differentials of the Koszul complex are morphisms of filtered abelian groups, for the resulting filtrations on the terms $K_{i}(f)$. Thus, we have the sought filtration $\text{Fil}_{\bullet}K_{\bullet}(f,A)$, and we let $\text{gr}_{\bullet}K_{\bullet}(f,A)$ be the associated complex of graded abelian groups; with this notation, a simple inspection shows that we have a natural isomorphism of complexes of abelian groups

$$(7.9.28) \quad \text{gr}_{\bullet}K_{\bullet}(f,A) \cong K_{\bullet}(\overline{f}, \text{gr}_{\bullet}A).$$

For every $j, k \in \mathbb{Z}$ with $j \geq k$ we set

$$K^{(j,k)}_{\bullet}(f,A) := \text{Fil}_{j}K_{\bullet}(f,A)/\text{Fil}_{k-1}K_{\bullet}(f,A).$$
We endow $K^{(j,k)}(f,A)$ with the filtration induced by $\text{Fil}_*K_*(f,A)$, and we let $\text{gr}_*K^{(j,k)}(f,A)$ be the complex of graded abelian groups associated with this filtered subquotient of $K_*(f,A)$. According to remark 7.2.16(i), we have a 1-spectral sequence

$$E_1^{pq} := H^{p+q}(\text{gr}_pK^{(j,k)}(f,A)) \Rightarrow H^{p+q}K^{(j,k)}(f,A).$$

However, (7.9.28) and the assumption on $f$ imply that $E_1^{pq} = 0$ whenever $p + q < 0$, and then proposition 7.2.18 implies that $H^n(K^{(j,k)}(f,A)) = 0$ for every $j,k,n$ with $j \geq k$ and $n < 0$. Set as well $K^{(k)}(f,A) := K_*(f,A)/\text{Fil}_{k-1}K_*(f,A)$ for every $k \in \mathbb{Z}$; it follows easily that $H_nK^{(k)}(f,A) = 0$ for every $n < 0$ and every $k \in \mathbb{Z}$.

Next, since $K_n(f,A)$ is a free $A$-module of finite rank for every $n \in \mathbb{Z}$, and since the filtration $\text{Fil}_A$ is separated and defines a complete topology, we get a natural isomorphism of abelian groups

$$K_n(f,A) \xrightarrow{\sim} \lim_{k \in \mathbb{Z}} K^{(k)}_n(f,A)$$

for every $n \in \mathbb{Z}$.

Lastly, in view of [125, Prop.3.5.7, Th.3.5.8] we conclude that $H^nK_*(f,A) = 0$ for every $n < 0$, i.e. the sequence $f$ is completely secant, as stated.

7.10. Some homotopical algebra. The methods of homotopical algebra allow to construct derived functors of non-additive functors, in a variety of situations. In this section, we present the basics of this theory, beginning with its cornerstone, the standard resolution associated with a triple, as explained in the following paragraph.

7.10.1. A triple $(\top, \eta, \mu)$ on a category $\mathcal{C}$ is the datum of a functor $\top : \mathcal{C} \to \mathcal{C}$ together with natural transformations :

$$\eta : 1_\mathcal{C} \Rightarrow \top \quad \mu : \top \circ \top \Rightarrow \top$$

such that the following diagrams commute :

$$\begin{array}{ccc}
(T \circ T) \circ T & \xrightarrow{\top \circ \mu} & T \circ (T \circ T) \\
\mu \circ T & \downarrow & \top \circ \mu \\
T \circ T & \xrightarrow{\mu} & T \\
\end{array}$$

$$\begin{array}{ccc}
T \circ T & \xrightarrow{\top \circ \eta} & T \\
\mu & \downarrow & 1_T \\
\top & \xrightarrow{\eta \circ \top} & \top \\
\end{array}$$

Dually, a cotriple $(\bot, \varepsilon, \delta)$ in a category $\mathcal{C}$ is a functor $\bot : \mathcal{C} \to \mathcal{C}$ together with natural transformations :

$$\varepsilon : \bot \Rightarrow 1_\mathcal{C} \quad \delta : \bot \Rightarrow \bot \circ \bot$$

such that the following diagrams commute :

$$\begin{array}{ccc}
\bot & \xrightarrow{\delta} & \bot \\
\varepsilon & \downarrow & \varepsilon \circ \delta \\
\bot \circ \bot & \xrightarrow{\delta \circ \bot} & \bot \\
\end{array}$$

$$\begin{array}{ccc}
\bot & \xrightarrow{1_\mathcal{C}} & \bot \\
\varepsilon & \downarrow & \varepsilon \circ \delta \\
\bot \circ \bot & \xrightarrow{1_\mathcal{C} \circ \delta} & \bot \\
\end{array}$$

Notice that a cotriple in $\mathcal{C}$ is the same as a triple in $\mathcal{C}^\circ$. 

A cotriple \(\perp\) on \(\mathcal{C}\) and an object \(A\) of \(\mathcal{C}\) determine a simplicial object \(\perp A[\bullet]\) in \(\mathcal{C}\); namely, for every \(n \in \mathbb{N}\) set \(\perp A[n] := \perp^{n+1} A\), and define face and degeneracy operators:
\[
\partial_i := (\perp^i * \perp^{n-i})_A : \perp A[n] \to \perp A[n-1]
\]
\[
\sigma_i := (\perp^i * \delta * \perp^{n-i})_A : \perp A[n] \to \perp A[n+1].
\]
Using the foregoing commutative diagrams, one verifies easily that the simplicial identities (7.4.9) hold. Moreover, the morphism \(\varepsilon_A : \perp A \to A\) defines an augmentation \(\perp A[\bullet] \to A\).

Dually, a triple \(\top\) and an object \(A\) of \(\mathcal{C}\) determine a cosimplicial object \(\top A[\bullet] := \top^{n+1} A\), such that
\[
\partial^i := (\top^i * \eta * \top^{n-i})_A : \top^n A \to \top^{n+1} A
\]
\[
\sigma^i := (\top^i * \mu * \top^{n-i})_A : \top^{n+2} A \to \top^{n+1} A
\]
which is augmented by the morphism \(\eta_A : A \to \top A\). Clearly, the rule : \(A \mapsto \perp A[\bullet]\) (resp. \(A \mapsto \top A[\bullet]\)) defines a functor

\[
\mathcal{C} \to \mathcal{C}' (\text{resp. } \mathcal{C} \to \mathcal{C}').
\]

An adjoint pair \((G, F)\) as in (1.1.13), with its unit \(\eta\) and counit \(\varepsilon\), determines a triple \((\top, \eta, \mu)\), where:
\[
\top := F \circ G : \mathcal{B} \to \mathcal{B} \quad \mu := F * \varepsilon * G : \top \circ \top \Rightarrow \top
\]
as well as a cotriple \((\perp, \varepsilon, \delta)\), where:
\[
\perp := G \circ F : \mathcal{A} \to \mathcal{A} \quad \delta := G * \eta * F : \perp \Rightarrow \perp \circ \perp.
\]
Indeed, the naturality of \(\varepsilon\) and \(\eta\) easily implies the commutativity of the diagrams of (7.10.1). The following proposition explains how to use these triples and cotriples to construct canonical resolutions.

**Proposition 7.10.4.** In the situation of (7.10.3), the following holds:

(i) For every \(A \in \text{Ob}(\mathcal{A})\) and \(B \in \text{Ob}(\mathcal{B})\), the augmented simplicial objects:

\[
\perp GB[\bullet] \xrightarrow{\varepsilon_{GB}} GB \quad F \perp A[\bullet] \xrightarrow{F \varepsilon_A} FA
\]

are homotopically trivial (notation of (7.10.2)).

(ii) Dually, the same holds for the augmented cosimplicial objects:

\[
GB \xrightarrow{G \varepsilon_B} G \top B[\bullet] \quad FA \xrightarrow{\eta_{FA}} \top FA[\bullet].
\]

**Proof.** Notice that
\[
F \perp A[n] = \top FA[n] \quad \text{for every } [n] \in \text{Ob}(\Delta^\perp).
\]
Therefore, for every morphism \(\varphi : [n] \to [m]\) in \(\Delta^\perp\), we have two morphisms
\[
F \perp A[\varphi] : F \perp A[m] \to F \perp A[n] \quad \top FA[\varphi] : F \perp A[n] \to F \perp A[m].
\]
Now, recall that the augmentation \(\varepsilon_A\) defines a natural morphism
\[
\perp A[\varepsilon_A^{n+1}_0] : \perp A[\bullet] \to s.A \quad [n] \mapsto \perp A[\varepsilon_A^{n+1}_0]\]
(notation of remark 7.4.12(iv)), and one sees that the system \((\top FA[\varepsilon_A^{n+1}_0] : [n] \in \text{Ob}(\Delta))\)

defines a morphism
\[
\top FA[\varepsilon_A^{n+1}_0] : s.FA \to F \perp A[\bullet]
\]
which is right inverse to \(F \perp A[\varepsilon_A^{n+1}_0]\). For every \(n, k \in \mathbb{N}\) such that \(k \leq n + 1\), set
\[
u_{n,k} := (\top FA[\varepsilon_A^{k}_{n-k,0}]) \circ (F \perp A[\varepsilon_A^{k}_{n-k,0}])
\]
(notation of example 7.4.7(ii)).
Claim 7.10.5. The system \( u_{\bullet} \) defines a homotopy from \( 1_{F \perp A[\bullet]} \) to \((\top FA[e_{-1,0}^{+1}]) \circ (F \perp A[e_{-1,0}^{+1}])\) (see (7.4.15)).

Proof of the claim. By unwinding the definitions, we see that \( F \perp A[e_{n-k,0}^{k}] \) is the composition

\[
F(e_{n+1-k,0} \circ \cdots \circ e_{n-1,0} \circ e_{n,0}) : F \perp n+1 \rightarrow F \perp n+1-k \quad \text{for } k > 0
\]

and \( \top FA[e_{n-k,0}^{k}] \) is the composition

\[
\eta_{F \perp n,0} \circ \cdots \circ \eta_{F \perp n+1-k,0} \circ \cdots \circ \eta_{F \perp n+1,0} : F \perp n+1-k \rightarrow F \perp n+1 \quad \text{for } k > 0
\]

and both equal \( 1_{F \perp n+1,0} \) for \( k = 0 \). Now, since the face operator \( \partial_{i} \) of \( F \perp A[n] \) is \( F \perp i \) \((e_{n-i,0})\) for every \( i \leq n \), the naturality of \( \eta \) yields a commutative diagram

\[
\begin{array}{ccc}
F \perp n A & \xrightarrow{\partial_{i-1}} & F \perp n-1 A \\
\downarrow \eta_{F \perp n,0} & & \downarrow \eta_{F \perp n-1,0} \\
F \perp n+1 A & \xrightarrow{\partial_{i}} & F \perp n A
\end{array}
\]

whereas \( \partial_{0} \circ \eta_{F \perp n,0} = 1_{F \perp n,0} \) for every \( n \in \mathbb{N} \); whence the identities:

\[
\partial_{i} \circ \top FA[e_{n-k,0}^{k}] = \begin{cases}
\top FA[e_{n-k,0}^{k-1}] & \text{for } i < k \\
\top FA[e_{n-k,0}^{k}] \circ \partial_{i-k} & \text{for } i \geq k.
\end{cases}
\]

On the other hand, we have the simplicial identities:

\[
ev_{i} \circ e_{n-k,0}^{k} = \begin{cases}
e_{n-k}^{k+1} & \text{for } i < k \\
e_{n-k}^{k} \circ e_{n-k}^{i-k} & \text{for } i \geq k.
\end{cases}
\]

Summing up, we conclude that

\[
\partial_{i} \circ u_{n,k} = \begin{cases}
u_{n-1,k-1} \circ \partial_{i} & \text{for } i < k \\
u_{n-1,k} \circ \partial_{i} & \text{for } i \geq k.
\end{cases}
\]

Arguing likewise, one deduces as well the corresponding commutation rule – spelled out in (7.4.15) – for the degeneracies \( \sigma_{i} \), and the claim follows. \( \diamond \)

Likewise, notice that

\[
G \top B[n] = \perp GB[n] \quad \text{for every } [n] \in \Delta^{\leq}.
\]

Therefore, for every morphism \( \varphi : [n] \rightarrow [m] \) in \( \Delta^{\leq} \), we have as well two morphisms

\[
\perp GB[\varphi] : \perp GB[m] \rightarrow \perp GB[n] \quad G \top B[\varphi] : G \top B[n] \rightarrow G \top B[m]
\]

and the system \( (G \top B[e_{-1,0}^{n+1} | [n]) \in \text{Ob}(\Delta^{\leq}) \) defines a morphism

\[
G \top B[e_{-1,0}^{n+1}] : s.GB \rightarrow \perp GB[\bullet]
\]

which is right inverse to the morphism \( \perp GB[e_{-1,0}^{n+1}] \) deduced from the augmentation. Arguing as in the proof of claim 7.10.5, one checks that the rule

\[
v_{n,k} := (G \top B[e_{n-k,0}^{k}]) \circ (\perp GB[e_{n-k,0}^{k}]) \quad \text{for every } n, k \in \mathbb{N} \text{ such that } k \leq n + 1
\]

yields a homotopy \( v \) from \( 1_{\perp GB[\bullet]} \) to \( (G \top B[e_{-1,0}^{n+1}]) \circ (\perp GB[e_{-1,0}^{n+1}]) \).

The dual statements admit the dual proof. \( \square \)
7.10.6. Now, denote by Set_0 the category of pointed sets, whose objects are all the pairs (S, s) where S is a small set, and s ∈ S is any element; the morphisms f : (S, s) → (S', s') are the mappings f : S → S' such that f(s) = s'. Next, let A be any ring, and consider the pointed forgetful functor

\[ F : A\text{-Mod} \to \text{Set}_0 \quad M \mapsto (M, 0_M) \]

(where 0_M ∈ M is the zero element of M). The functor F admits the left adjoint

\[ L : \text{Set}_0 \to A\text{-Mod} \quad (S, s) \mapsto A(S)/As \]

(where \(A(S)\) denotes the free A-module with basis given by S, so \(As \subset A(S)\) is the direct summand generated by the basis element \(s \in S\)). According to proposition 7.10.10, the adjoint pair \((L, F)\) yields a functor

\[ \perp^A_\bullet : A\text{-Mod} \to \widehat{\text{A-Mod}} \]

into the category of augmented simplicial A-modules (notation of (7.4.11)), such that

\[ F \perp^A_\bullet M \to FM \]

is a homotopically trivial augmented pointed simplicial set, for every A-module M. This functor is obtained by iterating the functor \(\perp^A_\bullet := L \circ F\), so in each degree it consists of a free A-module. We call \(\perp^A_\bullet M\) the standard free resolution of M.

Remark 7.10.7. Notice that \(\perp^A_0 0 = s.0\), the constant simplicial A-module associated with the trivial A-module (see (7.4.4)). This is the reason why we prefer the adjoint pair \((L, F)\), rather than the analogous pair considered in [82, I.1.5.5], arising from the forgetful functor from A-modules to non-pointed sets.

7.10.8. Let \(R\) be a simplicial A-algebra, and define the category \(R\text{-Mod}\) of \(R\)-modules, as in [59, §8.1]. Notice that any morphism \(S \to R\) of simplicial rings induces a base change functor

\[ S\text{-Mod} \to R\text{-Mod} \quad (M[n] | n \in \mathbb{N}) \mapsto (R[n] \otimes_{S[n]} M[n] | n \in \mathbb{N}) \]

which is left adjoint to the forgetful functor (details left to the reader).

Now, by applying the functors \(\perp^R_{\bullet[n]}\) to the terms \(M[n]\) of a given \(R\)-module \(M\), we obtain an augmented simplicial \(R\)-module

\[ \perp^R_\bullet M \to M \]

which amounts to a bisimplicial A-module, whose columns \(\perp^R_{\bullet} M[n] \to M[n]\) are augmented simplicial \(R[n]\)-modules, for every \(n \in \mathbb{N}\). Likewise, the row \(\perp^R_{\bullet[n]} M\) is an \(R\)-module, for every \(n \in \mathbb{N}\).

Lemma 7.10.10. In the situation of (7.10.8), let \(\varphi : M \to N\) be any quasi-isomorphism of \(R\)-modules. Then the induced morphism

\[ \perp^R_{\bullet} \varphi : \perp^R_{\bullet} M \to \perp^R_{\bullet} N \]

is a homotopy equivalence, for every \(n \in \mathbb{N}\).

Proof. Set \(\perp^R_{\bullet[n]} := M\), and notice the natural isomorphisms

\[ \perp^R_{\bullet[n]} M \cong R \otimes_{s.Z} \perp^R_{\bullet[Z]} \circ \perp^R_{\bullet[n-1]} M \quad \text{for every } n \in \mathbb{N} \]

(where \(s.Z\) is the constant simplicial ring arising from \(Z\) (see (7.4.4)), which is the initial object in the category of simplicial rings). The assumption means that \(\perp^R_{\bullet[n]} \varphi\) is a quasi-isomorphism. However, (7.10.11) and Whitehead’s theorem (82, I.2.2.3)) imply that if – for a given \(n \in \mathbb{N}\) – the map \(\perp^R_{\bullet[n-1]} \varphi\) is a quasi-isomorphism, then \(\perp^R_{\bullet[n]} \varphi\) is a homotopy equivalence. We may thus conclude by a simple induction on \(n\). \(\square\)
Example 7.10.12. Let $M$ and $N$ two $R$-modules. We may define two functors

$$
M \otimes_R - \quad \text{(resp.} \quad - \otimes_R N \text{)} : R\text{-Mod} \rightarrow R\text{-Mod}
$$

by the rules :

$$
P \mapsto M \otimes_R (\perp R P)^{\Delta} \quad \text{(resp.} \quad P \mapsto (\perp R P)^{\Delta} \otimes_R N \text{)} \quad \text{for every} \quad R\text{-module} \ P
$$

where $\Delta$ is the diagonal functor, from $C$-bisimplicial to $C$-simplicial objects (see 7.4.16).

(i) We claim that these functors descend to the derived category. That is, suppose that $\varphi : P \rightarrow P'$ is a quasi-isomorphism; then $M \otimes_R \varphi$ and $\varphi \otimes_R N$ are both quasi-isomorphisms. Indeed, lemma 7.10.10 implies that the induced morphisms

$$
M \otimes_R \perp n_P \varphi : M \otimes_R \perp n_P P \rightarrow M \otimes_R \perp n_P P'
$$

are quasi-isomorphisms, for every $n \in \mathbb{N}$, and likewise for $\varphi \otimes_R \perp n N$, so the assertion follows from Eilenberg-Zilber’s theorem 7.4.49(i).

(ii) Also, we claim that the notation $M \otimes_R N$ is unambiguous. That is, we may compute this object by applying the functor $M \otimes_R -$ to $N$, or by applying the functor $- \otimes_R N$ to $M$, and the resulting two $R$-modules are naturally isomorphic in $D(R\text{-Mod})$. Indeed, it suffices to check that the natural morphisms

$$
M \otimes_R (\perp R N)^{\Delta} \leftarrow (\perp R M)^{\Delta} \otimes_R (\perp R N)^{\Delta} \rightarrow (\perp R M)^{\Delta} \otimes_R N
$$

induced by the augmentation (7.10.9), are both quasi-isomorphisms. We check this for $\alpha$; the same argument shall apply to $\beta$. To ease notation, set $L := (\perp R N)^{\Delta}$. Then $\alpha$ is deduced by extracting the diagonal from the augmented simplicial $R$-module

\[
\perp n M \otimes_R L \rightarrow M \otimes_R L
\]

(7.10.13)

(so, the $n$-th column of $s.L$ is a constant and flat simplicial $R[n]$-module, for every $n \in \mathbb{N}$). Thus, we are reduced to checking that the columns of (7.10.13) are aspherical. However, for every $n \in \mathbb{N}$, the $n$-th column is the augmented simplicial $R[n]$-module $(\perp R[n] M[n]) \otimes R[n] L[n]$; since $L[n]$ is flat, it then suffices to recall that the standard free resolution is aspherical.

(iii) The foregoing discussion yields a well defined functor

$$
- \otimes_R - : D(R\text{-Mod}) \times D(R\text{-Mod}) \rightarrow D(R\text{-Mod})
$$

called the left derived tensor product. The same method shall be applied hereafter to construct derived functors of certain non-additive functors.

Remark 7.10.14. Let $M$ and $N$ be as in example 7.10.12 and set $P := (\perp R M) \otimes_R s.N$ (this is a simplicial $R$-module; especially, it is a bisimplicial $A$-module); by Eilenberg-Zilber’s theorem 7.4.49 the cochain complex associated with $M \otimes_R N$ is naturally isomorphic, in $D(A\text{-Mod})$ to the complex $\text{Tot}(P^{**})$, where $P^{**}$ denotes the double complex associated with $P$. There follows a spectral sequence :

$$
E^1_{pq} := \text{Tor}^{R[p]}_q(M[p], N[p]) \Rightarrow H_{p+q}(M \otimes_R N)
$$

whose differentials $d^1_{pq} : E^1_{pq} \rightarrow E^1_{p-1,q}$ are obtained as follows. For every integer $q \in \mathbb{N}$, let $T_q$ be the $R$-module given by the rule : $T_q[p] := E^1_{pq}$, with face and degeneracy maps deduced from those of $M$, $N$ and $R$, in the obvious way. Then $d^1_{pq}$ is the differential in degree $p$ of the chain complex $T_q \ast$ associated with $T_q$ (details left to the reader).
Example 7.10.15. (i) Another useful cotriple arises from the forgetful functor $A\text{-Alg} \to \text{Set}$ and its left adjoint, that attaches to any set $S$ the free $A$-algebra $A[S]$. There results, for every $A$-algebra $B$, a standard simplicial resolution by free $A$-algebras

$$F_A(B) \to B.$$ 

Now, if $R$ is again a simplicial $A$-algebra, and $S$ any $R$-algebra, we can proceed as in the foregoing, to obtain a bisimplicial resolution $F_R(S) \to S$ whose columns $F_R[n](S[n]) \to S[n]$ are augmented simplicial $R[n]$-algebras, for every $n \in \mathbb{N}$. A simple inspection shows that the proof of lemma 7.10.10 carries over – mutatis mutandis – to the present situation, hence a quasi-isomorphism $S \to S'$ of $R$-algebras induces a morphism $F_R(S)[n] \to F_R(S')[n]$ of $R$-algebras, which is a homotopy equivalence on the underlying $R$-modules, for every $n \in \mathbb{N}$.

(ii) We may then define a derived tensor product for $R$-algebras, proceeding as in example 7.10.12. Namely, if $S$ and $S'$ are any two $R$-algebras, we define two functors

$$S \otimes_R - \quad (\text{resp. } - \otimes_R S') : R\text{-Alg} \to R\text{-Alg}$$

by the rules:

$$T \mapsto S \otimes_R F_R(T) \Delta \quad (\text{resp. } T \mapsto F_R(T) \Delta \otimes_R N) \quad \text{for every } R\text{-algebra } T.$$ 

Arguing like in loc.cit. we see that both functors transform quasi-isomorphisms into quasi-isomorphisms, hence they descend to the derived category $D(R\text{-Alg})$, and moreover, the two functors are naturally isomorphic, so the notation $S \otimes_R S'$ is unambiguous: the detailed verification is left as an exercise for the reader.

7.10.16. Let $A\text{-Alg}.\text{Mod}$ be the category of all pairs $(B, M)$, where $B$ is any $A$-algebra, and $M$ any $B$-module. The morphisms $(B, M) \to (B', M')$ are the pairs $(f, \varphi)$, where $f : B \to B'$ is a morphism of $A$-algebras, and $\varphi : M \to f^*M'$ a $B$-linear map (here $f^*M'$ denotes the $B$-module obtained from the $B'$-module $M'$, by restriction of scalars along the map $f$). Suppose now that we have a commutative diagram of categories:

$$\begin{array}{ccc}
A\text{-Alg}.\text{Mod} & \xrightarrow{T} & \mathcal{C} \\
\downarrow F & & \downarrow f \\
A\text{-Alg} & \xrightarrow{g} & \mathcal{B}
\end{array}$$

such that:

- For every $X \in \text{Ob}(B)$, the fibre $f^{-1}X$ is an abelian category whose filtered colimits are representable and exact.
- $F$ is given by the rule $(B, M) \mapsto B$ for every $(B, M) \in \text{Ob}(A\text{-Alg}.\text{Mod})$.
- For every $A$-algebra $B$, the restriction

$$T_B : F^{-1}B \to f^{-1}(gB)$$

of $T$ commutes with filtered colimits, i.e., if $((B, M_i) \mid i \in I)$ is any filtered system of objects of $A\text{-Alg}.\text{Mod}$ (over the same $A$-algebra $B$), then the induced morphism

$$\text{colim}_{i \in I} T_B M_i \to T_B (\text{colim}_{i \in I} M_i)$$

is an isomorphism.

The functors $f$ and $g$ extend to functors $s.f : s.\mathcal{C} \to s.\mathcal{B}$, respectively $s.g : s.A\text{-Alg} \to s.\mathcal{B}$, and notice that – for $R$ any simplicial $A$-algebra – $T$ induces a functor

$$T_R : R\text{-Mod} \to s.\mathcal{C}/R := s.f^{-1}(s.gR) \quad (M[n] \mid n \in \mathbb{N}) \mapsto (T_R[n]M[n] \mid n \in \mathbb{N}).$$
For every $R$-module $M$, we set

$$LT_R(M) := T_R(\perp^R M)^\Delta.$$  

The augmentation $T_R(\perp^R M) \to T_R M$ can be regarded as a morphism of bisimplicial objects

$$T_R(\perp^R M) \to s.T_R M$$

(the columns of $s.T_R M$ are constant $\mathcal{C}$-simplicial objects), whence a morphism in $s.\mathcal{C}/_R$:

$$LT_R(M) \to s.T_R M = T_R M \quad \text{for every } R\text{-module } M.$$  

In many applications, $s.\mathcal{C}/_R$ will be also an abelian category, but anyhow we can state the following:

**Proposition 7.10.18.** With the notation of (7.10.16), suppose that $\mathcal{C}$ is an abelian category. Then the following holds:

(i) If $M$ is a flat $R$-module, then (7.10.17) is a quasi-isomorphism.

(ii) If $\varphi : M \to N$ is a quasi-isomorphism of $R$-modules, then the induced map

$$LT_R(M) \to LT_R(N)$$

is a quasi-isomorphism.

**Proof.** (i): The assumption means that $M[n]$ is a flat $R[n]$-module for every $n \in \mathbb{N}$. Denote by $C$ the unnormalized double complex associated with $T_R(\perp^R M)$, and by $C^\Delta$ (resp. by $D$) the unnormalized complex associated with $LT_R(M)$ (resp. to $T_R M$). By Eilenberg-Zilber’s theorem 7.4.49, we have a natural quasi-isomorphism

$$C^\Delta \to \text{Tot}(C)$$

given by the Alexander-Whitney map of (7.4.34), and a simple inspection shows that the map $C^\Delta \to D$ induced by (7.10.17) factors through (7.10.19). Hence, it suffices to show that the map

$$\text{Tot}(C) \to D$$

induced by the augmentation of $T_R(\perp^R M)$, is a quasi-isomorphism, under the stated condition.

To this aim, it suffices to check that the augmented $\mathcal{C}$-simplicial object

$$T_R(\perp^R M[n]) \to T_R M[n]$$

is aspherical for every $n \in \mathbb{N}$. However, since $M[n]$ is a flat $R[n]$-module, it can be written as a filtered colimit of a system of free $R[n]$-modules ([95, Ch.I, Th.1.2]); on the other hand, the functor $\perp^R$ commutes with all filtered colimits, and the same holds for $T_R$, by assumption. Since the filtered colimits of the fibres of the functor $f$ are exact, we are then reduced to checking the assertion in case $M[n]$ is a free $R[n]$-module; but in this case, (7.10.20) is even homotopically trivial, by virtue of proposition 7.10.4.

(ii): In light of Eilenberg-Zilber’s theorem 7.4.49, it suffices to show that the induced map

$$T_R(\perp^R M) \to T_R(\perp^R N)$$

is a quasi-isomorphism for every $n \in \mathbb{N}$. In turns, this follows readily from lemma 7.10.10.

**Remark 7.10.21.** (i) The proof of proposition 7.10.18(i) applies as well to the derived tensor product; namely, for any two $R$-modules $M$ and $N$ there is a natural morphism of $R$-modules

$$M \otimes_R N \to M \otimes_R N$$

which is a quasi-isomorphism, if either $M$ or $N$ is a flat $R$-module (details left to the reader).
(ii) Especially, let $S$ and $S'$ be any two $R$-algebras. Then, since the standard free resolution $F_R(S)$ of example 7.10.15 is a flat simplicial $R$-module, (i) implies that the $R$-module underlying the $R$-algebra $S \otimes_R S'$, is naturally isomorphic, in $D(R\text{-Mod})$, to the derived tensor product of the $R$-modules underlying $S$ and $S'$. In other words, the notation $- \otimes_R -$ is unambiguous, whether one refers to derived tensor products of algebras, or of their underlying modules.

(iii) Denote by $\sigma, \omega : R\text{-Mod} \to R\text{-Mod}$ respectively the suspension and loop functors ([82] I.3.2.1]), and recall that $\sigma$ is left adjoint to $\omega$. A simple inspection of the definitions yields natural identifications

$$(\sigma M) \otimes_R N \xrightarrow{\sim} \sigma(M \otimes_R N) \quad (\omega M) \otimes_R N \xrightarrow{\sim} \omega(M \otimes_R N)$$

for every $R$-modules $M$ and $N$. By the same token, it is clear that $\sigma$ and $\omega$ transform flat $R$-modules into flat $R$-modules. In view of (i), we deduce natural isomorphisms

$$(\sigma M) \otimes_R N \xrightarrow{\sim} \sigma(M \otimes_R N) \quad (\omega M) \otimes_R N \xrightarrow{\sim} \omega(M \otimes_R N)$$

in $D(R\text{-Mod})$ for every $R$-modules $M$ and $N$.

(iv) Let $f : N \to N'$ be any morphism of $R$-modules; in the same vein, we get a natural identification:

$$\text{Cone}(M \otimes_R f) \xrightarrow{\sim} M \otimes_R \text{Cone} f$$

for every $R$-module $M$ (see [82] I.3.2.2] for the definition of the cone of a morphism of $R$-modules). It follows immediately that the functor $M \otimes_R - : D(R\text{-Mod}) \to D(R\text{-Mod})$ transforms distinguished triangles into distinguished triangles (see [82] I.3.2.2.4] for the definition of distinguished triangle in $D(R\text{-Mod})$). For future reference, let us also point out:

**Lemma 7.10.22.** Let $R$ be a simplicial $A$-algebra, $X$ and $Y$ two $R$-modules, $n, m \in \mathbb{N}$ two integers, and suppose that $H_iX = 0 = H_jY$ for every $i < n$ and $j < m$. Then

$$H_i(X \otimes_R Y) = 0 \quad \text{for every } i < n + m.$$  

**Proof.** Set $\sigma^0 := 1_{R\text{-Mod}}$, and define inductively $\sigma^k : R\text{-Mod} \to R\text{-Mod}$ by the rule: $\sigma^k := \sigma \circ \sigma^{k-1}$ for every $k > 0$. Define likewise $\omega^k$, and notice that $\sigma^k$ is left adjoint to $\omega^k$, for every $k \in \mathbb{N}$ (remark 7.10.21(iii)). Let $f : \sigma^n \circ \omega^mX \to X$ denote the counit of adjunction, and notice that $\text{Cone} f = 0$ in $D(R\text{-Mod})$. In view of remark 7.10.21(iv,v), we deduce that the natural morphisms

$$\sigma^n(\omega^mX \otimes_R Y) \to (\sigma^n \circ \omega^mX) \otimes_R Y \to X \otimes_R Y$$

are isomorphisms in $D(R\text{-Mod})$. Likewise, the natural morphism

$$\sigma^m(\omega^nX \otimes_R \omega^mY) \to \omega^nX \otimes_R Y$$

is an isomorphism in $D(R\text{-Mod})$, so finally the same holds for the morphism

$$\sigma^{n+m}(\omega^nX \otimes_R \omega^mY) \to X \otimes_R Y$$

whence the claim. \qed

7.10.23. In view of proposition 7.10.18 it is clear that if $\mathcal{C}$ is an abelian category, $LT_R$ yields a well defined functor on derived categories

$$LT_R : D(R\text{-Mod}) \to D(s.\mathcal{C}/_R) \quad M \mapsto LT_R(M)$$
(where $D(s\mathcal{C}/R)$ is the localization of $s\mathcal{C}/R$ with respect to the class of quasi-isomorphisms, and likewise for $D(R\text{-Mod})$: see \cite[Def.8.1.3]{59}). More generally, suppose that $\mathcal{C}$ is endowed with a functor

$$\Phi : \mathcal{C} \to \mathcal{A}$$

to an abelian category $\mathcal{A}$ (usually, this will be a forgetful functor of some sort), and denote by $D_\Phi(s\mathcal{C}/R)$ the localization of $s\mathcal{C}/R$ with respect to the system of its morphisms whose image under $s\Phi$ are quasi-isomorphisms in $s\mathcal{A}$. Then, since clearly

$$s\Phi \circ LT_R = L(s\Phi \circ T_R)$$

we see that $LT_R$ descends to a well defined functor

$$LT_R : D(R\text{-Mod}) \to D_\Phi(s\mathcal{C}/R).$$

We will need also the following slight refinement:

**Corollary 7.10.24.** In the situation of proposition \cite[7.10.18]{7}, the following holds:

1. Let $\phi : M \to N$ be a morphism of $R$-modules, and $n \in \mathbb{N}$ an integer such that

$$H_i\phi : H_iM \to H_iN$$

is an isomorphism, for every $i < n$. Then the same holds for the induced map

$$H_i(LT_R\phi) : H_i(LT_RM) \to H_i(LT_RN).$$

2. Suppose that $T(B,0) = 0_{gB}$ (the initial and final object of $f^{-1}(gB)$) for every $A$-algebra $B$. Let $n \in \mathbb{N}$ be an integer, and $M$ an $R$-module such that $H_iM = 0$ for every $i < n$. Then $H_i(LT_RM) = 0_{gR_i}$ for every $i < n$.

**Proof.** (i): Denote by

$$\varphi_X : X \to \cosk_nX$$

for every $X \in \text{Ob}(R\text{-Mod})$

the unit of adjunction (see \cite[7.4.19]{7}). Taking into account corollary \cite[7.4.66]{7}(i), we have the following properties:

1. $X[i] = \cosk_nX[i]$ and $\varphi[i]$ is the identity map of $X[i]$, for every $i \leq n$.
2. $H_i(\cosk_nX) = 0$ for every $i \geq n$.

In view of proposition \cite[7.10.18]{7}, we are then easily reduced to checking the assertion for the special where $N := \cosk_nM$, and $\phi := \varphi_M$. However, since in this case $N[i] = M[i]$ for every $i \leq n$, it is clear that $\cosk_n\Phi[i]$ is the identity automorphism of $\cosk_n\Phi[i]$, for every $i \leq n$. After applying the functor $T_{\Phi}$, and extracting the diagonal, we see that the induced morphism $LT_{\Phi}\Phi \to LT_{\Phi}\Phi$ in $s\mathcal{C}$ is given by the identity automorphism of $(LT_{\Phi}\Phi)[i]$, in every degree $i \leq n$, whence the contention.

(ii): In light of (i), we may assume that $M = s.0$ (the trivial $R$-module). In this case, the assertion follows easily from remark \cite[7.10.7]{7}. \hfill \Box

7.10.25. In the situation of \cite[7.10.16]{7}, take $\mathcal{C} := A\text{-Alg.Mod}$, $f := F$, and $g$ the identity automorphism of $A\text{-Alg}$. If $B \to B'$ is a map of $A$-algebras, and $(B, M) \in \text{Ob}(\mathcal{C})$, we define $B' \otimes_B (B, M) := (B', B' \otimes_B M)$.

**Corollary 7.10.26.** In the situation of \cite[7.10.25]{7}, suppose moreover that, for every flat morphism $B \to B'$ of $A$-algebras, the natural map

$$B' \otimes_B T(B, M) \to T(B' \otimes_B (B, M))$$

is an isomorphism, for every $(B, M) \in \text{Ob}(\mathcal{C})$. Then, for every flat morphism $\phi : R \to S$ of simplicial $V$-algebras, the natural morphism

$(7.10.27)$

$$S \otimes_R LT_RM \to LT_S(S \otimes_R M)$$
is an isomorphism in $\mathsf{D}(S\text{-Mod})$, for every $R$-module $M$.

Proof. (Recall that $\varphi$ is flat if and only if $S[n]$ is a flat $R[n]$-algebra, for every $n \in \mathbb{N}$. The map of the proposition is deduced from the natural morphism $\Delta_{\bullet}^R M \rightarrow \bigwedge^S_{\bullet}(S \otimes_R M)$, given by functoriality of the standard free resolution.)

Let $\pi : \bigwedge^R_{\bullet} M \rightarrow M$ be the standard free resolution of $M$; by the flatness assumption on $S$, the morphism $S \otimes_R \pi : S \otimes_R \bigwedge^R_{\bullet} M \rightarrow S \otimes_R M$ is a free resolution of the $S$-module $S \otimes_R M$, whence a natural isomorphism

$$L T_S(S \otimes_R M) \sim T_S((S \otimes_R \bigwedge^R_{\bullet} M)^{\Delta}) \quad \text{in } \mathsf{D}(S\text{-Mod})$$

by proposition $[7.10.18]$ i) and Eilenberg-Zilber’s theorem $[7.4.49]$. On the other hand, the assumptions on $T$ yield a natural isomorphism

$$S \otimes_R L T_R(M) = S \otimes_R T_R((\bigwedge^R_{\bullet} M)^{\Delta}) \sim T_S((S \otimes_R \bigwedge^R_{\bullet} M)^{\Delta}) \quad \text{in } \mathsf{D}(S\text{-Mod}).$$

By combining these isomorphisms, we get an isomorphism $S \otimes_R L T_R M \rightarrow L T_S(S \otimes_R M)$, and a simple inspection shows that the latter is realized by the natural map $[7.10.27]$. □

7.10.28. Let now $R$ be any simplicial $A$-algebra, and $I \subset R$ any ideal, and set $R_0 := R/I$. The Rees algebra of $I$ is the graded $R$-algebra

$$R(R, I)^\bullet := \bigoplus_{p \in \mathbb{N}} I^p$$

(cp. example $[7.9.3]$). Notice the natural isomorphism of graded $R_0$-algebras

$$R(R, I) \otimes_R R_0 \sim \text{gr}_I^* R := \bigoplus_{p \in \mathbb{N}} I^p/I^{p+1}$$

as well as the exact sequence of $R(R, I)$-modules

$$0 \rightarrow \text{gr}_I^{*+1} R \rightarrow R(R, I) \otimes_R R/I^2 \rightarrow \text{gr}_I^* R \rightarrow 0$$

deduced from the natural projection $R/I^2 \rightarrow R_0$. Next, pick any quasi-isomorphism of $R$-algebras $P \rightarrow R_0$, with $P$ a flat $R$-algebra; there follows an exact sequence of $P \otimes_R R(R, I)$-modules

$$0 \rightarrow P \otimes_R \text{gr}_I^{*+1} R \rightarrow P \otimes_R R(R, I) \otimes_R R/I^2 \xrightarrow{\beta} P \otimes_R \text{gr}_I^* R \rightarrow 0$$

and notice that $\beta$ is actually a morphism of $P \otimes_R R(R, I)$-algebras. According to remark $[7.7.10]$ i), after forming the associated cochain complexes, we obtain an epimorphism $\beta^\bullet$ of differential graded $(P \otimes_R R(R, I))^\bullet$-algebras, whose kernel $(P \otimes_R \text{gr}_I^{*+1} R)^\bullet$ is a two-sided ideal of $(P \otimes_R R(R, I) \otimes_R R/I^2)^\bullet$. In this situation, we deduce a map of $H_\bullet(R_0 \otimes_R R(P, I))^\bullet$-modules

$$(7.10.29) \quad \delta : H_\bullet(R_0 \otimes_R \text{gr}_I^* R) \rightarrow H_\bullet(R_0 \otimes_R \text{gr}_I^{*+1} R)[1]$$

which is a graded derivation, according to lemma $[7.7.6]$ (recall that here the shift $[1]$ refers to the homological grading; the notation $\text{gr}_I^{*+1}$ denotes also a shift in degrees, which however does not alter the signs of the scalar multiplication in the way prescribed by remark $[7.7.4]$ v)).
7.10.30. Keep the situation of (7.10.28), and suppose furthermore that $R$ is a constant $A$-algebra and $I$ a constant ideal, i.e. $R = s.B$, and $I = s.J$ for some $A$-algebra $B$ and some ideal $J \subset B$. We set $B_0 := B/J$ and

$$G^* := R_0 \otimes_R \gr^*_J R \quad \Lambda_* := \Lambda_B^*(J/J^2) \quad S^* := \Sym^*_B(J/J^2)$$

where the derived tensor product is formed in $D(R \text{-Alg})$, as in example 7.10.15, so $G^*$ is represented by $P \otimes_R \gr^*_J R$, and $H_*G^*$ is a bigraded $A$-algebra, strictly anti-commutative for the (homological) grading $H_*$, and commutative for the (cohomological) grading deduced from the grading of $G^*$ (see remark 7.7.10(i)). Also, $\Lambda_*$ (resp. $S^*$) is a strictly anti-commutative (resp. a commutative) graded $B_0$-algebra, and we use the homological (resp. cohomological) conventions for grading, so $\Lambda_p$ (resp. $S^p$) is placed in degree $-p$ (resp. $p$). Moreover, a standard calculation yields a natural isomorphism of $B_0$-modules

$$H_0G^0 \simto B_0 \quad H_1G^0 \simto \Tor^B_1(B_0, B_0) \simto J/J^2$$

whence a natural map $\Lambda_* \to H_*G^0$ of strictly anti-commutative graded $B_0$-algebras, restricting to an isomorphism in degrees $\leq 1$. On the other hand, we have a surjective map of commutative graded $B_0$-algebras

$$(7.10.31) \quad S^* \to \gr^*_J B := \bigoplus_{p \in \mathbb{N}} J^p/J^{p+1}$$

restricting as well to an isomorphism in degrees $\leq 1$; since $P \otimes_R \gr^*_J R$ is naturally a simplicial $\gr^*_J B$-algebra, we obtain a natural map of bigraded $S^*$-algebras

$$\omega^* : \Lambda_* \otimes_B S^* \to H_*G^*.$$

Now, $H_*G^*$ has been endowed with a derivation $\delta : H_*G^* \to H_*G^{*+1}[1]$ in (7.10.30); on the other hand, there exists on $\Lambda_* \otimes_B S^*$ a natural $S^*$-linear graded derivation

$$\partial : \Lambda_* \otimes_B S^* \to \Lambda_* \otimes_B S^{*+1}[1]$$

as explained in [82, I.4.3.1.2]. We may then consider the diagram of $S^*$-linear maps

$$(7.10.32) \quad \Lambda_* \otimes_B S^* \xrightarrow{\omega^*} H_*G^* \xleftarrow{\delta} \Lambda_* \otimes_B S^{*+1}[1] \xrightarrow{\omega^{*+1}[1]} H_*G^{*+1}[1].$$

**Definition 7.10.33.** (i) In the situation of (7.10.30), we say that the ideal $J$ is *quasi-regular*, if the following conditions hold:

- The map $\omega^* : \Lambda_* \simto H_*G^0$.
- The $B_0$-module $J/J^2$ is flat.

(ii) Let $R$ be any simplicial $A$-algebra, and $I \subset R$ any ideal. We say that $I$ is *quasi-regular*, if $I/[n]$ is a quasi-regular ideal of $R/[n]$, for every $n \in \mathbb{N}$.

**Remark 7.10.34.** (i) Definition 7.10.33 is due to Quillen ([109, Def.8.4]). Notice that a sequence of elements $(f_1, \ldots, f_r)$ in a ring $B$ is $B$-quasi-regular, in the sense of definition 7.8.13 if and only if it generates an ideal $J \subset B$ such that $J/J^2$ is a free $B_0$-module of rank $r$, and (7.10.31) is an isomorphism (notation of (7.10.30)). The relationship between these two quasi-regularity notions is partially elucidated by the following proposition 7.10.35(ii).

(ii) Suppose that $\overline{B} := (B_i \mid i \in I)$ is any filtered system of rings, and $\overline{J} := (J_i \subset B_i \mid i \in I)$ a filtered system of ideals, such that $J_i$ is quasi-regular in $B_i$, for every $i \in I$. Denote by $B$ (resp. $J$) the colimit of $\overline{B}$ (resp. of $\overline{J}$); then it is easily seen that $J$ is quasi-regular in $B$. 

(iii) Let $B$ be any ring, and $C := B[X_i \mid i \in I]$ a free $B$-algebra (for any set $I$). Then the ideal $J := (X_i \mid i \in I) \subset C$ is quasi-regular. Indeed, (ii) reduces to the case where $I$ is a finite set, for which the assertion is a special case of proposition 7.10.37 below.

**Proposition 7.10.35.** In the situation of (7.10.30), we have:

(i) (7.10.32) is a commutative diagram.

(ii) Suppose that $J$ is a quasi-regular ideal. Then

(a) $\omega^\bullet_J$ is an isomorphism.

(b) There exists a natural isomorphism of $B_0$-modules:

$$\text{Tor}^B (B_0, B/J^n) \to \text{Coker}(\partial_{i+1}^{n-2} : \Lambda_{i+1} \otimes B S^{n-2} \to \Lambda_i \otimes B S^{n-1}) \quad \text{for every } n, i > 0.$$ 

**Proof.** (i): Since both derivations are $S^\bullet$-linear, it suffices to check that (7.10.32) commutes in (upper) degree 0. Moreover, since the $B$-algebra $\Lambda_\bullet$ is generated by $\Lambda_1$, it suffices to check the commutativity of the diagram

$$\Lambda_1 \xrightarrow{\omega^0_1} H_1 G^0 \xrightarrow{\partial^0_1} S^1 \xrightarrow{\omega^1_1} H_0 G^1.$$ 

(7.10.36)

However, according to [82, I.4.3.1.2], the map $\partial^0_1$ is just the identity of $J/J^2$. The map $\delta^0_1$ is the boundary map arising – by the snake lemma – from the exact sequence of complexes

$$0 \to JP^\bullet/J^2P^\bullet \xrightarrow{\cdot J^2} P^\bullet/J^2P^\bullet \to P^\bullet/JP^\bullet \to 0$$

(where $P^\bullet$ denotes the cochain complex associated with the flat resolution $P \to s.B_0$). The same boundary map is used to define the isomorphism $\omega^0_1$, and $\omega^1_1$ is the natural isomorphism $J/J^2 \to H_0(JP^\bullet/JP^\bullet)$. Summing up, the commutativity of (7.10.36) follows by simple inspection.

(ii.a): We prove, by induction on $n \in \mathbb{N}$, that every $\omega^n_\bullet$ is an isomorphism. For $n = 0, 1$ there is nothing to show, so suppose that $n > 1$, and the assertion is already known for every degree $< n$. In order to prove the assertion in degree $n$, it suffices to check that $\omega^n_0 : S^n \to \text{gr}_J^n B$ is an isomorphism; indeed, in this case $\text{gr}_J^n B$ is a flat $B_0$-module, and then a standard spectral sequence argument allows to conclude that $\omega^n_0$ is also an isomorphism, for every $j \in \mathbb{N}$.

Let $P \to R_\bullet$ be a resolution as in (7.10.23). The $I$-adic filtration has finite length on $P/I^kP$, for every $k \in \mathbb{N}$, and therefore yields a convergent spectral sequence

$$E^1_{pq} \Rightarrow \text{Tor}^B_{p+q}(B_0, B/J^k)$$

with

$$E^1_{pq} := \begin{cases} \text{Tor}^B_{p+q}(B_0, \text{gr}_J B^{I^p}) & \text{for } p > -k \\ 0 & \text{otherwise} \end{cases}$$

whose differentials $E^1_{pq} \to E^1_{p-1,q}$ agree – by direct inspection – with the derivation $\delta^{I^p}_{p+q}$, whenever $p > 1 - k$. Especially, for $k = n + 1$, we get a complex

$$\Sigma : H_2 G^{n-2} \xrightarrow{\delta^{n-2}_2} H_1 G^{n-1} \xrightarrow{\delta^{n-1}_1} \text{gr}_J^n B \to 0.$$ 

On the other hand, since $J/J^2$ is a flat $B_0$-module, the corresponding sequence

$$\Sigma' : \Lambda_2 \otimes B S^{n-2} \xrightarrow{\delta^{n-2}} \Lambda_1 \otimes B S^{n-1} \xrightarrow{\delta} S^n \to 0$$

is an exact complex (this is a segment of the Koszul complex of [82, I.4.3.1.7]). In light of (i), the maps $\omega^{n-2}_2$ and $\omega^{n-1}_1$ yield a morphism of complexes $\Sigma' \to \Sigma$, so we are reduced to checking that $\Sigma$ is exact, and the inductive assumption already says that $\Sigma$ is exact at the middle term $H_1 G^{n-1}$. Now notice that, since the Koszul complex is exact, the inductive assumption
implies that \( E_{pq}^2 = 0 \) for all \((p,q)\) such that \( p > 1 - n \) and \( q > 0 \); moreover, obviously we have \( E_{pq}^1 = 0 \) for \( p + q < 0 \) or \( p > 0 \), therefore
\[
E_{00}^\infty = E_{00}^1 \quad \text{and} \quad E_{-n,n}^\infty = E_{-n,n}^2 = \text{Coker} \, \delta_{-1}^{n-1}.
\]
But a simple inspection shows that the natural map \( H_0 P \to E_{00}^\infty \) is an isomorphism, so \( E_{-n,n}^\infty = 0 \), therefore \( \delta_{-1}^{n-1} \) is surjective, and \( \Sigma \) is exact, as required.

(ii.b): We use the previous spectral sequence, for \( k = n \). Taking into account (ii.a), and the exactness of the Koszul complex (821.4.3.1.7) we get
\[
E_{pq}^1 = 0 \quad \text{for} \ p + q < 0 \ \text{or} \ p > 0 \ \text{or} \ p \leq -n
\]
\[
E_{pq}^2 = 0 \quad \text{for every} \ (p,q) \ \text{with} \ p > 1 - n \ \text{and} \ q > 0
\]
\[
E_{i-n,i+n-1}^2 \xrightarrow{\sim} \text{Coker} \, \delta_{i+1}^{n-2} \quad \text{for every} \ i \in \mathbb{N}.
\]
It follows that \( E_{i-n+r,i+n-r}^1 = 0 \) for every \( r \geq 2 \) and every \( i \in \mathbb{N} \); indeed, this is clear if \( 1 - n + r > 0 \), and if the latter fails, we get \( 1 - n + r > 1 - n \) and \( i + n - r > 0 \), so the stated vanishing holds nevertheless. We deduce that \( E_{i-n,i+n-1}^1 = E_{i-n,i+n-1}^2 \) for every \( i \in \mathbb{N} \). Next, suppose that \( i > 0 \). Clearly we have \( E_{p,i-p}^2 = 0 \) both for \( p > 0 \) and \( p \leq -n \); and if \( 0 \geq p > 1 - n \), we get \( i - p \geq i > 0 \), so again \( E_{p,i-p}^\infty = 0 \). In conclusion, \( E_{p,i-p}^\infty = 0 \) except possibly for \( p = 1 - n \), and the contention follows.

**Proposition 7.10.37.** Let \( B \) be a ring, \( f_* := (f_1, \ldots, f_r) \) a finite sequence of elements of \( B \). Denote by \( J \) the ideal generated by \( f_* \), set \( B_0 := B/J \), and consider the following conditions :

(a) The sequence \( f_* \) is \( B \)-regular.
(b) The sequence \( f_* \) is completely secant in \( B \).
(c) The ideal \( J \) is quasi-regular and \( J/J^2 \) is a free \( B_0 \)-module of rank \( r \).
(d) The sequence \( f_* \) is \( B \)-quasi-regular.

Then (a) \( \Rightarrow \) (b) \( \Rightarrow \) (c) \( \Rightarrow \) (d), and if \( B \) is \( J \)-adically complete and separated, then (d) \( \Rightarrow \) (a).

**Proof.** (a) \( \Rightarrow \) (b) and (c) \( \Rightarrow \) (d) have already been pointed out respectively in proposition 7.8.7 and proposition 7.10.35(ii.a), and the same for the implication (d) \( \Rightarrow \) (a), when \( B \) is \( J \)-adically complete and separated.

(b) \( \Rightarrow \) (c): This becomes a paraphrase of proposition 7.8.10 once we have identified the graded \( B \)-algebra \( H_\bullet \mathcal{G}^\bullet \) with the graded \( B \)-algebra \( H_\bullet (B_0[0] \otimes_B B_0[0]) \). However, denote by \( P^* \) the cochain complex associated with the flat resolution \( P \to s.B_0 \); according to remark 7.7.10(i), \( P^* \) is naturally a differential graded \( B \)-algebra, and the induced map \( \varepsilon^* : P^* \to B_0[0] \) is a morphism of differential graded \( B \)-algebras (for the multiplication law \( \overline{P} \) on \( B_0[0] \) inherited from that of \( B_0 \)). Then there exists in \( D(BMod) \) a unique isomorphism \( \omega^* : P^*_{B_0} \to P^* \) whose composition with \( \varepsilon^* \) agrees with \( P^*_{B_0} \) notation of (7.3.36), and moreover we get a commutative diagram in \( D(BMod) \):

\[
\begin{array}{ccc}
P^*_{B_0} \otimes_B P^*_{B_0} & \xrightarrow{P^*_P} & P^*_{B_0} \\
\omega^* \otimes_B \varepsilon^* & \downarrow & \omega^* \\
P^* \otimes_B P^* & \xrightarrow{P^*} & P^*
\end{array}
\]

whose bottom horizontal arrow is the multiplication map of \( P^* \), and where \( P^*_P \) is defined as in (7.3.36). The assertion follows immediately.

The following is a well known theorem of Quillen, which is found in his typewritten notes [109, Th.8.8] that have been circulated since the late 60s, but have never been published. A version of this theorem, under more restrictive assumptions, is also found in [3, Ch.XIII, Prop.3].
Theorem 7.10.38. Let $R$ be any simplicial $A$-algebra, and $I \subset R$ a quasi-regular ideal such that $H_0I = 0$. Then we have:

$$H_iI^n = 0 \quad \text{for every } n \in \mathbb{N} \text{ and every } i < n.$$  

Proof. We argue by induction on $n \in \mathbb{N}$. For $n = 1$ there is nothing to prove, so suppose that $n > 1$, and that the assertion is already known for $I^{n-1}$. Set $R_k := R/I^{k+1}$ for every $k \in \mathbb{N}$, and let

$$\Lambda_\bullet \otimes_R S^\bullet := \Lambda^\bullet_R(I/I^2) \otimes_R \text{Sym}_R(I/I^2)$$

which is a bigraded $R_0$-module, endowed with the bigraded derivation $\partial^\bullet_S$ such that $\partial^\bullet_S[i]$ is the Koszul derivation of $\Lambda_\bullet \otimes_R S^\bullet[i]$, defined as in [82 1.4.3.1.2]. Set as well

$$C_i := \text{Coker}(\partial^{n-3}_i : \Lambda_i \otimes_R S^{n-3} \to \Lambda_{i-1} \otimes_R S^{n-2}) \quad \text{for every } i \in \mathbb{N}.$$  

From the inductive assumption and lemma [7.10.22] we already know that

$$(7.10.39) \quad H_i(I \otimes_R I^{n-1}) = 0 \quad \text{for every } i < n.$$  

However, according to remark [7.10.14] there is a spectral sequence

$$E^1_{pq} := \text{Tor}^R_{[p]}(I[p], I[p]^{n-1}) \Rightarrow H_{p+q}(I \otimes_R I^{n-1})$$

and proposition [7.10.35(ii.b)] yields natural isomorphisms

$$E^1_{pq} \sim \text{Tor}^R_{[p]}(R_0[p], I[p]^{n-1}) \sim \text{Tor}^R_{[p]}(R_0[p], R_{n-2}[p]) \sim C_{q+3}[p] \quad \text{for every } q > 0$$

under which, the differentials $E^1_{pq} \to E^1_{p-1,q}$ are identified with those of the chain complex associated with the $R_0$-module $C_{q+3}$. Now, since $I/I^2$ is a flat $R_0$-module, [82 1.4.3.1.7] says that the sequence of $R_0$-modules

$$\Sigma^i : 0 \to \Lambda_{n+i-3} \xrightarrow{\partial} \Lambda_{n+i-4} \otimes_R S^1 \to \cdots \to \Lambda_i \otimes_R S^{n-3} \xrightarrow{\partial} \Lambda_{i-1} \otimes_R S^{n-2} \to C_i \to 0$$

is an exact complex, for every $i > 0$. On the other hand, since $H_0I/I^2 = 0$, (and again, since $I/I^2$ is a flat $R_0$-module), combining [82 1.4.3.2.1] and lemma [7.10.22] we see that

$$H_i(\Lambda_j \otimes_R S^{n-j}) = 0 \quad \text{for every } q \in \mathbb{N}, \text{ every } j \leq q, \text{ and every } i < q.$$  

We recall the following general

Claim 7.10.40. Let $\mathcal{A}$ be any abelian category, $d \in \mathbb{N}$ any integer, and consider an exact sequence

$$0 \to K_d \xrightarrow{f_d} K_{d-1} \to \cdots \to K_1 \xrightarrow{f_1} K_0 \to 0$$

of objects of $C(\mathcal{A})$, such that $K_i = 0$ in $D(\mathcal{A})$, for every $i = 1, \ldots, d - 1$. Then there is a natural isomorphism

$$K_0 \sim K_d[d-1] \quad \text{in } D(\mathcal{A}).$$  

Proof of the claim. For every $i = 0, \ldots, d$, set $Z_i := \ker f_i$. We have short exact sequences

$$0 \to Z_i \to K_i \to Z_{i-1} \to 0 \quad \text{for } i = 1, \ldots, d.$$  

Since $K_i = 0$ in $D(\mathcal{A})$, there follows natural isomorphisms $Z_{i-1} \sim Z_i[1]$ for every $i = 1, \ldots, d - 1$. However, $Z_0 = K_0$ and $Z_{d-1} = K_d$, whence the claim.

By applying claim [7.10.40] to the exact sequence $\cosk_{n+i-3} \Sigma^i$, we easily deduce that

$$H_f C_i = 0 \quad \text{for every } i > 0 \text{ and every } j < n + i - 3$$

so finally $E^{2}_{pq} = 0$ for every $q > 0$ and every $p < n + q$, and clearly $E^{1}_{pq} = 0$ for every $q < 0$. Consequently, for every $i < n$ the term $E_{-q,q} = 0$ vanishes for $q > 0$, and equals $E^{2}_{i,0}$ for $q = 0$. Lastly, a simple calculation shows that

$$E^{2}_{i,0} = H_i(I \otimes_R I^{n-1}) \quad \text{for every } i \in \mathbb{N}.$$
Summing up, and taking into account 7.10.39 we conclude that $H_i(I \otimes_R I^{n-1}) = 0$ for every $i < n$, so we are reduced to checking:

**Claim 7.10.41.** The natural map $H_i(I \otimes_R I^{n-1}) \to H_i(I^n)$ is surjective, for every $i \leq n$.

**Proof of the claim.** Indeed, denote by $K$ the kernel of the epimorphism $I \otimes_R I^{n-1} \to I^n$; as in the foregoing, we get natural isomorphisms

$$K[i] \sim\simeq \Tor_1^{R[i]}(R_0[i], I[i]^{n-1}) \sim\simeq \Tor_2^{R[i]}(R_0[i], R[i]/I[i]^{n-1}) \sim\simeq C_3[i] \quad \text{for every } i \in \mathbb{N}$$

that amount to an isomorphism $K \sim\simeq C_3$ of $R_0$-modules. We have already seen that $H_iC_3 = 0$ for every $i < n$, whence the claim. 

\[\Box\]

### 7.11. Injective modules, flat modules and indecomposable modules.

7.11.1. **Indecomposable modules.** Recall that a unital (not necessarily commutative) ring $R$ is said to be local if $R \neq 0$ and, for every $x \in R$ either $x$ or $1-x$ is invertible. If $R$ is commutative, this definition is equivalent to the usual one.

7.11.2. Let $\mathcal{C}$ be any abelian category and $M$ an object of $\mathcal{C}$. One says that $M$ is indecomposable if it is non-zero and cannot be presented in the form $M = N_1 \oplus N_2$ with non-zero objects $N_1$ and $N_2$. If such a decomposition exists, then $\text{End}_\mathcal{C}(N_1) \times \text{End}_\mathcal{C}(N_2) \subset \text{End}_\mathcal{C}(M)$, especially the unital ring $\text{End}_\mathcal{C}(M)$ contains an idempotent element $e \neq 1, 0$ and therefore it is not a local ring.

However, if $M$ is indecomposable, it does not necessarily follow that $\text{End}_\mathcal{C}(M)$ is a local ring. Nevertheless, one has the following:

**Theorem 7.11.3** (Krull-Remak-Schmidt). *Let $(A_i)_{i \in I}$ and $(B_j)_{j \in J}$ be two finite families of objects of $\mathcal{C}$, such that:

(a) \( \oplus_{i \in I} A_i \simeq \oplus_{j \in J} B_j \),

(b) \( \text{End}_\mathcal{C}(A_i) \) is a local ring for every \( i \in I \), and \( B_j \neq 0 \) for every \( j \in J \).

Then we have:

(i) There is a surjection \( \varphi : I \to J \), and isomorphisms \( B_j \sim\simeq \oplus_{i \in \varphi^{-1}(j)} A_i \) for every \( j \in J \).

(ii) Especially, if \( B_j \) is indecomposable for every \( j \in J \), then \( I \) and \( J \) have the same cardinality, and \( \varphi \) is a bijection.*

**Proof.** Clearly, (i)⇒(ii). To show (i), let us begin with the following:

**Claim 7.11.4.** *Let $M_1, M_2$ be two objects of $\mathcal{C}$, and set $M := M_1 \oplus M_2$. Denote by $e_i : M_i \to M$ (resp. $p_i : M \to M_i$) the natural injection (resp. projection) for $i = 1, 2$. Suppose that $\alpha : P \to M$ is a subobject of $M$, such that $p_1\alpha : P \to M_1$ is an isomorphism. Then the natural morphism $\beta : P \oplus M_2 \to M$ is an isomorphism.*

**Proof of the claim.** Denote by $\pi_P : P \oplus M_2 \to P$ and $\pi_2 : P \oplus M_2 \to M_2$ the natural projections; then $\beta := \alpha \pi_P + e_2 \pi_2$. Of course, the assertion follows easily by applying the 5-lemma (which holds in any abelian category) to the commutative ladder with exact rows:

\[
\begin{array}{cccccc}
0 & \longrightarrow & M_2 & \longrightarrow & P \oplus M_2 & \longrightarrow & P & \longrightarrow & 0 \\
& & \downarrow{\beta} & & \downarrow{p_1\alpha} & & \downarrow{\pi_P} & \downarrow{\pi_2} & \downarrow{0} \\
0 & \longrightarrow & M_2 & \longrightarrow & M & \longrightarrow & P & \longrightarrow & 0.
\end{array}
\]

Equivalently, one can argue directly as follows. By definition, $\text{Coker} \beta$ represents the functor

\[\mathcal{C} \to \text{Z-Mod} : X \mapsto \text{Ker} \text{Hom}_\mathcal{C}(\beta, X)\]
and likewise for $\text{Coker } p_1 \alpha$; however, it is easily seen that these functors are naturally isomorphic, hence the natural morphism $\text{Coker } \beta \to \text{Coker } p_1 \alpha$ is an isomorphism, so $\beta$ is an epimorphism. Next, let $t : \text{Ker } \beta \to P \oplus M_2$ be the natural morphism; since $p_1 \alpha$ is an isomorphism, $\pi_P \circ t = 0$, so $t$ factors through a morphism $\bar{t} : \text{Ker } \beta \to M_2$. It follows that $e_2 \circ \bar{t} = \beta \circ t = 0$, therefore $\bar{t} = 0$, and finally $\text{Ker } \beta = 0$, since $t$ is a monomorphism.

Set $A := \bigoplus_{i \in I} A_i$, and denote $e_i : A_i \to A$ (resp. $p_i : A \to A_i$) the natural injection (resp. projection), for every $i \in I$. Also, endow $I' := I \cup \{\infty\}$ with any total ordering $(I', <)$ for which $\infty$ is the maximal element.

**Claim 7.11.5.** Let $(a_j : A \to A)_{j \in J}$ be a finite system of endomorphisms such that $\sum_{j \in J} a_j = 1_A$. Then there exists a mapping $\varphi : I \to J$ such that the following holds:

(i) $a_{\varphi(i)} e_i : A_i \to A$ is a monomorphism, for every $i \in I$, and let $P_i := \text{Im}(a_{\varphi(i)} e_i)$.

(ii) For every $l \in I'$, the natural morphism $\beta_l : \bigoplus_{j<l} P_j \oplus \bigoplus_{j \geq l} A_j \to A$ is an isomorphism.

**Proof of the claim.** We both define $\varphi(l)$ and prove (ii), by induction on $l$. If $l$ is the smallest element of $I$, then $\beta_1 = 1_A$, so (ii) is obvious. Hence, let $l \in I$ be any element, $l' \in I'$ the successor of $l$, and assume that $\beta_l$ is an isomorphism. Set $a'_j := \beta_l^{-1} a_j \beta_l$ for every $j \in J$, and let $M_l := \bigoplus_{i<l} P_i \oplus \bigoplus_{i \geq l} A_i$; also, let $\varphi' : J \to I$ be the natural morphisms.

Clearly $\sum_{j \in J} a'_j = 1_{M_l}$, so $\sum_{j \in J} p'_j a'_j \varphi_l = 1_{A_l}$; since $\text{End}_{l}(A_l)$ is a local ring, it follows that there exists $j_l \in J$ such that $p'_l a'_j \varphi_l = 1_{A_l}$ is an automorphism of $A_l$. However,

\[(7.11.6)\quad a'_j \varphi_l = \beta_l^{-1} a_j \beta_l \varphi_l = \beta_l^{-1} a_j e_l\]

so assertion (i) follows for the index $l$, by setting $\varphi(l) := j_l$.

Next, set $M_{1,1} := A_l$ and $M_{1,2} := \bigoplus_{i \leq l} P_i \oplus \bigoplus_{i > l} A_i$. The foregoing argument provides a subobject $\alpha : P'_l := \text{Im}(a'_{\varphi'(l)} \varphi_l) \to M_l = M_{1,1} \oplus M_{1,2}$ such that $p'_l \alpha : P'_l \to M_{1,1}$ is an isomorphism. By claim 7.11.4 it follows that the natural map $\beta'_l : P'_l \oplus M_{1,2} \to M_l$ is an isomorphism. On the other hand, (7.11.6) implies that $\beta_l$ restricts to an isomorphism $\gamma_l : P'_l \simeq P_l$. We deduce a commutative diagram

\[
\begin{array}{ccc}
P'_l \oplus M_{1,2} & \xrightarrow{\beta'_l} & M_l \\
\downarrow{\gamma_l \oplus 1_{M_{1,2}}} & & \downarrow{\beta_l} \\
M'_l & \xrightarrow{\beta'_l} & A \\
\end{array}
\]

whose vertical arrows and top arrow are isomorphisms. Thus, the bottom arrow is an isomorphism as well, as required.

For every $j \in J$, let $\varphi'_j : B_j \to A$ (resp. $p'_j : A \to B_j$) be the injection (resp. projection) deduced from a given isomorphism as in (a), and set $a_j := \varphi'_j p'_j$ for every $j \in J$. Then $\sum_{j \in J} a_j = 1_A$, so claim 7.11.5 yields a mapping $\varphi : I \to J$ such that the following holds.

Set $P_j := \bigoplus_{i < \varphi(j)} \text{Im}(a_{\varphi(i)} e_i)$ for every $j \in J$; then the natural morphism $\beta : \bigoplus_{i \in I} P_j \simeq A$ is an isomorphism. However, clearly $\beta(P_j)$ is a subobject of $\text{Im}(\varphi'_j)$, for every $j \in J$. Hence, $\varphi$ must be a surjection, and $\beta$ restricts to isomorphisms $P_j \simeq \text{Im}(\varphi'_j)$ for every $j \in J$, whence isomorphisms $P_j \simeq B_j$, from which (ii) follows immediately.

**Remark 7.11.7.** There are variants of theorem 7.11.3 that hold under different sets of assumptions. For instance, in [60, Ch.I, §6, Th.1] it is stated that part (ii) of the theorem still holds when $I$ and $J$ are small (not necessarily finite) sets, provided that $\mathcal{C}$ admits a small set of generators and that all small filtered colimits are representable and exact in $\mathcal{C}$. (One can moreover show that the latter result still holds even in the absence of a small set of generators for $\mathcal{C}$.)
7.11.8. Let us now specialize to the case of the category \( A\text{-Mod} \), where \( A \) is a (commutative) local ring, say with residue field \( k \). Let \( M \) be any finitely generated \( A \)-module; arguing by induction on the dimension of \( M \otimes_A k \), one shows easily that \( M \) admits a finite decomposition \( M = \oplus_{i=1}^r M_i \), where \( M_i \) is indecomposable for every \( i \leq r \).

**Lemma 7.11.9.** Let \( A \) be a henselian local ring, and \( M \) an \( A \)-module of finite type. Then \( M \) is indecomposable if and only if \( \text{End}_A(M) \) is a local ring.

**Proof.** In view of (7.11.2), we can assume that \( M \) is indecomposable, and we wish to prove that \( \text{End}_A(M) \) is local. Thus, let \( \varphi \in \text{End}_A(M) \).

**Claim 7.11.10.** The subalgebra \( A[\varphi] \subset \text{End}_A(M) \) is integral over \( A \).

**Proof of the claim.** This is standard: choose a finite system of generators \( (f_i)_{1 \leq i \leq r} \) for \( M \), then we can find a matrix \( \alpha := (a_{ij})_{1 \leq i,j \leq r} \) of elements of \( A \), such that \( \varphi(f_i) = \sum_{j=1}^r a_{ij}f_j \) for every \( i \leq r \). The matrix \( \alpha \) yields an endomorphism \( \psi \) of the free \( A \)-module \( A^{\oplus r} \); on the other hand, let \( e_1, \ldots, e_r \) be the standard basis of \( A^{\oplus r} \) and define an \( A \)-linear surjection \( \pi : A^{\oplus r} \to M \) by the rule: \( e_i \mapsto f_i \) for every \( i \leq r \). Then \( \varphi \circ \pi = \pi \circ \psi \); by Cayley-Hamilton, \( \psi \) is annihilated by the characteristic polynomial \( \chi(T) \) of the matrix \( \alpha \), whence \( \chi(\varphi) = 0 \).

Since \( A \) is henselian, Claim 7.11.10 implies that \( A[\varphi] \) decomposes as a finite product of local rings. If there were more than one non-zero factor in this decomposition, the ring \( A[\varphi] \) would contain an idempotent \( e \neq 1,0 \), whence the decomposition \( M = eM \oplus (1-e)M \), where both summands would be non-zero, which contradicts the assumption. Thus, \( A[\varphi] \) is a local ring, so that either \( \varphi \) or \( 1_M - \varphi \) is invertible. Since \( \varphi \) was chosen arbitrarily in \( \text{End}_A(M) \), the claim follows.

**Corollary 7.11.11.** Let \( A \) be a henselian local ring. Then:

(i) If \((M_i)_{i \in I}\) and \((N_j)_{j \in J}\) are two finite families of indecomposable \( A \)-modules of finite type such that \( \oplus_{i=1}^r M_i \simeq \oplus_{j=1}^s N_j \), then there is a bijection \( \beta : I \to J \) such that \( M_i \simeq N_{\beta(i)} \) for every \( i \in I \).

(ii) If \( M \) and \( N \) are two finitely generated \( A \)-modules such that \( M \oplus k \simeq N \oplus k \) for some integer \( k > 0 \), then \( M \simeq N \).

(iii) If \( M, N \) and \( X \) are three finitely generated \( A \)-modules such that \( X \oplus M \simeq X \oplus N \), then \( M \simeq N \).

**Proof.** It follows easily from theorem 7.11.3 and lemma 7.11.9, the details are left to the reader.

**Proposition 7.11.12.** Let \( A \to B \) be a faithfully flat map of local rings, \( M \) and \( N \) two finitely presented \( A \)-modules with a \( B \)-linear isomorphism \( \omega : B \otimes_A M \to B \otimes_A N \). Then \( M \simeq N \).

**Proof.** Under the standing assumptions, the natural \( B \)-linear map

\[
B \otimes_A \text{Hom}_A(M,N) \to \text{Hom}_B(B \otimes_A M, B \otimes_A N)
\]

is an isomorphism ([59 Lemma 2.4.29(i.a)]). Hence we can write \( \omega = \sum_{i=1}^r b_i \otimes \varphi_i \) for some \( b_i \in B \) and \( \varphi_i : M \to N \). Denote by \( k \) and \( K \) the residue fields of \( A \) and \( B \) respectively; we set \( \overline{\varphi}_i := 1_k \otimes_A \varphi_i : k \otimes_A M \to k \otimes_A N \). From the existence of \( \omega \) we deduce easily that \( n := \dim_k k \otimes_A M = \dim_k k \otimes_A N \). Hence, after choosing bases, we can view \( \overline{\varphi}_1, \ldots, \overline{\varphi}_r \) as endomorphisms of the \( k \)-vector space \( k^n \). We consider the polynomial \( p(T_1, \ldots, T_r) := |(\sum_{i=1}^r T_i \cdot \overline{\varphi}_i) \in k[T_1, \ldots, T_r]| \). Let \( \overline{b}_1, \ldots, \overline{b}_r \) be the images of \( b_1, \ldots, b_r \) in \( K \); it follows that \( p(\overline{b}_1, \ldots, \overline{b}_r) \neq 0 \), especially \( p(T_1, \ldots, T_r) \neq 0 \).

**Claim 7.11.13.** The proposition holds if \( k \) is an infinite field or if \( k = K \).
Proof of the claim. Indeed, in either of these cases we can find \( \overline{a}_1, \ldots, \overline{a}_r \in k \) such that \( p(\overline{a}_1, \ldots, \overline{a}_r) \neq 0 \). For every \( i \leq r \) choose an arbitrary representative \( a_i \in A \) of \( \overline{a}_i \), and set \( \varphi := \sum_{i=1}^r a_i \varphi_i \). By construction, \( 1_k \otimes_A \varphi : k \otimes_A M \to k \otimes_A N \) is an isomorphism. By Nakayama’s lemma we deduce that \( \varphi \) is surjective. Exchanging the roles of \( M \) and \( N \), the same argument yields an \( A \)-linear surjection \( \psi : N \to M \). Finally, [100, Ch.I, Th.2.4] shows that both \( \psi \circ \varphi \) and \( \varphi \circ \psi \) are isomorphisms, whence the claim.

Let \( A^h \) be the henselization of \( A \), and \( A^{sh}, B^{sh} \) the strict henselizations of \( A \) and \( B \) respectively. Now, the induced map \( A^{sh} \to B^{sh} \) is faithfully flat, the residue field of \( A^{sh} \) is infinite, and \( \omega \) induces a \( B^{sh} \)-linear isomorphism \( B^{sh} \otimes_A M \cong B^{sh} \otimes_A N \). Hence, claim 7.11.13 yields an \( A^{sh} \)-linear isomorphism \( \beta : A^{sh} \otimes_A M \cong A^{sh} \otimes_A N \). However, \( A^{sh} \) is the colimit of a filtered family \( (A_\lambda \mid \lambda \in \Lambda) \) of finite étale \( A^{sh} \)-algebras, so \( \beta \) descends to an \( A_\lambda \)-linear isomorphism \( \beta_\lambda : A_\lambda \otimes_A M \cong A_\lambda \otimes_A N \) for some \( \lambda \in \Lambda \). The \( A^{sh} \)-module \( A_\lambda \) is free, say of finite rank \( n \), hence \( \beta_\lambda \) can be regarded as an \( A^{sh} \)-linear isomorphism \( (A^{sh} \otimes_A M)_{\oplus n} \cong (A^{sh} \otimes_A N)_{\oplus n} \). Then \( A^{sh} \otimes_A M \cong A^{sh} \otimes_A N \), by corollary 7.11.11(ii). Since the residue field of \( A^{sh} \) is \( k \), we conclude by another application of claim 7.11.13.

7.11.14. Injective hulls. The notion of injective hull plays a central role in the theory of local duality : for a noetherian local ring, one constructs a dualizing module as the injective hull of the residue field (see [68, Exp.IV, Th.4.7]), and in section 11.6 injective hulls of the residue fields of a monoid algebra will also enable us to perform a certain computation of local cohomology, which is a crucial step in the proof of Hochster’s theorem. We present here the basic results on injective hulls, in the context of arbitrary abelian categories.

Definition 7.11.15. Let \( \mathcal{A} \) be any abelian category, and \( f : N \to M \) a monomorphism in \( \mathcal{A} \).

(i) We say that \( M \) is an essential extension of \( N \) if the following holds. For any subobject \( P \subset M \) we have either \( P = 0 \) or \( P \cap \text{Im } f \neq 0 \) (here 0 denotes the zero object of \( \mathcal{A} \) : see remark 3.6.29(i)).

(ii) We say that \( M \) is a proper essential extension of \( N \) if it is an essential extension of \( N \), and \( f \) is not an isomorphism.

(iii) We say that \( M \) is an injective hull of \( N \), if \( M \) is both an essential extension of \( N \), and an injective object of \( \mathcal{A} \).

Lemma 7.11.16. Let \( \mathcal{A} \) be an abelian category, and \( I \) an object of \( \mathcal{A} \). Suppose that :

(a) \( \mathcal{A} \) is cocomplete.

(b) All colimits of \( \mathcal{A} \) are universal (see example 1.4.17).

Then we have :

(i) \( I \) is injective if and only if it does not admit any proper essential extensions.

(ii) If \( N \to M \) is any monomorphism, the set of all essential extensions of \( N \) contained in \( M \) admits maximal elements.

Proof. (i): Suppose that \( I \) is injective, and let \( f : I \to M \) be any monomorphism which is not an isomorphism. Then \( f \) admits a left inverse, so \( I \) is a direct summand of \( M \), hence \( M \) is not an essential extension of \( I \). Conversely, suppose that \( I \) does not admit proper essential extensions; let \( f : N \to M \) be a monomorphism in \( \mathcal{A} \) and \( g : N \to I \) any morphism in \( \mathcal{A} \). We consider the cocartesian diagram in \( \mathcal{A} \):

\[
\begin{array}{ccc}
N & \xrightarrow{f} & M \\
\downarrow{g} & & \downarrow{g'} \\
I & \xleftarrow{f'} & P
\end{array}
\]
and notice that $f'$ is a monomorphism, since the same holds for $f$. By Zorn’s lemma – and due to conditions (a) and (b) – we may find a maximal subobject $Q \subset P$ such that $Q \cap I = 0$, and clearly $P/Q$ is an essential extension of $I$ (via $h$); therefore $P/Q = I$, so $P = I \oplus Q$, and if we let $p : P \to I$ be the resulting projection, we see that $p \circ g' : M \to I$ is an extension of $f$. This shows that $I$ is injective.

(ii): By Zorn’s lemma, it suffices to check the following assertion. Suppose that $(P_j \mid j \in J)$ is a non-empty totally ordered family of essential extensions of $N$ contained in $M$ (for some totally ordered small indexing set $J$). Then $P := \bigcup_{j \in J} P_j$ is again an essential extension of $N$ (notice that this union – i.e. colimit – is a subobject of $M$, due to condition (b)). However, say that $Q \subset P$ and $Q \cap N = 0$; due to condition (b), we have $Q = \bigcup_{j \in J}(Q \cap P_j)$, and clearly $(Q \cap P_j) \cap N = 0$, so $Q \cap P_j = 0$ for every $j \in J$, and finally $Q = 0$. □

**Proposition 7.11.17.** Let $\mathcal{A}$ be an abelian category fulfilling condition (a) and (b) of lemma 7.11.16 and $M$ any object of $\mathcal{A}$. We suppose moreover that:

(c) $\mathcal{A}$ has enough injective objects.

Then we have:

(i) $M$ admits an injective hull. More precisely, if $M \to I$ is any monomorphism into an injective object, then a maximal essential extension of $M$ in $I$ is an injective hull of $M$.

(ii) Let $f : M \to E$ be an injective hull of $M$, and $g : M \to I$ any monomorphism into an injective object. Then $g$ factors through $f$ and a monomorphism $h : E \to I$.

(iii) If $f : M \to E$ and $g : M \to E'$ are two injective hulls of $M$, there exists an isomorphism $h : E \cong E'$ such that $h \circ f = f'$.

**Proof.** (i): Let $E \subset I$ be such a maximal essential extension of $M$ (which exists by lemma 7.11.16(ii)); by virtue of lemma 7.11.16(i), it suffices to check that $E$ does not admit proper essential extensions. However, suppose that $E \to E'$ is a proper essential extension; since $I$ is injective, the inclusion morphism $E \to I$ extends to a morphism $f : E' \to I$. By maximality of $E$, we must then have $\ker f \neq 0$; on the other hand, obviously $E \cap \ker f = 0$, which is absurd, since $E'$ is an essential extension of $E$.

(ii): Since $I$ is injective, $g$ extends to a morphism $h : E \to I$, and clearly $M \cap \ker h = 0$. Since $E$ is an essential extension of $M$, it follows that $\ker h = 0$.

(iii): By (ii) there exists a monomorphism $h : E \to E'$ such that $h \circ f = f'$. Since $E$ is injective, it follows that $\Im h$ is a direct summand of $E'$; but $E'$ is an essential extension of $M$, so $\Im h = E'$, i.e. $h$ is also an epimorphism, hence an isomorphism. □

7.11.18. We specialize now to the case where $\mathcal{A}$ is the category $A$-$\text{Mod}$ of $A$-modules, with $A$ an arbitrary noetherian ring. Recall that if $M$ is any $A$-module, then the set $\text{Ass} M$ of all associated primes of $M$ consists of the prime ideals $p \subset A$ such that there exists $m \in M$ with $A \text{Ann}_A(m) = p$. (This is the correct definition only for noetherian rings: we shall see in definition 10.5.1 a more general notion that is well behaved for arbitrary rings.) By proposition 7.11.17(i,iii) the injective hull of $M$ exists and is well defined up to (in general, non-unique) isomorphism, and we shall denote by $E_A(M)$ a choice of such hull.

**Lemma 7.11.19.** Let $A$ be a noetherian ring. The following holds:

(i) If $(I_\lambda \mid \lambda \in \Lambda)$ is a (small) family of injective $A$-modules, then $I := \bigoplus_{\lambda \in \Lambda} I_\lambda$ is an injective $A$-module.

(ii) If $S \subset A$ is any multiplicative subset, and $M$ any injective $A$-module, then $M_S$ is an injective $A_S$-module.

**Proof.** (i): Let us first recall:

**Claim 7.11.20.** Let $R$ be any ring, $M$ an $R$-module. The following conditions are equivalent:
(a) $M$ is an injective $R$-module.
(b) For every ideal $J \subset R$, every $R$-linear map $J \rightarrow M$ extends to an $R$-linear map $R \rightarrow M$.
(c) $\text{Ext}^1_R(R/J, M) = 0$ for every ideal $J \subset R$.

Proof of the claim. Of course, (a)⇒(b)⇒(c). To check that (c)⇒(a), let $N \subset P$ be an inclusion of $R$-modules, and $f : N \rightarrow M$ an $A$-linear map. We let $S$ be the set of all pairs $(N, f')$, where $N' \subset P$ is an $R$-submodule containing $N$, and $f' : N' \rightarrow M$ an $R$-linear map extending $f$. The set $S$ is partially ordered by declaring that $(N', f') \geq (N'', f'')$ if $N'' \subset N'$ and $f'_{N''} = f''$, for any two pairs $(N', f'), (N'', f'') \in S$. By Zorn’s lemma, $S$ admits a maximal element $(Q, g)$. Suppose $Q \neq P$, and let $x \in P \setminus Q$. Set $Q' := Q + Rx$ and $J := \text{Ann}_R(Q'/Q)$; there follows an exact sequence of $R$-modules

$$0 \rightarrow Q \rightarrow Q' \rightarrow R/J \rightarrow 0$$

and then (c) implies that the restriction map $\text{Hom}_R(Q', M) \rightarrow \text{Hom}_R(Q, M)$ is surjective; especially, $g$ extends to an $R$-linear map $Q' \rightarrow M$, contradicting the maximality of $Q$. Hence $Q = P$, which shows (a).

In view of claim 7.11.20, it suffices to show that every $A$-linear map $f : J \rightarrow I$ from any ideal $J \subset A$, extends to an $A$-linear map $A \rightarrow I$. However, since $J$ is finitely generated, there exists a finite subset $N' \subset A$ such that the image of $f$ is contained in $I' := \bigoplus_{x \in N'} I_x$. Clearly $I'$ is an injective $A$-module, so $f$ extends to an $A$-linear map $A \rightarrow I'$, and the assertion follows.

(ii): Let $J \subset A_S$ be any ideal, and write $J = IS$ for some ideal $I \subset A$; since $A$ is noetherian, we have

$$\text{Ext}^1_{A_S}(A_S/J, M_S) = A_S \otimes_A \text{Ext}^1_A(A/I, M)$$

so the assertion follows from claim 7.11.20.

We may now state :

Proposition 7.11.21. Let $A$ be any noetherian ring, $M$ any $A$-module. We have :

(i) For every $p \in \text{Spec} A$, the $A$-module $E_A(A/p)$ is indecomposable (see (7.11.2)).
(ii) Let $I$ be any non-zero injective $A$-module, and $p \in \text{Ass} I$ any associated prime. Then $E_A(A/p)$ is a direct summand of $I$. Especially, if $I$ is indecomposable, then $I$ is isomorphic to $E_A(A/p)$.
(iii) $\text{Ass}_A M = \text{Ass}_A E_A(M)$.
(iv) If $p, q \in \text{Spec} A$ are any two prime ideals, then the $A$-modules $E_A(A/p)$ and $E_A(A/q)$ are isomorphic if and only if $p = q$.
(v) $E_A(M_S) \simeq A_S \otimes_A E_A(M)$ for any multiplicative subset $S \subset A$.

Proof. (i): Set $B := A/p$, and suppose that $E_A(B)$ is decomposable; especially, there exist non-zero submodules $M_1, M_2 \subset E_A(B)$ with $M_1 \cap M_2 = 0$. Thus, $(M_1 \cap B) \cap (M_2 \cap B) = 0$, and since $B$ is a domain, we deduce that $M_i \cap B = 0$ for $i = 1, 2$. But since $E_A(B)$ is an essential extension of $B$, this is absurd.

(ii): By assumption, there exists $x \in I$ such that $\text{Ann}_A(x) = p$, so the submodule $Ax \subset I$ is isomorphic to $A/p$; then, by proposition 7.11.17(ii) there exists a monomorphism $f : E_A(A/p) \rightarrow I$, and since $E_A(A/p)$ is injective, the image of $f$ is a direct summand of $I$.

(iii): Clearly $\text{Ass}_A(M) \subset \text{Ass}_A E_A(M)$. Conversely, suppose $p \in \text{Ass}_A E_A(M)$; then there exists an $A$-submodule $N \subset E_A(M)$ isomorphic to $A/p$. Since $E_A(M)$ is an essential extension of $M$, we have $N \cap M \neq 0$, so $p \in \text{Ass}_A(M)$.

(iv) follows directly from (iii).

(v): We know already that $E' := A_S \otimes_A E_A(M)$ contains $M_S$ and is injective (lemma 7.11.19(iii)), so it remains only to check that $E'$ is an essential extension of $M$. Thus, let $x \in E' \setminus M_S$; we have to check that $N := A_Sx \cap M_S \neq 0$, and clearly we may assume that
$x \in E_A(M)$. Set $\mathcal{F} := \{\text{Ann}_A(tx) \mid t \in S\}$; since $A$ is noetherian, $\mathcal{F}$ admits maximal elements, and notice that $A_{tx}x = A_{sx}$ for any $t \in S$. Hence, we may replace $x$ by $tx$ for some $t \in S$, after which we may assume that $\text{Ann}_A(x)$ is maximal in $\mathcal{F}$. We may write $Ax \cap M = Ix$ for some ideal $I \subset A$, so $N = Isx$; let $a_1, \ldots, a_k \in A$ be a system of generators for $I$, and notice that $Ix \neq 0$, since $E_A(M)$ is an essential extension of $M$. Suppose that $N = 0$; then there exists $t \in S$ such that the identity $ta_ix = 0$ holds in $A$ for $i = 1, \ldots, k$. However, $\text{Ann}_A(x) = \text{Ann}_A(tx)$ by construction, so $Ix = 0$, a contradiction. □

**Theorem 7.11.22.** Let $A$ be a noetherian ring, $I$ an injective $A$-module. We have:

1. $I$ decomposes as a direct sum of the form

$$I \simeq \bigoplus_{p \in \text{Spec } A} E_A(A/p)^{(R_p)} \quad \text{(7.11.23)}$$

   for a system of (small) sets $(R_p \mid p \in \text{Spec } A)$.

2. Moreover, the cardinality of $R_p$ equals $\dim_{\kappa(p)} \text{Hom}_{A_p}(\kappa(p), I_p)$, for every $p \in \text{Spec } A$ (where $\kappa(p) := A_p/p_p$). Especially, this cardinality is independent of the decompositon (7.11.23).

**Proof.** (i): Denote by $\mathcal{F}$ the set of all indecomposable injective submodules of $I$, and by $\mathcal{S}$ the set of all subsets $\mathcal{G} \subset \mathcal{F}$ such that the natural map $I_{\mathcal{G}} := \bigoplus_{G \in \mathcal{G}} G \to I$ is injective. The set $\mathcal{F}$ is partially ordered by inclusion, and by Zorn’s lemma, $\mathcal{F}$ admits a maximal element $\mathcal{M}$; in light of proposition 7.11.21(ii), it suffices to check that $I_{\mathcal{M}} = I$. However, $I_{\mathcal{M}}$ is injective (lemma 7.11.19(i)), hence $I = I_{\mathcal{M}} \oplus J$ for some $A$-module $J$, and it is easily seen that $J$ is injective as well. We are thus reduced to showing that $J = 0$. Now, if $J \neq 0$, let $p \in \text{Ass}_{A,J}$ be any associated prime (100, Th.6.1(ii)); then $E_A(A/p)$ is an indecomposable injective direct summand of $J$ (proposition 7.11.21(i,ii)), and therefore $I_{\mathcal{M}} \oplus E_A(A/p)$ is a submodule of $I$, contradicting the maximality of $\mathcal{M}$.

(ii): In light of (i) and proposition 7.11.21(iii,v) we have

$$\text{Hom}_{A_p}(\kappa(p), I_p) = \text{Hom}_{A_p}(\kappa(p), E_A(A/p)^{(R_p)}) = \kappa(p)^{(R_p)} \otimes_{\kappa(p)} \text{Hom}_{A_p}(\kappa(p), E_A(\kappa(p)))$$

so we are reduced to showing the following:

**Claim 7.11.24.** Let $m \subset A$ be any maximal ideal, and set $\kappa := A/m$; then

$$d := \dim_{\kappa} \text{Hom}_A(\kappa, E_A(\kappa)) = 1.$$  

**Proof of the claim.** Since $\kappa \subset E_A(\kappa)$, obviously $d \geq 1$. On the other hand, we have a natural identification

$$\text{Hom}_A(\kappa, E_A(\kappa)) = F := \{x \in E_A(\kappa) \mid mx = 0\}.$$

If $d > 1$, we may find $x \in F$ such that $Ax \cap \kappa = 0$; but this is absurd, since $E_A(\kappa)$ is an essential extension of $\kappa$. □

7.11.25. When dealing with the more general coherent rings that appear in sections 11.4 and 11.5, the injective hull is no longer suitable for the study of local cohomology, but it turns out that one can use instead a “coh-injective hull”, which works just as well.

**Definition 7.11.26.** Let $A$ be a ring; we denote by $A\text{-Mod}_{\text{coh}}$ the full subcategory of $A\text{-Mod}$ consisting of all coherent $A$-modules.

1. An $A$-module $J$ is said to be coh-injective if the functor

$$A\text{-Mod}_{\text{coh}} \to A\text{-Mod}^0 : M \mapsto \text{Hom}_A(M, J)$$

is exact.

2. An $A$-module $M$ is said to be $\omega$-coherent if it is countably generated, and every finitely generated submodule of $M$ is finitely presented.
Lemma 7.11.27. Let $A$ be a ring.

(i) Let $M, J$ be two $A$-modules, $N \subset M$ a submodule. Suppose that $J$ is coh-injective and both $M$ and $M/N$ are $\omega$-coherent. Then the natural map:

$$\text{Hom}_A(M, J) \to \text{Hom}_A(N, J)$$

is surjective.

(ii) Let $(J_\lambda \mid \lambda \in \Lambda)$ be a filtered family of coh-injective $A$-modules. Then $\operatorname{colim}_{\lambda \in \Lambda} J_\lambda$ is coh-injective.

(iii) Assume that $A$ is coherent, let $M_\bullet$ be an object of $\mathcal{D}^-(A\text{-Mod}_\text{coh})$ and $I^\bullet$ a bounded below complex of coh-injective $A$-modules. Then the natural map

$$\text{Hom}^\bullet_A(M_\bullet, I^\bullet) \to R\text{Hom}^\bullet_A(M_\bullet, I^\bullet)$$

is an isomorphism in $\mathcal{D}(A\text{-Mod})$.

Proof. (i): Since $M$ is $\omega$-coherent, we may write it as an increasing union $\bigcup_{n \in \mathbb{N}} M_n$ of finitely generated, hence finitely presented submodules. For each $n \in \mathbb{N}$, the image of $M_n$ in $M/N$ is a finitely generated, hence finitely presented submodule; therefore $N_n := N \cap M_n$ is finitely generated, hence it is a coherent $A$-module, and clearly $N = \bigcup_{n \in \mathbb{N}} N_n$. Suppose $\varphi: N \to J$ is any $A$-linear map; for every $n \in \mathbb{N}$, set $P_{n+1} := M_n + N_{n+1} \subset M$, and denote by $\varphi_n: N_n \to J$ the restriction of $\varphi$. We wish to extend $\varphi$ to a linear map $\varphi': M \to J$, and to this aim we construct inductively a compatible system of extensions $\varphi'_n: P_n \to J$, for every $n > 0$. For $n = 1$, one can choose arbitrarily an extension $\varphi'_1$ of $\varphi_1$ to $P_1$. Next, suppose $n > 0$, and that $\varphi'_n$ is already given; since $P_n \subset M_n$, we may extend $\varphi'_n$ to a map $\varphi''_n: M_n \to J$. Since $M_n \cap N_{n+1} = N_n$, and since the restrictions of $\varphi''_n$ and $\varphi_{n+1}$ agree on $N_n$, there exists a unique $A$-linear map $\varphi'_{n+1}: P_{n+1} \to J$ that extends both $\varphi''_n$ and $\varphi_{n+1}$.

(ii): Recall that a coherent $A$-module is finitely presented. However, it is well known that an $A$-module $M$ is finitely presented if and only if the functor $Q \mapsto \text{Hom}_A(M, Q)$ on $A$-modules, commutes with filtered colimits (see e.g. [59] Prop.2.3.16(ii)). The assertion is an easy consequence.

(iii): Since $A$ is coherent, one can find a resolution $\varphi: P_\bullet \to M_\bullet$ consisting of free $A$-modules of finite rank (cp. [59] §7.1.20]). One looks at the spectral sequences

$$E^{pq}_1 : \text{Hom}_A(P_p, I^q) \Rightarrow R^{p+q}\text{Hom}^\bullet_A(M_\bullet, I^\bullet)$$

$$F^{pq}_1 : \text{Hom}_A(M_p, I^q) \Rightarrow H^{p+q}\text{Hom}^\bullet_A(M_\bullet, I^\bullet).$$

The resolution $\varphi$ induces a morphism of spectral sequences $E_1^{pq} \to E_1^{pq'}$; on the other hand, since $I^q$ is coh-injective, we have $E_2^{pq} \simeq \text{Hom}_A(H_p P_\bullet, I^q) \simeq \text{Hom}_A(H_p M_\bullet, I^q) \simeq F_2^{pq}$, so the induced map $F_2^{pq} \to E_2^{pq}$ is an isomorphism for every $p, q \in \mathbb{N}$, whence the claim. □

7.11.28. Let $A$ be a coherent ring, $Z \subset \text{Spec } A$ a constructible closed subset; we denote by

$$A\text{-Mod}_{\text{coh}, Z}$$

the full subcategory of $A\text{-Mod}_{\text{coh}}$ whose objects are the (coherent) $A$-modules with support contained in $Z$. Let $I \subset A$ be any finitely generated ideal such that $Z = \text{Spec } A/I$; it is easily seen that

$$\text{Ob}(A\text{-Mod}_{\text{coh}, Z}) = \bigcup_{n \in \mathbb{N}} \text{Ob}(A/I^n\text{-Mod}_{\text{coh}}).$$

Now, consider a functor

$$T : A\text{-Mod}_{\text{coh}, Z} \to \mathbb{Z}\text{-Mod}.$$
Notice that $T_M$ is naturally an $A$-module, for every coherent $A$-module $M$: indeed, if $a \in A$ is any element, we may define the scalar multiplication by $a$ on $T_M$ as the $\mathbb{Z}$-linear endomorphism $T(a \cdot 1_M)$. In other words, $T$ factors through the forgetful functor $A\text{-Mod} \to \mathbb{Z}\text{-Mod}$; especially, if we set

$$H_T := \text{colim}_{n \in \mathbb{N}} T(A/I^n)$$

we get a natural $A$-linear map

$$M \xrightarrow{\sim} \text{colim}_{n \in \mathbb{N}} \text{Hom}_A(A/I^n, M) \to \text{colim}_{n \in \mathbb{N}} \text{Hom}_A(TM, T(A/I^n)) \to \text{Hom}_A(TM, H_T)$$

whence a bilinear pairing

$$M \times TM \to H_T$$

which in turns yields a natural transformation

$$\omega_M : TM \to \text{Hom}_A(M, H_T) \quad \text{for every } M \in \text{Ob}(A\text{-Mod}_{\text{coh}}, \mathbb{Z}).$$

Lemma 7.11.29. In the situation of (7.11.28), the following conditions are equivalent:

(a) $\omega_M$ is an isomorphism of functors $T \xrightarrow{\sim} \text{Hom}_A(\cdot, H_T)$.

(b) $T$ is left exact.

Proof. Clearly (a)$\Rightarrow$(b). For the converse, suppose first that $Z = \text{Spec} \ A$, in which case, notice that $H_T = TA$ and $\omega_A$ is the natural isomorphism $TA \xrightarrow{\sim} \text{Hom}_A(A, TA)$; then, if $M$ is any coherent $A$-module, pick a finite presentation

$$\Sigma : A^{\oplus n} \to A^{\oplus m} \to M \to 0$$

and apply the 5-lemma to the resulting ladder of $A$-modules $\omega_\Sigma$ with left exact rows, to deduce that $\omega_M$ is an isomorphism. Next, for a general ideal $I$ and $M$ an $A$-module with $\text{Supp} \ M \subset Z$, we may find $n \in \mathbb{N}$ such that $M$ is an $A/I^n$-module; since $A/I^k$ is coherent, the foregoing case then shows that the induced map

$$TM \to \text{Hom}_A(M, T(A/I^k))$$

is an isomorphism, for every $k \geq n$. To conclude, it suffices to remark that the natural map

$$\text{colim}_{k \in \mathbb{N}} \text{Hom}_A(M, T(A/I^k)) \to \text{Hom}_A(M, H_T)$$

is an isomorphism, since $M$ is finitely presented ([59, Prop.2.3.16(ii)]). □

We wish next to present a criterion that allows to detect, among the functors $T$ as in (7.11.28), those that are exact. A complete characterization shall be given only for a restricted class of coherent ring; namely, we make the following:

Definition 7.11.30. Let $A$ be a coherent ring. We say that $A$ is an Artin-Rees ring, if the following holds. For every finitely generated ideal $I \subset A$, every coherent $A$-module $M$, and every finitely generated $A$-submodule $N \subset M$, the $I$-adic topology of $M$ induces the $I$-adic topology on $N$.

We can then state:

Proposition 7.11.31. In the situation of (7.11.28) suppose furthermore that $A$ is an Artin-Rees ring. Then the following conditions are equivalent:

(a) $H_T$ is a coh-injective $A$-module.

(b) $T$ is exact.
Proof. Clearly (a)⇒(b). For the converse, let $M$ be any coherent $A$-module, and $N \subset M$ any finitely generated $A$-submodule; it suffices to check that the induced map

$$\text{Hom}_A(M, H_T) \to \text{Hom}_A(N, H_T)$$

is surjective. However, let $f : N \to H_T$ be any $A$-linear map; since $N$ is finitely presented, there exists $n \in \mathbb{N}$ such that $f$ factors through an $A$-linear map $f_n : N \to T(A/I^n)$ (see [59 Prop.2.3.16(ii)]), and clearly $I^n N \subset \text{Ker } f_n$, so $I^n N \subset \text{Ker } f$ as well. Since the $I$-adic topology of $N$ agrees with the topology induced by the $I$-adic topology of $M$, there exists $k \in \mathbb{N}$ such that $I^k M \cap N \subset I^n N$. Set $\overline{N} := N/(I^k M \cap N)$; then $\overline{N}$ is a finitely generated $A$-submodule of $M/I^k M$, and especially it is a coherent $A$-module. By construction, $f$ factors through an $A$-linear map $\overline{f} : \overline{N} \to H_T$; assumption (b) and lemma 7.11.29 imply that $\overline{f}$ extends to an $A$-linear map $M/I^k M \to H_T$, and the resulting map $M \to H_T$ extends $f$, whence (a). \qed

Remark 7.11.32. (i) In the terminology of definition 7.11.30, the standard Artin-Rees lemma implies that every noetherian ring is an Artin-Rees ring. We shall see later that if $V$ is any valuation ring, then every essentially finitely presented $V$-algebra is an Artin-Rees ring (corollary 9.1.27 and theorem 11.4.45).

(ii) On the other hand, if $A$ is noetherian, claim 7.11.20 easily implies that an $A$-module is coh-injective if and only if it is injective.

(iii) Combining (i) and (ii) with proposition 7.11.31 we recover [68 Exp.IV, Prop.2.1].

Example 7.11.33. Let $\kappa_0$ be a field, $A$ a noetherian $\kappa_0$-algebra, $m \subset A$ a maximal ideal such that $\kappa := A/m$ is a finite extension of $\kappa_0$, and set $Z := \{m\} \subset \text{Spec } A$. Then every object of $A\text{-Mod}_{\text{coh},Z}$ is a finite dimensional $\kappa_0$-vector space, and therefore the functor

$$T : A\text{-Mod}_{\text{coh},Z} \to \kappa_0\text{-Mod} \quad M \mapsto \text{Hom}_{\kappa_0}(M, \kappa_0)$$

is exact. Proposition 7.11.31 and remark 7.11.32 (ii) then say that

$$H_T := \colim_{n \in \mathbb{N}} \text{Hom}_{\kappa_0}(A/m^n, \kappa_0)$$

is an injective $A$-module. More precisely, notice that $\text{Hom}_A(\kappa, H_T) = \text{Ann}_{H_T}(m) = T(\kappa) \simeq \kappa$, therefore $H_T$ is the injective hull of the residue field $\kappa$.

7.11.34. Flatness criteria. The following generalization of the local flatness criterion answers affirmatively a question raised in [50, Ch.IV, Rem.11.3.12].

Lemma 7.11.35. Let $A$ be a ring, $I \subset A$ an ideal, $B$ a finitely presented $A$-algebra, $\mathfrak{p} \subset B$ a prime ideal containing $IB$, and $M$ a finitely presented $B$-module. Then the following two conditions are equivalent:

(a) $M_\mathfrak{p}$ is a flat $A$-module.

(b) $\frac{M_\mathfrak{p}}{IM_\mathfrak{p}}$ is a flat $A/I$-module and $\text{Tor}_i^A(M_\mathfrak{p}, A/I) = 0$.

Proof. Clearly, it suffices to show that (b)⇒(a), hence we assume that (b) holds. We write $A$ as the union of a filtered family $(A_\lambda \mid \lambda \in \Lambda)$ of its $\mathbb{Z}$-subalgebras of finite type, and set $A' := A/I$, $I_\lambda := I \cap A_\lambda$, $A'_\lambda := A_\lambda/I_\lambda$ for every $\lambda \in \Lambda$. Then, for some $\lambda \in \Lambda$, the $A$-algebra $B$ descends to an $A_\lambda$-algebra $B_\lambda$ of finite type, and $M$ descends to a finitely presented $B_\lambda$-module $M_\lambda$. For every $\mu \geq \lambda$ we set $B_\mu := A_\mu \otimes_{A_\lambda} B_\lambda$ and $M_\mu := B_\mu \otimes_{B_\lambda} M_\lambda$. Up to replacing $A$ by a cofinal family, we can assume that $B_\mu$ and $M_\mu$ are defined for every $\mu \in \Lambda$. Then, for every $\lambda \in \Lambda$ let $g_\lambda : B_\lambda \to B$ be the natural map, and set $\mathfrak{p}_\lambda := g_\lambda^{-1}\mathfrak{p}$.

Claim 7.11.36. There exists $\lambda \in \Lambda$ such that $M_{\lambda,\mathfrak{p}_\lambda}/IM_{\lambda,\mathfrak{p}_\lambda}$ is a flat $A'_\lambda$-module.

Proof of the claim. Set $B'_\lambda := B_\lambda \otimes_{A_\lambda} A'_\lambda$ and $M'_\lambda := M_\lambda \otimes_{A_\lambda} A'_\lambda$ for every $\lambda \in \Lambda$; clearly the natural maps

$$\colim_{\lambda \in \Lambda} A'_\lambda \to A/I A \quad \colim_{\lambda \in \Lambda} B'_\lambda \to B/IB \quad \colim_{\lambda \in \Lambda} M'_\lambda \to M/IM$$

are isomorphisms. Then the claim follows from (b) and [50, Ch.IV, Cor.11.2.6.1(i)].

In view of claim [7.11.36], we can replace \( \Lambda \) by a cofinal subset, and thereby assume that \( M_{\lambda,p,\lambda}/I_M M_{\lambda,p,\lambda} \) is a flat \( \lambda \)-module for every \( \lambda \in \Lambda \).

\textbf{Claim 7.11.37.} (i) More generally, let \( R_* := (R_\lambda : \lambda \in \Lambda) \) be any system of rings indexed by any filtered set \( \Lambda \), and let \( N_* := (N_\lambda : \lambda \in \Lambda) \) be any system of \( R_\lambda \)-modules for every \( \lambda \in \Lambda \), and \( R_\lambda \)-linear transition maps \( N_\lambda \rightarrow N_\mu \) for every \( \lambda, \mu \in \Lambda \) with \( \lambda \leq \mu \). Denote by \( R, N, N' \) the colimits of \( R_*, N_* \) respectively \( N'_* \); then the natural maps \( R_\lambda \rightarrow R, N_\lambda \rightarrow N, N'_\lambda \rightarrow N' \) induce isomorphisms:

\[
\colim_{\lambda \in \Lambda} \Tor^R_{\lambda}(N_\lambda, N'_\lambda) \rightarrow \Tor^R(N, N') \quad \text{for every } i \in \mathbb{N}.
\]

(ii) For every \( \lambda, \mu \in \Lambda \) with \( \mu \geq \lambda \), the natural map:

\[
f_{\lambda,\mu} : B_{\mu,\mu} \otimes_{R_\lambda} \Tor^A_{\lambda}(M_{\lambda,p,\lambda}, A'_\lambda) \rightarrow \Tor^A_{\mu}(M_{\mu,p,\mu}, A'_\mu)
\]

is surjective.

\textbf{Proof of the claim.} (i): For every \( \lambda \in \Lambda \), let \( L_\lambda(N'_\lambda) \) be the canonical free resolution of the \( R_\lambda \)-module \( N'_\lambda \) ([31, Ch.X, §3, n.3]). Similarly, denote by \( L_\lambda(N^*) \) the canonical free resolution of the \( R \)-module \( N^* \). It follows from [32, Ch.II, §6, n.6, Cor.] and the exactness properties of filtered colimits, that the natural map: \( \colim_{\lambda \in \Lambda} L_\lambda(N'_\lambda) \rightarrow L_* (N') \) is an isomorphism. Hence:

\[
\colim_{\lambda \in \Lambda} H_\bullet(N_\lambda \otimes_{R_\lambda} N'_\lambda) \simeq \colim_{\lambda \in \Lambda} H_\bullet(N_\lambda \otimes_R L_\lambda(N'_\lambda))
\]

\[
\simeq H_\bullet(N \otimes_R \colim_{\lambda \in \Lambda} L_\lambda(N'_\lambda))
\]

\[
\simeq H_\bullet(N \otimes_R L_\bullet(N'))
\]

\[
\simeq H_\bullet(L^L(N \otimes_R N')).
\]

(ii): We use the change of ring spectral sequences for \( \Tor \) ([125, Th.5.6.6])

\[
E^2_{pq} : \Tor^A_{p+q}(M_{\lambda,p,\lambda}, A'_\mu) \Rightarrow \Tor^A_p(M_{\lambda,p,\lambda}, A'_\mu)
\]

\[
E^2_{pq} : \Tor^A_{p+q}(M_{\lambda,p,\lambda}, A'_\mu) \Rightarrow \Tor^A_p(M_{\lambda,p,\lambda}, A'_\mu).
\]

Since \( F^2_{10} = F^2_{20} = 0 \), the natural map

\[
\alpha : F^2_{01} := A'_\mu \otimes_{A'_\lambda} \Tor^A_{\lambda}(M_{\lambda,p,\lambda}, A'_\lambda) \rightarrow \Tor^A_{\lambda}(M_{\lambda,p,\lambda}, A'_\lambda)
\]

is an isomorphism. On the other hand, we have a surjection:

\[
\beta : \Tor^A_{\lambda}(M_{\lambda,p,\lambda}, A'_\lambda) \rightarrow E^2_{10} := \Tor^A_{\lambda}(M_{\mu,p,\lambda}, A'_\lambda)
\]

and \( f_{\lambda,\mu} = (\beta \circ \alpha)_{\mu,\lambda} \), whence the claim.

We deduce from claim [7.11.37(i)] that the natural map

\[
\colim_{\lambda \in \Lambda} \Tor^A_{\lambda}(M_{\lambda,p,\lambda}, A'_\lambda) \rightarrow \Tor^A_{\lambda}(M_{\mu,p,\lambda}, A'_\lambda) = 0
\]

is an isomorphism. However, \( \Tor^A_{\lambda}(M_{\lambda,p,\lambda}, A'_\lambda) \) is a finitely generated \( B_{\lambda,p,\lambda} \)-module by [31, Ch.X, §6, n.4, Cor.]. We deduce that \( f_{\lambda,\mu,\lambda} = 0 \) for some \( \mu \geq \lambda \); therefore \( \Tor^A_{\lambda}(M_{\mu,p,\lambda}, A'_\lambda) = 0 \), in view of claim [7.11.37(ii)], and then the local flatness criterion of [46, Ch.0, §10.2.2] says that \( M_{\mu,p,\mu} \) is a flat \( A_\mu \)-module, so finally \( M_\mu \) is a flat \( A \)-module, as stated.

\[ \square \]

\section{Complements of topology and topological algebra}

This chapter is a miscellanea of results of topology and topological algebra that shall be needed in the rest of the treatise.
8.1. **Spectral spaces and constructible subsets.** The class of spectral topological spaces was first introduced in Hochster’s paper [73], where it was shown to coincide precisely with the class of those spaces that are homeomorphic to (Zariski) spectra of commutative rings. Since then, spectral spaces have reappeared in a variety of unrelated contexts; their ubiquity has all to do with the very agreeable properties of their boolean algebras of constructible subsets; especially, the constructible subsets of a spectral space generate a quasi-compact and separated topology. The many corollaries springing from this basic observation add up to a handy toolkit for dealing in a uniform way with the kind of non-separated spaces that most frequently occur in geometric applications of an algebraic bent.

In this section we introduce spectral spaces and prove their basic properties. We also collect a few results showing the interplay between algebraic and topological properties of schemes and their constructible subsets.

**Definition 8.1.1.** Let $X$ be a topological space.

(i) We say that $X$ is **quasi-separated** if the intersection of any two quasi-compact open subsets of $X$ is still quasi-compact.

(ii) We say that $X$ is **coherent** if it is quasi-compact and it admits a basis consisting of quasi-compact open subsets, and closed under finite intersections.

(iii) We say that $X$ is **reducible** if there exist non-empty closed subsets $Z,Z' \subset X$ such that $Z \cup Z' = X$ and $Z,Z' \neq X$. We say that $X$ is **irreducible** if it is non-empty and not reducible.

(iv) We say that $X$ is **sober** if for every irreducible closed subset $Z \subset X$ (with the topology induced from $X$) there exists a unique point $\eta_Z \in Z$ such that $Z$ is the topological closure of $\{\eta_Z\}$ in $X$. In this case, we say that $\eta_Z$ is the **generic point** of $Z$.

(v) We say that $X$ is **spectral** if it is sober and coherent.

(vi) We say that $X$ is **noetherian**, if for every descending chain

$$
\cdots \subset Z_2 \subset Z_1 \subset Z_0
$$

of closed subsets of $X$, there exists $n \in \mathbb{N}$ such that $Z_m = Z_n$ for every $m \geq n$.

(vii) We say that $X$ is **locally coherent** (resp. **locally spectral**, resp. **locally noetherian**) if every point of $X$ admits an open neighborhood which is coherent (resp. spectral, resp. noetherian).

(viii) We say that $X$ is **$T_0$** if, for every pair of points $x,y \in X$, there exists an open subset $U \subset X$ such that $U \cap \{x,y\}$ contains exactly one point.

(ix) We say that $X$ is **compact** if it is quasi-compact and separated.

**Remark 8.1.2.** (i) Let $X$ be a topological space, $(Z_i \mid i \in I)$ a family of irreducible closed subsets of $X$, totally ordered by inclusion, and denote by $Z$ the topological closure in $X$ of $\bigcup_{i \in I} Z_i$. Then $Z$ is also irreducible. Indeed, say that $Z = Y_1 \cup Y_2$ for two closed subsets $Y_1,Y_2$ of $X$. If $Z_i \subset Y_1 \cap Y_2$ for every $i \in I$, then $Z \subset Y_1$; otherwise, say that $Z_i \not\subset Y_1$ for some $i \in I$; then $Z_i \subset Y_2$ for every $i \in I$, whence $Z \subset Z_2$.

(ii) By Zorn’s lemma, it follows that every irreducible closed subset of $X$ is contained in a maximal one. A maximal irreducible closed subset of $X$ is called an **irreducible component** of $X$, and clearly $X$ is the union of its irreducible components.

(iii) Let $Z_1,Z_2 \subset X$ be any two closed subsets, and endow $Z_1,Z_2$ and $Z_3 := Z_1 \cup Z_2$ with the topology induced by $X$. For $j \leq 3$, denote by $I_j$ the set of all irreducible components of $Z_i$; then $I_3 \subset I_1 \cup I_2$. Indeed, let $Y \in I_3$; then $Y = (Y \cap Z_1) \cup (Y \cap Z_2)$, so we must have $Y = Y \cap Z_i$ for some $i \in \{1,2\}$.

(iv) Let $k \in \mathbb{N}$ be any integer, and $Z_* := (Z_i \mid i = 0, \ldots, k)$ a strictly descending finite chain of irreducible closed subsets of $X$. The integer $k$ is the **length** of $Z_*$. The supremum of
the lengths of all such chains is an invariant called the \textit{(Krull) dimension} of $X$, and denoted 
\[ \dim X \]
\( \text{(especially, } \dim \emptyset = -\infty) \). We say that $X$ has \textit{finite Krull dimension} if \( \dim X \in \mathbb{N} \cup \{-\infty\} \).

(v) Suppose that $X$ is the union of finitely many closed subsets $Z_1, \ldots, Z_k$. Then it follows directly from (iii) that \( \dim X = \sup(\dim Z_1, \ldots, \dim Z_k) \).

(vi) If $X$ is sober, then $X$ is also $T_0$. Indeed, let $x, y \in X$ be any two distinct points, and denote by $Z_y$ the topological closure of $\{y\}$ in $X$; if $X$ is sober, we may assume – up to swapping the roles of $x$ and $y$ – that $x \notin Z_y$. In this case, the set $X \setminus Z_y$ is an open neighborhood of $x$ that does not contain $y$, whence the claim.

\begin{lemma}
Let $X$ be a topological space, $T \subset X$ any subset, $T$ the topological closure of $T$ in $X$, and endow $T$ and $\overline{T}$ with the topologies induced from $X$. The following holds:

(i) $T$ is irreducible if and only if the same holds for $\overline{T}$.
(ii) If $T$ is non-empty and open in $X$, and $X$ is irreducible, then $T$ is irreducible.
(iii) If $X$ is sober, and $T$ is locally closed in $X$, then $T$ is sober as well.
(iv) Suppose that $T = T_1 \cup T_2$ for two subsets $T_1$ and $T_2$, and endow also $T_1$ and $T_2$ with the topologies induced from $X$. If $T_1$, $T_2$ and $X$ are sober, the same holds for $T$.
(v) Let $f : X \to Y$ be any continuous map, and endow $f(X)$ with the topology induced by $Y$. If $X$ is irreducible, the same holds for $f(X)$.
\end{lemma}

\textbf{Proof.} For any subset $Y \subset X$, let $\overline{Y}$ denote the topological closure of $Y$ in $X$.

(i): Suppose that $T$ is irreducible, and say that $\overline{T} = V \cup V'$ for two closed subsets $V, V'$ of $\overline{T}$; then $T = (T \cap V) \cup (T \cap V')$, so we may assume that $T = T \cap V$, in which case $\overline{T} = V$.

Conversely, suppose that $\overline{T}$ is irreducible, and $T = Z_1 \cup Z_2$ for some closed subsets $Z_1, Z_2$ of $T$; then $\overline{T} = \overline{Z}_1 \cup \overline{Z}_2$, so we may assume that $\overline{T} = \overline{Z}_1$, in which case $T = T \cap \overline{Z}_1 = Z_1$.

(ii): Indeed, say that $T = Z_1 \cup Z_2$ for two non-empty closed subsets of $T$; then $X = \overline{Z}_1 \cup \overline{Z}_2 \cup (X \setminus T)$. By assumption, $X \not\subset X \setminus T$; as $X$ is irreducible, we may then assume that $X = \overline{Z}_1$, whence $T = Z_1$.

(iii): This is clear if $T$ is closed in $X$, so we may assume that $T$ is open in $X$. However, say that $Z \subset T$ is an irreducible closed subset; by (i), the topological closure $\overline{Z}$ of $Z$ in $X$ is irreducible, and clearly its generic point $\overline{\eta}_Z$ lies in $Z$, so $\overline{\eta}_Z$ is the unique point of $Z$ such that the closure of $\{\overline{\eta}_Z\}$ in $T$ equals $\overline{Z}$.

(iv): Let $Z$ be any irreducible closed subset of $T$, and set $Z_i := Z \cap T_i$ for $i = 1, 2$. According to (i), $\overline{Z}$ is irreducible; since $\overline{Z} = \overline{Z}_1 \cup \overline{Z}_2$, we may then assume that $\overline{Z} = \overline{Z}_1$, especially $\overline{Z}_1$ is irreducible, so $Z_1$ is irreducible, by (i). Therefore $Z_1$ admits a generic point $\eta$, since $T_1$ is sober. By construction, the topological closure of $\{\eta\}$ in $T$ equals $T \cap \overline{Z} = Z$, and it remains to see that $\eta$ is the unique point of $Z$ with this property. However, if $\eta'$ is any other such point, then clearly the topological closures in $X$ of both $\{\eta\}$ and $\{\eta'\}$ equal $\overline{Z}$, so $\eta = \eta'$, since $X$ is sober.

(v): Indeed, suppose that $f(X) = Z_1 \cup Z_2$ for two closed subsets $Z_1, Z_2$ of $f(X)$; then $X = f^{-1}(Z_1) \cup f^{-1}(Z_2)$, so we may assume that $X = f^{-1}Z_1$, in which case $f(X) = Z_1$. \hfill \Box

\begin{proposition}
Let $X$ be any topological space. Then $X$ is noetherian if and only if the following conditions hold:

(a) Every closed subset of $X$ has a finite number of irreducible components.

(b) For every descending chain $(Z_n \mid n \in \mathbb{N})$ of irreducible closed subsets of $X$, there exists $N \in \mathbb{N}$ such that $Z_n = Z_N$ for every $n \geq N$.
\end{proposition}

\textbf{Proof.} Suppose first that $X$ is noetherian. Then (b) clearly holds. To show (a), let $S$ denote the set of all closed subsets of $X$ that have infinitely many irreducible components; since $X$ is noetherian, if $S$ is not empty, it admits minimal elements, so say that $Z$ is such a minimal element. Then clearly $Z$ cannot be irreducible, so $Z = Z_1 \cup Z_2$ for some non-empty closed
subsets of \( X \) strictly contained in \( Z \). By minimality of \( Z \), we have \( Z_1, Z_2 \notin S \); but then remark 8.1.2(iii) implies that \( Z_1 \cup Z_2 \notin S \) as well, a contradiction.

For the converse, we show more precisely the following:

**Claim 8.1.5.** Let \( X \) be any topological space, \( Z_\bullet := (Z_n \mid n \in \mathbb{N}) \) a descending non-stationary chain of closed subsets of \( X \), such that \( Z_n \) has a finite number of irreducible components, for every \( n \in \mathbb{N} \). Then there exists a descending, non-stationary chain \((Z'_n \mid n \in \mathbb{N})\) of closed subsets of \( X \), such that \( Z'_n \) is an irreducible component of \( Z_n \), for every \( n \in \mathbb{N} \).

**Proof of the claim.** For every \( n \in \mathbb{N} \), let \( I_n \) be the (finite) set of irreducible components of \( Z_n \), and denote by \( I'_n \subseteq I_n \) the subset of all \( T \in I_n \) such that \( T \in I_m \) for every \( m \geq n \). Notice that, since \( Z_\bullet \) is descending and non-stationary, the subset \( I'_n := I_n \setminus I'_n \) is non-empty, for every \( n \in \mathbb{N} \). Moreover, for every \( n > 0 \), every \( T \in I'_n \) and every \( T' \in I_{n-1} \) such that \( T \subseteq T' \), we must have \( T' \in I'_{n-1} \); indeed, otherwise we would have \( T' \in I_n \), hence \( T = T' \), hence \( T \in I'_n \), a contradiction. Hence, for every \( n \in \mathbb{N} \), denote by \( S_n \) the set of all chains \((T_k \mid k = 0, \ldots, n)\) such that

- \( T_k \in I'_k \) for every \( k = 0, \ldots, n \).
- \( T_k \supseteq T_{k-1} \) for every \( k = 1, \ldots, n \).

The foregoing observations easily imply that \( S_n \) is a finite non-empty set for every \( n \in \mathbb{N} \). Moreover, we have an obvious map \( S_m \to S_n \) whenever \( m \geq n \), that assigns to any \( T_\bullet \in S_m \) the truncated chain \((T_k \mid k = 0, \ldots, n)\). The limit \( S \) of the system \((S_n \mid n \in \mathbb{N})\) is then non-empty; say that \((T^*_k \mid k \in \mathbb{N})\) is any element of \( S \), and set \( Z'_n := T^*_n \) for every \( n \in \mathbb{N} \). We claim that the chain \((Z'_n \mid n \in \mathbb{N})\) will do. Indeed, suppose by way of contradiction, that the chain \( Z'_\bullet \) is stationary, so there exists \( N \in \mathbb{N} \) such that \( Z'_n = Z'_N \) for every \( n \geq N \); but then we would have \( Z_N \subseteq I_n \) for every \( n \geq N \), hence \( Z_N \in I'_N \), which is absurd. \( \Box \)

**Remark 8.1.6.** Let \( X \) be a topological space, \( U \subseteq X \) an open subset, and endow \( U \) with the topology induced from \( X \).

(i) If \( X \) is quasi-separated, then the same holds for \( U \). If \( X \) is coherent, then \( X \) is quasi-separated. Indeed, let \((U_i \mid i \in I)\) be a basis for \( X \) consisting of quasi-compact open subsets and closed under finite intersections, and \( U_1, U_2 \) two quasi-compact open subsets. Then there exist finite subsets \( I_j \subseteq I \) such that \( U_i = \bigcup_{j \in I_j} U_j \) for \( i = 1, 2 \); consequently \( U_1 \cap U_2 = \bigcup_{(j,j') \in I_j \times I_j, U_j \cap U_{j'} \text{ is quasi-compact}} U_j \cap U_{j'} \), and by assumption each \( U_j \cap U_{j'} \) is quasi-compact, whence the claim.

(ii) If \( X \) is coherent (resp. spectral) and \( U \) is quasi-compact, then \( U \) is coherent (resp. spectral) for the topology induced from \( X \). Indeed, lemma 8.1.3(iii) says that \( U \) is sober whenever the same holds for \( X \), and if \((U_i \mid i \in I)\) is a basis of quasi-compact open subsets of \( X \), then \((U \cap U_i \mid i \in I)\) is a basis of quasi-compact open subsets of \( U \).

(iii) It follows easily from (ii) that if \( X \) is locally coherent (resp. locally spectral) then the same holds for \( U \).

(iv) If \( X \) is noetherian, every open subset of \( X \) is quasi-compact, so \( X \) is coherent. Also, every locally closed subset of \( X \) is noetherian as well.

(v) Furthermore, suppose that \( T_1, \ldots, T_k \) is any finite family of subsets of \( X \), such that \( X = \bigcup_{i=1}^{k} T_i \), and endow each \( T_i \) with the topology induced from \( X \); then, if each \( T_i \) is noetherian, the same holds for \( X \).

8.1.7. Let us denote by \( \text{Top} \) the category of topological spaces (whose morphisms are the continuous maps), and by \( \text{Sober} \) the full subcategory of \( \text{Top} \) whose objects are the sober topological spaces.

**Proposition 8.1.8.** The inclusion functor

\[
\text{Sober} \to \text{Top}
\]

admits a left adjoint.
Proof. For any topological space $X$, denote by $S_X$ the set of all irreducible closed subsets of $X$. If $Z$ is any irreducible closed subset of $X$, we shall use the notation $\eta_Z$ to refer to $Z$, when we wish to regard the latter as an element of $S_X$. From lemma 8.1.3(i,ii) we see that, for every open subset $U \subset X$, we have a natural bijection

$$S_U \sim \{\eta_Z \in S_X \mid Z \cap U \neq \emptyset\} \quad T \mapsto \eta_T$$

(where, for any subset $T$ of $X$, we let $\overline{T}$ be the topological closure of $T$ in $X$). We may then identify $S_U$ with its image in $S_X$, and we notice

Claim 8.1.9. (i) $S_U \cap S_V = S_{U \cap V}$ for every open subsets $U, V \subset X$.

(ii) For any family $(U_i \mid i \in I)$ of open subsets of $X$, we have $S_{\bigcup_{i \in I} U_i} = \bigcup_{i \in I} S_{U_i}$.

Proof of the claim. (i) Clearly $S_{U \cap V} \subset S_U \cap S_V$. For the converse inclusion, suppose that $Z$ is closed subset of $X$, such that $Z \cap U, Z \cap V \neq \emptyset$ and $Z \cap U \cap V = \emptyset$. Then $Z = (Z \cap U) \cup (Z \cap V)$, so $Z$ is not irreducible in $X$. The assertion is an immediate consequence.

(ii) is trivial. $\diamond$

From claim 8.1.9 we see that the family $(S_U \mid U$ is open in $X$) is a topology on $S_X$, and we endow $S_X$ with this topology. Next, there is a natural map

$$f_X : X \to S_X \quad x \mapsto \eta_{\{x\}}$$

and it is easily seen that $f_X^{-1}(S_U) = U$ for every open subset $U \subset X$; especially $f_X$ is continuous. It also follows that the rule $Z \mapsto f_X^{-1}Z$ establishes a bijection from the closed subsets of $S_X$ to those of $X$; since this bijection respects inclusion of closed subsets, we deduce that it restricts to a bijection from the irreducible closed subsets of $S_X$ to those of $X$. Moreover, in light of lemma 8.1.3(v), it is easily seen that the inverse of this bijection assigns to any irreducible closed subset $Z$ of $X$, the topological closure of $f_X(Z)$ in $S_X$.

Claim 8.1.10. $S_X$ is a sober topological space.

Proof of the claim. Let $Z$ be any irreducible closed subset of $X$, and denote by $S_Z$ the topological closure of $\{\eta_Z\}$ in $S_X$; then $S_Z = S_X \setminus S_U$, where $S_U$ is the largest open subset of $S_X$ that does not contain $\eta_Z$, i.e. $U$ is the largest open subset of $X$ that does not intersect $Z$. So $U = X \setminus Z$, and therefore $f_X^{-1}(S_Z) = Z$. We conclude that the topological closure of $f_X(Z)$ in $S_X$ equals $S_Z$. Summing up, we see that the rule $\eta_Z \mapsto S_Z$ establishes a bijection from $S_X$ to the set of irreducible closed subsets of $S_X$, whence the claim.

Now, let $Y$ be any sober space, and $g : X \to Y$ any continuous map; in light of claim 8.1.10, it suffices to show that there exists a unique continuous map $h : S_X \to Y$ such that $g = h \circ f_X$. However, it is easily seen that any continuous map $h$ with this property must assign to every $\eta_Z \in S_X$ the generic point $\eta_{g(Z)}$ of the topological closure of $g(Z)$ in $S$ (lemma 8.1.3(v)); conversely, one checks easily that the rule

$$\eta_Z \mapsto \eta_{g(Z)}$$

defines a map $h : S_X \to Y$ such that $h^{-1}U = S_{g^{-1}U}$ for every open subset $U \subset Y$; especially, $h$ is continuous : the details shall be left to the reader. $\square$

Remark 8.1.11. Keep the notation of the proof of proposition 8.1.8 and let $U \subset X$ be any open subset; it is easily seen that $U = \emptyset$ if and only if $S_U = \emptyset$. It follows that the rule $V \mapsto f_X^{-1}V$ defines a bijection from the set of open subsets of $S_X$ to the set of open subsets of $X$. Consequently, $X$ is quasi-compact (resp. quasi-separated) if and only if the same holds for $S_X$, and $X$ is coherent if and only if $S_X$ is spectral.
Let $X_\bullet := (X_i \mid i \in \text{Ob}(I))$ be a system of sober and quasi-compact topological spaces, indexed by a category $I$, with continuous transition maps $p_u : X_i \to X_j$ for every morphism $u : i \to j$ in $I$, and set

$$X := \lim_{\text{in} I} X_i$$

where the limit is taken in the category of topological spaces. For every $i \in \text{Ob}(I)$, denote by $p_i : X \to X_i$ the induced projection, and recall that the system of all subsets of the form $
bigcap_{j \in J} p_i^{-1} U_j$, where $J$ ranges over all finite subsets of $\text{Ob}(I)$, and $U_j$ ranges over all open subsets of $X_j$, is a basis of the topology of $X$.

**Proposition 8.1.13.** In the situation of (8.1.12), the following holds:

(i) $X$ is a sober topological space.

(ii) Suppose furthermore, that the system $X_\bullet$ is cofiltered. We have:

(a) If $X_i \not= \emptyset$ for every $i \in \text{Ob}(I)$, then $X$ is quasi-compact and non-empty.

(b) If $p_u$ is quasi-compact for every morphism $u$ of $I$, then $p_i$ is quasi-compact, for every $i \in \text{Ob}(I)$.

**Proof.** (i) follows immediately from corollary 1.3.26(i,ii) and proposition 8.1.8.

(ii.a): By virtue of proposition 1.5.20, we may assume that $I$ is a partially ordered set, and to ease notation, for every $u : i \to j$ in $I$ (i.e. for every $i, j \in I$ such that $i \leq j$), we set $p_{ij} := p_u$.

Now, consider the family $\mathcal{F}$ consisting of all compatible systems $Z_\bullet := (Z_i \mid i \in I)$, where:

- $Z_i$ is a non-empty closed subset of $X_i$, for every $i \in I$.
- $p_{ij}(Z_i) \subseteq Z_j$ for every $i, j \in I$ with $i \leq j$.

and endow $\mathcal{F}$ with a partial ordering, by declaring that, for any $Z_\bullet, Z_\bullet' \in \mathcal{F}$, we have $Z_\bullet \leq Z_\bullet'$ if and only if $Z_i \subseteq Z_i'$ for every $i \in I$. Suppose now that $(Z_\lambda \mid \lambda \in \Lambda)$ is a totally ordered subset of $\mathcal{F}$, and set $C_i := \bigcap_{\lambda \in \Lambda} Z_\lambda^i$ for every $i \in I$.

**Claim 8.1.14.** The resulting system $C_\bullet$ lies in $\mathcal{F}$.

**Proof of the claim.** Indeed, the assertion comes down to saying that $C_i \not= \emptyset$ for every $i \in I$. But notice that, for every finite subset $\Lambda' \subseteq \Lambda$ and every $i \in I$, the intersection $\bigcap_{\lambda \in \Lambda'} Z_\lambda^i$ is obviously closed and non-empty in $X_i$. Since $X_i$ is quasi-compact for every $i \in I$, the claim follows.

Since $(X_i \mid i \in I) \in \mathcal{F}$, we have $\mathcal{F} \neq \emptyset$. From claim 8.1.14 and Zorn’s lemma, we deduce that $\mathcal{F}$ admits minimal elements. We notice:

**Claim 8.1.15.** Let $Z_\bullet$ be a minimal element of $\mathcal{F}$. We have:

(i) $Z_i$ is irreducible in $X_i$, for every $i \in I$.

(ii) $p_{ij}(Z_i)$ is dense in $Z_j$, for every $i, j \in I$ with $i \leq j$.

**Proof of the claim.** (i): Suppose, by way of contradiction, that there exist $i \in I$ and closed non-empty proper subsets $Z_1^{(1)}, Z_2^{(2)}$ of $Z_i$, such that $Z_i = Z_1^{(1)} \cup Z_2^{(2)}$. For $t = 1, 2$, we consider the compatible system $Z_\bullet^{(t)}$ such that

$$Z_j^{(t)} := \begin{cases} Z_j \cap p_{ji}^{-1} Z_i^{(t)} & \text{if } j \leq i \\ Z_j & \text{otherwise.} \end{cases}$$

By the minimality of $Z_\bullet$, neither $Z_1^{(1)}$ nor $Z_2^{(2)}$ lies in $\mathcal{F}$, hence there must exist $j, k \in I$ such that $Z_j^{(1)} = Z_k^{(2)} = \emptyset$. Since $I$ is cofiltered, we may then assume that $j = k$, in which case $Z_k = Z_k \cap p_{ki}^{-1} Z_i = Z_k^{(1)} \cup Z_k^{(2)} = \emptyset$, which is absurd.
(ii): Fix any \(i, j \in I\) with \(i \leq j\), and denote by \(T\) the topological closure of \(p_{ij}(Z_i)\) in \(Z_j\). We consider the compatible system \(T_\bullet\) such that
\[
T_k := \begin{cases} 
p^{-1}_{kj}T & \text{if } k \leq j \\
Z_k & \text{otherwise.}
\end{cases}
\]
Notice that \(T_k = Z_k\) for every \(k \leq i\); especially \(T_k \neq \emptyset\) for every \(k \in I\), and therefore \(T_\bullet \in \mathcal{F}\).

By the minimality of \(Z_\bullet\), we must have \(T_\bullet = Z_\bullet\), and therefore \(T = Z_j\), as stated. \(\diamondsuit\)

Let now \(Z_\bullet\) be any minimal element of \(\mathcal{F}\); according to claim 8.1.15 every \(Z_i\) is irreducible, say with generic point \(\eta_i\), and \(p_{ij}\) maps \(\eta_i\) to \(\eta_j\), whenever \(i, j \in I\) with \(i \leq j\). The compatible system of points \((\eta_i \mid i \in I)\) is then a point of \(X\), so the latter is not empty.

Next, notice that every open covering of \(X\) can be refined to a covering of the form:
\[
(8.1.16) \quad X = \bigcup_{i \in I} p^{-1}_{i}U_i \quad \text{for a family of open subsets } U_i \subseteq X_i
\]

hence, in order to prove that \(X\) is quasi-compact, it suffices to check that, for a covering as \((8.1.16)\), there exists a finite subset \(J \subseteq I\) such that the family \((p^{-1}_{j}U_j \mid j \in J)\) already covers \(X\). To this aim, set
\[
Z_i := X_i \setminus U_i \quad \text{and} \quad Z_i' := \bigcap_{j \geq i} p^{-1}_{ij}Z_j \quad \text{for every } i \in I.
\]

Notice that \((8.1.16)\) means that \(\bigcap_{i \in I} p^{-1}_{i}Z_i = \emptyset\), and \(a\ f\ o\ r\ t\ i\ o\ r\ y\ \text{we have}
\[
(8.1.17) \quad \bigcap_{i \in I} p^{-1}_{i}Z_i' = \emptyset
\]
as well. However, by construction we have \(p_{ij}(Z'_i) \subseteq Z'_j\) for every \(i, j \in I\) with \(i \leq j\), so \((Z'_i \mid i \in I)\) is a cofiltered system of sober and quasi-compact topological spaces (lemma 8.1.3 (iii)), and \((8.1.17)\) shows that the limit of this system is the empty topological space; in light of the foregoing, we conclude that there exists \(i \in I\) such that \(Z'_i = \emptyset\). Since \(X_i\) is quasi-compact, this in turns means that there exists a finite subset \(J \subseteq \{j \in I \mid j \geq i\}\) such that \(\bigcap_{j \in J} p^{-1}_{ij}Z_j = \emptyset\). Lastly, this means precisely that the family \((p^{-1}_{j}U_j \mid j \in J)\) covers \(X\).

(ii.b): Fix \(i_0 \in I\), and let \(U_{i_0}\) be any quasi-compact open subset of \(X_{i_0}\); the subset \(I_0 := \{j \in I \mid j \leq i_0\}\) is cofinal in \(I\), so we may replace \(I\) by \(I_0\) and assume that \(i_0\) is the largest element of \(I\). In this case, for every \(j \leq i_0\) we may set \(U_j := p^{-1}_{i_0j}U_{i_0}\) and \((U_i \mid i \in I)\) is a cofiltered system of quasi-compact and sober topological spaces (lemma 8.1.3 (iii)), hence its limit \(U\) is quasi-compact (and sober), by (i) and (ii.a); on the other hand, the induced map \(U \to X\) is an open immersion, whence the contention. \(\square\)

**Remark 8.1.18.** (i) Proposition 8.1.13 fails in general for non-cofiltered systems of quasi-compact and sober spaces. For instance, a fibre product of such spaces shall not be quasi-compact, in general.

(ii) It is clear that the topological space underlying every affine scheme is spectral, and that of any scheme is locally spectral. Conversely, it is shown in [73] that to every spectral space \(X\) one can attach naturally a commutative ring \(A_X\) whose spectrum is isomorphic to \(X\). This rule \(X \mapsto A_X\) is functorial with respect to continuous maps of a certain type, which are introduced in the next definition.

**Definition 8.1.19.** Let \(f : X \to Y\) be a continuous map of topological spaces, \(T \subseteq X\) any subset, and endow \(T\) with the topology induced from \(X\).

(i) We say that \(f\) is **quasi-compact** (resp. **quasi-separated**) if, for every quasi-compact (resp. quasi-separated) open subset \(U \subseteq X\), the preimage \(f^{-1}U\) is quasi-compact (resp. quasi-separated).
(ii) We say that $f$ is **spectral** if, for every pair of quasi-compact quasi-separated open subsets $U \subset X, V \subset Y$ with $f(U) \subset V$, the restriction $f|_U : U \to V$ is quasi-compact.

(iii) We say that $T$ is **retro-compact in $X$** if the inclusion map $T \to X$ is quasi-compact.

(iv) We say that $T$ is **globally constructible** if $T$ lies in the boolean algebra of subsets of $X$ generated by all retro-compact open subsets of $X$.

(v) We say that $T$ is **constructible** if every point of $X$ admits an open neighborhood $U$ such that $T \cap U$ is globally constructible in $U$.

(vi) We say that $T$ is **pro-constructible** (resp. **ind-constructible**) if every point of $X$ admits an open neighborhood $U$ such that $T \cap U$ is the intersection (resp. the union) of constructible subsets of $U$.

**Remark 8.1.20.** Let $f : X \to Y$ and $g : Y \to Z$ be two continuous maps of topological spaces.

(i) If $f$ and $g$ are quasi-compact (resp. quasi-separated), then the same holds for $g \circ f$.

(ii) If $f$ and $g$ are spectral, and both $X$ and $Y$ are locally coherent, then $g \circ f$ is spectral. Indeed, say that $U \subset X$ and $V \subset Z$ are quasi-compact and quasi-separated open subsets such that $g \circ f(U) \subset V$; for every $x \in U$ we may find a quasi-compact and quasi-separated open subset $W_x \subset Y$ such that $g(W_x) \subset V$ and $f(x) \in W_x$. Since $X$ is locally coherent, we may find a quasi-compact and quasi-separated open neighborhood $U_x$ of $x$ in $X$, such that $f(U_x) \subset W_x$. Then both $f|_{U_x} : U_x \to W_x$ and $g|_{W_x} : W_x \to V$ are quasi-compact, so (i) says that the same holds for their composition $(g \circ f)|_{U_x} : U_x \to V$. However, finitely many such $U_x$ suffice to cover $U$, whence the assertion.

(iii) Let us say that $f$ is **strongly spectral** if the following holds. For every quasi-compact inclusion map $U \to U'$ between open subsets of $Y$, the induced open immersion $f^{-1}U \to f^{-1}U'$ is also quasi-compact. We claim that if $f$ is strongly spectral, then $f$ is spectral. Indeed, let $U \subset X, V \subset Y$ be two quasi-compact and quasi-separated open subsets, and $V' \subset V$ another quasi-compact open subset; by assumption, the induced inclusion map $i : f^{-1}V' \to f^{-1}V$ is quasi-compact, so $f^{-1}_i V' = i^{-1}U$ is quasi-compact, whence the claim.

(iv) Obviously, a composition of strongly spectral maps is strongly spectral. Moreover, it is easily seen that any open immersion $i : U \to X$ is strongly spectral. In view of (iii), it follows that every open immersion is spectral.

**Lemma 8.1.21.** Let $X$ be any topological space. We have:

(i) $X$ is quasi-separated if and only if it admits a covering consisting of retro-compact open quasi-separated subsets.

(ii) $X$ is sober if and only if it admits a covering consisting of sober open subsets.

(iii) The following conditions are equivalent:
   
   (a) $X$ is locally coherent and quasi-separated.
   
   (b) $X$ admits a basis consisting of quasi-compact open subsets, which is closed under finite intersections.

(iv) The following conditions are equivalent:
   
   (a) $X$ is coherent (resp. spectral).
   
   (b) $X$ is quasi-compact and admits a covering consisting of coherent (resp. spectral) retro-compact open subsets.
   
   (c) $X$ is quasi-compact, quasi-separated and locally coherent (resp. locally spectral).

(v) $X$ is noetherian if and only if it is locally noetherian and quasi-compact.

(vi) If $X$ is locally noetherian, then $X$ is locally coherent and quasi-separated.

**Proof.** (i): The condition is trivially necessary. Suppose then that $(U_i \mid i \in I)$ is a covering of $X$ such that $U_i$ is quasi-separated, retro-compact and open in $X$ for every $i \in I$; pick any two quasi-compact open subsets $U, U'$. We may find a finite subset $J \subset I$ such that $U \cup U' \subset \bigcup_{j \in J} U_j$,
and our assumptions imply that, for every \( j \in J \), the subset \( V_j := U \cap U' \cap U_j \) is quasi-compact, so the same holds for \( \bigcup_{j \in J} V_j = U \cap U' \).

(ii): Again, necessity is trivial. For the converse, let \( (U_i \mid i \in I) \) be an open covering of \( X \) such that \( U_i \) is sober for every \( i \in I \). Say that \( Z \subset X \) is any irreducible closed subset, and that \( Z_i := U_i \cap Z \neq \emptyset \) for some \( i \in I \); then \( Z_i \) is an irreducible subset of \( U_i \) and the topological closure of \( Z_i \) in \( X \) equals \( Z \) (lemma \([8.1.3](#8.1.3)\)). Let \( \eta \) be the generic point of \( Z_i \); then clearly the topological closure of \( \{ \eta \} \) in \( X \) equals \( Z \). It remains to check that \( \eta \) is the unique element of \( Z \) with this property. However, say that \( \eta' \) is another such element; then it is easily seen that \( \eta' \in U_i \) as well, and \( \eta' \) is then also the generic point of \( Z_i \), whence the contention.

(iii): It is easily seen that (b)\( \Rightarrow \)(a). Conversely, suppose that (a) holds, and choose a covering \( (U_i \mid i \in I) \) of \( X \) consisting of coherent open subsets; for each \( i \in I \) we then have a basis \( (U_{ij} \mid j \in J_i) \) of the topology of \( U_i \), consisting of quasi-compact open subsets. Set \( F := \bigcup_i \bigcup_j (U_{ij} \mid i \in I, j \in J_i) \), and let \( F' \) be the family of all finite non-empty intersections of elements of \( F \); then \( F' \) is a basis of the topology of \( X \), and since \( X \) is quasi-separated, any element of \( F' \) is still a quasi-compact open subset of \( X \), whence (b).

(iv): Obviously (a)\( \Rightarrow \)(b), and (b)\( \Rightarrow \)(c) by virtue of (i) and remark \([8.1.6](#8.1.6)\). Lastly, (c)\( \Rightarrow \)(a), by (iii) and (ii).

(v): Suppose that \( X \) is locally noetherian and quasi-compact, in which case it admits a finite covering \( (U_i \mid i \in I) \) of \( X \) consisting of open noetherian subsets. Now, let \( Z_* := (Z_n \mid n \in \mathbb{N}) \) be a descending chain of closed subsets of \( X \); by assumption, every resulting chain \( (Z_n \cap U_i \mid n \in \mathbb{N}) \) is stationary, and since \( I \) is finite, it follows that \( Z_* \) is stationary as well.

(vi): \( X \) is locally coherent, by virtue of remark \([8.1.6](#8.1.6)\); next, if \( U, V \subset X \) are quasi-compact open subsets, then they are noetherian, by (v), so their intersection is quasi-compact. \qed

**Proposition 8.1.22.** Let \( f : X \to Y \) be a continuous map of topological spaces, \( (Y_i \mid i \in I) \) an open covering of \( Y \), and \( f_i : f^{-1}Y_i \to Y_i \) the restriction of \( f \), for every \( i \in I \). We have:

(i) If \( Y \) is locally coherent, then \( f \) is quasi-compact if and only if \( f_i \) is quasi-compact for every \( i \in I \).

(ii) If both \( X \) and \( Y \) are locally coherent, then \( f \) is quasi-separated and spectral if and only if \( f_i \) is quasi-separated and spectral for every \( i \in I \).

(iii) Suppose that both \( X \) and \( Y \) are locally coherent, and let \( (X_i \mid i \in I) \) be an open covering of \( X \) such that \( X_i \subset f^{-1}Y_i \) for every \( i \in I \). Then \( f \) is spectral if and only if the restriction \( f_i : X_i \to Y_i \) of \( f \) is spectral for every \( i \in I \).

**Proof.** (i): Clearly, if \( f \) is quasi-compact, the same holds for every \( f_i \). Hence we may assume that \( f_i \) is quasi-compact for every \( i \in I \), and we have to check that \( f \) is quasi-compact. To this aim, let \( U \subset Y \) be any quasi-compact open subset, and set \( U_i := Y_i \cap U \) for every \( i \in I \); since \( Y \) is locally coherent, we may find, for every \( i \in I \), a covering \( (U_{i, \lambda} \mid \lambda \in \Lambda_i) \) of \( U_i \) consisting of quasi-compact open subsets. Since \( U \) is quasi-compact, finitely many of these \( U_{i, \lambda} \) suffice to cover \( U \), hence \( f^{-1}U \) is covered by finitely many subsets of the type \( f_i^{-1}U_{i, \lambda} \), and the latter are quasi-compact by assumption, so the same holds for \( U \).

(iii): To begin with, we remark

**Claim 8.1.23.** Suppose that both \( X \) and \( Y \) are locally coherent. Then \( f \) is spectral if and only if it is strongly spectral (see remark \([8.1.20](#8.1.20)\)(iii)).

**Proof of the claim.** In view of remark \([8.1.20](#8.1.20)\)(iii), we may assume that \( f \) is spectral, and we show that \( f \) is strongly spectral. Indeed, let \( U \subset U' \) be any inclusion of open subset of \( Y \), with \( U \) retro-compact in \( U' \). We need to check that \( f^{-1}U \) is retro-compact in \( f^{-1}U' \), and by (i), the assertion can be checked locally on \( f^{-1}U' \). However, since \( X \) and \( Y \) are locally coherent, for every \( x \in f^{-1}U' \) we may find quasi-compact and quasi-separated open neighborhoods \( V' \) of \( x \) in \( f^{-1}U' \) and \( W' \) of \( f(x) \) in \( U' \) such that \( f(V') \subset W' \). By assumption, \( W' \cap U \) is quasi-compact,
so the same holds for \( V := V' \cap f^{-1}U \) (because \( f \) is spectral); since \( V' \) is quasi-separated, the inclusion map \( V \to V' \) is then quasi-compact, as required. \( \diamond \)

Now, in light of claim [8.1.23] for the proof of (iii) we may assume that each restriction \( X_i \to Y_i \) is strongly spectral, and it suffices to check that the same holds for \( f \). However, let \( U_1 \subset U_2 \) be any quasi-separated open subset, and show that the inclusion \( f^{-1}U_1 \to f^{-1}U_2 \) is quasi-compact, as required.

(ii): Again, we may assume that each restriction \( X_i \to Y_i \) is quasi-separated and spectral for every \( i \in I \); since \( U \) is quasi-separated, \( U_{i,\lambda} \) is quasi-compact in \( U \) for every \( i \in I \) and every \( \lambda \in \Lambda_i \), hence \( f^{-1}U_{i,\lambda} \) is quasi-compact in \( f^{-1}U \), by claim [8.1.23] in light of claim [8.1.18](ii) : with the terminology of definition [8.1.19](ii), we may now say that the continuous map \( \text{Spec} \varphi : \text{Spec} B \to \text{Spec} A \) attached to any ring homomorphism \( \varphi : A \to B \) is spectral (verification left to the reader). In light of proposition [8.1.22](iii) it follows that the continuous map underlying any morphism of schemes \( f : X \to Y \) is spectral as well. Moreover, let \((Y_i \mid i \in I)\) be any covering of \( Y \) consisting of open subschemes; proposition [8.1.22](i,ii) implies that \( f \) is quasi-compact (resp. quasi-separated) if and only the same holds for each restriction \( f|_{Y_i} : f^{-1}Y_i \to Y_i \).

Example 8.1.24. We return briefly to remark [8.1.18](ii) : with the terminology of definition [8.1.19](ii), we may now say that the continuous map \( \text{Spec} \varphi : \text{Spec} B \to \text{Spec} A \) attached to any ring homomorphism \( \varphi : A \to B \) is spectral (verification left to the reader). In light of proposition [8.1.22](iii) it follows that the continuous map underlying any morphism of schemes \( f : X \to Y \) is spectral as well. Moreover, let \((Y_i \mid i \in I)\) be any covering of \( Y \) consisting of open subschemes; proposition [8.1.22](i,ii) implies that \( f \) is quasi-compact (resp. quasi-separated) if and only the same holds for each restriction \( f|_{Y_i} : f^{-1}Y_i \to Y_i \).

Lemma 8.1.25. Let \( X \) be a topological space, \( U \subset X \) an open subset, \( T \subset X \) any subset, and endow \( U \) and \( T \) with the topology induced from \( X \). The following holds:

(i) Every closed subset of \( X \) is retro-compact. The union of any finite number of retro-compact subsets of \( X \) is still retro-compact. The intersection of any open retro-compact subset of \( X \) with an arbitrary retro-compact subset of \( X \) is retro-compact.

(ii) Every globally constructible subset of \( X \) is retro-compact, and it is a finite union of subsets of the form \( V \setminus V' \), where \( V \) and \( V' \) are retro-compact open subsets of \( X \).

(iii) Suppose that \( T \) is retro-compact, and let \( S \subset T \) be any subset. If \( S \) is retro-compact in \( T \), then it is retro-compact in \( X \) as well. If \( T \) is also open and \( S \) is globally constructible in \( T \), then \( S \) is globally constructible in \( X \) as well.

(iv) \( T \) is pro-constructible if and only if \( X \setminus T \) is ind-constructible.

(v) If \( T \) is retro-compact (resp. globally constructible, resp. pro-constructible, resp. ind-constructible) in \( X \), then \( T \cap U \) is retro-compact (resp. globally constructible, resp. constructible, resp. pro-constructible, resp. ind-constructible) in \( U \).

(vi) The constructible subsets of \( X \) form a boolean algebra.

(vii) If \( X \) is quasi-separated and \( U \) is quasi-compact, then \( U \) is retro-compact in \( X \).

(viii) Suppose that \( X \) is quasi-compact; then we have:

(a) If \( T \) is retro-compact in \( X \), then \( T \) is quasi-compact.

(b) Every globally constructible subset of \( X \) is quasi-compact.

(ix) Suppose that \( X \) is quasi-compact and quasi-separated; then we have:

(a) \( U \) is retro-compact in \( X \) if and only if it is quasi-compact.
(b) The globally constructible subsets of $X$ are precisely the finite unions of subsets of the form $V \setminus V'$, where $V$ and $V'$ are arbitrary quasi-compact open subsets of $X$.

(x) Suppose that $X$ is coherent; then we have:

(a) $T$ is constructible in $X$ if and only if it is globally constructible in $X$ (in which case $T$ is also retro-compact, by (ii)).
(b) $T$ is pro-constructible (resp. ind-constructible) if and only if it is the intersection (resp. the union) of a family of constructible subsets of $X$.
(c) The constructible open (resp. closed) subsets of $X$ are precisely the quasi-compact open subsets (resp. the complements of quasi-compact open subsets) of $X$.
(d) If $T$ is retro-compact in $X$ and $S$ is any constructible (resp. pro-constructible, resp. ind-constructible) subset of $X$, then $T \cap S$ is constructible (resp. pro-constructible, resp. ind-constructible) in $T$.
(e) If $T$ is retro-compact in $X$, then it is a coherent topological space, and the inclusion map $i_T : T \to X$ is quasi-separated.
(f) If $T$ is constructible in $X$, and $S$ is any constructible subset of $T$, then $S$ is constructible in $X$.

(xi) If $X$ is spectral and $T$ is constructible in $X$, then $T$ is spectral as well.

Proof. (i) shall be left to the reader, and (ii) follows easily from (i).

(iii): The first assertion is obvious, and the second follows from (ii) and the first assertion.

(v): The proof for the case where $T$ is retro-compact or globally constructible is left to the reader. Suppose that $T$ is constructible in $X$; then, for any given point $x \in U$, we may find an open neighborhood $U'$ of $x$ in $X$, such that $T \cap U'$ is globally constructible in $U'$; then by the foregoing case, we know that $U' \cap U$ is an open neighborhood of $x$ in $U$ such that $T \cap U' \cap U$ is globally constructible in $U' \cap U$, so $T \cap U$ is constructible in $U$. The assertion for the case where $T$ is pro-constructible or ind-constructible, is an immediate consequence.

(vi): It is easily seen that the complement of a constructible subset is constructible. Next, suppose that $T$ and $T'$ are two constructible subsets of $X$, and $x \in X$ is any point; then we may find open neighborhoods $U$ and $U'$ of $x$ such that $T \cap U$ (resp. $T' \cap U'$) is globally constructible in $U$ (resp. in $U'$). By (v), it follows that $T \cap U \cap U'$ and $T \cap U \cap U'$ are globally constructible in $U \cap U'$, and therefore the same holds for both $(T \cap T') \cap U \cap U'$ and $(T \cup T') \cap U \cap U'$. We conclude that both $T \cap T'$ and $T \cup T'$ are constructible, whence the assertion.

(iv) follows easily from from (vi).

(vii) and (viii.a) are obvious, and (viii.b) follows from (viii.a) and (ii).

(ix.a) follows from (vii) and (viii.a), and (ix.b) follows from (ix.a) and (ii).

(x.a): Indeed, by assumption we may find for every $x \in X$ an open neighborhood $U_x$ of $x$ in $X$ such that $T \cap U_x$ is globally constructible in $U_x$; by (v) we may then assume that $U_x$ is quasi-compact, so $U_x$ is retro-compact, by (ix.a) and remark 8.1.6(i), and consequently $T \cap U_x$ is globally constructible in $X$, by (iii). Finitely many of such $U_x$ suffice to cover $X$, whence the assertion.

(x.b): Indeed, say that $T$ is ind-constructible; arguing as in the proof of (x.a) we may find, for every $x \in X$, a quasi-compact open subset $U_x$ such that $T \cap U_x$ is the union of a family $(T_{i,x} \mid i \in I_x)$ of constructible subsets of $U_x$. By (x.a) and remark 8.1.6(ii), each $T_{i,x}$ is globally constructible in $U_x$, hence also in $X$, by (viii.a), (iii) and remark 8.1.6(i); since $T = \bigcup_{x \in X} \bigcup_{i \in I_x} T_{i,x}$, the claim follows. The assertion for pro-constructible subsets is reduced to this case, by taking complements and using (iv).

(x.c): Indeed, every quasi-compact open subset is constructible, by (vii); conversely, (x.a) and (ix.b) show that every constructible subset of $X$ is quasi-compact. The assertion about constructible closed subsets of $X$ then follows immediately, taking into account (vi).
(x.d): In view of (x.b), it suffices to consider the case where $S$ is constructible, and so $S$ is even globally constructible in $X$, by (x.a). Then, we are further reduced to the case where $S$ is an open retro-compact subset of $X$, i.e. $S$ is open and quasi-compact in $X$, by (x.c), and it suffices to check that $T \cap S$ is retro-compact in $T$. Thus, let $V$ be any quasi-compact open subset of $T$; since $X$ is coherent, we may write $V = V' \cap T$, for some quasi-compact open subset $V'$ of $X$ (details left to the reader), and then $V \cap (T \cap S) = (V' \cap S) \cap T$. Now, $V' \cap S$ is open and quasi-compact in $X$ (remark 8.1.6(i)) and therefore $V \cap (T \cap S)$ is quasi-compact in $T$, and therefore also in $T \cap S$, since the latter is open in $T$.

(x.e): $T$ is quasi-compact by (viii.a), and if $(U_i \mid i \in I)$ is a basis of quasi-compact open subsets of $X$ which is closed under finite intersections, then $(T \cap U_i \mid i \in I)$ is a basis of quasi-compact open subsets for $T$ which is also closed under finite intersections, so $T$ is coherent. Next, let $U \subset X$ be any open subset (then $U$ is quasi-separated, by remark 8.1.6(i)), and $V_1, V_2$ any two quasi-compact open subsets of $U \cap T$; then $V_1$ and $V_2$ are also quasi-compact in $T$, so the same follows for $V_1 \cap V_2$ (again, by remark 8.1.6(i)), which shows that $i_T$ is quasi-separated.

(x.f): In view of (x.e), the topological space $T$ is coherent, so $S$ is globally constructible in $T$ by (x.a), and in light of (ii) and (vi) we may assume that $S = V \setminus V'$, for two retro-compact open subsets $V, V'$ of $T$. Then $V$ and $V'$ are quasi-compact in $T$, by (viii.a), and since $X$ is coherent, we may find quasi-compact open subsets $W, W'$ of $X$ such that $V = W \cap T$ and $V' = W' \cap T$, so that $S = (W \setminus W') \cap T$, and the latter is constructible in $X$, again by (vi) and (x.c).

(xi): In light of (x.e) and (x.a), it remains to show that $T$ is sober, and taking into account (ii) and lemma 8.1.3(iv), we may assume that $T$ is locally closed in $X$, in which case it suffices to invoke lemma 8.1.3(iii)).

\[\text{Remark 8.1.26.}\] Let $f : X \to Y$ be any quasi-compact continuous map of topological spaces.

(i) If $T \subset X$ is a retro-compact subset of $X$, then $f(T)$ is a retro-compact subset of $Y$. Indeed, if $U \subset Y$ is any quasi-compact open subset, we have $f(T) \cap U = f(T \cap f^{-1}U)$, and $f^{-1}U$ is a quasi-compact open subset of $X$, by assumption.

(ii) If $f$ is quasi-separated, $Y$ is locally coherent, and $T \subset Y$ is any constructible (resp. pro-constructible, resp. ind-constructible) subset in $Y$, then $f^{-1}T$ enjoys the same property in $X$. To see this, we may assume that $Y$ is coherent, in which case $X$ is quasi-separated and $T$ is constructible (resp. an intersection, resp. a union of constructible subsets, by lemma 8.1.25(x.b)); then it suffices to consider the case where $T$ is constructible, and we are further reduced to the case where $T$ is open and quasi-compact (lemma 8.1.25(x.b.x.a)), for which the assertion follows from lemma 8.1.25(vii).

(iii) If $f$ is quasi-separated, then $f$ is spectral. Indeed, say that $U \subset X$ and $V \subset U$ are quasi-compact and quasi-separated open subsets such that $f(U) \subset V$, and let $V' \subset V$ be any quasi-compact open subset of $V$; then $f^{-1}V'$ is quasi-compact and quasi-separated, and $f^{-1}V'' = U \cap f^{-1}V'$, which is quasi-compact, under the current assumptions, because $U$ and $f^{-1}V'$ are quasi-compact open subsets of $f^{-1}V$.

(iv) Suppose that $X$ is locally coherent, $T \subset X$ is any retro-compact subset, and endow $T$ with the topology induced from $X$. Then the inclusion map $i_T : T \to X$ is spectral. To see this, first we invoke proposition 8.1.22(i,iii) to reduce to the case where $X$ is coherent. Then the assertion follows from (iii) and lemma 8.1.25(x.e). Together with lemma 8.1.25(i), we see especially that any closed immersion $Z \to X$ is quasi-compact, quasi-separated and spectral.

\[\text{Definition 8.1.27.}\] Let $(X, \mathcal{S})$ be a topological space. The set of ind-constructible subsets of $X$ is closed under finite unions and finite intersections, and forms a basis for a topology $\mathcal{C}$ on $X$ called the \textit{constructible topology}. We shall denote by $X^c$ the topological space $(X, \mathcal{C})$.

\[\text{Remark 8.1.28.}\] Let $f : X \to Y$ be a continuous map of topological spaces.

(i) The map $f$ is not necessarily continuous with respect to the constructible topologies on $X$ and $Y$, but remark 8.1.26(ii) says that if $f$ is quasi-separated and quasi-compact, and $Y$ is
locally coherent, then the induced map
\[ f^c : X^c \to Y^c \]
(whose underlying map of sets is the same as \( f \)) is continuous.

(ii) Let \( U \) be any open subset of a topological space \( X \), and endow \( U \) with the topology induced from \( X \). Then the topology of \( U^c \) is finer than the topology on \( U \) induced from the topology of \( X^c \) (lemma 8.1.25(v)). The same holds if \( X \) is coherent and \( U \) is retro-compact (lemma 8.1.25(x,d)).

(iii) Suppose that \( X \) is locally coherent. By lemma 8.1.25(xiv, x.b), it follows that the open (resp. closed) subsets of \( X^c \) are the ind-constructible (resp. pro-constructible) subsets of \( X \).

**Proposition 8.1.29.** Let \( f : X \to Y \) be any spectral map between locally coherent topological spaces, \( T \subset Y \) any subset. The following holds:

(i) \( f^c \) is continuous.

(ii) If \( T \) is constructible (resp. ind-constructible, resp. pro-constructible) in \( Y \), then \( f^{-1}T \) is constructible (resp. ind-constructible, resp. pro-constructible) in \( X \).

**Proof.** Clearly, it suffices to check (ii). However, let \( T \subset Y \) be any subset as in (ii), and pick a covering \( (U_i \mid i \in I) \) of \( Y \) consisting of open coherent subsets; it suffices to check that \( f^{-1}(T \cap U_i) \) is constructible (resp. ind-constructible, resp. pro-constructible) in \( f^{-1}U_i \) for every \( i \in I \), so we may replace \( Y \) by any \( U_i \), and assume that \( Y \) is coherent, in which case, lemma 8.1.25(x.b) implies that it suffices to consider the case where \( T \) is constructible in \( Y \). Then, \( T \) shall be a finite union of subsets of the form \( T' \setminus T'' \), where \( T'' \subset T' \) are any two quasi-compact open subsets of \( Y \) (lemma 8.1.25(ix.b,x.a)), and we may further reduce to the case where \( T \) is an open quasi-compact subset of \( Y \). Now, let \( U \) be any coherent open subset of \( X \); it suffices to check that \( W := U \cap f^{-1}V \) is quasi-compact in \( U \) (lemma 8.1.25(x.c)), and the latter holds, since \( f \) is spectral.

**Lemma 8.1.30.** Let \( X \) be a locally coherent topological space, \( T \subset X \) any subset, and endow \( T \) with the topology induced from \( X \). We have:

(i) If \( T \) is either constructible or open in \( X \), the topology on \( T \) induced from \( X^c \) agrees with the topology of \( T^c \).

(ii) The topology of \( X^c \) is finer than that of \( X \).

**Proof.** (i): It suffices to show that:

(a) if \( S \) is any ind-constructible subset of \( X \), then \( S \cap T \) is ind-constructible in \( T \)

(b) if \( S \) is any ind-constructible subset of \( T \), then \( S \) is ind-constructible in \( X \).

However, fix a basis \( (U_i \mid i \in I) \) of \( X \) consisting of coherent open subsets, and set \( T_i := T \cap U_i \) for every \( i \in I \). If \( S \) is as in (a), and if \( S \cap T_i \) is ind-constructible in \( T_i \) for every \( i \in I \), then clearly \( S \cap T \) is ind-constructible in \( T \). If \( S \) is as in (b), and \( S \cap T_i \) is ind-constructible in \( U_i \) for every \( i \in I \), then \( S \) is ind-constructible in \( X \). Hence, it suffices to prove (a) and (b) with \( X \) and \( T \) replaced by respectively \( U_i \) and \( T_i \) for every \( i \in I \). We may then assume from start that \( X \) is coherent. In this case, \( T \) is either open or retro-compact in \( X \) (lemma 8.1.25(x.a)), hence the topology of \( T^c \) is finer than the topology \( \mathcal{T} \) on \( T \) induced from \( X^c \) (remark 8.1.28(ii)), whence (a). To show (b), suppose first that \( T \) is constructible in \( X \); then, any ind-constructible subset of \( T \) is a union of constructible subsets in \( T \) (lemma 8.1.25(x.b,e)), and therefore it is also a union of constructible subsets in \( X \) (lemma 8.1.25(x.f)), whence (b), in this case. Lastly, if \( T \) is open in \( X \), and \( S \) is ind-constructible in \( T \), pick a covering \( (T_i \mid i \in I) \) of \( T \) consisting of open coherent subsets; then \( S_i := S \cap T_i \) is ind-constructible in \( T_i \) for every \( i \in I \), so for every such \( i \) we may find a family \( (S_{i,\lambda} \mid \lambda \in \Lambda_i) \) of globally constructible subsets of \( T_i \), whose union is \( S_i \) (lemma 8.1.25(x.a,b)). However, \( T_i \) is retro-compact in \( X \), so \( S_{i,\lambda} \) is constructible...
in $X$, for every $i \in I$ and every $\lambda \in \Lambda_i$ (lemma 8.1.25(iii)); finally, $S = \bigcup_{i \in I} \bigcup_{\lambda \in \Lambda_i} S_{i, \lambda}$ is ind-constructoric in $X$, so (b) holds also in this case.

(ii): We have to check that every open subset $U$ of $X$ is ind-constructoric in $X$; however, $U$ is ind-constructoric in $U$, so the assertion follows from the foregoing. \hfill $\square$

8.1.31. We come now to the main theorem of this section. To prepare the proof, we introduce the following terminology. Let $\mathcal{F}$ be any family of subsets of a topological space $T$; we say that $\mathcal{F}$ is a closed filter (resp. a constructible filter) if:

- every $Z \in \mathcal{F}$ is closed (resp. constructible) in $T$
- $\emptyset \notin \mathcal{F}$ and $\mathcal{F} \neq \emptyset$
- if $Z, Z' \in \mathcal{F}$, then $Z \cap Z' \in \mathcal{F}$
- if $Z \in \mathcal{F}$ and $Z'$ is any closed (resp. constructible) subset of $T$ containing $Z$, then $Z' \in \mathcal{F}$.

The center of a filter $\mathcal{F}$ is the subset $\bigcap_{Z \in \mathcal{F}} Z$. It is easily seen that a topological space $T$ is quasi-compact if and only if every closed filter of $T$ has non-empty center.

Theorem 8.1.32. Let $X$ be a topological space. We have:

(i) If $X$ is spectral, $X^c$ is compact.

(ii) If $X$ is locally spectral and quasi-separated, then $X^c$ is locally compact and separated.

Proof. (We say that a topological space is locally compact if it admits a covering consisting of compact open subsets.)

(i): We check first that $X^c$ is separated. To this aim, let $x, y$ be any two points of $X$, and denote by $\{x\}$ and $\{y\}$ the topological closures of $\{x\}$ and $\{y\}$ with respect to $\mathcal{F}$. If $x \notin \{y\}$, it follows from lemma 8.1.30(ii) that we may find a constructible subset $T \subset X$ such that $x \in T$ and $y \notin T$; then the complement $S$ of $T$ in $X$ is also constructible, and $T$ and $S$ separate the points $x$ and $y$. Likewise one argues in the symmetric case where $y \notin \{x\}$. Lastly, if neither of these conditions hold, we must have $x = y$, since $X$ is sober and both $x$ and $y$ are generic points of the same closed subset of $X$.

To show that $X^c$ is quasi-compact, we check that its closed filters have non-empty center. However, let $\mathcal{F}$ be any such filter, and denote by $\mathcal{F}'$ the set of all constructible subsets $T$ of $X$ such that there exists $F \in \mathcal{F}$ with $F \subset T$. Clearly $\mathcal{F}'$ is a constructible filter of $X$, thus, we come down to:

Claim 8.1.33. (i) $\mathcal{F}$ and $\mathcal{F}'$ have the same center.

(ii) Every constructible filter of $X$ has non-empty center.

Proof of the claim. (i): Clearly the center of $\mathcal{F}'$ contains the center of $\mathcal{F}$. For the converse, it suffices to remark that every closed subset of $X$ is pro-constructoric in $X$ (lemma 8.1.30(ii) and remark 8.1.28(iii)), and therefore it is the intersection of the constructible subsets that contain it (lemma 8.1.25(x.b)).

(ii): In view of lemma 8.1.25(xi), every such filter can be regarded as a cofiltered system of spectral spaces, with continuous transition maps. Then the assertion is a special case of proposition 8.1.13(ii.a). \hfill $\diamond$

(ii): Lemma 8.1.30 and (i) imply that $X^c$ is locally compact. To see that $X$ is separated, let $x, y \in X$ be any two distinct points. We may then find a quasi-compact open subset $U$ of $X$ containing both $x$ and $y$, and the induced map $U^c \to X^c$ is an open immersion (lemma 8.1.30), so we may replace $X$ by $U$, and assume from start that $X$ is is spectral (lemmata 8.1.21(iv) and 8.1.25(vii)), which is the case covered by (i). \hfill $\square$

Corollary 8.1.34. Let $X$ be any spectral topological space, $U \subset X$ a subset. We have:

(i) $U$ is open and quasi-compact in $X^c$ if and only if it is constructible in $X$. 

(ii) $X^c$ is a spectral topological space.
(iii) If $Y$ is any locally spectral topological space, the same holds for $Y^c$.

**Proof.** (i): Suppose first that $U$ is open and quasi-compact in $X^c$; then $U$ is a union of a family $(U_i \mid i \in I)$ constructible subsets of $X$ (lemma 8.1.25 x.b), and there exists a finite subset $J \subset I$ such that $(U_i \mid i \in J)$ already covers $U$, so $U$ is constructible.

Conversely, suppose that $U$ is constructible in $X$, in which case it is both open and closed in $X^c$; since the latter is quasi-compact (theorem 8.1.32(i)), we see that $U$ is quasi-compact in $X^c$.

(ii): Indeed, (i) and lemma 8.1.25 vii) easily imply that $X^c$ is coherent, and $X^c$ is trivially sober, since in any separated space the irreducible closed subsets are exactly those that contain a unique point.

(iii) follows from (ii) and lemma 8.1.30: details left to the reader. □

**Corollary 8.1.35.** Let $f : X \to Y$ be a continuous map of locally spectral topological spaces. The following holds:

(i) $f$ is spectral if and only if the same holds for $f^c$.
(ii) Suppose furthermore that $f$ is spectral. Then:
(a) $f$ is quasi-compact if and only if the same holds for $f^c : X^c \to Y^c$.
(b) $f$ is quasi-separated if and only if the same holds for $f^c$.

**Proof.** We notice first:

**Claim 8.1.36.** In order to prove the corollary, we may assume that $Y$ is spectral.

**Proof of the claim.** Let $(Y_i \mid i \in I)$ be a covering of $Y$ consisting of spectral open subsets; then each $Y_i^c$ is open in $Y^c$, and its topology agrees with the topology induced from $Y^c$ (lemma 8.1.30 i,ii), so $(Y_i^c \mid i \in I)$ is an open covering of $Y^c$. Then the claim follows immediately from proposition 8.1.22 iii) and corollary 8.1.34 iii).

Thus, we assume henceforth that $Y$ is spectral. Next, we remark, quite generally:

**Claim 8.1.37.** Let $g : T \to S$ be any continuous map between locally spectral topological spaces, with $S$ locally compact. Then $g$ is spectral.

**Proof of the claim.** By lemma 8.1.22 iii), we may assume that $S$ is compact and that $T$ is quasi-compact and quasi-separated. Now, let $V \subset S$ be any quasi-compact open subset; since $S$ is separated, $V$ is also closed in $S$, hence $g^{-1}V$ is closed in $T$, so it is quasi-compact, since the same holds for $T$. Thus, $g$ is quasi-compact, and it is also obviously quasi-separated (due to remark 8.1.6 ii), so the claim follows from remark 8.1.26 iii).

(i): In light of claim 8.1.37, proposition 8.1.29 i) and theorem 8.1.32 i), we see that if $f$ is spectral, the same holds for $f^c$, hence we may assume that $f^c$ is spectral, and we show that the same holds for $f$. Thus, let $U \subset X$ and $V \subset Y$ be quasi-compact and quasi-separated open subsets such that $f(U) \subset V$; it suffices to check that $f|_U : U \to V$ is quasi-compact, and since $U^c$ (resp. $V^c$) is open in $X^c$ (resp. in $Y^c$, by lemma 8.1.30 ii)), the restriction $f|_U : U^c \to V^c$ is still spectral, so we may replace $X$ by $U^c$ and $Y$ by $V^c$, and assume that $X$ is quasi-compact and quasi-separated, in which case it is spectral (lemma 8.1.21 iv), and we need to show that $f$ is quasi-compact. Now, let $V \subset Y$ be any quasi-compact open subset; then $V$ is spectral (remark 8.1.6 ii), and $V^c$ is open and quasi-compact in $Y^c$ (lemma 8.1.30 ii) and theorem 8.1.32 i)). Hence, $V^c$ is closed in $Y^c$, and therefore $f^{-1}V^c$ is closed, and therefore quasi-compact, in $X^c$. Since the topology of the latter is finer than that of $X$, we conclude that $f^{-1}V$ is quasi-compact in $X$.

(ii.a): If $f$ is quasi-compact, it follows that $X$ admits a finite covering consisting of spectral open subsets, and if $U$ is any such subset, the restriction $f|_U$ is quasi-compact, since $f$ is spectral. Clearly it suffices to check that $f|_U$ is quasi-compact for every such $U$, so we may replace $X$
by \( U \) and assume that \( X \) is spectral as well, in which case, notice that \( f \) is obviously quasi-separated. Now, say that \( U \subset Y^c \) is open and quasi-compact; so, \( U \) is constructible in \( Y \) (corollary 8.1.34(i)), and then \( V := f^{-1}U \) is constructible in \( X \), by remark 8.1.26(ii), so it is quasi-compact in \( X^c \) (corollary 8.1.34(i)).

Conversely, say that \( f^c \) is quasi-compact, and \( U \) is a quasi-compact open subset of \( Y \). Then \( U \) is constructible in \( Y \), so it is open and quasi-compact in \( Y^c \) (corollary 8.1.34(i)), therefore \( f^{-1}U \) is quasi-compact in \( X^c \), and since the topology of \( X^c \) is finer than that of \( X \) (lemma 8.1.30(ii)), we conclude that \( f^{-1}U \) is quasi-compact in \( X \).

(ii.b): Suppose that \( f \) is quasi-separated; then \( X \) is quasi-separated, so \( X^c \) is separated (theorem 8.1.32(ii)), and it follows easily that \( f^c \) is quasi-separated (details left to the reader).

Conversely, if \( f^c \) is quasi-separated, then \( X^c \) is quasi-separated, since \( Y^c \) is separated (by theorem 8.1.32(i)). Then, say that \( U, V \) are two quasi-compact open subsets of \( X \); we may cover \( U \) (resp. \( V \)) by a finite family \( (U_i \mid i \in I) \) (resp. \( (V_j \mid j \in J) \)) of spectral open subsets, and the resulting maps \( U_i^c \to X^c, V_j^c \to X^c \) are open immersions (lemma 8.1.30). Moreover, each \( U_i^c \) and \( V_j^c \) is compact, by theorem 8.1.32(i), so \( U_i^c \cap V_j^c \) is quasi-compact in \( X^c \), for every \( i \in I \) and every \( j \in J \); consequently \( U \cap V \) is quasi-compact in \( X^c \), and a fortiori also in \( X \), since the topology of the latter is coarser than that of \( X^c \) (lemma 8.1.30(ii)).

\[ \square \]

**Corollary 8.1.38.** (i) In the situation of (8.1.12), suppose moreover that:

(a) The topological space \( X_i \) is spectral for every \( i \in \text{Ob}(I) \).

(b) The transition map \( p_u \) is quasi-compact, for every morphism \( u \) of \( I \).

Then \( X \) is spectral.

(ii) Suppose furthermore, that the system \( X_i \) is cofiltered. Then:

(a) For every constructible (resp. open and quasi-compact) subset \( U \subset X \) there exist \( i \in \text{Ob}(I) \) and a constructible (resp. open and quasi-compact) subset \( U_i \subset X_i \) such that \( U = p_i^{-1}U_i \).

(b) For any \( i \in \text{Ob}(I) \) and any two constructible subsets \( U, U' \) of \( X_i \) such that \( p_i^{-1}U \subset p_i^{-1}U' \), there exists a morphism \( u : j \to i \) in \( I \), such that \( p_u^{-1}U \subset p_u^{-1}U' \).

**Proof.** (i): By proposition 8.1.13(i) we know already that \( X \) is sober, so it remains only to check that \( X \) is coherent. However, under the stated conditions, the datum \( (X_i^c \mid i \in \text{Ob}(I)) \) is a system of quasi-compact and separated topological spaces, with continuous transition maps (theorem 8.1.32 and remark 8.1.28(ii)); denote by \( X^c \) the limit of this system (in the category of topological spaces). Now, the product \( Y := \prod_{i \in \text{Ob}(I)} X_i^c \) is likewise quasi-compact and separated, and we remark:

**Claim 8.1.39.** The natural map \( X^c \to Y \) is a closed immersion.

**Proof of the claim.** For every \( i \in \text{Ob}(I) \), denote by \( q_i : Y \to X_i^c \) the natural projection; the image of \( X^c \) in \( Y \) is the intersection of the subsets \( Y_u := \{ y_* \in Y \mid p_u \circ q_i(y_*) = q_j(y_*) \} \), for every morphism \( u : i \to j \) in \( I \), so it suffices to check that \( Y_u \) is closed in \( Y \), for every such \( u \). This is a special case of the following more general assertion. Let \( f, g : T \to T' \) be two continuous maps of topological spaces, with \( T' \) separated; then the subset

\[ S := \{ t \in T \mid f(t) = g(t) \} \]

is closed in \( T \). To show the latter, denote \( F : T \to T' \times T' \) the map such that \( F(t) = (f(t), g(t)) \) for every \( t \in T \); then \( S = F^{-1} \Delta_{T'} \), where \( \Delta_{T'} := \{ (t', t') \mid t' \in T' \} \) is the diagonal of \( T' \times T' \), and \( F \) is continuous for the product topology on \( T' \times T' \). We then come down to showing that \( \Delta_{T'} \) is closed in \( T' \times T' \), which holds if (and only if) \( T' \) is separated. \( \Diamond \)

It follows from claim 8.1.39 that \( X^c \) is quasi-compact and separated; the topology of \( X^c \) is obviously finer than that of \( X \), so the latter is quasi-compact as well. It remains to check that
X admits a basis of quasi-compact open subsets closed under finite intersections. To this aim, let $J \subset \text{Ob}(I)$ be any finite subset, pick a quasi-compact open subset $U_j$ of $X_j$ for each $j \in J$, and set

$$V := \prod_{i \in I \setminus J} X_i \times \prod_{j \in J} U_j \quad U := X \cap V.$$  

It suffices to show that $U$ is quasi-compact in $X$. However, notice that $U_j$ is constructible in $X_j$, so it is both open and closed in $X_j^c$, and therefore $V$ is closed in $Y$; since $X^c$ is closed in $Y$ by claim 8.1.39, it follows that $U$ is quasi-compact in $X^c$, and a fortiori, also in $X$.

(ii.a): Suppose first that $U$ is open and quasi-compact; then $U$ is a finite union of open subsets of the form $U_j := \bigcap_{i \in J} p_j^{-1}U_j$, where $J \subset \text{Ob}(I)$ is a finite subset, and $U_j$ is an open quasi-compact subset of $X_j$, for every $j \in J$. For such a given $U_j$, since $I$ is cofiltered, there exists $i \in \text{Ob}(I)$ with morphisms $u_j : i \to j$ for every $j \in J$, and therefore $U_j = p_i^{-1}U_i$, where $V_i := \bigcap_{j \in J} u_j^{-1}U_j$ is quasi-compact in $X_i$, since each $u_j$ is quasi-compact and $X_i$ is quasi-separated (remark 8.1.6(ii)). Thus, $U = \bigcup_{j \in J} V_j$ for a finite subset $J' \subset \text{Ob}(I)$ and quasi-compact open subsets $V_j \subset X_j$; again, we may find $i \in \text{Ob}(I)$ and a morphism $v_j : i \to j$ for every $j \in J'$, so that $U = p_i^{-1}U_i$, where $U_i := \bigcup_{j \in J'} v_j^{-1}V_j$ is open and quasi-compact in $X_i$.

The case where $U$ is constructible is reduced easily to the foregoing case, taking into account (i) and lemma 8.1.25(ix.b.x.a), and arguing as above, using the assumption that $X_\bullet$ is cofiltered (details left to the reader).

(ii.b) Let $Z := U \setminus U'$, set $Z_u := p_u^{-1}Z$ for every morphism $u : j \to i$ in $I$, and endow $Z_u$ with the topology induced from $X_j^c$. From theorem 8.1.32(i) and lemma 8.1.25(xi) we see that $Z_\bullet := (Z_u \mid u \in \text{Ob}(I/i))$ is a cofiltered system of compact topological spaces (see example 1.5.8(ii)), and the assumption means that the limit of $Z_\bullet$ is empty, so there exists $u \in \text{Ob}(I/i)$ such that $Z_u = \emptyset$, whence the assertion. □

**Corollary 8.1.40.** Let $X$ be any spectral topological space, $T \subset X$ a pro-constructible subset, and endow $T$ with the topology induced from $X$. Then $T$ is spectral and retro-compact in $X$.

**Proof.** By lemma 8.1.25(x.b), we may write $T$ as the intersection of a system $(T_i \mid i \in I)$ of constructible subsets of $X$. Let $J$ be the set of all finite subsets of $I$, and for every $S \subset J$, endow $T_S := \bigcap_{i \in S} T_i$ with the topology induced from $X$. Then $T_S$ is a constructible subset of $X$ for every $S \subset J$, and clearly the topological space $T$ is the limit of the (cofiltered) inverse system $(T_S \mid S \in J)$. By lemma 8.1.25(xi) each such $T_S$ is spectral and retro-compact in $X$ (lemma 8.1.25(x.a)); therefore, if $S \subset S'$ are any two elements of $J$, then $T_S$ is constructible in $T_{S'}$ (lemma 8.1.25(x.d)), hence also retro-compact in $T_{S'}$ (lemma 8.1.25(x.a)), i.e. the induced map $T_S \to T_{S'}$ is quasi-compact, and the assertion follows from corollary 8.1.38(i) and proposition 8.1.13(ii.b). □

**Proposition 8.1.41.** Let $(X, \mathcal{F})$ be a compact topological space, $\mathcal{U}$ a family of open and closed subsets of $X$, and endow $X$ with the coarsest topology $\mathcal{I}_\mathcal{U}$ containing $\mathcal{U}$. Then the following conditions are equivalent:

(a) $(X, \mathcal{I}_\mathcal{U})$ is a $T_0$ topological space.

(b) $(X, \mathcal{I}_\mathcal{U})$ is a spectral space.

Moreover, if these conditions hold, then $(X, \mathcal{I}_\mathcal{U})^c = (X, \mathcal{F})$.

**Proof.** From remark 8.1.2(vi) we get (b)⇒(a).

(a)⇒(b): Since $\mathcal{F}$ is compact, every $U \in \mathcal{U}$ is compact as well in $\mathcal{F}$, and therefore it is quasi-compact in $\mathcal{I}_\mathcal{U}$; Thus, $(X, \mathcal{I}_\mathcal{U})$ is coherent, and it remains only to check that $X$ is sober. To this aim, let $Z$ be any irreducible closed subset of $(X, \mathcal{I}_\mathcal{U})$, and set

$$\mathcal{U}_Z := \{U \in \mathcal{U} \mid U \cap Z \neq \emptyset\} \quad \text{and} \quad Z' := Z \cap \bigcap_{U \in \mathcal{U}_Z} U.$$
Since \( \mathcal{T}_Y \) is \( T_0 \), the subset \( Z' \) contains at most one point of \( X \), and to conclude, it suffices to check that \( Z' \neq \emptyset \). However, notice that \( Z \) is closed also in \( \mathcal{T} \), hence it is compact in this latter topology, so the same holds for every finite intersection \( U_1 \cap \cdots \cap U_k \cap Z \) with \( U_1, \ldots, U_k \in \mathcal{U}_Z \). We are then reduced to showing that every such finite intersection is non-empty. Suppose that the latter fails, and set \( V_i := Z \setminus U_i \) for every \( i = 1, \ldots, k \); then \( Z = V_1 \cup \cdots \cup V_k \), and since \( Z \) is irreducible in \( \mathcal{T}_Y \), it follows that \( Z = V_i \) for some \( i \leq k \), which is absurd.

Lastly, suppose that \((X, \mathcal{T}_Y)\) is spectral; we claim that in this case the identity map of \( X \) yields a continuous map \( i : (X, \mathcal{T}) \to (X, \mathcal{T}_Y)' \). Indeed, let \( T \subset X \) be a subset that is globally constructible for the topology \( \mathcal{T}_Y \); in view of lemma 8.1.25(iv.a.x.b), it suffices to show that \( T \) is open in the topology \( \mathcal{T} \). Then lemma 8.1.25(iv.b) further reduces to the case where \( T = V \setminus V' \) for two quasi-compact open subsets \( V, V' \) of \((X, \mathcal{T}_Y)\). However, \( V \) and \( V' \) are finite unions of subsets of the form \( U_1 \cap \cdots \cap U_k \), where \( k \in \mathbb{N} \) is arbitrary, and \( U_1, \ldots, U_k \in \mathcal{U}_Z \); it follows that \( V \) and \( V' \) are open and closed in \((X, \mathcal{T})\), and therefore the same holds for their difference. Lastly, since \((X, \mathcal{T})\) is separated and \((X, \mathcal{T}_Y)\) is quasi-compact (theorem 8.1.32(i)), it follows that \( i \) is a homeomorphism, whence the proposition. \( \square \)

**Definition 8.1.42.** Let \( X \) be a topological space, \( x, x' \in X \) any two points.

(i) We say that \( x \) is a specialization of \( x' \) in \( X \), or equivalently, that \( x' \) is a generization of \( x \) in \( X \), if \( x \) lies in the topological closure of \( \{x'\} \) in \( X \).

(ii) We say that \( x \) is an immediate specialization of \( x' \) in \( X \), or equivalently, that \( x' \) is an immediate generization of \( x \) in \( X \), if \( x \neq x' \), \( x \) is a specialization of \( x' \) in \( X \), and any other point of \( X \) that is both a specialization of \( x' \) and a generization of \( x \) in \( X \) is equal to either \( x \) or \( x' \).

(iii) We denote by \( X(x) \) the set of all generizations of \( x \) in \( X \), and we endow \( X(x) \) with the topology induced by \( X \).

(iv) Let \( f : X \to Y \) be any continuous map of topological spaces. We say that \( f \) is specializing (resp. generization) if the following holds. For every \( x \in X \) and every specialization (resp. generization) \( y \) of \( f(x) \) in \( Y \), there exists a specialization (resp. generization) \( x' \) of \( x \) in \( X \), such that \( f(x') = y \).

**Remark 8.1.43.** Let \( X \) be a topological space, and \( x \) any point of \( X \).

(i) Clearly \( X(x) \) is the intersection of all open neighborhoods of \( x \) in \( X \). Especially, if \( X \) is coherent, \( X(x) \) is a pro-constructible subset of \( X \). If \( X \) is \( T_0 \) (i.e. for any two distinct points of \( X \), at least one of them admits an open neighborhood not containing the other), \( x \) is the unique closed point of \( X \). If \( X \) is spectral, the same holds for \( X(x) \), and the inclusion map \( j_x : X(x) \to X \) is quasi-compact (corollary 8.1.40); since \( X(x) \) is quasi-separated, \( j_x \) is also quasi-separated, and even spectral, by remark 8.1.26(iii).

(ii) Clearly, the relation

\[
    x \leq x' \iff x \text{ is a specialization of } x' \text{ in } X
\]

defines a preordering on \( X \) (see example 1.1.6(iii)), and every continuous map \( f : X \to Y \) is also a morphism of preordered sets \((X, \leq) \to (Y, \leq)\). If \( X \) is \( T_0 \) and non-empty; in general, \((X, \leq)\) admits neither maximal nor minimal points, but if \( X \) is sober, it follows easily from remark 8.1.2(ii) that \((X, \leq)\) admits maximal points. If \( X \neq \emptyset \) is quasi-compact and \( T_0 \), then \((X, \leq)\) also admits minimal elements: indeed, if \( \{x_i \mid i \in I\} \) is any (non-empty) totally ordered subset of \( X \), let \( \{x_i \} \) be the topological closure of \( \{x_i \} \) in \( X \), for every \( i \in I \); then \( Z := \bigcap_{i \in I} \{x_i\} \neq \emptyset \), so any point of \( Z \) is smaller than every \( x_i \), and then the assertion follows as usual, by Zorn’s lemma.

(iii) Suppose that \( X \) is sober. Then, \( X \) is noetherian if and only if the following holds:

(a) Every closed subset of \( X \) has finitely many maximal points.
(b) Every descending sequence \((x_n \mid n \in \mathbb{N})\) in \((X, \leq)\) is stationary, i.e. it admits \(N \in \mathbb{N}\) such that \(x_n = x_N\) for every \(n \geq N\).

Indeed, for a sober space, (a) and (b) are rephrasing of the corresponding conditions of proposition [8.1.4]. It is also clear that, in this situation, the dimension of \(X\) is the supremum of the lengths of all finite strictly descending sequences in \((X, \leq)\) (see remark 8.1.2(iv)).

**Proposition 8.1.44.** Let \(X\) be any locally spectral topological space, \(T \subset X\) a pro-constructible subset, and \(U \subset X\) an ind-constructible subset. The following holds:

(i) The topological closure of \(T\) in \(X\) is the set of all specializations of all points of \(T\).

(ii) \(U\) is open in \(X\) if and only if it contains the generizations of all its points.

(iii) \(T\) is dense in \(X\) if and only if it contains all the maximal points of the partially ordered set \((X, \leq)\) (notation of remark 8.1.3(ii)).

**Proof.**

(i): Denote by \(\overline{T}\) the topological closure of \(T\) in \(X\), and by \(T^*\) the set of all specializations in \(X\) of points of \(T\). Clearly \(T^* \subset \overline{T}\), so we need only prove the converse inclusion. However, let \(V\) be any open subset of \(X\); on the one hand, the topological closure of \(T \cap V\) in \(V\) equals \(V \cap \overline{T}\). On the other hand, say that \(x \in V\) is a specialization in \(X\) of a point \(y \in T\); then clearly \(y \in T \cap V\), i.e. \(x\) is a specialization in \(V\) of \(y\), so \(V \cap T^*\) is the set of specializations in \(V\) of the points of \(T \cap V\). Since \(X\) admits a covering consisting of spectral open subsets, we may then replace \(X\) by any of these subsets, and assume from start that \(X\) is spectral.

Now, suppose that there exists \(x \in \overline{T} \setminus T^*\), denote by \(\mathcal{F}\) the family of all quasi-compact open neighborhoods of \(x\) in \(X\), and notice that \(\mathcal{F}\) is cofiltered, since \(X\) is quasi-separated, and not empty, since \(X\) is quasi-compact. Since \(x \in \overline{T}\), we must have \(W \cap T \neq \emptyset\) for every \(W \in \mathcal{F}\); on the other hand, we have

\[
\bigcap_{W \in \mathcal{F}} (W \cap T) = \emptyset
\]

since \(x \notin T^*\). But both \(T\) and the elements of \(\mathcal{F}\) are closed in \(X^c\), so \((W \cap T \mid W \in \mathcal{F})\) is a closed filter of \(X^c\), therefore its center cannot be empty (theorem 8.1.32(i) and (8.1.31)), a contradiction.

(ii) follows easily from (i), by considering the pro-constructible subset \(X \setminus U\).

(iii) is an immediate consequence of (i). \(\Box\)

**Example 8.1.45.** Let \(X\) be a spectral space of dimension \(\leq 0\). It follows easily from proposition 8.1.44(i) that every quasi-compact open subset of \(X\) is closed. Then \(X\) is separated: indeed, let \(x, x' \in X\) be any two distinct points; since \(X\) is sober, we may assume that \(x\) does not lie in the topological closure of \(\{x'\}\), in which case there exists a quasi-compact open neighborhood \(U\) of \(x\) that does not contain \(x'\), and the foregoing implies that \(X \setminus U\) is an open neighborhood of \(x'\), whence the contention. Conversely, every separated and compact topological space whose quasi-compact open subsets form a basis of the topology is a spectral space of dimension \(\leq 0\); indeed, such a space is coherent, and it is obviously sober, since all its points are closed. A topological space with this properties is sometimes called a compact boolean space: see [91] p.168,169], where it is also explained that, by virtue of the Stone representation theorem, such spaces are characterized as those topological spaces which are homeomorphic to the maximal spectra of (unital) boolean algebras. More precisely, to such any compact boolean space \(X\), one attaches its characteristic ring \(R_X\), which is the boolean algebra of all continuous functions \(X \rightarrow \mathbb{Z}/2\mathbb{Z}\), and then \(X\) is naturally homeomorphic to \(\text{Max } R_X\).

**Corollary 8.1.46.** Let \(X\) be a spectral space, and \(T \subset X\) a subset that contains the generizations of all its points, and endow \(T\) with the topology induced by \(X\). The following conditions are equivalent:

(a) \(T\) is quasi-compact.
Let \( f : X \rightarrow Y \) be a continuous map of locally spectral topological spaces, and \( T \subset X \) (resp. \( S \subset Y \)) any pro-constructible subset. Then:

(i) If \( f \) is quasi-compact, \( f(T) \) is a pro-constructible subset of \( Y \).

(ii) If \( f \) is spectral and generizing, the topological closure in \( X \) of \( f^{-1}S \) is the preimage of the topological closure of \( S \) in \( Y \).

**Proof.** (i): The assertion is local on \( Y \), hence we may assume that \( Y \) is spectral; then \( X \) admits a finite covering consisting of open spectral subsets, and we are easily reduced to the case where \( X \) is spectral as well. Now, by theorem 8.1.32(i,ii), the subset \( T \) is closed, and therefore quasi-compact, in \( X^c \). Then \( f(T) \) is quasi-compact in \( Y^c \); hence it is closed in \( Y^c \), and therefore pro-constructible in \( Y \).

(ii): Let \( \overline{S} \) denote the topological closure of \( S \) in \( Y \); clearly the topological closure of \( f^{-1}S \) lies in \( f^{-1}\overline{S} \), so we have only to check the converse inclusion. Thus, say that \( x \in f^{-1}\overline{S} \), so \( s := f(x) \in \overline{S} \), and therefore \( s \) is a specialization of a point \( s' \in S \) (proposition 8.1.44(i)); since \( f \) is generizing, it follows that there exists a generization \( x' \) of \( x \) in \( X \), such that \( f(x') = s' \). This shows that \( x \) lies in the set of specializations of the points of \( f^{-1}S \), and the contention follows.

**Proposition 8.1.48.** Let \( f : Y \rightarrow X \) be a surjective, spectral map of locally spectral topological spaces, and suppose that \( f \) is either specializing or generizing. Then \( X \) is the (topological) quotient of \( Y \), under the equivalence relation induced by \( f \).

**Proof.** The assertion means that a subset \( Z \subset X \) is open (resp. closed) in \( X \) if and only if \( Z' := f^{-1}Z \) is closed in \( Y \). For any subset \( Z \) of \( X \) (resp. of \( Y \)), we denote by \( \overline{Z} \) the topological closure of \( Z \) in \( X \) (resp. in \( Y \)). Of course, we may assume that \( Z' \) is closed in \( Y \), and we check that \( Z \) is closed in \( X \). Now, \( Z' \) is pro-constructible in \( Y \) (lemma 8.1.30(ii)), so \( f(Z') = Z \) is pro-constructible in \( X \) (corollary 8.1.47(i)). If \( f \) is generizing, it follows that \( Z' = \overline{f^{-1}Z} = f^{-1}\overline{Z} \) (corollary 8.1.47(ii)); since \( f \) is surjective, we deduce that \( Z = \overline{Z} \), i.e. \( Z \) is closed, as required. Lastly, suppose that \( f \) is specializing, and notice that \( \overline{Z} \) is the set of all specializations of all points of \( Z \) (proposition 8.1.44(i)); thus, let \( x \in Z \), \( x' \in X \) a specialization of \( x \) and \( y \in Z' \) such that \( f(y) = x \); since \( f \) is specializing, there exists \( y' \in Y \) with \( f(y') = x' \). But since \( Z' \) is closed, we have \( y' \in Z' \), so \( x' \in Z \), as required.

**Corollary 8.1.49.** Let \( X \) be a spectral topological space, whose set \( \text{Min} X \) (resp. \( \text{Max} X \)) of minimal (resp. maximal) points is finite. If \( Z \subset X \) is a subset closed under specializations and generizations, then \( Z \) is open and closed.

**Proof.** When \( \text{Max} X \) is finite, any such \( Z \) is a finite union of irreducible components, hence it is closed. But the same applies to the complement of \( Z \), whence the contention. When \( \text{Min} X \) is finite, consider the continuous map

\[
g : Y := \coprod_{x \in \text{Min} X} X(x) \rightarrow X
\]

(b) \( T \) is a pro-constructible subset of \( X \).

(c) \( T \) is spectral.

**Proof.** We know already that (b)\( \Rightarrow \)(c), by corollary 8.1.40, and clearly (c)\( \Rightarrow \)(a).

(i)\( \Rightarrow \)(b): For every \( x \in X \setminus T \), let \( \overline{\{x\}} \) be the topological closure of \( \{x\} \) in \( X \); by assumption, \( \overline{\{x\}} \cap T = \emptyset \), so for every \( t \in T \) there exists a quasi-compact open subset \( U_{x,t} \) such that \( t \in U_{x,t} \) and \( \overline{\{x\}} \cap U_{x,t} = \emptyset \). Since \( T \) is quasi-compact, we then have a finite subset \( S_x \subset T \), such that \( T \subset \bigcup_{x \in S_x} U_{x,t} \), and clearly \( U_x \) is a constructible open subset of \( X \). We have \( T = \bigcap_{x \in X \setminus T} U_x \), whence (b).

\[
\text{Corollary 8.1.47.}
\]

Let \( f : X \rightarrow Y \) be a continuous map of locally spectral topological spaces, and \( T \subset X \) (resp. \( S \subset Y \)) any pro-constructible subset. Then:

(i) If \( f \) is quasi-compact, \( f(T) \) is a pro-constructible subset of \( Y \).

(ii) If \( f \) is spectral and generizing, the topological closure in \( X \) of \( f^{-1}S \) is the preimage of the topological closure of \( S \) in \( Y \).

**Proof.**
whose restriction to each $X(x)$ is the inclusion map. Now, $Y$ is spectral, and $g$ is surjective, continuous and spectral (remark 8.1.43(i)), and it is obviously also generizing; on the other hand, clearly the assertion holds for $Y$, hence for $X$, by proposition 8.1.48. □

Remark 8.1.50. Hochster defines in \([73]\) an involution

$$X \mapsto X^*$$

of the category of spectral topological spaces and spectral maps, with the following properties. For every spectral space $X$, the set underlying $X^*$ is the same as that underlying $X$, and the constructible closed subsets of $X$ form a basis of the topology of $X^*$. He shows that the partially ordered set $(X^*, \leq)$ is the opposite of $(X, \leq)$ (\([73\), Prop.8]). Using this construction, it is possible to give an alternative proof of corollary 8.1.49.

8.1.51. In the study of the valuation spectrum to be carried out in section 9.2 we shall encounter certain subsets of a spectral space that are not pro-constructible, but nevertheless are spectral spaces, when endowed with the subspace topology. In the following proposition we describe the general principle underlying these constructions.

Let $X$ be any topological space, $S \subset X \times X$ a subset of specializations of $X$: i.e. for every $(x, y) \in S$ the point $y$ is a specialization in $X$ of the point $x$, in which case we shall also say that $y$ is an $S$-admissible specialization of $x$, and $x$ is an $S$-admissible generization of $y$. We say that a subset $T \subset X$ is $S$-closed if every $S$-admissible specialization of every point of $T$ lies also in $T$. Furthermore, we shall say that $S$ is a transitive set of specializations, if the following holds: if $x, y, z \in X$ are any three points, and $(x, y), (y, z) \in S$, then $(x, z) \in S$ as well. We may then state:

**Proposition 8.1.52.** Let $X$ be any spectral space, $S$ a given set of specializations of $X$, set

$$Y := \{ x \in X \mid x \text{ has no proper } S\text{-admissible specializations} \}$$

and endow $Y$ with the topology induced by the inclusion map $Y \to X$. Suppose that:

- (S1) Every $y \in Y$ has a fundamental system of open neighborhoods in $X$ consisting of constructible $S$-closed open subsets.
- (S2) For every $x \in X$ there exists an $S$-admissible specialization $y$ of $x$ that lies in $Y$.

Then the following holds:

- (i) For every $x \in X$ there exists a unique point $r(x) \in Y$ that is an $S$-admissible specialization of $x$ in $X$.
- (ii) The topological space $Y$ is spectral, and the resulting retraction

$$r : X \to Y$$

is spectral.
- (iii) More precisely, a subset $T \subset Y$ is constructible in $Y$ if and only if $r^{-1}T$ is constructible in $X$.

**Proof.** (i): Suppose that a given $x \in X$ has two $S$-admissible specialization $y, y' \in Y$; by remark 8.1.2(vi) we know that $X$ is $T_0$, so we may assume that there exists an open neighborhood $U$ of $y$ that does not contain $y'$. If $V \subset U$ is any open neighborhood of $y$, then $x \in V$, but $V$ does not contain the $S$-admissible specialization $y'$ of $x$, contradicting (S1).

(ii): Let $\mathcal{P}$ (resp. $\mathcal{D}$) be the set of all open subsets $T \subset Y$ such that $r^{-1}T$ is constructible (resp. open and constructible) in $X$.

**Claim 8.1.53.** $\mathcal{P}$ is a basis of the topology of $Y$, and $Y$ is a $T_0$ topological space.

**Proof of the claim.** Since $X$ is $T_0$, condition (S1) implies easily that the same holds for $Y$. Next, notice that we have $U = r^{-1}r(U)$ for every open and $S$-closed subset $U \subset X$, and therefore
Let \( U = r^{-1}(U \cap Y) \) for every such \( U \). Thus, \( U \cap Y \in \mathscr{P} \) for every open, constructible and \( S \)-closed subset \( U \subset X \), and the claim follows from (S1).

Let now \( \mathcal{T} \) be the topology whose basis is \( \mathcal{Q} \); clearly every element of \( \mathcal{Q} \) is open and closed in the topology \( \mathcal{T} \). Moreover, since \( X \) is quasi-compact, it is easily seen that the same holds for \( (Y, \mathcal{T}) \). Then proposition 8.1.41 and claim 8.1.53 show that \( Y \) is spectral. It is also clear that \( r \) is continuous and quasi-compact, so it is spectral, by remark 8.1.26(iii).

(iii): Proposition 8.1.41 also shows that \( \mathcal{Q} \) is the set of constructible subsets of \( Y \), whence the assertion. \( \square \)

**Corollary 8.1.54.** In the situation of proposition 8.1.52 suppose moreover that the following condition holds:

(S3) For every \( x \in X \), any two \( S \)-admissible specializations are comparable, i.e. if \( y, z \in X \) are any two \( S \)-admissible specializations of \( x \), then either \( y \) is an \( S \)-admissible specialization of \( z \) or else \( z \) is an \( S \)-admissible specialization of \( y \).

Then, for every subset \( T \subset X \) the following conditions are equivalent:

1. \( T = r^{-1}r(T) \).
2. \( T \) is \( S \)-closed, and every \( S \)-admissible generization of every point of \( T \) lies in \( T \).

**Proof.** It is easily seen that (b) \( \Rightarrow \) (a). Hence, suppose that (a) holds, let \( x \in T \) be any point, and \( y \in X \) any \( S \)-admissible generization of \( x \). By (S3), either \( x \) is an \( S \)-admissible specialization of \( r(y) \), or \( r(y) \) is an \( S \)-admissible specialization of \( x \). If \( r(y) \) is an \( S \)-admissible specialization of \( x \), then \( r(x) = r(y) \), by proposition 8.1.52(i); therefore \( y \in T \), by (a). If \( x \) is an \( S \)-admissible specialization of \( r(y) \), we must have \( x = r(y) \), since \( r(y) \in Y \); then (a) yields again \( y \in T \).

Lastly, let \( y \) be an \( S \)-admissible specialization of \( x \). By (S3), either \( r(x) \) is an \( S \)-admissible specialization of \( y \), or \( y \) is an \( S \)-admissible specialization of \( r(x) \). If \( r(x) \) is an \( S \)-admissible specialization of \( y \), then \( r(x) = r(y) \), by proposition 8.1.52(i); then (a) yields \( y \in T \). If \( y \) is an \( S \)-admissible specialization of \( r(x) \), then \( y = r(x) \), since \( r(x) \in Y \); then again \( y \in T \), by (a). \( \square \)

The foregoing notions shall be applied also to the study of schemes and their underlying topological spaces, which are always locally spectral (see remark 8.1.18(ii)). For future reference, we make the following:

**Definition 8.1.55.** Let \( X \) be any scheme.

(i) We say that \( X \) is \textit{locally coherent}, if \( \mathcal{O}_X \) is a coherent sheaf of rings.

(ii) We say that \( X \) is \textit{coherent}, if it is locally coherent, quasi-compact and quasi-separated.

Notice that the topological space underlying a coherent scheme is always spectral, by lemma 8.1.21(iv). We conclude this section with a few miscellaneous results concerning the topology of schemes.

**Proposition 8.1.56.** Let \( X \) be any reduced and coherent scheme, and endow the set \( \text{Max} \ X \) of maximal points of \( X \) with the topology induced from \( X \). Then \( \text{Max} \ X \) is quasi-compact.

**Proof.** Clearly we have \( \text{Max} \ U = U \cap \text{Max} \ X \) for any open subset \( U \subset X \); then, if \( (U_i \mid i \in I) \) is any finite covering of \( X \) consisting of affine open subsets, it suffices to show that \( \text{Max} \ U_i \) is quasi-compact for every \( i \in I \). We may therefore assume from start that \( X \) is affine, say \( X = \text{Spec} \ A \) for some reduced coherent ring \( A \). We notice:

**Claim 8.1.57.** Let \( R \) be any reduced ring and \( f \in R \) any element; we have:

\[
\text{Max} \ (\text{Spec} \ R_f) = \text{Max} \ (\text{Spec} \ R) \cap \text{Spec} \ R/\text{Ann}_R(f).
\]
Proof of the claim. Set $I := \text{Ann}_R(f)$ and let $p$ be any minimal prime ideal of $R$; then $p \in \text{Max}(\text{Spec } R_f)$ if and only if $p \in \text{Max}(\text{Spec } R)$ and $f \notin p$. Thus, it suffices to check that $f \notin p$ if and only if $I \subset p$. However, if $f \notin p$, clearly $I \subset p$. For the converse, notice that $I_p = \text{Ann}_R(f)$, and $R_p$ is a field, since $R$ is reduced; hence $I_p$ is either $R_p$ or $0$, depending on whether the image of $f$ is invertible or not in $R_p$, and the assertion follows easily.  

Now, pick any covering $(U_i \mid i \in I)$ of $\text{Max } X$ consisting of open subsets; we have to show that there exists a finite subset $J \subset I$ such that $(U_i \mid i \in J)$ already covers $\text{Max } X$. To this aim, we may assume without loss of generality that every $U_i$ is of the form $\text{Max}(\text{Spec } A_{f_i})$ for some $f_i \in A$. Notice that $\text{Ann}_A(f_i)$ is an ideal of finite type, since $A$ is coherent; in view of claim 8.1.57, we deduce that for every $i \in I$ there exists a constructible open subset $V_i$ of $X$ such that $\text{Max } X \setminus U_i = V_i \cap \text{Max } X$. By assumption, $\text{Max } X \cap \bigcap_{i \in J} V_i = \emptyset$; since every $V_i$ contains the generizations of all its points, it follows that $\bigcap_{i \in J} V_i = \emptyset$. By corollary 8.1.34(i) and theorem 8.1.32, we deduce that there exists a finite subset $J \subset I$ such that $\bigcap_{i \in J} V_i = \emptyset$. Then clearly this subset $J$ will do.

Lemma 8.1.58. Let $A$ be a ring, $I \subset A$ an ideal. Then:

(i) The following are equivalent:

(a) The map $A \to A/I$ is flat.

(b) The map $A \to A/I$ is a localization.

(c) For every prime ideal $p \subset A$ containing $I$, we have $IA_p = 0$, especially, $V(I)$ is closed under generizations in $\text{Spec } A$.

(ii) Suppose $I$ fulfills the conditions (a)-(c) of (i). Then the following are equivalent:

(a) $I$ is finitely generated.

(b) $I$ is generated by an idempotent.

(c) $V(I) \subset \text{Spec } A$ is open.

Proof. (i): Clearly (b)⇒(a). Also (a)⇒(c), since every flat local homomorphism is faithfully flat. Suppose that (c) holds; we show that the natural map $B := (1 + I)^{-1} A \to A/I$ is an isomorphism. Indeed, notice that $IB$ is contained in the Jacobson radical of $B$, hence it vanishes, since it vanishes locally at every maximal ideal of $B$.

(ii): Clearly (ii.c)⇒(ii.b)⇒(ii.a). If (ii.a) holds, then $V(I)$ is constructible and closed under generizations, by (ii.c), so it is open (proposition [8.1.44(ii)], i.e. (ii.a)⇒(ii.c).  

8.1.59. For every ring $A$, we let $\mathcal{I}(A)$ be the set of all ideals $I \subset A$ fulfilling the equivalent conditions (i.a)-(i.c) of lemma 8.1.58 and $\mathcal{Z}(A)$ the set of all closed subset $Z \subset \text{Spec } A$ that are closed under generizations in $\text{Spec } A$. In light of lemma 8.1.58(i.c), we have a natural mapping:

(8.1.60) $\mathcal{I}(A) \to \mathcal{Z}(A) : I \mapsto V(I)$.

Lemma 8.1.61. The mapping (8.1.60) is a bijection, whose inverse assigns to any $Z \in \mathcal{Z}(A)$ the ideal $I[Z]$ consisting of all the elements $f \in A$ such that $fA_p = 0$ for every $p \in Z$.

Proof. Notice first that $I[V(I)] = I$ for every $I \in \mathcal{I}(A)$; indeed, clearly $I \subset I[V(I)]$, and if $f \in I[V(I)]$, then $fA_p = 0$ for every prime ideal $p$ containing $I$, hence the image of $f$ in $A/I$ vanishes, so $f \in I$. To conclude the proof, it remains to show that if $Z$ is closed and closed under generizations, then $V(I[Z]) = Z$. However, say that $Z = V(J)$, let $p \in Z$ be any prime ideal, and suppose that $f \in J$; then $\text{Spec } A_p \subset Z$, hence $f$ is nilpotent in $A_p$, so there exist $n \in \mathbb{N}$ and an open neighborhood $U \subset \text{Spec } A$ of $p$ such that $f^n = 0$ in $U$. Since $Z$ is quasi-compact, finitely many such $U$ suffice to cover $Z$, hence we may find $n \in \mathbb{N}$ large enough such that $f^n \in I[Z]$, whence the contention.  

The following result improves upon [106 Cor.2.6].
Proposition 8.1.62. Let $R$ be a ring, $R'$ any finitely generated $R$-algebra, $\varphi : \text{Spec } R' \to \text{Spec } R$ the induced morphism of schemes, $\Sigma \subset \text{Spec } R$ any subset, and endow $\Sigma$ (resp. $\varphi^{-1}\Sigma$) with the topology induced from $\text{Spec } R$ (resp. from $\text{Spec } R'$). If $\Sigma$ is a noetherian topological space, then the same holds for $\varphi^{-1}\Sigma$.

Proof. Set $X := \text{Spec } R$ and $X' := \text{Spec } R'$; we may find an integer $n \in \mathbb{N}$ and a closed immersion $X' \to \text{Spec } R[T_1, \ldots, T_n]$, so it suffices to prove the assertion for $R' = R[T_1, \ldots, T_n]$, and by factoring the map $R \to R'$ as a composition $R \to R[T_1, \ldots, T_{n-1}] \to R'$, an easy induction reduces to the case where $R' = R[T]$.

Now suppose, by way of contradiction, that the proposition fails, and let $\mathcal{F}$ be the family of all closed subsets $Z$ of $\Sigma$ such that $\varphi^{-1}Z$ is not noetherian. Since $\Sigma$ is noetherian, and $\mathcal{F}$ is not empty, $\mathcal{F}$ admits minimal elements. Let $Z$ be a minimal element of $\mathcal{F}$, and endow $Z$ with the topology induced from $\Sigma$; then $Z$ is also noetherian (remark 8.1.6(v)), so we may replace $\Sigma$ by $Z$, and assume that no proper closed subset of $\Sigma$ lies in $\mathcal{F}$. We claim that in this case, $\Sigma$ is irreducible. Indeed, let $\Sigma_1, \ldots, \Sigma_k$ be the finitely many irreducible components of $\Sigma$ (proposition 8.1.4); if $k > 1$, we have $\Sigma_i \notin \mathcal{F}$ for $i = 1, \ldots, k$, but then remark 8.1.6(v) easily implies that $\Sigma \notin \mathcal{F}$ as well, a contradiction. Hence, the topological closure $\Sigma$ of $\Sigma$ in $X$ is irreducible in $X$ (lemma 8.1.3)); we endow $\Sigma$ with the reduced closed subscheme structure induced by the closed immersion $\Sigma \to X$, so $\Sigma$ is isomorphic to the spectrum of some quotient of $R$. We may then replace $X$ by $\Sigma$, after which we may assume that $R$ is a domain, and $\Sigma$ is dense in $X$. In this case, denote by $K$ the field of fractions of $R$. We notice:

Claim 8.1.63. Let $A$ be a domain, $K$ the field of fractions of $A$, $I \subset A[T]$ any ideal, and $p(T) \in I$ a monic polynomial that generates $I \cdot K[T]$. Then $p(T)$ generates $I$.

Proof of the claim. Consider any $q(T) \in I$, and let $g(T) = q(T) \cdot p(T) + r(T)$ be the euclidean division of $g$ by $p$ in $K[T]$. Since $p$ generates $I \cdot K[T]$, we have $r = 0$, and since $p$ is monic, it is easily seen that $q \in A[T]$, whence the claim.

Now, suppose that $(Z_n \mid n \in \mathbb{N})$ is a strictly descending chain of closed subsets of $\varphi^{-1}\Sigma$, and for each $n \in \mathbb{N}$, let $\overline{Z}_n$ be the topological closure of $Z_n$ in $\text{Spec } R'$, and $I_n \subset R'$ the largest ideal such $\text{Spec } R'/I_n = \overline{Z}_n$. There follows an increasing chain of ideals $(I_n \mid n \in \mathbb{N})$. The corresponding sequence $(I_n \cdot K[T] \mid n \in \mathbb{N})$ is stationary and consists of principal ideals of $K[T]$, so we may find $N \in \mathbb{N}$ and a monic polynomial $p(T)$ such that $p(T)$ generates $I_n \cdot K[T]$ for every $n \geq N$. Moreover, we may find some $f \in R \setminus \{0\}$ such that $p(T) \in R_f[T]$ (where $R_f := R[f^{-1}]$), and we may even assume that $p(T) \in I_n \cdot R_f[T]$ for every $n \geq N$, in which case claim 8.1.63 shows that $p(T)$ generates $I_n \cdot R_f[T]$ for every $n \geq N$. Set $U := \text{Spec } R_f$; we conclude that the chain of subsets $(\overline{Z}_n \cap \varphi^{-1}U \mid n \in \mathbb{N})$ is stationary. However, $Z'_n := Z_n \cap \varphi^{-1}U = \overline{Z}_n \cap \varphi^{-1}(U \cap \Sigma)$ for every $n \in \mathbb{N}$, so the chain $(Z'_n \mid n \in \mathbb{N})$ is stationary as well. On the other hand, by construction $U \neq \emptyset$, so $\Sigma' := \Sigma \setminus U$ is a proper closed subset of $\Sigma$, therefore $\varphi^{-1}\Sigma'$ is noetherian, and especially, the chain $(Z_n \cap \varphi^{-1}\Sigma' \mid n \in \mathbb{N})$ is stationary. Summing up, we deduce that the chain $(Z_n \mid n \in \mathbb{N})$ is stationary, which is absurd.

8.2. Topological groups. This section collects a few generalities on topological groups that shall be used in later sections.

Definition 8.2.1. A topological group is a pair $(G, \mathcal{G})$ where $(G, \cdot , e_G)$ is a group and $\mathcal{G}$ a topology on the set underlying $G$, such that:

- the composition law of $G$ is a continuous map $(G, \mathcal{G}) \times (G, \mathcal{G}) \to (G, \mathcal{G})$
- the rule $g \mapsto g^{-1}$ for every $g \in G$ yields a continuous map $(G, \mathcal{G}) \to (G, \mathcal{G})$.

A morphism of topological groups $\varphi : (G, \mathcal{G}) \to (H, \mathcal{H})$ is a group homomorphism $\varphi : G \to H$ that is continuous for the topologies $\mathcal{G}$ and $\mathcal{H}$.
Remark 8.2.2. Let \((G, \mathcal{T})\) be any topological abelian group.

(i) If \(U \subset G\) is any open neighborhood of the neutral element \(0\), set \(-U := \{-g \mid g \in U\}\). Clearly \(-U\) is still an open neighborhood of \(0\) in \(G\), and thus the same holds for \(U \cap -U\). Especially, \(G\) admits a fundamental system of open neighborhoods of \(0\) consisting of subsets \(U\) such that \(U = -U\).

(ii) Let \(\mathcal{U}\) be any fundamental system of open neighborhoods of \(0\) in \(G\). It is easily seen that a subset \(V \subset G\) is open if and only if for every \(g \in V\) there exists \(U \in \mathcal{U}\) such that \(g + U := \{g + h \mid h \in U\} \subset V\). Especially, \(\mathcal{U}\) determines completely the topology of \(G\). Notice also that, due to the continuity of the composition law of \(G\), for every \(U \in \mathcal{U}\) there exists \(U' \in \mathcal{U}\) such that \(U' + U' := \{g + g' \mid g, g' \in U'\} \subset U\).

(iii) Conversely, let \(\mathcal{U}\) be any family of subsets of \(G\) such that:

\begin{enumerate}
  
  \item \(0 \in U\) for every \(U \in \mathcal{U}\).
  
  \item \(U = -U\) for every \(U \in \mathcal{U}\).
  
  \item for every \(U \in \mathcal{U}\) there exists \(U' \in \mathcal{U}\) such that \(U' + U' \subset U\).
  
  \item for every \(U, U' \in \mathcal{U}\) there exists \(U'' \in \mathcal{U}\) such that \(U'' \subset U \cap U'\).
  
  \item for every \(U \in \mathcal{U}\) and every \(g \in U\) there exists \(U' \in \mathcal{U}\) such that \(g + U' \subset U\).
\end{enumerate}

Then there exists a unique topology \(\mathcal{T}\) on \(G\) such that \(\mathcal{U}\) is a fundamental system of neighborhoods of \(0\) in \(G\) relative to the topology \(\mathcal{T}\), and \((G, \mathcal{T})\) is a topological group. Indeed, the uniqueness is clear from (ii), which also describes \(\mathcal{T}\) explicitly, and it is easily seen that the composition law \(G \times G \to G\) and the map \(G \to G : g \mapsto -g\) are both continuous for this topology; details left to the reader.

(iv) Let \(\varphi : G' \to G\) be a group homomorphism with \(G'\) also abelian, and endow \(G'\) with the topology \(\mathcal{T}'\) induced by \(\mathcal{T}\). Then \((G', \mathcal{T}')\) is a topological group. Indeed, pick any fundamental system \(\mathcal{U}\) of open neighborhoods of \(0\) in \(G\) fulfilling conditions (a)-(e) of (iii); it is easily seen that the system \(\varphi^{-1}\mathcal{U} := \{\varphi^{-1}U \mid U \in \mathcal{U}\}\) is a fundamental system of open neighborhoods of the neutral element \(0'\) of \(G'\) relative to the topology \(\mathcal{T}'\), and clearly \(\varphi^{-1}\mathcal{U}\) fulfills the same conditions (a)-(e), whence the assertion.

(v) Likewise, let \(\psi : G \to G''\) be a group homomorphism with \(G''\) also abelian; for any system \(\mathcal{U}\) of open neighborhoods of \(0\) as in (iv), set \(\psi(\mathcal{U}) := \{\psi(U) \mid U \in \mathcal{U}\}\); it is easily seen that the system \(\psi(\mathcal{U})\) fulfills again conditions (a)-(e) of (iii), hence there exists a unique topology \(\mathcal{T}''\) on \(G''\) for which \(\mathcal{U}\) is a fundamental system of open neighborhoods of the neutral element \(0''\) in \(G''\), and such that \((G'', \mathcal{T}'')\) is a topological abelian group. If \(\psi\) is surjective, it is easily seen that \(\mathcal{T}''\) agrees with the topology induced by \(\mathcal{T}\) via \(\psi\). More generally, \(\psi(G)\) is an open subgroup of \(G''\) for the topology \(\mathcal{T}''\), and the topology on \(\psi(G'')\) induced by \(\mathcal{T}''\) agrees with the quotient topology induced by \(\mathcal{T}\) via the surjection \(\psi : G \to \psi(G)\); details left to the reader. Especially, \(\mathcal{T}''\) is independent of the choice of \(\mathcal{U}\), and is the finest topology on \(G''\) such that \(\psi : (G, \mathcal{T}) \to (G'', \mathcal{T}'')\) is a morphism of topological abelian groups.

(vi) Let \((G', \mathcal{T}')\) be another topological abelian group, and \(\varphi : G \to G'\) a group homomorphism. Then \(\varphi\) is continuous if and only if it is continuous at the point \(0 \in G\), i.e. if and only if for every open neighborhood \(U' \subset G'\) of the neutral element \(0' \in G'\) there exists an open neighborhood \(U \subset G\) in \(G\) with \(\varphi(U) \subset U'\). Indeed, the condition is obviously necessary. Conversely, suppose this condition holds, and let \(V' \subset G'\) be any open subset; for every \(g \in \varphi^{-1}V\) we may pick an open neighborhood \(U'\) of \(0'\) in \(G'\) such that \(U' \subset -\varphi(g) + V\), and by assumption there exists an open neighborhood \(U \subset G\) of \(0\) such that \(U \subset \varphi^{-1}(U')\), whence \(g + U \subset \varphi^{-1}V\), so \(\varphi^{-1}V\) is open in \(G\), whence the contention.

(vii) Notice that \(G\) is separated if and only if the subset \(\{0\}\) is closed in \(G\). Indeed, the condition is obviously necessary. For the converse, suppose that \(\{0\}\) is closed, and let \(g \in G \setminus \{0\}\) be any other point; it suffices to show that there exist open neighborhoods \(U\) and \(U'\) respectively of \(0\) and of \(g\), such that \(U \cap U' = \emptyset\). However, by assumption there exists an open
neighborhood $V$ of 0 that does not contain $g$; then let $U$ be any open neighborhood of 0 such that $U = -U$ and $U + U \subset V$, and set $U' := g + U$. Suppose $u \in U \cap U'$; then there exists $u' \in U$ such that $u = g + u'$, whence $g = u - u' \in U + U \subset V$, a contradiction.

**Lemma 8.2.3.** Let $G$ be a topological abelian group, $I_0 \subset G_0 \subset G$ two subgroups, that we endow with the topology induced from $G$. Also, let $\mathcal{T}_0$ and $\mathcal{T}$ be the quotient topologies of $G_0 := G_0/I_0$ and respectively $G := G/I_0$. The following holds:

(i) $\mathcal{T}_0$ agrees with the topology induced by $\mathcal{T}$ via the inclusion map $j : G_0 \to G$.

(ii) Suppose that $I_0$ is closed in $G_0$, denote by $I \subset G$ the topological closure of $I_0$ in $G$, and endow $G' := G/I$ with the quotient topology $\mathcal{T}'$. Then the induced map

$$j' : G_0 \to G'$$

is injective, and $\mathcal{T}_0$ agrees with the topology induced by $\mathcal{T}'$ via $j'$.

**Proof.** (i): We remark, quite generally:

**Claim 8.2.4.** Let

$$
\begin{array}{ccc}
X' & \xrightarrow{g'} & X \\
\downarrow{j'} & & \downarrow{j} \\
Y' & \xrightarrow{g} & Y
\end{array}
$$

be a cartesian diagram of topological spaces. If $f$ is an open map, the same holds for $f'$.

**Proof of the claim.** Every open subset of $X'$ is a union of subsets of the form $U \times_Y V = g'^{-1}U \cap f'^{-1}V$, for arbitrary open subsets $U \subset X$ and $V \subset Y'$. Then $f'(U \times_Y V) = V \cap g'^{-1}f(U)$ is open in $Y'$, whence the claim.

We consider the diagram

$$
\begin{array}{ccc}
G_0 & \longrightarrow & G \\
\downarrow{\pi_0} & & \downarrow{\pi} \\
\overline{G_0} & \xrightarrow{j} & \overline{G}
\end{array}
$$

whose vertical arrows are the projections, and whose top horizontal arrow is the inclusion map. It is easily seen that this diagram is cartesian, provided we endow $G_0$ and $\overline{G_0}$ with the topologies induced by the inclusions into $G$ and respectively $\overline{G}$. Then $\pi$ is an open map, so the same holds for $\pi_0$, by claim [8.2.4] whence the assertion.

(ii): Since $I_0$ is closed in $G_0$, we have $I_0 = G_0 \cap I$, so $j'$ is clearly injective. Let $\mathcal{T}_0'$ be the topology on $\overline{G_0}$ induced by $\mathcal{T}'$ via $j'$; the identity map is a continuous bijection

$$(\overline{G_0}, \mathcal{T}_0') \to (\overline{G_0}, \mathcal{T}'_0)$$

so it suffices to check that it is also a closed map. Now, let $\pi' : G \to \overline{G}'$ and $\pi'_0 : G_0 \to \overline{G}_0$ be the projections, and let $Z \subset \overline{G}_0$ be a subset that is closed relative to the topology $\mathcal{T}_0'$; by definition, this means that $\pi'^{-1}_0 Z = Z + I_0$ is closed in $G_0$. Let $(Z + I_0)\overline{\epsilon}$ be the topological closure of $Z + I_0$ in $G$; it is easily seen that $(Z + I_0)\overline{\epsilon} = \pi'^{-1}_0(\pi'((Z + I_0)\overline{\epsilon}))$, so $\pi'((Z + I_0)\overline{\epsilon})$ is closed in $\overline{G}'$, and hence $\overline{G_0} \cap \pi'((Z + I_0)\overline{\epsilon})$ is closed in $\overline{G_0}$, relative to the topology $\mathcal{T}'_0$; lastly

$$\overline{G_0} \cap \pi'((Z + I_0)\overline{\epsilon}) = (G_0 \cap (Z + I_0)\overline{\epsilon})/I_0 = (Z + I_0)/I_0 = Z$$

since $Z + I_0$ is closed in $G_0$. The assertion follows. \[\square\]

**Lemma 8.2.5.** Let $f : G \to H$ and $g : H \to K$ be two continuous homomorphisms of topological groups. If $g \circ f$ is an open map, the same holds for $g$. 
Remark 8.2.7. rated topological groups.

Define the category of abelian topological groups (with morphisms given by the continuous group homomorphisms) and its full subcategory whose objects are the complete and separated groups, respectively the category of abelian topological groups (with morphisms given by the continuous group homomorphisms) and its full subcategory whose objects are the complete and separated groups.

Definition 8.2.6. Let \( G \) be any abelian topological group.

(i) A Cauchy net on \( G \) is a family \((g_\lambda \mid \lambda \in \Lambda)\) of elements of \( G \) indexed by a filtered partially ordered set \( \Lambda \), such that the following holds. For every open neighborhood \( U \) of the neutral element \( 0 \in G \) there exists \( \lambda \in \Lambda \) such that \( g_\mu - g_\nu \in U \) for every \( \mu, \nu \geq \lambda \).

(ii) We say that two Cauchy nets \( g_\ast := (g_\lambda \mid \lambda \in \Lambda) \) and \( g'_\ast := (g'_\lambda' \mid \lambda' \in \Lambda') \) of \( G \) are equivalent, and we write \( g_\ast \sim g'_\ast \), if the following holds. For every open neighborhood \( U \) of \( 0 \in G \) there exist \( \lambda \in \Lambda \) and \( \lambda' \in \Lambda' \) such that \( g_\mu - g'_\mu \in U \) for every \( \mu \geq \lambda \) and every \( \mu' \geq \lambda' \).

(iii) We say that an element \( h \in G \) is a limit point for the Cauchy net \( g_\ast := (g_\lambda \mid \lambda \in \Lambda) \) if \( g_\ast \) is equivalent to the trivial Cauchy net \( (h, \lambda' := h \mid \lambda' \in \Lambda' \) indexed by a partially ordered set \( \Lambda' \) that has exactly one element. In this case, we also say that \( g_\ast \) converges to \( h \in G \).

(iv) We say that \( G \) is complete if every Cauchy net of \( G \) admits a limit point. We denote by

\[
\text{AbTopGrp} \quad \text{and} \quad \text{AbTopGrp}_{\text{cp,sep}}.
\]

respectively the category of abelian topological groups (with morphisms given by the continuous group homomorphisms) and its full subcategory whose objects are the complete and separated topological groups.

Remark 8.2.7. (i) In view of remark 8.2.7(vii), it is easily seen that an abelian topological group \( G \) is separated if and only if every Cauchy net of \( G \) admits at most one limit point. In this case, the unique limit point of a Cauchy net \( (g_\lambda \mid \lambda \in \Lambda) \) shall be often denoted

\[
\lim_{\lambda \in \Lambda} g_\lambda.
\]

(ii) Moreover, it is easily seen that the relation \( \sim \) introduced by definition 8.2.6 is indeed an equivalence relation on the set of all Cauchy nets on \( G \). Clearly, if \( g_\ast \sim g'_\ast \), then an element \( h \in G \) is a limit point for \( g_\ast \) if and only if it is a limit point for \( g'_\ast \).

(iii) Furthermore, if \( \varphi : G \to G' \) is a continuous group homomorphism of topological abelian groups, and \((g_\lambda \mid \lambda \in \Lambda)\) a Cauchy net of \( G \), then \( \varphi(g_\ast) := (\varphi(g_\lambda) \mid \lambda \in \Lambda) \) is a Cauchy net of \( G' \), and if \( g'_\ast \) is another Cauchy net of \( G \) with \( g_\ast \sim g'_\ast \), then \( \varphi(g_\ast) \sim \varphi(g'_\ast) \).

(iv) Suppose that \( G \) is complete and separated, and let \( H \subset G \) be any subgroup, that we endow with the topology induced by \( G \). Then it is easily seen that \( H \) is complete if and only if it is topologically closed in \( G \).

Theorem 8.2.8. (i) The inclusion functor \( \text{AbTopGrp}_{\text{cp,sep}} \to \text{AbTopGrp} \) admits a left adjoint

\[
\text{AbTopGrp} \to \text{AbTopGrp}_{\text{cp,sep}.} \quad (G, \mathcal{T}) \mapsto (G^\wedge, \mathcal{T}^\wedge)
\]

called the completion functor.

(ii) For every topological abelian group \((G, \mathcal{T})\), the unit of adjunction \( i_G : G \to G^\wedge \) is called the completion map of \( G \). It has dense image, and \( \mathcal{T} \) agrees with the topology induced by \( \mathcal{T}^\wedge \) via \( i_G \).

(iii) Let \( \varphi : (G, \mathcal{T}) \to (G', \mathcal{T}') \) be a morphism of topological abelian groups with dense image and with \( G' \) complete and separated, and such that \( \mathcal{T} \) agrees with the topology induced by \( \mathcal{T}' \) via \( \varphi \). By the adjunction of (i), the map \( \varphi \) factors through \( i_G \) and a unique continuous group homomorphism \( \varphi^\wedge : G^\wedge \to G' \), and \( \varphi^\wedge \) is an isomorphism of topological groups.
Proof. Let \((G, +, 0)\) be any topological abelian group. We let \(G^\wedge\) be the set of equivalence classes of Cauchy nets of \(G\). For any such Cauchy net \(g_\bullet\), we denote by \([g_\bullet]\) the class of \(g_\bullet\) in \(G^\wedge\). We define a composition law on \(G^\wedge\) as follows. Given two Cauchy nets \(g_\bullet := (g_\lambda | \lambda \in \Lambda)\) and \(g'_\bullet := (g'_{\lambda'} | \lambda' \in \Lambda')\), let \(\Lambda \times \Lambda'\) be the product of \(\Lambda\) and \(\Lambda'\) in the category of partially ordered sets (whose underlying set is the cartesian product of \(\Lambda\) and \(\Lambda'\)); it is easily seen that the family \(g''_{\bullet, \bullet} := (g_\lambda + g'_{\lambda'} | (\lambda, \lambda') \in \Lambda \times \Lambda')\) is also a Cauchy net of \(G\), and we set

\[ [g_\bullet] + [g'_\bullet] := [g''_{\bullet, \bullet}] \]

One checks easily that \([g''_{\bullet, \bullet}]\) depends only on the classes of \(g_\bullet\) and \(g'_\bullet\), so we get by this rule a well defined mapping \(G^\wedge \times G^\wedge \rightarrow G^\wedge\). Clearly the neutral element for this addition law is the class \([0]\) of any constant Cauchy net \((0_\lambda | \lambda \in \Lambda)\) with \(0_\lambda := 0\) for every \(\lambda \in \Lambda\). Also, set \(-g_\bullet := (-g_\lambda | \lambda \in \Lambda)\); then it is easily seen that \([g_\bullet] + [-g_\bullet] = [0]\). The associativity and commutativity of the addition law are likewise immediate, so \(G^\wedge\) is indeed an abelian group.

Claim 8.2.9. The set \(G^\wedge\) is essentially small.

Proof of the claim. Let \(g_\bullet := (g_\lambda | \lambda \in \Lambda)\) be any Cauchy net of \(G\). Fix any fundamental system \(\mathcal{U}\) of open neighborhoods of \(0\) in \(G\), and endow it with the partial ordering such that \(U \leq U'\) if and only \(U' \subseteq U\), for every \(U, U' \in \mathcal{U}\); for every \(U \in \mathcal{U}\) there exists \(\lambda(U) \in \Lambda\) such that \(g_\lambda - g_\mu \in U\) for every \(\lambda, \mu \geq \lambda(U)\). It is easily seen that the family \((g_\lambda(U) | U \in \mathcal{U})\) is a Cauchy net of \(G\) equivalent to \(g_\bullet\). Thus, \(G^\wedge\) has the cardinality of the set of equivalence classes \(G^\wedge_{\mathcal{U}}\) of all Cauchy nets indexed by \(\mathcal{U}\); clearly \(\mathcal{U}\) is small, so the same holds for \(G^\wedge_{\mathcal{U}}\), whence the claim.

In light of claim 8.2.9 we may replace \(G^\wedge\) by an isomorphic small group, that we shall still denote by \(G^\wedge\). We also have a natural group homomorphism

\[ i_G : G \rightarrow G^\wedge \quad g \mapsto [g] \]

that assigns to every \(g \in G\) the class of any constant Cauchy net with value \(g\). Next, by remark 8.2.2(i), we may find a fundamental system \(\mathcal{U}\) of open neighborhoods of \(0\) in \(G\) such that \(-U = U\) for every \(U \in \mathcal{U}\); for every \(U \in \mathcal{U}\), we denote by \(U^\wedge \subseteq G^\wedge\) the subset consisting of the classes of all Cauchy nets \((g_\lambda | \lambda \in \Lambda)\) fulfilling the following condition. There exists \(U' \in \mathcal{U}\) such that \(g_\lambda + U' \subseteq U\) for every \(\lambda \in \Lambda\).

Claim 8.2.10. The system \(\mathcal{U}^\wedge := (U^\wedge | U \in \mathcal{U})\) fulfills conditions (a)-(e) of remark 8.2.2(iii).

Proof of the claim. Indeed, (a) and (d) are obvious. To see that (b) holds, let \((g_\lambda | \lambda \in \Lambda)\) be any Cauchy net, and \(U', U \in \mathcal{U}\) such that \(g_\lambda + U' \subseteq U\) for every \(\lambda \in \Lambda\); then \(-g_\lambda + (-U') \subseteq -U\), i.e. \(-g_\lambda + U' \subseteq U\) for every \(\lambda \in \Lambda\), whence the contention. Next, for any \(U \in \mathcal{U}\), pick \(U' \in \mathcal{U}\) such that \(U' + U' \subseteq U\); to check (c) it suffices to show that \(U' + U' \subseteq U^\wedge\). Thus, say that \((g_\lambda | \lambda \in \Lambda)\) and \((g'_{\lambda'} | \lambda' \in \Lambda')\) are two Cauchy nets whose classes lie in \(U^\wedge\), and choose \(U'' \in \mathcal{U}\) such that \(g_\lambda + U'' \subseteq U'\) for every \(\lambda \in \Lambda\) and every \(\lambda' \in \Lambda'\); it follows that \(g_\lambda + g'_{\lambda'} + U'' \subseteq U' + U' \subseteq U\) for every such \(\lambda\) and \(\lambda'\), as arrested. To check (e), let \((g_\lambda | \lambda \in \Lambda)\) be a Cauchy net, \(U, U' \in \mathcal{U}\) such that \(g_\lambda + U' \subseteq U\) for every \(\lambda \in \Lambda\), and \((g'_{\lambda'} | \lambda' \in \Lambda)\) another Cauchy net such that there exists \(U'' \in \mathcal{U}\) with \(g'_{\lambda'} + U'' \subseteq U'\) for every \(\lambda' \in \Lambda'\); it follows that \(g_\lambda + g'_{\lambda'} + U'' \subseteq U\) for every such \(\lambda\) and \(\lambda'\), whence the contention.

From claim 8.2.10 and remark 8.2.2(iii) we deduce that there exists a unique topology \(\mathcal{T}^\wedge\) on \(G^\wedge\) for which \(\mathcal{U}^\wedge\) is a fundamental system of open neighborhoods of \(0\), and \((G^\wedge, \mathcal{T}^\wedge)\) is a topological group. Moreover, we claim that

\[ i_G(U^\wedge) = U \quad \text{for every } U \in \mathcal{U}. \]

Indeed, the inclusion \(U \subseteq i_G^{-1}(U^\wedge)\) is obvious. For the converse, suppose that the class of the Cauchy net \(g_\bullet := (g_\lambda | \lambda \in \Lambda)\) lies in \(U^\wedge\), and there exists \(h \in G\) such that \(i_G(h) = [g_\bullet]\). This
means that there exists $U' \in \mathcal{U}$ such that $g_{\lambda} + U' \subset U$ for every $\lambda \in \Lambda$ and $\lambda_0 \in \Lambda$ such that $h - g_{\lambda} \in U'$ for every $\lambda \geq \lambda_0$; thus, $h, g_{\lambda} + U' \subset U$, whence the contention. Taking into account remark 8.2.2(vi), it follows that $i_G$ is a continuous group homomorphism, and more precisely, the topology of $G$ agrees with the topology induced by $\mathcal{J}^\Lambda$ via $i_G$. Furthermore, it is clear that the image of $i_G$ is dense in $G^\Lambda$. Let us remark, more precisely:

\textbf{Claim 8.2.11.} (i) For every $U \in \mathcal{U}$ and every open subset $V \subset G^\Lambda$, we have:

$$V \subset U^\Lambda \iff i_G^{-1}V \subset U.$$  

(ii) For every $U \in \mathcal{U}$, the subset $U^\Lambda$ lies in the topological closure $i_G(U)^c$ of $i_G(U)$ in $G^\Lambda$.

\textbf{Proof of the claim.} (i): By the foregoing, we know already that if $V \subset U^\Lambda$, then $i_G^{-1}V \subset U$. Conversely, suppose that $i_G^{-1}V \subset U$, and let $h \in V \setminus U^\Lambda$; then $h$ is the class of a Cauchy net $h_* := (h_\lambda \mid \lambda \in \Lambda)$ with the following property. For every $U' \in \mathcal{U}$ there exist $x_{U'} \in U'$ and $\lambda(U') \in \Lambda$ such that $g_{\lambda(U')} := h_{\lambda(U')} + x_{U'} \notin U$. It is easily seen that the family $g_* := (g_{\lambda(U')} \mid U' \in \mathcal{U})$ is a Cauchy net of $G$ equivalent to $h_*$. We may thus replace $h_\lambda$ by $g_\lambda$, and assume from start that $h_\lambda \in G \setminus U$ for every $\lambda \in \Lambda$. Next, since $V$ is open in $G^\Lambda$, and since we know already that $i_G$ is continuous, there exists $\lambda \in \Lambda$ such that $i_G(h_\lambda) \in V$; by assumption, this implies that $h_\lambda \in U$, a contradiction.

(ii): Explicitly, $i_G(U)^c$ is the set of equivalence classes of all Cauchy nets $g_* := (g_\lambda \mid \lambda \in \Lambda)$ such that $((g_\lambda + V') \cap i_G(U)) \neq \emptyset$ for every $V' \in \mathcal{U}$. Now, suppose that $[g_*] \in U^\Lambda$, so we may assume that $g_{\lambda_0} \in U$ for every $\lambda \in \Lambda$, and for any given $V \in \mathcal{U}$ pick $V' \in \mathcal{U}$ such that $V' + V' \subset V$; we may then find $\lambda(V') \in \Lambda$ such that $g_\lambda - g_{\lambda'} \in V'$ for every $\lambda, \lambda' \geq \lambda(V')$. Set $\Lambda' := \{\lambda \in \Lambda \mid \lambda \geq \lambda(V')\}$, $h := g_{\lambda(V')}$ and $k_\lambda := h - g_\lambda$ for every $\lambda \in \Lambda'$. Clearly $k_* := (k_\lambda \mid \lambda \in \Lambda')$ is a Cauchy net, $h \in U$ and $[g_*] + [k_*] = i_G(h)$; lastly, we have $k_{\lambda} + V' \subset V' \subset V$ for every $\lambda \in \Lambda'$, whence $[k_*] \in V^\Lambda$.\hfill\Box

\textbf{Claim 8.2.12.} $(G^\Lambda, \mathcal{J}^\Lambda)$ is complete and separated.

\textbf{Proof of the claim.} Let $(g_{*,i} \mid i \in I)$ a family of Cauchy nets of $G$ indexed by a partially ordered set $I$, such that $([g_{*,i}] \mid i \in I)$ is a Cauchy net in $G^\Lambda$. Hence, for every $i \in I$ we have a partially ordered set $\Lambda_i$ such that $g_{*,i} := (g_\lambda \mid \lambda \in \Lambda_i)$. For every $U \in \mathcal{U}$ we may find $i(U) \in I$ such that $[g_{*,i(U)}] - [g_{*,j(U)}] \in U^\Lambda$ for every $j \geq i(U)$. The latter means that there exist a Cauchy net $(h_k \mid k \in K)$ of $G$ and $U' \in \mathcal{U}$ such that $h_k + U' \subset U$ for every $k \in K$, as well as $\lambda(U') \in \Lambda(U'), \mu(U', j') \in \Lambda_j$ and $k_0 \in K$ such that $g_{\mu,j} - g_{\lambda(U') \mu(U', j')} - h_k \in U'$ for every $k \geq k_0$, every $\mu \geq \mu(U', j)$ and every $\lambda \geq \lambda(U')$. Therefore $g_{\mu,j} \in g_{\lambda(U') \mu(U', j)}, h_k \subset g_{\lambda(U') \mu(U', j)} + U$ for every such $j, \mu$ and $\lambda$. Last, we may also assume that $g_{\lambda(U') \mu(U', j)} - g_{\lambda(U') \mu(U', j)} \in U$ for every $\lambda \geq \lambda(U')$, whence $g_{\mu,j} \in g_{\lambda(U') \mu(U', j)} + U$ for every $j \geq i(U)$ and every $\mu \geq \mu(U', j)$. Hence, the system $l_* := (h_\mu \mid [g_{*,i(U)}] \in \mathcal{U})$ is a Cauchy net in $G$ (for the partial ordering on $\mathcal{U}$ such that $U \leq U'$ if and only if $U' \subset U$, for every $U, U' \in \mathcal{U}$), and it is easily seen that $[l_*]$ is a limit point of $([g_{*,i}] \mid i \in I)$, which shows that $G^\Lambda$ is complete.

Lastly, suppose that $g_* := (g_\lambda \mid \lambda \in \Lambda)$ is a Cauchy net such that $[g_*]$ lies in $U^\Lambda$ for every $U \in \mathcal{U}$. This means that for every such $U$ there exists a Cauchy net $h_{\lambda(U')} := (h_{\lambda(U')}^{(U)} \mid \lambda(U') \in \Lambda(U))$ such that $h_{\lambda(U')} \in U$ for every $\lambda(U') \in \Lambda(U)$ and such that $g_{*,i(U')} \sim h_{\lambda(U')}^{(U)}$. The latter condition implies that there exist $\lambda(U) \in \Lambda$ and $\Lambda(U) \in \Lambda(U)$ such that $g_{\lambda(U)} - h_{\lambda(U)}^{(U)} \in U$ for every $\lambda \geq \lambda(U)$ and every $\lambda' \geq \lambda(U')$. We conclude that $g_{\lambda(U)} \in U + U$ for every $\lambda \geq \lambda(U)$, so $g_{*,i(U)}$ is equivalent to $[0]$, which shows that $G^\Lambda$ is separated.\hfill\Box

Next, consider a continuous group homomorphism $\varphi : G \to H$ to a complete and separated topological abelian group $H$. In view of remark 8.2.7(i,iii), it follows easily that $\varphi$ factors through $i_G$ and the group homomorphism $\varphi^\Lambda : G^\Lambda \to H$ that assigns to every equivalence class $[g_*]$ the unique limit point of the Cauchy net $\varphi(g_*)$ in $H$. In view of remark 8.2.2(vi), we need to check that $\varphi^\Lambda$ is continuous at the point $0$. Thus, let $V \subset H$ be any open neighborhood of the
neutral point $0_H$ of $H$, and let $g_* := (g_\lambda | \lambda \in \Lambda)$ be a Cauchy net in $G$ with $h := \varphi^\vee([g_*]) \in V$; we may find an open neighborhood $V'$ of $0_H$ in $H$ such that $V' = -V'$ and $h + V' + V' + V' \subset V$, and set $U := \varphi^{-1}V'$, so that $U = -U$. Now, let $g'_* := (g'_\lambda | \lambda' \in \Lambda')$ be any Cauchy net in $G$ such that $[g'_*] \in [g_*] + U^\wedge$. The condition means that there exist a Cauchy net $(h_i | i \in I)$ in $G$ and an open neighborhood $U'$ of $0$ in $G$ such that $h_i + U' \subset U$ for every $i \in I$, and moreover there exist $\lambda_0 \in \Lambda$, $\lambda'_0 \in \Lambda'$, and $i_0 \in I$ such that $g'_\lambda - g_\lambda - h_{i_0} \in U'$ for every $\lambda \geq \lambda_0$, every $\lambda' \geq \lambda'_0$, and every $i \geq i_0$. Thus, $g'_\lambda \in g_\lambda + U$, and consequently $\varphi(g'_\lambda) \in \varphi(g_\lambda) + V'$ for every $\lambda \geq \lambda_0$ and $\lambda' \geq \lambda'_0$. Set $h' := \varphi^\vee([g'_*])$; we may also assume that $\varphi(g_\lambda) - h, h' - \varphi(g'_\lambda) \in V'$ for every $\lambda \geq \lambda_0$ and every $\lambda' \geq \lambda'_0$. We deduce that

$$h' \in \varphi(g'_\lambda) + V' \subset \varphi(g_\lambda) + V' \subset h + V' \subset V$$

i.e. $\varphi^\vee([g_*] + U^\wedge) \subset V$, whence the assertion. Lastly, since the image of $i_G$ is dense in $G^\wedge$, the uniqueness of $\varphi^\wedge$ is clear.

(iii): The existence of the continuous group homomorphism $\varphi^\wedge : G^\wedge \to G'$ has just been established. Next, since $\varphi$ has dense image, every $g' \in G'$ is the unique limit point of a Cauchy net of $G'$ of the form $(\varphi(g_\lambda) | \lambda \in \Lambda)$ for a family $g_* := (g_\lambda | \lambda \in \Lambda)$ of elements of $G$, and since $\mathcal{T}$ agrees with the topology induced by $\mathcal{T}'$, it is easily seen that $g_*$ is a Cauchy net in $G$. It then follows that $\varphi^\vee([g_*]) = g'$, which shows that $\varphi^\wedge$ is surjective. Let $g_* := (g_\lambda | \lambda \in \Lambda)$ be a Cauchy net in $G$ whose class $[g_*]$ lies in the kernel of $\varphi^\wedge$; this means that $([\varphi(g_\lambda) | \lambda \in \Lambda])$ converges to $0$ in $G'$, and since $\mathcal{T}$ is induced by $\mathcal{T}'$, it follows easily that $g_*$ converges to $0$ in $G$, which shows that $\varphi^\vee$ is also injective. It remains therefore only to check that the topology on $G^\wedge$ induced by $\mathcal{T}'$ via $\varphi^\wedge$ is finer than $\mathcal{T}^\wedge$. To this aim, consider any $U \in \mathcal{U}$; by assumption, there exists an open neighborhood $W$ of $0$ in $G'$ such that $\varphi^{-1}W \subset U$. Set $V := \varphi^\wedge W$; then $i_G^{-1}V \subset U$, and therefore $V \subset U^\wedge$, by virtue of claim 8.2.11(i). Since $\mathcal{U}^\wedge$ is a fundamental system of open neighborhoods of $0$ in $G^\wedge$, the assertion follows. \hfill $\Box$

**Proposition 8.2.13.** Let $(G, \mathcal{T}_G)$ be a topological abelian group, $H \subset G$ a subgroup, and endow $H$ (resp. $G/H$) with the topology $\mathcal{T}_H$ (resp. $\mathcal{T}_{G/H}$) induced by $\mathcal{T}_G$ via the inclusion map $j : H \to G$ (resp. via the projection $\pi : G \to G/H$). Let also $i_G : G \to G^\wedge$ be the completion map. Then we have:

(i) The resulting sequence of separated completions is exact:

$$0 \to H^\wedge \xrightarrow{j^\wedge} G^\wedge \xrightarrow{\pi^\wedge} (G/H)^\wedge.$$

(ii) The topology $\mathcal{T}_H^\wedge$ of $H^\wedge$ agrees with the one induced by the topology $\mathcal{T}_G^\wedge$ of $G^\wedge$ via $j^\wedge$.

(iii) The image of $j^\wedge$ is the topological closure in $G^\wedge$ of $i_G(H)$.

(iv) Endow $L := G^\wedge/H^\wedge$ with the quotient topology $\mathcal{T}_L$ induced by $G^\wedge$ via the projection $G^\wedge \to L$. Also, let $k : L \to (G/H)^\wedge$ be the injective map deduced from $\pi^\wedge$. Then $\mathcal{T}_L$ agrees with the subspace topology induced by $(G/H)^\wedge$ via $k$.

(v) Suppose that $G$ admits a countable fundamental system of open neighborhoods of $0$. Then $\pi^\wedge$ is surjective.

**Proof.** (i): Let $g_* := (g_\lambda | \lambda \in \Lambda)$ be a Cauchy net of $H$; a direct inspection of the definitions shows that $0$ is a limit point of $\varphi^\vee([g_*])$, relative to the topology $\mathcal{T}_G$ of $G$, whence the injectivity of $\varphi^\vee$. Next, by functoriality we have $\pi^\wedge j^\wedge = (\pi \circ j)^\wedge = 0 : H^\wedge \to (G/H)^\wedge$. To conclude, suppose then that $g_* := (g_\lambda | \lambda \in \Lambda)$ is a Cauchy net of $G$ such that $\pi(g_\lambda) := (\pi(g_\lambda) | \lambda \in \Lambda)$ admits $0$ as limit point, and pick a fundamental system $\mathcal{U}$ of open neighborhoods of $0$ in $G$; the assertion means that for every $U \in \mathcal{U}$ there exists $\lambda(U) \in \Lambda$ such that $\pi(g_\lambda) \in \pi(U)$ for every $\lambda \geq \lambda(U)$, i.e. $g_\lambda \in H + U := \{h + u | h \in H, u \in U\}$ for every such $\lambda$. Thus, for every $U \in \mathcal{U}$ pick $h_U \in H$ such that $g_U(M_U) - h_U \in U$; it follows that the families $(g_\lambda(U) | U \in \mathcal{U})$ and $h_* := (h_U | U \in \mathcal{U})$ are also
Cauchy nets in \(G\), and
\[
g_{\bullet} \sim (g_{\lambda \in \Lambda} \mid U \in \mathcal{U}) \sim h_{\bullet}
\]
which shows that the class of \(g_{\bullet}\) in \(G^\wedge\) lies in the image of \(j^\wedge\), as stated.

(ii): Let \(h_{\bullet} := (h_{\lambda} \mid \lambda \in \Lambda)\) be a Cauchy net of \(H\) whose class \([h_{\bullet}] \in H^\wedge\) lies in \(j^\wedge -1 (U^\wedge)\), for a given \(U \in \mathcal{U}\) (notation of the proof of theorem 8.2.8); this means that there exist a Cauchy net \(g_{\bullet} := (g_{\lambda} \mid \lambda' \in \Lambda')\) of \(G\), and \(U' \in \mathcal{U}\), such that \(g_{\lambda'} + U' \subset U\) for every \(\lambda' \in \Lambda'\), and such that \(h_{\bullet} \sim g_{\bullet}\). Pick any \(U'' \in \mathcal{U}\) such that \(U'' + U'' \subset U';\) after replacing \(\Lambda\) and \(\Lambda'\) by some cofinal subsets, we may assume that \(h_{\lambda} - g_{\lambda} \in U''\) for every \(\lambda \in \Lambda\) and every \(\lambda' \in \Lambda'.\) Whence, \(h_{\lambda} + U'' \in g_{\lambda'} + U'' \subset U\) for every \(\lambda \in \Lambda,\) which shows that \(H^\wedge \cap U^\wedge \subset (H \cap U)^\wedge.\) The converse inclusion is clear, and the assertion follows.

(iii): On the one hand, the image of \(j^\wedge\) is a complete subgroup of \(G^\wedge,\) so it is topologically closed (remark 8.2.7(iv)); on the other hand, \(i_{G}(H)\) is dense in \(H^\wedge,\) whence the contention.

(iv): Denote by \((G, \mathcal{T}_G)\) the maximal separated quotient of \(G\) (i.e. the quotient \(G/\{0\}^c\), where \(\{0\}^c\) denotes the topological closure of \(\{0\}\) in \(G\)), endowed with the quotient topology induced by \(G;\) let also \(\overline{H}\) be the topological closure of the image of \(H\) in \(G\), and endow \(\overline{H}\) with the topology \(\mathcal{T}_{H}\) induced by \(\mathcal{T}_G\) via the inclusion map \(\overline{H} \rightarrow \overline{G}\). Endow as well \(\overline{G}/\overline{H}\) with the quotient topology \(\mathcal{T}_{G/H}\) induced by \(\overline{G};\) we get a sequence of separated abelian topological groups
\[
0 \rightarrow \overline{H} \rightarrow \overline{G} \rightarrow \overline{G}/\overline{H} \rightarrow 0
\]
and after taking separated completions, a commutative ladder of continuous group homomorphisms:
\[
\begin{array}{ccc}
0 & \rightarrow & H^\wedge \\
\rightarrow & & \downarrow \\
0 & \rightarrow & (G/H)^\wedge
\end{array}
\]
On the other hand, it is easily seen that \(\mathcal{T}_H\) (resp. \(\mathcal{T}_{G/H}\)) agrees with the topology induced by \(\mathcal{T}_G\) (resp. by \(\mathcal{T}_{G/H}\)) via the natural map \(H \rightarrow \overline{H}\) (resp. \(G/H \rightarrow \overline{G}/\overline{H}\)): details left to the reader. It follows immediately that the central and right-most vertical arrows are isomorphisms of topological groups. By the 5-lemma, we deduce that the left-most vertical arrow is a group isomorphism; but then it is also a homeomorphism, by virtue of (ii). Summing up, we may replace \(G\) by \(\overline{G}\) and \(H\) by \(\overline{H}\), and assume from start that \(G\) is separated and \(H\) is topologically closed in \(G;\) especially, the completion map \(G \rightarrow G^\wedge\) is also injective. We now consider the commutative diagram of continuous group homomorphisms
\[
\begin{array}{ccc}
G/H & \xrightarrow{f} & L \\
\downarrow{i_{G/H}} & & \downarrow{k} \\
(G/H)^\wedge & \xrightarrow{g} & L^\wedge
\end{array}
\]
where \(i_{G/H}\) and \(i_L\) are the completion maps. By (iii) and lemma 8.2.3(ii), the map \(f\) is injective, and \(\mathcal{T}_{G/H}\) agrees with the topology induced by \(\mathcal{T}_L\) via \(f\). By theorem 8.2.8(ii), the topology \(\mathcal{T}_L\) in turn is induced via \(i_L\) by the topology \(\mathcal{T}_{L^\wedge}\) of its completion \(L^\wedge\). Thus, \(\mathcal{T}_{G/H}\) is induced by \(\mathcal{T}_{L^\wedge}\) via \(i_L \circ f;\) Lastly, \(i_L \circ f\) has dense image. Taking into account theorem 8.2.8(iii), we conclude that \(g\) is an isomorphism of topological groups, whence the assertion.

(v): Let \(\overline{g}_{\bullet} := (\overline{g}_{\lambda} \mid \lambda \in \Lambda)\) be a Cauchy net in \(G/H\), and pick a countable fundamental system \(\mathcal{U} := \{U_n \mid n \in \mathbb{N}\}\) of open neighborhoods of \(0\) in \(G\). A simple induction shows that we may assume:

\[
(8.2.14) \quad U_{n+1} + U_{n+1} \subset U_n \quad \text{for every } n \in \mathbb{N}.
\]
Now, for every \( n \in \mathbb{N} \) there exists \( \lambda(n) \in \Lambda \) such that \( \overline{g}_\lambda - \overline{g}_\mu \in \pi(U_n) \) for every \( \lambda, \mu \geq \lambda(n) \). It follows that the family \( (\overline{g}_{\lambda(n)} | n \in \mathbb{N}) \) is a Cauchy net in \( G/H \) equivalent to \( g_* \) (for the standard ordering on \( \mathbb{N} \)); thus, we may assume from start that the class \([g_*]\) in \((G/H)^{\wedge}\) is represented by a Cauchy sequence \( (\overline{g}_n | n \in \mathbb{N}) \) of \( G/H \), such that \( \overline{g}_{n+1} - \overline{g}_n \in \pi(U_n) \) for every \( n \in \mathbb{N} \). Pick an arbitrary sequence \( (g_n | n \in \mathbb{N}) \) in \( G \) with \( \pi(g_n) = \overline{g}_n \) for every \( n \in \mathbb{N} \); by construction, for every \( n \in \mathbb{N} \) there exists \( h_n \in H \) such that \( g_{n+1} + h_n - g_n \in U_n \). Set \( g'_n := g_n + \sum_{i=n}^{n-1} h_i \) for every \( n \in \mathbb{N} \); we then see that \( g'_{n+1} - g'_n \in U_n \) for every \( n \in \mathbb{N} \). Lastly, using (8.2.14), a simple induction shows more generally that \( g'_i - g'_j \in U_{n-1} \) whenever \( i \geq j > 0 \). Therefore \( g'_* := (g'_n | n \in \mathbb{N}) \) is a Cauchy sequence in \( G \), and clearly \( \pi^!(\langle g'_* \rangle) = [g_*] \), whence the contention. \( \square \)

**Corollary 8.2.15.** Suppose that the topological group \( G \) is the product of a (small) family \((G_i | i \in I)\) of topological groups, and for every \( i \in I \) denote by \( G_i^{\wedge} \) the separated completion of \( G_i \). Then the natural map \( j : G \to \prod_{i \in I} G_i^{\wedge} \) factors uniquely through the completion map \( G \to G^{\wedge} \) and an isomorphism of topological groups:

\[ G^{\wedge} \cong \prod_{i \in I} G_i^{\wedge}. \]

*Proof.* It is easily seen that the product \( P := \prod_{i \in I} G_i^{\wedge} \) is complete and separated; also, \( j \) has dense image, and the topology of \( G \) is induced by that of \( P \) via \( j \). Then the assertion follows from theorem 8.2.8[iii]. \( \square \)

**Corollary 8.2.16.** Let \( G_* := (G_i | i \in \text{Ob}(I)) \) be any system of topological abelian groups, indexed by any small category \( I \). We have:

(i) If \( G_i \) is complete and separated for every \( i \in \text{Ob}(I) \), then \( \lim_{\leftarrow i} G_* \) is a complete and separated topological abelian group.

(ii) Suppose that \( I \) is cofiltered and countable (see example 1.5.25), and that the system \( G_* \) satisfies the following Mittag-Leffler condition:

(ML) For every \( i \in \text{Ob}(I) \) there exists a morphism \( \varphi : j \to i \) in \( I \) such that for every morphism \( \psi : k \to j \) in \( I \) we have

\[ \text{Im}(G(\varphi \circ \psi) : G_k \to G_i) = \text{Im}(G(\varphi) : G_j \to G_i). \]

Then the natural map

\[ (\lim_{\leftarrow i} G_*)^{\wedge} \to \lim_{\leftarrow i} G_i^{\wedge} \]

is an isomorphism of topological groups.

*Proof.* (i): Indeed, the limit \( L \) of the system \( G_* \) is a closed subgroup of the product \( P := \prod_{i \in \text{Ob}(I)} G_i \), and the topology of \( L \) is induced by that of \( P \) via this closed inclusion map; then the assertion follows from corollary 8.2.15 and remark 8.2.7[iv].

(ii): In light of theorem 8.2.8[ii], it is easily seen that the topology of \( L \) is induced by that of \( L' := \lim_{\leftarrow i} G_i^{\wedge} \), via the natural map \( \beta : L \to L' \). Taking into account (i) and theorem 8.2.8[iii], we are then reduced to checking that \( \beta \) has dense image. Moreover, by virtue of example 1.5.25, we may assume that \( I \) is the totally ordered set \( \mathbb{N}^{\mathbb{N}} \). Now, for every \( i, j \in \mathbb{N} \) with \( j \geq i \) let \( \varphi_{j,i} : G_j \to G_i \) be the transition map; for every \( i \in \mathbb{N} \) we set

\[ H_i := \bigcap_{j \geq i} \text{Im} \varphi_{j,i} \]

and we endow \( H_i \) with the topology induced by \( G_i \). Condition (ML) easily implies that \( \varphi_{j,i} \) restricts to a surjective continuous group homomorphism \( H_j \to H_i \) for every \( i, j \in \mathbb{N} \) with \( j \geq i \), and the natural morphisms

\[ \lim_{\mathbb{N}^{\mathbb{N}}} H_* \to L \quad \lim_{\mathbb{N}^{\mathbb{N}}} H_*^{\wedge} \to L' \]
are isomorphisms of topological groups. We may then replace $G_\bullet$ by $H_\bullet$, and assume from start that the map $\varphi_{j,i}$ is a surjection, for every $j \geq i$. In this case we come down to checking that the inclusion map $H_i \to H_i^\wedge$ is dense for every $i \in \text{Ob}(I)$, which we know by theorem [8.2.3](ii).

**Corollary 8.2.17.** Let $G$ be any topological abelian group, $H \subset G$ an open subgroup, $G^\wedge$ and $H^\wedge$ the separated completions of $H$ and $G$, and $i_G : G \to G^\wedge$ the completion map. Then:

(i) $H^\wedge$ is an open subgroup of $G^\wedge$, and the natural map $G/H \to G^\wedge/H^\wedge$ is a group isomorphism.

(ii) $H = i_G^{-1}H^\wedge$.

(iii) Suppose that $G$ admits a fundamental system $(H_\lambda \mid \lambda \in \Lambda)$ of open neighborhoods of 0, consisting of open subgroups. Then $(H^\wedge_\lambda \mid \lambda \in \Lambda)$ is a fundamental system of open neighborhoods of 0 for $G^\wedge$.

**Proof.** Under these assumptions, $G$ induces the discrete topology on the quotient $G/H$, hence the latter is complete and separated; taking into account proposition [8.2.13](i,ii), we get an exact sequence

$$0 \to H^\wedge \to G^\wedge \to G/H$$

from which both (i) and (ii) follow easily. Assertion (iii) follows by inspecting the proof of theorem [8.2.8](i). □

**Proposition 8.2.18.** Let $G$, $H$, $K$ be three topological groups, and $\varphi : G \times H \to K$ a continuous and $\mathbb{Z}$-bilinear map. Let also $i_G : G \to G^\wedge$, $i_H : H \to H^\wedge$ and $i_K : K \to K^\wedge$ be the completion maps. Then there exists a unique continuous $\mathbb{Z}$-bilinear map

$$\varphi^\wedge : G^\wedge \times H^\wedge \to K^\wedge$$

such that $\varphi^\wedge \circ (i_G \times i_H) = i_K \circ \varphi$.

**Proof.** Let $x_\bullet := (x_\lambda \mid \lambda \in \Lambda)$ and $y_\bullet := (y_\lambda \mid \lambda' \in \Lambda')$ be two Cauchy nets in $G$ and respectively $H$, and let $\Lambda \times \Lambda'$ be the product of $\Lambda$ and $\Lambda'$ in the category of partially ordered sets; i.e. the product of the underlying sets, endowed with the partial ordering such that $(\lambda,\lambda') \leq (\mu,\mu')$ if and only if $\lambda \leq \mu$ and $\lambda' \leq \mu'$. Set $x^{(\lambda,\lambda')} := x_\lambda$ and $y^{(\lambda,\lambda')} := y_{\lambda'}$ for every $(\lambda,\lambda') \in \Lambda \times \Lambda'$; it is easily seen that the family $(x^{(\mu)} \mid \mu \in \Lambda \times \Lambda')$ is a Cauchy net in $G$ equivalent to $x_\bullet$, and likewise for the family $(y^{(\mu)} \mid \mu \in \Lambda \times \Lambda')$. Thus, we may replace $\Lambda$ and $\Lambda'$ by $\Lambda \times \Lambda'$, after which we may assume that $\Lambda = \Lambda'$.

**Claim 8.2.19.** The family $(\varphi(x_\lambda, y_\lambda) \mid \lambda \in \Lambda)$ is a Cauchy net of $K$.

**Proof of the claim.** Indeed, let $\mathcal{U}_G$, $\mathcal{U}_H$ and $\mathcal{U}_K$ be fundamental systems of open neighborhoods of the neutral element for respectively $G$, $H$ and $K$, fulfilling conditions (a)-(e) of remark [8.2.2](iii); since $\varphi$ is continuous for the product topology on $G \times H$, for every $V \in \mathcal{U}_K$ there exist $U_1 \in \mathcal{U}_G$ and $U_2 \in \mathcal{U}_H$ such that $\varphi(U_1 \times U_2) \subset V$. On the other hand, there exists $\lambda(V) \in \Lambda$ such that $x_\lambda - x_\mu \in U_1$ and $y_\lambda - y_\mu \in U_2$ for every $\lambda, \mu \geq \lambda(V)$. It follows that

$$v^{(1)}_{\lambda,\mu} := \varphi(x_\lambda - x_\mu, y_\lambda - y_\lambda(V)), v^{(2)}_{\lambda,\mu} := \varphi(x_\mu - x_\lambda(V), y_\lambda - y_\mu) \in V$$

for every $\lambda, \mu \geq \lambda(V)$.

Moreover, the continuity of $\varphi$ also yields $\beta(V) \in \Lambda$ such that

$$v^{(3)}_{\lambda,\mu} := \varphi(x_\lambda - x_\mu, y_\lambda(V)), v^{(4)}_{\lambda,\mu} := \varphi(x_\lambda(V), y_\lambda - y_\mu) \in V$$

and clearly we may assume that $\beta(V) \geq \lambda(V)$ for every $V \in \mathcal{U}_K$. We deduce

$$\varphi(x_\lambda, y_\lambda) - \varphi(x_\mu, y_\mu) = v^{(1)}_{\lambda,\mu} + v^{(2)}_{\lambda,\mu} + v^{(3)}_{\lambda,\mu} + v^{(4)}_{\lambda,\mu} \in V + V + V + V$$

for every $\lambda, \mu \geq \beta(V)$

whence the contention. □
In view of claim \[8.2.19\], we denote by \(\varphi(x_\bullet, y_\bullet) := \lim_{\lambda\in\Lambda} \varphi(x_\lambda, y_\lambda) \in K^\wedge\). Next, we consider the group homomorphism
\[\varphi_{x_\bullet} : H \to K^\wedge \quad y \mapsto \lim_{\lambda\in\Lambda} \varphi(x_\lambda, y).\]
It is easily seen that \(\varphi_{x_\bullet}\) is a continuous map, hence it factors uniquely through \(i_H\) and a continuous group homomorphism \(\varphi_{x_\bullet}^\wedge : H^\wedge \to K^\wedge\).

Claim 8.2.20. \(\varphi(x_\bullet, y_\bullet) = \varphi_{x_\bullet}^\wedge(\lim_{\lambda\in\Lambda} y_\lambda)\).

Proof of the claim. We resume the notation of the proof of claim \[8.2.19\] and notice that
\[\varphi(x_\lambda, y_\lambda) - \varphi(x_\mu, y_\lambda) = v_{1,\lambda\mu}^{(1)} + v_{2,\lambda\mu}^{(3)} \in V + V \quad \text{for every } \lambda, \mu \geq \beta(V).\]
On the other hand, we may find \(\gamma(V) \geq \beta(V)\) in \(\Lambda\) such that
\[\varphi(x_\lambda, y_\lambda) - \varphi(x_\lambda, y_\lambda) \in V \quad \text{for every } \lambda \geq \gamma(V)\]
as well as an element \(\delta(V) \geq \gamma(V)\) in \(\Lambda\) such that
\[\varphi(x_\mu, y_\gamma(V)) - \varphi(x_\mu, y_\gamma(V)) \in V \quad \text{for every } \mu \geq \delta(V).\]
Summing up, we conclude that
\[\varphi(x_\bullet, y_\bullet) - \varphi_{x_\bullet}^\wedge(y_\bullet) \in V + V + V \quad \text{for every } \mu \geq \delta(V)\]
and since \(V\) is arbitrary, the assertion follows. ☐

Claim \[8.2.20\] shows that \(\varphi(x_\bullet, y_\bullet)\) depends only the class \(y_\bullet\) of \(y_\bullet\) in \(H^\wedge\). Swapping the roles of \(x_\bullet\) and \(y_\bullet\), one may define a similar map \(\varphi_{y_\bullet} : G^\wedge \to K^\wedge\) such that \(\varphi_{y_\bullet}^\wedge(x_\bullet) = \varphi(x_\bullet, y_\bullet)\) as well, which says likewise that \(\varphi(x_\bullet, y_\bullet)\) depends only on the class \(x_\bullet\) of \(x_\bullet\) in \(G^\wedge\), so we obtain a bilinear map \(\varphi^\wedge : G^\wedge \times H^\wedge \to K^\wedge\) as sought, and it remains only to check that \(\varphi^\wedge\) is continuous. To this end, define the fundamental systems \(\mathcal{U}_L^\wedge, \mathcal{U}_H^\wedge, \mathcal{U}_K^\wedge\) of open neighborhoods of the neutral element respectively in \(G^\wedge, H^\wedge\) and \(K^\wedge\), as in the proof of theorem \[8.2.8\] we remark:

Claim 8.2.21. For every \(W^\wedge \in \mathcal{U}_K^\wedge\) there exist \(U^\wedge \in \mathcal{U}_G^\wedge, V^\wedge \in \mathcal{U}_H^\wedge\) with \(\varphi^\wedge(U^\wedge \times V^\wedge) \subset W^\wedge\).

Proof of the claim. Choose \(W^\wedge \in \mathcal{U}_H\) such that \(W^\wedge + W^\wedge \subset W\); then we may find \(U \in \mathcal{U}_G, V \in \mathcal{U}_H\) such that \(\varphi(U \times V) \subset W^\wedge\), whence \(\varphi(U \times V) + W^\wedge \subset W^\wedge\). It follows easily that the corresponding open neighborhoods \(U^\wedge, V^\wedge\) will do. ☐

Now, for a given \(W^\wedge \in \mathcal{U}_K^\wedge\), pick \(U^\wedge \in \mathcal{U}_G^\wedge, V^\wedge \in \mathcal{U}_H^\wedge\) as in claim \[8.2.21\], we may also assume that \(\varphi_{x_\bullet}^\wedge(V^\wedge) \subset W^\wedge\) and \(\varphi_{y_\bullet}^\wedge(U^\wedge) \subset W^\wedge\). It follows that
\[\varphi^\wedge((x + U^\wedge) \times (y + V^\wedge)) - \varphi^\wedge(x, y) \subset \varphi^\wedge(U^\wedge \times V^\wedge) + \varphi_{x_\bullet}^\wedge(V^\wedge) + \varphi_{y_\bullet}^\wedge(U^\wedge) \subset W^\wedge + W^\wedge + W^\wedge\]
whence the contention. Lastly, the uniqueness of \(\varphi^\wedge\) is clear, since the image of \(G \times H\) is dense in \(G^\wedge \times H^\wedge\). ☐

8.3. **Topological rings and topological modules.** If \(T\) is any topological space and \(S \subset T\) any subset, we shall denote by \(S^c\) the topological closure of \(S\) in \(T\).

**Definition 8.3.1.** (i) A **topological ring** is a pair \((A, \mathcal{T}_A)\) where \(A\) is a (commutative, unital) ring and \(\mathcal{T}_A\) a topology on the set underlying \(A\), such that:
- the multiplication law of \(A\) is a continuous map \((A, \mathcal{T}_A) \times (A, \mathcal{T}_A) \to (A, \mathcal{T}_A)\)
- the pair \(((+), (0)), (\mathcal{T}_A)\) is a topological group.

(ii) Let \((A, \mathcal{T}_A)\) be a topological ring, \(M\) an \(A\)-module, \(\mathcal{T}_M\) a topology on the set underlying \(M\). We say that \((M, \mathcal{T}_M)\) is a **topological \((A, \mathcal{T}_A)\)-module** (briefly: a **topological \(A\)-module**) if
- the scalar multiplication is a continuous map \((A, \mathcal{T}_A) \times (M, \mathcal{T}_M) \to (M, \mathcal{T}_M)\)
- the pair \(((+, (0)), \mathcal{T}_M)\) is a topological abelian group.
(iii) Let \((A, \mathcal{T}_A), (B, \mathcal{T}_B)\) be two topological rings. A morphism of topological rings is a ring homomorphism \(A \to B\) that is continuous for the topologies \(\mathcal{T}_A\) and \(\mathcal{T}_B\). Such a morphism \((A, \mathcal{T}_A) \to (B, \mathcal{T}_B)\) is also called a topological \((A, \mathcal{T}_A)\)-algebra. The topological \(A\)-algebras form a category

\[A\text{-TopAlg}\]

whose morphisms are the continuous \(A\)-algebra homomorphisms. Especially, the ring \(\mathbb{Z}\) with its discrete topology is a topological ring, and \(\mathbb{Z}\text{-TopAlg}\) is the category of topological rings and continuous ring homomorphisms.

(iv) Let \((A, \mathcal{T}_A)\) be a topological ring, \(B \to A\) a ring homomorphism, \((M, \mathcal{T}_M)\) a topological \(A\)-module. We say that the topology \(\mathcal{T}_M\) is \(B\)-linear if there exists a fundamental system of open neighborhoods of \(0 \in M\) for the topology \(\mathcal{T}_M\), consisting of \(B\)-submodules of \(M\).

(v) Especially, in the situation of (iv) we say that the topology \(\mathcal{T}_A\) is \(B\)-linear, if the same holds for the topological \(A\)-module \((A, \mathcal{T}_A)\). We say also simply that \(\mathcal{T}_A\) is linear if it is \(A\)-linear. We denote by

\[A\text{-TopAlg}_{B\text{-lin}}\]

the full subcategory of \(A\text{-TopAlg}\) whose objects are the \(B\)-linear topological \(A\)-algebras.

**Remark 8.3.2.** (i) Let \(A\) be a ring, and \(\mathcal{T}_A\) a topology on \(A\) such that \((A, \mathcal{T}_A)\) is a topological group, for the addition law of \(A\). Let \(\mathcal{U}\) be a fundamental system of open neighborhoods of 0 in \(A\); it is easily seen that \((A, \mathcal{T}_A)\) is a topological ring if and only if the system \(\mathcal{U}\) fulfills the following conditions:

(a) For every \(U \in \mathcal{U}\) there exists \(U' \in \mathcal{U}\) such that \(U' \cdot U' := \{a \cdot b \mid a, b \in U'\} \subset U\).

(b) For every \(a \in A\) and every \(U \in \mathcal{U}\) there exists \(U' \in \mathcal{U}\) such that \(a \cdot U' \subset U\).

(ii) Especially, if \(I_\bullet := (I_\lambda \mid \lambda \in \Lambda)\) is any system of ideals of \(A\) that is cofiltered by inclusion, then there is a unique group topology \(\mathcal{T}_{I_\bullet}\) on \(A\) for which \(I_\bullet\) is a fundamental system of open neighborhoods of 0, and \((A, \mathcal{T}_{I_\bullet})\) is a topological ring. We call \(\mathcal{T}_{I_\bullet}\) the \(I_\bullet\)-adic topology on \(A\). Likewise, if \(M\) is any \(A\)-module, the \(I_\bullet\)-adic topology on \(M\) is the unique group topology \(\mathcal{T}_{I_\bullet}\) on \(M\) for which \((I_\lambda M \mid \lambda \in \Lambda)\) is a fundamental system of open neighborhoods of 0 in \(M\), and \((M, \mathcal{T}_{I_\bullet})\) is a topological \((A, \mathcal{T}_{I_\bullet})\)-module.

**Remark 8.3.3.** Let \((A, \mathcal{T}_A)\) be any topological ring and \((M, \mathcal{T}_M)\) any topological \(A\)-module.

(i) Let \((A^\wedge, \mathcal{T}_{I_\bullet}^\wedge)\) be the separated completion of the topological group underlying \(A\); from proposition [8.2.18] we see that the multiplication law of \(A\) induces a continuous \(\mathbb{Z}\)-bilinear map \(A^\wedge \times A^\wedge \to A^\wedge\), which furnishes \(A^\wedge\) with a natural structure of topological ring, such that the completion map \(A \to A^\wedge\) is a morphism of topological rings. Likewise, the separated completion \((M^\wedge, \mathcal{T}_{I_\bullet}^\wedge)\) of \((M, \mathcal{T}_M)\) is naturally a topological \(A^\wedge\)-module.

(ii) Suppose that \(\mathcal{T}_A\) is the linear topology defined by a cofiltered system \(I_\bullet := (I_\lambda \mid \lambda \in \Lambda)\) of ideals of \(A\), and let \(I \subset A\) be any open ideal. Also, suppose that \(\mathcal{T}_M\) is the \(I_\bullet\)-adic topology on \(M\). Then it follows easily from (i) and corollary [8.2.17](iii), that \(\mathcal{T}_{I_\bullet}^\wedge\) is the \(A^\wedge\)-linear topology defined by the cofiltered system \(((I_\lambda M)^\wedge \mid \lambda \in \Lambda)\) of submodules of \(M^\wedge\). Moreover, \((IM)^\wedge\) is an open \(A^\wedge\)-submodule in \(M^\wedge\), the natural map \(M/IM \to M^\wedge/(IM)^\wedge\) is an isomorphism, and the completion map \(M \to M^\wedge\) identifies \((IM)^\wedge\) with the topological closure of the image of \(IM\) in \(M^\wedge\) (corollary [8.2.17](i)).

(iii) In the situation of (ii), suppose furthermore that for every \(\lambda \in \Lambda\) there exists \(\mu \in \Lambda\) with \(I_\mu \subset I_\lambda^2\) (where \(I_\lambda^2\) is the usual square of the ideal \(I_\lambda\)). Then it is easily seen that the \(I_\bullet\)-adic topology on \(IM\) agrees with the topology induced by \(\mathcal{T}_M\) on \(IM\).

(iv) In the situation of (iii), suppose additionally that \(\Lambda\) is countable and \(I\) is finitely generated. Then the image of \((IM)^\wedge\) in \(M^\wedge\) equals \(IM^\wedge\): indeed, by assumption we may find \(k \in \mathbb{N}\) and a surjective \(A\)-linear map \(\varphi : M^{\oplus k} \to IM\), and it is easily seen that \(\varphi\) is an open
map; especially, the quotient topology induced on \(IM\) via the map \(\varphi\) agrees with \(\mathcal{T}_{IM}\). By proposition \(8.2.13(v)\), the separated completion of \(\varphi\) is a surjective map

\[
\varphi^\wedge : (M^\oplus k)^\wedge \to (IM)^\wedge
\]

and on the other hand we have a natural identification \((M^\oplus k)^\wedge \sim M^\wedge\oplus k\), whence the contention (details left to the reader).

**Example 8.3.4.** (i) Let \(A \neq 0\) be a ring, \(\Sigma\) a set, and \(\mathcal{F}\) a filter of \(\Sigma\), i.e. a family of subsets of \(\Sigma\) fulfilling the following conditions: (a) for every \(F, F' \in \mathcal{F}\) we have \(F \cap F' \in \mathcal{F}\); (b) for every \(F \subset F' \subset \Sigma\) with \(F \in \mathcal{F}\), we have \(F' \in \mathcal{F}\). Let us endow \(A\) with the discrete topology, and \(M := A^{(\Sigma)}\) with the linear topology \(\mathcal{T}_M\) defined by the system of submodules \((A^{(F)} \mid F \in \mathcal{F})\). Notice that \(\mathcal{T}_M\) is separated if and only if \(\bigcap_{F \in \mathcal{F}} F = \emptyset\). Notice as well the natural isomorphism of \(A\)-modules

\[
M/A^{(F)} \sim A^{(\Sigma \setminus F)}
\]

for every subset \(F \subset \Sigma\).

For \(F \subset F' \subset \Sigma\), these isomorphisms identify the natural projection \(M/A^{(F)} \to M/A^{(F')}\) with the \(A\)-linear map \(\pi_{F,F'} : A^{(\Sigma,F)} \to A^{(\Sigma',F')} : (a_\sigma \mid \sigma \in \Sigma \setminus F) \mapsto (a_\sigma \mid \sigma \in \Sigma \setminus F')\). The completion of \(M\) is then isomorphic to the inverse limit of the cofiltered system \(((A^{\Sigma,F} \mid F \in \mathcal{F}), \pi_{\bullet,\bullet})\). If \(\mathcal{T}_M\) is separated, a direct inspection shows that this limit is represented by the submodule \(L\) of \(A^{\Sigma}\) consisting of all sequences \((a_\sigma \mid \sigma \in \Sigma)\) with support \(\Lambda := \{\sigma \in \Sigma \mid a_\sigma \neq 0\}\) satisfying the following condition: \(\Lambda \cap (\Sigma \setminus F)\) is a finite set for every \(F \in \mathcal{F}\).

(ii) In the situation of (i), suppose moreover that for every finite or countable subset \(\Lambda \subset \Sigma\) there exists \(F \in \mathcal{F}\) with \(\Lambda \cap F = \emptyset\). Then \(M\) is complete and separated. Indeed, the condition implies that \(\bigcap_{F \in \mathcal{F}} F = \emptyset\), so \(M\) is separated. To check the completeness of \(M\), say that \(a_* := (a_\sigma \mid \sigma \in \Sigma) \in L\); if the support \(\Lambda\) of \(a_*\) is not finite, we may find a countable subset \(\Lambda' \subset \Lambda\), and by assumption there exists \(F \in \mathcal{F}\) such that \(\Lambda \cap F = \emptyset\). But then \(\Lambda' \subset \Lambda \cap (\Sigma \setminus F)\) is not a finite set, a contradiction. Thus \(a_* \in M\), whence the assertion.

**Example 8.3.5.** Let \(A\) be any topological ring whose topology is linear, complete and separated, \(I \subset A\) a closed ideal, and endow \(A/I\) with the quotient topology. In case \(A\) admits a fundamental system of open neighborhoods of \(0\) consisting of a countable family of ideals, then \(A/I\) is still complete and separated (proposition \(8.2.13(v)\)). But if this latter condition is omitted, \(A/I\) will still be separated, but it will not necessarily be complete. For a counterexample, take \(A := K[T_\lambda \mid \lambda \in \Lambda]\), where \(K\) is a non-zero ring, and \(\Lambda\) is the (small) set of all countable ordinal numbers, and let \(I \subset A\) be the ideal generated by \((T_\lambda - T_\mu \mid \lambda, \mu \in \Lambda)\). We endow \(A\) with the linear topology defined by the cofiltered system of ideals \((J^\lambda_n \mid (\lambda, n) \in \Lambda \times \mathbb{N})\), where \(J_\lambda \subset A\) is the ideal generated by \((T_\mu \mid \mu \in \Lambda, \mu > \lambda)\), for every \(\lambda \in \Lambda\). Let \(\Sigma \subset A\) be the subset of monomials, which is in natural bijection with the set of all maps \(\varphi : \Lambda \to \mathbb{N}\) such that \(\varphi^{-1}(\mathbb{N} \setminus \{0\})\) is a finite set. For every \((\lambda, n) \in \Lambda \times \mathbb{N}\), set \(\Sigma_{\lambda,n} := J^\lambda_n \cap \Sigma\), and let \(\mathcal{F}\) be the set of all subsets \(F \subset \Sigma\) such that \(\Sigma_{\lambda,n} \subset F\) for some \((\lambda, n) \in \Lambda \times \mathbb{N}\). Then we have a natural identification \(A \sim K^{(\Sigma)}\), and the topology of \(A\) is defined by the cofiltered system of \(K\)-submodules \((K^{(F)} \mid F \in \mathcal{F})\). It is easily seen that \(\mathcal{F}\) fulfills the condition of example \(8.3.4\) hence \(A\) is complete and separated. Now, \((\text{the quotient } A/I)\) is isomorphic to \(K[T]\), endowed with its \(T\)-adic topology, which is separated but not complete.

**Lemma 8.3.6.** Let \(A\) be a topological ring, \(B \subset A\) an open subring, \(C\) the integral closure of \(B\) in \(A\); endow \(B\) and \(C\) with the topologies induced by \(A\), and denote by \(A^\wedge, B^\wedge\) and \(C^\wedge\) the respective separated completions. Then \(C^\wedge\) is the integral closure of \(B^\wedge\) in \(A^\wedge\).

**Proof.** Notice that \(C^\wedge = B^\wedge \cdot C\), hence \(C^\wedge\) lies in the integral closure of \(B^\wedge\) in \(A^\wedge\), and we are therefore reduced to checking that \(B\) is integrally closed in \(A\) if and only if \(B^\wedge\) is integrally closed in \(A^\wedge\). Let \(j : A \to A^\wedge\) be the completion map. Suppose first that \(B\) is integrally
closed in $A$, and let $a \in A^\wedge$ be any element that is integral over $B^\wedge$; pick any monic polynomial $P(T) \in B^\wedge[T]$ with $P(a) = 0$. Since $B$ is open in $A$, we may then find $a' \in A$ and a monic polynomial $Q(T) \in B[T]$ such that

$$j(a') - a, P(a'), j(Q(a')) - P(j(a')) \in B^\wedge.$$  

It follows that $Q(a') \in j^{-1}B^\wedge = B$ (corollary 8.2.17 ii). Set $R(T) := Q(T) - Q(a')$; then $R(T) \in B[T]$ and $R(a') = 0$, so $a' \in B$, by assumption, and finally $a \in B^\wedge$, as required. Conversely, if $a \in A$ is integral over $B$, it follows easily that $j(a)$ is integral over $B^\wedge$, and hence $j(a) \in B^\wedge$, if $B^\wedge$ is integrally closed in $A^\wedge$; in this case, $a \in j^{-1}B^\wedge = B$, which shows that $B$ is integrally closed in $A$.  

8.3.7. For any topological ring $A$, let $\mathcal{C}_A$ denote the full subcategory of $A$-TopAlg whose objects are the complete and separated topological $A$-algebras whose topology is linear. Then the finite coproducts of $\mathcal{C}_A$ are representable. Indeed, consider more generally any two topological $A$-modules $M, N$ whose topologies are $A$-linear; we denote by $\mathcal{F}_{M,N}$ the $A$-linear topology on $M \otimes_A N$ defined by the system of submodules

$$\text{Im}(M' \otimes_A N + M \otimes_A N' \to M \otimes_A N)$$

where $M'$ (resp. $N'$) ranges over the system of all open $A$-submodules of $M$ (resp. of $N$), and following [44, Ch.0, §7.7.2] we denote by

$$M \hat{\otimes}_A N$$

the separated completion of $(M \otimes_A N, \mathcal{F}_{M,N})$. Notice that if $(M_\lambda | \lambda \in \Lambda)$ and $(N_\lambda' | \lambda' \in \Lambda')$ are any two fundamental systems of open submodules of $M$ and respectively $N$, we have a natural isomorphism of topological $A$-modules

$$M \hat{\otimes}_A N \xrightarrow{\sim} \lim_{(\lambda,\lambda') \in \Lambda \times \Lambda'} M/M_\lambda \otimes_A N/N_{\lambda'}$$

where the tensor products $M/M_\lambda \otimes_A N/N_{\lambda'}$ are endowed with their discrete topologies.

By the same token, if $M'$ and $N'$ are two other topological $A$-modules whose topologies are $A$-linear, and $f : M \to M'$ and $g : N \to N'$ are any two continuous $A$-linear maps, then the map $f \otimes_A g : M \otimes_A N \to M' \otimes_A N'$ is continuous for the topologies $\mathcal{F}_{M,N}$ and $\mathcal{F}_{M',N'}$, and therefore its separated completion is a well defined continuous $A$-linear map

$$f \hat{\otimes}_A g : M \hat{\otimes}_A N \to M' \hat{\otimes}_A N'.$$

Now, if $B$ and $C$ are any two topological $A$-algebras whose topologies are linear, notice that the topology $\mathcal{F}_{B,C}^\wedge$ is defined by a cofiltered system of ideals of $B \otimes_A C$, hence $(B \otimes_A C, \mathcal{F}_{B,C}^\wedge)$ is a topological $A$-algebra. We claim that if $B$ and $C$ are complete and separated, then $B \otimes^\wedge_A C$ represents the coproduct of $B$ and $C$ in the category $\mathcal{C}_A$. For the proof, consider any two morphisms $f : B \to D$ and $g : C \to D$ in the category $\mathcal{C}_A$; there exists a unique morphism of $A$-algebras $h : B \otimes^\wedge_A C \to D$ such that $h(b \otimes c) := f(b) \cdot g(c)$ for every $b \in B$ and $c \in C$, and since $D$ is complete and separated, it remains only to check that $h$ is continuous for the topology $\mathcal{F}_{B,C}^\wedge$. However, let $I \subset D$ be any open ideal; then $J := f^{-1}I$ (resp. $K := g^{-1}I$) is an open ideal of $B$ (resp. of $C$) and clearly $h(J \otimes_A C + B \otimes_A K) \subset I$, whence the contention.

**Definition 8.3.8.** Let $(A, \mathcal{T})$ be any topological ring, and $S \subset A$ any subset.

(i) $S \subset A$ is bounded in $A$, if for every open neighborhood $U$ of $0 \in A$ there exists an open neighborhood $V$ of $0 \in A$ such that $v \cdot s \in U$ for every $v \in V$ and $s \in S$.

(ii) For every $n \in \mathbb{N}$, let $S(n) := \{a_1 \cdot \cdots \cdot a_n \mid a_1, \ldots, a_n \in S\}$. We say that $S$ is power bounded in $A$ if the subset $\bigcup_{n \in \mathbb{N}} S(n)$ is bounded in $A$. An element $a \in A$ is power bounded
Remark 8.3.9. Let $T$ be a topological ring induced by an adic (resp. $c$-adic) topology on $M$ is the (unique) $A$-linear topology such that $(I^n M | n \in \mathbb{N})$ is a fundamental system of open neighborhoods of $0$. Indeed, set $T = \bigcup_{n \in \mathbb{N}} T(n)$ for $i = 1, \ldots, k$ (notation of definition 8.3.8(ii)); by definition, $T$ is power bounded if and only if the product $S_1 \cdots S_k$ is bounded, so the assertion follows from (i).

(iii) We say that $(A, \mathcal{T})$ is adic (resp. $c$-adic) if there exists an ideal $I$ of $A$ such that $(I^n | n \in \mathbb{N})$ (resp. $(I^n)^c | n \in \mathbb{N}$).

is a fundamental system of open neighborhood of zero in $A$. Then, we call any such $I$ an ideal of adic definition (resp. an ideal of $c$-adic definition) of $(A, \mathcal{T})$, and we also say that $\mathcal{T}$ is $I$-adic (resp. $I$-$c$-adic). If $M$ is any $A$-module, the $I$-adic topology on $M$ is the (unique) $A$-linear topology such that $(I^n M | n \in \mathbb{N})$ is a fundamental system of open neighborhoods of $0$.

(iv) We say that $(A, \mathcal{T})$ is $f$-adic if there exists an open subring $A_0 \subset A$ that is adic for the topology induced by $\mathcal{T}$, and such that $A_0$ admits a finitely generated ideal of adic definition.

(v) Let $(A, \mathcal{T})$ be any $f$-adic ring. An open subring $A_0$ of $A$ is called a ring of definition of $A$, if $\mathcal{T}$ induces a linear topology on $A_0$.

(vi) We say that $(A, \mathcal{T})$ is a Tate ring if it is $f$-adic and $A^\times \cap A^{\circ\circ} \neq \emptyset$.

Remark 8.3.10. Let $(A, \mathcal{T})$ be any topological ring.

(i) Let $S_1, S_2 \subset A$ be two bounded subsets. Clearly $S_1 \cup S_2$ is bounded. Moreover, also $S_1 S_2 := \{s_1 s_2 \mid s_1 \in S_1, s_2 \in S_2\}$ is bounded. Indeed, for any given open neighborhood $U$ of $0$ in $A$, let us pick an open neighborhood $V$ of $0$ in $A$ such that $S_1 V \subset U$, and an open neighborhood $V'$ of $0$ in $A$ such that $S_2 V' \subset U'$; then $S_1 S_2 V' \subset U$, whence the contention.

(ii) Let $T_1, \ldots, T_k \subset A$ be any finite family of subsets. Then $T := T_1 \cup \cdots \cup T_k$ is power bounded in $A$ if and only if every $T_1, \ldots, T_k$ is power bounded in $A$. Indeed, set $S_i := \bigcup_{n \in \mathbb{N}} T_i(n)$ for $i = 1, \ldots, k$ (notation of definition 8.3.8(ii)); by definition, $T$ is power bounded if and only if the product $S_1 \cdots S_k$ is bounded, so the assertion follows from (i).

(iii) Let $T \subset A$ be any subset. Then $T$ is bounded (resp. power bounded) in $A$ if and only if the same holds for the topological closure $T^c$ of $T$ in $A$. Indeed, suppose that $T$ is bounded, and let $U \subset A$ be an open neighborhood of $0 \in A$; pick an open neighborhood $U'$ of $0$ in $A$ such that $U' + U' \subset U$. By assumption, there exists an open neighborhood $V$ of $0$ in $A$ such that $T \cdot V \subset U'$, whence $T^c \cdot V \subset U^c$; but notice that $U^c \subset U' + U'$: indeed, if $x \in U^c$, we have $(x - U') \cap U' \neq \emptyset$, whence $x \in U' + U'$. Summing up, we get $T^c \cdot V \subset U$, which shows that $T^c$ is bounded. Next, suppose that $T$ is power bounded, i.e. $T' := \bigcup_{n \in \mathbb{N}} T(n)$ is bounded, and notice that $\bigcup_{n \in \mathbb{N}} T^c(n) \subset T^c$; by the foregoing $T^c$ is bounded, so $T^c$ is power bounded.

(iv) Let $a \in A$ be any element, and $n \geq 1$ an integer. Then $a$ is topologically nilpotent if and only if the same holds for $a^n$. Indeed, obviously if $a$ is topologically nilpotent, the same holds for $a^n$. Conversely, suppose that $a^n$ is topologically nilpotent; since the map $A \to A : b \mapsto a^n b$ is continuous for every $r \in \mathbb{N}$, it follows that the sequences $(a^{kn+r} | k \in \mathbb{N})$ converge to $0$ in $A$ for every $r = 0, \ldots, n-1$; the claim is an immediate consequence.

(v) Let $a, b \in A$ be any two elements. If $a$ is power bounded and $b$ is topologically nilpotent, $ab$ is topologically nilpotent. Indeed, for any open neighborhood $U$ of $0$ in $A$ there exists an open neighborhood $V$ of $0$ in $A$ such that $\{b^k | k \in \mathbb{N}\} \cdot V \subset U$, and on the other hand, there exists $n \in \mathbb{N}$ such that $a^n \in V$ for every integer $k \geq n$; thus, $(ab)^k \in U$ for every $k \geq n$, whence the claim.

Remark 8.3.10. Let $(A, \mathcal{T})$ be a topological ring whose topology $\mathcal{T}$ is $\mathbb{Z}$-linear.

(i) The subset $A^{\circ\circ}$ is an additive subgroup of $A$. Indeed, let $a, b \in A^{\circ\circ}$ be any two elements, $U$ any open additive subgroup in $A$, and pick an open neighborhood $V$ of $0$ in $A$ such that
$V \cdot V \subset U$; we may find $r \in \mathbb{N}$ such that $a^i b^j \in V$ for every $i \geq r$. Then, we may also find an integer $s \geq r$ such that $a^i b^j \in U$ for every $i, j \in \mathbb{N}$ such that $i + j \geq s$ and $\min(i, j) < r$. It follows easily that $(a + b)^n \in U$ for every $n \geq s$, and since $U$ is arbitrary, we conclude that $a + b$ is topologically nilpotent.

(ii) For any subset $T \subset A$, denote by $\langle T \rangle \subset A$ the additive subgroup generated by $T$ in $A$. Then $T$ is bounded (resp. power bounded) if and only if the same holds for $\langle T \rangle$. Indeed, suppose that $T$ is bounded, and let $U \subset A$ be any open additive subgroup; by assumption there exists an open neighborhood $V$ of $0$ in $A$ such that $T \cdot V \subset U$. But then clearly $\langle T \rangle \cdot V \subset U$, so $\langle T \rangle$ is bounded. Likewise, suppose that $T$ is power bounded, and set $S := \bigcup_{n \in \mathbb{N}} T(n)$ (notation of definition 8.3.8(ii)); since $S$ is bounded, we know already that the same holds for $\langle S \rangle$. However, clearly $\langle S \rangle = \bigcup_{n \in \mathbb{N}} \langle T \rangle(n)$, so $\langle T \rangle$ is power bounded.

(iii) Let $T \subset A$ be any power bounded subset; in light of (ii), it is easily seen that the $\mathbb{Z}$-subalgebra $\mathbb{Z}[T] \subset A$ generated by $T$ is bounded in $A$, and especially, every element of $\mathbb{Z}[T]$ is power bounded. Combining with remark 8.3.9(ii), we deduce that $A^\circ$ is the filtered union of all the bounded subrings of $A$. Especially, $A^\circ$ is a subring of $A$.

(iv) Moreover, $A^\circ$ is integrally closed in $A$, and $A^{\circ \circ}$ is a radical ideal of $A^\circ$. Indeed, say that $x \in A$ is integral over $A^\circ$, so that there exist $a_1, \ldots, a_n \in A^\circ$ (for some $n \in \mathbb{N}$) such that $x^n + a_1 x^{n-1} + \cdots + a_n = 0$, and set $B := \mathbb{Z}[a_1, \ldots, a_n] \subset A$; by (iii), the subring $B$ is bounded in $A$, and it is easily seen that $B(x) = \sum_{n=0}^\infty B x^n$, so $B(x)$ is bounded as well, therefore $B(x) \subset A^\circ$, which shows the first assertion. Lastly, (i) and remark 8.3.9(v) imply easily that $A^{\circ \circ}$ is an ideal of $A^\circ$, and remark 8.3.9(iv) shows that $A^{\circ \circ}$ is a radical ideal.

(v) Lastly, if the topology $\mathcal{T}$ is also complete and separated, $A^{\circ \circ}$ lies in the Jacobson radical of $A^\circ$. Indeed, in this case, for every $a \in A^{\circ \circ}$ the series $1 - a + a^2 - a^3 + \cdots$ converges in $A$ to a unique element $b$ such that $b \cdot (1 + a) = 1$. Now, $b$ lies in the topological closure $\mathbb{Z}[a]$ of $\mathbb{Z}[a] \subset A$, and notice that $\mathbb{Z}[a]$ is the additive subgroup generated by the subset $T := \{a^n \mid n \in \mathbb{N}\}$; since $a$ is power bounded, obviously $T$ is a power bounded subset, and then the same holds for $\mathbb{Z}[a]^\circ$, by (ii) and remark 8.3.9(iii). Thus, $b \in A^\circ$, whence the contention.

**Lemma 8.3.11.** Let $A$ be a ring, and $I \subset A$ an ideal; consider a cartesian diagram of topological $A$-modules

\[
\begin{array}{ccc}
M_0 & \longrightarrow & M_1 \\
\downarrow & & \downarrow f_1 \\
M_2 & \underset{f_2}{\longrightarrow} & M_3
\end{array}
\]

and suppose that the topology of $M_3$ is discrete, and the topologies of $M_1$ and $M_2$ are $I$-adic. Then the topology of $M_0$ is $I$-adic as well.

**Proof.** By assumption, we may find $c \in \mathbb{N}$ such that $f_1(I^c M_1) = f_2(I^c M_2) = 0$, and it follows easily that $I^n M_1 \times I^n M_2 \subset M_0$ for every $n \geq c$. Especially, $(I^n M_1 \times I^n M_2 \mid n \geq c)$ is a fundamental system of open neighborhoods of $0$ in $M_0$. We also see that

\[
I^{n+c} M_1 \times I^{n+c} M_2 = I^n (I^c M_1 \times I^c M_2) \subset I^n M_0 \subset I^n M_1 \times I^n M_2 \quad \text{for every } n \in \mathbb{N}
\]

whence the claim. \(\square\)

**Lemma 8.3.12.** Let $A$ be a topological ring, $(M, \mathcal{T}_M)$ a topological $A$-module whose topology is $A$-linear, complete and separated, and $I \subset A$ an ideal such that the $I$-adic topology on $M$ is finer than $\mathcal{T}_M$. Suppose moreover that either one of the following conditions holds:

(a) $I^n M$ is closed in the topology $\mathcal{T}_M$, for every $n \in \mathbb{N}$.

(b) $I$ is finitely generated.

Then $M$ is separated and complete for the $I$-adic topology.
Proof. Let \((J_\lambda \mid \lambda \in \Lambda)\) be a fundamental system of open submodules in \(M\); by assumption, for every \(\lambda \in \Lambda\) there exists \(n(\lambda) \in \mathbb{N}\) such that \(I^{n(\lambda)}M \subset J_\lambda\). Suppose first that (a) holds; it follows that the natural map
\[
M/I^nM \to \lim_{\lambda \in \Lambda} M/(I^nM + J_\lambda)
\]
is injective for every \(n \in \mathbb{N}\). Taking into account example [1.5.14] ii), we deduce that both of the induced maps
\[
M \to \lim_{n \in \mathbb{N}} M/I^nM \quad \text{and} \quad \lim_{n \in \mathbb{N}} M/I^nM \to \lim_{(\lambda, n) \in \Lambda \times \mathbb{N}} M/(I^nM + J_\lambda)
\]
are injective. However, notice that the subset \(\Sigma \subset \Lambda \times \mathbb{N}\) of all \((n, \lambda)\) such that \(n \geq n(\lambda)\), is cofinal, hence the composition of these two maps is an isomorphism. We conclude that both these maps are bijective, and the assertion follows.

Next, suppose that (b) holds, and let \(a_1, \ldots, a_r\) be a finite system of generators for \(I\). Clearly \(M\) is separated for the \(I\)-adic topology. Now, suppose \(x_\cdot := (x_n \mid n \in \mathbb{N})\) is a sequence of elements of \(M\) such that \(x_n - x_m \in I^nM\) for every \(n, m \in \mathbb{N}\) with \(m \geq n\). The sequence \(x_\cdot\) converges for the topology \(\mathcal{T}_M\) to an element \(x \in M\), and it remains to check that \(x\) is also the limit of \(x_\cdot\) for the \(I\)-adic topology of \(M\). To this aim, for every \(n \in \mathbb{N}\), let
\[
S_n := \{ (j_1, \ldots, j_r) \in \mathbb{N}^r \mid j_1 + \cdots + j_r = n \}
\]
and for every \(\sigma := (j_1, \ldots, j_r) \in \mathbb{N}^r\) set \(a^\sigma := a_1^{j_1} \cdots a_r^{j_r}\). For every \(k, l \in \mathbb{N}\) we may find inductively a system of elements \((y_l, \sigma) \mid \sigma \in S_k\) of \(M\) such that
- \(x_{k+l} - x_k = \sum_{\sigma \in S_k} y_{l, \sigma} a^\sigma\)
- \(y_{l', \sigma} - y_{l, \sigma} \in I^kM\) whenever \(l' \geq l\) and for every \(\sigma \in \mathbb{N}^r\).

Thus, the sequence \((y_l, \sigma) \mid l \in \mathbb{N}\) converges in the topology \(\mathcal{T}_M\) to some element \(y_\sigma \in M\) for every \(\sigma \in \mathbb{N}^r\), and we get \(x - x_k = \sum_{\sigma \in S_k} y_\sigma a^\sigma\); so this difference lies in \(I^kM\) for every \(k \in \mathbb{N}\), whence the contention. \(\square\)

**Proposition 8.3.13.** Let \(A\) be a ring, \(I \subset A\) an ideal, and \(M\) a faithful \(A\)-module of finite type. The following holds:

(i) If \(M\) is \(I\)-adically complete and separated, then \(I\) lies in the Jacobson radical of \(A\).

(ii) If moreover \(A\) is noetherian, then \(M\) is \(I\)-adically complete and separated if and only if the same holds for \(A\).

**Proof.** (i): Let \(A^\wedge\) be the \(I\)-adic completion of \(A\), so that \(M\) is naturally an \(A^\wedge\)-module. Suppose by contradiction that there exists a maximal ideal \(m \subset A\) that does not contain \(I\). Then there exist \(a \in I\) and \(b \in m\) with \(a + b = 1\), whence \(b = 1 - a \in (A^\wedge)^\times\) (with \(b^{-1} = \sum_{n \in \mathbb{N}} a^n\)), so that \(M = mM\), and therefore \(M_m = 0\), by Nakayama’s lemma. On the other hand, since by assumption we have \(\text{Ann}_A(M) = 0\), we get \(\text{Ann}_{A_m}(M_m) = 0\), so \(A_m = 0\), which is absurd.

(ii): If \(A\) is \(I\)-adically complete and separated, the same holds for \(M\), by [100, Th.8.7]. Conversely, if \(M\) is \(I\)-adically complete and separated, then \(I\) lies in the Jacobson radical of \(A\), by (i). Moreover, since \(M\) is faithful and of finite type, there exists \(k \in \mathbb{N}\) and an injective map \(f : A \to M^\oplus k\) (details left to the reader). Clearly \(M^\oplus k\) is \(I\)-adically complete and separated, and \(f(A)\) is a closed subset for the \(I\)-adic topology of \(N^\oplus\) ([100, Th.8.10]), hence \(A\) is complete and separated for the topology \(\mathcal{T}\) induced by \(M^\oplus k\); but the latter agrees with the \(I\)-adic topology ([100, Th.8.6]). \(\square\)

**Proposition 8.3.14.** Let \(A\) be a noetherian ring, \(I \subset J \subset A\) two ideals, and \(M\) an \(A\)-module; set \(\overline{A} := A/I\), \(\overline{J} := J/I\) and \(\overline{M} := M/IM\). Suppose that \(M\) is \(I\)-adically separated and complete, and that either one of the following conditions holds:

(a) \(M\) is of finite type.

(b) \(M\) is flat.
Then \( M \) is \( J \)-adically separated and complete if and only if the same holds for \( \overline{M} \).

**Proof.** For every \( A \)-module \( N \), let \( N^\wedge \) be the \( J \)-adic completion of \( N \). We notice:

**Claim 8.3.15.** For every flat \( A \)-module \( P \), the following holds:

(i) Every \( A \)-module of finite type \( N \) induces an isomorphism \( f_N : N \otimes_A P^\wedge \overset{\sim}{\rightarrow} (N \otimes_A P)^\wedge \).

(ii) Moreover, \( P^\wedge \) is a flat \( A^\wedge \)-module.

**Proof of the claim.** (i): We consider a short exact sequence of \( A \)-modules of finite type

\[
\Sigma : 0 \rightarrow N_1 \rightarrow N_2 \rightarrow N_3 \rightarrow 0
\]

and we first show that the induced sequence of \( J \)-adic completions:

\[
0 \rightarrow (N_1 \otimes_A P)^\wedge \rightarrow (N_2 \otimes_A P)^\wedge \rightarrow (N_3 \otimes_A P)^\wedge \rightarrow 0
\]

is still short exact. To this aim, since \( \Sigma \otimes_A P \) is still short exact, it suffices to check that the \( J \)-adic topology of \( N_1 \otimes_A P \) is induced by that of \( N_2 \otimes_A P \) (proposition 8.2.13(i,v)). But by the Artin-Rees lemma there exists \( c \in \mathbb{N} \) such that \( J^{n+c}N_2 \cap N_1 \subset J^nN_1 \subset J^nN_2 \cap N_1 \) for every \( n \in \mathbb{N} \). Since \( P \) is a flat \( A \)-module, it follows that

\[
J^{n+c}(N_2 \otimes_A P) \cap (N_1 \otimes_A P) \subset J^n(N_1 \otimes_A P) \subset J^n(N_2 \otimes_A P) \cap (N_1 \otimes_A P)
\]

for every \( n \in \mathbb{N} \), whence the assertion. Now, let \( \varphi : A^{\mathbb{Z}_n} \rightarrow M \) be an \( A \)-linear surjection, and \( N' := \ker \varphi \). By the foregoing, we have a commutative ladder:

\[
\begin{array}{ccc}
N' \otimes_A P^\wedge & \rightarrow & A^{\mathbb{Z}_n} \otimes_A P^\wedge \\
\downarrow f_{N'} & & \downarrow f_{A^{\mathbb{Z}_n}} \\
0 & \rightarrow & (N' \otimes_A P)^\wedge \\
0 & \rightarrow & (A^{\mathbb{Z}_n} \otimes_A P)^\wedge & \rightarrow & (N \otimes_A P)^\wedge & \rightarrow & 0
\end{array}
\]

whose bottom (resp. top) horizontal row is short exact (resp. right exact). Clearly \( f_{A^{\mathbb{Z}_n}} \) is an isomorphism, hence \( f_N \) is surjective for every \( A \)-module \( N \) of finite type. Especially, \( f_{N'} \) is surjective; but the snake lemma yields an exact sequence \( \ker f_{A^{\mathbb{Z}_n}} \rightarrow \ker f_N \rightarrow \coker f_{N'} \), so \( f_N \) is an isomorphism.

(ii): It is easily seen that the natural map \( P \rightarrow A^\wedge \otimes_A P \) induces an isomorphism on \( J \)-adic completions; after replacing \( A \) by \( A^\wedge \), and \( P \) by \( A^\wedge \otimes_A P \), we may thus assume from start that \( A \) is \( J \)-adically complete and separated, and then we need to check that \( P \) is a flat \( A \)-module. Now, let \( i : L \rightarrow A \) be the inclusion map of an ideal; by (i), the map \( i \otimes_A P^\wedge : L \otimes_A P^\wedge \rightarrow P^\wedge \) is naturally identified with the \( J \)-adic completion \( (i \otimes_A P)^\wedge \) of \( i \otimes_A P : L \otimes_A P \rightarrow P \). Since \( P \) is a flat \( A \)-module, \( i \otimes_A P \) is injective; then the foregoing shows that the same holds for \( (i \otimes_A P)^\wedge \), hence also for \( i \otimes_A P^\wedge \), so \( P^\wedge \) is a flat \( A \)-module ([100], Th.7.2).

Now, if (b) holds, claim 8.3.15(ii) implies that the natural map \( M^\wedge/I^nM^\wedge \rightarrow \overline{M}^\wedge \) is an isomorphism; the latter holds also under condition (a), by [100], Th.8.11. In either case, we already deduce that if \( M \) is \( J \)-adically complete and separated, then the same holds for \( \overline{M} \).

Conversely, suppose that \( \overline{M} \) is \( J \)-adically complete and separated. If (a) holds, let \( \overline{A}_0 := \overline{A}/\Ann_{\overline{A}}(\overline{M}) \); then \( \overline{M} \) is a faithful \( \overline{A}_0 \)-module of finite type, and therefore \( \overline{A}_0 \) is \( J \)-adically complete and separated (proposition 8.3.13(ii)), so that every \( \overline{A}_0 \)-module of finite type is \( J \)-adically complete and separated ([100], Th.8.7). Now, notice that, for every \( n \in \mathbb{N} \), the \( \overline{A} \)-module \( I^nM/I^{n+1}M \) is a quotient of \( I^n/I^{n+1} \otimes_{\overline{A}} \overline{M} \), hence it is an \( \overline{A}_0 \)-module of finite type, so it is \( J \)-adically complete and separated. By [100], Th.8.7, this means that the natural map \( I^nM/I^{n+1}M \rightarrow (I^nM/I^{n+1}M) \otimes_A A^\wedge \) is an isomorphism for every \( n \in \mathbb{N} \). Since \( A^\wedge \) is a flat \( A \)-algebra, it follows easily that, for every \( n \in \mathbb{N} \), the natural map

\[
f_n : M/I^nM \rightarrow (M/I^nM) \otimes_A A^\wedge \overset{\sim}{\rightarrow} M^\wedge/I^nM^\wedge
\]
is an isomorphism. Since $M$ is $I$-adically complete and separated, the limit of the system $(f_n | n \in \mathbb{N})$ is an isomorphism from $M$ to the $I$-adic completion of $M$. But $M$ is $I$-adically complete and separated (Lemma 8.3.12), so $M$ is $J$-adically complete and separated, as stated.

Lastly, if (b) holds, then $M$ is a flat $A$-module (Claim 8.3.15(ii)), and therefore, for every $n \in \mathbb{N}$, both vertical arrows of the commutative diagram:

$$
\begin{array}{ccc}
(I^n/I^{n+1}) \otimes_{\mathbb{Z}} M & \longrightarrow & (I^n/I^{n+1}) \otimes_{\mathbb{Z}} M^\wedge /IM^\wedge \\
\downarrow & & \downarrow \\
I^n M/I^{n+1} M & \longrightarrow & I^n M^\wedge /I^{n+1} M^\wedge
\end{array}
$$

are isomorphisms. The same holds for the top horizontal arrow, by Claim 8.3.15(i), so also for the bottom horizontal one. Then we argue as in the foregoing case, to conclude. □

Remark 8.3.16. Claim 8.3.15 is a special case of Proposition 14.2.43.

Corollary 8.3.17. Let $A$ be a noetherian ring, $I \subset J \subset A$ two ideals, $M$ an $A$-module that is either flat or of finite type, and such that $M/IM$ is $J$-adically complete and separated. Denote by $M_I^\wedge$ (resp. $M_J^\wedge$) the $I$-adic (resp. $J$-adic) completion of $M$. Then the natural map

$$
\alpha : M_I^\wedge \rightarrow M_J^\wedge
$$

is an isomorphism.

Proof. Let also $A_I^\wedge$ be the $I$-adic completion of $A$; if $M$ is a flat (resp. finitely generated) $A$-module, then $M_I^\wedge$ is a flat (resp. finitely generated) $A_I^\wedge$-module (Claim 8.3.15(ii)); moreover, $M/IM$ is trivially $I$-adically complete and separated. Hence, the natural map $M/IM \rightarrow M_I^\wedge /IM_I^\wedge$ is bijective, by Claim 8.3.15(i) (resp. by [100, Th.8.11]). Especially, $M_I^\wedge /IM_I^\wedge$ is $J$-adically complete and separated, so the same holds for $M_J^\wedge$, by Proposition 8.3.14. Thus, there exists a unique $A$-linear map $\beta : M_J^\wedge \rightarrow M_J^\wedge$ whose composition with the $J$-adic completion map $i_{M,J} : M \rightarrow M_J^\wedge$ agrees with the $I$-adic completion map $i_{M,I} : M \rightarrow M_I^\wedge$. Likewise, by definition we have $\alpha \circ i_{M,I} = i_{M,J}$, so that

$$
\alpha \circ \beta \circ i_{M,J} = i_{M,I} \quad \text{and} \quad \beta \circ \alpha \circ i_{M,J} = i_{M,I}.
$$

By the universal properties of $i_{M,I}$ and $i_{M,J}$, it follows that $\alpha \circ \beta = 1_{M_J^\wedge}$ and $\beta \circ \alpha = 1_{M_I^\wedge}$, whence the assertion. □

Proposition 8.3.18. Let $(A, \mathcal{T})$ be any $f$-adic ring. We have:

(i) If $A_0$ is any ring of definition of $A$, then the topology of $A_0$ is adic and admits a finitely generated ideal of adic definition.

(ii) A subring of $A$ is a ring of definition of $A$ if and only if it is open and bounded in $A$.

(iii) The following conditions are equivalent:

(a) The topology $\mathcal{T}$ is linear.

(b) The topology $\mathcal{T}$ is adic and admits a finitely generated ideal of adic definition.

Proof. Fix an open subring $A_1$ and a finitely generated ideal $I$ of $A_1$, such that $\mathcal{T}$ induces the $I$-adic topology on $A_1$.

(i): Since $A_0$ is open in $A$, it follows that there exists an open subring $A_1$ and a finitely generated ideal $I$ of $A_1$, such that $\mathcal{T}$ induces the $I$-adic topology on $A_1$. But

(ii): Clearly, every ring of definition of $A$ is open and bounded. Conversely, suppose that $A_0$ is open and bounded. As in the foregoing, we find an integer $n > 0$ such that $I^n \subset A_0$ and
we set $J := I^n A_0$. Let now $U$ be any open neighborhood of zero in $A_0$; since $A_1$ admits a fundamental system of open neighborhoods of zero consisting of additive subgroups, we may assume that $U$ is an additive subgroup of $A_0$. Since $A_0$ is bounded, there exists $m \in \mathbb{N}$ such that $x \cdot a \in U$ for every $x \in I^m$ and every $a \in A_0$; then clearly $J^m \subset U$. Lastly, it is easily seen that $J^k$ is open in $A_0$ for every $k \in \mathbb{N}$, whence (ii).

(iii): If $\mathcal{T}$ is linear, then $A$ is bounded in itself, so the assertion follows directly from (ii). \[\square\]

**Corollary 8.3.19.** Let $(A, \mathcal{T})$ be any $f$-adic ring. We have:

(i) If $A_0$ and $A_1$ are rings of definition of $A$, then the same holds for $A_0 \cap A_1$ and $A_0 \cdot A_1$.

(ii) Let $B$ (resp. $C$) be a bounded (resp. open) subring of $A$, with $B \subset C$. Then there exists a ring of definition $A_0$ of $A$ with $B \subset A_0 \subset C$.

(iii) $(A, \mathcal{T})$ is adic if and only if $A$ is bounded in the topology $\mathcal{T}$.

(iv) $A^\circ$ is the filtered union of all the subrings of definition of $A$.

**Proof.** (i): The assertion for $A_0 \cap A_1$ is immediate from proposition 8.3.18(ii). The assertion for $A_0 \cdot A_1$ follows likewise, taking into account that $A$ has a fundamental system of open neighborhoods of zero consisting of additive subgroups: details left to the reader.

(ii): Let $A_1$ be any ring of definition of $A$; by proposition 8.3.18(ii), the subring $C_1 := A_1 \cap C$ is a ring of definition of $A$, and we may take $A_0 := B \cdot C_1$.

(iii): If $(A, \mathcal{T})$ is adic, then clearly $A$ is bounded. Conversely, if $A$ is bounded, (ii) implies that $A$ is a subring of definition of $(A, \mathcal{T})$, and then $(A, \mathcal{T})$ is adic, by proposition 8.3.18(ii).

(iv): By remark 8.3.10(iii), we know that $A^\circ$ is the filtered union of the family $\mathcal{T}$ of bounded subrings of $A$; notice that any subring containing an open subring of $A$ is also open in $A$. Since the family of bounded and open subring of $A$ is not empty (proposition 8.3.18(ii)), we conclude that this family is cofinal in $\mathcal{T}$, whence the contention. \[\square\]

**Corollary 8.3.20.** Let $(A, \mathcal{T}_A)$ be any topological ring, $B \subset A$ an open subring, and endow $B$ with the topology $\mathcal{T}_B$ induced from $\mathcal{T}_A$. The following holds:

(i) $(A, \mathcal{T}_A)$ is $f$-adic if and only if the same holds for $(B, \mathcal{T}_B)$.

(ii) Suppose that $(A, \mathcal{T}_A)$ is a Tate ring, and $B$ is a ring of definition of $A$. Then we have:

(a) $B$ contains an element of $A^\times \cap A^\infty$.

(b) Let $s \in B \cap A^\times \cap A^\infty$ be any element. Then $sB$ is an ideal of adic definition for $B$, and $B_s = A$.

(iii) Conversely, let $C$ be any ring, $f \in C$ any element, $D$ the image of $C$ in the localization $C_f$, and endow $C_f$ with the unique $D$-linear topology $\mathcal{T}_f$ such that $\{ f^n D \mid n \in \mathbb{N} \}$ is a fundamental system of neighborhoods of 0 in $C_f$. Then $(C_f, \mathcal{T}_f)$ is a Tate ring.

**Proof.** (i): Directly from the definition we see that if $(B, \mathcal{T}_B)$ is $f$-adic, the same holds for $(A, \mathcal{T}_A)$. Conversely, if $(A, \mathcal{T}_A)$ is $f$-adic, let $A_0 \subset A$ be any subring of definition; by corollary 8.3.19(ii) we may find a subring of definition $A_1$ of $A$ contained in $A_0 \cap B$; especially, $A_1$ is an open subring of $B$ whose topology is adic with a finitely generated ideal of adic definition (proposition 8.3.18(ii)), whence the assertion.

(ii.a) is clear. Next, for every $a \in A$ there exists $n \in \mathbb{N}$ such that $s^n a \in B$, so $B_s = A$. Also, the map $a \mapsto s^n a$ is an automorphism of $(A, \mathcal{T}_A)$, so $s^n B$ is open for every $n \in \mathbb{N}$. Lastly, since $B$ is bounded in $A$, for every open neighborhood $U$ of 0 in $A$ there exists $n \in \mathbb{N}$ such that $s^n B \subset U$, whence (ii.b).

(iii): Explicitly, the open subsets of $(C_f, \mathcal{T}_f)$ are the arbitrary unions of subsets of the form $a + f^n D$, where $a \in C_f$ is arbitrary and $m \in \mathbb{N}$ is any integer; indeed, it is easily seen that the intersection of any two subsets of this type is either empty, or equal to one of them, so such arbitrary unions define a topology $\mathcal{T}_f$, and it is easily seen that $(C_f, \mathcal{T}_f)$ is a topological ring (details left to the reader). A simple inspection then shows that $(C_f, \mathcal{T}_f)$ is a Tate ring. \[\square\]
Lemma 8.3.21. Let $A$ be any $c$-adic, complete and separated topological ring, $I, J \subset A$ two ideals, with $I$ finitely generated. We have:

(i) $I$ is open in $A$ if and only if the same holds for $I^c$.

(ii) If $I$ is an ideal of $c$-adic definition for $A$, the following holds:
   (a) $A$ is adic and $I$ is an ideal of adic definition for $A$.
   (b) $J$ is open in $A$ if and only if the same holds for $J^c$.

Proof. Assertion (i) is a special case of \cite[Lemma 5.3.5(ii) and 5.3.8(i)]{99}, and (ii.a) follows directly from (i). Lastly, suppose that $J^c$ is open in $A$; by (ii.a) there exists $n \in \mathbb{N}$ such that $I^n \subset J^c \subset J + I^{n+1}$. Letting $M := (I^n + J)/J$, it follows that $IM = M$, and since $A$ is complete and separated for its $I$-adic topology, $I$ lies in the Jacobson radical of $A$ (remark 8.3.10(v)); therefore $M = 0$ by Nakayama’s lemma, i.e. $I^n \subset J$, so $J$ is open in $A$.

Lemma 8.3.22. Let $A$ be a complete and separated adic topological ring, $I \subset A$ an ideal of adic definition. $M$ an $A$-module whose $I$-adic topology $\mathcal{T}_M$ is separated, $N \subset M$ a finitely generated submodule, and $N^c$ the topological closure of $N$ in $(M, \mathcal{T}_M)$. We have:

(i) If the $I$-adic topology $\mathcal{T}_N$ of $N^c$ agrees with the one induced by $\mathcal{T}_M$, then $N = N^c$.

(ii) $N$ is open in $(M, \mathcal{T}_M)$ if and only if the same holds for $N^c$.

Proof. (i): By assumption, $IN^c$ is an open submodule of $N^c$ for the topology induced by $(M, \mathcal{T}_M)$, hence $N^c = N + IN^c$, and the assertion follows from \cite[Th.8.4]{100}.

(ii): If $N$ is open in $M$, then $N = N^c$ and the assertion is clear. Conversely, if $N^c$ is open in $M$, then $I^nM \subset N^c$ for some $n \in \mathbb{N}$, hence $\mathcal{T}_N$ agrees with the topology induced from $\mathcal{T}_M$; then we get again $N = N^c$, by (i).

Definition 8.3.23. Let $(A, \mathcal{T})$ and $(A', \mathcal{T}')$ be two topological rings, and $f : A \to A'$ a ring homomorphism.

(i) We say that $f$ is $c$-adic (resp. adic) if $\mathcal{T}$ and $\mathcal{T}'$ are linear, and the family of ideals

$$((f(I) \cdot A')^c \mid I \text{ open ideal in } A) \quad (\text{resp. } (f(I) \cdot A' \mid I \text{ open ideal in } A))$$

is a fundamental system of open neighborhoods of zero in $A'$.

(ii) Suppose that $A$ and $A'$ are $f$-adic. Then we say that $f$ is $f$-adic if there are rings of definition $A_0$ of $A$ and $A'_0$ of $A'$ such that $f(A_0) \subset A'_0$ and the restriction $f|_{A_0}$ is adic.

(iii) Let $Q$ be any property of ring homomorphisms (e.g. “of finite type”, “flat”, “étale” and so on). We say that $f$ is an adically $Q$ morphism (resp. a $c$-adically $Q$ morphism) if $f$ is adic (resp. $c$-adic) and for every open ideal $I \subset A$ the induced map $A/I \to B/(IB)^c$ is a $Q$ ring homomorphism.

Lemma 8.3.24. Let $f : (A, \mathcal{T}) \to (A', \mathcal{T}')$ be any ring homomorphism of topological rings.

(i) If $f$ is $c$-adic, the following holds:

(a) $f$ is a continuous ring homomorphism.

(b) If the topology $\mathcal{T}$ is $c$-adic, the same holds for $\mathcal{T}'$, and if $I$ is any ideal of $c$-adic definition for $A$, then $f(I)A'$ is an ideal of $c$-adic definition for $A'$.

(c) If the topologies $\mathcal{T}$ and $\mathcal{T}'$ are $f$-adic, linear and complete, then $f$ is adic.

(ii) If the topologies $\mathcal{T}$ and $\mathcal{T}'$ are adic, the following conditions are equivalent:

(a) $f$ is adic.

(b) There exists an ideal of adic definition $I$ of $A$ such that $f(I) \cdot A'$ is an ideal of adic definition of $A'$.

(c) For every ideal $I$ of adic definition of $A$, the ideal $f(I) \cdot A'$ is of adic definition for $A'$.

(iii) Suppose that $f$ is an $f$-adic map of $f$-adic topological rings. Then the following holds:

(a) $f$ is continuous and bounded (i.e. if $S$ is any bounded subset of $A$, the subset $f(S)$ is bounded in $A'$). Especially, $f(A^\circ) \subset A'^\circ$.  

(b) For every ring of definition \( A_0 \) of \( A \) and \( A'_0 \) of \( A' \) such that \( f(A_0) \subset A'_0 \), and every ideal of adic definition \( I \) of \( A_0 \), the ideal \( f(I) \cdot A'_0 \) is of adic definition for \( A'_0 \).

(c) For every ring of definition \( A_0 \) of \( A \) and every open subring \( B \subset A' \) such that \( f(A_0) \subset B \), there exists a ring of definition \( A'_0 \) of \( A' \) such that \( f(A_0) \subset A'_0 \subset B \).

(d) If \( B \subset A \), \( B' \subset A' \) are open subrings with \( f(B) \subset B' \), then the restriction \( f_{|B} : B \to B' \) is \( f \)-adic, for the topologies of \( B \) and \( B' \) induced by \( \mathcal{T} \) and \( \mathcal{T}' \).

(iv) If \( f \) is a continuous open map, and the topologies \( \mathcal{T} \) and \( \mathcal{T}' \) are \( f \)-adic, then \( f \) is \( f \)-adic.

(v) Suppose that \( f(A) \) is open in \( A' \), that \( \mathcal{T} \) is a linear topology and that \( \mathcal{T}' \) is adic. Then \( f \) is adic if and only if it is a continuous open map.

Proof. (i.a) is obvious, and (i.c) follows easily from proposition \[8.3.18\](iii) and lemma \[8.3.21\](i). To show (i.b), let us first remark, quite generally :

Claim 8.3.25. Let \( f : X \to Y \) be any continuous map between arbitrary topological spaces, and \( S, T \subset X \) two subsets such that \( S^c = T^c \). Then \( (fS)^c = (fT)^c \).

Proof of the claim. It suffices to show that \( fS \subset (fT)^c \). However, clearly we have \( T \subset f^{-1}((fT)^c) \), therefore \( S \subset T^c \subset f^{-1}((fT)^c) \), whence the contention. \( \boxdot \)

Claim 8.3.26. Let \( B \) be any topological ring, \( J_1, J_2 \subset B \) two additive subgroups. Denote \( J_1, J_2 \) the additive subgroup generated by \( (j_1, j_2) \mid j_1 \in J_1, j_2 \in J_2 \), and define likewise \( J_i, J_i' \). Then

\[
(J_i, J_i')^c = (J_i', J_i)^c
\]

for every \( n \in \mathbb{N} \).

Proof of the claim. Since \( J_1, J_2 \subset J_i, J_i' \), we have \( (J_1, J_2)^c \subset (J_i, J_i')^c \). For the converse, it suffices to show that \( J_i, J_i' \subset (J_i, J_i')^c \). However, for every \( k \in \mathbb{N} \), consider the map

\[
\mu_k : (B^\oplus 2)^{\oplus k} \to B \quad (b_{ij} \mid i = 1, 2; j = 1, \ldots, k) \mapsto \sum_{i=1}^{k} b_{i1} b_{i2}.
\]

Then \( J_i, J_i' = \bigcup_{k \in \mathbb{N}} \mu_k((J_i, J_i')^c)^{\oplus k} \). Now, \( \mu_k \) is clearly continuous for the product topology on \( (B^\oplus 2)^{\oplus k} \), and \( (J_i, J_i')^{\oplus k} \) is the topological closure of \( (J_i, J_i')^{\oplus k} \) in this topology, so \( \mu_k((J_i, J_i')^{\oplus k})^{\oplus k} \) is contained in the topological closure in \( B \) of \( \mu_k((J_i, J_i')^{\oplus k})^{\oplus k} \) (claim \[8.3.25\]), which in turns is contained in \( (J_i, J_i')^c \), whence the contention.

Now, let \( B \) be any ideal of \( c \)-adic definition of \( A' \); by assumption, for every open ideal \( I' \) of \( A' \) there exists \( n \in \mathbb{N} \) such that \( (f(I'))^c \subset I \). Set \( J := f(I)A' \); then \( J \) is open in \( B \), and by claims \[8.3.26\] and \[8.3.25\] we deduce that

\[
(f((I^n)')^c)^c = ((f((I^n)')^c)^c)^c = ((f(I'))^c)^c = (f(I')A')^c = (J)^c
\]

whence the contention.

(ii): If \( I_1, I_2 \) are any two ideals of adic definition of \( A \), then there exist \( n, m \in \mathbb{N} \) such that \( I_1^n \subset I_2^m \subset I_1 \). The assertion is an easy consequence: details left to the reader.

(iii.a): The continuity of \( f \) is obvious. Suppose that \( S \subset A \) is a bounded subset, and let \( U' \subset A' \) be any open neighborhood of zero; we have to exhibit an open neighborhood of zero \( V' \) in \( A' \) such that \( f(S) \cdot V' \subset U' \). To this aim, let \( A_0 \) and \( A'_0 \) be rings of definition of \( A \) and \( A' \), such that \( f(A_0) \subset A'_0 \), and \( I \subset A_0 \) an ideal of adic definition such that \( IA'_0 \) is an ideal of adic definition of \( A'_0 \); we may assume that \( U \) is an open ideal of \( A_0 \), and we may find \( n, m \in \mathbb{N} \) such that \( f(I^n) \subset U' \) and \( S \cdot I^m \subset I^n \). Thus, \( f(S) \cdot f(I^m) \subset U' \), so \( V' := f^m A_0 \) will do.

(iii.b): Let \( A_1 \) and \( A'_1 \) be rings of definitions of \( A \) and \( A' \) such that \( f(A_1) \subset A'_1 \), and \( J \subset A_1 \) an ideal of adic definition such that \( K := f(J) \cdot A'_1 \) is an ideal of adic definition of \( A'_1 \). Then there exist \( n, m \in \mathbb{N} \) such that \( J^n \subset I \) and \( K^m \subset A'_0 \), so that \( K^{n+m} = f(J^n) \cdot K^m \subset f(I) \cdot A'_0 \); especially, \( f(I) \cdot A'_0 \) is open in \( A'_0 \). Moreover, since \( f \) is topologically nilpotent and finitely generated in \( A_0 \), it is easily seen that \( f(I)A'_0 \) is topologically nilpotent in \( A'_0 \); thus \( f(I)A'_0 \) is an ideal of adic definition of \( A'_0 \), as stated.
(iii.c) follows easily from (iii.a) and corollary 8.3.19(ii).

(iii.d): By corollary 8.3.20, both $B$ and $B'$ are f-adic rings. Let $A_0 \subset A$ and $A'_0 \subset A'$ be subrings of definition with $f(A_0) \subset A'_0$; hence $B_0 := A_0 \cap B$ and $B'_0 := A'_0 \cap B'$ are subrings of definition of $B$ and $B'$ respectively, with $f(B_0) \subset B'_0$ (proposition 8.3.18(ii)); then the assertion follows from (iii.b).

(iv): Let $A_0$ and $A'_0$ be rings of definition of $A$ and $A'$; after replacing $A_0$ by $A_0 \cap f^{-1}A'_0$ we may assume that $f(A_0) \subset A'_0$ (proposition 8.3.18(ii)); by assumption, $f(A_0)$ is open in $A'$, so we may further replace $A'_0$ by $f(A'_0)$, and assume from start that $f$ restricts to an open surjective map $A_0 \to A'_0$. In this case, let $I \subset A_0$ be any ideal of adic definition; it follows easily that $f(I)$ is an ideal of adic definition for $A'_0$, so $f$ is adic.

(v) If $f$ is a continuous open map, then for every pair of open ideals $J \subset A'$ and $I \subset A$ with $f(I) \subset J$, we have $f(I) \cdot A' \subset J$, and clearly $f(I) \cdot A'$ is open in $A'$. This shows that $f$ is adic.

Conversely, if $f$ is adic and $f(A)$ is open in $A'$, let $J \subset f(A)$ be an open ideal of $A'$. For every open ideal $I \subset A$, the ideal $f(I) \cdot A'$ is open in $A'$, hence the same holds for $f(I) \cdot J$; but $f(I) \cdot J \subset f(I)$, so $f(I)$ is open for every such $I$, and thus $f$ is open.

Example 8.3.27. Let $(A, \mathcal{T})$ be a topological ring, $f : A \to A'$ a surjective ring homomorphism, and endow $A'$ with the topology $\mathcal{T}'$ induced by $A$ via $f$. We have:

(i) It is easily seen that a subset $U' \subset A'$ is open if and only if $U' = f(U)$ for some open subset $U$ of $A$. It follows that $(A', \mathcal{T}')$ is a topological ring.

(ii) Moreover, if $(A, \mathcal{T})$ is c-adic, the same holds for $(A', \mathcal{T}')$, and $f : (A, \mathcal{T}) \to (A', \mathcal{T}')$ is c-adic. Indeed, let $I \subset A$ be an ideal of c-adic definition, and set $J := f(I)$; by (i) we know that $f((I^n)^c)$ is open in $A'$ for every $n \in \mathbb{N}$, and then claim 8.3.25 implies that $f((I^n)^c) = (J^n)^c$, so the latter is open in $A'$ for every $n \in \mathbb{N}$, again by (i), and the system of such ideals is a fundamental system of open neighborhoods of $0$ in $A'$.

(iii) Likewise, if $(A, \mathcal{T})$ is adic (resp. f-adic), the same holds for $(A', \mathcal{T}')$, and $f$ is adic (resp f-adic).

Definition 8.3.28. For any f-adic ring $A$, set

$$X_A := \text{Spec } A \quad X_A^\infty := \text{Spec } A/A^\infty A.$$ 

We call $X_A^\infty$ the non-analytic locus of $X_A$ and its complement $X_A \setminus X_A^\infty$ the analytic locus.

Lemma 8.3.29. Let $A$ and $B$ be two f-adic rings, $f : A \to B$ a continuous ring homomorphism, and set $\varphi := \text{Spec } f$. We have:

(i) $X_A^\infty = \{ p \in X_A \mid p \text{ is open in } A \}$. 

(ii) $\varphi$ restricts to a map $X_B^\infty \to X_A^\infty$.

(iii) If $f$ is an injective and open map, $\varphi$ restricts to an isomorphism of schemes:

$$X_B \setminus X_B^\infty \cong X_A \setminus X_A^\infty.$$ 

(iv) The homomorphism $f$ is f-adic if and only if $\varphi^{-1}(X_A^\infty) = X_B^\infty$.

(v) Let $J \subset A$ be any ideal. Then $J$ is open if and only if $\text{Spec } A/J \subset X_A^\infty$.

Proof. (i) and (ii) are clear.

(v): If $J$ is open, then the same holds for every prime ideal $p$ containing $J$; in light of (i) it then follows that $A^\infty \subset p$ for every such $p$, so the radical of $J$ also contains $A^\infty$, i.e. Spec $A/J \subset X_A^\infty$. Conversely, suppose that the radical of $J$ contains $A^\infty$, and pick any subring of definition $A_0 \subset A$, and a finitely generated ideal $I \subset A_0$ of adic definition; it follows easily that $J$ contains $I^n$ for every sufficiently large $n \in \mathbb{N}$, so $J$ is open.

Next, let us check that if $f$ is adic, then $\varphi^{-1}(X_A^\infty) = X_B^\infty$. Indeed, pick subrings of definition $A_0 \subset A$, $B_0 \subset B$ such that $f(A_0) \subset B_0$, and an ideal of adic definition $I$ of $A_0$; then $J :=$
\(f(I) \cdot B_0\) is an ideal of adic definition of \(B_0\) (lemma \[8.3.24\] iii.b)). It is easily seen that \(X^\infty_A = \text{Spec} A/IA\) and \(X^\infty_B = \text{Spec} B/JB\), whence the stated condition.

(iii): Notice first that \(f\) is \(f\)-adic in the current situation, so the foregoing already shows that \(\varphi^{-1}(X^\infty_A) = X^\infty_B\). The latter means that \(X_B \setminus X^\infty_B = \bigcup_{x \in A^\infty} \text{Spec} B_x\). Now, let \(p \in X_A \setminus X^\infty_A\) be any non-open prime ideal of \(A\); then there exists \(s \in A^\infty\) such that \(s \notin p\), and it suffices to check that the localization \(f_s : A_s \to B_s\) is an isomorphism. However, \(f_s\) is obviously injective; let \(b \in B\) be any element; since \(A\) is open in \(B\), there exists \(n \in \mathbb{N}\) such that \(s^n b \in A\), so \(f_s\) is surjective as well.

(iv): By the foregoing, we may assume that \(\varphi^{-1}(X^\infty_A) = X^\infty_B\), and we check that \(f\) is adic. Indeed, pick a subring of definition \(B_0 \subset B\); since \(f\) is continuous, \(f^{-1} B_0\) is open in \(A_0\), so we may find a subring of definition \(A_0\) of \(A\) such that \(A_0 \subset f^{-1} B_0\) (corollary \[8.3.19\] ii)). Let \(f_0 : A_0 \to B_0\) be the restriction of \(f\), and set \(\varphi_0 := \text{Spec} f_0\); we get a commutative diagram

\[
\begin{array}{ccc}
X_B & \xrightarrow{\varphi} & X_A \\
\downarrow & & \downarrow \\
X_{B_0} & \xrightarrow{\varphi_0} & X_{A_0}
\end{array}
\]

whose vertical arrows are induced by the corresponding inclusion maps. The assumption implies that \(\varphi^{-1}(X_A \setminus X^\infty_A) = X_B \setminus X^\infty_B\), together with (iii), we deduce that \(\varphi^{-1}_0(X_{A_0} \setminus X^\infty_{A_0}) = X_{B_0} \setminus X^\infty_{B_0}\), which is equivalent to \(\varphi^{-1}_0(X^\infty_{A_0}) = X^\infty_{B_0}\). On the other hand, it suffices to show that \(f_0\) is an adic ring homomorphism, so we may replace \(A\) and \(B\) by \(A_0\) and \(B_0\), and assume from start that \(A\) and \(B\) are adic topological rings. However, our assumption on \(\varphi^{-1}(X^\infty_A)\) means that the radical of \(f(A^\infty) \cdot B\) equals \(B^\infty\); now, pick any finitely generated ideal of adic definition \(I\) of \(A\) (resp. \(J\) of \(B\)); then the radical of \(f(I) \cdot B\) also equals \(B^\infty\), and according to (v), the latter condition implies that \(f(I) \cdot B\) is open in \(B\), so \(f\) is adic. \(\square\)

**Proposition 8.3.30.** With the notation of definition \[8.3.28\] let \(U \subset X_A\) be a quasi-compact open subset containing the analytic locus. We have:

(i) There exists a unique ring topology \(\mathcal{T}_U\) on \(A_U := \mathcal{O}_{X_A}(U)\) such that \((A_U, \mathcal{T}_U)\) is \(f\)-adic and the restriction map \(\rho_U : A \to A_U\) is open.

(ii) Suppose moreover that \(A\) admits a complete, separated and noetherian ring of definition. Then \((A_U, \mathcal{T}_U)\) is complete and separated.

(iii) Let \(\varphi : A \to B\) be any morphism of \(f\)-adic topological rings, such that the image of \(\text{Spec} \varphi\) lies in \(U\). Then the resulting map \(\varphi_U : (A_U, \mathcal{T}_U) \to (B_U, \mathcal{T}_U)\) is continuous.

**Proof.** (i): Clearly, there exists a unique topology \(\mathcal{T}_U\) on \(A_U\) such that \(\rho_U\) is open and \((A_U, \mathcal{T}_U)\) is a topological group for its additive group structure, and we need to check that \((A_U, \mathcal{T}_U)\) is a topological ring. Let \(I\) be a finitely generated ideal of adic definition for a ring of definition \(A_0\) of \(A\); the assertion comes down to the following. For every \(a \in A_U\) and every \(n \in \mathbb{N}\) there exists \(k \in \mathbb{N}\) such that

\[a \cdot \rho_U(I^k) \subset \rho_U(I^n)\]

Now, pick a finite system of generators \((f_1, \ldots, f_r)\) of \(I\), and notice that \(A^\infty\) is the radical of the ideal \(IA^\infty\) in the subring \(A^\circ\) of \(A\) (remark \[8.3.10\] iv)), hence

\[X^\infty_A = \text{Spec} A/IA\]

Let \(j : U \to X_A\) be the inclusion map; then \(j_* \mathcal{O}_U\) is a quasi-coherent \(\mathcal{O}_{X_A}\)-module ([44, Ch.I, Cor.9.2.2]), and on the other hand, from (8.3.31) and our assumption on \(U\) we see that \(\text{Spec} A_{f_i} \subset U\). Hence

\[A_{f_i} = \mathcal{O}_{X_A}(\text{Spec} A_{f_i}) = j_* \mathcal{O}_U(\text{Spec} A_{f_i}) = j_* \mathcal{O}_U(X_A)_{f_i} = A_U[f_i^{-1}]\quad \text{for } i = 1, \ldots, r.\]
Thus, there exists \( m \in \mathbb{N} \) such that \( f^{n_0}a \in \rho_U(A) \) for every \( i = 1, \ldots, r \). Then there also exists \( t \in \mathbb{N} \) such that \( \rho_U(I_0)^t \cdot f^{n_0}a \subset \rho_U(I^n) \) for \( i = 1, \ldots, r \), and the assertion follows easily. It is then also clear that the topology \( \mathcal{T}_U \) is \( f \)-adic, and \( \rho_U(A_0) \) is a ring of definition of \( A_U \), with \( \rho_U(I) \) as ideal of \( f \)-adic definition.

(ii) Let \( A_0 \subset A \) be a noetherian, complete and separated subring of definition; it suffices to check that \( A_0 \cap \text{Ker } \rho_U \) is a closed ideal, but this holds, by \[100\] Th.8.10(i).

(iii) Let \( H \subset B \) be any open additive subgroup; then \( \varphi_U^{-1}H \) contains the open subgroup \( \rho_U(\varphi^{-1}H) \), so it is open, whence the contention. \( \Box \)

**Lemma 8.3.32.** Let \( f : (A, \mathcal{T}_A) \to (B, \mathcal{T}_B) \) be a \( c \)-adic morphism of topological rings. Then:

(i) The completion map \( (A, \mathcal{T}_A) \to (A^\wedge, \mathcal{T}^\wedge_A) \) is \( c \)-adic, and \( A \) is \( c \)-adic if and only if the same holds for \( A^\wedge \).

(ii) The separated completion \( f^\wedge : (A^\wedge, \mathcal{T}^\wedge_A) \to (B^\wedge, \mathcal{T}^\wedge_B) \) of \( f \) is \( c \)-adic.

(iii) Let \( Q \) be any property of ring homomorphisms. If \( f \) is a \( c \)-adically \( Q \) morphism, the same holds for \( f^\wedge \) (see definition 8.3.23(iii)).

(iv) If the topology \( \mathcal{T}_A \) is \( I \)-adic for some finitely generated ideal \( I \subset A \), the topology \( \mathcal{T}^\wedge_A \) is \( IA^\wedge \)-adic.

**Proof.** (i): Let \( (I_\lambda | \lambda \in \Lambda) \) be any fundamental system of open ideals of \( A \), and set \( I_\lambda^\wedge := (I_\lambda A^\wedge)^c \) for every \( \lambda \in \Lambda \). From remark 8.3.3(ii) we see that \( (I_\lambda^\wedge | \lambda \in \Lambda) \) is a fundamental system of open neighborhoods of zero in \( A^\wedge \), so \( \mathcal{T}^\wedge_A \) is a linear topology, and the completion map \( A \to A^\wedge \) is \( c \)-adic. In view of lemma 8.3.24(i, b), it follows that if \( A \) is \( c \)-adic, the same holds for \( A^\wedge \). For the converse, suppose that \( A^\wedge \) is \( c \)-adic, and pick an ideal of \( c \)-adic definition of the form \((IA^\wedge)^c \), where \( I \) is an open ideal of \( A \); for every \( n \in \mathbb{N} \) we let \((I^n)^c \) (resp. \((I^n)^\wedge \)) be the topological closure of \( I^n \) in \( A \) (resp. in \( A^\wedge \)); then

\[
(I^n)^c = A \cap (I^n)^\wedge \quad \text{for every } n \in \mathbb{N}.
\]

Now, let \( J \subset A \) be any open ideal; the topological closure \( J^\wedge \) of \( J \) in \( A^\wedge \) is open in \( A^\wedge \), so there exists \( n \in \mathbb{N} \) such that \((I^n)^c \subset J^\wedge \), and therefore \((I^n)^c \subset A \cap J^\wedge = J \), which says that \( A \) is \( c \)-adic with \( I \) as ideal of \( c \)-adic definition.

(ii): We know already that \( \mathcal{T}^\wedge_A \) and \( \mathcal{T}^\wedge_B \) are both linear topologies. Next, by assumption, for every open ideal \( J \subset B \) there exists \( \lambda \in \Lambda \) such that \((I_\lambda B)^c \subset J \); it follows that \((I_\lambda B^\wedge)^c \subset (J B^\wedge)^c \). Likewise, for every \( \lambda \in \Lambda \) there exists an open ideal \( J \) of \( B \) such that \( J \subset (I_\lambda B)^c \), and therefore \((J B^\wedge)^c \subset (I_\lambda B^\wedge)^c \). Since the family \(((J B^\wedge)^c | J \subset B) \) is a fundamental system of open ideals of \( B \), it follows that the same holds for the family \(((I_\lambda B^\wedge)^c | \lambda \in \Lambda) \), whence the contention.

(iii): This follows easily from (ii), taking into account the natural isomorphisms

\[
A^\wedge/(IA^\wedge)^c \sim A/I \quad \text{and} \quad B^\wedge/(JB^\wedge)^c \sim B/J
\]

for every open ideals \( I \) of \( A \) and \( J \) of \( B \), as well as the equality : \((IA^\wedge)^c B^\wedge) = (IB^\wedge)^c \), which identify the map \( A^\wedge/(IA^\wedge)^c \to B^\wedge/(IB^\wedge)^c \) induced by \( f^\wedge \) with the map \( A/I \to B/(IB)^c \) induced by \( f \).

(iv) follows easily from remark 8.3.3(ii, iv). \( \Box \)

**Proposition 8.3.33.** Let \( A \) be an \( f \)-adic topological ring, \( A_0 \) an open subring of \( A \), and \( A^\wedge_0 \), \( A^\wedge \) the separated completions of \( A_0 \) and respectively \( A \). We have :

(i) \( A^\wedge \) is an \( f \)-adic topological ring.

(ii) If \( A_0 \) is a ring of definition of \( A \), then \( A^\wedge_0 \) is a ring of definition for \( A^\wedge \).

(iii) The natural map \( j : A \otimes_{A_0} A_0^\wedge \to A^\wedge \) is a ring isomorphism.

**Proof.** By corollary 8.2.17(i), the natural map \( A^\wedge_0 \to A^\wedge \) is an open immersion, so (i) and (ii) follow from lemma 8.3.32(iv).
(iii): Suppose first that $A_0$ is a ring of definition of $A$. Since $A_0$ is open in $A$, the topology induced by $A$ on $B := A/A_0$ via the projection $A \to B$ is discrete, so the completion map $B \to B^\wedge$ is an isomorphism of topological groups, and there follows a commutative ladder:

\[
\begin{array}{cccccc}
0 & \longrightarrow & A_0^\wedge & \longrightarrow & A \otimes_{A_0} A_0^\wedge & \longrightarrow & B \otimes_{A_0} A_0^\wedge & \longrightarrow & 0 \\
\end{array}
\]

whose bottom row is short exact, by proposition [8.2.13](v). It follows that the top row is exact as well, and to conclude, it suffices to show that $j_B$ is an isomorphism. To this aim, let us write $B$ as the colimit of the filtered system $(B_\lambda | \lambda \in \Lambda)$ of its finitely generated $A_0$-submodules; clearly it suffices to show that the restriction $j_\lambda : B_\lambda \otimes_{A_0} A_0^\wedge \to B_\lambda$ of $j_B$ is an isomorphism for every such $\lambda$. However, for every $\lambda \in \Lambda$ there exists an open ideal $I_\lambda \subset A_0$ such that $I_\lambda B_\lambda = 0$, so $j_\lambda$ factors as the composition of the isomorphism $B_\lambda \otimes_{A_0} A_0^\wedge \cong B_\lambda \otimes_{A_0} A_0^\wedge / I_\lambda \otimes_{A_0} A_0^\wedge$ and the natural identifications $B_\lambda \otimes_{A_0} A_0^\wedge / I_\lambda \otimes_{A_0} A_0^\wedge \cong B_\lambda \otimes_{A_0} A_0^\wedge / I_\lambda$, whence the contention, in this case. Next, if $A_0$ is an arbitrary open subring of $A$, then $A_0$ is an f-adic ring (corollary [8.3.20](i)); we let $A_1$ be a ring of definition of $A_0$, and we notice that $A_1$ is also a ring of definition for $A$ (proposition [8.3.18](ii)). By the foregoing, both natural maps $A_0 \otimes_{A_1} A_1^\wedge \to A_0^\wedge$ and $A \otimes_{A_1} A_1^\wedge \to A^\wedge$ are isomorphisms, so the same follows for $j$. □

**Proposition 8.3.34.** Let $A, B, B'$ be three f-adic topological rings and $f : B \to A, g : B \to B'$ two f-adic ring homomorphisms. Then we have:

(i) There exists a unique f-adic ring topology $\mathcal{T}_A'$ on $A' := B' \otimes_B A$ such that the resulting diagram (with $f' := 1_{B'} \otimes_B f$ and $g_{A'} := g \otimes_B 1_A$)

\[
\begin{array}{cccccc}
B & \xrightarrow{f} & A \\
\downarrow{g} & & \downarrow{g_{A'}} \\
B' & \xrightarrow{f'} & (A', \mathcal{T}_A')
\end{array}
\]

is cocartesian in the category $\mathbb{Z}$-TopAlg$_{\mathbb{Z}}$-lin (notation of definition [8.3.1](v)). Moreover, both $f'$ and $g_{A'}$ are f-adic ring homomorphisms.

(ii) Suppose additionally that $f$ is open. Then the same holds for $f'$, and (8.3.35) is cocartesian in the category $\mathbb{Z}$-TopAlg.

(iii) In the situation of (ii), suppose moreover that $B$ is a ring of definition of $A$, and $g$ induces an isomorphism $g^\wedge : B^\wedge \cong B'^\wedge$ on separated completions; then

(a) $g_{A'}$ induces an isomorphism $g_{A'}^\wedge : A'^\wedge \cong A^\wedge$ on separated completions

(b) $A'^\circ$ (resp. $A'^\circ\circ$) is the image of $B' \otimes_B A^\circ$ (resp. $B' \otimes_B A'^\circ\circ$) in $A'$.

**Proof.** (i): In light of corollary [8.3.19](i) and lemma [8.3.24](iii,b) we may find subrings of definitions $B_0 \subset B, A_0 \subset A$ and $B'_0 \subset B'$ such that $f$ and $g$ restrict to adic ring homomorphisms $f_0 : B_0 \to A_0$ and $g_0 : B_0 \to A'_0$. Let also $I_0 \subset B_0$ be an ideal of adic definition; denote by $A_0'$ the image of the induced map $A'_0 := B'_0 \otimes_{B_0} A'_0 \to A'$, and endow $A_0'$ with its $I_0 A_0'$-adic topology. There exists a unique group topology $\mathcal{T}_A'$ on $A'$ such that $\overline{A_0'}$ is an open subgroup, and we claim that $\mathcal{T}_A'$ is a ring topology. This comes down to the following assertion. For every $a' \in A'$ and every $n \in \mathbb{N}$ there exists $m \in \mathbb{N}$ such that

\[
a' \cdot I_0^m \overline{A_0'} \subset I_0^n \overline{A_0'}.
\]

However, we may write $a'$ as a finite sum of terms of the form $b' \otimes a$, with $a \in A$ and $b' \in B'$, so we are easily reduced to the case where $a' = b' \otimes a$ for such $a$ and $b'$. But since $f$ and $g$ are f-adic, we may find, for every $n \in \mathbb{N}$, integers $m_1, m_2 \in \mathbb{N}$ such that $a \cdot I_0^{m_1} A_0 \subset I_0^n A_0$, and
$b' \cdot I_0^{m_2} B_0' \subseteq B_0'$; obviously $m := m_1 + m_2$ will do. It is now clear that $f'$ and $g_A$ are both f-adic ring homomorphisms for this topology $\mathcal{F}_k$ on $A'$. Lastly, let $(\mathcal{C}, \mathcal{F}_c)$ be any topological ring whose topology is $\mathbb{Z}$-linear, $h : B' \to C$ and $k : A \to C$ two continuous ring homomorphisms such that $k \circ f = h \circ g$; there follows a unique ring homomorphism $l : A' \to C$ such that $l \circ i = h$ and $l \circ g_A = k$. To conclude, we have to check that $l$ is continuous, and it suffices to show that the restriction $l_0 : A_0' \to C$ is continuous. But the topology of $A_0'$ agrees with the quotient topology induced from the $I_0 A_0'$-adic topology $\mathcal{F}_{k_0}$ on $A_0'$, so we reduced to checking that the induced map $l_0 : (A_0', \mathcal{F}_{k_0}) \to C$ is continuous in a neighborhood of 0. Thus, let $U$ be a neighborhood of 0 in $C$; since $\mathcal{F}_c$ is $\mathbb{Z}$-linear, we may assume that $U$ is a subgroup of $C$. Moreover, there exists an open neighborhood $U'$ of 0 in $C$ such that $U' \cdot U' \subseteq U$. Then we may find $n \in \mathbb{N}$ such that $k(I_0^n A_0), h(I_0^n B_0') \subseteq U'$, so that $l_0(I_0^{2n} A_0') \subseteq U$, whence the contention.

(ii): Indeed, if $f$ is open, we may replace $A_0$ by $f(B_0)$ in the foregoing, in which case the induced map $B_0' \to A_0'$ is surjective and open; since the same holds for the projection $A_0' \to A_0'$, we see that $f'$ is open. Next, let $C$ be any topological ring, and $h, k$ two continuous ring homomorphisms as in the foregoing. We have to show that the induced map $l : A' \to C$ is continuous, and we are again reduced to showing that the same holds for its restriction $l_0 : \mathcal{A}_0' \to C$. But we have just seen that the topology of $\mathcal{A}_0'$ agrees with the quotient topology induced by the surjective map $f'_0 : B_0' \to \mathcal{A}_0'$ (the restriction of $f'$); thus $l_0$ is continuous if and only if the same holds for $l_0 \circ f'_0$, and the latter is none else than the restriction of $h$.

(iii): Indeed, under these assumptions, we get a cocartesian diagram of rings

$$
\begin{array}{cccc}
B' & \xrightarrow{f'} & A' \\
\downarrow j & & \downarrow \\
B^\wedge & \xrightarrow{g_{\wedge}^{-1}} & B^\wedge \otimes B' A' & \xrightarrow{\sim} & B^\wedge \otimes_B A & \xrightarrow{\sim} & A^\wedge
\end{array}
$$

where $j$ is the completion map, and the rightmost isomorphism on the bottom row is provided by proposition 8.3.33(iii). Since the natural map $B^\wedge \to A^\wedge$ is injective, it follows especially that $\text{Ker} f' \subseteq \text{Ker} j$, and therefore $f'$ induce an isomorphism $B'^{\wedge} \xrightarrow{\sim} \mathcal{A}_0'^{\wedge}$ on separated completions. Invoking again proposition 8.3.33(iii) we deduce a commutative diagram

$$
\begin{array}{cccc}
B^\wedge \otimes_B A & \xrightarrow{\sim} & B'^{\wedge} \otimes_{B'} A' & \xrightarrow{\sim} & \mathcal{A}_0'^{\wedge} \otimes_{\mathcal{A}_0'} A' \\
\downarrow & & \downarrow & & \downarrow \\
A^\wedge & \xrightarrow{g_{\wedge}} & A'^{\wedge}
\end{array}
$$

whose top horizontal and vertical arrows are isomorphisms, so the same holds for the bottom horizontal arrow. Set $\overline{A} := \text{Im} g_A$, and endow $\overline{A}$ with the quotient topology induced by $A$ via the surjection $A \to \overline{A}$. Recall that the topology of $A$ (resp. of $A'$) agrees with the topology induced by $A^\wedge$ (resp. by $A'^\wedge$) via the completion map $A \to A^\wedge$ (resp. $A' \to A'^\wedge$); since we already know that $g_A$ is an isomorphism of topological rings, it follows easily that the topology of $\overline{A}$ agrees with the topology induced by $A'$ via the inclusion map $\overline{A} \to A'$ (details left to the reader). Moreover, recall that $g_A$ is f-adic, so lemma 8.3.24(iii) implies that the image of $B' \otimes_B A'$ lies in $A'^{\wedge}$; for the converse, say that $x \in A'^{\wedge}$, and write $x = \sum_{i=1}^n b_i \otimes a_i$ for some $n \in \mathbb{N}$ and elements $a_i \in A, b_i \in B'$, for $i = 1, \ldots, n$. Let $I \subseteq B$ be any ideal of definition; we may find $m \in \mathbb{N}$ such that $a_i, b_i \subseteq A^{\wedge}$ for every $i = 1, \ldots, n$, and since $g_{\wedge}$ is an isomorphism, we may also find $b_i' \in B, b_i'' \in I \cdot B'$ such that $b_i = g(b_i') + b_i''$ for $i = 1, \ldots, n$. Clearly $b_i'' \otimes a_i$ lies in the image of $B' \otimes_B A^{\wedge}$ for every $i = 1, \ldots, n$, so $y := 1 \otimes (\sum_{i=1}^n a_i b_i'') \in \overline{A} \cap A'^{\wedge} \subseteq \overline{A}^\wedge$, and it remains only to observe that $\overline{A}^\wedge = g_A(A^\wedge)$, because the kernel of the surjection $A \to \overline{A}$ is contained in the kernel of the completion map $A \to A^\wedge$ (details left to the reader). Likewise,
if \( x \in A^{\infty} \), then \( y \in \overline{A} \cap A^{\infty} = \overline{A}^{\infty} = g(A^{\infty}) \), which shows that \( A^{\infty} \) lies in the image of \( B' \otimes_B A^{\infty} \), and the converse inclusion is obvious. 

8.3.36. Let \( A \) be any topological ring; for any two subsets \( S, T \subset A \) we denote by \( S \cdot T \) the additive subgroup of \( A \) generated by \( \{st \mid s \in S, \ t \in T\} \). We define inductively

\[
T^0 := \{1\} \quad \text{and} \quad T^{n+1} := T \cdot T^n \quad \text{for every} \ n \in \mathbb{N}.
\]

Now, let \( (T_\lambda \mid \lambda \in \Lambda) \) be any (small) family of subsets of \( A \); then, for every \( \nu \in \mathbb{N}(\Lambda) \) the additive subgroup

\[
T^\nu := \prod_{\lambda \in \Lambda} T^\nu_\lambda
\]

is well defined. We consider the polynomial \( A \)-algebra

\[
A[X_\lambda] := A[X_\lambda \mid \lambda \in \Lambda]
\]

and we also set \( X^\nu := \prod_{\lambda \in \Lambda} X^\nu_\lambda \) for every such \( \nu \). Furthermore, let \( \mathcal{U}_A \) be the set of all open neighborhood \( U \) of 0 in \( A \), and set

\[
U[T_\lambda X^\nu] := \left\{ \sum_{\nu \in \mathbb{N}(\Lambda)} a_\nu X^\nu \in A[X_\lambda] \mid a_\nu \in T^\nu \cdot U \text{ for every } \nu \in \mathbb{N}(\Lambda) \right\} \quad \text{for every } U \in \mathcal{U}_A.
\]

**Proposition 8.3.37.** In the situation of (8.3.36), suppose that \( A \) is an \( f \)-adic ring, and \( T_\lambda \cdot A \) is an open ideal of \( A \) for every \( \lambda \in \Lambda \), and let \( A_0 \subset A \) be a subring of definition. Then we have:

(i) There exists a unique ring topology \( \mathcal{T}_{A,T} \) on \( A[X_\lambda] \) for which the family

\[
\mathcal{U}_{A[X_\lambda]} := (U[T_\lambda X^\nu] \mid U \in \mathcal{U}_A)
\]

is a fundamental system of open neighborhoods of 0.

(ii) The topological ring

\[
A[X_\lambda] := (A[X_\lambda], \mathcal{T}_{A,T})
\]

is \( f \)-adic, and \( A_0[T_\lambda X^\nu] \) is a subring of definition of \( A[X_\lambda] \). Moreover, if \( I \subset A_0 \) is an ideal of adic definition, then \( I[T_\lambda X^\nu] \) is an ideal of adic definition for \( A_0[T_\lambda X^\nu] \).

(iii) The structure map \( h : A \to A[X_\lambda] \) is \( f \)-adic for the topology \( \mathcal{T}_{A,T} \), and the subset \( \{tX_\lambda \mid \lambda \in \Lambda, \ t \in T_\lambda\} \) is power bounded in \( A[X_\lambda] \).

(iv) Moreover, for every \( f \)-adic ring \( B \), every family \( (b_\lambda \mid \lambda \in \Lambda) \) of elements of \( B \), and every continuous ring homomorphism \( f : A \to B \) such that \( F := \{f(t) \cdot b_\lambda \mid \lambda \in \Lambda, \ t \in T_\lambda\} \) is power bounded in \( B \), there exists a unique continuous ring homomorphism \( g : (A[X_\lambda], \mathcal{T}_{A,T}) \to B \) with \( g \circ h = f \) and \( g(X_\lambda) = b_\lambda \) for every \( \lambda \in \Lambda \).

**Proof.** (i): Notice that every element of \( \mathcal{U}_{A[X_\lambda]} \) is an additive subgroup of \( A[X_\lambda] \); it follows easily that there exists a unique group topology on \( A[X_\lambda] \) that admits \( \mathcal{U}_{A[X_\lambda]} \) as a fundamental system of neighborhoods of 0. Moreover, for \( U \in \mathcal{U}_A \) we may find \( V \in \mathcal{U}_A \) with \( V \cdot V \subset U \), whence \( V[T_\lambda X^\nu] \cdot V[T_\lambda X^\nu] \subset U[T_\lambda X^\nu] \). Therefore, it remains only to check that for every \( P \in A[X_\lambda] \) and every \( U \in \mathcal{U}_A \) there exists \( V \in \mathcal{U}_A \) such that

\[
P \cdot V[T_\lambda X^\nu] \subset U[T_\lambda X^\nu].
\]

To this aim, notice first that, since \( A \) is \( f \)-adic and \( T_\lambda \cdot A \) is open in \( A \) for every \( \lambda \in \Lambda \), then \( T^\nu \cdot U \in \mathcal{U}_A \) for every \( \nu \in \mathbb{N}(\Lambda) \) and every \( U \in \mathcal{U}_A \) (details left to the reader). Say that

\[
P = \sum_{\nu \in \mathbb{N}(\Lambda)} a_\nu X^\nu;
\]

since \( a_\nu = 0 \) except for finitely many \( \nu \in \mathbb{N}(\Lambda) \), we may find \( V \in \mathcal{U}_A \) small enough that \( a_\nu \cdot V \in T^\nu \cdot U \) for every \( \nu \in \mathbb{N}(\Lambda) \). It is easily seen that such \( V \) will do.

(ii): From the foregoing, it is clear that \( A_0[T_\lambda X^\nu] \) is an open subring of \( A[X_\lambda] \) and \( I[T_\lambda X^\nu] \) is an ideal of \( A_0[T_\lambda X^\nu] \). Moreover, \( I^n[T_\lambda X^\nu] = I[T_\lambda X^\nu]^n \) for every \( n \in \mathbb{N} \), so the topology \( \mathcal{T}_{A,T} \) induces the \( I[T_\lambda X^\nu] \)-adic topology on \( A_0[T_\lambda X^\nu] \).
(iii): The continuity of \( h \) is obvious; moreover, \( h \) restricts to a map \( A_0 \to A_0[T_\bullet X_\bullet] \), and \( T \cdot A_0[T_\bullet X_\bullet] = f[T_\bullet X_\bullet] \), so \( h \) is \( f \)-adic. Lastly, we have \( tX_\lambda \in A_0[T_\bullet X_\bullet] \) for every \( \lambda \in \Lambda \) and \( t \in T_\lambda \), whence the assertion.

(iv): Obviously there exists a unique map of \( A \)-algebras \( g : A[X_\bullet] \to B \) such that \( g(X_\lambda) = b_\lambda \) for every \( \lambda \in \Lambda \), and it suffices to check that \( g \) is continuous. To this aim, for any open additive subgroup \( U \) of \( B \) pick \( V \in \mathcal{U}_B \) such that \( F^n \cdot V \subset U \) for every \( n \in \mathbb{N} \). Set also \( W := f^{-1}V \); then \( g(W[T_\bullet X_\bullet]) \subset U \), whence the contention. \( \square \)

8.3.38. Modules of finite type over topological rings. Let \( (A, \mathcal{T}_A) \) be a topological ring, and \( M \) any \( A \)-module of finite type. We choose any surjective \( A \)-linear map \( \pi : A^\oplus_n \to M \) (for some \( n \in \mathbb{N} \)) and we endow \( A^\oplus_m := A \times \cdots \times A \) with the product of the topologies of its direct factors, and \( M \) with the topology \( \mathcal{T}_M \) induced by \( A^\oplus_m \) via the map \( \pi \).

Lemma 8.3.39. With the notation of (8.3.38), the following holds:

(i) The topology \( \mathcal{T}_M \) is independent of the choice of \( \pi \).
(ii) \( \pi : (A, \mathcal{T}_A)^n \to (M, \mathcal{T}_M) \) is an open map.

Proof. (i): Let \( \pi' : A^\oplus_m \to M \) be any other \( A \)-linear surjection; we define \( \pi'' : A^\oplus_{n+m} = A^\oplus_n \oplus A^\oplus_m \to M \) as the unique \( A \)-linear map whose restriction to \( A^\oplus_n \oplus 0 \) agrees with \( \pi \) and whose restriction to \( 0 \oplus A^\oplus_m \) agrees with \( \pi' \). It suffices to check that the topologies on \( M \) induced by \( A^\oplus_n \) and \( A^\oplus_m \) via \( \pi \) and respectively \( \pi' \) agree with the topology \( \mathcal{T}_M \) induced by \( A^\oplus_{n+m} \) via \( \pi'' \). Thus, we are reduced to comparing \( \mathcal{T}_M^A \) and \( \mathcal{T}'' \). Now, let \( e_1, \ldots, e_{n+m} \) be the standard basis of \( A^\oplus_{n+m} \), and for each \( i = 1, \ldots, m \) choose \( f_i \in A^\oplus_n \oplus 0 \) such that \( \pi''(f_i) = \pi''(e_{i+n}) \); we consider the \( A \)-linear automorphism

\[
\omega : A^\oplus_{n+m} \to A^\oplus_{n+m} \quad \quad e_j \mapsto \begin{cases} e_j & \text{for } j = 1, \ldots, n \\ e_j - f_{j-n} & \text{for } j = n + 1, \ldots, n+m. \end{cases}
\]

Clearly \( \omega : (A, \mathcal{T}_A)^{n+m} \to (A, \mathcal{T}_A)^{n+m} \) is a homeomorphism, and the restriction of \( \pi'' \circ \omega \) to \( A^\oplus_n \oplus 0 \) still agrees with \( \pi \). We may then replace \( \pi'' \) by \( \pi'' \circ \omega \) and assume from start that \( 0 \oplus A^\oplus_m \subset \ker \pi'' \). Now, let \( U \subset M \) be any subset; we have \( U \subset \mathcal{T}_M^A \) if and only if \( \pi^{-1}U \) is open in \( (A, \mathcal{T}_A)^n \), and the latter holds if and only if \( (\pi^{-1}U) \times A^\oplus_m \) is open in \( (A, \mathcal{T}_A)^{n+m} \), which in turn is equivalent to \( U \subset \mathcal{T}_M^A \), whence the contention.

(ii): Let \( U \subset A^\oplus_m \) be any open subset and set \( U' := U + \ker \pi := \{ u + v \mid u \in U, v \in \ker \pi \} \); then \( U' \) is open in \( A^\oplus_{n+m} \) and \( \pi^{-1}(U') = U' \), whence the contention. \( \square \)

Definition 8.3.40. In the situation of (8.3.38), we call \( \mathcal{T}_M \) the canonical topology of the \( A \)-module \( M \) of finite type.

Proposition 8.3.41. Let \( (A, \mathcal{T}_A) \) be a topological ring, \( M_1, \ldots, M_k \) a finite sequence of \( A \)-modules of finite type, \( (N, \mathcal{T}_N) \) a topological \( A \)-module and \( \beta : M_1 \times \cdots \times M_k \to N \) any \( A \)-multilinear map. Then we have:

(i) The canonical topology of the \( A \)-module \( M_1 \times \cdots \times M_k \) is the product of the canonical topologies \( \mathcal{T}_{M_1}, \ldots, \mathcal{T}_{M_k} \).
(ii) \( \beta \) is a continuous map \( (M_1, \mathcal{T}_{M_1}) \times \cdots \times (M_k, \mathcal{T}_{M_k}) \to (N, \mathcal{T}_N) \).

Proof. (i): By a simple induction on \( k \), we are easily reduced to the case where \( k = 2 \). Let then \( \mathcal{T} \) be the product of the topologies \( \mathcal{T}_{M_i} \) and \( \mathcal{T}_M \); pick \( A \)-linear surjections \( \pi_i : A^\oplus_{m_i} \to M_i \) for \( i = 1, 2 \). It is easily seen that if \( U \in \mathcal{T} \), then \( (\pi_1 \times \pi_2)^{-1}U \) is open in \( (A, \mathcal{T}_A)^{n_1+n_2} \), hence \( U \in \mathcal{T}_{M_1 \times M_2} \) (details left to the reader). Conversely, if \( U \in \mathcal{T}_{M_1 \times M_2} \), then \( (\pi_1 \times \pi_2)^{-1}U \) is a union of subsets of the form \( V_1 \times V_2 \), where \( V_i \subset A^\oplus_{m_i} \) is an arbitrary open subset, for \( i = 1, 2 \); therefore \( (\pi_1 \times \pi_2)(V_1 \times V_2) = (\pi_1 V_1) \times (\pi_2 V_2) \in \mathcal{T} \) since \( \pi_1 \) and \( \pi_2 \) are open maps (lemma 8.3.39(ii)), and so \( U \in \mathcal{T} \).
(ii) Pick $A$-linear surjections $\pi_i: A^{\oplus n_i} \to M_i$ for $i = 1, \ldots, k$, and set $n := \sum_{i=1}^k n_i$ and $eta' := \beta \circ (\pi_1 \times \cdots \times \pi_k)$. It is easily seen that $eta': (A, \mathcal{T}_A)^n \to (N, \mathcal{T}_N)$ is a continuous map (details left to the reader). Now, let $U \subset N$ be any open subset; we have $eta^{-1}(U) = (\pi_1 \times \cdots \times \pi_k)(\beta^{-1}(U))$, which is open in $M_1 \times \cdots \times M_k$, since $\pi_1 \times \cdots \times \pi_k$ is an open map (lemma 8.3.39(ii)).

**Corollary 8.3.42.** Let $(A, \mathcal{T}_A)$ be any topological ring, $B \to A$ a ring homomorphism, $I \subset A$ an ideal, and $M$ and $N$ two $A$-modules of finite type. The following holds:

(i) $(M, \mathcal{T}_M^A)$ is a topological $A$-module.

(ii) Every $A$-linear surjection $M \to N$ is a continuous open map $(M, \mathcal{T}_M^A) \to (N, \mathcal{T}_N^A)$.

(iii) If the topology $\mathcal{T}_A$ is $B$-linear (resp. $1$-adic), the same holds for $\mathcal{T}_M^A$.

**Proof.** Pick an $A$-linear surjection $\pi: A^{\oplus n} \to M$.

(i): Let $\sigma_M: M \oplus M \to M$ and $\mu_M: A \times M \to M$ be respectively the addition law and the scalar multiplication law of $M$; we need to check that these maps are continuous for the product topologies $(M, \mathcal{T}_M^A) \times (M, \mathcal{T}_M^A)$ and $(A, \mathcal{T}_A) \times (M, \mathcal{T}_M^A)$. However, we have the commutative diagrams

$$
\begin{array}{ccc}
A^{\oplus n} & \xrightarrow{\sigma_M} & A^{\oplus n} \\
\pi \downarrow & & \pi \\
M \oplus M & \xrightarrow{\pi_M} & M
\end{array}
\quad
\begin{array}{ccc}
A \times A^{\oplus n} & \xrightarrow{\mu_M} & A^{\oplus n} \\
\pi \downarrow & & \pi \\
A \times M & \xrightarrow{\mu_M} & M
\end{array}
$$

where $\sigma_M^A$ and $\mu_M^A$ are the addition law and the scalar multiplication law of $A^{\oplus n}$, which are clearly continuous for the product topologies. Now, if $U \subset \mathcal{T}_M^A$, then $V := \pi^{-1}U$ is open in $(A, \mathcal{T}_A)^n$ and $W := \sigma_M^{-1}(V)$ is open in $A^{\oplus n} \oplus A^{\oplus n}$; hence $\sigma_M^{-1}(U) = (\pi \oplus \pi)(W)$ is open in $M \oplus M$, since $\pi \oplus \pi$ is open (lemma 8.3.39(ii)). Likewise one checks the continuity of $\mu_M$.

(ii): The continuity of $f: M \to N$ follows from (i) and proposition 8.3.41(ii). Next, we easily reduce to checking that the map $f \circ \pi: (A, \mathcal{T}_A)^n \to (N, \mathcal{T}_N^A)$ is open; but this map is surjective, so the assertion follows from lemma 8.3.39(i).

(iii): Suppose that $(J_\lambda \mid \lambda \in \Lambda)$ is a fundamental system of open neighborhoods of $0 \in A$ consisting of $B$-submodules; since $\pi$ is open, the family $(\pi(J_\lambda^{\oplus n}) \mid \lambda \in \Lambda)$ is a fundamental system of open neighborhoods of $0 \in M$ (details left to the reader); in view of (i), the assertion follows. Likewise, if $\mathcal{T}_A$ is the $1$-adic topology, then $(I^k A^{\oplus n} \mid k \in \mathbb{N})$ is a fundamental system of open neighborhoods of $0 \in A^{\oplus n}$, so $(I^k M \mid k \in \mathbb{N})$ is a fundamental system of open neighborhoods of $0 \in M$, i.e. $\mathcal{T}_M^A$ is the $1$-adic topology of $M$.

**Remark 8.3.43.** (i) Let $(A, \mathcal{T}_A)$ be a topological ring and $B$ any finite $A$-algebra. In light of proposition 8.3.41(ii) and corollary 8.3.42(i), it is easily seen that $(B, \mathcal{T}_B^A)$ is a topological $A$-algebra; moreover, if $\mathcal{T}_A$ is the $1$-adic topology (for some ideal $I \subset A$), then $\mathcal{T}_B^A$ is the $IB$-adic topology (corollary 8.3.42(ii)).

(ii) Let $N$ be any finite $B$-module. On the one hand, we may endow $N$ with its canonical topology $\mathcal{T}_N^B$ as $B$-module of finite type (that is, relative to the topological ring $(B, \mathcal{T}_B^A)$); on the other hand, by restriction of scalars, $N$ is also an $A$-module of finite type, so we have as well the canonical topology $\mathcal{T}_N^A$. We claim that these topologies coincide. Indeed, pick an $A$-linear surjection $\pi: A^{\oplus n} \to B$ and a $B$-linear surjection $\pi'^*: B^{\oplus m} \to N$; there follows an $A$-linear surjection $\pi^{\oplus m}: A^{\oplus nm} \to B^{\oplus m}$ and by virtue of proposition 8.3.41(i) the product topology of $B^{\oplus m} = (B, \mathcal{T}_B^A) \times \cdots \times (B, \mathcal{T}_B^A)$ agrees with the topology induced by $A^{\oplus nm}$ via $\pi^{\oplus m}$. Then the topology $\mathcal{T}_N^B$ is also induced by $\pi' \circ \pi^{\oplus m}$, whence the contention.

(iii) In the situation of (i), suppose that the topology $\mathcal{T}_A$ is $f$-adic; let $A_0 \subset A$ be a subring of definition, $I_0 \subset A_0$ a finitely generated ideal of adic definition and $(x_\lambda \mid \lambda \in \Lambda)$ a finite system of generators of $I_0$. Say that $B = \sum_{i=1}^n A b_i$ for some elements $b_1, \ldots, b_n \in B$ with $b_1 := 1,$
and let \( \pi : A^{\oplus n} \to B \) be the \( A \)-linear surjection such that \( \pi(a_1, \ldots, a_n) = \sum_{i=1}^n a_ib_i \) for every \( a_1, \ldots, a_n \in A \). We have a system \( \{c_{ijk} | i, j, k = 1, \ldots, n\} \) of elements of \( A \) such that

\[
b_ib_j = \sum_{k=1}^n c_{ijk}b_k \quad \text{for every } i, j = 1, \ldots, n.
\]

After replacing \( I_0 \) by \( I_0^k \) for \( k \in \mathbb{N} \) large enough, we may assume that \( I_0c_{ijk} \in A_0 \) for every \( i, j, k \in \{1, \ldots, n\} \). Let \( B_0 \subset B \) be the \( A_0 \)-submodule generated by \( \{1\} \cup \{b_ix_\lambda | \lambda \in \Lambda, i = 2, \ldots, n\} \). It is easily seen that \( B_0 \) is a subring of \( B \), and moreover \( J := \pi(I_0^{\oplus n}) \subset B_0 \), so \( B_0 \) is open in \( B \) (Lemma 8.3.39(ii)). Furthermore, a simple calculation shows that \( J \) is an ideal of \( B_0 \), and clearly \( I_0B_0 \subset J \). Lastly, the family \( \{\pi((I_0^{k+1})^{\oplus n}) | k \in \mathbb{N}\} \) is a fundamental system of neighborhoods of \( 0 \in B \), and we have \( \pi((I_0^{k+1})^{\oplus n}) = I_0^kJ \) for every \( k \in \mathbb{N} \), so the topology of \( B_0 \) induced by the inclusion into \((B, T_B^A)\) is \( I_0B_0 \)-adic. We conclude that the topology \( T_B^A \) is \( f \)-adic, and the structure map \( A \to B \) is \( f \)-adic and restricts to an adic finite ring homomorphism \( A_0 \to B_0 \) between subrings of definition.

### 8.4. Topologically local and topologically henselian rings

Localization and henselization are basic techniques in the study of commutative algebra; in this section we introduce suitable variants of these constructions for \( f \)-adic topological rings.

**Definition 8.4.1.** (i) Let \( A := A \) be any \( f \)-adic ring.

(i) We say that \( A \) is **topologically local** if \( A^{\circ \circ} \) lies in the Jacobson radical of \( A^e \).

(ii) We say that \( A \) is **topologically henselian** if \( (A^e, A^{\circ \circ}) \) is a henselian pair.

**Proposition 8.4.2.** Let \( A \) be any \( f \)-adic ring, and \( B \) any open subring of \( A \). We have:

(i) \( A \) is topologically local if and only if the same holds for \( B \).

(ii) If \( A \) is topologically henselian, then \( A \) is also topologically local.

(iii) \( A \) is topologically henselian if and only if the same holds for \( B \).

(iv) Suppose that \( A \) is topologically henselian, let \( C \) be any finite \( A \)-algebra, and endow \( C \) with its canonical \( A \)-module topology \( T_C^A \) (see remark 8.3.43(i)). Then \( (C, T_C^A) \) is a topologically henselian \( f \)-adic ring.

**Proof.** (i): Indeed, suppose first that \( B \) is topologically local, and let \( a \in A^{\circ \circ} \) be any element; we may find \( n \in \mathbb{N} \) such that \( a^{n+1} \in B^{\circ \circ} \), therefore \( 1 - a^{n+1} \in B^{\circ \circ} \) and

\[
(1 - a)^{-1} = (1 + a + \cdots + a^n)/(1 - a^{n+1}) \in A^e
\]

so \( a \) lies in the Jacobson radical of \( A^e \). Conversely, suppose that \( A \) is topologically local, and let \( b \in B^{\circ \circ} \) be any element; then \( 1 - b \in A^{\circ \circ} \), and we may find \( n \in \mathbb{N} \) such that \( b^{n+1}/(1 - b) \in B^e \). Therefore

\[
(1 - b)^{-1} = b^n/(1 - b) + 1 + b + \cdots + b^n \in B^e
\]

so that \( b \) lies in the Jacobson radical of \( B^e \).

(ii): Quite generally, if \((R, I)\) is a henselian pair, then \( I \) lies in the Jacobson radical of \( R \) (details left to the reader).

(iii): Indeed, suppose first that \( B \) is topologically henselian; then \( B \) is topologically local, by (ii), and therefore the same holds for \( A \), by (i); in view of [59, Rem.5.1.10(ii)] we then see that \( A \) is topologically henselian if and only if the same holds for the open subring \( C := B[A^{\circ \circ}] \) (which is \( f \)-adic, by corollary 8.3.20(i)). However, it is easily seen that the inclusion map \( B^e \to C^e \) is integral, and moreover the ideal \( A^{\circ \circ} \) of \( C^e \) is the radical of \( B^{\circ \circ} \cdot C^e \) (details left to the reader). Then the assertion follows from [59, Rem.5.1.10(i,v)].

In order to prove the converse, consider – for every scheme \( X \) – the set \( \text{oc}(X) \) of all open and closed subsets of \( X \); clearly any morphism of schemes \( \phi : Y \to X \) induces a mapping

\[
\text{oc}(\phi) : \text{oc}(X) \to \text{oc}(Y) \quad Z \mapsto \phi^{-1}Z.
\]
With this notation we have, quite generally:

**Claim 8.4.3.** Let $\varphi : Y \to X$ be any closed (resp. open) and surjective morphism of schemes, and $p_1, p_2 : Y \times_X Y \to Y$ the induced projections. Then the diagram of sets

$$\begin{array}{ccc}
oc(Y) & \xrightarrow{\text{oc}(\varphi)} & \noc(Y) \\
\downarrow{\text{oc}(p_1)} & & \downarrow{\text{oc}(p_2)} \\
\noc(Y \times_X Y) & & \end{array}$$

identifies $\text{oc}(X)$ with the equalizer of the mappings $\text{oc}(p_1)$ and $\text{oc}(p_2)$.

**Proof of the claim.** Since $\varphi$ is surjective, $\text{oc}(\varphi)$ is injective, and obviously its image lies in the equalizer of $\text{oc}(p_1)$ and $\text{oc}(p_2)$. Conversely, let $Z$ be an open and closed subset of $Y$ such that $p_1^{-1}Z = p_2^{-1}Z$. Since $\varphi$ is surjective, we have $Z \subset \varphi^{-1}(Z)$, and we claim that in fact $Z = \varphi^{-1}(Z)$. Indeed, let $y \in \varphi^{-1}(Z)$ be any point; then there exists $z \in Z$ such that $\varphi(y) = \varphi(z)$, and we may find $w \in Y \times_X Y$ such that $p_1(w) = z$ and $p_2(w) = y$. The condition on $Z$ then implies that $y \in Z$ as well, as required. Next, set $Z' := Y \setminus Z$, and notice that $Z'$ lies as well in the equalizer of $\text{oc}(p_1)$ and $\text{oc}(p_2)$, so we have also $Z' = \varphi^{-1}(Z')$; it follows that $\varphi(Z) \cap \varphi(Z') = \emptyset$, and since $\varphi$ is a closed (resp. open) mapping, we conclude that $\varphi(Z)$ is an open and closed subset of $X$ whose preimage in $Y$ equals $Z$, whence the claim. $\blacklozenge$

Now, if $A$ is topologically henselian, the foregoing shows that the same holds for $C$, and taking into account lemma [8.3.29](iii), to conclude the proof of (iii) it suffices to remark:

**Claim 8.4.4.** Let $f : R \to S$ be an integral ring homomorphism, $I \subset R$ any ideal. Suppose that the image of the induced morphism of schemes $\varphi : \text{Spec} S \to \text{Spec} R$ contains $\text{Spec} R \setminus \text{Spec} R/I$. Then we have:

(i) $I$ lies in the Jacobson radical of $R$ if and only if $IS$ lies in the Jacobson radical of $S$.

(ii) The pair $(R, I)$ is henselian if and only if the same holds for the pair $(S, IS)$.

**Proof of the claim.** Set $S' := S \times (R/I)$ and let $\pi : R \to R/I$ be the projection; the pair $(f, \pi)$ determines a unique integral ring homomorphism $f' : R \to S'$, and it is easily seen that the pair $(S, IS)$ is henselian if and only if the same holds for the pair $(S', IS')$. Likewise, obviously $IS$ lies in the Jacobson radical of $S$ if and only if $IS'$ lies in the Jacobson radical of $S'$. Moreover, $\text{Spec} f'$ is surjective; thus, we may replace $S$ by $S'$, and assume from start that $\varphi$ is surjective.

(i): Suppose first that $I$ lies in the Jacobson radical of $R$, and let $m \subset S$ be any maximal ideal; then $m' := \varphi(m)$ is a maximal ideal of $R$ ([100], Th.9.4(i)), therefore $I \subset m'$, and hence $IS \subset m$, so $IS$ lies in the Jacobson radical of $S$. Conversely, suppose that the latter condition holds, and let $m'$ be any maximal ideal of $R$; by assumption, we may find a prime ideal $m$ of $S$ with $\varphi(m) = m'$, and then $m$ must be a maximal ideal, so $IS \subset m$, and finally $I \subset m'$.

(ii): If $(R, I)$ is henselian, the same holds for $(S, IS)$ ([59], Rem.5.1.10(v)), so we may assume that $(S, IS)$ is henselian, and we show that the same holds for $(R, I)$. Indeed, let $R \to R'$ be any finite ring homomorphism; we have to check that the induced map $R' \to R'/IR'$ restricts to a bijection $\text{oc}(\text{Spec} R') \xrightarrow{\sim} \text{oc}(\text{Spec} R'/IR')$. However, set $S' := R' \otimes_R S$, and notice that the pair $(S', IS')$ is henselian (again, by [59], Rem.5.1.10(v)), and moreover the induced map $\text{Spec} S' \to \text{Spec} R'$ is surjective; thus, we may replace $R$ by $R'$, and we reduce to showing that the projection $R \to R/I$ induces a bijection $\text{oc}(\text{Spec} R) \to \text{oc}(\text{Spec} R/I)$. However, $\varphi$ is a universally closed morphism ([45], Ch.II, Prop.6.1.10), so claim [8.4.3] further reduces to checking that the induced projections $S \to S_0 := S/IS$ and $S \otimes_R S \to S_0 \otimes_R S_0$ induce bijections

$$\text{oc}(\text{Spec} S) \to \text{oc}(\text{Spec} S_0) \quad \text{oc}(\text{Spec} S \otimes_R S) \to \text{oc}(\text{Spec} S_0 \otimes_R S_0).$$

In turns, this is clear, since $(S, IS)$ and $(S \otimes_R S, IS \otimes_R S)$ are both henselian pairs (again, by [59], Rem.5.1.10(v)). $\blacklozenge$
(iv): Let $A_0 \subset A$ be a subring of definition, and $I_0 \subset A_0$ an ideal of adic definition; by remark \[8.3.43\](iii), we know that the topology $\mathcal{T}_c^A$ on $A$ is $f$-adic, and $C$ admits a subring $C_0$ of definition such that the structure map $A \to C$ restricts to an adic finite ring homomorphism $A_0 \to C_0$. Then the pair $(C_0, I_0C_0)$ is henselian (\footnote{59 Rem.5.1.10(v)}), and therefore $(C, \mathcal{T}_c^A)$ is topologically henselian, by (iii).

\[\square\]

**Remark 8.4.5.** If $A$ is a topologically local $f$-adic ring, we have a homeomorphism

\[(8.4.6) \quad 1 + A^{ao} \simeq 1 + A^{ao} : x \mapsto x^{-1}.\]

Indeed, say that $a \in A^{ao}$; then there exists $n \in \mathbb{N}$ such that

\[(8.4.7) \quad 1/(1 - a) - (1 + a + \cdots + a^n) = a^{n+1}/(1 - a) \in A^{ao}\]

and since $A^{ao}$ is an ideal of $A$, we deduce that $1/(1 - a) \in 1 + A^{ao}$. It remains only to check that \eqref{8.4.6} is continuous on $A^{ao}$. However, if $a, b \in A^{ao}$, we may write

\[(1 - a)^{-1} - (1 - a - b)^{-1} = (1 - a)^{-1} \cdot (1 - 1/(1 - (1 - a)^{-1}b))\]

so we are reduced to checking the continuity of \eqref{8.4.6} at the point $x = 1$, and the latter follows easily from \eqref{8.4.7}. Notice that the same argument proves more precisely that

\[(1 + U)^{-1} = 1 + U\]

for every open additive subgroup $U \subset A^{ao}$ such that $U \cdot U \subset U$ : details left to the reader.

8.4.8. Let $A$ be any $f$-adic ring, $B$ a ring of definition of $A$, and $I$ a finitely generated ideal of adic definition of $B$. We let

\[B_{loc} := (1 + I)^{-1}B \quad \text{and} \quad A_{loc} := A \otimes_B B_{loc}\]

and endow $B_{loc}$ with the unique topology such that the localization map $B \to B_{loc}$ is adic, and $A_{loc}$ with the unique $f$-adic ring topology $\mathcal{T}_{a}^B$ such that the inclusion map $B_{loc} \to A_{loc}$ is open and the induced map $A \to A_{loc}$ is $f$-adic (proposition \[8.3.34\](ii)). We claim that $A_{loc}$ is topologically local. Indeed, suppose that $a \in A_{loc}$; we may find $n \in \mathbb{N}$ such that $a^n \in IB_{loc}$, so $a^n = b/(1 + t)$ for some $b, t \in I$. Therefore, $1 - a^n = (1 + t - b)/(1 + t) \in B_{loc}$, and arguing as in the proof of proposition \[8.4.2\](i) we deduce that $1 - a \in A_{loc}$, whence the claim. It follows especially that $A_{loc}$ is independent of the choice of $I$ : indeed, suppose that $J \subset I$ is another ideal of adic definition for $B$, and let $A' := (1 + J)^{-1}A$; then there exist a unique map of $A$-algebras $\rho' : A' \to A_{loc}$, and a natural isomorphism $A_{loc} \simeq (1 + I)^{-1}A'$ of $A$-algebras that identifies $\rho'$ with the localization map; however, the foregoing shows that the image of $1 + I$ lies in $A^{ao}$, so $\rho'$ is bijective, and a simple inspection then shows that $\rho''$ is also an isomorphism of topological rings. Lastly, let $f : A \to C$ be any continuous ring homomorphism of $f$-adic rings, with $C$ topologically local, and let $C_0$ be a ring of definition of $C$, and $J$ an ideal of adic definition for $C_0$; by the foregoing, we may replace $I$ by a smaller open ideal, and assume that $f(I) \subset J$. Moreover $C_0$ is topologically local, by proposition \[8.4.2\](ii), whence $f(1 + I) \subset 1 + J \subset C_0^{ao}$, so that $f$ factors uniquely through the localization map $A \to A_{loc}$ and a ring homomorphism $g : A_{loc} \to C$. Furthermore, $g$ is a continuous map : indeed, $g(IB_{loc}) = g((1 + I)^{-1}I) \subset (1 + J)^{-1}J \subset J$, whence the assertion. Thus, the localization map $\rho : A \to A_{loc}$ is initial in the category of topologically local topological $A$-algebras with $f$-adic topologies; especially, the pair $(A_{loc}, \rho)$ is determined up to unique isomorphism, and we call it the **topological localization** of the $f$-adic ring $A$. 

8.4.9. For any topological ring $R$, denote by
\[ \text{R-TopAlg}_{f\text{-adic}} \quad \text{and} \quad \text{R-TopHens}_{f\text{-adic}} \]
the full subcategories of $\text{R-TopAlg}$ whose objects are respectively the f-adic topological $R$-algebras, and the topologically henselian f-adic topological $R$-algebras (definition 8.3.1(iii)).

Now, let again $A$, $B$ and $I$ as in (8.4.8), denote by $(B_i^h, I^h)$ the henselization of the pair $(B, I)$, endow $B_i^h$ with its $I^h$-adic topology, and set
\[ A^h := A \otimes_B B_i^h. \]

We endow $A^h$ with the unique topology $\mathcal{T}_h^h$ such that $(A^h, \mathcal{T}_h^h)$ is an f-adic topological ring, the natural map $B_i^h \to A^h$ is open and if the natural map $A \to A^h$ is f-adic (proposition 8.3.34(ii)).

We may then state:

**Theorem 8.4.10.** With the notation of (8.4.9), the following holds:

(i) $(A^h, \mathcal{T}_h^h)$ is a topologically henselian f-adic ring, independent of the choice of $B$ and $I$, up to unique isomorphism of topological $A$-algebras.

(ii) The rule $A \mapsto (A^h, \mathcal{T}_h^h)$ extends to a functor
\[ \text{Z-TopAlg}_{f\text{-adic}} \to \text{Z-TopHens}_{f\text{-adic}} \]
that is left adjoint to the forgetful functor (here $\text{Z}$ is endowed with its discrete topology).

**Proof.** Let us consider as well the full subcategories of $\text{Z-TopAlg}$ denoted
\[ \text{Z-TopAlg}_{ad\text{-adic}} \quad \text{and} \quad \text{Z-TopHens}_{ad\text{-adic}} \]
whose objects are respectively the adic topological rings, and the adic topological rings $R$ such that the pair $(R, R^\text{ho})$ is henselian (notice that $R^\text{ho}$ is an ideal of $R$). For every adic ring $R$, we let $(R_h, (R^\text{ho})_h)$ the henselization of the pair $(R, R^\text{ho})$, and we endow $R_h$ with the unique ring topology $\mathcal{T}_R^h$ such that the natural map $R \to R_h$ is adic. We notice:

**Claim 8.4.11.** The rule $R \mapsto (R_h, \mathcal{T}_R^h)$ extends to a functor
\[ \text{Z-TopAlg}_{ad\text{-adic}} \to \text{Z-TopHens}_{ad\text{-adic}} \]
that is left adjoint to the forgetful functor.

**Proof of the claim.** More generally, let $f : R \to S$ and $g : R \to R'$ be two ring homomorphisms, and $I \subset R$ and $J \subset S$ two ideals such that:

- $f(I) \subset J$
- $J$ lies in the Jacobson radical ideal of $S$
- $g$ is unramified, and $g \otimes_R R/I$ is an isomorphism.

Then we claim that there exists at most one ring homomorphism $h : R' \to S$ such that $h \circ g = f$. Indeed, let $h, h' : R' \to S$ be any two such maps; according to [51] Ch.IV, Prop.17.4.6], the maximal subscheme $U \subset \text{Spec} S$ such that $(\text{Spec} h)_{|U} = (\text{Spec} h')_{|U}$ is open and closed in $\text{Spec} S$, and on the other hand, $U$ contains $\text{Spec} S/J$, since $g \otimes_R R/I$ is an isomorphism. But $\text{Spec} S/J$ meets every open and closed subset of $\text{Spec} S$, since $J$ lies in the Jacobson radical of $S$, whence the assertion. Next, suppose that the pair $(S, J)$ is henselian, and $g$ is étale; in this case, the map $g \otimes_R S : S \to R' \otimes_R S$ admits a section $s : R' \otimes_R S \to S$ (51 Ch.IV, Prop.18.5.4), and we set $h := s \circ (R' \otimes_R f) : R' \to S$. By the foregoing, $h$ is the unique ring homomorphism such that $h \circ g = f$. Now, let $(R_h, I_h)$ be the henselization of the pair $(R, I)$, and recall that $R_h$ is the colimit of a filtered system $(g_\lambda : R \to R_h^\lambda \mid \lambda \in \Lambda)$ of étale ring homomorphisms such that $g_\lambda \otimes_R R/I$ is an isomorphism for every $\lambda \in \Lambda$. Summing up, we conclude that $f$ factors uniquely through a morphism of $R$-algebras $R_h \to S$. Lastly, if $R$ and $S$ are adic topological rings, then every continuous ring homomorphism $g : R \to S$ maps $I := R^\text{ho}$ into $J := S^\text{ho}$, and if $(S, S^\text{ho})$ is henselian, the foregoing yields a unique
ring homomorphism \( f^h : R^h \to S^h \) extending \( f \); to conclude, it suffices to check that \( f^h \) is continuous. However, if \( J' \) is any ideal of adic definition for \( S \), we may find an ideal \( I' \) of adic definition for \( R \) such that \( f(I') \subset J' \); by construction, \( I'R^h \) is an ideal of adic definition of \( R^h \), and \( f^h(I'R^h) \subset J' \), whence the contention. \( \Box \)

(i): Let us check first that \( A^h \) is independent of the choice of \( B \) and \( I \). Indeed, since \( B^\infty \) is the radical of \( I \), there exists a unique isomorphism \( \varphi : B^h_1 \xrightarrow{\sim} B^h \) of \( B \)-algebras, where \( B^h \) is as in the foregoing; it is then clear that the \( I^h \)-adic topology on \( B^h \) agrees with the topology \( \mathcal{T}^h_B \), under the isomorphism \( \varphi \). Let us endow \( A \otimes_B B^h \) with the unique ring topology such that the natural map \( B^h \to A \otimes_B B^h \) is open (proposition 8.3.34(ii)); it follows that \( \varphi \otimes_B A : A^h \xrightarrow{\sim} A \otimes_B B^h \) is an isomorphism of topological \( A \)-algebras, which shows that \( A^h \) does not depend on \( I \). By the same token, we also deduce that \( A^h \) is topologically henselian (proposition 8.4.2(iii)). Next, let \( C \subset A \) be another ring of definition, \( I_C \subset C \) an ideal of definition of \( C \), and \((C^h, I^h_C)\) the henselization of the pair \((C, I_C)\); endow \( C^h \) with its \( I^h_C \)-adic topology, set \( A' := A \otimes_C C^h \), and endow again \( A' \) with the unique ring topology such that the natural map \( C^h \to A' \) is open and the induced map \( A \to A' \) is \( f \)-adic. We need to show:

Claim 8.4.12. There exists a unique isomorphism of topological \( A \)-algebras \( A^h \xrightarrow{\sim} A' \).

Proof of the claim. In light of corollary 8.3.19(i) we are easily reduced to the case where \( B \subset C \), and since we have already established that the construction of \( C^h \) and \( B^h \) is independent of the ideals of definition, we may moreover assume that \( I_C = I \) (details left to the reader). In this situation, set \( D := B^h \otimes_B C \); the induced ring homomorphism \( B^h \to D \) identifies \( I^h = B^h \otimes_B I \) with the ideal \( ID \) of \( D \), and therefore the pair \((D, ID)\) is henselian ([59, Rem.5.1.10(ii)]). Let us endow \( D \) with its \( ID \)-adic topology; then \( D^\infty \) is the radical of \( ID \), and therefore \( D \) is topologically henselian ([59, Rem.5.1.10(i)]); moreover, the natural map \( C \to D \) is continuous, so by claim 8.4.11 it factors uniquely through a continuous map \( C^h \to D \) of \( C \)-algebras. We claim that the latter is an isomorphism of topological rings. Indeed, let \( E \) be any other object of \( \mathbb{Z} \text{-}\text{TopHens}_{\text{adic}} \); any continuous ring homomorphism \( B \to E \) admits a unique continuous extension \( B^h \to E \), so the set of continuous ring homomorphisms \( D \to E \) is in natural bijection with the set of continuous ring homomorphisms \( C \to E \), and the latter are as well in natural bijection with the set of continuous ring homomorphisms \( C^h \to E \), whence the claim (details left to the reader). There follows an isomorphism of \( A \)-algebras

\[ \psi : A^h \xrightarrow{\sim} A \otimes_C D \xrightarrow{\sim} A' \]

and since the structure maps of these \( A \)-algebras are \( f \)-adic, it is clear that \( \psi \) is an isomorphism of topological rings. Furthermore, suppose that \( \psi' : A^h \xrightarrow{\sim} A' \) is another isomorphism of topological \( A \)-algebras, and set \( R := \psi(B^h) \cdot \psi'(B^h) \); then \( R \) is a ring of definition of \( A' \) (corollary 8.3.19(i)), so it is an object of \( \mathbb{Z} \text{-}\text{TopHens}_{\text{adic}} \) (proposition 8.4.2(iii)), and the restrictions \( B^h \to R \) of \( \psi \) and \( \psi' \) agree on \( B \). By claim 8.4.11 it follows that \( \psi \) and \( \psi' \) agree on \( B^h \), and therefore they coincide, whence the contention. \( \Box \)

Lastly, let \( f : A \to R \) be any continuous ring homomorphism from \( A \) to a topologically henselian \( f \)-adic topological ring, and pick any ring of definition \( R_0 \) of \( R \); after replacing \( B \) by \( B \cap f^{-1}R_0 \) we may assume that \( f \) restricts to a map \( f_0 : B \to R_0 \) (proposition 8.3.18(ii)), and since \( R_0 \) is topologically henselian (proposition 8.4.2(iii)), the map \( f_0 \) factors uniquely through a continuous ring homomorphism \( f_0^h : B^h \to E \) (claim 8.4.11). The datum of \( f \) and \( f_0^h \) determines a unique continuous map of \( A \)-algebras \( A^h \to E \) (proposition 8.3.34(ii)), so the proof is concluded. \( \Box \)

Definition 8.4.13. Let \( A \) be any \( f \)-adic topological ring. The topological \( A \)-algebra \((A^h, \mathcal{T}^h_A)\) provided by theorem 8.4.10 is called the topological henselization of \( A \).
Corollary 8.4.14. Let \( A \) be any \( f \)-adic topological ring, and denote by \( A_{\text{loc}} \), \( A^h \), \( A^\wedge \) respectively the topologically localization, the topological henselization, and the separated completion of \( A \). The following holds:

(i) The localization map \( A \to A_{\text{loc}} \) and the henselization map \( A \to A^h \) induce isomorphisms of topological rings on separated completions:
\[
A^{h\wedge} \overset{\sim}{\to} A^\wedge \overset{\sim}{\to} A_{\text{loc}}^\wedge.
\]

(ii) The inclusion maps \( A^\circ \to A \) and \( A^{\circ\circ} \to A \) induce natural identifications:
\[
(A^\circ)_{\text{loc}} \overset{\sim}{\to} (A_{\text{loc}})^\circ \quad (A^\circ)^h \overset{\sim}{\to} (A^h)^\circ \quad (A^\circ)^\wedge \overset{\sim}{\to} (A^\wedge)^\circ.
\]
\[
A^{\circ\circ} \otimes_{A^\circ} A_{\text{loc}}^\circ \overset{\sim}{\to} (A_{\text{loc}})^{\circ\circ} \quad A^{\circ\circ} \otimes_{A^h} A^h \overset{\sim}{\to} (A^h)^{\circ\circ} \quad (A^{\circ\circ})^\wedge \overset{\sim}{\to} (A^\wedge)^{\circ\circ}.
\]

(iii) Let \( R \) be any open subring of \( A^\circ \), and denote by \( (R^h, R^{\circ\circ}) \) the henselization of the pair \((R, R^{\circ\circ})\). Then we have:

(a) There exists a unique ring topology \( \mathcal{T}_R^h \) on \( R^h \) such that the natural map \( R \to R^h \) is \( f \)-adic and \( (R^h, \mathcal{T}_R^h) \) is isomorphic to the topological henselization of \( R \).

(b) Endow \( A \otimes_R R^h \) with the unique \( f \)-adic topology such that the natural map \( R^h \to A \otimes_R R^h \) is open (see proposition 8.3.34(ii)). There exists a unique isomorphism of topological \( A \)-algebras \( A^h \overset{\sim}{\to} A \otimes_R R^h \).

Proof. (i): Let \( B \) be any ring of definition of \( A \); a simple inspection of the construction in (8.4.8) shows that the natural map
\[
A' := A \otimes_B B_{\text{loc}} \to A_{\text{loc}}
\]
is an isomorphism of topological rings, for the \( f \)-adic topology on \( A' \) described in proposition 8.3.34(ii). Moreover, the localization map \( B \to B_{\text{loc}} \) clearly induces an isomorphism \( B^\wedge \overset{\sim}{\to} (B_{\text{loc}})^\wedge \). Then the assertion for \( A^\wedge_{\text{loc}} \) follows from proposition 8.3.34(iii.a). Likewise, the natural map \( B \to B^h \) induces an isomorphism on separated completions, so the same argument yields the assertion for \( A^{h\wedge} \).

(ii): The assertions for \( (A_{\text{loc}})^\circ \) and \( (A_{\text{loc}})^{\circ\circ} \) follow by the same token, from proposition 8.3.34(iii.b). Likewise, we get the assertions for \( (A^h)^\circ \) and \( (A^h)^{\circ\circ} \). In the case of the completion functor, we know that the natural map \( A \otimes B^\wedge \to A^\wedge \) is an isomorphism of topological rings (proposition 8.3.33(iii)), so we may still apply proposition 8.3.34(iii) to deduce that \( (A^\circ)^\wedge \) (resp. \( (A^{\circ\circ})^\wedge \)) is the topological closure in \( A^\circ \) of the image of \( A^\circ \) (resp. \( A^{\circ\circ} \)).

(iii): Suppose first that \( R = A \); especially, \( A^\circ = A \). Then, according to corollary 8.3.19(iv), the ring \( A \) is the filtered union of the system \((B_\lambda | \lambda \in \Lambda)\) of its subrings of definitions containing \( B \), whence an induced isomorphism of \( A \)-algebras
\[
A^h \overset{\sim}{\to} \text{colim}_{\lambda \in \Lambda} B_\lambda \otimes B^h
\]
where \( B^h \) denotes the topological henselization of \( B \). On the other hand, \( B \) is also a subring of definition of \( B_\lambda \), and \( B^{\circ\circ}_\lambda = B_\lambda \cap B^{\circ\circ} \) for every \( \lambda \in \Lambda \). Let \((B^h_\lambda, J_\lambda)\) be the henselization of the pair \((B_\lambda, B^{\circ\circ}_\lambda)\); by theorem 8.4.10(i) we deduce a unique isomorphism
\[
B^h_\lambda \overset{\sim}{\to} B_\lambda \otimes B^h \quad \text{for every } \lambda \in \Lambda
\]
of topological \( B_\lambda \)-algebras. Lastly, we have a unique isomorphism of \( A \)-algebras
\[
\text{colim}_{\lambda \in \Lambda} B^h_\lambda \overset{\sim}{\to} R^h
\]
whence the sought isomorphism \( \varphi : A^h \overset{\sim}{\to} R^h \) of \( A \)-algebras. The uniqueness of \( \varphi \) follows from the universal property of the henselization functor. If we may endow \( R^h \) with the topology induced from \( A^h \) via \( \varphi \), clearly both (iii.a) and (iii.b) hold in this case.
Next, if \( R \subset A^\circ \) is an arbitrary open subring, choose a ring of definition \( B \) of \( A \) contained in \( R \); by the foregoing case, \( R^h \) is naturally isomorphic to the topological henselization of \( R \), so that we have unique isomorphisms

\[
R^h \xrightarrow{\sim} R \otimes_A A_0^h \quad A^h \xrightarrow{\sim} A \otimes_A A_0^h
\]

respectively of topological \( R \)-algebras and topological \( A \)-algebras, such that both natural maps \( A_0^h \to R^h \) and \( A_0^h \to A^h \) are open. There follows an isomorphism of topological \( A \)-algebras \( \varphi: A^h \xrightarrow{\sim} A \otimes_R R^h \) as sought. The uniqueness of \( \varphi \) follows again from the universal property of the topological henselization \( A^h \) of \( A \).

\[\square\]

**8.5. Graded structures on topological rings.** Let \( \Gamma \) be a monoid, \( A := \bigoplus_{\gamma \in \Gamma} A_\gamma \) a \( \Gamma \)-graded ring, and \( \mathcal{T} \) a topology on \( A \). The \( \Gamma \)-graded structure of \( A \) is not usually inherited by the completion \( (A, \mathcal{T})^\wedge \) of \( (A, \mathcal{T}) \). This observation motivates the following definition, that introduces a more flexible notion of graded structure on topological rings, preserved under completions and related operations.

**Definition 8.5.1.** Let \( (A, \mathcal{T}) \) be a separated topological ring, \( \Gamma \) a monoid.

(i) A \( \Gamma \)-pre-graded structure on \( (A, \mathcal{T}) \) is a datum \((A, B, \Gamma)\) consisting of a subring \( B \subset A \) with a \( \Gamma \)-graded \( \mathbb{Z} \)-algebra structure \( B \) on \( B \) (definition \[7.6.9](i)) such that the following holds:

(a) The topology induced on \( B \) by \( \mathcal{T} \) agrees with the linear topology defined by a cofiltered system of graded ideals of \( B \) (see definition \[7.6.9](iii)).

(b) \( B \) is a dense subset of \( A \).

(ii) A \( \Gamma \)-graded structure on \( (A, \mathcal{T}) \) is a \( \Gamma \)-pre-graded structure \((A, B)\) such that \( \text{gr}_\gamma B \) is a closed subset of \( A \), for every \( \gamma \in \Gamma \).

(iii) Let \((A, B, \Gamma)\) and \((A', B', \Gamma')\) be two topological rings with pre-graded structures. A morphism of topological rings with pre-graded structures \((A, B) \to (A', B')\) is a pair \((f, \varphi)\) consisting of a continuous ring homomorphism \( f : A \to A' \) and a morphism of monoids \( \varphi : \Gamma \to \Gamma' \) such that \( f(B) \subset B' \), and such that the restriction \( f|_B : B \to B' \) induces a morphism of \( \Gamma \)-graded \( \mathbb{Z} \)-algebras (notation of definition \[7.6.9](iv))

\[
B \to \Gamma \times_{\Gamma'} B'.
\]

Clearly, we get therefore a category of topological rings with pre-graded structures:

\[
\text{pre-gr.TopAlg}.
\]

We also have the full subcategory of pre-gr.TopAlg denoted

\[
\text{gr.TopAlg}
\]

whose objects are the topological rings with graded structures.

**Remark 8.5.2.** Let \((\Gamma, +, 0)\) be a monoid, \((A, B)\) a \( \Gamma \)-pre-graded structure on the topological ring \((A, \mathcal{T})\). Pick a fundamental system \((J_\lambda | \lambda \in \Lambda)\) of graded open ideals of \( B \), and endow \( \text{gr}_\lambda B \) with the topology \( \mathcal{T}_\lambda \) induced by \( \mathcal{T} \), for every \( \gamma \in \Gamma \).

(i) Since \( J_\lambda = \bigoplus_{\gamma \in \Gamma} \text{gr}_\gamma J_\lambda \) for every \( \lambda \in \Lambda \), the topology \( \mathcal{T}_\gamma \) agrees with the linear topology defined by the cofiltered system of \( \text{gr}_0 B \)-submodules \((\text{gr}_\lambda J_\lambda | \lambda \in \Lambda)\), for every \( \gamma \in \Gamma \). Moreover, a graded ideal \( I \) of \( B \) is closed in the topology of \( B \) if and only if \( \text{gr}_\gamma I \) is closed in \( \text{gr}_\gamma B \) for every \( \gamma \in \Gamma \). Indeed, since \( I \cap \text{gr}_\gamma B = \text{gr}_\gamma I \) for every such \( \gamma \), the condition is clearly necessary. Conversely, notice that the natural projection \( \pi_\gamma : B \to \text{gr}_\gamma B \) is continuous for every \( \gamma \in \Gamma \), hence the same holds for the composition \( \rho_\gamma : B \to \text{gr}_\gamma B/I \) of \( \pi_\gamma \) with the quotient map \( \text{gr}_\gamma B \to \text{gr}_\gamma B/I \); now, if \( \text{gr}_\gamma I \) is closed in \( \text{gr}_\gamma B \), the topology of \( \text{gr}_\gamma B/I \) is separated, hence \( \text{Ker} \rho_\gamma \) is closed in \( B \), and to conclude it suffices to remark that \( I \) is the intersection of such kernels, for \( \gamma \) ranging over all elements of \( \Gamma \).
(ii) For every \( \gamma \in \Gamma \), denote by \( (\text{gr}_\gamma B^\wedge, \mathcal{T}_\gamma^\wedge) \) the completion of \( (\text{gr}_\gamma B, \mathcal{T}_\gamma) \). Also, let \( \text{gr}_\gamma J_\lambda^\wedge \) be the topological closure of \( \text{gr}_\gamma J_\lambda \) in \( \text{gr}_\gamma B^\wedge \), for every \( \lambda \in \Lambda \) and \( \gamma \in \Gamma \), and set

\[
J_\lambda^\wedge := \prod_{\gamma \in \Gamma} \text{gr}_\gamma J_\lambda^\wedge, \quad B' := \prod_{\gamma \in \Gamma} \text{gr}_\gamma B^\wedge, \quad J_\lambda'' := \bigoplus_{\gamma \in \Gamma} \text{gr}_\gamma J_\lambda^\wedge, \quad B'' := \bigoplus_{\gamma \in \Gamma} \text{gr}_\gamma B^\wedge.
\]

Notice that \( B'' \) (resp. \( B' \)) is a ring (resp. a \( \text{gr}_0 B \)-module), and \( J_\lambda'' \) (resp. \( J_\lambda' \)) is an ideal of \( B'' \) (resp. a \( \text{gr}_0 B \)-submodule of \( B' \)), for every \( \lambda \in \Lambda \). We endow \( B' \) with the linear topology defined by the cofiltered system of submodules \( (J_\lambda' \mid \lambda \in \Lambda) \). Notice that \( B' \) is complete and separated, and the induced map

\[
j_B : B \to B'
\]

is continuous; more precisely, the topology of \( B \) agrees with the topology induced by \( B' \) via \( j_B \). Moreover, for every \( \gamma \in \Gamma \), let \( \pi'_\gamma : B' \to \text{gr}_\gamma B^\wedge \) be the projection; since \( J_\lambda' \subset \pi'^{-1}_{\gamma}(\text{gr}_\gamma J_\lambda) \) for every \( \lambda \in \Lambda \), we see that \( \pi'_\gamma \) is continuous for the topology \( \mathcal{T}_\gamma \), for every \( \gamma \in \Gamma \).

(iii) Next, since \( B \) is dense in \( A \), the inclusion map \( B \to A \) extends uniquely to an isomorphism between the completion \( (A^\wedge, \mathcal{T}_\wedge^\wedge) \) of \( (A, \mathcal{T}) \) and the completion of \( B \) (theorem 8.2.8 (iii)); it follows that \( j_B \) factors uniquely through a continuous map of topological \( \text{gr}_0 B \)-modules

\[
j_A : A^\wedge \to B' \quad a \mapsto (a_\gamma \mid \gamma \in \Gamma)
\]

and \( j_A \) is injective, since the topology of \( B \) is induced by that of \( B' \) (proposition 8.2.13 (i)). For every \( \gamma \in \Gamma \) we call \( \pi'_\gamma := \pi'_\gamma \circ j_A : A^\wedge \to \text{gr}_\gamma B^\wedge : a \mapsto a_\gamma \) the canonical \( \gamma \)-projection and set

\[
a_S := \sum_{\gamma \in S} a_\gamma \quad \text{for every } a \in A^\wedge \text{ and every finite subset } S \subset \Gamma.
\]

(iv) For every finite subset \( S \subset \Gamma \), let \( i_S : \text{gr}_S B := \bigoplus_{\gamma \in S} \text{gr}_\gamma B \to A \) be the inclusion map; since \( J_\lambda \) is a graded ideal for every \( \lambda \in \Lambda \), it is easily seen that the topology on \( \text{gr}_S B \) induced by \( A \) via \( i_S \) is the product topology \( \prod_{\gamma \in S} \mathcal{T}_\gamma \). Hence, \( i_S \) extends uniquely to a continuous map

\[
\prod_{\gamma \in S} (\text{gr}_\gamma B^\wedge, \mathcal{T}_\wedge^\wedge) = (\text{gr}_S B^\wedge) \to (A^\wedge, \mathcal{T}_\wedge^\wedge)
\]

which is still injective (proposition 8.2.13 (i)), whence an injective map \( B'' \to A^\wedge \). We endow the \( \Gamma \)-graded ring \( B'' := (B'', \text{gr}_\gamma B'') \) with the topology induced from \( A^\wedge \) via this map, and set

\[
(A, B)^\wedge := (A^\wedge, B'').
\]

(v) Notice that, in case \( \Gamma \neq 0 \), the separation condition on \( \mathcal{T} \) can be deduced from condition (b) in definition 8.5.1: indeed, if \( \gamma, \gamma' \) are two distinct elements of \( \Gamma \), we have

\[
\{0\}^c \subset \text{gr}_\gamma B \cap \text{gr}_{\gamma'} B = 0
\]

whence the contention. Thus, the separation condition in definition 8.5.1 only serves to rule out the somewhat trivial case of a non-separated topological space \( A \) endowed with the \( \{0\} \)-graded \( \mathbb{Z} \)-algebra structure.

**Proposition 8.5.3.** Let \( (\Gamma, +, 0) \) be a monoid, \( (A, B) \) a \( \Gamma \)-pre-graded structure on the topological ring \( (A, \mathcal{T}) \). We have:

(i) The topology \( \mathcal{T} \) is linear.

(ii) In the situation of remark 8.5.2 (iii), the system \( (a_S \mid S \subset \Gamma) \), with \( S \) ranging over the filtered set of finite subsets of \( \Gamma \), is a Cauchy net in \( B'' \), whose unique limit point is \( a \).

(iii) In the situation of remark 8.5.2 (iv), the datum \( (A, B)^\wedge \) is a \( \Gamma \)-graded structure on \( (A^\wedge, \mathcal{T}_\wedge^\wedge) \).
(iv) The inclusion functor $\text{gr.} \text{TopAlg} \to \text{pre-gr.} \text{TopAlg}$ admits a left adjoint 
$$\text{pre-gr.} \text{TopAlg} \to \text{gr.} \text{TopAlg} \quad (A, B, \Gamma) \mapsto (A, B, \Gamma)^c$$

that assigns to each topological ring with pre-graded structure its associated graded structure.

Proof. Fix a fundamental system $(J_\lambda \mid \lambda \in \Lambda)$ of graded open ideals of $B$. 

(i): Since $A$ is separated, the completion map $(A, \mathcal{T}) \to (A^\wedge, \mathcal{T}^\wedge)$ is injective, $B$ is naturally identified with a dense subring of $A^\wedge$, and the inclusion map $B \to A^\wedge$ extends to an isomorphism between $(A^\wedge, \mathcal{T}^\wedge)$ and the completion $B^\wedge$ of $B$ ([34, Ch.II. §3, n.7, Prop.13]). However, for every $\lambda \in \Lambda$, let $J_\lambda^c$ be the topological closure of $J_\lambda$ in $B^\wedge$; then $(J_\lambda^c \mid \lambda \in \Lambda)$ is a fundamental system of open ideals in $B^\wedge$ (remark 8.3.3(ii)), and lastly, $(J_\lambda^c \cap A \mid \lambda \in \Lambda)$ is a fundamental system of open ideals in $A$, whence the contention.

(ii): By remark 8.2.7(iv), the subset $\text{gr}_\gamma B^c$ is closed in the topology of $A^\wedge$, for every $\gamma \in \Gamma$. Moreover, $B \subset B^c$, so $B^c$ is dense in $A^\wedge$. In light of the proof of (i), it remains only to check that $J_\lambda^c \cap B^c = J_\lambda^c$, for every $\lambda \in \Lambda$. To this aim, say that $x \in B^c \cap J_\lambda^c$ for some such $\lambda$; then there exists a finite subset $S \subset \Gamma$ such that $x = \sum_{\gamma \in S} x_\gamma$ with $x_\gamma \in \text{gr}_\gamma B^c$ for every $\gamma \in S$. It follows that $\pi_\gamma^c(x) = x_\gamma$ for $\gamma \in S$ and $\pi_\gamma^c(x) = 0$ otherwise. On the other hand, from claim 8.3.25 we get

$$\pi_\gamma^c(x) \in \pi_\gamma^c(J_\lambda^c) \subset (\pi_\gamma(J_\lambda))^c = \text{gr}_\gamma J_\lambda^c$$

and the contention follows.

(iii): In the light of the proof of (iii), we have to check that for every $\lambda \in \Lambda$ there exists a finite subset $S_\lambda \subset \Gamma$ such that $a_S - a_{S'} \in J_\lambda^c$ for every finite subsets $S, S' \subset \Gamma$ containing $S_\lambda$. However, the proof of (i) shows that the topological closure $J_\lambda^c$ of $J_\lambda$ in $A$ is an open ideal of $A$; since $B$ is dense in $A$, it follows that there exists $b \in B$ such that $a - b \notin J_\lambda$. Write $b = \sum_{\gamma \in T} b_\gamma$ for some finite subset $T \subset \Gamma$; in view of claim 8.3.25, we deduce that

$$\pi_\gamma^c(b - a) = b_\gamma - a_\gamma \in \pi_\gamma^c(J_\lambda^c) \subset \pi_\gamma(J_\lambda)^c = \text{gr}_\gamma J_\lambda^c$$

for every $\gamma \in \Gamma$ (notation of remark 8.5.2(ii)). Especially, $a_\gamma \in \text{gr}_\gamma J_\lambda^c$ for every $\gamma \in \Gamma \setminus T$, and consequently $\pi_\gamma^c(a_S - a_{S'}) \in \text{gr}_\gamma J_\lambda^c$ for every $\gamma \in \Gamma$ and every $S, S' \subset \Gamma$ containing $T$; i.e. $a_S - a_{S'} \in J_\lambda^c$ for every such $S, S'$, so that $S_\lambda := T$ will do. By the same token, $a - a_S = (a - b) + (b - a) \in J_\lambda^c$ for every finite subset $S \subset \Gamma$ containing $T$, so $a$ is the unique limit of this Cauchy net.

(iv): For every $\gamma \in \Gamma$, let $\text{gr}_\gamma B^c$ be the topological closure of $\text{gr}_\gamma B$ in $A$, and set $B^c := \bigoplus_{\gamma \in \Gamma} \text{gr}_\gamma B^c$; clearly $B^c \subset B^\wedge$, and in light of (iii), it is clear that the pair $(A, B^c)$ is a topological ring with graded ring structure. Moreover, if $(f, \phi) : (A, B, \Gamma) \to (X, Y, \Gamma')$ is any morphism to a topological ring with graded structure, then claim 8.3.25 implies easily that $f$ maps $B^c$ into $Y$, so we get the sought left adjoint by setting $(A, B^c, \Gamma)^c := (A, B^c, \Gamma)$.

□

Example 8.5.4. Let $\Gamma$ be a monoid and $(A, B)$ a topological ring with $\Gamma$-graded structure. We have the following elementary operations:

(i) If $I \subseteq B$ is any graded ideal, let $I^c$ (resp. $I_A$) be the topological closure of $I$ in $B$ (resp. in $A$), and endow $A/I_A$ with the quotient topology arising from the projection $A \to A/I_A$. Remark 8.5.2(i) implies that $I^c$ is a graded ideal of $B$; namely, $\text{gr}_\gamma I^c$ is the topological closure of $\text{gr}_\gamma I$ in $B$, for every $\gamma \in \Gamma$. It follows that $B/I^c$ is a $\Gamma$-graded subring of $A/I_A$, and the topology induced by $A/I_A$ on $B/I^c$ agrees with the quotient topology induced by $B$ (lemma 8.2.3(ii)), so the former is linear, and we get therefore a topological ring with pre-graded structure $(A/I_A, B/I^c)$. We then may form the associated graded structure

$$(A, B, \Gamma)^c/I := (A/I_A, B/I^c)^c$$

(note of proposition 8.5.3(iv)). Explicitly, this is the pair $(A/I_A, C)$, where

$$\text{gr}_\gamma C := (\text{Im}(\text{gr}_\gamma B \to A/I_A))^c = (\text{gr}_\gamma B/I^c)^c$$

for every $\gamma \in \Gamma$. 
(i) Keep the situation of (i), and suppose additionally that $A$ is complete and separated. Then we claim that $\text{Im}(\text{gr}_B \to A/I_A)$ is already closed in $A/I_A$, so the graded subring of $A/I_A$ is just $B/I^c$ in this case. Indeed, under these assumptions $\text{gr}_B$ is also complete and separated, hence the canonical $\gamma$-projection $\pi^\gamma_B : A/I_A \to \text{gr}_B$ factors through the completion map $\text{gr}_B(B/F^c) \to \text{gr}_B(C^\gamma)$; on the other hand, $\pi^\gamma_B$ restricts to an injective map $\text{gr}_C \to \text{gr}_B$, so there results an injective map $\text{gr}_C \to \text{gr}_B(B/F^c)$, whose restriction to $\text{gr}_B(B/F^c)$ is the identity map. Thus, $\text{gr}_C = \text{gr}_B(B/F^c)$, as stated.

(ii) Lastly, let $C := (C, \text{gr}_C) \subset B$ be any closed $\Gamma$-graded subring, and we endow $C$ and the topological closure $C^\gamma$ of $C$ in $A$ with the topologies induced from $A$; then $\text{gr}_C = C \cap \text{gr}_B$ is closed in $\text{gr}_B$, and hence also in $A$, for every $\gamma \in \Gamma$, so the pair

$$(A, B) \cap C := (C^\gamma, C)$$

is again a topological ring with $\Gamma$-graded structure.

8.5.5. Let $p \geq 2$ be a prime integer, $(A, B)$ any $\Gamma$-graded topological ring, $a \in A^\wedge$ any element, and $(a_\gamma \mid \gamma \in \Gamma)$ the sequence attached to $a$, as in remark 8.5.2(iii). For every finite subset $S \subseteq \Gamma$, let $S^*$ be the set of non-constant mappings $\{1, \ldots, p\} \to S$; choose also a cyclic subgroup $G$ of order $p$ of the group of permutations of $\{1, \ldots, p\}$, and endow $S^*$ with the right $G$-action given by the rule $g(\varphi) := \varphi \circ g$ for every $g \in G$ and $\varphi \in S^*$. Clearly, for every $\varphi \in S^*$, the product $a_{\varphi(1)} \cdots a_{\varphi(p)}$ depends only on the class $\overline{\varphi}$ of $\varphi$ in $S^*/G$, so we denote it $a_{\overline{\varphi}}$. Also, notice that every such class $\overline{\varphi}$ has cardinality $p$, since $p$ is a prime; with this notation, we may then write

$$(a^p)_S = c_S + p \cdot d_S \quad \text{where } c_S := \sum_{\gamma \in S} (a_\gamma)^p \quad \text{and } d_S := \sum_{\overline{\varphi} \in S^*/G} a_{\overline{\varphi}}.$$ 

Lemma 8.5.6. With the notation of (8.5.5), we have:

(i) The systems $(c_S \mid S \subseteq \Gamma)$ and $(d_S \mid S \subseteq \Gamma)$ are Cauchy nets in $B''$.

(ii) Suppose moreover that the topology of $A$ is coarser than the $p$-adic topology, and the $p$-Frobenius $p_\Gamma$ of $\Gamma$ is injective. Then the following conditions are equivalent:

(a) $a$ is topologically nilpotent in $A^\wedge$.

(b) $a_\gamma$ is topologically nilpotent in $B''$ for every $\gamma \in \Gamma$.

Proof. (i): According to proposition 8.5.3(ii), for every open graded ideal $J \subset B''$ there exists a finite subset $S_J \subset \Gamma$ such that $a_\gamma \in \text{gr}_J$ for every $\gamma \in \Gamma \setminus S_J$. Now, if $S \subset \Gamma$ is any finite subset containing $S_J$, let $S^*_1$ be the subset of $S^*$ consisting of all mappings $\{1, \ldots, p\} \to S$ whose image is contained in $S_J$, and set $S^*_2 := S^* \setminus S^*_1$. Clearly $a_{\overline{\varphi}} \in J$ for every $\overline{\varphi} \in S^*_2/G$ (notation of remark 8.5.2(ii)), and $S^*_1$ is (finite and) independent of $S$, whence $d_S \in J$ for every finite subsets $S, S' \subset \Gamma$ containing $S_J$. The assertion for $d_S$ follows. Likewise, it is clear that $c_S - c_{S'} \in J^p$ for every $S, S'$ as in the foregoing, so the assertion for $c_S$ follows immediately.

(ii): Let $I \subset B$ be any graded open ideal; by assumption there exists $n \in \mathbb{N}$ such that $p^n \in I$. We consider the image $\overline{a}$ of $a$ in the quotient topological ring with $\Gamma$-graded structure $(A, B)/(I + pB)$, as in example 8.5.4, whose underlying topological ring is $A/J$, where $J$ is the topological closure of $I + pB$ in $A$. Let also $I^\wedge$ (resp. $J^\wedge$) be the topological closure of $I$ (resp. of $J$) in $A^\wedge$. Then the system of $\gamma$-projections $(\overline{a}_\gamma \mid \gamma \in \Gamma)$ of $\overline{a}$ is the image of $(a_\gamma \mid \gamma \in \Gamma)$. Now, if $a$ is topologically nilpotent, we may find $k \in \mathbb{N}$ such that $\overline{a}_\gamma^p = 0$; since $p \in J$ and since $p_\Gamma$ is injective, assertion (i) implies that $(\overline{a}_\gamma)^{p^k} = 0$ for every $\gamma \in \Gamma$, i.e. $(a_\gamma)^{p^k} \in J^\wedge$, and therefore $(a_\gamma)^{p^n} \in (J^\wedge)^n \subset I^\wedge$ (claim 8.3.2(b)). Since $I$ is arbitrary, this shows that $a_\gamma$ is topologically nilpotent for every $\gamma \in \Gamma$. Conversely, if the latter condition holds, for every $\gamma \in \Gamma$ there exists $i \geq n$ such that $\overline{a}_\gamma^i = 0$. On the other hand, notice that the topology of $A/J$
Example 8.5.7. (i) Let \( \Gamma, \Delta \) be two monoids, and \( (A, B) \) a topological ring with \( \Delta \)-graded structure. Endow the ring \( A[\Gamma] \) with the unique topology such that the inclusion map \( A \to A[\Gamma] \) is continuous, and \( B[\Gamma] \) with its natural \( \Delta \oplus \Gamma \)-graded structure. Then we claim that the pair

\[
(A, B)[\Gamma] := (A[\Gamma], B[\Gamma])
\]

is a topological ring with \( \Delta \oplus \Gamma \)-graded structure. Indeed, let \( (I_\lambda : \lambda \in \Lambda) \) be a fundamental system of \( \Delta \)-graded open ideals for \( B \); then the family \( \{I_\lambda[\Gamma] : \lambda \in \Lambda\} \) is a fundamental system of open ideals for \( A[\Gamma] \), and \( I_\lambda[\Gamma] \cap B[\Gamma] = I_\lambda[B] \) for every \( \lambda \in \Lambda \). Moreover, it is easily seen that the projection \( p_\gamma : A[\Gamma] \to A : \sum_{\gamma' \in \Gamma} \gamma \cdot a_{\gamma} \mapsto a_{\gamma} \) is a continuous map, for every \( \gamma \in \Gamma \); now, each direct summand \( gr(\delta, \gamma) B[\Gamma] \) equals \( p_\gamma^{-1}(gr_\delta B) \cap \gamma' \not\in \gamma (\ker p_\gamma) \), so it is a closed subset, whence the contention.

(ii) Let \( \varphi : \Gamma \to \Gamma' \) be any morphism of monoids, \( (A, B) \) any topological ring with \( \Gamma \)-graded structure. We obtain a topological ring with \( \Gamma' \)-pre-graded structure \( (A, B)_{\Gamma'} \), and by virtue of proposition [8.5.3 IV], we may then form the associated \( \Gamma' \)-graded structure

\[
(A, B)_{\Gamma'} := (A, B)_{\Gamma'}^c.
\]

(iii) In the situation of (ii), notice also that the pair \( (1_A, \varphi) \) yields a morphism of topological rings with graded structures:

\[
(A, B, \Gamma) \to (A, B, \Gamma')_{\Gamma'}. \tag{8.5.7}
\]

Moreover, suppose that \( (A, D, \Gamma') \) is another \( \Gamma' \)-graded structure on \( A \), such that \( (1_A, \varphi) \) induces a morphism of topological rings with graded structures

\[
(A, B, \Gamma)_{\Gamma'} \to (A, D, \Gamma')
\]

and set \( (A, C) := (A, B, \Gamma)_{\Gamma'}. \) Then we claim that \( D = C. \) Indeed, by assumption \( gr_\delta D \) is closed in \( A \), hence also in \( gr_\delta C \), for every \( \gamma' \in \Gamma' \); arguing as in remark [8.5.2 ii] we easily see that \( D \) is a closed subset of \( C \), whence the contention, as \( D \) is dense in \( A \), hence also in \( B \).

We deduce that the morphism \( (1_A, \varphi) \) enjoys the following universal property. For every morphism \( (f, \psi) : (A, B, \Gamma) \to (A', B', \Gamma') \) such that \( \psi \) factors through \( \varphi \), there exists a unique morphism of topological rings with \( \Gamma' \)-graded structures \( (f, 1_{\Gamma'}) : (A, B, \Gamma)_{\Gamma'} \to (A', B', \Gamma') \) such that \( (f, \psi) = (f, 1_{\Gamma'}) \circ (1_A, \psi). \)

8.5.8. To state the following proposition [8.5.11] it is convenient to introduce a special class of monoids; we shall say that a monoid \( (\Gamma, +, 0) \) is weakly integral if we have the following partial cancellation property:

\[
2 \cdot \gamma + \delta = 2 \cdot \gamma + \delta' \Rightarrow \gamma + \delta = \gamma + \delta' \quad \text{for every } \gamma, \delta, \delta' \in \Gamma.
\]

Lemma 8.5.9. Let \( (\Gamma, +, 0) \) be any monoid, \( n \geq 2 \) any integer, and suppose that the \( n \)-Frobenius endomorphism of \( \Gamma \) is injective. Then \( \Gamma \) is weakly integral.

Proof. Indeed, let \( \gamma, \delta, \delta' \in \Gamma \) be three elements such that \( 2 \cdot \gamma + \delta = 2 \cdot \gamma + \delta' \). Then clearly \( n \cdot \gamma + \delta = n \cdot \gamma + \delta' \). A simple induction on \( k \) then shows that \( n \cdot \gamma + k \cdot \delta = n \cdot \gamma + k \cdot \delta' \) for every \( k \in \mathbb{N} \). Especially\( n \cdot (\gamma + \delta) = n \cdot (\gamma + \delta'), \) whence \( \gamma + \delta = \gamma + \delta', \) as required. \( \square \)

Lemma 8.5.10. Let \( (\Gamma, +, 0) \) be a weakly integral monoid, \( (A, B) \) a topological ring with \( \Gamma \)-graded structure, \( a \in A, \alpha \in \Gamma \) and \( f \in gr_\alpha B \) any three elements. Then we have:

(i) \( \pi_{2\alpha + \delta}(f^2 a) = f \cdot \pi_{\alpha + \delta}(fa) \) for every \( \delta \in \Gamma. \)

(ii) \( \pi_{\gamma}(fa) = 0 \) whenever \( \gamma \notin \alpha + \Gamma. \)
Proof. Since \( \pi \), is a continuous map for every \( \gamma \in \Gamma \), it suffices to check these identities for \( a \in B \), and then there exists a finite subset \( S \subset \Gamma \) such that \( a = a_S \).

(ii): We have \( f \cdot a = \sum_{\delta \in S} f \cdot \pi^\delta_{\alpha}(a) \), and \( \pi \cdot \delta(a) \in \text{gr}_{\alpha+\delta}B \) for every \( \delta \in S \), whence the assertion.

(i): Clearly \( \pi^{\delta}_{2\alpha+\delta}(f^2a) = \sum_{\gamma \in T} a \cdot \pi^{\gamma}_{\alpha}(fa) \), where \( T := \{ \gamma \in S \mid \alpha + \gamma = 2\alpha + \delta \} \). But due to (ii), we have \( \pi^{\gamma}_{\alpha}(fa) = 0 \) unless \( \gamma \in \alpha + \Gamma \), so we may replace \( T \) by the subset of all elements of the form \( \alpha + \delta' \) such that \( 2\alpha + \delta' = 2\alpha + \delta \). Since \( \Gamma \) is weakly integral, \( T = \{ \alpha + \delta \} \), whence the assertion. \( \square \)

**Proposition 8.5.11.** Let \( (\Gamma, +, 0) \) be a monoid, \( (A, B) \) a \( \Gamma \)-graded structure on the topological ring \( (A, \mathcal{T}) \), and \( i_0 : \text{gr}_0B \to A \) the inclusion map. We have :

(i) Suppose that the topology of \( A \) is \( f \)-adic, complete and separated. Then :

(a) There exists a finitely generated graded ideal \( J \) of \( B \) such that \( JA \) is an ideal of \( A \) of adic definition for \( A \).

(b) If moreover, \( J = (\text{gr}_0J) \cdot B \) or else \( \Gamma \) is weakly integral, \( \mathcal{T} \) induces on \( B \) the \( J \)-adic topology.

(ii) Suppose that \( i_0 \) is \( c \)-adic. Then \( A \) is \( c \)-adic if and only if the same holds for \( \text{gr}_0B \).

(iii) Suppose that \( A \) is complete and separated, and \( i_0 \) is \( c \)-adic. Then \( A \) is \( f \)-adic if and only if the same holds for \( \text{gr}_0B \).

Proof. (i.a): Let \( I \) be any finitely generated ideal of adic definition of \( A \); by assumption, we may find a graded ideal \( I_B \) of \( B \) and an integer \( n \in \mathbb{N} \) with \( I^n \cap B \subset I_B \subset I \). For every subset \( S \) of \( A \) we denote as usual by \( S^c \) the topological closure of \( S \) in \( A \); since \( I^n \) is an open and closed subset of \( A \), we have

\[
I^n = I^n \cap B^c = (I^n \cap B)^c \subset (I^n \cap I_B)^c
\]

so that \( I^n = (I^n \cap I_B) + I^{n+1} \). We may then find a finitely generated graded subideal \( J \) of \( I_B \) such that \( I^n = (I^n \cap J) + I^{n+1} \). On the other hand, since \( A \) is \( I \)-adically complete and separated, the ideal \( I \) is contained in the Jacobson radical of \( A \) (remark 8.3.10(v)), so that \( I^n = (I^n \cap J) \), by Nakayama’s lemma, and therefore \( I^n \subset JA \); by construction, we have as well \( JA \subset I \), so \( J \) is an ideal with the sought properties.

(i.b): We prove more precisely:

**Claim 8.5.12.** In the situation of (i), let \( J \subset B \) be any graded ideal, and suppose that either one of the following conditions holds:

(a) \( \Gamma \) is integral.

(b) \( \Gamma \) is weakly integral and \( JA \) is open in \( A \).

(c) \( J = (\text{gr}_0J) \cdot B \).

Then \( J = B \cap JA \) for every \( n \in \mathbb{N} \).

**Proof of the claim.** Say that \( x \in B \cap JA \), so we may find a mapping \( \varphi : \{1, \ldots, k\} \to \Gamma \) and elements \( a_i \in \text{gr}_{\varphi(i)}J \), \( y_i \in A \) for \( i = 1, \ldots, k \), such that \( x = \sum_{i=1}^{k} a_i y_i \), as well as a finite subset \( S \subset \Gamma \) such that \( x = x_S \). Suppose first that \( J = (\text{gr}_0J) \cdot B \), in which case we may assume that \( a_i \in \text{gr}_0J \) for \( i = 1, \ldots, k \); we compute

\[
x = \sum_{\gamma \in S} \sum_{i=1}^{k} a_i \cdot \pi^\gamma_{\alpha}(y_i)
\]

whence the claim, in this case. Next, suppose that \( \Gamma \) is integral, so that the natural map \( \Gamma \to \Gamma^{\text{gp}} \) is injective; we may then replace \( \Gamma \) by \( \Gamma^{\text{gp}} \), and assume from start that \( \Gamma \) is an abelian group.
We compute
\[ x = \sum_{\gamma \in S} \sum_{i=1}^{k} a_i \cdot \pi_{\gamma - \varphi(i)}(y_i) \]
so the claim follows also in this case. Lastly, suppose that condition (b) holds; then we may find homogeneous elements \( f_1, \ldots, f_r \in J \) such that \( \sum_{i=1}^{r} f_i A \) is an open ideal of \( A \), and the same holds therefore for the ideal \( I := \sum_{i=1}^{r} f_i^2 A \). Next, we may find \( y'_i \in B \) such that \( y_i - y'_i \in I \) for \( i = 1, \ldots, k \), and clearly it suffices to check that \( x' := x - \sum_{i=1}^{k} y'_i a_i \in J \). We may then replace \( x \) by \( x' \), and assume as well that \( x \in I \); in this case, lemma 8.5.10 says that \( \pi_{\gamma}(x) \in \sum_{i=1}^{r} f_i B \) for every \( \gamma \in S \), whence the contention.

(ii): Due to lemma 8.3.32(i) and proposition 8.5.3(iii), we may replace \( (A, B) \) by \( (\hat{A}, \hat{B}) \), after which we may assume that \( A \) is complete and separated. We know already that if the topology of \( \text{gr}_0 B \) is c-adic, the same holds for \( \mathcal{F} \) (lemma 8.3.24(i.b)). Thus, suppose that \( \mathcal{F} \) is c-adic, and let \( I \) be any ideal of c-adic definition of \( A \); by assumption, there exists an open ideal \( I_0 \subset \text{gr}_0 B \) with \( (I_0 A)_{c} \subset I \). Now, let \( J \subset \text{gr}_0 B \) be any other open ideal; we know that there exists \( n \in \mathbb{N} \) such that \( (I^n)_{c} \subset (JA)_{c} \), and taking into account claim 8.3.26 we deduce that \( (I_0^n A)_{c} \subset (JA)_{c} \). Combining with claim 8.3.25 we get
\[ \pi_{0}^c(I_0^n A)_{c} \subset \pi_{0}^c(JA)_{c} \]
But notice that, since \( A \) is complete, \( \pi_{0}^c(I_0^n A) = I_0^n \) and \( \pi_{0}^c(JA) = J \), so finally \( (I_0^n)_{c} \subset J \), whence the assertion.

(iii): Suppose first that \( \text{gr}_0 B \) is f-adic (in which case, it is also adic, by proposition 8.3.18(iii)). Then lemmata 8.3.24(i.b) and 8.3.21(ii.a) imply that the same holds for \( A \). Conversely, suppose that \( A \) is f-adic (and adic), and let \( I \subset A \) be any finitely generated ideal of adic definition. By assumption, there exists an open ideal \( J \subset \text{gr}_0 B \) such that \( I^n \subset (JA)_{c} \subset I \) for some \( n \in \mathbb{N} \). Since \( I^n \) is both open and closed in \( A \), we deduce
\[ I^n = I^n \cap (JA)_{c} = (I^n \cap JA)_{c} = I^{n+1} + (JA \cap I^n) \]
It follows that there exists a finitely generated graded subideal \( K \subset J \) such that \( I^n \subset KA + I^{n+1} \), and so \( I^n \subset KA \subset I \), by virtue of Nakayama’s lemma and remark 8.3.10(v). Then \( (K^r A \mid r \in \mathbb{N}) \) is a fundamental system of open ideals in \( A \), and therefore \( (K^r \cap \text{gr}_0 B \mid r \in \mathbb{N}) \) is a fundamental system of open ideals in \( \text{gr}_0 B \). But from claims 8.3.26 and 8.3.25 we get
\[ K^r \subset K^r A \cap \text{gr}_0 B \subset \pi_{0}^c(K^r A) \subset \pi_{0}^c(K^r B)_{c} = K^r \]
so \( K^r A \cap \text{gr}_0 B = K^r \) for every \( r \in \mathbb{N} \), and finally \( \text{gr}_0 B \) is f-adic.

8.6. Homological algebra for topological modules. Let \( A \) be any topological ring. The category of topological \( A \)-modules and continuous \( A \)-linear maps, denoted \( A\text{-TopMod} \)
is additive and with representable kernels and cokernels but, generally, not abelian; indeed, if \( f : M \to N \) is a continuous map of topological \( A \)-modules, \( \text{Coker}(\text{Ker} f \to M) \) is not necessarily isomorphic to \( \text{Ker}(N \to \text{Coker} f) \), since the quotient topology (induced from \( M \)) on \( \text{Im} f \) may be finer than the subspace topology (induced from \( N \)). It is therefore useful to introduce the following:

Definition 8.6.1. Let \( A \) be a topological ring, \( f : M \to N \) a morphism of topological \( A \)-modules. We say that \( f \) is strict, if the natural map
\[ \text{Coker}(\text{Ker} f \to M) \to \text{Ker}(N \to \text{Coker} f) \]
is an isomorphism of topological \( A \)-modules (where these kernels and cokernels are formed in the additive category \( A\text{-TopMod} \); see remark 3.6.29(v)).
The category $A$-$\text{TopMod}$ is exact in the sense of \[\text{[110]}\]; namely, the admissible monomorphisms (resp. epimorphisms) are the continuous injections (resp. surjections) $f : M \to N$ that are strict, in the sense of definition \[\text{[8.6.1]}\], i.e. that induce homeomorphisms $M \xrightarrow{f} f(M)$ (resp. $M/\text{Ker } f \xrightarrow{\sim} N$), where $f(M)$ (resp. $M/\text{Ker } f$) is endowed with the subspace (resp. quotient) topology induced from $N$ (resp. from $M$). An admissible epimorphism is also called a quotient map of topological $A$-modules. Correspondingly there is a well defined class of admissible short exact sequences of topological $A$-modules. The following lemma exhibits a useful class of admissible short exact sequences.

**Lemma 8.6.2.** Consider an inverse system, with surjective transition maps

$$(E_n \mid n \in \mathbb{N}) : 0 \to (M'_n \mid n \in \mathbb{N}) \to (M_n \mid n \in \mathbb{N}) \to (M''_n \mid n \in \mathbb{N}) \to 0$$

of short exact sequences of discrete $A$-modules. Then the induced complex of inverse limits:

$$\lim_{n \in \mathbb{N}} E_n : 0 \to M' := \lim_{n \in \mathbb{N}} M'_n \to M := \lim_{n \in \mathbb{N}} M_n \to M'' := \lim_{n \in \mathbb{N}} M''_n \to 0$$

is an admissible short exact sequence of topological $A$-modules.

**Proof.** For every pair of integers $i, j \in \mathbb{N}$ with $i \leq j$, let $\varphi_{ji} : M_j \to M_i$ be the transition map in the inverse system $(M_n \mid n \in \mathbb{N})$, and define likewise $\varphi'_{ji}$ and $\varphi''_{ji}$; the assumption means that all these maps are onto. Set $K_{ji} := \text{Ker } \varphi_{ji}$ and define likewise $K'_{ji}$, $K''_{ji}$. By the snake lemma we deduce, for every $i \in \mathbb{N}$, an inverse system of short exact sequences:

$$0 \to (K'_{ji} \mid j \geq i) \to (K_{ji} \mid j \geq i) \to (K''_{ji} \mid j \geq i) \to 0$$

where again, all the transition maps are surjective. However, by definition, the decreasing family of submodules $(K_i := \lim_{j \geq i} K_{ji} \mid i \in \mathbb{N})$ is a fundamental system of open neighborhoods of $0 \in M$ (and likewise one defines the topology on the other two inverse limits). It follows already that the surjection $M \to M''$ is a quotient map of topological $A$-modules. To conclude it suffices to remark:

**Claim 8.6.3.** The natural map $K'_i := \lim_{j \geq i} K'_{ji} \to K_i$ induces an identification:

$$K'_i = K_i \cap M' \quad \text{ for every } i \in \mathbb{N}.$$  

**Proof of the claim.** Indeed, for every $j \geq i$ we have a left exact sequence:

$$E_j : (0 \to K'_{ji} \to M'_j \oplus K_{ji} \xrightarrow{\alpha} M_j)$$

where $\alpha(m', m) = m' - m$ for every $m' \in M'_j$ and $m \in K_{ji}$. Therefore $\lim_{j \geq i} E_j$ is the analogous left exact sequence $0 \to K'_i \to M' \oplus K_i \to M$, whence the claim. \[\square\]

**Remark 8.6.4.** Let $(C^*, d^*)$ be a complex of topological $A$-modules with continuous differentials. Then, for every $i \in \mathbb{Z}$, the cohomology $H^i C^*$ inherits a well defined topology: namely, we can take either

$$\text{Coker}(d^{i-1} : C^{i-1} \to \text{Ker } d^i) \quad \text{ or } \quad \text{Ker}(d^i : \text{Coker } d^{i-1} \to C^{i+1})$$

(where these kernels and cokernels are formed in the additive category $A$-$\text{TopMod}$) and by lemma \[\text{[8.2.3(ii)]}\), these two topologies coincide (regardless of whether the differentials are strict or otherwise). Notice also that for every $i \in \mathbb{Z}$ the following conditions are equivalent:

(a) The differential $d^i$ factors through an open map $C^i \to \text{Ker } d^{i+1}$.

(b) The differential $d^i$ is strict and the topology of $H^{i+1} C^*$ is discrete.
8.6.5. Consider an admissible short exact sequence of complexes of topological $A$-modules

$$0 \to (C_1^\bullet, d_1^\bullet) \xrightarrow{f_1^i} (C_2^\bullet, d_2^\bullet) \xrightarrow{g_1^i} (C_3^\bullet, d_3^\bullet) \to 0$$

i.e. a double complex of $A$-TopMod whose rows $0 \to C_k^1 \to C_k^2 \to C_k^3 \to 0$ are admissible short exact sequences for every $k \in \mathbb{Z}$. For every $i \in \mathbb{Z}$ and for $j = 1, 2, 3$, denote by $\delta_j^i : C_i^j \to \text{Ker} d_j^{i+1}$ the continuous map induced by the differential $d_j^i : C_j^i \to C_j^{i+1}$ of $C_j^\bullet$.

Proposition 8.6.6. In the situation of (8.6.5), fix also $i \in \mathbb{Z}$. We have:

(i) If $\delta_1^i$ and $\delta_3^{i-1}$ are open maps, the same holds for $\delta_1^i$.
(ii) If $\delta_1^i$ and $\delta_3^i$ are open maps, the same holds for $\delta_2^i$.
(iii) If $\delta_1^i$ and $\delta_3^{i-1}$ are open maps, the same holds for $\delta_3^i$.

Proof. (i): Endow $D := g^{i+1}(\text{Ker} d_2^{i+1})$ with the quotient topology induced by the restriction $h : \text{Ker} d_2^{i+1} \to D$ of $g^{i+1}$, and notice that $\text{Im} d_3^i \subset D$; we claim that $d_3^i$ induces a continuous and open map $C_3^i \to D$. Indeed, since $g^i$ is an admissible epimorphism, it suffices to check that the composition $d_2^i \circ g^i : C_2^i \to D$ is continuous and open; however, the latter equals $h \circ \delta_2^i$, whence the assertion. Moreover, $f^{i+1}$ restricts to an admissible monomorphism $\text{Ker} d_1^{i+1} \to \text{Ker} d_2^{i+1}$. Summing up, we may replace $C_j^{i+1}$ with $\text{Ker} d_j^{i+1}$ for $j = 1, 2$, and $C_3^{i+1}$ with $D$, and assume from start that $C_j^{i+2} = 0$ for $j = 1, 2, 3$. Then $d_j^i : C_j^i \to C_j^{i+1}$ is open for $j = 2, 3$, and it remains to check that $d_1^i$ is open as well.

Next, set $C_1^i := \text{Coker} d_1^{i-1}$ and $C_2^i := \text{Coker} d_2^{i-1} \circ f^{i-1}$ (endowed with the topologies induced by $C_1^i$ and respectively $C_2^i$). Clearly $d_2^i$ factors through a continuous map $d_2^i : C_2^i \to C_3^{i+1}$ for $j = 1, 2$, and $f^i$ (resp. $g^i$) induces an injective (resp. surjective) continuous map $f^i : C_1^i \to C_2^i$ (resp. $g^i : C_2^i \to C_3^i$). Moreover, by lemma 8.2.3(i) the topology of $C_1^i$ is induced by the topology of $C_2^i$ via $f^i$, i.e. $f^i$ is an admissible monomorphism. Likewise, $g^i$ is an admissible epimorphism. We may then replace $C_2^i$ by $C_2^i$ for $j = 1, 2$, and assume from start $C_1^{i-1} = 0$, in which case we obtain a commutative diagram of continuous maps

$$\begin{array}{cccccccc}
0 & \longrightarrow & 0 & \longrightarrow & C_1^{i-1} & \xrightarrow{g_1^{i-1}} & C_3^{i-1} & \longrightarrow & 0 \\
\downarrow d_2^{i-1} & & \downarrow d_3^{i-1} & & \downarrow d_3^i & & \downarrow d_3^i & \\
0 & \longrightarrow & C_1^i & \xrightarrow{f_1^i} & C_2^i & \xrightarrow{g_1^i} & C_3^i & \longrightarrow & 0 \\
\end{array}$$

(8.6.7)

whose rows are admissible short exact sequences, and where $d_2^i$ and $d_3^{i-1}$ are still open. Consider the diagram of topological $A$-modules

$$\begin{array}{cccc}
\text{Ker} (d_3^i \circ g^i) & \xrightarrow{\varphi} & \text{Ker} d_3^i \\
\downarrow \varphi & & \downarrow \\
\text{Ker} g^{i+1} & \longrightarrow & 0 \\
\end{array}$$

(8.6.8)

deduced from the right bottom square of (8.6.7). In view of claim 8.2.4 we deduce that $\varphi$ and $\varphi$ are open maps. Moreover, $f^i$ and $f^{i+1}$ factor through admissible monomorphisms $C_1^i \to \text{Ker} (d_3^i \circ g^i)$ and $C_1^{i+1} \to \text{Ker} g^{i+1}$. Likewise, $d_2^{i-1}$ and $d_3^{i-1}$ factor through continuous maps $C_2^{i-1} \to \text{Ker} (d_3^i \circ g^i)$ and $C_2^{i-1} \to \text{Ker} d_3^i$. Thus, we may replace the bottom right square of (8.6.7) with (8.6.8), and assume from start that $C_3^{i+1} = 0$ as well. In this situation, $g^{i-1}$ and $f^{i+1}$
are both isomorphisms of topological $A$-modules, and $d_5^{i-1}$ is an open map, so we are reduced to showing:

**Claim 8.6.9.** Consider a diagram of topological $A$-modules

\[
0 \rightarrow C_1 \xrightarrow{f} C_2 \xrightarrow{g} C_3 \rightarrow C_5
\]

such that:

(a) The horizontal row is an admissible short exact sequence.
(b) $g \circ h$ and $k$ are open maps and $k \circ h = 0$.

Then $k \circ f$ is an open map.

**Proof of the claim.** After pulling back the short exact admissible sequence of $(f, g)$ along the map $g \circ h$, we obtain the short exact sequence of topological modules

\[
0 \rightarrow C_1 \xrightarrow{f'} C_2 \times C_3 \xrightarrow{g'} C_4 \rightarrow C_5
\]

Notice that $g'$ is still an admissible epimorphism, by claim 8.2.4. Likewise, $f'$ is an admissible monomorphism, since its composition with the projection $\pi : C_2 \times C_3 C_4 \rightarrow C_2$ equals $f$, which is an admissible monomorphism by assumption. Moreover, since $g \circ h$ is open, the same holds for $\pi$, again by claim 8.2.4, and therefore also for $k' := k \circ \pi : C_2 \times C_3 C_4 \rightarrow C_5$. Furthermore, the pair $(h, \mathbf{1}_{C_3})$ defines a continuous section $s : C_4 \rightarrow C_2 \times C_3 C_4$ for $g'$, whence a continuous isomorphism of $A$-modules

\[
\omega : C_1 \times C_4 \xrightarrow{\sim} C_2 \times C_3 C_4 \quad (x, y) \mapsto f'(x) + s(y) = (f(x) + h(y), y)
\]

and we notice that $\omega$ is an isomorphism of topological $A$-modules: indeed, let us endow $f(C_1)$ with the topology induced by the inclusion into $C_2$, so that $f$ factors through an isomorphism $u : C_1 \xrightarrow{\sim} f(C_1)$ of topological $A$-modules; then the inverse of $\omega$ is the continuous map

\[
C_2 \times C_3 C_4 \rightarrow C_1 \times C_4 \quad (a, b) \mapsto (u^{-1}(a - h(b)), b)
\]

whence the assertion. Summing up, we deduce that the continuous map $\psi := k \circ \pi \circ \omega : C_1 \times C_4 \rightarrow C_5$ is open, and notice that $\psi(x, y) = k \circ f(x)$ for every $(x, y) \in C_1 \times C_4$, since $k \circ h = 0$. Lastly, let $U \subset C_1$ be any open subset; then $U \times C_4$ is open in $C_1 \times C_4$, and $\psi(U \times C_4) = k \circ f(U)$ is open in $C_5$, whence the claim.

(ii): Define the $A$-module $D$ and the $A$-linear map $h : \text{Ker } d_2^{i+1} \rightarrow D$ as in (i), and endow $D$ with the topology induced by the inclusion into $C_3^{i+1}$. Then $h$ is continuous, and it is also an open map, since the same holds for $h \circ \delta_3^i = \delta_3^i \circ g' : C_2 \rightarrow D$ (lemma 8.2.5). We may then argue as in the proof of (i), to reduce to the case where $C_3^{i+2} = 0$ for $j = 1, 2, 3$, in which case $d_1^i$ and $d_2^i$ are both open maps, and we must show that the same holds for $d_2^i$. 

\[\Box\]
Next, we pull back the admissible short exact sequence \((f^i, g^i)\) (resp. \((f^{i+1}, g^{i+1})\)) along the map \(g^i\) (resp. along the map \(d_3^i \circ g^i\)) to get the commutative diagram of topological \(A\)-modules:

\[
\begin{array}{ccc}
0 & \xrightarrow{f^i} & C_2 \times C_2^{i+1} \xrightarrow{g^i} C_2 \times C_2^i \xrightarrow{d_2^i} 0 \\
\downarrow d_1^i & & \downarrow \pi^{i+1} \\
0 & \xrightarrow{f^{i+1}} & C_2 \times C_2^{i+1} \xrightarrow{g^{i+1}} C_2 \times C_2^i \xrightarrow{d_2^i \circ g^i} 0.
\end{array}
\]

(8.6.10)

Arguing as in the proof of claim 8.6.9 we easily see that the rows of (8.6.10) are still admissible short exact sequences. Moreover, the pair \((1_{C_2^i}, 1_{C_3^i})\) (resp. \((d_2^i, 1_{C_3^i})\)) gives a section \(s^i\) (resp. \(s^{i+1}\)) for \(g^i\) (resp. \(g^{i+1}\)). Furthermore, \(\pi^{i+1}\) is an open map, by claim 8.2.4 and if \(\pi^i : C_2 \times C_2^{i+1} \to C_2\) denotes the projection, we have

\[d_2^i \circ \pi^i = \pi^{i+1} \circ d_2^i.\]

Thus, in order to show that \(d_2^i\) is open, it suffices to check that the same holds for \(d_3^i\) (lemma 8.2.5). Summing up, we may replace the exact rows \((f^i, g^i)\) and \((f^{i+1}, g^{i+1})\) by \((f^i, g^i)\) and \((f^{i+1}, g^{i+1})\), and assume also from start that \(C_3 = C_3^{i+1}\) and \(d_3 = 1_{C_3^i}\), and moreover, that \(g^i\) and \(g^{i+1}\) admit continuous sections \(s^i\) and respectively \(s^{i+1}\), such that \(d_2^i \circ s^i = s^{i+1}\). Arguing as in the proof of claim 8.6.9 we deduce isomorphisms of topological \(A\)-modules

\[\omega^k : C_1^k \times C_3^k \xrightarrow{\sim} C_2^k \quad (x, y) \mapsto f^k(x) + s^k(y) \quad \text{for } k = i, i + 1\]

fitting into a commutative diagram

\[
\begin{array}{ccc}
C_1^i \times C_3^i & \xrightarrow{\omega^i} & C_2^i \\
\downarrow d_1^i & & \downarrow d_2^i \\
C_1^{i+1} \times C_3^i & \xrightarrow{\omega^{i+1}} & C_2^{i+1}
\end{array}
\]

and since \(d_1^i\) is an open map, the same holds for \(d_1^i \times 1_{C_3^i}\), whence the assertion.

(iii): Arguing as in the proof of (i), we reduce to the case where \(C_2^j = 0\) for every \(j = 1, 2, 3\), in which case \(d_1^i\) is an open map. Then, we define \(\overline{C}_j^i\) for \(j = 1, 2\) as in the proof of (i), so that \(d_j^i\) factors through a continuous map \(\overline{d}_j^i : C_j^i \to \overline{C}_3^i\) for \(j = 1, 2\). Notice that \(\overline{d}_1^i\) is an open map, and \(\delta_2^i\) induces an open map \(\text{Coker } f^{i-1} \to \text{Ker } \overline{d}_2^i\). We may then replace \(C_j^i\) by \(\overline{C}_j^i\) for \(j = 1, 2\), and assume from start that \(C_3^{i-1} = 0\), in which case we obtain a commutative diagram (8.6.7) whose rows are admissible short exact sequences, and where \(d_1^i\) and \(\delta_2^i\) are open maps. Next, we may argue again as in the proof of (i), to reduce to the case where \(C_2^{i+2} = 0\) as well, in which case we have to show that \(d_3^{i-1}\) is an open map. To this aim, we consider the cartesian diagram

\[
\begin{array}{ccc}
C_1^i \times C_2^{i+1} & \xrightarrow{\pi_1^i} & C_2^i \\
\downarrow \pi_1^i & & \downarrow d_2^i \\
C_1^i & \xrightarrow{f^{i+1} \circ d_1^i} & C_2^{i+1}
\end{array}
\]

and we notice that the pair \((1_{C_1^i}, f^i)\) defines a continuous section \(s : C_1^i \to C_1^i \times C_2^{i+1} C_2^i\) for \(\pi_1^i\). Likewise, the pair consisting of the zero map \(\text{Ker } d_2^i \to C_1^i\) and the inclusion map \(\text{Ker } d_2^i \to C_1^i\)
defines a continuous map $t : \text{Ker } d_2^i \to C_1^i \times_{C_2^{i+1}} C_2^i$, whence an isomorphism of topological $A$-modules

$$\omega : C_1^i \times \text{Ker } d_2^i \xrightarrow{\sim} C_1^i \times_{C_2^{i+1}} C_2^i \quad (x, y) \mapsto s(x) + t(y) = (x, f^i(x) + y).$$

Furthermore, under the current assumptions, $f^{i+1}$ is an isomorphism of topological $A$-modules, so $f^{i+1} \circ d_1^i$ is an open map, and then the same holds for $\pi_2^i$, according to claim \ref{claim:8.2.4}. Lastly, notice the commutative diagram

$$
\begin{array}{ccc}
C_1^i \times C_2^{i-1} & \xrightarrow{\pi_2^{i-1}} & C_2^{i-1} \\
\downarrow & & \downarrow g^{i-1} \\
C_1^i \times \text{Ker } d_2^i & \xrightarrow{\omega} & C_1^i \times_{C_2^{i+1}} C_2^i \xrightarrow{\pi_2^i} C_2^i \\
& & \downarrow d_3^{i-1} \\
& & C_3^i
\end{array}
$$

where $\pi_2^{i-1}$ is the projection. Since $\delta_2^{i-1}$ is an open map, the same holds for $1_{C_1^i} \times \delta_2^{i-1}$, and then also for $d_3^{i-1} \circ g^{i-1} \circ \pi_2^{i-1}$. By lemma \ref{claim:8.2.5} we conclude that $d_3^{i-1}$ is open as well, as required.

8.6.11. Consider an object $C^{**}$ of $C_2(A\text{-TopMod})$, i.e. a double complex of topological $A$-modules whose horizontal and vertical differentials

$$d_h^{p,q} : C^{p,q} \to C^{p+1,q} \quad d_v^{p,q} : C^{p,q} \to C^{p,q+1}$$

are continuous maps, and therefore induce continuous maps

$$\delta_h^{p,q} : C^{p,q} \to \text{Ker } d_h^{p+1,q} \quad \delta_v^{p,q} : C^{p,q} \to \text{Ker } d_v^{p,q+1} \quad \text{for every } p, q \in \mathbb{Z}.$$ 

With this notation, we have:

**Corollary 8.6.12.** In the situation of \ref{claim:8.6.11}, suppose moreover that:

(a) $C^{p,q} = 0$ whenever $p < 0$ or $q < 0$.

(b) The maps $\delta_v^{p,q}$ are open for every $p, q \in \mathbb{Z}$.

(c) The maps $\delta_h^{p,q}$ are open for every $p \in \mathbb{Z}$ and every $q > 0$.

Then the maps $\delta_h^{p,0}$ are open for every $p \in \mathbb{Z}$.

**Proof.** To ease notation, set

$$B_v^{p,q} := \text{Im } d_v^{p,q-1} \quad Z_v^{p,q} := \text{Ker } d_v^{p,q} \quad H_v^{p,q} := \text{Coker } \delta_h^{p,q}$$

and denote by $d_B^{p,q} : B_v^{p,q} \to B_v^{p+1,q}$ and $d_Z^{p,q} : Z_v^{p,q} \to Z_v^{p+1,q}$ the restrictions of $d_h^{p,q}$, for every $p, q \in \mathbb{Z}$. Then $(B_v^{*,q}, d_B^{*,q})$ and $(Z_v^{*,q}, d_Z^{*,q})$ are complexes of topological $A$-modules, and we get admissible short exact sequences of complexes

$$0 \to (Z_v^{*,q}, d_Z^{*,q}) \to (C^{*,q}, d_h^{*,q}) \to (B_v^{*,q+1}, d_B^{*,q+1}) \to 0$$

$$0 \to (B_v^{*,q}, d_B^{*,q}) \to (Z_v^{*,q}, d_Z^{*,q}) \to H_v^{*q} \to 0.$$

Let also

$$\delta_B^{p,q} : B_v^{p,q} \to \text{Ker } d_B^{p+1,q} \quad \delta_Z^{p,q} : Z_v^{p,q} \to \text{Ker } d_Z^{p+1,q}$$

be the continuous maps induced by $d_B^{p,q}$ and respectively $d_Z^{p,q}$, for every $p, q \in \mathbb{Z}$.

**Claim 8.6.13.** For every $p, q$ the following holds:

(d) If $\delta_Z^{p,q}$ is an open map, the same holds for $\delta_B^{p,q}$.

(e) If $\delta_B^{p-1,q+1}$ is an open map, the same holds for $\delta_Z^{p,q}$, provided $q > 0$. 

Proof of the claim. Indeed, $H^q_{v,*}$ is complex of discrete topological $A$-modules, for every $q \in \mathbb{Z}$, due to assumption (b), so its differentials $d^{p,q}_{v,*}$ trivially induce open maps $H^p_{v,*} \to \text{Ker } d^{p+1,q}_{v,*}$ for every $q$; then (d) follows from proposition \[8.6.6\]i. Likewise, (e) follows from assumption (b) and proposition \[8.6.6\]i.

We now show that, for every $n \in \mathbb{Z}$, the maps $\delta^p_B$ are open for every $p, q \in \mathbb{Z}$ such that $p + q = n$ and $q > 0$. We argue by induction on $p$. For $p < -1$, assumption (a) says that $B^p_{v,*} = B^{p+1,q} = 0$, so the assertion trivially holds. Suppose then that $p \geq -1$, and that we already know that $\delta^{p-1,q+1}$ is open; from claim \[8.6.13\]we deduce that $\delta^{p,q}$ is also open, as stated. Especially, we see that $\delta^{p,1}_B$ is an open map, for every $p \in \mathbb{Z}$. Lastly, notice that (a) and (b) also imply that the topology of $Z^p_{v,*}$ is discrete for every $p \in \mathbb{Z}$; then we apply proposition \[8.6.6\]ii to the admissible short exact sequence $0 \to Z^0_{v,*} \to C^{*0} \to B^{*1}$ to conclude.

8.6.14. Let $A$ be any topological ring, $(C^*,d^*)$ any complex of topological $A$-modules, $\varphi^*: C^* \to C^*$ an endomorphism of $C^*$ and $h^*$ a chain homotopy from $1_{C^*}$ to $\varphi^*$ in the category $\mathcal{C} = (\text{A-TopMod})$, so that $\varphi^*: C^i \to C^i$ and $h^i: C^i \to C^{i-1}$ are continuous $A$-linear maps, for every $i \in \mathbb{Z}$.

Lemma 8.6.15. In the situation of \[8.6.14\], fix $i \in \mathbb{Z}$ and suppose that $\varphi^i = 0$. Then we have:

(i) $d^{i-1}$ induces an open and surjective map $\delta^i: C^{i-1} \to \text{Ker } d^i$.

(ii) $\text{Ker } d^i$ is a direct summand of the topological $A$-module $C^i$ (i.e. the inclusion map $\text{Ker } d^i \to C^i$ admits a continuous left inverse).

Proof. The assumption means that

$$d^{i-1} \circ h^i + h^{i+1} \circ d^i = 1_{C^i}.$$  

Now, set $e^i := d^{i-1} \circ h^i$; we compute

$$(1_{C^i} - e^i) \circ e^i = h^{i+1} \circ d^i \circ d^{i-1} \circ h^i = 0$$

and therefore $e^i$ is an idempotent continuous endomorphism of $C^i$. According to example \[3.6.36\] it follows that $e^i$ and $1_{C^i} - e^i$ induce a natural isomorphism of topological $A$-modules

$$\text{Ker } (e^i) \oplus \text{Ker } (1_{C^i} - e^i) \cong C^i.$$  

Notice as well that $d^i \circ e^i = 0$, whence $d^i = d^i \circ (1_{C^i} - e^i)$, and we deduce easily that

$$\text{Ker } (1_{C^i} - e^i) = \text{Ker } d^i$$

whence (ii). By the same token, we see that $e^i$ restricts to the identity map on $\text{Ker } d^i$, i.e. $\delta^i$ admits a continuous right inverse, given by the restriction $\text{Ker } d^i \to C^{i-1}$ of $h^i$. Taking into account lemma \[8.2.5\] we then get also (i).

8.6.17. Extensions of topological rings. Let $A$ be any topological ring whose topology is linear; we shall consider for any $A$-algebra $C$, the category

$$\text{Exal}_A(C)$$

whose objects are all short exact sequences of $A$-modules

$$\Sigma : 0 \to M \to E \xrightarrow{\psi} C \to 0$$  

such that $E$ is an $A$-algebra (with $A$-module structure given by the structure map $A \to E$), and $\psi$ is a map of $A$-algebras. The morphisms in $\text{Exal}_A(C)$ are the commutative ladders of $A$-modules whose central vertical arrow $g$ is a map of $A$-algebras:

$$0 \to M' \xrightarrow{g} E' \to C \to 0$$

$$0 \to M'' \xrightarrow{g} E'' \to C \to 0.$$  

\[8.6.19\]
For any topological $A$-algebra $C$ whose topology is linear, we shall consider the category

$$\text{Exaltop}_A(C)$$

whose objects are the short exact sequences of $A$-modules such that $E$ is a topological $A$-algebra whose topology is linear (and again, with $A$-module structure given by the structure map $A \to E$), and $\psi$ is a continuous and open map of topological $A$-algebras, whose kernel $M$ is a discrete topological space, for the topology induced from $E$. The morphisms in $\text{Exaltop}_A(C)$ are the commutative ladders such that $g$ is a continuous map of topological $A$-algebras.

8.6.20. Now, let $A$ be as in [8.6.17], $C$ any topological $A$-algebra whose topology is linear, $\varphi : A \to C$ the structure morphism, and $(I_\lambda \mid \lambda \in \Lambda)$ (resp. $(J_\lambda \mid \lambda \in \Lambda')$) a collection of open ideals of $A$ (resp. of $C$), which is a fundamental system of open neighborhoods of $0$. Let $\Lambda'' \subset \Lambda \times \Lambda'$ be the subset of all $(\lambda, \lambda')$ such that $\varphi(I_\lambda) \subset J_{\lambda'}$; the set $\Lambda''$ is partially ordered, by declaring that $(\lambda, \lambda') \leq (\mu, \mu')$ if and only if $I_\mu \subset I_\lambda$ and $J_{\mu'} \subset J_{\lambda'}$. Set $A_\lambda := A/I_\lambda$ for every $\lambda \in \Lambda$ (resp. $C_{\lambda} := C/J_{\lambda}$ for every $\lambda' \in \Lambda'$); for $(\lambda, \lambda'), (\mu, \mu') \in \Lambda''$ with $(\lambda, \lambda') \leq (\mu, \mu')$, the surjection $\pi_{\mu,\lambda'} : C_{\mu'} \to C_\lambda$ induces a functor

$$\text{Exal}_{A_\lambda}(C_{\lambda'}) \to \text{Exal}_{A_\mu}(C_{\mu'}) \quad \Sigma \mapsto \Sigma \ast \pi_{\mu,\lambda'}$$

(see [59] §2.5.5]) and clearly the rule $(\lambda, \lambda') \mapsto \text{Exal}_{A_\lambda}(C_{\lambda'})$ yields a pseudo-functor

$$E : (\Lambda'', \leq) \to \text{Cat}.$$ 

Moreover, we have a pseudo-cocone:

$$(8.6.21) \quad E \Rightarrow \text{Exaltop}_A(C)$$

defined as follows. To any $(\lambda, \lambda') \in \Lambda''$ and any object $\Sigma_{\lambda,\lambda'} : 0 \to M \to E_{\lambda'} \to C_{\lambda} \to 0$ of $\text{Exal}_{A_\lambda}(C_{\lambda'})$, one assigns the extension obtained by pulling back $\Sigma_{\lambda,\lambda'}$ along the projection $\pi_{\lambda'} : C \to C_{\lambda'}$. Let $\beta : E \to E_{\lambda'}$ be the induced projection; we endow $E$ with the linear topology defined by the fundamental system of all open ideals of the form $\psi^{-1}J \cap \beta^{-1}J'$ where $J$ (resp. $J'$) ranges over the set of open ideals of $C$ (resp. over the set of all ideals of $E_{\lambda'}$). With this topology, it is easily seen that both $\psi$ and the induced structure map $A \to E$ are continuous ring homomorphisms. Moreover, if $J \subset J_{\lambda'}$, then $\psi^{-1}J \cap \beta^{-1}J' = J \times (J' \cap M)$, from which it follows that $\psi$ is an open map. Furthermore, $M \cap \beta^{-1}0 = 0$, which shows that $M$ is discrete, for the topology induced by the inclusion map $M \to E$. Summing up, we have attached to $\Sigma_{\lambda,\lambda'}$ a well defined object $\Sigma_{\lambda,\lambda'} \ast \pi_{\lambda'}$ of $\text{Exaltop}_A(C)$, and it is easily seen that the rule $\Sigma_{\lambda,\lambda'} \mapsto \Sigma_{\lambda,\lambda'} \ast \pi_{\lambda'}$ is functorial in $\Sigma_{\lambda,\lambda'}$, and for $(\lambda, \lambda') \in \Lambda''$, there is a natural isomorphism in $\text{Exaltop}_A(C)$:

$$\Sigma_{\lambda,\lambda'} \ast \pi_{\lambda'} \sim (\Sigma_{\lambda,\lambda'} \ast \pi_{\mu,\lambda'}) \ast \pi_{\mu'}$$

(details left to the reader).

**Lemma 8.6.22.** The pseudo-cocone (8.6.21) induces an equivalence of categories:

$$\beta : 2\text{-colim}_{\Lambda''} E \sim \text{Exaltop}_A(C).$$

**Proof.** Let $\Sigma$ as in (8.6.18) be any object of $\text{Exaltop}_A(C)$. By assumption, there exists an open ideal $J \subset E$ such that $M \cap J = 0$. Since $\psi$ is an open map, there exists $\lambda' \in \Lambda'$ such that $J_{\lambda'} \subset \psi(J)$, and after replacing $J$ by $J \cap \psi^{-1}J_{\lambda'}$, we may assume that $\psi(J) = J_{\lambda'}$. Likewise, if $\varphi_E : A \to E$ is the structure morphism, there exists $\lambda \in \Lambda$ such that $I_\lambda \subset \varphi_E^{-1}J$, and it follows that the induced extension

$$\Sigma_{\lambda,\lambda'} : 0 \to M \to E/J \to C_{\lambda} \to 0$$

is an object of $\text{Exal}_{A_\lambda}(C_{\lambda'})$. We notice:

**Claim 8.6.23.** There exists a natural isomorphism $\Sigma \sim \Sigma_{\lambda,\lambda'} \ast \pi_{\lambda'}$ in $\text{Exaltop}_A(C)$. 
Proof of the claim. (i): By construction, \( \psi \) and the projection \( \pi_J : E \to E/J \) define a unique morphism \( \gamma : E \to (E/J) \times_{C_{\lambda'}} C \) of \( A \)-algebras, restricting to the identity map on \( M \) (which is an ideal in both of these \( A \)-algebras). It is clear that \( \gamma \) is an isomorphism, and therefore it yields a natural isomorphism \( \Sigma \sim \Sigma_{\lambda'} \times \pi_{\lambda'} \) in \( \text{Exal}_A(C) \). It remains to check that \( \gamma \) is continuous and open. For the continuity, it suffices to remark that, for every ideal \( J \subset E/J \) and every \( \mu' \in \Lambda' \), the ideals \( \gamma^{-1}(I \times_{C_{\lambda'}} C) = \pi_{\lambda'}^{-1}I \) and \( \gamma^{-1}(E/J \times_{C_{\lambda'}} \mu') = \psi^{-1}J \mu' \) are open in \( E \), which is obvious, since \( J \) is an open ideal and \( \psi \) is continuous. Lastly, let \( I \subset E \) be any open ideal such that \( I \subset J \cap \psi^{-1}J_{\lambda'} \); since \( \psi \) is an open map, it is easily seen that \( \gamma(I) = 0 \times \psi(I) \) is an open ideal of \( (E/J) \times_{C_{\lambda'}} C \), so \( \gamma \) is open. 

From claim 8.6.23 we see already that \( \beta \) is essentially surjective. It also follows easily that \( \beta \) is full. Indeed, consider any morphism \( s : \Sigma' \to \Sigma'' \) of \( \text{Exal}_A(C) \) as in (8.6.19), and pick an open ideal \( J'' \subset E'' \) with \( J \cap M'' = 0 \); set \( J' := g^{-1}J'' \), and notice that \( J'' \cap M' = 0 \). Moreover, if the image of \( J'' \) in \( C \) equals \( J_{\lambda'} \) for some \( \lambda' \in \Lambda' \), then clearly the same holds for the image of \( J' \) in \( C \). Therefore, in this case the foregoing construction yields objects \( \Sigma_{\lambda',\lambda'}' \) and \( \Sigma_{\lambda',\lambda'}'' \) of \( \text{Exal}_A(C_{\lambda'}) \) (for a suitable \( \lambda \in \Lambda \)), whose middle terms are respectively \( E'/J' \) and \( E''/J'' \), and \( s \) descends to a morphism \( s_{\lambda'} : \Sigma_{\lambda',\lambda'}' \to \Sigma_{\lambda',\lambda'}'' \), whose middle term is the map \( \gamma_{\lambda'} : E'/J' \rightarrow E''/J'' \) induced by \( g \). By inspecting the proof of claim 8.6.23 we deduce a commutative diagram

\[
\begin{array}{ccc}
E' & \xrightarrow{\sim} & (E'/J') \times_{C_{\lambda'}} C \\
\downarrow{g} & & \downarrow{\gamma_{\lambda'} \times C_{\lambda'}} C \\
E'' & \xrightarrow{\sim} & (E''/J'') \times_{C_{\lambda'}} C
\end{array}
\]

whose horizontal arrows are the maps that define the isomorphisms \( \Sigma' \sim \Sigma_{\lambda',\lambda'}' \times \pi_{\lambda'} \) and \( \Sigma'' \sim \Sigma_{\lambda',\lambda'}'' \times \pi_{\lambda'} \) in \( \text{Exal}_A(C) \). It follows easily that \( s_{\lambda'} \times \pi_{\lambda'} = s \), whence the assertion. Lastly, the faithfulness of \( \beta \) is immediate, since the projections \( \pi_{\lambda'} \) are surjective maps. □

8.6.24. Let \( A \) be as in 8.6.17 and \( C \) any \( A \)-algebra (resp. any topological \( A \)-algebra); we denote by

\[
\text{nilExal}_A(C) \quad \text{(resp. nilExal}_A(C) \text{)}
\]

the full subcategory of \( \text{Exal}_A(C) \) (resp. of \( \text{Exal}_A(C) \)) whose objects are the \textit{nilpotent extensions} of \( C \), i.e. those extensions (8.6.18), where \( M \) is a nilpotent ideal of \( E \). Moreover, in the situation of (8.6.20), clearly \( E \) restricts to a pseudo-functor

\[
\text{nil} : (\Lambda'', \leq) \to \text{Cat} \quad (\lambda, \lambda') \mapsto \text{nilExal}_{A_{\lambda'}}(C_{\lambda'}). \]

Also, (8.6.21) restricts to a pseudo-cocone on nil\( E \), and lemma 8.6.22 immediately implies an equivalence of categories

(8.6.25) \[
2\text{-colim}_{\Lambda''} \text{nil}E \sim \text{nilExal}_A(C).
\]

**Proposition 8.6.26.** Let \( A \) and \( C \) be as in (8.6.20). The following holds:

(i) Suppose that \( J_{\lambda'}^2 \) is open in \( C \), for every \( \lambda' \in \Lambda' \). Then the forgetful functor

(8.6.27) \[
\text{nilExal}_A(C) \to \text{nilExal}_A(C)
\]

is fully faithful.

(ii) Suppose additionally, that:

(a) \( C \) is noetherian, and \( I \subset C \) is an ideal such that the topology of \( C \) is \( I \)-adic.

(b) \( I_{\lambda'}^2 \) is open in \( A \), for every \( \lambda \in \Lambda \).

Then the essential image of (8.6.27) is the (full) subcategory of all nilpotent extensions (8.6.18) such that the \( C \)-module \( M/M^2 \) is annihilated by a power of \( I \).
Proof. (i): The functor is obviously faithful, and in light of (8.6.25), we come down to the following situation. We have a commutative ladder of extensions of $A$-algebras

$$
\begin{array}{ccc}
0 & \to & M & \to & E & \xrightarrow{\psi} & C & \to & 0 \\
& & \downarrow & & \downarrow g & & \downarrow \pi_{M'} & & \\
0 & \to & N & \to & E' & \to & C_{M'} & \to & 0
\end{array}
$$

for some $\lambda' \in \Lambda$, whose top (resp. bottom) row is an object of $\text{nilExal}_{A}(C)$ (resp. of $\text{nilExal}_{A}(C_{\lambda'})$, for some $\lambda \in \Lambda$), and we need to show that the kernel of $g$ contains an open ideal. To this aim, we remark:

Claim 8.6.28. For any open ideal $I \subset E$, the ideal $J^2$ is open as well.

Proof of the claim. Recall that $M$ is a discrete $A$-module for the topology induced by $E$; then, after replacing $J$ by a smaller open ideal, we may assume that $J \cap M = 0$. We have $I := \psi(J^2) = \psi(J)^2$, so the assumption in (i) say that $I$ is open in $C$, and therefore $\psi^{-1}I = J^2 \oplus M$ is open in $E$, so finally $J \cap \psi^{-1}I = J^2$ is open in $E$, as stated. $\Box$

Now, set $J := \psi^{-1}J_{\lambda'}$; then $J$ is an open ideal of $E$, and clearly $g(I) \subset N$. Say that $N^k = 0$; then $g(I^k) = 0$, and $I^k$ is an open ideal of $E$, by claim 8.6.28 hence the contention.

(ii): It is easily seen that, for every extension in the essential image of (8.6.25) in the ideal image of (8.6.27), we must have $I^k(M/M^2) = 0$ for every sufficiently large $k \geq 0$ (details left to the reader). Conversely, consider a nilpotent extension $\Sigma$ as in (8.6.18), with $I^k(M/M^2) = 0$ and $M^t = 0$ for some $k, t \in \mathbb{N}$. Pick a finite system $f := (f_1, \ldots, f_r)$ of elements of $E$ whose images in $B$ form a system of generators for $I^k$; notice that the ideal $(f^n)B$ is open in $B$, and $(f^n)M = 0$ for every $n \geq t$. There follows an inverse system of exact sequences (notation of remark 7.8.1(ii))

$$H_1(f^n, B) \to M \xrightarrow{\beta_n} E/(f^n)E \to B/(f^n)B \to 0$$

with transition maps induced by the morphisms $\varphi_{f}$ of (7.8.20). As $B$ is noetherian, lemma 7.8.44 and remark 7.8.45 imply that the system $(H_1(f^n, B) \mid n \in \mathbb{N})$ is essentially zero. Therefore, the same holds for the inverse system $(\text{Ker} \beta_n \mid n > 0)$. However, the transition map $\text{Ker} \beta_{n+1} \to \text{Ker} \beta_n$ is obviously injective for every $n \geq t$, so we conclude that $\beta_n$ is injective for some sufficiently large integer $n$. For such $n$, we obtain a nilpotent extension (8.6.29)

$$0 \to M \to E/(f^n)E \to B/(f^n)B \to 0$$

Lastly, let $\varphi : A \to B$ be the structure map, and pick $\lambda \in \Lambda$ such that $I_\lambda \subset \varphi^{-1}I^k$; it is easily seen that $I_\lambda M = 0$ and $\varphi(I_\lambda) \subset (f^n)B$ for $s \in \mathbb{N}$ large enough. Therefore, some sufficiently large power of $I_\lambda$ annihilates $E/(f^n)E$; under our assumption (b), such power of $I_\lambda$ contains another open ideal $I^k$, so (8.6.29) is an object of $\text{nilExal}_{A_n}(B/(f^n)B)$ whose image in $\text{nilExal}_{A}(B)$ agrees with $\Sigma$. $\square$

Proposition 8.6.30. Let $A$ be a topological ring (whose topology is linear), $B$ a noetherian $A$-algebra, $I \subset B$ an ideal, and suppose that :

(a) The structure map $A \to B$ is continuous for the $I$-adic topology on $B$.
(b) For every open ideal $J \subset A$, the ideal $J^2$ is also open.

Then the following conditions are equivalent :

(c) $B$ (with its $I$-adic topology) is a formally smooth $A$-algebra.
(d) $\Omega^1_{B/A} \otimes_B B/I$ is a projective $B/I$-module, and $H_1(\Lambda_{B/A} \otimes_B B/I) = 0$.

Proof. More generally, let $A$ and $C$ be as in (8.6.20), and $M$ a discrete $C$-module, i.e. a $C$-module annihilated by an open ideal; we denote by $\text{Exal}_{A}(C, M)$ the $C$-module of square zero topological $A$-algebra extensions of $C$ by $M$. Likewise, for every $(\lambda, \lambda') \in \Lambda^n$, and every
$C_{\lambda'}$-module $M$, let $\text{Exal}_{A_{\lambda'}}(C_{\lambda'}, M)$ be the $C_{\lambda'}$-module of isomorphism classes of square zero $A_{\lambda'}$-algebra extensions of $C_{\lambda'}$ by $M$. For $(\lambda, \lambda') \leq (\mu, \mu')$, we get a natural map of $C_{\mu'}$-modules
\[(8.6.31) \quad \text{Exal}_{A_{\lambda}}(C_{\lambda'}, M) \rightarrow \text{Exal}_{A_{\mu}}(C_{\mu'}, M) \quad \text{for every } C_{\lambda'}\text{-module } M\]
and [8.6.25] implies a natural isomorphism:
\[\colim_{(\lambda, \lambda') \in \Lambda''} \text{Exal}_{A_{\lambda}}(C_{\lambda'}, M) \cong \text{Exaltop}_{A}(C, M)\]
which is well defined for every discrete $C$-module $M$. By inspecting the definitions, and taking into account [43] Ch.0, Prop.19.4.3, it is easily seen that $C$ is a formally smooth $A$-algebra if and only if $\text{Exaltop}_{A}(C, M) = 0$ for every such discrete $C$-module $M$. We also have a natural $C$-linear map:
\[(8.6.32) \quad \text{Exaltop}_{A}(C, M) \rightarrow \text{Exal}_{A}(C, M) \quad \text{for every } C\text{-module } M\]
and proposition [8.6.26] shows that (8.6.32) is an injective map, provided $J^2_{\lambda'}$ is an open ideal of $C$, for every $\lambda' \in \Lambda'$. Moreover, for $C := B$ (with its $I$-adic topology), the map (8.6.32) is an isomorphism, by virtue of proposition [8.6.26]ii).

Now, recall the natural isomorphism of $C_{\lambda'}$-modules ([82] Ch.III, Th.1.2.3])
\[\text{Exal}_{A}(B, M) \cong \text{Ext}_{B}^{1}(\mathbb{L}_{B/A}, M) \quad \text{for every } B\text{-module } M.\]
Combining with the foregoing, we deduce a natural $B$-linear isomorphism
\[\text{Exaltop}_{A}(B, M) \cong \text{Ext}_{B}^{1}(\mathbb{L}_{B/A}, M)\]
for every $B$-module $M$ annihilated by some ideal $I^k$. Summing up, $B$ is a formally smooth $A$-algebra if and only if $\text{Ext}_{B}^{1}(\mathbb{L}_{B/A}, M)$ vanishes for every discrete $B$-module $M$. Set $B_0 := B/I$; by considering the $I$-adic filtration on a given $M$, a standard argument shows that the latter condition holds if and only if it holds for every $B_0$-module $M$, and in turns, this is equivalent to the vanishing of $\text{Ext}_{B_0}^{1}(\mathbb{L}_{B/A} \otimes_B B_0, M)$ for every $B_0$-module $M$. This last condition is equivalent to (d), as stated.

We conclude this section with a list of topological corollaries of the conditions (a)$_f$ – (f)$_f$ that were introduced in [7.8.21].

8.6.33. Let $A$ be a ring, $f := (f_1, \ldots, f_r)$ a finite sequence of elements of $A$ that generate an ideal $I \subset A$. Let also $(C_{\bullet}, d_{\bullet})$ be any bounded above complex of flat $A$-modules such that, for every $j \in \mathbb{Z}$ the annihilator ideal of $H_{j}C_{\bullet}$ contains a power of $I$. Denote also by $A^\wedge$ the $I$-adic completion of $A$, and by $C^\wedge_{\bullet}$ the complex whose term (resp. differential) in degree $j$ is the $I$-adic completion of $C_{j}$ (resp. of $d_{j}$), for every $j \in \mathbb{Z}$. Lastly, set $Q_{\bullet} := \text{Cone}(A[0] \rightarrow A^\wedge[0])$, the cone of the morphism given by the completion map, and let $f^\wedge$ be the image in $A^\wedge$ of the sequence $f$.

**Corollary 8.6.34.** In the situation of [8.6.33], the following holds:

(i) If $A$ satisfies condition (a)$_f$ of [7.8.21], the natural maps
\[C_{\bullet} \rightarrow A^\wedge \otimes_A C_{\bullet} \rightarrow C^\wedge_{\bullet}\]
are quasi-isomorphisms.

(ii) The following conditions are equivalent:
(a) $A$ satisfies condition (a)$_f$.
(b) $A^\wedge$ satisfies condition (a)$_f$ and $Q_{\bullet} \otimes_A A/I[0]$ is acyclic.
Proof. (i): According to [125, Th.3.5.8], for every \( i \in \mathbb{Z} \) we have a natural short exact sequence
\[
0 \to L := \lim_{n \in \mathbb{N}}^1 H_{i+1}(C_\bullet \otimes_A A/I^n) \to H_i(C^\wedge) \xrightarrow{\omega} \lim_{n \in \mathbb{N}} H_i(C_\bullet \otimes_A A/I^n) \to 0.
\]
On the other hand, the complex \( C_\bullet \) fulfills condition (f) of (7.8.21), so the kernel and cokernel of the natural morphism of inverse systems \( (H_i(C_\bullet) | n \in \mathbb{N}) \to (H_i(C_\bullet \otimes_A A/I^n) | n \in \mathbb{N}) \) are both essentially zero, hence the induced map
\[
H_i(C_\bullet) \to \lim_{n \in \mathbb{N}} H_i(C_\bullet \otimes_A A/I^n)
\]
is an isomorphism for every \( i \in \mathbb{Z} \), and \( L = 0 \) ([125, Prop.3.5.7]). Hence, \( \omega \) is an isomorphism, and it is easily seen that the resulting isomorphism \( H_i(C^\wedge) \xrightarrow{\sim} H_i(C) \) is the inverse of the map induced by the completion map \( C_\bullet \to C^\wedge \), hence the latter is a quasi-isomorphism. Next we remark:

Claim 8.6.35. Let \( B \) be any ring, \( g \) a finite sequence of elements of \( B \) that generates an ideal \( J \), and \( K_\bullet \) a bounded above complex of \( B \)-modules. The following conditions are equivalent:

(a) \( K_\bullet \otimes_B B/J[0] \) is acyclic.

(b) \( K_\bullet(g, K_\bullet) \) is acyclic.

Proof of the claim. (a)\( \Rightarrow \) (b): For every \( q \in \mathbb{N} \) we consider the spectral sequences
\[
E^2_{pq} := H_p(K_\bullet \otimes_B H_qK_\bullet(g)[0]) \Rightarrow H_{p+q}(g, K_\bullet)
\]
\[
F(q)_{ij}^2 := \operatorname{Tor}^B/J_{ij}(H_j(K_\bullet \otimes_B B/J[0]), H_qK_\bullet(g)) \Rightarrow E^2_{i+j,q}
\]
for every \( q \in \mathbb{Z} \).

Assumption (a) implies that \( F(q)_{ij}^2 = 0 \) for every \( i, j, q \in \mathbb{Z} \), so that \( E^2_{pq}^L = 0 \) for every \( p \in \mathbb{Z} \), whence (b). Conversely, if (b) holds, we show – by induction on \( n \) that \( H_n(K_\bullet \otimes_B B/J[0]) = 0 \) for every \( n \in \mathbb{Z} \). First, since \( K_\bullet \) is bounded above, we may find \( n_0 \in \mathbb{Z} \) such that the assertion holds for every \( n \leq n_0 \). Next, let \( k > n_0 \), and suppose that the assertion is already known for every \( n < k \). It follows that \( F(q)_{ij}^2 = 0 \) whenever \( j < k \), and clearly the same holds also whenever \( i < 0 \); thus \( F(q)_{0k}^2 = E^2_{0k} \) for every \( q \in \mathbb{Z} \). By the same token, we deduce that \( E^2_{pq}^L = 0 \) for every \( p < k \), and clearly the same holds whenever \( q < 0 \). Summing up, it follows that \( E^2_{k0} = H_k(g, K_\bullet) = 0 \); however, \( F(0)_{0k}^2 = H_k(K_\bullet \otimes_B B/J[0]) \), whence the contention. ◇

Claim 8.6.36. Suppose that \( A \) satisfies condition (a) of (7.8.21), let \( k \in \mathbb{N} \) be any integer, and \( N \) any \( A/I^k \)-module. The completion map \( A \to A^\wedge \) induces an isomorphism
\[
N \xrightarrow{\sim} A^\wedge \otimes_A N \quad \text{and} \quad \operatorname{Tor}^A_i(A^\wedge, N) = 0 \quad \text{for every} \quad i > 0.
\]

Proof of the claim. Notice that, since \( K_\bullet(f) \) is a free \( A \)-module of finite rank for every \( j \in \mathbb{Z} \), the natural map \( A^\wedge \otimes_A K_\bullet(f) \to K_\bullet(f^\wedge) \) is an isomorphism. But we have already shown that the completion map \( K_\bullet(f) \to K_\bullet(f^\wedge) \) is a quasi-isomorphism, hence \( K_\bullet(f, Q_\bullet) \) is acyclic, and in light of claim 8.6.35 we see that the same holds for \( Q_\bullet \otimes_A A/I[0] \). Let \( M \) be any \( A/I \)-module; from the change of ring spectral sequence
\[
\operatorname{Tor}_i^{A/I}(H_j(Q_\bullet \otimes_A A/I[0]), M) \Rightarrow H_{i+j}(Q_\bullet \otimes_A M[0])
\]
we deduce that \( Q_\bullet \otimes_A M[0] \) is also acyclic. Lastly, by considering, for \( t = 0, \ldots, k - 1 \) the distinguished triangles
\[
Q_\bullet \otimes_A I^tN/I^{t+1}N[0] \to Q_\bullet \otimes_A N/I^{t+1}N[0] \to Q_\bullet \otimes_A N/I^tN[0] \to Q_\bullet \otimes_A I^tN/I^{t+1}N[1]
\]
a simple induction shows that $Q_{\bullet} \otimes_A N[0]$ is acyclic as well; the latter assertion is equivalent to the claim. ◊

Now, let us consider the spectral sequence

$$E^2_{pq} := \text{Tor}^A_p(A^\wedge, H_qC_{\bullet}) \Rightarrow H_{p+q}(A^\wedge[0] \otimes_A C_{\bullet})$$

and notice that $A^\wedge[0] \otimes_A C_{\bullet} = A^\wedge \otimes_A C_{\bullet}$, since $C_{\bullet}$ is a complex of flat $A$-modules. By assumption, for every $q \in \mathbb{Z}$ there exists $k \in \mathbb{N}$ such that $I^k \cdot H_qC_{\bullet} = 0$; taking into account claim $8.6.36$ we conclude that $E^2_{pq} = 0$ whenever $p > 0$, and $E^2_{0q} = H_qC_{\bullet}$ for every $q \in \mathbb{Z}$; it is then easily seen that the resulting isomorphism $H_qC_{\bullet} \xrightarrow{\sim} H_q(A^\wedge \otimes_A C_{\bullet})$ is the map induced by the completion map $A \rightarrow A^\wedge$.

(ii.a)⇒(ii.b): We have already remarked in the proof of (i) that if $A$ satisfies condition $(a)_{\mathfrak{f}}$, then $Q_{\bullet} \otimes_A A/I[0]$ is acyclic. Next, define $A_{\mathfrak{r}}$ and $\beta_{\mathfrak{f}} : A_{\mathfrak{r}} \rightarrow A$ as in $(7.8.21)$, and consider the spectral sequence

$$E(n)_{ij}^2 := H_i(\text{Tor}^{A_{\mathfrak{r}}}_{j}(A_{\mathfrak{r}}/I^n_{\mathfrak{r}} A_{\mathfrak{r}} \otimes_A Q_{\bullet}) \Rightarrow H_{i+j}(A_{\mathfrak{r}}/I^n_{\mathfrak{r}} \otimes_{A_{\mathfrak{r}}} Q_{\bullet}) \quad \text{for every } n \in \mathbb{N}.$$ 

In light of claim $8.6.36$ we see that $E(n)^{2}_{ij} = 0$ for every $i \in \mathbb{Z}$ and $j, n \in \mathbb{N}$, so $A_{\mathfrak{r}}/I^n_{\mathfrak{r}} \otimes_{A_{\mathfrak{r}}} Q_{\bullet}$ is acyclic, and therefore the completion map $A \rightarrow A^\wedge$ induces quasi-isomorphisms

$$(8.6.37) \quad A_{\mathfrak{r}}/I^n_{\mathfrak{r}} \otimes_{A_{\mathfrak{r}}} A \xrightarrow{\sim} A_{\mathfrak{r}}/I^n_{\mathfrak{r}} \otimes_{A_{\mathfrak{r}}} A^\wedge \quad \text{for every } n \in \mathbb{N}$$

so $A^\wedge$ satisfies $(a)_{\mathfrak{f}}$.

(ii.b)⇒(ii.a): Arguing as in the proof of claim $8.6.36$ we see that $N \otimes_A Q_{\bullet}$ is acyclic for every $k \in \mathbb{N}$ and every $\bar{A}/I^k$-module $N$. Then we find again $E(n)^{2}_{ij} = 0$ for every $i \in \mathbb{Z}$ and every $j, n \in \mathbb{N}$, as well as the quasi-isomorphisms $(8.6.37)$, and the assertion follows. □

**Corollary 8.6.38.** In the situation of $(7.8.35)$, set $Z := \text{Spec } A/I$, and suppose that $U := \text{Spec } A \setminus Z$ is an affine scheme. Then $\bar{A}$ satisfies condition $(c)_{\mathfrak{u}}$ of $(7.8.21)$.

**Proof.** Endow $A$ with its $I$-adic topology, and $A_U := \mathcal{O}_U(U)$ with the $\mathfrak{f}$-adic topology $\mathcal{T}_U$ provided by proposition $8.3.30(i)$. Clearly, the restriction map $\rho_U : A \rightarrow A_U$ factors through $\bar{A}$, so the latter is an open subring of $A_U$. Now, by definition there is no prime ideal of $U$ that contains all the elements $\bar{f}_1, \ldots, \bar{f}_r$; since $U$ is affine by assumption, it follows that there exist $g_1, \ldots, g_r \in A_U$ such that $\sum_{i=1}^{r} g_i \cdot \bar{f}_i = 1$ in $A_U$. Next, since $\bar{A}$ is a ring of definition of $A_U$, and $\bar{T} := I/J$ an ideal of adic definition, it follows that there exists $k \in \mathbb{N}$ such that $g_i \cdot \bar{T}^k \subset \bar{A}$ for $i = 1, \ldots, r$. It follows easily that the scalar multiplication by $g_i$ induces an $\bar{A}$-linear map $\bar{T}^{n+k} \rightarrow \bar{T}^n$ for every $n \in \mathbb{N}$, and the latter in turn induces a map of complexes

$$\psi_{i,n} : K_{\bullet}(\bar{T}, \bar{T}^{n+k}) \rightarrow K_{\bullet}(\bar{T}, \bar{T}^n) \quad \text{for every } n \in \mathbb{N} \text{ and } i = 1, \ldots, r.$$ 

On the other hand, scalar multiplication by $\bar{f}_i$ induces a map of complexes

$$\varphi_{i,n} : K_{\bullet}(\bar{T}, \bar{T}^n) \rightarrow K_{\bullet}(\bar{T}, \bar{T}^n) \quad \text{for every } n \in \mathbb{N} \text{ and } i = 1, \ldots, r$$

that equals the zero morphism in the homotopy category (see lemma $(7.8.2)$). Summing up, we conclude that $\sum_{i=1}^{r} \varphi_{i,n} \circ \psi_{i,n}$ is the zero morphism $K_{\bullet}(\bar{T}, \bar{T}^{n+k}) \rightarrow K_{\bullet}(\bar{T}, \bar{T}^n)$ in the homotopy category, and on the other hand it coincides with the inclusion map. The assertion follows. □

**Remark 8.6.39.** (i) Let $A$ be a ring, $J \subset A$ an ideal of finite type; endow $A$ with its $J$-adic topology, denote by $A^\wedge$ the completion of $A$, and set $X_A := \text{Spec } A$, $X_{A^\wedge} := \text{Spec } A^\wedge$. Let also
$U \subset X_A$ be an affine open subset containing the analytic locus of $X_A$ (see definition [8.3.28]), and set $U^\wedge := U \times_{X_A} X_A$. Moreover, let

$$A_U := \mathcal{O}_{X_A}(U) \quad A_{U^\wedge} := \mathcal{O}_{X_A^\wedge}(U^\wedge) \quad \tau_A := \text{Ker}(A \to A_U) \quad \tau_A^\wedge := \text{Ker}(A^\wedge \to A_{U^\wedge})$$

and denote by $(\tau_A A^\wedge)^c$ the topological closure of $\tau_A A^\wedge$ in $A^\wedge$. Then we have

$$\tau_A^\wedge \subset (\tau_A A^\wedge)^c.$$

Indeed, endow $A_U$ with the $f$-adic topology characterized by proposition [8.3.30](i), and let $A_U^\wedge$ be the completion of $A_U$; then $A/\tau_A$ is a ring of definition of $A_U$, hence its completion $(A/\tau_A)^\wedge = A^\wedge/(\tau_A A^\wedge)^c$ is a ring of definition of $A_U^\wedge$, and the natural map $A^\wedge/(\tau_A A^\wedge)^c \otimes_A A_U \to A_U^\wedge$ is an isomorphism (propositions [8.2.13](iii) and [8.3.33](i,iii)). On the other hand, $A_{U^\wedge} = A^\wedge \otimes_A A_U$, so we get a commutative diagram of rings:

$$
\begin{array}{c}
A^\wedge \quad \xrightarrow{\sim} \quad A^\wedge/(\tau_A A^\wedge)^c \\
\downarrow \quad \quad \quad \downarrow \\
A_{U^\wedge} \quad \xrightarrow{\sim} \quad A_U^\wedge
\end{array}
$$

whose right vertical arrow is injective, whence the assertion.

(ii) In the situation of (i), say furthermore that $X_A \setminus U = \text{Spec} A/I$, for some ideal $I \subset A$ generated by a finite sequence $f := (f_1, \ldots, f_r)$ of elements of $A$, and suppose that $\tau_A \cdot I^k = 0$ for some $k \in \mathbb{N}$. Then $\tau_A \cap I^n = 0$ for some $n \in \mathbb{N}$. Indeed, by virtue of corollary [8.6.38] and proposition [7.8.36] the ring $A$ satisfies condition (c)$_f^\text{un}$ of (7.8.21), and the proof of proposition 7.8.36 shows that the sought identity follows from condition (c)$_f$. In particular, $\tau_A$ is a discrete subset of $A$, and the natural map $\tau_A \to \tau_A A^\wedge$ is an isomorphism; then, $\tau_A$ is (naturally identified with) a discrete subset of $A^\wedge$ as well, and (i) implies that the natural map $\tau_A \to \tau_A^\wedge$ is an isomorphism as well.

(iii) Consider now the special case where $J = bA$ for some $b \in A$. Then we claim more precisely that $\text{Ann}_{A^\wedge}(b^n)$ is the topological closure of the image of $\text{Ann}_A(b^n)$ in $A^\wedge$, for every $n \in \mathbb{N}$. Indeed, let $x \in \text{Ann}_{A^\wedge}(b^n)$; for every $k \in \mathbb{N}$ we may find $x_k \in A$ and $y_k \in A^\wedge$ such that $x = x_k^b + b^n y_k$ in $A^\wedge$. Then $b^n x_k \in (b^n + k A^\wedge) \cap A = b^n + k A$; say that $b^n x_k = b^n + k z_k$ with $z_k \in A$. Hence the sequence $(x_k - b^n z_k \mid k \in \mathbb{N})$ lies in $\text{Ann}_A(b^n)$ and converges $b$-adically to $x$, whence the contention.

**Corollary 8.6.40.** In the situation of (8.6.33), let $B$ be a ring, $\varphi : B \to A$ a ring homomorphism, $K \subset B$ and $J \subset I$ two ideals. Set $M := K \otimes_B A$, and denote by

$$\psi : M \to A$$

the $A$-linear map induced by $\varphi$. Suppose moreover that $A$ satisfies condition (a)$_f$ of (7.8.21), and the image of $\psi$ is open in the $I$-adic topology of $A$. Then we have:

(i) There exists $n \in \mathbb{N}$ such that $I^n M \cap \text{Ker} \psi = 0$.

(ii) $A$ is $J$-adically complete and separated if and only if the same holds for $M$.

**Proof.** (i): Notice first that $\text{Ker} \psi = \text{Tor}^B_1(B/K, A)$. Especially, $\text{Ker} \psi$ is naturally a $B/K$-module. By assumption, there exists $k \in \mathbb{N}$ such that $I^k \subset \text{Im} \psi = \varphi(K) \cdot A$; we deduce that $\text{Ker} \psi$ is also an $A/I^k$-module. Next, we consider the short exact sequences

$$0 \to \text{Ker} \psi \to M \to \text{Im} \psi \to 0$$

and

$$0 \to \text{Im} \psi \to A \to A/\text{Im} \psi \to 0.$$

There follows exact sequences of inverse systems

$$
\begin{align*}
T_\bullet := & (\text{Tor}^A_1(A_r/I^n_r, \text{Im} \psi) \mid n \in \mathbb{N}) \to K_\bullet := (A/I^n \otimes_A \text{Ker} \psi \mid n \in \mathbb{N}) \to (M/I^n M \mid n \in \mathbb{N}) \\
T'_\bullet := & (\text{Tor}^A_2(A_r/I^n_r, A/\text{Im} \psi) \mid n \in \mathbb{N}) \to T_\bullet \to T''_\bullet := (\text{Tor}^A_1(A_r/I^n_r, A) \mid n \in \mathbb{N}).
\end{align*}
$$
Now, since \( A \) satisfies condition (a), the inverse system \( T' \) is essentially zero, and the same holds for \( T'' \), by virtue of lemma 7.8.24; hence, \( T \) is essentially zero, by lemma 7.8.19. Moreover, \( K_n = \ker \psi \) for every \( n \geq k \), and the transition maps \( K_{n+1} \to K_n \) are the identities. Then the assertion follows by a simple diagram chase: we leave the details to the reader.

(ii): Since \( \text{Im} \, \psi \) is open in \( A \) for the \( I \)-adic topology, it is also open in \( A \) for the \( J \)-adic topology, and the latter agrees with the topology induced by the \( J \)-adic topology of \( A \); therefore, \( A \) is \( J \)-adically complete and separated if and only if the same holds for \( \text{Im} \, \psi \). On the other hand, the \( J \)-adic topology on \( \text{Im} \, \psi \) also agrees with the quotient topology induced by the \( J \)-adic topology of \( M \). Moreover, (ii) implies that the \( J \)-adic topology of \( M \) induces the discrete topology on \( \ker \psi \). Then, proposition 8.2.13(i,v) yields a short exact sequence of \( J \)-adic completions:

\[
0 \to \ker \psi \to M^\wedge \to (\text{Im} \, \psi)^\wedge \to 0
\]

which shows that \( \text{Im} \, \psi \) is \( J \)-adically complete and separated if and only if the same holds for \( M \), whence (ii).

\[\square\]

9. COMPLEMENTS OF COMMUTATIVE ALGEBRA

This chapter is a miscellanea of results of commutative algebra that shall be needed in the rest of the treatise.

9.1. Valuation theory. This section is a selection of topics in valuation theory, and will be complemented by the section 9.2 devoted to Huber’s theory of the valuation spectrum.

Definition 9.1.1. Recall that an ordered abelian group is a datum \((\Gamma, \cdot, 1, \leq)\) consisting of an abelian group \((\Gamma, \cdot, 1)\) and a total ordering \(\leq\) on \(\Gamma\) (see example 1.1.6(iii)) such that

\[
\gamma \leq \gamma' \Rightarrow \gamma \cdot \gamma'' \leq \gamma' \cdot \gamma'' \quad \text{for every} \quad \gamma, \gamma', \gamma'' \in \Gamma.
\]

(i) We denote by \(\Gamma^+ \subset \Gamma\) the submonoid of all \(\gamma \in \Gamma\) such that \(\gamma \leq 1\).

(ii) A subgroup \(\Delta\) of the ordered abelian group \(\Gamma\) is said to be convex if it satisfies the following condition. If \(\delta \in \Delta^+ := \Delta \cap \Gamma^+\), and \(\gamma \in \Gamma\) is any element with \(1 \geq \gamma \geq \delta\), then \(\gamma \in \Delta\). The spectrum of \(\Gamma\) is the set of all convex subgroups of \(\Gamma\), denoted \(\text{Spec} \, \Gamma\).

(iii) The convex rank of \(\Gamma\), denoted

\[
c.rk(\Gamma) \in \mathbb{N} \cup \{\infty\}
\]

is the supremum over the lengths \(r\) of the chains \(0 \subset \Delta_1 \subset \cdots \subset \Delta_r := \Gamma\) of convex subgroups of \(\Gamma\). The rational rank of \(\Gamma\) is

\[
\rk(\Gamma) := \dim_\mathbb{Q}(\Gamma \otimes_\mathbb{Z} \mathbb{Q}) \in \mathbb{N} \cup \{\infty\}.
\]

(iv) A morphism of ordered abelian groups is a group homomorphism that is an order-preserving map for the underlying totally ordered sets.

Remark 9.1.2. Let \((\Gamma, \cdot, 1, \leq)\) be any ordered abelian group.

(i) It is easily seen that \(\Gamma\) is a torsion-free abelian group. Moreover, we have quite generally

\[
c.rk(\Gamma) \leq \rk(\Gamma)
\]

(details left to the reader).

(ii) Notice as well that there exists a unique structure of ordered abelian group on \(\Gamma \otimes_\mathbb{Z} \mathbb{Q}\) such that the natural map \(\Gamma \to \Gamma \otimes_\mathbb{Z} \mathbb{Q}\) is a morphism of ordered groups. Namely, we have \(\gamma \otimes q \leq 1\) in \(\Gamma \otimes_\mathbb{Z} \mathbb{Q}\) whenever \(\gamma \leq 1\) in \(\Gamma\) and \(q \geq 0\). Moreover, for every \(q \in \mathbb{Q}\) we have a well defined group endomorphism

\[
\Gamma \otimes_\mathbb{Z} \mathbb{Q} \to \Gamma \otimes_\mathbb{Z} \mathbb{Q} \quad (\gamma \otimes r) \mapsto (\gamma \otimes r)^q := \gamma \otimes qr.
\]
(iii) A subgroup $\Delta$ of $\Gamma$ is convex if and only if there exists an ordered abelian group structure on $\Gamma/\Delta$ such that the projection $\Gamma \to \Gamma/\Delta$ is a morphism of ordered abelian groups. Then the ordered abelian group structure with this property is unique. Moreover, notice that the intersection of an arbitrary family of convex subgroups of $\Gamma$ is still convex. Especially, for every subgroup $\Delta$ of $\Gamma$, there exists a minimal convex subgroup of $\Gamma$ containing $\Delta$, called the convex hull of $\Delta$; explicitly, it is the subgroup of all elements $\gamma \in \Gamma$ such that there exists $\delta \in \Delta^+$ with $\delta \leq \gamma \leq \delta^{-1}$.

(iv) There is a natural inclusion-reversing bijection

$$\text{Spec } \Gamma \overset{\sim}{\to} \text{Spec } \Gamma^+ \quad \Delta \mapsto \Gamma^+ \setminus \Delta^+$$

(notation of (6.1.10) and definition 9.1.1(ii)). Indeed, it is easily seen that $\Gamma^+ \setminus \Delta^+$ is a prime ideal of $\Gamma^+$, for every convex subgroup $\Delta$ of $\Gamma$. Conversely, for any prime ideal $p \subseteq \Gamma^+$, the subset $\Delta(p)^+ := \Gamma^+ \setminus p$ is a submonoid, and we claim that the subgroup $\Delta(p)$ generated by $\Delta(p)^+$ is convex. Indeed, suppose that $\gamma \in \Delta(p)^+$ and $\gamma' \in \Gamma^+$ is any other element such that $\gamma \leq \gamma'$; then $\beta := \gamma \cdot \gamma'^{-1} \in \Gamma^+$, therefore $\gamma'$ cannot lie in $p$, for otherwise the same would hold for $\gamma = \beta \cdot \gamma'$. The contention follows.

(v) Let $f : \Gamma \to \Gamma'$ be a morphism of ordered abelian groups. Then $f$ induces a mapping

$$\text{Spec } \Gamma' \to \text{Spec } \Gamma \quad \Delta \mapsto f^{-1} \Delta.$$ For instance, if $\Delta \subseteq \Gamma$ is any convex subgroup, and $\pi : \Gamma \to \Gamma/\Delta$ the projection, then $\text{Spec } \pi : \text{Spec } \Gamma/\Delta \to \text{Spec } \Gamma$ is an injective map, whose image is the subset of all convex subgroups of $\Gamma$ containing $\Delta$. In the same vein, notice that the inclusion map $i : \Gamma \to \Gamma \otimes_{\mathbb{Z}} \mathbb{Q}$ induces a bijection

$$\text{Spec } i : \text{Spec } \Gamma \otimes_{\mathbb{Z}} \mathbb{Q} \overset{\sim}{\to} \text{Spec } \Gamma$$

(details left to the reader). Moreover, if $f$ as above is injective, then $\text{Spec } f$ is surjective: indeed, if $\Delta \subseteq \Gamma$ is any convex subgroup, let $\Delta'$ be the convex hull of $f(\Delta)$ in $\Gamma'$; then it is easily seen that $f^{-1}\Delta' = \Delta$.

(vi) If $c.\text{rk}(\Gamma) = 1$, we may find an injective morphism of ordered abelian groups

$$\rho : (\Gamma, \cdot, 1, \leq) \to (\mathbb{R}, +, 0, \leq).$$

Indeed, pick an element $\gamma \in \Gamma$ with $\gamma > 1$. For every $\delta \in \Gamma$ and every positive integer $n$, there exists a largest integer $k(n)$ such that $\gamma^{k(n)} < \delta^n$. Then $(k(n)/n | n \in \mathbb{N})$ is a Cauchy sequence and we let $\rho(\gamma) := \lim_{n \to \infty} k(n)/n$. One verifies easily that $\rho$ is an order-preserving group homomorphism, and since the convex rank of $\Gamma$ equals one, it follows that $\rho$ is injective.

(vii) To any $\gamma \in \Gamma^+$ we may attach two convex subgroups

$$o(\gamma) := \bigcap_{n \in \mathbb{N}} \{ \delta \in \Gamma \mid \gamma \leq \delta^n \leq \gamma^{-1} \} \quad \text{and} \quad O(\gamma) := \bigcup_{n \in \mathbb{N}} \{ \delta \in \Gamma \mid \gamma^n \leq \delta \leq \gamma^{-n} \}.$$ Clearly $o(\gamma) \subseteq O(\gamma)$, and if $\gamma \neq 1$, the quotient $Q(\gamma) := O(\gamma)/o(\gamma)$ has convex rank one (for its natural ordered group structure as in (iii)). Indeed, suppose that $\delta, \mu$ are two elements of $O(\gamma)$ with classes $\delta, \mu \in Q(\gamma)_+$ and $\delta \neq 1$: the assumptions mean that there exist $n, k \in \mathbb{N}$ such that $\delta^k < \gamma$ and $\gamma^n \leq \mu \leq \gamma^{-n}$. Then $\delta^{kn} \leq \mu$; thus, the only convex subgroups of $Q(\gamma)$ are $Q(\gamma)$ and $\{1\}$, as claimed.

(viii) Standard examples of ordered abelian groups are $(\mathbb{Q}, +, 0, \leq)$ and $(\mathbb{R}, +, 0, \leq)$; the latter is also isomorphic to the ordered group $(\mathbb{R}_{>0}, 1, \leq)$ of strictly positive real numbers. We shall also use the notation: $Q_{>0} := \mathbb{Q} \cap \mathbb{R}_{>0}$, $Q_+ := \mathbb{R}_{>0} \cup \{0\}$ and $Q_+ := Q_{>0} \cup \{0\}$.

**Definition 9.1.3.** Let $A$ be any ring. $(\Gamma, \cdot, 1, \leq)$ any ordered abelian group; we extend the ordering and the composition law of $\Gamma$ to $\Gamma_0 := \Gamma \cup \{0\}$ (cp. remark 4.8.14(i)), by the rule

$$0 < \gamma \quad \text{and} \quad 0 \cdot \gamma = 0 = \gamma \cdot 0 \quad \text{for every } \gamma \in \Gamma.$$
Moreover, for every \( q \in \mathbb{Q}_+ \) we extend to \((\Gamma \otimes_{\mathbb{Z}} \mathbb{Q})_q\), the \( q \)-th power operation of remark \([9.1.2]\) (ii), by declaring that \( 0^q := 1 \) and \( 0^0 := 0 \) for every strictly positive \( q \in \mathbb{Q} \).

(i) A \( \Gamma \)-valued semi-norm on \( A \) is a mapping

\[
v : A \to \Gamma_0
\]

such that:

1. \( v(0) = 0 \) and \( v(1) \leq 1 \).
2. \( v(a - b) \leq \max(v(a), v(b)) \) for every \( a, b \in A \).
3. \( v(ab) \leq v(a) \cdot v(b) \) for every \( a, b \in A \).

The value group of \( v \) is the subgroup

\[
\Gamma_v
\]

of \( \Gamma \) generated by \( \text{Im}(v) \setminus \{0\} \). The rank of \( v \) is the convex rank of its value group.

(ii) We say that the semi-norm \( v \) is power-multiplicative if we have:

\[
v(a^n) = v(a)^n \quad \text{for every } a \in A \text{ and every integer } n > 0.
\]

(iii) We say that the semi-norm \( v \) is a valuation if we have:

\[
v(1) = 1 \quad \text{and} \quad v(ab) = v(a) \cdot v(b) \quad \text{for every } a, b \in A.
\]

(iv) We say that \( v \) is a norm if \( v(a) \neq 0 \) for every \( a \neq 0 \) in \( A \).

(v) We say that the semi-norm \( v \) is real-valued if its value group is a subgroup of \( \mathbb{R}_{>0} \).

(vi) Let \( \Gamma \) and \( \Gamma' \) be two ordered abelian groups, \( v \) (resp. \( v' \)) a \( \Gamma \)-valued (resp. \( \Gamma' \)-valued) semi-norm on \( A \). We say that \( v \) is equivalent to \( v' \) if there exist an ordered abelian group \( \Gamma'' \) and a semi-norm \( v'' : A \to \Gamma'' \), together with injective maps of ordered abelian groups \( \varphi : \Gamma'' \to \Gamma \) and \( \varphi' : \Gamma'' \to \Gamma' \) such that \( \varphi \circ v'' = v \) and \( \varphi' \circ v'' = v' \) (notation of remark \([4.8.14]\) (ii)).

**Remark 9.1.4.** Let \( A \) and \( \Gamma \) be as in definition \([9.1.3]\) and \( | \cdot |_A \) any \( \Gamma \)-valued semi-norm on \( A \).

(i) Notice that \( |1|_A = |1 \cdot 1|_A \leq |1|_A^2 \leq |1|_A \), whence \( |1|_A = |1|_A^2 \), so that either \( |1|_A = 1 \) or \( |1|_A = 0 \). In case \( |1|_A = 0 \), then \( |a|_A = |a \cdot 1|_A \leq |a|_A \cdot 0 = 0 \), and in this case \( | \cdot |_A \) is the trivial semi-norm with constant value 0.

(ii) We have \( |-a|_A = |a|_A \) for every \( a \in A \). Indeed, \( |-a|_A = |0 - a|_A \leq \max(|0|_A, |a|_A) = |a|_A \); after replacing \( a \) by \(-a\) we get also \( |a|_A \leq |-a|_A \), whence the claim.

(iii) Let \( a, b \in A \) be any two elements such that \( |a|_A > |b|_A \). Then we have \( |a + b|_A = |a|_A \). Indeed, suppose that \( |a + b|_A < |a|_A \); taking into account (ii) we get

\[
|a|_A \leq \max(|a + b|_A, |b|_A) < |a|_A
\]

which is absurd.

(iv) Let \( S \subset A \) be any multiplicative subset such that \( |s|_A \neq 0 \) for every \( s \in S \). If \( | \cdot |_A \) is a valuation, there exists a unique valuation

\[
| \cdot |_{S^{-1}A} : S^{-1}A \to \Gamma_0
\]

whose composition with the localization map \( A \to S^{-1}A \) agrees with \( | \cdot |_A \).

(v) Notice that the sets

\[
\text{Ker}(| \cdot |_A) := \{a \in A \mid |a|_A = 0\} \subset (A, | \cdot |_A)^+ := \{a \in A \mid |a|_A \leq 1\}
\]

are respectively an ideal and a subring of \( A \). Clearly \( | \cdot |_A \) is the composition of the projection

\[
A \to A/\text{Ker}(| \cdot |_A)
\]

and a unique \( \Gamma \)-valued norm on \( A/\text{Ker}(| \cdot |_A) \). Moreover, if \( | \cdot |_A \) is a valuation, then \( \text{Ker}(| \cdot |_A) \) is a prime ideal of \( A \) called the support of \( | \cdot |_A \), and we define the residue field of \( | \cdot |_A \) as

\[
\kappa(| \cdot |_A) := \text{Frac} A/\text{Ker}(| \cdot |_A).
\]
In light of (iv), in this case $| \cdot |_A$ factors uniquely through the projection $A \to \kappa (| \cdot |_A)$ and a valuation $| \cdot |_\kappa$ on $\kappa (| \cdot |_A)$, called the residual valuation of $| \cdot |_A$. Conversely, if $p$ is any prime ideal of $A$, and $| \cdot |_{\kappa(p)}$ is any valuation on the residue field $\kappa(p)$ of $p$, then the composition of $| \cdot |_{\kappa(p)}$ with the projection $A \to \kappa(p)$ is a valuation on $A$.

(vi) With the notation of (v), we claim that if $| \cdot |_A$ is a power-multiplicative semi-norm, then the subring $(A, | \cdot |_A)$ is integrally closed in $A$. Indeed, let $a \in A$ be any element that satisfies an identity of the type

$$a^n + b_1 a^{n-1} + \cdots + b_n = 0$$

with $b_1, \ldots, b_n \in (A, | \cdot |_A)$. It follows that $|a|^n_A = |a^n|_A \leq \max(|b_1|_A \cdot |a|^{n-i}_A | i = 1, \ldots, n)$. Hence, say that $|a|^n_A \leq |b_i| \cdot |a|^{n-i}_A$ for some $i \leq n$; if $|a| = 0$, obviously $a \in (A, | \cdot |_A)$. Otherwise, we deduce $|a|^n_A \leq |b_i|_A \leq 1$, whence $|a|_A \leq 1$, and the claim follows.

(vii) Let $p \subset A$ be any prime ideal. Then there exists a unique (up to equivalence) rank zero valuation on $A$ with support $p$, defined by the rule:

$$|x| := \begin{cases} 0 & \text{if } x \in p \\ 1 & \text{otherwise.} \end{cases}$$

Any valuation of this type is called a trivial valuation on $A$.

**Example 9.1.5.** (i) Let $A$ be any ring, $P$ a monoid, $(\Gamma, \cdot, 1, \leq)$ an ordered abelian group, and $\varphi : P \to \Gamma_0$ a morphism of monoids. We deduce a mapping (notation of (4.8.50))

$$v_\varphi : A[P] \to \Gamma_0 \sum_{x \in P} a_x \cdot x \mapsto \max(\varphi(x) | x \in P, a_x \neq 0)$$

(where the maximum of the empty set is taken to be 0 in $\Gamma_0$, so that $w_\varphi(0) = 0$). It is easily seen that $v_\varphi$ is a $\Gamma$-valued seminorm on $A[P]$. Also, $v_\varphi$ is a norm if and only if $\varphi(P) \subset \Gamma$.

(ii) Suppose moreover that $A$ is a reduced ring, $P$ is integral and $P_{\text{gp}}$ is a torsion-free abelian group; then $v_\varphi$ is valuation. Indeed, consider the first the case where $A$ is a domain; then the same holds for $A[P]$, since the latter is a subring of $A[P_{\text{gp}}]$, which in turn is the filtered union of its subrings $A[G]$, with $G$ ranging over all free abelian subrings of finite rank contained in $P_{\text{gp}}$. Now, let

$$a := \sum_{x \in P} a_x \cdot x, \quad b := \sum_{x \in P} b_x \cdot x$$

be any two non-zero elements of $A[P]$, and set $\alpha := v_\varphi(a)$ and $\beta := v_\varphi(b)$; let also $a' := \sum_{\varphi(x) = \alpha} a_x \cdot x$, and $b' := \sum_{\varphi(x) = \beta} b_x \cdot x$. It is easily seen that $v_\varphi(ab) = v_\varphi(a'b')$; on the other hand we have $a'b' \neq 0$ since $A[P]$ is a domain, so we must have $v_\varphi(a'b') = \alpha \beta$, whence the assertion. If $A$ is an any reduced ring, we have a natural inclusion $A \to \prod_p A_p$, where $p$ ranges over all minimal prime ideals of $A$, and each factor $A_p$ is a field. Then we get likewise an inclusion $A[P] \to \prod_p A_p[P]$, and the assertion is easily reduced to the foregoing case: details left to the reader.

9.1.6. Real-valued semi-norms, of course, occur frequently in algebraic and analytic questions. The datum $(A, | \cdot |_A)$ of a ring and a real valued semi-norm $| \cdot |_A$ is usually called a (real valued) semi-normed ring. If $| \cdot |_A$ is power-multiplicative, one also says that $(A, | \cdot |_A)$ is a uniform semi-normed ring. A morphism of semi-normed rings $f : (A, | \cdot |_A) \to (B, | \cdot |_B)$ is a ring homomorphism $f : A \to B$ for which there exists a real number $C \geq 0$ such that

$$|f(a)|_B \leq C \cdot |a|_A$$

for every $a \in A$.

Clearly a composition of morphisms of semi-normed ring is again a morphism of semi-normed rings, hence the semi-normed rings and their morphisms form a category $\mathcal{S}$, and we let $\mathcal{S} \subset$
be the full subcategory whose objects are the uniform semi-normed rings. Notice that if \( f \) verifies (9.1.7) and \((B, | \cdot |_B)\) is a uniform semi-normed ring, then we have
\[
|f(a)|_B^n = |f(a^n)|_B \leq C \cdot |a|^n \leq C \cdot |a|^{n} \quad \text{for every } n \in \mathbb{N} \text{ and } a \in A
\]
whence \(|f(a)|_B \leq C^1/n \cdot |a|_A\) for every such \( n \) and \( a \); especially, (9.1.7) holds with \( C \leq 1 \).

**Lemma 9.1.8.** Let \((A, | \cdot |)\) be any (real valued) semi-normed ring. Then the following holds:

(i) The sequence \(|a^n|/n| \in \mathbb{N}\) converges in \(\mathbb{R}\) for every \( a \in A \). We set
\[
|a|^* := \lim_{n \to +\infty} |a^n|^{1/n}.
\]
(ii) The mapping \(| \cdot |^* : A \to \mathbb{R}\) is a power-multiplicative semi-norm on \( A \).

(iii) \(|a|^* \leq |a|\) for every \( a \in A \).

(iv) The rule \((A, | \cdot |) \mapsto (A, | \cdot |^*)\) defines a left adjoint for the inclusion functor \( u : \mathcal{U} \to \mathcal{R} \).

**Proof.** (i) Fix \( a \in A \), and set \( \nu_n := |a^n|^{1/n} \) for every integer \( n > 0 \). Suppose first that \( \nu_k = 0 \) for some \( k \in \mathbb{N} \); it follows easily that \( \nu_n = 0 \) for every \( n \geq k \), whence the assertion, in this case. Hence, we may assume that \( \nu_n > 0 \) for every \( n \in \mathbb{Z} \); we notice that
\[
\nu_{kn} \leq \nu_n \quad \text{for every } k, n > 0
\]
and therefore
\[
\nu_{kn+r} \leq (|a|^{kn} \cdot |a^r|)^{1/(kn+r)} \leq \nu_n^{1-1/(k+1)} \cdot |a^r|^{1/(nk+r)}
\]
for every \( k, n, r \in \mathbb{N} \) with \( 0 \leq r < n \) and \( k > 0 \). Now, for a given integer \( n > 0 \) and a real number \( \varepsilon > 0 \), pick \( k \in \mathbb{N} \) large enough, so that \(|a^r|^{1/(nk)} > 1 - \varepsilon\) for every \( r = 0, \ldots, n-1 \), and \( 1/(k+1) < \varepsilon\); it follows that
\[
\nu_t \leq \nu_n^{1-\varepsilon} \cdot (1 - \varepsilon) \quad \text{for every integer } t \geq kn.
\]
Consequently
\[
\limsup_{n \to +\infty} \nu_n = \liminf_{n \to +\infty} \nu_n
\]
whence the assertion.

(ii) Fix \( a, b \in A \) and a real number \( \varepsilon > 0 \); by (i), there exists \( k_0 \in \mathbb{N} \) such that
\[
|a^k|^{1/k} < |a|^* \cdot (1 + \varepsilon) \quad \text{and} \quad |b^k|^{1/k} < |b|^* \cdot (1 + \varepsilon) \quad \text{for every } k > k_0.
\]
Pick an integer \( t \geq 2k_0 \), and large enough, so that
\[
|a^i|^{1/i}, |b^i|^{1/i} < 1 + \varepsilon \quad \text{for every } n \geq t \text{ and every } i \leq k_0.
\]
Now, we have:
\[
|(a + b)^n|^{1/n} \leq \max\{|a^i|^{1/n} \cdot |b^{n-i}|^{1/n} | i = 0, \ldots, n\}.
\]
On the other hand, we may assume that \(|a|^* \geq |b|^*\); set also
\[
M := \max(|a|^* \cdot (1 + \varepsilon), |a|^* \cdot (1 + \varepsilon)).
\]
Then, for every \( n \in \mathbb{N} \) such that \( n \geq t \) and \( k_0/n \leq \varepsilon \), we get
\[
|a^i|^{1/i} \cdot |b^{n-i}|^{1/i} \leq \begin{cases} |a|^* \cdot (1 + \varepsilon) & \text{whenever } i, n-i > k_0 \\ M \cdot (1 + \varepsilon) & \text{otherwise.} \end{cases}
\]
We immediately deduce that \(|a + b|^* \leq \max(|a|^*, |b|^*)\) for every \( a, b \in A \).

The inequality \(|ab|^* \leq |a|^* \cdot |b|^*\) for every \( a, b \in A \) is an immediate consequence of the corresponding property for \(| \cdot |\), and the power-multiplicative condition follows easily from the definition of \(| \cdot |^*\).

(iii) follows easily by remarking that \(|a^n| \leq |a|^n\) for every \( a \in A \).

(iv): Let \((B, | \cdot |_B)\) be a uniform semi-normed ring, and \( f : (A, | \cdot |) \to (B, | \cdot |_B)\) a morphism of semi-normed rings, so that (9.1.7) holds for some \( C \geq 0 \). We get:
\[
|f(a)|_B = |f(a^n)|^{1/n}_B \leq C^1/n \cdot |a|_B
\]
We deduce a corresponding inequality for asymptotic Samuel functions: namely, for every \(a \in A\) and the two foregoing conditions can be unified in the following assertion. For every \(\nu\) we have either

\[
\nu(I) = \{ a \in A \mid \nu_I(a) \neq -\infty \}.
\]

It is easily seen that \(A(I)\) is a subring of \(A\). Moreover, fix any real number \(\rho \in ]0, 1[\), and set

\[
|a|_I := \rho^{\nu_I(a)} \in \mathbb{R}_{\geq 0}, \quad \text{for every } a \in A(I)
\]

(with the convention that \(\rho^{+\infty} := 0\)). It is clear that \(|\cdot|_I\) is a semi-norm on \(A(I)\). The corresponding power-multiplicative semi-norm \(|\cdot|_I\) provided by lemma 9.1.8 is sometimes called the asymptotic Samuel function of \(I\).

(ii) In the situation of (i), let \(J \subset A_0\) be another ideal, with \(I \subset J\). Then it is easily seen that, for every \(a \in A\), we have either \(\nu_J(a) \geq \nu_I(a) \geq 0\), or else \(0 > \nu_I(a) \geq \nu_J(a)\). Therefore

\[
A(J) \subset A(I)
\]

and the two foregoing conditions can be unified in the following assertion. For every \(a \in A(J)\) we have either \(\nu_J(a) = 0\), in which case \(\nu_I(a) = 0\) as well, or else

\[
0 \leq \nu_I(a)/\nu_J(a) \leq 1.
\]

We deduce a corresponding inequality for asymptotic Samuel functions: namely, for every \(a \in A(J)\) with \(|a|_J^* \neq 0\) we have either \(|a|_J^* = 1\), in which case \(|a|_I^* = 1\) as well, or else

\[
0 \leq \frac{\log |a|_I^*}{\log |a|_J^*} \leq 1.
\]

(iii) For instance, for any integer \(n > 0\) we have \(A(I) = A(I^n)\) and

\[
\nu_{I^n}(a^n) \geq \nu_I(a) \geq n \cdot \nu_{I^n}(a) \quad \text{for every } a \in A
\]

from which it follows easily that

\[
|a|_I^* = (|a|_J^*)^{1/n} \quad \text{for every } a \in A(I).
\]

(iv) Let \(I\) and \(I'\) two ideals of \(A_0\), and suppose that the \(I\)-adic topology on \(A_0\) agrees with the \(I'\)-adic topology. Combining (ii) and (iii) we deduce that

\[
A(I) = A(I')
\]

and for every \(a \in A(I)\) we have \(|a|_I^* = 1\) (resp. \(|a|_J^* = 0\)) if and only if \(|a|_{I'}^* = 1\) (resp. \(|a|_{I'}^* = 0\)); also, there exists a real number \(C \geq 0\) (independent of \(a\)) such that

\[
0 \leq \frac{\log |a|_I^*}{\log |a|_{I'}^*}, \frac{\log |a|_J^*}{\log |a|_{I'}^*} \leq C \quad \text{whenever } |a|_I^* \neq 1, 0.
\]
(v) We notice as well that the asymptotic Samuel function is independent of the subring $A_0$. Namely, in the situation of (i), suppose that $A'_0$ is another subring of $A$ such that $I$ is also an ideal of $A'_0$. Then we may set

$$I^n := I^n \quad \text{for every } n > 0, \quad \text{and} \quad I^{n-k} := \{ a \in A \mid aI^k \subset A'_0 \} \quad \text{for every } k \geq 0
$$

(where $I^0 := A_0$). Using the system of powers $(I^n \mid n \in \mathbb{Z})$ we define the function $\nu_I$ and the subring $A(I)$ as in (i), and with the system of powers $(I^n \mid n \in \mathbb{Z})$ we may define likewise the function $\nu_{I'}$ and the subring $A(I')$. After fixing $\rho \in [0, 1]$, we then may define correspondingly the semi-norms $|\cdot|_I$ and $|\cdot|_{I'}$, as well as the associated power multiplicative semi-norms $|\cdot|_I^*$ and $|\cdot|_{I'}^*$. Obviously, for every $a \in A$ we have $\nu_I(a) > 0$ if and only $\nu_{I'}(a) > 0$, and $\nu_I(a) = \nu_{I'}(a)$ for every $a \in A$ such that $\nu_I(a) > 0$. Moreover, suppose that $\nu_I(a) = -n$ for some $n \in \mathbb{N}$; this means especially that $aI^n \subset A_0$, so that $aI^{n+1} \subset I \subset A'_0$, whence $\nu_I(a) \geq -n - 1$. It follows easily that

$$A(I) = A(I') \quad \text{and} \quad |a|_I^* = |a|_{I'}^* \quad \text{for every } a \in A(I).
$$

(vi) It follows especially from (v) that the subring $(A(I), |\cdot|_I^*)$ of $A(I)$ is independent of $A_0$ (notation of remark 9.1.4(v)), and moreover, if $B \subset A$ is any subring such that $I$ is also an ideal of $B$, then $B \subset (A(I), |\cdot|_I^*)$. More generally, we have:

**Proposition 9.1.10.** In the situation of example 9.1.9(i), consider any subring $B$ of $A$ with

$$I \subset B \subset (A(I), |\cdot|_I^*).
$$

Then the following holds:

(i) $A(I) \subset A(IB)$ and $|a|_I^* = |a|_{IB}^*$ for every $a \in (A(I), |\cdot|_I^*)$.

(ii) Suppose moreover that $I$ is a finitely generated ideal of $A_0$. Then $A(I) = A(IB)$ and $|a|_I^* = |a|_{IB}^*$ for every $a \in A(I)$.

**Proof.** (i): Arguing as in example 9.1.9(v), we easily see that $\nu_{IB}(a) \geq \nu_I(a)$ for every $a \in A$ such that $\nu_I(a) > 0$, and $\nu_{IB}(a) \geq \nu_I(a) - 1$ if $\nu_I(a) \leq 0$. This already implies the stated inclusion of subrings, as well as the inequality

\begin{equation}
|a|_{IB}^* \leq |a|_I^* \quad \text{for every } a \in A(I).
\end{equation}

Now, suppose that $|a|_{IB}^* = \rho^c$ for some real number $c > 0$. Set $n(k) := \nu_{IB}(a^k)$ for every $k \in \mathbb{N}$. It follows that $\lim_{k \to +\infty} n(k)/k = c$, and especially $n(i) > 0$ for every sufficiently large $i \in \mathbb{N}$. It suffices to check that $|a|_I^* \leq \rho^c$, so we may replace $a$ by $a^i$ for such sufficiently large $i$, and assume from start that $\nu_{IB}(a) \geq 0$. In this situation, for every $k \in \mathbb{N}$ we may then write $a^k = \sum_{j=1}^\infty a_ib_j$, for some $a_1, \ldots, a_r \in I^{n(k)}$ and $b_1, \ldots, b_r \in B$. Since by assumption $|b_i|_I^* \leq 1$ for every $i \leq r$, taking into account lemma 9.1.8(ii,iii) we deduce that

$$|a|_I^* \leq \sup \{|x|_I \mid x \in I^{n(k)}\} \leq \sup \{|x|_I \mid x \in I^{n(k)}\} \leq \rho^{n(k)}
$$

whence $|a|_I^* \leq \rho^{n(k)/k}$ for every $k \in \mathbb{N}$, and therefore $|a|_I^* \leq |a|_{IB}^*$.

(ii): Indeed, we know already that $A(I) \subset A(IB)$, and to show the converse inclusion, pick any finite system of generators $(t_1, \ldots, t_r)$ for $I$, and let $a \in A(IB)$ be any element. This means that $a \cdot (IB)^n \subset B \subset A(I)$ for some $n \in \mathbb{N}$. Hence we may find $m \in \mathbb{N}$ such that

$$a \cdot t_1^{k_1} \cdots t_r^{k_r} \cdot I^m \subset A_0 \quad \text{for every } (k_1, \ldots, k_r) \in \mathbb{N}^r \text{ with } k_1 + \cdots + k_r = n
$$

whence $a \cdot I^{m+n} \subset A_0$, so $a \in A(I)$, as stated. Next, to conclude, in light of (9.1.11), it suffices to show that $|a|_I^* \leq |a|_{IB}^*$, for every $a \in A(I)$. However, in case $|a|_{IB}^* = \rho^c$ for some real number $c > 0$, we may argue as in the proof of (i) to deduce the sought inequality. We may therefore assume that $|a|_{IB}^* \leq \rho^c$ for some real number $c > 0$, and we have to show that $|a|_I^* \leq \rho^{-c}$ as well. Define $n(k)$ as in the proof of (i), for every $k \in \mathbb{N}$. Notice that, if $n(k) > 0$
for some \( k \in \mathbb{N} \), we have \( |a^k|_B \leq \rho \), whence \( |a|^k |_B \leq \rho^{1/k} \), in which case the assertion is already known. Hence, we may further assume that \( n(k) \leq 0 \) for every \( k \in \mathbb{N} \), in which case
\[
\lim_{k \to +\infty} -n(k)/k \leq c \quad \text{and} \quad a^k \cdot (IB)^{-n(k)} \subset B \quad \text{for every} \quad k \in \mathbb{N}.
\]

Pick any integers \( p, q > 0 \) such that \( c < p/q \); it follows easily that
\[
a^{mq} \cdot (IB)^{np-1} \subset B \quad \text{for every sufficiently large} \quad n \in \mathbb{N}.
\]

Fix such a sufficiently large \( n \in \mathbb{N} \); we deduce
\[
x(k^\bullet) := a^{mq} \cdot t_1^{k_1} \cdots t_r^{k_r} \in IB \quad \text{for every} \quad k^\bullet := (k_1, \ldots, k_r) \in \mathbb{N}^r \quad \text{with} \quad k_1 + \cdots + k_r = np
\]
in which case \( |x(k^\bullet)|_B < 1 \), and therefore \( |x(k^\bullet)|_I < 1 \) as well, by the foregoing, for every such \( k^\bullet \). Then we may find \( m \in \mathbb{N} \) such that
\[
a^{mnq} \cdot t_1^{mk_1} \cdots t_r^{mk_r} \in A_0 \quad \text{for every} \quad k^\bullet := (k_1, \ldots, k_r) \in \mathbb{N}^r \quad \text{with} \quad k_1 + \cdots + k_r = np.
\]

However, let \( J \subset A_0 \) be the ideal generated by \( t_1^{m}, \ldots, t_r^{m} \), and notice that
\[
f^{(m-1)(r+np)+1} \subset J^{np} \quad \text{for every} \quad s \in \mathbb{N}.
\]

We conclude that
\[
a^{mnqs} \cdot f^{(m-1)(r+np)+1} \subset A_0 \quad \text{for every} \quad s \in \mathbb{N}
\]
from which we see that
\[
\lim_{s \to +\infty} -n_1(a^{mnqs})/(mnqs) \leq \lim_{s \to +\infty} ((m-1)(r+np)+1)/(mnqs) < p/q
\]
and since the rational number \( p/q \) can be taken arbitrary close to \( c \), the sought inequality follows.

\[\square\]

**Definition 9.1.12.** Let \( F \) be a field.

(i) We say that a subring \( V \subset F \) is a valuation ring of \( F \) if the following holds. For every \( x \in F^\times \) we have either \( x \in V \) or \( x^{-1} \in V \).

(ii) Let \((A, m_A), (B, m_B)\) be two local subrings of \( F \). We say that \( B \) dominates \( A \) if \( A \subset B \) and \( A \cap m_B = m_A \).

**Remark 9.1.13.** (i) Let \( K \) be any field; notice that any semi-norm, and especially, any valuation on \( K \) is necessarily a norm.

(ii) Let \( | \cdot |_K \) be any such valuation, and let \( K^+ := (K, | \cdot |_K)^+ \), as in remark 9.1.4(v). Then it is easily seen that \( K^+ \) is a valuation ring of \( K \). Also, the invertible elements of \( K^+ \) are precisely those \( x \in K \) such that \( |x|_K = 1 \), and the set \( \{ x \in K \mid |x|_K < 1 \} \) is the unique maximal ideal of \( K^+ \); especially, \( K^+ \) is a local domain.

(iii) Furthermore, \( K^+ \) is integrally closed. Indeed, let \( x \in K \) be integral over \( K^+ \), so that \( x^n + y_1 x^{n-1} + \cdots + y_n = 0 \) for some \( y_1, \ldots, y_n \in K^+ \), and suppose, by way of contradiction, that \( x \notin K^+ \), i.e. that \( |x|_K > 1 \); it follows easily that \( |x^n|_K > |y_i x^{n-1}|_K \) for every \( i = 1, \ldots, n \), so that remark 9.1.4(iii) yields \( |x^n + y_1 x^{n-1} + \cdots + y_n|_K = |x^n|_K \neq 0 \), which is absurd.

(iv) Conversely, if \( V \) is any valuation ring of \( K \), set \( \Gamma := K^+/V^+ \). Thus, \( \Gamma \) is an abelian group, and we define an ordering on \( \Gamma \) as follows. For given classes \( \bar{x}, \bar{y} \in \Gamma \), we declare that \( \bar{x} \leq \bar{y} \) if and only if \( y^{-1} x \in V \). Then it is easily seen that \( (\Gamma, \leq) \) is an ordered abelian group, and the projection \( K^+ \to \Gamma \) is the restriction to \( K^+ \) of a well defined valuation \( | \cdot |_K \) of \( K \), such that \( V = (K, | \cdot |_K)^+ \), so the maximal ideal \( m_V \) of \( V \) and the subset \( V^+ \) are also described as in (ii) (details left to the reader).

(v) If the valuation \( | \cdot |_K \) is a surjective map, we say that \((K, | \cdot |_K)\) is a valued field. In view of (iv), we see that a valuation ring of \( K \) is the same as the datum of the equivalence class (in the sense of definition 9.1.3(vi)) of a valued field \((K, | \cdot |_K)\).
(vi) Let $A$ be any ring, $|\cdot|$ and $|\cdot'|$ two valuations on $A$; in light of (v), we see that the following conditions are equivalent:

(a) the valuations $|\cdot|$ and $|\cdot'|$ are equivalent

(b) $|\cdot|$ and $|\cdot'|$ have the same support and $(\kappa(|\cdot|), |\cdot|_\kappa)^+ = (\kappa(|\cdot'|), |\cdot'|_\kappa)^+$

(c) for every $a, b \in A$ we have $|a| \leq |b|$ if and only if $|a'| \leq |b'|$.

(vii) Let $(K, |\cdot|)$ be any valued field, and $\Gamma$ the value group of $|\cdot|$. There is an inclusion-reversing bijection

$$\text{Spec}\, \Gamma \overset{\sim}{\to} \text{Spec}\, K^+$$

that assigns to every convex subgroup $\Delta \subset \Gamma$ the prime ideal

$$p(\Delta) := \{x \in K^+ \mid \gamma > |x| \text{ for every } \gamma \in \Delta\}$$

and whose inverse assigns, to every prime ideal $p \subset K^+$, the convex subgroup

$$\Delta(p) := \{\gamma \in \Gamma \mid \gamma, \gamma^{-1} > |x| \text{ for every } x \in p\}.$$

Indeed, it is easily seen that $p(\Delta)$ is a prime ideal, and we check that $\Delta(p)$ is a convex subgroup.

First, say that $\gamma, \gamma' \in \Delta(p)$; if either $\gamma > 1$ or $\gamma' > 1$, it is clear that $\gamma \cdot \gamma' > |x|$ for every $x \in p$. If $\gamma, \gamma' \leq 1$, we may find $y, y' \in K^+$ such that $\gamma = |y|$ and $\gamma' = |y'|$, and by assumption, neither $y$ nor $y'$ lie in $p$, so also $y \cdot y' \notin p$, and therefore $\gamma \cdot \gamma' > |x|_K$ for every $x \in p$. Hence, $\Delta(p)$ is a subgroup of $\Gamma$, and the convexity of $\Delta(p)$ is obvious. Next, set $q := p(\Delta)$; directly from the definitions we see that $\Delta \subset \Delta(q)$. Conversely, let $\gamma \in \Gamma^+ \setminus \Delta$; then $\gamma = |y|$ for some $y \in K^+$, and since $\gamma < \delta$ for every $\delta \in \Delta$, we get $y \notin q$, so that $\gamma \notin \Delta(q)$. Hence, $\Delta = \Delta(q)$, and especially, the rule $p \mapsto \Delta(p)$ is surjective from $\text{Spec}\, K^+$ to $\text{Spec}\, \Gamma$; but it is easily seen that this rule is also injective, whence the contention.

**Definition 9.1.14.** Let $(K, |\cdot|_K)$ be any valued field, and $\Gamma$ the value group of $|\cdot|_K$.

(i) For every $\gamma \in \Gamma^+$, set $U_\gamma := \{x \in K^+ \mid |x|_K < \gamma\}$. The **valuation topology** of $K^+$ is the unique linear topology $\mathcal{T}_{K^+}$ that admits the family $\{U_\gamma \mid \gamma \in \Gamma^+\}$ as a fundamental system of open neighborhoods of 0.

(ii) In view of remark [8.3.2](i) there exists a unique ring topology $\mathcal{T}_K$ on $K$ such that:

(a) $K^+$ is an open subring of $K$

(b) $\mathcal{T}_K$ induces on $K^+$ the valuation topology $\mathcal{T}_{K^+}$

We call $\mathcal{T}_K$ the **valuation topology** of $K$.

(iii) We say that $(K, |\cdot|_K)$ is a **Tate valued field**, if the valuation topology of $K$ is f-adic and not discrete.

(iv) Let $A$ be any ring, and $v$ any valuation on $A$. We say that $v$ is a **Tate valuation** if the residual valued field $(\kappa(v), \overline{\nu})$ is a Tate valued field.

**Proposition 9.1.15.** With the notation of definition 9.1.14 let $(K^{+^\wedge}, \mathcal{T}_{K^{+^\wedge}})$ (resp. $(K^\wedge, \mathcal{T}_K^\wedge)$) be the completion of the topological ring $(K^+, \mathcal{T}_{K^+})$ (resp. $(K, \mathcal{T}_K)$). We have:

(i) Let $\mathcal{T}'$ be any topology on $K^+$ that is linear and separated. Then either $\mathcal{T}' = \mathcal{T}_{K^+}$, or else $\mathcal{T}'$ is the discrete topology.

(ii) $(K, |\cdot|_K)$ is a Tate valued field if and only if $(K, \mathcal{T}_K)$ is a Tate topological ring.

(iii) $K^{+^\wedge}$ is a valuation ring and $\mathcal{T}_{K^{+^\wedge}}$ is the valuation topology on $K^{+^\wedge}$.

(iv) $K^\wedge$ is the field of fractions of $K^+$, and $\mathcal{T}_K^\wedge$ is the valuation topology on $K^\wedge$.

(v) The valuation $|\cdot|_K : K \to \Gamma_0$ extends uniquely to a valuation $|\cdot|_K^\wedge : K^\wedge \to \Gamma_0$ whose valuation ring is $K^{+^\wedge}$.

**Proof.** (i): Let $x \in K^+ \setminus \{0\}$ be any element; since $\mathcal{T}'$ is separated, there exists an ideal $I \subset K^+$ that is open for the topology $\mathcal{T}'$, and such that $x \notin I$. Then $I \subset U_\gamma$, with $\gamma := |x|_K$ (notation of definition 9.1.14(i)), so $\mathcal{T}'$ is finer than $\mathcal{T}_{K^+}$. If $\mathcal{T}'$ is not the discrete topology, there exists $y \in I \setminus \{0\}$, and therefore $U_\delta \subset I$, with $\delta := |y|_K$, so in this case $\mathcal{T}' = \mathcal{T}_{K^+}$. 

(ii): Suppose that $\mathcal{T}_K$ is f-adic; then, since $K^+$ is a bounded subset of $K$, the valuation topology $\mathcal{T}_{K^+}$ must be adic with a finitely generated ideal of adic definition $I$ (proposition 8.3.18(ii)). Such $I$ is necessarily principal, and $I \neq 0$, if $\mathcal{T}_K$ is not discrete; in this case, any generator of $I$ is a topologically nilpotent unit in $K$. Conversely, if $a \in K$ is a topologically nilpotent unit for the valuation topology of $K$, then $a \in K^+$, and it is easily seen that the valuation topology of $K^+$ agrees with the $K^+$-adic topology, so $\mathcal{T}_{K^+}$ is adic and $\mathcal{T}_K$ is f-adic.

(iii): Let $a_* := \{a_i \mid i \in I\}$ be any Cauchy net in $K$ (indexed by a filtered ordered set $I$); for every $\gamma \in \Gamma$, pick $i(\gamma) \in I$ such that $|a_i - a_k|_K < \gamma$ for every $j, k \geq i(\gamma)$. Suppose first that $|a_i(\gamma)|_K \leq \gamma$ for every $\gamma \in \Gamma$; then $|a_j|_K \leq \gamma$ for every $j \geq i(\gamma)$ and every $\gamma \in \Gamma$, i.e. $a_*$ converges to 0, and we set $|a_*|^\wedge_K := 0$. Otherwise, there exists $\delta \in \Gamma$ such that $|a_i(\delta)|_K > \delta$ and then $|a_j|_K = \delta$ for every $j \geq i(\delta)$, in which case we set $|a_*|_K := |a_i(\delta)|_K$. It is easily seen that $|a_*|^\wedge_K$ depends only on the class of $a_*$ in $K^\wedge$, and if $b_*$ is any other Cauchy sequence, then

$$|(a_i b_i \mid i \in I)|_K = |a_*|^\wedge_K \cdot |b_*|^\wedge_K$$

and

$$|(a_i + b_i \mid i \in I)|_K \leq \max(|a_*|^\wedge_K, |b_*|^\wedge_K)$$

(details left to the reader). It follows already that $K^\wedge$ is a domain. Moreover, we have $|a_*|^\wedge_K \leq 1$ if and only if the class of $a_*$ is equivalent to the class of a Cauchy net in $K^+$. Next, suppose that $1 \geq |a_*|^\wedge_K \geq |b_*|^\wedge_K > 0$, in which case there exists $i_0 \in I$ such that

$$|a_j|_K \geq |b_j|_K \text{ and } |a_j|_K = \beta := |a_*|^\wedge_K$$

for every $j \geq i_0$

and set $v_j := 1$ for every $j \in I$ such that $j < i_0$ and $v_j := a_{i_0}^{-1}b_j$ for every $j \geq i_0$. We claim that $v_* := \{v_j \mid j \in I\}$ is a Cauchy net in $K^+$; indeed, for any $\gamma \in \Gamma$, pick $i(\gamma) \in I$ such that $|a_i - a_k|_K, |b_j - b_k|_K < \gamma$ for every $j, k \geq i(\gamma)$; a simple calculation shows that $|v_j - v_k| < \gamma \cdot 2^\delta$ whenever $j, k \geq \max(i_0, i(\gamma))$, as required. Now, since $(v_j a_j \mid j \in I)$ and $b_*$ represent the same element in $K^+\wedge$, it follows that the class of $a_*$ divides the class of $b_*$ in $K^\wedge$ (the quotient is the class of $v_*$). Lastly, (i) easily implies that $\mathcal{T}_{K^+}$ is the valuation topology on $K^\wedge$, whence the assertion.

(v): Furthermore, notice that if the class $x$ of $a_*$ in $K^\wedge$ is not 0, we have $x = a_{i(\delta)} \cdot y$, with $y$ an invertible element of $K^\wedge$, so we must have $|x| = |a_{i(\delta)}|_K$ for every valuation $| \cdot |$ on $K^\wedge$ that extends $| \cdot |_K$.

(iv): By the same token, we have $x^{-1} = a_{i(\delta)}^{-1} \cdot y^{-1}$, which shows that $K$ is a field, and concludes the proof.

\[\Box\]

**Proposition 9.1.16.** Let $(K, |\cdot|_K)$ be a valued field such that the valuation ring $K^+$ is henselian, $K^s$ a separable closure of $K$, and $(K^\wedge, |\cdot|_K, \mathcal{T}_K)$ the completion of $(K, |\cdot|_K, \mathcal{T}_K)$. Then:

(i) The valuation ring $K^\wedge$ of $K^\wedge$ is henselian.

(ii) The ring $K'^\wedge := K^\wedge \otimes_K K^s$ is an algebraic separably closed field extension of $K^\wedge$.

(iii) Especially, we have a natural group isomorphism:

$$\text{Gal}(K'^\wedge/K) \cong \text{Gal}(K'^\wedge/K^\wedge) \quad \sigma \mapsto K^\wedge \otimes_K \sigma.$$ 

**Proof.** (i): The assertion follows immediately from the more general:

**Claim 9.1.17.** Let $(A_\lambda, J_\lambda) := (A_\lambda, J_\lambda) | \lambda \in \text{Ob}(\Lambda))$ be a system of henselian pairs indexed by any small category, with transition morphisms $f_\varphi : A_\lambda \to A_\mu$ such that $f_\varphi(J_\lambda) \subset J_\mu$ for every morphism $\varphi : \lambda \to \mu$ of $\Lambda$. Let $A$ (resp. $J$) be the limit of the system $A_\lambda$ (resp. of the system $J_\lambda$); then the pair $(A, J)$ is henselian.

**Proof of the claim.** Let $\mathcal{A}$ be the category whose objects are all the pairs $(B, I)$, where $B$ is a ring and $I \subset B$ an ideal, and whose morphisms $(B, I) \to (B', I')$ are all the ring homomorphisms $f : B \to B'$ with $f(I) \subset I'$. Denote by $\mathcal{A}^h$ the full subcategory of $\mathcal{A}$ whose objects are the henselian pairs. Then the inclusion functor $\mathcal{A} \to \mathcal{A}^h$ admits a left adjoint, which assigns to every pair $(B, I)$ its henselization $(B^h, I^h)$. It is easily seen that $\mathcal{A}^h$ is complete, so the claim follows directly from corollary 13.3.26.
Let \( K^\circ \) be an algebraic closure of \( K \) containing \( K^a \) and contained in an algebraic closure \( K^{a\circ} \) of \( K^{\circ} \), and notice that the valuation \( | \cdot |_K \) extends uniquely to a valuation \( | \cdot |_E \) on every subextension \( E \subset K^a \), since \( K^+ \) is henselian ([59, Rem.6.1.12(iv)]). Especially, for every such \( E \) and every \( K \)-algebra homomorphism \( \sigma : E \to K^a \) we must have

\[
|a|_E = |\sigma(a)|_{K^a} \quad \text{for every } a \in E.
\]

**Claim 9.1.18.** (Krasner’s lemma) With the foregoing notation, let \( a \in K^a \), \( b \in K^a \), and suppose that for every homomorphism \( \sigma : K\{a\} \to K^a \) of \( K \)-algebras with \( \sigma(a) \neq a \) we have

\[
|b - a|_{K^a} < |\sigma(a) - a|_{K^a}.
\]

Then \( K\{a\} \subset K\{b\} \).

**Proof of the claim.** It suffices to show that for every \( K\{b\} \)-algebra homomorphism \( \tau : K\{a\} \to K^a \) we have \( \tau(a) = a \). However, suppose that \( \tau(a) \neq a \) for such a map \( \tau \); we deduce that

\[
|b - a|_{K^a} < |\tau(a) - a|_{K^a} \quad \text{and} \quad |b - \tau(a)|_{K^a} = |\tau(b - a)|_{K^a} = |b - a|_{K^a}
\]

whence:

\[
|\tau(a) - a|_{K^a} = |\tau(a) - b + b - a|_{K^a} \leq \max(|\tau(a) - b|_{K^a}, |b - a|_{K^a}) < |\tau(a) - a|_{K^a}
\]

a contradiction. \( \diamondsuit \)

Let now \( K^\circ \subset E^\circ \) be a non-trivial finite Galois extension with \( E^\circ \subset K^{a\circ} \), and pick \( a \in E^\circ \) such that \( E^\circ = K^{a\circ}[a] \). Let \( P(X) \in K^\circ[X] \) be the minimal polynomial of \( a \) over \( K^\circ \); in light of (i) and ([59, Rem.6.1.12(iv)]), the valuation \( | \cdot |_K^\circ \) of \( K^\circ \) extends uniquely to a valuation of \( | \cdot |_{E^\circ} \) of \( E^\circ \); with this notation, we set

\[
G := \Gal(E^\circ/K^\circ) \quad \gamma := \min \{|\sigma(a) - a|_{E^\circ} | \sigma \in G \setminus \{1_{E^\circ}\} \} \in |E^\circ|_{E^\circ}^\gamma.
\]

Say that \( P = X^n + c_1 X^{n-1} + \cdots + c_n \) and pick a polynomial \( Q(X) \in K[X] \) of degree \( n \), say \( Q = X^n + d_1 X^{n-1} + \cdots + d_n \) such that

\[
|c_i - d_i|_{K^\circ} < \gamma^n / |a|^n \quad \text{for } i = 1, \ldots, n.
\]

It follows easily that \( |Q(a)|_{E^\circ} < \gamma^n \). Then, say that \( Q(X) = \prod_{i=1}^n (X - b_i) \) for some \( b_1, \ldots, b_n \in K^a \); we deduce that \( |a - b| < \gamma \) for some \( b \in \{b_1, \ldots, b_n\} \), in which case claim 9.1.18 implies that \( E^\circ \subset K^\circ[b] \), and since \( P \) and \( Q \) have the same degree, we see that \( Q \) is irreducible over \( K^\circ \) and \( E^\circ = K^\circ[b] \). Especially, \( b \) is separable over \( K^\circ \), so the roots of \( Q \) are all distinct, and therefore \( b \) is also separable over \( K \). Summing up, we have already shown that \( K^\circ K^a \subset K^{a\circ} \) is a separable closure of \( K^\circ \). It remains to check that the natural map \( K^\circ \otimes_K K^a \to K^\circ K^a \) is injective. To this aim, let \( K \subset E \) be any finite Galois extension with \( E \subset K^a \), and denote by \( \tr_{E/K} : E \to K \) the \( K \)-linear trace map, so that \( \tr_{E/K}(a) = \sum_{\sigma \in \Gal(E/K)} \sigma(a) \). Clearly \( \tr_{E/K} \) is continuous for the valuation topologies \( \mathcal{V}_E \) and \( \mathcal{V}_K \) of \( E \) and \( K \); on the other hand, since \( E \) is separable over \( K \), the trace map induces a perfect pairing \( E \otimes_K E \to K : x \otimes y \mapsto \tr_{E/K}(xy) \) for every \( x, y \in E \). Hence, let \( x_1, \ldots, x_n \) be a basis of the \( K \)-vector space \( E \), and \( y_1, \ldots, y_n \in E \) the unique elements such that \( \tr_{E/K}(x_i y_j) = \delta_{ij} \) for every \( i, j = 1, \ldots, n \). There follow \( K \)-linear isomorphisms

\[
K^\circ \otimes K^\circ \xrightarrow{\varphi} E \xrightarrow{\psi} K^\circ \otimes K^\circ
\]

such that \( \psi \circ \varphi = 1_{K^\circ \otimes K^\circ} \), where \( \varphi(a_1, \ldots, a_n) := \sum_{i=1}^n a_i x_i \) and \( \psi(b) := (\tr_{E/K}(b y_1), \ldots, \tr_{E/K}(b y_n)) \) for every \( b \in E \) and every \((a_1, \ldots, a_n) \in K^{\circ n}\). Clearly both \( \varphi \) and \( \psi \) are continuous for the topology \( \mathcal{V}_E \) and
the product topology on $K^\otimes n$, hence they are both homeomorphisms. Let $(E^\wedge, \mathscr{E}_E^\wedge)$ be the completion of $(E, \mathscr{E}_E)$; we deduce a commutative diagram of $K^\wedge$-linear maps

$$
\begin{array}{ccc}
K^\wedge \otimes_K E & \longrightarrow & K^\wedge \otimes_K K^\otimes n \\
\mu & & \downarrow \\
E^\wedge & \xrightarrow{\psi^\wedge} & (K^\wedge)^\otimes n
\end{array}
$$

where $\psi^\wedge$ is the completion of $\psi$ and $\mu$ is the multiplication map; especially both horizontal arrows are bijections, and the same holds for the right vertical arrow. Then $\mu$ is bijective as well, whence the contention.

(iii) is an immediate consequence of (ii).

\[\square\]

**Remark 9.1.19.** The left adjoint property of the topological henselization $A \to A^h$ implies that for every f-adic ring $A$, the identity map $1_{A^h}$ is the unique continuous $A$-algebra endomorphism of $A^h$. However, $A^h$ in general will admit also non-continuous $A$-algebra endomorphisms. For instance, let $K$ be an algebraically closed field of characteristic zero, and set

$$F_0 := K[\mathbb{Q}_+] = K[T^{1/n} \mid n \in \mathbb{N}] \quad F := \text{Frac } F_0.$$ 

Let also $v : F_0 \to \mathbb{Q}_0$ be the valuation of $F_0$ associated with the inclusion map $\mathbb{Q}_+ \to \mathbb{Q}$ as in example 9.1.5 (where $\mathbb{Q}$ is endowed with its standard ordering). Then $F^+ := \kappa(v)^+$ is a valuation ring of $F$, and $(F, v)$ is a Tate valued field. Clearly the value group of $v$ is $\mathbb{Q}$ and the residue field is $K$. Let $m_F \subset F^+$ be the maximal ideal, and $(F^{+h}, m_{F^h})$ the henselization of the pair $(F^+, m)$; then $F^{+h}$ is a valuation ring with the same value group $\mathbb{Q}$, and the same residue field $K$ (59, Lemma 6.2.5)). Moreover, the topological henselization $F^h$ of the Tate valued field $F$ is the field of fractions of $F^{+h}$. It then follows easily from [59, Prop.6.2.12] that $F^h$ is algebraically closed; on the other hand, it is easily seen that $F$ is not algebraically closed, so there exists a non-trivial automorphism of $F^h$ that fixes $F$.

**Theorem 9.1.20.** Let $K$ be a field, $A \subset K$ a subring, and $p \subset A$ a prime ideal of $A$. Then there exists a valuation ring $(V, m_V)$ of $K$ such that

$$A \subset V \quad \text{and} \quad p = m_V \cap A.$$ 

**Proof.** We may replace $A$ by $A_p$, and assume from start that $A$ is a local ring. Denote by $\mathscr{F}$ the set of all subrings $B$ of $K$ containing $A$ such that $1 \notin pB$; we endow $\mathscr{F}$ with the partial ordering given by inclusion of subrings. Then $A \in \mathscr{F}$, and if $\mathscr{F}$ is a non-empty totally ordered subset of $\mathscr{F}$, then $\bigcup_{B \in \mathscr{F}} B$ still lies in $\mathscr{F}$. By Zorn’s lemma, it follows that $\mathscr{F}$ admits a maximal element $V$. First, we claim that $V$ is local. Indeed, by assumption $1 \notin pV$, so $pV$ is contained in a maximal ideal $m$ of $V$, and $1 \notin pV_m$, so $V_m \in \mathscr{F}$, and therefore $V = V_m$, since $V$ is maximal. Let $m_V$ be the maximal ideal of $V$; by construction, $p \subset m_V \cap A$, and since $p$ is maximal in $A$, we get $p = m_V \cap A$. It remains only to check that $V$ is a valuation ring of $K$. Thus, say that $x \in K$ and $x \notin V$; by maximality of $V$, we have $V[x] \notin \mathscr{F}$, so $1 \notin pV[x]$, i.e. there exists an identity of the form $1 = a_0 + a_1 x + \cdots + a_n x^n$ for some $a_0, \ldots, a_n \in pV \subset m_V$. Since $1 - a_0 \in V^\times$, we deduce a relation of the form

$$1 = b_1 x + \cdots + b_n x^n \quad \text{where } b_1, \ldots, b_n \in m_V. \quad (9.1.21)$$

Likewise, if $x^{-1} \notin V$, we find an identity of the form

$$1 = c_1 x^{-1} + \cdots + c_m x^{-m} \quad \text{where } c_1, \ldots, c_m \in m_V \quad (9.1.22)$$

and we may assume that $m, n \in \mathbb{N}$ are the minimal integers for which there exist identities (9.1.21) and (9.1.22). Up to swapping the roles of $x$ and $x^{-1}$, we may also assume that $n \geq m$. 

In this case we deduce
\[ 1 = b_1 x + \cdots + b_{n-1} x^{n-1} + b_n \cdot (c_1 x^{n-1} + \cdots + c_m x^{n-m}) \]
which is another identity of the type (9.1.21), but with a strictly smaller value of \( n \), a contradiction. We conclude that either \( x \in V \) or \( x^{-1} \in V \), as required. \( \square \)

9.1.23. Let \( K \) be any field, and denote by \( \mathcal{L}_K \) the set of all local subrings of \( K \). We endow \( \mathcal{L}_K \) with a partial ordering, by declaring that, for every \( A, B \in \mathcal{L}_K \), we have \( A \subseteq B \) if and only if \( B \) dominates \( A \) (see definition 9.1.12(ii)).

**Corollary 9.1.24.** With the notation of (9.1.23), the following holds:

1. For every \( A \in \mathcal{L}_K \) there exists a maximal element of \( \mathcal{L}_K \) that dominates \( A \).
2. An element of \( \mathcal{L}_K \) is maximal if and only if it is a valuation ring of \( K \).

**Proof.**

(i): Let \( (B_i \mid i \in I) \) be a non-empty totally ordered subset of \( \mathcal{L}_K \) such that \( A \leq B_i \) for every \( i \in I \), and set \( B := \bigcup_{i \in I} B_i \). It is easily seen that \( B \in \mathcal{L}_K \), and \( A \leq B \). Then the assertion follows from Zorn’s lemma.

(ii): Let \( A \) be any maximal element of \( \mathcal{L}_K \); by theorem 9.1.20 there exists a valuation ring \( V \) of \( K \) that dominates \( A \), so \( A = V \). Conversely, if \( (V, m_V) \) is a valuation ring of \( K \) and \( (A, m_A) \) any element of \( \mathcal{L}_K \) that dominates \( V \), then we must have \( A = V \); indeed, if the latter fails, there exists \( a \in A \setminus V \), so that \( a^{-1} \in m_V \subset m_A \), which is absurd. \( \square \)

9.1.25. Henceforth, and until the end of this section, we let \((K, \cdot, \cdot)\) be a given valued field, whose valuation ring (resp. maximal ideal, resp. residue field, resp. value group) shall be denoted \( K^+ \) (resp. \( m_K \), resp. \( \kappa \), resp. \( \Gamma \)). The following result is due to Nagata ([104, Th.3]).

**Proposition 9.1.26.** Let \( A \) be an essentially finitely presented \( K^+ \)-algebra, \( M \) a finitely generated \( K^+ \)-flat \( A \)-module. Then \( M \) is a finitely presented \( A \)-module.

**Proof.** Let us write \( A = S^{-1}B \) for some finitely presented \( K^+ \)-algebra \( B \), and some multiplicative subset \( S \subseteq B \); then we may find a finitely generated \( B \)-module \( M_B \) with an isomorphism \( \varphi : S^{-1}M_B \sim M \) of \( A \)-modules. Let \( M_B' \) be the image of \( M_B \) in \( M_B \otimes_{K^+} K \); since \( M \) is \( K^+ \)-flat, \( \varphi \) induces an isomorphism \( S^{-1}M_B' \sim M \). It then suffices to show that \( M_B' \) is a finitely presented \( B \)-module; hence we may replace \( A \) by \( B \) and \( M \) by \( M_B' \), and assume that \( A \) is a finitely presented \( K^+ \)-algebra.

We are further easily reduced to the case where \( A = K^+[T_1, \ldots, T_n] \) is a free polynomial \( K^+ \)-algebra. Pick a finite system of generators \( \Sigma \) for \( M \); define increasing filtrations \( \text{Fil}_A M \) on \( A \) and \( M \), by letting \( \text{Fil}_A M \) be the \( K^+ \)-submodule of all polynomials \( P(T_1, \ldots, T_n) \in A \) of total degree \( \leq k \), and setting \( \text{Fil}_k M := \text{Fil}_k A \cdot \Sigma \subset M \) for every \( k \in \mathbb{N} \). We consider the Rees algebra \( R(A) \) and the Rees module \( R(M) \) associated with these filtrations as in definition 7.9.1(iii,iv). Say that \( \Sigma \) is a subset of cardinality \( N \); we obtain a \( A \)-linear surjection \( \varphi : A^\otimes N \sim M \), and we set \( M_k' := (\text{Fil}_k A)^\otimes N \cap \ker \varphi \) for every \( k \in \mathbb{N} \). Notice that the resulting graded \( K^+ \)-module \( M_k' := \bigoplus_{k \in \mathbb{N}} M_k' \) is actually a \( R(A) \)-module and we get a short exact sequence of graded \( R(A) \)-modules
\[
C_k : 0 \to M_k' \to R(A)^\otimes N \to R(M) \to 0.
\]
Notice also that the \( K^+ \)-modules \( R(A)^\otimes N_k \) and \( R(M)_k \) are torsion-free and finitely generated, hence they are free of finite rank (see [59, Rem.6.1.12(ii)]); then the same holds for \( M_k' \), for every \( k \in \mathbb{N} \). It follows that the complex \( C_k \otimes_{K^+} \kappa \) is still short exact. On the other hand, \( R(A) \) is a \( K^+ \)-algebra of finite type (see example 7.9.5), hence \( R := R(A) \otimes_{K^+} \kappa \) is a noetherian ring; therefore, \( M_k' \otimes_{K^+} \kappa \) is a graded \( R \)-module of finite type, say generated by the system of homogeneous elements \( \{ x_1, \ldots, x_t \} \). Lift these elements to a system \( \Sigma' := \{ x_1, \ldots, x_t \} \) of homogeneous elements of \( M_k' \), and denote by \( M'' \subset M_k' \) the \( R(A) \)-submodule generated by \( \Sigma' \).
By construction, $M_k^p \otimes_{K^+} \kappa = M_k^p \otimes_{K^+} \kappa$, hence $M_k^p = M_k^p$ for every $k \in \mathbb{N}$, by Nakayama’s lemma. In other words, $\Sigma'$ is a system of generators for $M_\bullet^p$; it follows easily that the image of $\Sigma'$ in $\operatorname{Ker} \varphi$ is also a system of generator for the latter $A$-module, and the proposition follows. \hfill \Box

**Corollary 9.1.27.** Every essentially finitely presented $K^+$-algebra is a coherent ring.

**Proof.** One reduces easily to the case of a free polynomial $K^+$-algebra $K^+[T_1, \ldots, T_n]$, in which case the assertion follows immediately from proposition 9.1.26: the details shall be left to the reader. \hfill \Box

**Lemma 9.1.28.** If $A$ is a finitely presented $K^+$-algebra, the subset $\operatorname{Min} A \subset \operatorname{Spec} A$ of minimal prime ideals is finite.

**Proof.** We begin with the following:

**Claim 9.1.29.** The assertion holds when $A$ is a flat $K^+$-algebra.

**Proof of the claim.** Indeed, in this case, by the going-down theorem ([100, Th.9.5]) the minimal primes lie in $\operatorname{Spec} A \otimes_{K^+} K$, which is a noetherian ring.

In general, $A$ is defined over a $\mathbb{Z}$-subalgebra $R \subset K^+$ of finite type. Let $L \subset K$ be the field of fractions of $R$, and set $L^+ := L \cap K^+$; then $L^+$ is a valuation ring of finite rank, and there exists a finitely presented $L^+$-algebra $A'$ such that $A \simeq A' \otimes_{L^+} K^+$. For every prime ideal $p \subset L^+$, let $\kappa(p)$ be the residue field of $L^+_p$, and set:

\[ A'(p) := A' \otimes_{L^+} \kappa(p), \quad K^+(p) := K^+ \otimes_{L^+} \kappa(p). \]

Since $\operatorname{Spec} L^+$ is a finite set, it suffices to show that the subset $\operatorname{Min} A \otimes_{L^+} \kappa(p)$ is finite for every $p \in \operatorname{Spec} L^+$. However, $A \otimes_{L^+} \kappa(p) \simeq A'(p) \otimes_{\kappa(p)} K^+(p)$, so this ring is a flat $K^+(p)$-algebra of finite presentation. Let $I$ be the nilradical of $K^+(p)$; since $K^+(p)/I$ is a valuation ring, claim 9.1.29 applies with $A$ replaced by $A \otimes_{K^+} K^+(p)/I$, and concludes the proof. \hfill \Box

**Lemma 9.1.30.** Let $(A, m_A)$ be a local ring, $K^+ \rightarrow A$ a local and essentially finitely presented ring homomorphism. Then there exists a local morphism $\varphi : V \rightarrow A$ of essentially finitely presented $K^+$-algebras, such that the following holds:

(i) $V$ is a valuation ring, its maximal ideal $m_V$ is generated by the image of $m_K$, and the map $K^+ \rightarrow V$ induces an isomorphism $\Gamma \rightarrow \Gamma_V$ of value groups.

(ii) $\varphi$ induces a finite field extension $V/m_V \rightarrow A/m_A$.

**Proof.** Set $X := \operatorname{Spec} A, S := \operatorname{Spec} K^+$ and let $x \in X$ be the closed point. Pick $a_1, \ldots, a_d \in A$ whose classes in $\kappa(x)$ form a transcendence basis over $\kappa(s)$. The system $(a_i \ | \ i \leq d)$ defines a factorization of the morphism $\operatorname{Spec} \varphi : X \rightarrow S$ as a composition $X \xrightarrow{g} Y := A_d^s \xrightarrow{h} S$, such that $\xi := g(x)$ is the generic point of $h^{-1}(s) \subseteq Y$. The morphism $g$ is essentially finitely presented ([48, Ch.IV, Prop.1.4.3(v)]) and moreover:

**Claim 9.1.31.** The stalk $\mathcal{O}_{X,\xi}$ is a valuation ring with value group $\Gamma$.

**Proof of the claim.** Indeed, set $B := K^+[T_1, \ldots, T_d]$; one sees easily that $V := \mathcal{O}_{X,\xi}$ is the valuation ring of the Gauss valuation $\mid \cdot \mid_B : \operatorname{Frac}(B) \rightarrow \Gamma \cup \{0\}$ such that

\[ \left| \sum_{\alpha \in \mathbb{N}^d} a_\alpha T^\alpha \right|_B = \max\{|a_\alpha| \ | \alpha \in \mathbb{N}^d\} \]

(where $a_\alpha \in K^+$ and $T^\alpha := T_1^{\alpha_1} \cdots T_d^{\alpha_d}$ for all $\alpha := (\alpha_1, \ldots, \alpha_d) \in \mathbb{N}^d$, and $a_\alpha = 0$ except for finitely many $\alpha \in \mathbb{N}^d$).

In view of claim 9.1.31 to conclude the proof it suffices to notice that $\kappa(x)$ is a finite extension of $\kappa(\xi)$. \hfill \Box
Proposition 9.1.32. Let \( \varphi : K^+ \to A \) and \( \psi : A \to B \) be two essentially finitely presented ring homomorphisms. Then:

(i) If \( \psi \) is integral, \( B \) is a finitely presented \( A \)-module.

(ii) If \( A \) is local, \( \varphi \) is local and flat, and \( A/m_K A \) is a field, then \( A \) is a valuation ring and \( \varphi \) induces an isomorphism \( \Gamma \cong \Gamma_A \) of value groups.

Proof. (i): The assumption means that there exist a finitely presented \( A \)-algebra \( C \) and a multiplicative system \( T \subseteq C \) such that \( B = T^{-1}C \). Let \( I := \bigcup_{t \in T} \text{Ann}_C(t) \). Then \( I \) is the kernel of the localization map \( C \to B \); the latter is integral by hypothesis, hence for every \( t \in T \) there is a monic polynomial \( P(X) \in C[X] \), say of degree \( n \), such that \( P(t^{-1}) = 0 \) in \( B \), hence \( t^n \cdot P(t^{-1}) = 0 \) in \( C \), for some \( t' \in T \), i.e. \( t'(1 - ct) = 0 \) holds in \( C \) for some \( c \in C \), in other words, the image of \( t \) is already a unit in \( C/I \), so that \( B = C/I \). Then lemma 8.1.61 says that \( V(I) \subseteq \text{Spec} \, C \) is closed under generizations, hence \( V(I) \) is open, by corollary 8.1.49 and lemma 9.1.28 and finally \( I \) is finitely generated, by lemma 8.1.58(ii). So \( B \) is a finitely presented \( A \)-algebra. Then (i) follows from the well known:

Claim 9.1.33. Let \( R \) be any ring, \( S \) a finitely presented and integral \( R \)-algebra. Then \( S \) is a finitely presented \( R \)-module.

Proof of the claim. Let us pick a presentation: \( S = R[x_1, \ldots, x_n]/(f_1, \ldots, f_m) \). By assumption, for every \( i \leq n \) we can find a monic polynomial \( P_i(T) \in R[T] \) such that \( P_i(x_i) = 0 \) in \( S \). Let \( S' := R[x_1, \ldots, x_n]/(P_1(x_1), \ldots, P_n(x_n)) \); then \( S' \) is a free \( R \)-module of finite rank, and there is an obvious surjection \( S' \to S \) of \( R \)-algebras, the kernel of which is generated by the images of the polynomials \( f_1, \ldots, f_m \). The claim follows.\( \Box \)

(ii): By lemma 9.1.30 we may assume from start that the residue field of \( A \) is a finite extension of \( \kappa \). We can write \( A = C_p \) for a \( K^+ \)-algebra \( C \) of finite presentation, and a prime ideal \( p \subseteq C \) containing \( m_K \); under the stated assumptions, \( A/m_K A \) is a finite field extension of \( \kappa \), hence \( p \) is a maximal ideal of \( C \), and moreover \( p \) is isolated in the fibre \( g^{-1}(s) \) of the structure morphism \( g : Z := \text{Spec} \, C \to \text{Spec} \, K^+ \). It then follows from [50, Ch.IV, Cor.13.1.4] that, up to shrinking \( Z \), we may assume that \( g \) is a quasi-finite morphism ([45, Ch.II, §6.2]). Let \( K^{h+} \) be the henselization of \( K^+ \), and set \( C^h := C \otimes_{K^+} K^{h+} \). There exists precisely one prime ideal \( q \subseteq C^h \) lying over \( p \), and \( C^h_q \) is a flat, finite and finitely presented \( K^{h+} \)-algebra by [51, Ch.IV, Th.18.5.11], so \( C^h_q \) is henselian, by [51, Ch.IV, Prop.18.5.6(i)], and then \( C^h_q \) is the henselization of \( A \), since the natural map \( A \to C^h_q \) is ind-étale and induces an isomorphism \( C^h_q \otimes_{K^+} \kappa \cong \kappa(x) \). Finally, \( C^h_q \) is also a valuation ring with value group \( \Gamma \), by virtue of [59, Lemma 6.1.13 and Rem.6.1.12(vi)]. To conclude the proof of (ii), it now suffices to remark:

Claim 9.1.34. Let \( V \) be a valuation ring, \( \varphi : R \to V \) a faithfully flat morphism. Then \( R \) is a valuation ring and \( \varphi \) induces an injection \( \varphi_\Gamma : \Gamma_R \to \Gamma_V \) of the respective value groups.

Proof of the claim. Clearly \( R \) is a domain, since it is a subring of \( V \). To show that \( R \) is a valuation ring, it then suffices to prove that, for any two ideals \( I, J \subseteq R \), we have either \( I \subseteq J \) or \( J \subseteq I \). However, since \( V \) is a valuation ring, we know already that either \( I \cdot V \subseteq J \cdot V \) or \( J \cdot V \subseteq I \cdot V \); since \( \varphi \) is faithfully flat, the assertion follows. By the same token, we deduce that an ideal \( I \subseteq R \) is equal to \( R \) if and only if \( I \cdot V = V \), which implies that \( \varphi_\Gamma \) is injective (see [59, §6.1.11]).\( \square 

9.2. Huber’s theory of the valuation spectrum. In this section we present the first elements of Huber’s theory of the valuation spectrum of an arbitrary ring, for which the original reference is his Habilitationschrift [78]. Let \( A \) be any ring. We denote by

\[ \text{Spv} \, A \]
the set of equivalence classes of valuations on $A$. For every $a, b \in A$ we set

$$R_A\left(\frac{a}{b}\right) := \{v \in \text{Spv} \ A \mid v(a) \leq v(b) \neq 0\}$$

and more generally, with every $n \in \mathbb{N}$ and every $a_1, \ldots, a_n, b_1, \ldots, b_n \in A$ we associate the rational subset

$$R_A\left(\frac{a_1}{b_1}, \ldots, \frac{a_n}{b_n}\right) := \prod_{i=1}^{n} R_A\left(\frac{a_i}{b_i}\right)$$

and we denote $\mathcal{B}_A$ the boolean algebra generated by the system of rational subsets of $\text{Spv} \ A$. Explicitly, every element of $\mathcal{B}_A$ is a finite union of subsets of the form

$$\{v \in \text{Spv} \ A \mid v(a_1) < v(b_1), \ldots, v(a_n) < v(b_n), v(c_1) \leq v(d_1), \ldots, v(c_m) \leq v(d_m)\}$$

where $n, m \in \mathbb{N}$ are arbitrary integers, and $a_1, b_1, \ldots, a_n, b_n, c_1, d_1, \ldots, c_m, d_m \in A$ are arbitrary elements.

**Definition 9.2.1.** For every ring $A$, we endow $\text{Spv} \ A$ with the topology $\mathcal{T}_A$ with basis given by the rational subsets. The pair $(\text{Spv} \ A, \mathcal{T}_A)$ will be called the valuation spectrum of $A$.

**Theorem 9.2.2.** For every ring $A$, the topological space $(\text{Spv} \ A, \mathcal{T}_A)$ is spectral, and $\mathcal{B}_A$ is the set of all constructible subsets of $\text{Spv} \ A$.

**Proof.** We endow $\text{Spv} \ A$ with the topology $\mathcal{T}_{\text{cons}}$ with basis $\mathcal{B}_A$. Endow as well the set $\{0, 1\}$ with its discrete topology, and the set $\mathcal{P} := \{0, 1\}^{A \times A}$ with the product topology. We attach to every valuation $v$ of $A$ a mapping $\varphi_v : A \times A \to \{0, 1\}$, by declaring that $\varphi_v(a, b) = 1$ if and only if $v(a) \geq v(b)$. If $v, w$ are any two valuations on $A$, then it is clear that $\varphi_v = \varphi_w$ if and only if $v$ is equivalent to $w$, so that the rule $v \mapsto \varphi_v$ yields a well defined injective map

$$\varphi : \text{Spv} \ A \to \mathcal{P}$$

and it is easily seen that the topology on $\text{Spv} \ A$ induced by $\mathcal{P}$ via $\varphi$ agrees with $\mathcal{T}_{\text{cons}}$.

**Claim 9.2.3.** The image of $\varphi$ is the subset of $\mathcal{P}$ of all mappings $f : A \times A \to \{0, 1\}$ fulfilling the following conditions for every $a, b, c \in A$:

1. (a) we have either $f(a, b) = 1$ or $f(b, a) = 1$
2. (b) if $f(a, b) = f(b, c) = 1$, then $f(a, c) = 1$
3. (c) we have either $f(a, a + b) = 1$ or $f(b, a + b) = 1$
4. (d) if $f(a, b) = 1$, then $f(ac, bc) = 1$
5. (e) if $f(ac, bc) = 1$ and $f(0, c) = 0$, then $f(a, b) = 1$
6. (f) $f(0, 1) = 0$.

**Proof of the claim.** It is clear that $\varphi_v$ fulfills these conditions for every $v \in \text{Spv} \ A$. Conversely, let $f$ be a mapping fulfilling conditions (a)–(f); from (f), (a) and (d) we deduce:

1. (g) $f(x, 0) = 1$ for every $x \in A$.

Set $p := \{a \in A \mid f(0, a) = 1\}$. We show that $p$ is an ideal of $A$. Indeed, from (a) it follows that $0 \in p$. Next, say that $a, b \in p$; from (c) we may assume that $f(a, a + b) = 1$, and then (b) implies that $a + b \in p$. Lastly, if $a \in p$ and $b \in A$, then (d) implies that $ab \in p$, as required. Moreover, (e) and (f) imply that $p$ is a prime ideal, and we set $\kappa := \text{Frac} A/p$. We notice:

1. (h) $f(a + x, a) = f(a, a + x) = 1$ for every $a \in A$ and $x \in p$.

Indeed, suppose that $f(a + x, a) = 0$ for such $a$ and $x$; then (c) implies that $f(-x, a) = 1$, and combining with (b) we get $f(0, a) = 1$. On the other hand, (g) says that $f(a + x, 0) = 1$, and combining again with (b) we derive $f(a + x, a) = 1$, a contradiction. To derive the second identity, set $b := a + x$, so that $f(b - x, b) = 1$, by the foregoing, as required.
We can now show that \( f \) factors through a mapping 
\[
\overline{f} : A/p \times A/p \to \{0, 1\}.
\]
Indeed, let \( a, b \in A \) and \( c \in p \) be arbitrary elements, and assume first that \( f(a, b) = 1 \); we need to show that \( f(a+c, b) = 1 \), and this follows from (b) and (h). Similarly, we get \( f(a, b+c) = 1 \). Lastly, if \( f(a, b) = 0 \) we must have \( f(a+c, b) = 0 \), for otherwise the foregoing would give \( f(a, b) = f(a+c-c, b) = f(a+c, b) = 1 \), a contradiction; similarly, we see that \( f(a, b+c) = 0 \) in this case. This shows that \( \overline{f} \) is well defined, and by construction we have

(i) \( \overline{f}(0, x) = 0 \) for every \( x \in A/p \setminus \{0\} \).

Now, for every \( x \in \kappa \), write \( x = a^{-1}b \) for some \( a, b \in A/p \), with \( a \neq 0 \); we say that \( x \) is \( f \)-positive if \( \overline{f}(a, b) = 1 \). From (i) and (e) it follows easily that this condition does not depend on the choice of \( a \) and \( b \), and we let \( V \subset \kappa \) be the subset of all \( f \)-positive elements. Suppose that \( x, y \in V \), and write \( x = a^{-1}b \) for some \( a, b, b' \in A/p \) with \( a \neq 0 \); this means that \( \overline{f}(a, b) = \overline{f}(a, b') = 1 \), and by virtue of (c) we may assume that \( \overline{f}(b, b') = 1 \). Then (b) implies that \( \overline{f}(a, b + b') = 1 \), so \( x + y \in V \). Likewise, (d) implies \( \overline{f}(aa', ba') = 1 \) and \( \overline{f}(ba', bb') = 1 \), and then (b) yields \( f(aa', bb') = 1 \), so \( xy \in V \). Also, we have either \( \overline{f}(-1, 1) = 1 \) or \( \overline{f}(1, -1) = 1 \) by (a), so \(-1 \in V \); summing up, we conclude that \( V \) is a subring of \( \kappa \), and (a) implies that \( V \) is a valuation ring of \( \kappa \). Now, let \( w \) be the valuation of \( \kappa \) attached to \( V \) as in remark 9.1.13(iv), and set \( v := w \circ \pi \), where \( \pi : A \to \kappa \) is the natural map; it is easily seen that \( \varphi_v = f \), whence the claim.

Claim 9.2.3 implies that the image of \( \varphi \) is a closed subset of the quasi-compact and separated topological space \( \mathcal{P}_s \), so \( (Spv A, \mathcal{F}_{cons}) \) is quasi-compact and separated as well. Now, it is clear that every rational subset of \( Spv A \) is open and closed in the topology \( \mathcal{F}_{cons} \). Moreover, it follows easily from remark 9.1.13(vi) that \( (Spv A, \mathcal{T}_A) \) is a \( T_0 \) topological space. Then the theorem follows from proposition 8.1.41.

\[
\text{Claim 9.2.3 implies that the image of } \varphi \text{ is a closed subset of the quasi-compact and separated topological space } \mathcal{P}_s, \text{ so } (Spv A, \mathcal{F}_{cons}) \text{ is quasi-compact and separated as well. \]
natural homeomorphism

\[(9.2.5)\quad \sigma_A^{-1}(p) \cong \text{Spv } \kappa(p) \quad \text{for every } p \in \text{Spec } A\]

where the fiber $\sigma_A^{-1}(p)$ is endowed with the topology induced by $\text{Spv } A$ via the inclusion map.

(iv) Let $S \subset A$ be any multiplicative system, and $i : A \to S^{-1}A$ the localization map; taking into account remark 9.1.4(iv), it is easily seen that $\text{Spv } i$ is injective, and

\[\text{Im } \text{Spv } i = \bigcap_{s \in S} R_A \left( \frac{s}{a} \right).\]

Moreover, we have

\[R_{S^{-1}A} \left( \frac{s^{-1}a}{t^{-1}b} \right) = (\text{Spv } i)^{-1} R_A \left( \frac{at}{bs} \right) \quad \text{for every } a, b \in R \text{ and } s, t \in S\]

so the topology of $\text{Spv } S^{-1}A$ is induced by the topology of $\text{Spv } A$, via the mapping $\text{Spv } i$, and therefore the latter identifies $\text{Spv } S^{-1}A$ with a pro-constructible subset of $\text{Spv } A$.

(v) For any ring $A$, we set

\[\text{Spv}^+ A := \{ v \in \text{Spv } A \mid v(a) \leq 1 \text{ for every } a \in A \}.\]

Hence, $\text{Spv}^+ A$ is a pro-constructible subset of $\text{Spv } A$, and we endow it with the topology induced by the inclusion map into $\text{Spv } A$, so that $\text{Spv}^+ A$ is a spectral space (theorem 9.2.2 and corollary 8.1.40). For every $v \in \text{Spv}^+ A$, let also

\[\sigma_A^+(v) := \{ a \in A \mid v(a) < 1 \}.\]

It is easily seen that $\sigma_A^+(v)$ is a prime ideal of $A$, so we get a well defined map

\[\sigma_A^+ : \text{Spv}^+ A \to \text{Spec } A.\]

Notice that $\sigma_A^+$ is surjective: indeed, for every prime ideal $p$, the trivial valuation $v_p$ with support equal to $p$ lies in $\text{Spv}^+ A$, and $\sigma_A^+(v_p) = p$. Moreover, we have

\[(\sigma_A^+)^{-1}(\text{Spec } A_s) = R_A \left( \frac{1}{s} \right) \cap \text{Spv}^+ A \quad \text{for every } s \in A\]

so $\sigma_A^+$ is continuous and spectral (corollary 8.1.40). In many references, the prime ideal $\sigma_A^+(v)$ is called the center of the valuation $v$. Notice also that, for every ring homomorphism $f : A \to B$, the map $\text{Spv } f$ restricts to a continuous spectral map

\[\text{Spv}^+ f : \text{Spv}^+ B \to \text{Spv}^+ A.\]

9.2.6. Let $X$ be any scheme. A valuation of $X$ is a pair $(x, v)$ consisting of a point $x \in X$ and the equivalence class of a valuation $v$ of the residue field $\kappa(x)$; then we say that $x$ is the support of $(x, v)$. We denote by $\text{Spv } X$

the set of valuations of $X$, and we endow it with the coarsest topology $\mathcal{T}_X$ containing the subsets

\[U \left( \frac{a}{b} \right) := \{(x, v) \in \text{Spv } X \mid x \in U, \ v(a(x)) \leq v(b(x)) \neq 0 \}\]

where $U$ ranges over all the open subsets of $X$, and $a, b$ are arbitrary elements of $\mathcal{O}_X(U)$ (and $a(x), b(x)$ are the images of $a$ and $b$ in $\kappa(x)$). The topological space $(\text{Spv } X, \mathcal{T}_X)$ is called the valuation spectrum of $X$. Any morphism of schemes $f : Y \to X$ induces a mapping

\[\text{Spv } f : \text{Spv } Y \to \text{Spv } X \quad (y, w) \mapsto (f(y), w \circ f_y^*)\]
where \( f^\circ_y : \kappa(f(y)) \to \kappa(y) \) is the ring homomorphism induced by the morphism of structure sheaves \( f^\circ : \mathcal{O}_X \to \mathcal{O}_Y \) associated with \( f \). Notice that

\[
(\text{Spv} f)^{-1}U \left( \frac{a}{b} \right) = f^{-1}U \left( \frac{f^\circ_U(a)}{f^\circ_U(b)} \right)
\]

for every \( U, a \) and \( b \) as in the foregoing, so \( \text{Spv} f \) is a continuous mapping. In the same vein, consider the support map

\[
\sigma_X : \text{Spv} X \to X \quad (x, v) \to x.
\]

Clearly \( \sigma_X^{-1}U = U(\frac{1}{1}) \) for every open subset \( U \subset X \), so \( \sigma_X \) is continuous as well.

**Remark 9.2.7.** The construction of (9.2.6) generalizes that of (9.2) : indeed, let \( A \) be any ring; we have a natural mapping

\[
\text{Spv} A \to \text{Spv}(\text{Spec} A) \quad v \mapsto (\text{Ker} v, \overline{v})
\]

where, for any valuation \( v \) on \( A \), we let \( \overline{v} \) be the residual valuation of \( v \) (see remark 9.1.4)(v)). In light of remarks 9.1.13(iv) and 9.2.4(iv) it is easily seen that (9.2.8) is a homeomorphism (details left to the reader). Taking into account theorem 9.2.2, we see that \( \text{Spv} X \) is locally spectral for every scheme \( X \), and if \( X \) is quasi-compact and quasi-separated, then \( \text{Spv} X \) is spectral (lemma 8.1.21(iv)). Moreover, remark 9.2.4(ii) and proposition 8.1.22(iii) imply that \( \text{Spv} f \) is a spectral map, for every morphism of schemes \( f : Y \to X \).

**Proposition 9.2.9.** Let \( f : A \to B \) and \( g : A \to A' \) be two ring homomorphisms, and set \( B' := A' \otimes_A B \). Then the induced continuous map of topological spaces

\[
\varphi : \text{Spv} B' \to \text{Spv} A' \times_{\text{Spv} A} \text{Spv} B
\]

is surjective.

**Proof.** Let \( v' \in \text{Spv} A' \) and \( w \in \text{Spv} B \) be two elements such that \( v := \text{Spv}(g)(v') = \text{Spv}(f)(w) \), and denote by

\[
\overline{v} \in \text{Spv} \kappa(v) \quad \overline{v'} \in \text{Spv} \kappa(v') \quad \overline{w} \in \text{Spv} \kappa(w)
\]

the residual valuations of \( v, v' \), and \( w \); the maps \( f \) and \( g \) induce field extensions \( \kappa(v) \to \kappa(v') \) and \( \kappa(v) \to \kappa(w) \), whence a ring homomorphism \( h : B' \to C := \kappa(v') \otimes_{\kappa(v)} \kappa(w) \). Suppose that \( u \in \text{Spv} C \) is an element whose image in \( \text{Spv} \kappa(v') \times_{\text{Spv} \kappa(v)} \text{Spv} \kappa(w) \) equals the pair \((\overline{v'}, \overline{w})\); then \( \varphi \circ \text{Spv}(h)(u) = (v', w) \). Thus, we are reduced to the case where \( A, A' \) and \( B \) are three fields. To ease notation, set \( A^+ := \kappa(v)^+ \), and define likewise \( A'^+ \) and \( B^+ \); let as well \( B'^+ := A'^+ \otimes_{A^+} B^+ \). Since the maps \( A^+ \to A'^+ \) and \( A^+ \to B^+ \) are flat, it is easily seen that the induced map \( B'^+ \to B^+ \) is injective. Pick any prime ideal \( p \in \text{Spec} B'^+ \) whose image in \( \text{Spec} B^+ \) (resp. in \( \text{Spec} B'^+ \)) is the (unique) closed point; the induced map \( B'^+_p \to B^+_p \) is still injective, and especially, \( B'_p^+ \neq 0 \), so we may find a maximal ideal \( m \) of \( B'_p^+ \); we denote by \( \kappa(m) \) the residue field of \( m \). The image of \( B'^+_p \) in \( \kappa(m) \) is a local ring \( D \), and by corollary 9.1.24 we may find a valuation ring \((V, m_V)\) of \( \kappa(m) \) that dominates \( D \). Lastly, \( V \) yields a well defined point \( u \in \text{Spv} B' \), and a simple inspection shows that \( \varphi(u) = (v', w) \), as required.

**9.2.10.** We wish next to investigate the specializations in the valuation spectrum. Thus, let \( A \) be any ring, \( v : A \to \Gamma_v \) a valuation. The convex subgroup of \( \Gamma_v \) generated by \( \text{Im } (v) \setminus \Gamma_v^+ \) is called the characteristic subgroup of \( v \), and shall be denoted

\[ c \Gamma_v. \]
Now, let $\Delta \subset \Gamma$ be any convex subgroup, and $\pi : \Gamma \to \Gamma/\Delta$ the projection; we associate with $\Delta$ two mappings

$$v_\Delta : A \to (\Gamma/\Delta)_o \quad a \mapsto \pi_o \circ v(a)$$

$$v^\Delta : A \to \Delta_o \quad a \mapsto \begin{cases} v(a) & \text{if } v(a) \in \Delta \\ 0 & \text{otherwise.} \end{cases}$$

Lemma 9.2.11. With the notation of \((9.2.10)\), the following holds:

(i) $v_\Delta$ is a valuation on $A$.
(ii) $v^\Delta$ is a valuation if and only if $c\Gamma_o \subset \Delta$.

Proof. (i) is clear. For (ii), suppose first that $c\Gamma_o \subset \Delta$, pick any $a, b \in A$, and let us show that $v(a + b)^\Delta \leq \max(v(a)^\Delta, v(b)^\Delta)$. This is clear if both $v(a), v(b) \in \Delta_o$, so we may assume that $v(b) \notin \Delta_o$, in which case notice that $v(b) < 1$, since $c\Gamma_o \subset \Delta$. Now, if $v(a) \in \Delta$, then we must have $v(b) < v(a)$, as $\Delta$ is convex; therefore, $v(a + b) = v(a)$ (remark 9.1.4(ii)), and the contention follows easily in this case. Lastly, if neither of $v(a), v(b)$ lies in $\Delta$, the foregoing yields $v(a), v(b) < 1$, hence $v(a + b) < 1$, and moreover we may assume that $v(a + b) \leq v(a)$; then $v(a + b)$ cannot lie in $\Delta$, as the latter is convex, so $v(a + b)^\Delta = 0$, and the assertion follows also in this case. Next, let us check that $v(ab)^\Delta = v(a)^\Delta \cdot v(b)^\Delta$. Again, this is clear if both $v(a), v(b) \in \Delta_o$, hence suppose that $v(b) \notin \Delta_o$; if $v(a) \in \Delta_o$, then it follows easily that $v(ab) \notin \Delta$, in which case the assertion holds. If neither of $v(a), v(b)$ is in $\Delta_o$, we have already remarked that $v(a), v(b) < 1$, hence $v(ab) < v(a), v(b) < 1$, so $v(ab)$ cannot lie in $\Delta$, as the latter is convex. Thus, the assertion holds also in this case.

Conversely, suppose that $c\Gamma_o \not\subset \Delta$; then there exists $a \in A$ such that $v(a) > 1$ but $v(a) \notin \Delta$. Set $b := 1 - a$; it follows that $v(b) = v(a)$, and $v(a + b) = 1 \in \Delta$, so $v(a + b)^\Delta = 1$ but $v(a)^\Delta = v(b)^\Delta = 0$, and therefore $v^\Delta$ is not a semi-norm. \[\square\]

Example 9.2.12. In the situation of example 9.1.5, suppose that $A$ is a domain and $P$ is integral with $P^{\text{gp}}$ torsion-free, so that $v_\varphi$ is a valuation on $A[P]$, and let $\Delta \subset \Gamma$ be a convex subgroup.

(i) Lemma 9.2.11(ii) implies that $v_\varphi^\Delta$ is a valuation on $A[P]$ if and only if $\varphi(P) \subset \Gamma_o^+ \cap \Delta$. Moreover, if the latter condition holds, the mapping

$$\varphi^\Delta : P \to \Gamma_o \quad x \mapsto \begin{cases} \varphi(x) & \text{if } \varphi(x) \in \Delta \\ 0 & \text{otherwise.} \end{cases}$$

is a morphism of monoids, and $v_\varphi^\Delta = v_{\pi_0\varphi}^\Delta$.

(ii) Furthermore, $(v_\varphi^\Delta) = v_{\pi_0\varphi^\Delta}$, where $\pi : \Gamma \to \Gamma/\Delta$ is the projection.

Remark 9.2.13. With the notation of \((9.2.10)\), we notice:

(i) Let $\overline{v} : \kappa(v) \to \Gamma_o$ be the residual valuation of $v$, and $\kappa(v)^+$ the valuation ring of $\overline{v}$; the correspondence of remark 9.1.13(vii) assigns to $\Delta$ a prime ideal $p(\Delta) \subset \kappa(v)^+$, and we have

$$\text{Ker } v_\Delta = \text{Ker } v = \kappa(v)^+ = \kappa(v)^+_{p(\Delta)} = \overline{v}^{-1}(\Gamma^+ \cdot \Delta_o).$$

(ii) Let $\pi : A \to \kappa(v)$ be the natural map; then $c\Gamma_o \subset \Delta$ if and only if $\pi(A) \subset \kappa(v)^+_{p(\Delta)}$.

(iii) Suppose now that $c\Gamma_o \subset \Delta$; then:

$$\kappa(v^\Delta) \subset \text{Frac } \kappa(v)^+_{p(\Delta)} \quad \text{and} \quad \kappa(v^\Delta)^+ = \kappa(v^\Delta) \cap \kappa(v)^+_{p(\Delta)}.$$

(iv) The valuation $v_\Delta$ is a generalization of $v$ in $\text{Spv } A$. Indeed, if $a, b \in A$ are any two elements such that $v(a) \leq v(b)$, then clearly $v_\Delta(a) \leq v_\Delta(b)$, whence the claim.

(v) Also, if $c\Gamma_o \subset \Delta$, then $v^\Delta$ is a specialization of $v$ in $\text{Spv } A$; indeed, if $v^\Delta(a) \leq v^\Delta(b)$, it is easily seen that $v(a) \leq v(b)$.

Definition 9.2.14. Let $A$ be a ring, and $v, w \in \text{Spv } A$ any two elements.
Lemma 9.2.15. Let $A$ be any ring, $v, w, u \in \text{Spv } A$ any three elements. We have:

(i) If $w$ is a primary specialization of $v$ and $u$ is a primary specialization of $w$, then $u$ is a primary specialization of $v$.

(ii) If $w$ is a secondary specialization of $v$ and $u$ is a secondary specialization of $w$, then $u$ is a secondary specialization of $v$.

(iii) Suppose that $w$ is a specialization of $v$. Then $w$ is a secondary specialization of $v$ if and only if $\text{Ker } w = \text{Ker } v$.

(iv) The primary specializations (resp. the secondary specializations) of $v$ form a totally ordered subset of the partially ordered set $\text{Spv } A$.

(v) The supports of the primary specializations of $v$ are the $v$-convex prime ideals of $A$.

Proof. (i) and (ii) are clear from the explicit description in (9.2.10).

(iii): Suppose that $w$ is a specialization of $v$ whose support equals that of $v$, and let $\overline{v}$ and $\overline{w}$ be the respective residual valuations on $\kappa := \kappa(v) = \kappa(w)$; from (9.2.5) we deduce that $\overline{w}$ is a specialization of $\overline{v}$ in $\text{Spv } \kappa$, which means that $\kappa(\overline{v})^+ \subset \kappa(\overline{w})^+$. Then, let $\Delta \subset \Gamma_v$ be the image of $(\kappa(w)^+)^v$; it follows easily that $\Delta$ is a convex subgroup, and taking into account remark 9.1.13(iv), we see that $\Gamma_w$ is naturally identified with $\Gamma_v/\Delta$, and $w = v^\Delta$.

(iv): Indeed, the explicit description of (9.2.10) implies more precisely that the partially ordered set of secondary specializations of $v$ is naturally identified with $\text{Spec } \Gamma_v$, where the latter is totally ordered by inclusion (see definition (9.1.1)(iii)). Likewise, we have a surjective order-preserving map from $\text{Spec } \Gamma_v/\Gamma_w$ onto the set of primary specializations of $v$.

(v): Let $\Delta \subset \Gamma_v$ be a convex subgroup containing $c \Gamma_v$; let also $a \in A$ and $b \in \text{Ker } (v^\Delta)$ with $v(a) \leq v(b)$. Then $v(b) \notin \Delta$, and in particular $v(b) < 1$, since $c \Gamma_v \subset \Delta$; since $\Delta$ is convex, it follows that $v(a) \notin \Delta$, hence $a \in \text{Ker } (v^\Delta)$. This shows that $\text{Ker } (v^\Delta)$ is $v$-convex. Conversely, suppose that the prime ideal $p \subset A$ is $v$-convex. Hence, $v(x) \neq 0$ for every $x \in A \setminus p$, and we let $\Delta \subset \Gamma_v$ be the subgroup generated by $v(A \setminus p)$. We claim that $\gamma > v(x)$ for every $\gamma \in \Delta$ and every $x \in p$. Indeed, suppose that this condition fails for some $\gamma \in \Delta$ and $x \in p$; since $A \setminus p$ is a submonoid of $(A, \cdot)$, we may write $\gamma = v(a) \cdot v(b)^{-1}$ for some $a, b \in A \setminus p$, and we get $v(a) \leq v(bx)$, which is absurd, since $p$ is $v$-convex. Now, let $\Delta' \subset \Gamma_v$ be the smallest convex subgroup containing $\Delta$; it is easily seen that we still have $\gamma > v(x)$ for every $\gamma \in \Delta'$ and every $x \in p$. On the other hand, by construction we have $v(A \setminus p) \subset \Delta'$, so $p = \{x \in A \mid \gamma > v(x) \text{ for every } \gamma \in \Delta'\}$. Moreover, say that $a \in A$ and $v(a) \geq 1$; then $a \in A \setminus p$, since $p$ is $v$-convex, and consequently $v(a) \in \Delta'$, i.e. the characteristic subgroup of $v$ lies in $\Delta'$, so that $v^{\Delta'} \in \text{Spv } A$, and to conclude, it suffices to remark that $\text{Ker } v^{\Delta'} = p$. □

Proposition 9.2.16. Let $A$ be any ring, $v$ a valuation of $A$, and $p \subset A$ a prime ideal. We have:
(i) If \( p \subset \text{Ker} v, \) there exists a primary generalization \( w \) of \( v \) with \( \text{Ker} w = p. \) Especially, the map \( \sigma_A \) of remark 9.2.4(iii) is specializing.

(ii) If \( v \in \text{Spv}^+ A, \) then every primary specialization and every primary generalization of \( v \) in \( \text{Spv} A \) lies also in \( \text{Spv}^+ A, \) and if \( w \) is any primary specialization (or generalization) of \( v, \) then \( \sigma_A^+(w) = \sigma_A^+(v) \) (notation of remark 9.2.4(v)).

(iii) If \( v \in \text{Spv}^+ A \) and \( p \) contains the center of \( v, \) there exists a secondary specialization \( w \in \text{Spv}^+ A \) of \( v \) with center equal to \( p. \) Especially, the map \( \sigma_A^+ \) is specializing.

Proof. (i): The valuation \( v \) factors through the projection \( A \to A' := A/p \) and a valuation \( v' \) of \( A'; \) after replacing \( A \) and \( v \) by \( A' \) and \( v', \) we may then assume that \( A \) is a domain and \( p = 0. \) In this case, let \( q := \text{Ker} v \subset A; \) according to theorem 9.1.20 there exists a valuation ring \( (V,m_v) \) of \( K := \text{Frac} A \) such that \( A \subset V \) and \( q = m_v \cap A; \) by the same token, there exists a valuation ring \( (W,m_W) \) of \( V/m_v \) such that \( W \cap \kappa(q) = \kappa(v)^+. \) Let \( \pi_V : V \to W/m_v \) be the projection; then \( W = \pi_V^{-1}(W) \) is a valuation ring of \( K; \) let \( w_K \) be the unique valuation of \( K \) with \( \kappa(w_K)^+ = W, \) and \( v \) the restriction of \( w_K \) to the subring \( A. \) Notice that \( m_w = \text{Ker} (W \to W) \) is a prime ideal of \( W; \) then \( w_K \) is a valuation ring of \( A \) of \( (9.2.17). \) If \( a \) is a secondary specialization of a generalized primary specialization of \( v, \) then \( \pi_V(a) = \pi_V(w) = q. \) We need to check that \( w^{\Delta} \) is equivalent to \( v. \) Notice first that for every \( a,b \in A \) we have :

\[(9.2.17) \quad w(a) \leq w(b) \iff a \in bW \quad \text{and} \quad v(a) \leq v(b) \iff \pi_V(a) \in \pi_V(b)W.\]

Now, suppose that \( w^{\Delta}(a) \leq w^{\Delta}(b), \) and let us show that \( v(a) \leq v(b) \). Indeed, if \( w^{\Delta}(b) \neq 0, \) we have \( w^{\Delta} \in R_A (\frac{a}{b}), \) whence \( w \in R_A (\frac{a}{b}) \), so \( w(a) \leq w(b), \) and thus \( v(a) \leq v(b), \) in light of \( (9.2.17). \) If \( w^{\Delta}(b) = 0, \) we have as well \( w(a) = 0, \) and then \( v(a) = v(b) = 0, \) since \( \text{Ker}(v) = \text{Ker}(w). \) Conversely, suppose that \( v(a) \leq v(b); \) if \( v(b) = 0, \) we see as in the foregoing that \( w^{\Delta}(a) = w^{\Delta}(b) = 0. \) Thus, let \( v(b) \neq 0, \) and suppose by contradiction that \( w^{\Delta}(a) > w^{\Delta}(b); \) we deduce that \( w^{\Delta}(a), w^{\Delta}(b) \neq 0, \) hence \( a,b \neq 0 \) and \( w(a) < w(b). \) Let \( m_W = \pi_V^{-1}(m_W) \) be the maximal ideal of \( W; \) we get \( b \in a \cdot m_W, \) so that \( \pi_V(b) \in \pi_V(a) \cdot m_W, \) i.e. \( v(a) > v(b), \) against our assumption. We may now apply remark 9.1.13(vi) to conclude.

(ii) is clear from the definitions.

(iii): Let \( V \subset \kappa(v) \) be the valuation ring of the residual valuation of \( v, \) and \( m_v \) the maximal ideal of \( V; \) then \( v \) induces a ring homomorphism \( \pi : A \to V \) such that \( q := \pi^{-1}(m_v) \) is the center of \( v. \) We deduce an injective ring homomorphism \( \overline{A} := A/q \to \kappa := V/m_v, \) and we denote by \( \overline{m} \subset \overline{A} \) the image of \( m. \) By corollary 9.1.24, there exists a valuation ring \( \overline{W} \) of \( \kappa \) that dominates the image of \( \overline{m}, \) and we denote by \( W \subset V \) the preimage of \( \overline{W}. \) Then \( W \) is a valuation ring of \( \kappa(v), \) and it corresponds to a secondary specialization of \( v \) in \( \text{Spv}^+ A. \)

\[\square\]

Proposition 9.2.18. Let \( A \) be any ring, and \( v \in \text{Spv} A \) any element. Then, every specialization of \( v \) is a secondary specialization of a generalized primary specialization of \( v. \)

Proof. Let \( w \) be a specialization of \( v. \) If \( c_{\Gamma_v} = \{1\} \) and \( v(a) \geq 1 \) for every \( a \in A \setminus \text{Ker} w, \) then \( \text{Ker} v^{(1)} \subset \text{Ker} w, \) so the trivial semi-norm \( u \) with support \( \text{Ker} w \) is a generalized primary specialization of \( v, \) and \( w \) is a secondary specialization of \( u. \) We may therefore assume that either \( c_{\Gamma_v} \neq \{1\}, \) or \( v(a) < 1 \) for some \( a \in A \setminus \text{Ker} w. \)

Claim 9.2.19. Let \( a, b \in A \) be any two elements with \( v(a) \leq v(b), \) \( w(a) \neq 0 \) and \( w(b) = 0. \) Then \( v(a) = v(b) \neq 0. \)

Proof of the claim. The assumptions imply that \( w \in R_A (\frac{b}{a}), \) and since \( v \) is a generalization of \( w, \) it follows that \( v \in R_A (\frac{b}{a}), \) as well, whence the claim.

\[\diamond\]

Claim 9.2.20. \( \text{Ker} w \) is \( v \)-convex.
Proof of the claim. Indeed, let \( x, y \in A \) be two elements with

\[
(9.2.21) \quad v(x) \leq v(y) \quad \text{and} \quad w(y) = 0
\]

and suppose, by way of contradiction, that \( w(x) \neq 0 \); by claim 9.2.19 it follows that

\[
(9.2.22) \quad v(x) = v(y) \neq 0.
\]

Consider first the case where \( c\Gamma_v \neq \{1\} \), and pick \( a \in A \) with \( v(a) > 1 \); combining with (9.2.21) we get \( v(x) \leq v(ay) \) and \( w(ay) = 0 \), so claim 9.2.19 yields \( v(ay) = v(x) \), which contradicts (9.2.22). Next, if \( v(a) < 1 \) for some \( a \in A \) such that \( w(a) \neq 0 \), we get \( v(ax) \leq v(y) \) and \( w(ax) \neq 0 \), again by combining with (9.2.21), and claim 9.2.19 yields \( v(ax) = v(y) \), again a contradiction.

By claim 9.2.20 and lemma 9.2.15(iv,v), there exists a unique primary specialization \( u \) of \( v \) with \( \text{Ker} u = \text{Ker} w \), and in view of lemma 9.2.15(iii), it suffices to show that \( w \) is a specialization of \( u \). To this aim, let \( a, b \in A \) be any two elements such that \( w \in R_A(\frac{a}{b}) \); since \( v \) is a generization of \( w \), we have \( v \in R_A(\frac{a}{b}) \) as well, and since \( u \) is a primary specialization of \( v \), we deduce \( u(a) \leq u(b) \). Lastly, since \( \text{Ker} u = \text{Ker} w \) and \( w(b) \neq 0 \), we get \( u(b) \neq 0 \), so \( u \in R_A(\frac{a}{b}) \), and the assertion follows.

**Lemma 9.2.23.** Let \( A \) be a ring, \( v, w \in \text{Sp}_v A \) be two elements, such that \( w \) is a primary specialization of \( v \). We have:

(i) For every secondary specialization \( v' \) of \( v \) there exists a unique secondary specialization \( w' \) of \( w \) such that \( w' \) is a primary specialization of \( v' \).

(ii) For every secondary specialization \( w' \) of \( w \) there exists a secondary specialization \( v' \) of \( v \) such that \( w' \) is a primary specialization of \( v' \).

(iii) For every secondary specialization \( v' \) of \( v \) there exists a unique secondary specialization \( w' \) of \( w \) such that \( w' \) is a primary specialization of \( v' \).

(iv) For every secondary specialization \( v' \) of \( v \) there exists a secondary specialization \( v' \) of \( v \) such that \( w' \) is a primary specialization of \( v' \).

**Proof.** (i): The uniqueness of \( w' \) follows from lemma 9.2.15(iii,iv). For the existence, let \( \Delta' \) be a convex subgroup of \( \Gamma_v \) such that \( v = v'_{\Delta'} \), and \( \Sigma \) a convex subgroup of \( \Gamma_v = \Gamma_v/\Delta' \) containing \( c\Gamma_v \) and such that \( w = v^\Sigma \). Denote by \( \Sigma' \) the unique convex subgroup of \( \Gamma_v \) such that \( \Delta' \subset \Sigma' \) and \( \Sigma'/\Delta' = \Sigma \); then \( c\Gamma_v \subset \Sigma' \) and we may take \( w' := (v')^{\Sigma'} \).

(ii): By remark 9.2.13(ii), there exists a prime ideal \( p \subset \kappa(w)^+ \) such that \( \kappa(w) \subset K := \text{Frac} k(v)^+/p \) and \( \kappa(w)^+ \supset \kappa(w) \cap K^+ \), where \( K^+ := k(v)^+/p \). On the other hand, \( \kappa(w') = \kappa(w) \) and \( \kappa(w')^+ \subset \kappa(w)^+ \). Let \( m_K, m_w, m_{w'} \) be the maximal ideals of respectively \( K^+ \), \( \kappa(w)^+ \) and \( \kappa(w')^+ \); it follows easily that \( m_K \cap m(w) = m_w \subset m_{w'} \). Then \( m_w \) is an ideal of \( \kappa(w')^+ \), and we have injective ring homomorphisms

\[
B := \kappa(w')^+/m_w \to \kappa(w)^+/m_w \to K^+/m_K.
\]

According to corollary 9.1.24, we may then find a valuation ring \( \overline{V} \) of \( K^+/m_K \) that dominates \( B \). Since \( B \) is a valuation ring, we easily deduce that \( B = \overline{V} \cap \text{Frac} B \). Let \( V \subset K^+ \) be the preimage of \( \overline{V} \); then \( V \) is a valuation ring of \( K \) such that \( \kappa(w')^+ = V \cap \kappa(w') \) (details left to the reader). Let \( \nu' \subset \kappa(v)^+ \) be the preimage of \( \nu \); then \( \nu' \) is a valuation ring of \( \kappa(v) \), and we let \( v' \) be the unique valuation of \( A \) with \( \text{Ker} v' = \text{Ker} \nu' \) and \( \kappa(v')^+ = V' \); it is easily seen that \( v' \) is the sought secondary specialization of \( v \).

(iii): The uniqueness of \( w' \) follows from lemma 9.2.15(iii,iv), and the existence follows from proposition 9.2.18.

(iv): Let \( \Delta \) be a convex subgroup of \( \Gamma_v \) containing \( c\Gamma_v \) and such that \( w = v^\Delta \), and \( \Sigma \) a convex subgroup of \( \Delta \) such that \( w' = v^\Sigma \). Set \( v' := v_{\Sigma} \); then \( \Delta' := \Delta/\Sigma \) is a convex subgroup of \( \Gamma_v = \Gamma_v/\Sigma \) that contains \( c\Gamma_v \), and \( w' = (v')^{\Delta'} \). \( \square \)
Proposition 9.2.24. Let $A$ be a ring, and $v \in \text{Spv } A$ any element. Then every specialization of $v$ is a primary specialization of a secondary specialization of $v$.

Proof. Let $w$ be a specialization of $v$. If $w$ is a secondary specialization of a primary specialization of $v$, the assertion follows from lemma 9.2.23(ii). In light of proposition 9.2.18, we may then assume that the characteristic subgroup of $v$ is trivial and $K_{v(1)} \subset K_w$. In this case, proposition 9.2.16(i) yields a primary generization $w'$ of $w$ with $K_{w'} = K_{v(1)}$. Clearly $w'$ is a secondary specialization of $v(1)$, so lemma 9.2.23(ii) ensures that we may find a secondary specialization $v'$ of $v$ which is also a primary generization of $w'$, and then $w$ is a primary specialization of $v'$ (lemma 9.2.15(i)). \hfill $\square$

Lemma 9.2.25. Let $f : A \to B$ be any ring homomorphism, and $v, w \in \text{Spv } B$ any two elements. We have:

(i) If $w$ is a primary (resp. secondary) specialization of $v$, then $\text{Spv}(f)(w)$ is a primary (resp. secondary) specialization of $\text{Spv}(f)(v)$.

(ii) If $\text{Spec } f$ is an open immersion, and $\text{Spv}(f)(w)$ is a primary (resp. secondary) specialization of $\text{Spv}(f)(v)$, then $w$ is a primary (resp. secondary) specialization of $v$.

(iii) $\text{Spv } f$ restricts to a surjection from the set of secondary specializations (resp. generizations) of $v$ onto the set of secondary specializations (resp. generizations) of $\text{Spv}(f)(v)$.

(iv) Suppose that $w$ is a primary specialization of $v$, and denote by $P$ (resp. $Q$) the set of primary specializations of $v$ in $\text{Spv } B$ (resp. of $\text{Spv}(f)(v)$ in $\text{Spv } A$) that are also primary specializations of $w$ in $\text{Spv } B$ (resp. of $\text{Spv}(f)(w)$ in $\text{Spv } A$). Then $\text{Spv } f$ restricts to a surjection $P \to Q$.

Proof. (i) is immediate from the definitions.

(ii): Set $v' := \text{Spv}(f)(v)$; if $\text{Spec } f$ is an open immersion, $f$ induces an isomorphism $\kappa(v') \to \kappa(v)$, and similarly for $w$. The assertion is an immediate consequence.

(iii): Clearly, $f$ induces an injective map $i : \Gamma_v \to \Gamma_{v'}$, and $\text{Spec } i$ is surjective, by remark 9.1.2(v), so $\text{Spv } f$ maps surjectively the secondary specializations of $v$ onto the ones of $v'$. Next, let $w'$ be a secondary specialization of $v'$ in $\text{Spec } A$; then $\kappa(w') = \kappa(v')$ and $\kappa(w')^+$ is a valuation ring of $\kappa(v')$ contained in $\kappa(v')^+$. Let $m \subset \kappa(v')^+$ be the maximal ideal, so that $m' := m \cap \kappa(v')$ is the maximal ideal of $\kappa(v')^+$ and a prime ideal of $\kappa(w')^+$; then $K^+ := \kappa(w')^+ / m'$ is a valuation ring of $K := \kappa(v')^+ / m'$, and by corollary 9.1.24 there exists a valuation ring $V$ of $\kappa(v')^+ / m$ that dominates $K^+$. The preimage of $V$ in $\kappa(v')^+$ is a valuation ring of $\kappa(v)$ and the corresponding valuation $w$ of $B$ is a secondary specialization of $v$ with $\text{Spv}(f)(w) = w'$.

(iv): Again, since the induced morphism of ordered groups $i$ is injective, the assertion follows easily from remark 9.1.2(v). \hfill $\square$

Theorem 9.2.26. Let $f : A \to B$ be a flat ring homomorphism, and $v \in \text{Spv } B$ any element. Then the following holds:

(i) $\text{Spv } f$ restricts to a surjection from the set of primary generizations of $v$ in $\text{Spv } B$ to the set of primary generizations of $\text{Spv}(f)(v)$ in $\text{Spv } A$.

(ii) $\text{Spv } f$ is generizing.

Proof. (i): Let $t$ be any primary generization of $s := \text{Spv}(f)(v)$. According to remark 9.2.13(i), there exists a prime ideal $p \subset \kappa(t)^+$ such that

- the image of the natural map $A \to \kappa(t)$ lies in $A' := \kappa(t)^+_p$
- $\kappa(s)$ is naturally identified with a subfield of the residue field $\overline{\kappa} := A'/pA'$ of $A'$
- under this identification, we have $\kappa(s)^+ = \kappa(s) \cap (\kappa(t)^+/p)$.

With this notation, let $h : A \to A'$ the resulting map, and

$$\overline{\kappa} : \kappa(t) = \text{Frac } A' \to \Gamma_{t_0} \quad \text{and} \quad \overline{\kappa} : \kappa(s) \to \Gamma_{s_0}$$
be respectively the residual valuation of \( t \) and the valuation of \( \pi \) such that \( \kappa(\pi)^+ = \kappa(t)^+/p \).

Then, \( \ell \) and \( \pi \) yield elements \( t' \) and respectively \( s' \) of \( \text{Spv} A' \) such that

\[
s = \text{Spv}(h)(s') \quad \text{and} \quad t = \text{Spv}(h)(t').
\]

Let \( f' : A' \to B' := A' \otimes_A B \) be the induced map; by proposition \[9.2.9\], we may find \( v' \in \text{Spv} B' \) whose image in \( \text{Spv} A' \) (resp. in \( \text{Spv} B \)) equals \( s' \) (resp. \( v \)), and in light of lemma \[9.2.25\] (i), it suffices to exhibit a primary generization \( w' \) of \( v' \) in \( \text{Spv} B' \) with \( \text{Spv}(f')(w') = t' \). However, since \( f' \) is flat, there exists a prime ideal \( \ell \subset q := \ker v' \in B' \), such that \( f^{-1}_{\ell} = 0 \) (\[100\] Th.9.5); we set \( B'' := B'/\ell B_q \) and we let \( f'' : A' \to B'' \) be the resulting map. There exists a unique valuation \( v'' \) of \( B'' \) whose image in \( \text{Spv} B' \) equals \( v' \), and it suffices to exhibit a primary generization \( w'' \) of \( v'' \) in \( \text{Spv} B'' \) such that \( \text{Spv}(f'')(w'') = t' \). To this aim, set \( K'' := \text{Frac} B'' \); by corollary \[9.1.24\] we may find a valuation ring \( V \) of \( K'' \) that dominates \( B'' \). Let \( \kappa'' \) be the residue field of \( V \), and denote by \( R \) the image of \( \kappa(v'')^+ \) in \( \kappa'' \); we may find a valuation ring \( V' \) of \( \kappa'' \) that dominates \( R \) (corollary \[9.1.24\]). Denote by \( V'' \subset V \) the preimage of \( V' \). Then \( V'' \) is a valuation ring of \( K'' \), and we may take for \( w'' \) the unique valuation of \( B'' \) with \( \kappa(w'')^+ = V'' \).

(ii) is an immediate consequence of (i), lemma \[9.2.25\] (iii) and proposition \[9.2.24\]. \( \square \)

**Theorem 9.2.27.** Let \( f : A \to B \) be an integral ring homomorphism, \( v \in \text{Spv} B \) any element. The following holds:

(i) If \( v' \in \text{Spv} B \) is a specialization of \( v \) with \( \text{Spv}(f)(v') = \text{Spv}(f)(v) \), then \( v = v' \).

(ii) \( \text{Spv} f \) restricts to a bijection from the set of primary specializations of \( v \) in \( \text{Spv} B \) to the set of primary specializations of \( \text{Spv}(f)(v) \) in \( \text{Spv} A \).

(iii) \( \text{Spv} f \) is specializing.

(iv) If \( f \) is injective, \( \text{Spv} f \) is surjective.

(v) If \( A \) is integral and normal, \( B \) is integral and \( f \) is injective, then \( \text{Spv} f \) restricts to a surjection from the set of primary generizations of \( v \) in \( \text{Spv} B \) onto the set of primary generizations of \( \text{Spv}(f)(v) \) in \( \text{Spv} A \).

**Proof.** Set \( w := \text{Spv}(f)(v) \), and let \( \Gamma_v \) and \( \Gamma_w \) be the value groups of \( v \) and \( w \).

(i): Let \( p \) and \( q \) be the supports of \( v \) and respectively \( v' \); under the current assumptions, we have \( f^{-1}p = f^{-1}q \), and \( q \) is a specialization of \( p \) in \( \text{Spec} B \); then \( q = q' \), by \[100\] Th.9.3(ii).

Taking into account proposition \[9.2.24\], we conclude that \( v' \) is a secondary specialization of \( v \).

However, since \( f \) is integral, it induces an isomorphism \( \Gamma_v \otimes Q \cong \Gamma_w \otimes Q \). On the other hand, we have a natural bijection between \( \text{Spec} \Gamma_v \) and the set \( S_v \) of secondary specializations of \( v \) in \( \text{Spv} B \), and likewise for the set \( S_w \) of secondary specializations of \( w \); taking into account remark \[9.1.2\](v), we deduce that \( f \) induces a bijection \( S_v \cong S_w \), whence the assertion.

(ii): We remark:

**Claim 9.2.28.** Under the assumptions of the theorem, let \( b \in B \) be any element. Then there exists \( a \in A \) such that \( v(b) \leq w(a) \).

**Proof of the claim.** Since \( f \) is integral, we may find \( a_1, \ldots, a_n \in A \) such that \( b^n + a_1 b^{n-1} + \cdots + a_n = 0 \). It follows that \( v(b)^n \leq v(b)^i \cdot w(a_{n-i}) \) for some \( i < n \). If \( v(b) = 0 \), there is nothing to prove; otherwise, we get \( v(b)^{n-1} \leq w(a_{n-i}) \). If \( v(b) \leq 1 \), there is nothing to prove; otherwise, we deduce that \( v(b) \leq w(a_{n-i}) \), as required.

From claim \[9.2.28\] it follows easily that \( c \Gamma_w = c \Gamma_v \cap \Gamma_w \), whence the assertion.

(iii) follows immediately from (ii), proposition \[9.2.24\] and lemma \[9.2.25\] (iii).

(iv): Notice first that \( \text{Spec} f \) is surjective, under these assumptions. Indeed, let \( p \subset A \) be any prime ideal, and pick a minimal prime ideal \( q \subset A \) contained in \( p \); the induced ring homomorphism \( f_q : A_q \to B_q \) is still injective, so \( B \not= 0 \); now, if \( q' \subset B_q \) is any prime ideal, then \( f_q^{-1}(q') = q \), and by \[100\] Th.9.4(i) there exists a specialization \( p' \) of \( q' \) in \( \text{Spec} B \) such that \( \text{Spec}(f)(p') = p \). Now, let \( w \in \text{Spv} A \) be any element, and \( p' \in \text{Spec} B \) any prime ideal
such that $f^{-1}p' = p := \text{Ker } w$; it follows easily from theorem [9.1.20] that there exists a valuation $w'$ of the residue field $\kappa(p')$ whose restriction to $\kappa(p)$ is equivalent to $v$.

(v): Let $w'$ be a primary specialization of $w$ in $\text{Spv } A$. We need to exhibit a primary specialization $v'$ of $v$ in $\text{Spv } B$ such that $\text{Spv}(f)(v') = w'$. To this aim, pick a normal algebraic field extension $E$ of $\text{Frac } A$ containing $\text{Frac } B$, and denote by $C$ the integral closure of $A$ in $E$. By (iv), we may find $w'', v'' \in \text{Spv } C$ such that $w''_{|A} = w'$ and $v''_{|B} = v$. By (ii), we may find a primary specialization $t$ of $w''$ in $\text{Spv } C$ such that $t_{|A} = w$. By construction, $t_{|A} = v''_{|A}$, so there exists an automorphism $h$ of the $A$-algebra $C$ such that $\text{Spv}(h)(t) = v''$ ([28] Ch.V, §2, no.3, Prop.6 and Ch.VI, §8, no.6, Cor.1)). It is easily seen that $v' := \text{Spv}(h)(w''_{|B})$ will do. □

**Theorem 9.2.29.** Let $f : A \to B$ be a finitely presented ring homomorphism, and $T \subset \text{Spv } B$ any constructible subset. Then $\text{Spv}(f)(T)$ is a constructible subset of $\text{Spv } A$.

**Proof.** We may assume that there exist elements $a_1, b_1, \ldots, a_n, b_n, c_1, d_1, \ldots, c_m, d_m \in B$ such that $T$ is the set of all $v \in \text{Spv } B$ with $v(a_i) < v(b_i)$ and $v(c_j) \leq v(d_j)$ for every $i = 1, \ldots, n$ and $j = 1, \ldots, m$. We remark:

**Claim 9.2.30.** The theorem holds if $\text{Spec } f$ is a closed immersion.

**Proof of the claim.** Indeed, in this case the map $f$ is a surjective map, whose kernel is a finitely generated ideal $I \subset A$. Pick a finite system $x_1, \ldots, x_r \in A$ of generators of $I$, and for every $i = 1, \ldots, n$, $j = 1, \ldots, m$ choose elements $a'_i, b'_i, c'_j, d'_j \in A$ whose images equal respectively $a_i, b_i, c_j, d_j$ in $B$. Then, $\text{Spv}(f)(T)$ is the constructible subset of $\text{Spv } A$ of all valuations $v$ of $A$ such that $v(x_k) = 0$ for every $k = 1, \ldots, r$, and $v(a'_i) < v(b'_i)$ and $v(c'_j) \leq v(d'_j)$ for every $i = 1, \ldots, n$ and $j = 1, \ldots, m$. ◇

**Claim 9.2.31.** (i) We may assume that $A$ and $B$ are $\mathbb{Z}$-algebras of finite type.

(ii) For every $\mathbb{Z}$-algebra $R$ of finite type, $\text{Spv}^+ R$ is a rational subset of $\text{Spv } R$ (notation of remark 9.2.4(v)).

**Proof of the claim.** (i): Indeed, we may write $A$ as the union of the filtered system $(A_\lambda \mid \lambda \in \Lambda)$ of its $\mathbb{Z}$-subalgebras of finite type, and then there exists $\lambda \in \Lambda$ such that $B = B_\lambda \otimes_{A_\lambda} A$ for a ring homomorphism $f_\lambda : A_\lambda \to B_\lambda$ of finite type. Moreover, after replacing $\lambda$ by a larger index, we may assume that there exist elements $a'_1, b'_1, \ldots, a'_n, b'_n, c'_j, d'_j, \ldots, c'_m, d'_m \in B_\lambda$ such that $a'_1 \otimes 1 = a_1, b'_1 \otimes 1 = b_1, c'_j \otimes 1 = c_j, d'_j \otimes 1 \in B, \text{ for every } i = 1, \ldots, n \text{ and } j = 1, \ldots, m$. Then we let $T' \subset \text{Spv } B_\lambda$ be the constructible subset of all $v \in \text{Spv } B_\lambda$ such that $v(a'_i) < v(b'_i)$ and $v(c'_j) \leq v(d'_j)$ for every $i = 1, \ldots, n$ and $j = 1, \ldots, m$. There follows a commutative diagram of topological spaces

$$
\begin{array}{ccc}
\text{Spv } B & \xrightarrow{\pi_B} & \text{Spv } B_\lambda \\
|spv f| & & |spv f_\lambda| \\
\text{Spv } A & \xrightarrow{\pi_A} & \text{Spv } A_\lambda
\end{array}
$$

Clearly $T = \pi_B^{-1}T'$, and it follows easily from proposition 9.2.9 that

$$
\pi_A^{-1}(\text{Spv}(f_\lambda)(T')) = \text{Spv}(f)(T).
$$

Since $\pi_A$ is spectral (remark 9.2.4(ii)), we are then reduced to showing that the theorem holds for the map $f_\lambda$. ◇

(ii): Pick a finite system $x_1, \ldots, x_r$ of elements of $R$ such that $R = \mathbb{Z}[x_1, \ldots, x_r]$; then it is easily seen that $\text{Spv}^+ R = R_\lambda(\mathbb{A}^+_r, \mathbb{A}^+_r)$.

Henceforth, we assume that $A$ and $B$ are $\mathbb{Z}$-algebras of finite type, and we set

$$
C := B[X_i, Y_j \mid i = 1, \ldots, n, \ j = 1, \ldots, m]/I
$$
where \( I \) is the ideal generated by the system \((a_i - X_i b_i, c_j - Y_j d_j \mid i = 1, \ldots, n, \ j = 1, \ldots, m)\). We let \( T' \subset \text{Spv} C \) be the constructible subset of all \( w \in \text{Spv} C \) such that

\[
0 < w(b_i) \quad w(X_i) < 1 \quad w(Y_j) \leq 1 \quad \text{for } 1 \leq i \leq n \text{ and } 1 \leq j \leq m
\]

and denote by \( g : B \to C \) the natural ring homomorphism.

**Claim 9.2.32.** \( \text{Spv}(g)(T') = T. \)

**Proof of the claim.** Let \( w \in T' \) be any element, and set \( v := \text{Spv}(g)(w) \); we may regard \( w \) as a valuation of \( B[X_1, \ldots, X_n, Y_1, \ldots, Y_m] \) such that \( w(b_i) > 0 \) and \( w(a_i) = w(X_i) \cdot w(b_i) \) for every \( i = 1, \ldots, n \), and \( w(c_j) = w(Y_j) \cdot w(d_j) \) for every \( j = 1, \ldots, m \). It follows easily that \( v \in T \). Conversely, let \( v \in T \) be any element, and set \( D := C \otimes_B \kappa(v) \). Moreover, set \( \Sigma := \{ 1 \leq j \leq m \mid v(d_j) = 0 \} \). A simple inspection yields an isomorphism

\[
h : D \xrightarrow{\sim} \kappa(v)[Y_j \mid j \in \Sigma]
\]

of \( \kappa(v) \)-algebras, such that:

- \( h(X_i) = h(a_i) \cdot h(b_i)^{-1} \) for \( i = 1, \ldots, n \)
- \( h(Y_j) = Y_j \) for \( j \in \Sigma \)
- \( h(Y_j) = h(c_j) \cdot h(d_j)^{-1} \) for every \( j \in \{ 1, \ldots, m \} \setminus \Sigma \).

Let \((V, m_V)\) be any valuation ring of \( \text{Frac} D \) containing \( \kappa(v)^+[Y_j \mid j \in \Sigma] \) and such that \( m_V \cap \kappa(v) \) is the maximal ideal of \( \kappa(v)^+ \) (Theorem 9.1.20); then \( V \) corresponds to a valuation \( \varpi \) of \( D \) whose restriction to \( \kappa(v) \) is equivalent to the residual valuation \( v \) of \( v \). So, \( \varpi \) induces a valuation \( w \) of \( C \) with \( \text{Spv}(g)(w) = v \), and by construction we have \( w(X_i) = v(a_i) \cdot v(b_i)^{-1} < 1 \) for every \( i = 1, \ldots, n \); likewise, we get \( w(Y_j) = v(c_j) \cdot v(d_j)^{-1} \leq 1 \) for \( j \in \Sigma \), and \( w(Y_j) \leq 1 \) for \( j \in \{ 1, \ldots, m \} \setminus \Sigma \). The claim follows.

In view of claim 9.2.32, we may replace \( B \) by \( C \), and \( T \) by \( T' \), after which we may assume:

(C) There exist finite sequences \( a_* := (a_1, \ldots, a_n), b_* := (b_0, b_1, \ldots, b_m) \) of elements of \( B \) such that

\[
T = R_B\left( b_0, \frac{b_1}{b_0}, \ldots, \frac{b_m}{b_0} \right) \setminus \left( R_B\left( \frac{1}{a_1} \right) \cup \cdots \cup R_B\left( \frac{1}{a_n} \right) \right).
\]

We shall argue by induction on the dimension of \( B \). Since \( B \) is noetherian, \( \text{Spec} B \) has finitely many irreducible components \( Z_1, \ldots, Z_k \), and

\[
\text{Spv} B = \bigcup_{i=1}^k \text{Spv} Z_i
\]

(notation of (9.2.6)); moreover, since the inclusion map \( Z_i \to \text{Spec} B \) is spectral, the subset \( \text{Spv} Z_i \cap T \) is constructible in \( \text{Spv} Z_i \), for every \( i = 1, \ldots, k \). Thus, it suffices to show that the restriction \( \text{Spv} Z_i \to \text{Spec} A \) of \( \text{Spv} f \) maps constructible subsets to constructible subsets, for every \( i = 1, \ldots, k \). We may therefore assume from start that \( \text{Spec} B \) is also irreducible and reduced, i.e. that \( B \) is a domain. Then, the topological closure \( W \) of \( \text{Spec}(f)(\text{Spec} B) \) in \( \text{Spec} A \) is irreducible (Lemma 8.1.3(v)); by virtue of claim 9.2.30 it suffices to show that the induced map \( \text{Spv} B \to \text{Spv} W \) sends constructible subsets to constructible subsets. We may then assume as well that \( A \) is a domain, and \( f \) is injective. In this situation, if \( \dim B = 0 \), we see that \( A \) and \( B \) are finite fields, and the assertion is obvious. Hence, we suppose henceforth that \( d := \dim B > 0 \), and that the theorem has already been shown for every \( \mathbb{Z} \)-algebra \( B \) of finite type of dimension \( < d \).
Pick finite subsets $I \subseteq A$ and $J \subseteq B$ such that $A = \mathbb{Z}[I]$ and $B = A[J]$ and $I \cap J = \emptyset$. For every pair of subsets $I' \subseteq I$ and $J' \subseteq J$ consider the constructible open subsets

$$S_A(I') := R_A \left( \frac{x}{1} \mid x \in I' \right) \cap R_A \left( \frac{1}{x} \mid x \in I \setminus I' \right) \subset \text{Spv } A$$

$$S_B(I', J') := R_B \left( \frac{x}{1} \mid x \in I' \cup J' \right) \cap R_B \left( \frac{1}{x} \mid x \in (I \cup J) \setminus (I' \cup J') \right) \subset \text{Spv } B.$$

Clearly $\text{Spv } A = \bigcup_{I' \subseteq I} S_A(I')$, and likewise for $\text{Spv } B$, so it suffices to show that the subset $\text{Spv}(f)(T \cap S_B(I', J'))$ is constructible in $S_A(I')$, for any such $I'$ and $J'$ (lemma [8.1.25 iii,a]).

Now, for given $I'$ and $J'$, let:

- $A_1 := \mathbb{Z}[I' \cup \{x^{-1} \mid x \in I \setminus I'\}] \subset \text{Frac } A$
- $A_2 := A_1[\{J' \cup \{x^{-1} \mid x \in J \setminus J'\} \cup a_1 \cup b_1\}] \subset \text{Frac } B$
- $A_2 := A \cdot A_1 \subset \text{Frac } A$ and $B_2 := B \cdot B_1 \subset \text{Frac } B$.

The natural inclusions maps $A \to B_2 \leftarrow A_1$ and $B \to B_2 \leftarrow B_1$ are localizations, so $\dim B_1 = \dim B_2 = d$ ([50, Ch.IV, Prop.10.6.1(ii)]), and $f$ extends to an injective ring homomorphism $f_2 : A_2 \to B_2$, which in turn restricts to a map $f_1 : A_1 \to B_1$. So we get a commutative diagram of continuous maps

$$\begin{array}{ccc}
\text{Spv } B_1 & \longrightarrow & \text{Spv } B_2 \\
\text{Spv } f_1 \downarrow & & \text{Spv } f_2 \downarrow \\
\text{Spv } A_1 & \longrightarrow & \text{Spv } A_2 \\
\end{array}$$

whose horizontal arrows are quasi-compact open immersions. Moreover, $S_A(I')$ and $S_B(I', J')$ lie respectively in the images of $\text{Spv } A_2$ and $\text{Spv } B_2$, and their images in $\text{Spv } A_1$ and $\text{Spv } B_1$ are the subsets

$$Z_A(I') := \{ v \in \text{Spv }^+ A_1 \mid v(x^{-1}) \neq 0 \text{ for every } x \in I \setminus I' \}$$

$$Z_B(I', J') := \{ v \in \text{Spv }^+ B_1 \mid v(x^{-1}) \neq 0 \text{ for every } x \in (I \cup J) \setminus (I' \cup J') \}.$$ 

Hence, we may replace $A$ by $A_1$, $B$ by $B_1$, and suppose that

$$T = \left( R_B \left( \frac{b_0}{b_0} \right) \setminus R_B \left( \frac{1}{b_1} \right) \cup \cdots \cup R_B \left( \frac{1}{b_n} \right) \right) \cap \text{Spv }^+ B \quad \text{for certains } b_0, \ldots, b_n \in B.$$

Next, by [69 Partie I, Th.5.2.2] we may find an integer $r > 0$ and elements $t_1, \ldots, t_r \in A \setminus \{0\}$ such that, for every $i = 1, \ldots, r$ the inclusion map of subrings of $B_i' := B[t_i^{-1}]$

$$A_i := A \left[ \frac{t_1}{t_i}, \ldots, \frac{t_r}{t_i} \right] \to B_i := B \left[ \frac{t_1}{t_i}, \ldots, \frac{t_r}{t_i} \right]$$

is flat. We consider the constructible subsets

$$S_0 := \{ v \in \text{Spv } B \mid v(t_i) = 0 \text{ for } i = 1, \ldots, r \} \quad S_i := R_B \left( \frac{t_1}{t_i}, \ldots, \frac{t_r}{t_i} \right) \quad (i = 1, \ldots, r).$$

Since $\text{Spv } B = \bigcup_{i=0}^r S_i$, it suffices to show that $\text{Spv}(f)(T \cap S_i)$ is constructible in $\text{Spv } A$ for every $i = 0, \ldots, r$. However, $T \cap S_0$ is a constructible subset of $\text{Spv } B/I$, where $I \subset B$ is the ideal generated by $t_1, \ldots, t_r$; since $\dim B/I < \dim B$, the inductive assumption yields the assertion for $i = 0$. For $i = 1, \ldots, r$, set $A_i' := A[t_i^{-1}]$; we get a commutative diagram of continuous maps

$$\begin{array}{ccc}
\text{Spv } B_i' & \longrightarrow & \text{Spv } B_i \\
\varphi_i' \downarrow & & \varphi_i \downarrow \\
\text{Spv } A_i' & \longrightarrow & \text{Spv } A_i \\
\psi_i \downarrow & & \psi_i \downarrow \\
& & \text{Spv } A
\end{array}$$
and we notice that the maps $\varphi'_i$, $\psi'_i$, $\psi_i \circ \varphi'_i$ and $\varphi_i \circ \varphi'_i$ are quasi-compact open immersions, and $T \cap S_i = \varphi_i(T_i)$, for the constructible subsets of $Spv B'_i$
\[
T_i := \left( R_{B_i}(t_i/b_0, b_0) \setminus \left( R_{B_i}(\frac{1}{b_1}) \cup \cdots \cup R_{B_i}(\frac{1}{b_n}) \right) \right) \cap Spv^+ B_i \subset \varphi'_i(Spv B'_i).
\]
In light of lemma [8.1.25 iii,x.a], it then suffices to show that the image of $T_i$ is constructible in $Spv A_i$. Thus, we may replace $A_i$, $B_i$, $t_i b_0$ and $T_i$, and assume furthermore that $f$ is a flat ring homomorphism.

Let $\varphi : Spec B/b_0B \to Spec A$ be the restriction of $Spec f$; there exists a non-empty affine open subset $U \subset Spec A$ such that the restriction $\varphi^{-1}U \to U$ of $\varphi$ is a flat morphism of schemes ([49 Ch.IV, Th.6.9.1]). For every $p \in U$, we have a short exact sequence of $A$-modules
\[
\mathcal{E} : 0 \to B_p \to B_p \to b_0B_p \to 0
\]
and the induced sequence $\mathcal{E} \otimes_A \kappa(p)$ is still exact, since $B_p/b_0B_p$ is a flat $A_p$-module (notation of definition [4.9.17](i)). In other words, we have :

(D) The image of $b_0$ in $B \otimes_A \kappa(p)$ is a regular element, for every $p \in U$.

Set
\[
Z := Spec A \setminus U \quad Z_B := Spec(f)^{-1} Z \quad U_B := Spec(f)^{-1} U.
\]
Then $Spv Z$ is a constructible closed subset of $Spv A$ and $Z_B$ is an affine scheme of dimension $< d$; also, $T' := T \cap Spv Z_B$ is a constructible subset of $Spv Z_B$, so our inductive assumption says that $Spv(f)(T')$ is constructible in $Spv A$. It remains therefore only to show that the subset
\[
Spv(f)(T' \cap Spv U_B)
\]
is constructible in $Spv^+ A$ (remark [9.2.4](v)). In light of claim [9.2.31](ii), to conclude the proof, it then suffices to show :

Claim 9.2.33. Under the current assumptions, we have
\[
Spv(f)(T \cap Spv U_B) = Spv^+ W \cap Spv U.
\]

Proof of the claim. A simple inspection shows that $Spv(f)(T) \subset Spv^+ W$, so it remains only to check that $Spv^+ W \cap Spv U \subset Spv(f)(T \cap Spv U_B)$. Now, let $v \in Spv^+ W \cap Spv U$ be any element, and let $\pi : A \to \kappa(v)$ be the induced map. Since $v \in Spv^+ A$, we have $Im \pi \subset V := \kappa(v)^+$, and we set $B' := B \otimes_A V$. Let also $m_V$ and $\eta_V$ be respectively the closed point and the generic point of $Spec V$; since $v \in Spv U$, the image of $\eta_V$ in $Spec A$ lies in $U$. By construction, there exists $p \in W$ such that $Spec f(p)$ is the center of $v$, i.e. the image of $m_V$ in $Spec A$ (see remark [9.2.4](v)). Then we may find $p' \in Spec B'$ whose images in $Spec B$ and $Spec V$ equal respectively $p$ and $m_V$. We pick a minimal prime ideal $q'$ of $B'$ contained in $p'$.Since $f$ is flat, the same holds for the induced map $V \to B \otimes_A V$, and therefore the image of $q'$ in $Spec V$ equals $\eta_V$ ([100 Th.9.5]); consequently the image of $q'$ in $Spec B$ lies in $U_B$. Let $b_0 \in B'$ be the image of $b_0$; from condition (D) and [100 Th.6.1(ii), Th.6.5(iii)], we deduce that
\[
(9.2.34)
\]
Choose a valuation ring $V'$ of the residue field $\kappa(q')$ that dominates the image of the local ring $B'_{p'}$ (corollary 9.1.24). Then, $V'$ corresponds to a point $v' \in Spec B$, and we notice that $Spv f(v') = v$ : indeed, the induced map $V \to \kappa(q')$ is injective, and $V'$ dominates the image of this map, whence the assertion. To conclude the proof of the claim, it suffices to check that $v' \in T' \cap Spv U_B$. However, (9.2.34) already implies that $v'(b_0) \neq 0$. Moreover, since $V'$ contains the image of $B$, we have $v(b_i) \leq 1$ for every $i = 1, \ldots, m$, and since the image of $p'$
lies in the maximal ideal of $V$, we have $v(b_i) < 1$ for every $i = 1, \ldots, n$. Thus, $v \in T$. Lastly, since the image of $q'$ in $\text{Spec } B$ lies in $U_B$, we get $v \in \text{Spv } U_B$ as well, as needed.

**Remark 9.2.35.** Our proof of theorem 9.2.29 employs crucially Gruson and Raynaud’s technique of flattening stratifications ([69]). On the other hand, Huber in [78] recovers this theorem rather easily via “elimination of quantifiers” for the first order theory of algebraically closed valued fields with non-trivial valuation. However, the latter is of course a deep model theoretic result, so Huber’s proof is hardly more elementary than ours.

We wish next to explain how the valuation spectrum can be applied to the study of integral closures of rings and ideals. We begin with the following:

**Definition 9.2.36.** Let $f : A \to B$ be any ring homomorphism, $I \subset A$ any ideal. The integral closure of $I$ in $B$ is the set denoted

$$i.c.(I, B)$$

and consisting of all $x \in B$ that satisfy, for some $n \in \mathbb{N}$, an equation of the type:

\[(9.2.37) \quad x^n + f(a_1) \cdot x^{n-1} + \cdots + f(a_n) = 0 \quad \text{where } a_j \in I^j \text{ for } j = 1, \ldots, n.
\]

Notice that for $I = A$, the set $i.c.(A, B)$ is the usual integral closure of $A$ in $B$. We have:

**Lemma 9.2.38.** In the situation of definition 9.2.36 let $b \in B$ be any element.

(i) The following conditions are equivalent:

(a) $b \in i.c.(I, B)$.

(b) $bU^\infty \in i.c.(R(A, I)_\kappa, R(B)_\kappa)$ (notation of example 7.9.3).

(ii) Especially, $i.c.(I, B)$ is an ideal of $i.c.(A, B)$.

(iii) For every prime ideal $p \in \text{Spec } B$, let $\overline{b}_p \in \kappa(p)$ denote the image of $b$ (notation of definition 4.9.17(ii)). The following conditions are equivalent:

(a) $b \in i.c.(I, B)$.

(b) $\overline{b}_p \in i.c.(I, \kappa(p))$ for every minimal prime ideal $p$ of $B$.

**Proof.** Suppose that $b$ satisfies an identity (9.2.37), and set $T := U^{-1}$ to ease notation; we get

\[(bT)^n + T \cdot f(a_1) \cdot (bT)^{n-1} + \cdots + T^n \cdot f(a_n) = 0
\]

where $T^j f(a_j) \in R(A, I)_\kappa$ for $j = 1, \ldots, n$. Conversely, suppose the $bT$ is integral over $R(A, I)_\kappa$, so that we have a monic polynomial $P(X) = X^n + u_1X^{n-1} + \cdots + u_n$, with coefficients in $R(A, I)_\kappa$, such that $P(bT) = 0$; for every $j = 1, \ldots, n$, denote by $v_j$ the component of $u_j$ in degree $n$ (for the grading of $R(A, I)_\kappa$; since $bT$ is homogeneous of degree 1, it follows that $(bT)^n + v_1 \cdot (bT)^{n-1} + \cdots + v_n = 0$, and letting $T = 1$, we deduce that $b$ is integral over $I$. This proves (i), and assertion (ii) is an immediate consequence.

(iii): Clearly (iii.a)$\Rightarrow$(iii.b), and for every minimal prime ideal $p$ of $B$, pick a monic polynomial $P_p(X) \in A[X]$, say of degree $n_p$, such that $P_p(\overline{b}_p) = 0$, and whose coefficient in degree $n_p - j$ lies in $I^j$, for $j = 1, \ldots, n_p$. For every such $p$, let $V_p \subset \text{Spec } B$ denote the subset of all prime ideals containing $P_p(b)$. Hence, $Z := \bigcup_{p \in \text{Min}(B)} V_p$ contains the set $\text{Min}(B)$ of minimal prime ideals of $B$; but each $V_p$ is a constructible closed subset of $\text{Spec } B$, hence $Z = \text{Spec } B$, and there exists a finite subset $S \subset \text{Min}(B)$ such that $\bigcup_{p \in S} V_p = \text{Spec } B$ (theorem 8.1.32(ii)). Set $P := \prod_{p \in S} P_p$; it follows that $P(b)$ lies in the nilpotent ideal of $B$, so $P^r(b) = 0$ for a sufficiently large $r \in \mathbb{N}$. However, let $N$ be the degree of $P^r$; it is easily seen that the coefficient in degree $N - j$ of $P^r$ lies in $I^j$, for every $j = 1, \ldots, N$ (details left to the reader), whence (iii.a).

Concerning integral closures of ideals, much more can be found in the treatise [81], a comprehensive reference for this subject. For our purposes, proposition 9.2.42 hereafter will suffice. For its proof, we shall employ the technical lemma 9.2.40 which shall be applied also later to
the study of the adic spectrum of a topological ring, and for this reason, is stated here in wider generality than needed for our immediate purposes in this section.

9.2.39. Let $B$ be any ring, $A \subset B$ a subring, $I$ an ideal of $A$, and $\Sigma, \Sigma'$ two sets; denote by $\mathcal{P}_I$ the subset of the free polynomial $A$-algebra

$$R[Z] \quad \text{where} \quad R := A[X_i, Y_j \mid i \in \Sigma, j \in \Sigma']$$

consisting of all polynomials $P$ fulfilling the following conditions:

- We have $P = Z^n + \sum_{k=1}^n Z^{n-k} \cdot P_k(X_\bullet, Y_\bullet)$ for some $P_1, \ldots, P_n \in R$ such that $P_k$ is homogeneous of degree $k$ for every $k = 1, \ldots, n$ (for the standard $\mathbb{N}$-grading on $R$ such that $X_i, Y_j \in \deg_i R$ for every $i \in \Sigma$ and $j \in \Sigma'$).
- For every $k = 1, \ldots, n$, denote by $P_k(0, Y_\bullet)$ the image of $P_k$ by the evaluation map $R \to A[Y_j \mid j \in \Sigma']$ such that $X_i \mapsto 0$ for every $i \in \Sigma$; then $P_k(0, Y_j) \in I[Y_i \mid j \in \Sigma']$.

Set as well

$$T := \{v \in \text{Spv } B \mid v(a) \leq 1 \text{ and } v(b) < 1 \text{ for every } a \in A \text{ and } b \in I\}$$

$$T_0 := \{v \in T \mid \text{Ker } v \text{ is a minimal prime ideal of } B\}.$$

Notice that $T$ is a pro-constructible subset of $\text{Spv } B$, and it contains all the primary generizations of its points.

**Lemma 9.2.40.** In the situation of (9.2.39), suppose moreover that $I$ is contained in the Jacobson radical of $A$, and let also $(g_i \mid i \in \Sigma)$ and $(h_j \mid j \in \Sigma')$ be two systems of elements of $B$. Then for every $f \in B$ the following conditions are equivalent:

(a) For every $v \in T$ with $v(f) \neq 0$ there exists either $i \in \Sigma$ such that $v(f) \leq v(g_i)$ or else $j \in \Sigma'$ such that $v(f) < v(h_j)$.

(b) For every $v \in T_0$ with $v(f) \neq 0$ there exists either $i \in \Sigma$ such that $v(f) \leq v(g_i)$ or else $j \in \Sigma'$ such that $v(f) < v(h_j)$.

(c) There exists a polynomial $P \in \mathcal{P}_I$ such that $P(f, g_\bullet, h_\bullet) = 0$ in $B$.

**Proof.** (c)$\Rightarrow$(a): Let $P \in \mathcal{P}_I$ such that (c) holds, and write $P = Z^n + \sum_{k=1}^n Z^{n-k} \cdot P_k(X_\bullet, Y_\bullet)$ for some $P_1, \ldots, P_n \in R$. Fix $v \in T$; then there exists $k \leq n$ such that

$$v(f^n) \leq v(f^{n-k} \cdot P_k(g_\bullet, h_\bullet)).$$

If $v(f) = 0$, there is nothing to show; otherwise, we deduce that $v(f^k) \leq v(P_k(g_\bullet, h_\bullet))$. By assumption, $P_k$ is homogeneous of degree $k$, so there exist two systems of non-negative integers $\nu_\bullet := (\nu_i \mid i \in \Sigma)$, $\mu_\bullet := (\mu_j \mid j \in \Sigma')$, and an element $a \in A$ such that the monomial $aX_\bullet^\nu \cdot Y_\bullet^\mu$ appears in $P_k$ and

$$v(f^k) \leq v(a) \cdot v(g_\bullet^\nu) \cdot v(h_\bullet^\mu).$$

Especially, set $|\nu_\bullet| := \sum_{i \in \Sigma} \nu_i$, and define likewise $|\mu_\bullet|$; then $|\nu_\bullet| + |\mu_\bullet| = k$. Suppose first that $|\nu_\bullet| > 0$; if there exists $i \in I$ with $v(f) \leq v(g_i)$, we are done. Otherwise, we have $v(f^{\nu_\bullet}) > v(g_\bullet^\nu)$, and therefore $v(f^{\nu_\bullet}) < v(h_\bullet^\mu)$, since $v(a) \leq 1$. In this case, we easily get $v(f) < v(h_j)$ for some $j \in \Sigma'$. Lastly, if $|\nu_\bullet| = 0$, by assumption we must have $a \in I$, so that $v(a) < 1$, and therefore $v(f^k) < v(h_\bullet^\mu)$, so we conclude as in the previous case.

(a)$\Rightarrow$(b) is obvious.

(b)$\Rightarrow$(c): We suppose that (c) fails, and we exhibit $v \in T_0$ such that $v(f) \neq 0$ and $v(g_i) < v(f)$, $v(h_j) \leq v(f)$ for every $i \in \Sigma$ and $j \in \Sigma'$. To this aim, consider the subring

$$A' := A[g_i/f, h_j/f \mid i \in \Sigma, j \in \Sigma'] \subset B' := B[f^{-1}]$$

and the ideal $J_0$ of $A'$ generated by the system $(g_i/f \mid i \in \Sigma)$; set $J := J_0 + IA'$.

**Claim 9.2.41.** If (c) fails, we have $J \neq A'$. 

Proof of the claim. If $J = A'$, we may find an expression of the form

$$1 = \sum_{i \in \Sigma} \frac{g_i}{f} \cdot F_i\left(\frac{g_i}{f}, \frac{h_i}{f}\right) + \sum_{k=1}^{r} a_k \cdot G_k\left(\frac{g_k}{f}, \frac{h_k}{f}\right) \quad \text{in } A'$$

for systems $(F_i(X_*, Y_*) \mid i \in \Sigma)$ and $(G_k(X_*, Y_*) \mid k = 1, \ldots, r)$ of elements of $R$, with $F_i = 0$ except for finitely many values of $i \in \Sigma$, and a system $(a_1, \ldots, a_r)$ of elements of $I$. We may then multiply both sides of this identity by $f^{n+1}$ for a sufficiently large $n \in \mathbb{N}$, and obtain an identity in $A$ of the form $P(f, g_*, h_*) = 0$, with

$$P(Z, X_*, Y_*) = Z^{n+1} - \sum_{i \in \Sigma} Z^n \cdot X_i \cdot F_i(X_*/Z, Y_*/Z) - \sum_{k=1}^{r} Z^{n+1} \cdot a_k \cdot G_k(X_*/Z, Y_*/Z).$$

A simple inspection shows that the coefficient of the monomial $Z^{n+1}$ appearing in $P$ is of the form $1 - a$ for some $a \in I$; namely, $a$ is the sum of the terms $a_k$ such that $G_k \in A$. However, $1 - a \in A^\times$, since $I$ is contained in the Jacobson radical of $A$; to conclude the proof, it suffices to observe that $(1 - a)^{-1} \cdot P \in \mathcal{P}_f$; details left to the reader. \hfill \Box

By virtue of claim 9.2.41, we may find a maximal ideal $m$ of $A'$ containing $J$, and we let $p \subset m$ be any minimal prime ideal of $A'$; then $A'_p \subset B'_p$ and we pick any minimal prime ideal $q$ of $B'_p$. Clearly $q \cap A'_p = pA'_p$, so the induced map $C := A'/p \to D := B'_p/q$ is still injective. Let $\overline{m} \subset C$ be the image of $m$; by corollary 9.1.24 we may find a valuation ring $V$ of $\text{Frac } D$ that dominates $C_{\overline{m}}$. The valuation ring $V$ corresponds to an element $v \in T_0$ with the required properties. \hfill \Box

Proposition 9.2.42. Let $i : A \to B$ be an injective ring homomorphism, $J$ any ideal of $A$. Set

$$\mathcal{V}_{B/A} := \text{Spv}(i)^{-1}(\text{Spv}^+ A) \quad \mathcal{V}_{0/B/A} := \{v \in \mathcal{V}_{B/A} \mid \text{ker } v \text{ is a minimal prime ideal of } B\}.$$

For every $v \in \mathcal{V}_{B/A}$, let also $\pi_v : B \to \kappa(v)$ be the natural map. Then we have :

$$i.c.(J, B) = \bigcap_{v \in \mathcal{V}_{B/A}} \pi_v^{-1}(J \cdot \kappa(v)^+) = \bigcap_{v \in \mathcal{V}_{0/B/A}} \pi_v^{-1}(J \cdot \kappa(v)^+).$$

Proof. By applying lemma 9.2.40 with $I = 0$, $(g_i \mid i \in \Sigma)$ any (non-empty) set of generators for $J$, and $\Sigma = \emptyset$, we see that $i.c.(J, B)$ is the set of elements $f \in B$ such that the following holds. For every $v \in \mathcal{V}_{B/A}$ (respectively, for every $v \in \mathcal{V}_{0/B/A}$) there exists $i \in \Sigma$ with $v(f) \leq v(g_i)$. The proposition is an immediate consequence. \hfill \Box

Remark 9.2.43. For every ring homomorphism $f : A \to B$, every ideal $I \subset A$, and every $q \in \mathbb{Q}_+$, write $q = m/n$ for integers $m, n \in \mathbb{N}$, and let

$$i.c.(I, B, q) := \{b \in B \mid b^n \in i.c.(I^m, B)\}.$$

(i) Define $\mathcal{V}_{B/A} := \text{Spv}(f)^{-1}(\text{Spv}^+ A)$. We claim that $i.c.(I, B, q)$ is the set of all $b \in B$ fulfilling the following condition. For every $v \in \mathcal{V}_{B/A}$ there exists $x \in I$ such that $v(b) \leq v(f(x))^q$ (see remark 9.1.2(ii)). Indeed, by proposition 9.2.42 we have :

$$i.c.(I, B, q) = \{b \in B \mid \pi_v(b^n) \in I^m \cdot \kappa(v)^+ \text{ for every } v \in \mathcal{V}_{B/A}\}.$$

The latter condition can be restated as follows. For every $v \in \mathcal{V}_{B/A}$ there exists $x \in I^m \cdot \kappa(v)^+$ such that $v(b^n) \leq v(x)$. We may write such $x$ as a sum $\sum_{i=1}^{k} f(x_i) \cdot y_i$ for certain $x_i \in I^m$, $y_i \in V$, and then $v(x) \leq v(f(x_i))$ for at least one index $i \leq r$. By the same token, we may assume that $x_i$ is a product $a_1 a_2 \cdots a_m$ of elements of $I$, and then $v(x_i) \leq v(f(a_j)^m)$ for at least one index $j \leq m$. 

Foundations for Almost Ring Theory 797
(ii) Especially, (i) shows that \( \i.c.(I, B, q) \) depends only on \( q \) (and not on the integers \( m, n \)). Notice as well that

\[(9.2.44) \quad \i.c.(I^m, B) = \i.c.(I, B, m) \quad \text{for every } m \in \mathbb{N}.\]

Moreover, a simple inspection of the definition reveals that \( \i.c.(I, B, q) \subset \i.c.(A, B) \), and then the criterion of (i) also implies that \( \i.c.(I, B, q) \) is an ideal of \( \i.c.(A, B) \), for every \( q \in \mathbb{Q}_+ \). Furthermore, we have

\[(9.2.45) \quad \i.c.(I, B, q) = \i.c.(\i.c.(I, A), B, q) \quad \text{for every } q \in \mathbb{Q}_+.\]

Indeed, since \( I \subset \i.c.(I, A) \), we have obviously \( \i.c.(I, B, q) \subset \i.c.(\i.c.(I, A), B, q) \). Conversely, if \( b \in \i.c.(\i.c.(I, A), B, q) \) and \( \nu \in \mathcal{V}_{B/A} \) is any element, (i) says that there exists \( x \in \i.c.(I, A) \) such that \( \nu(b) \leq \nu(f(x))^q \); by the same token, there exists \( y \in I \) such that \( \nu(x) \leq \nu(f(y))^q \), which shows that \( b \in \i.c.(I, B, q) \). Next, let us set

\[
\overline{\i.c.}(I, B, r) := \bigcap_{q \in \mathbb{Q}_+} \bigcap_{q < r} \i.c.(I, B, q)
\]

and define as well \( \overline{\i.c.}(I, B, 0) := \i.c.(A, B) \). Denote also by \( \mathcal{R}_{B/A} \) the set of all real valued valuations \( | \cdot | \) on \( B \) that lie in \( \mathcal{V}_{B/A} \). We have:

**Lemma 9.2.46.** With the notation of remark 9.2.43(ii), let \( r \in \mathbb{R}_+ \) be any real number, \( b \in B \) any element, and denote by \( A[b] \) the \( A \)-subalgebra of \( B \) generated by \( b \). The following conditions are equivalent:

(a) \( b \in \overline{\i.c.}(I, B, r) \).

(b) \( |b| \leq \sup_{x \in I} |f(x)|^r \) for every element \( \cdot | \) of \( \mathcal{R}_{A[b]/A} \).

**Proof.** (a)\( \Rightarrow \)(b): The assumption means that \( b \in \i.c.(A, A[b], q) \) for every non-negative rational number \( q < r \). By remark 9.2.43(iii), this implies that, for every \( | \cdot | \) in \( \mathcal{R}_{A[b]/A} \) and every such \( q \), there exists \( x \in I \) such that \( |b| \leq |f(x)|^q \). Assertion (b) is an immediate consequence.

(b)\( \Rightarrow \)(a): Suppose first that \( r = 0 \). In this case, we have \( |b| \leq 1 \) for every \( \mathcal{R}_{A[b]/A} \), and we need to show that \( b \in \i.c.(A, B) \). Suppose, that the latter fails; then, by remark 9.2.43(i), there exist a valuation \( | \cdot | \) in \( \mathcal{V}_{A[b]/A} \) such that \( |b| > 1 \). It is easily seen that the characteristic subgroup of \( | \cdot | \) equals \( \Delta := O(b) \) (notation of \( 9.2.10 \) and remark \( 9.1.2 \)(ii)), hence \( | \cdot | \Delta \) is still an element of \( \mathcal{V}_{A[b]/A} \) and \( |b|^\Delta > 1 \) (lemma \( 9.2.11 \)(ii)). We may therefore assume that the value group of \( | \cdot | \) equals \( \Delta \), and \( | \cdot | := | \cdot |_o(b) \) is then a valuation of rank one (lemma \( 9.2.11 \)(i) and remark \( 9.1.2 \)(ii)). Lastly, \( | \cdot | \) is equivalent to an element of \( \mathcal{R}_{A[b]/A} \), by remark \( 9.1.2 \)(vi), and by construction we have \( |b'| > 1 \), a contradiction.

Next, suppose that \( q > 0 \), in which case – by remark 9.2.43(i) – it suffices to show that, for every \( | \cdot | \) in \( \mathcal{V}_{A[b]/A} \) and every non-negative rational number \( q < r \), there exists \( x \in I \) such that \( |b| \leq |f(x)|^q \). However, by the foregoing case we know already that \( |b| \leq 1 \) for every such \( | \cdot | \).

- If \( |b| = 0 \), there is nothing to prove, so suppose now that \( 0 < |b| < 1 \), and set \( \Delta := O(b) \), \( \Delta' := o([b]) \); notice also that the characteristic subgroup of \( | \cdot | \) is \( \{1\} \), hence \( | \cdot | \Delta \) lies still in \( \mathcal{V}_{A[b]/A} \) (lemma \( 9.2.11 \)(ii)) and \( |b|^\Delta = |b| \). The same then holds for \( | \cdot |' := | \cdot |_{\Delta'} \) (lemma \( 9.2.11 \)(i)), and as in the foregoing, we see that the latter valuation is equivalent to an element of \( \mathcal{R}_{A[b]/A} \). Moreover, since \( |b| \notin \Delta' \), we still have \( |b'| < 1 \). Assumption (b) then implies that \( |b'| \leq \sup_{x \in I} |f(x)|^r \). Explicitly, for every real number \( \varepsilon > 0 \) there exists \( x_e \in I \) such that \( |f(x_e)|^r > |b' - \varepsilon| \). Then \( |f(x_e)|^q > t_e := (|b' - \varepsilon|)^r/q \), and since \( q/r < 1 \) and \( |b'| < 1 \), we may find \( \varepsilon \) small enough, so that \( t_e > |b'| \), and consequently \( |f(x_e)|^q > |b'| \). It follows that \( |f(x_e)|^q > |b'| \), as required.

- Lastly, suppose that \( |b| = 1 \). In this case, we must exhibit some \( x \in I \) with \( |f(x)| = 1 \). Suppose that no such element exist, and let \( \pi : A[b] \to \kappa := \kappa(\cdot |) \) be the projection (notation of remark \( 9.1.4 \)(v)); in the current situation, the image of \( \pi \) lies in the valuation ring \( \kappa^+ \) of the
induced valuation $|·|_κ$, and the assumption means that $\pi(I)$ lies in the maximal ideal $\mathfrak{m}$ of $κ^+$. Then, denote by $|·|''_κ$ the trivial valuation on $κ^+/\mathfrak{m}$; the composition of $|·|''_κ$ with the induced projection $A \to κ^+/\mathfrak{m}$ gives an element $|·|''_A$ of $\mathscr{R}_A[β]/A$ such that $|β|''_A = 1$ and $|f(x)|''_A = 0$ for every $x ∈ I$, contradicting assumption (b).

For future reference, we point out the following “approximation lemma” for integral closures:

**Lemma 9.2.47.** Let $A$ be any ring, $a_• := (a_1, \ldots, a_n)$ and $b_• := (b_1, \ldots, b_n)$ two sequences of elements of $A$, and $q > 1$ any rational number such that

$$b_i - a_i ∈ \text{i.c.}(I, A, q) \quad \text{for every } i = 1, \ldots, n.$$ 

Denote by $I ⊂ A$ (resp. $J ⊂ A$) the ideal generated by $a_•$ (resp. by $b_•$), and suppose that:

(a) either, the radical of $I$ equals the radical of $J$

(b) or else, $I$ is contained in the Jacobson radical of $A$.

Then $\text{i.c.}(I, A) = \text{i.c.}(J, A)$.

**Proof.** Since $\text{i.c.}(I, A, q) ⊂ \text{i.c.}(I, A)$, it is clear that $\text{i.c.}(J, A) ⊂ \text{i.c.}(I, A)$. To show the converse inclusion, set

$$r_v := \max(v(a_1), \ldots, v(a_n)) \quad s_v := \max(v(b_1), \ldots, v(b_n)) \quad \text{for every } v ∈ \text{Spv } A^+.$$ 

By virtue of proposition 9.2.42, it suffices to check that $s_v ≥ r_v$ for every such $v$. Now, suppose first that (a) holds, and say that $r_v = v(a_i)$ for some $i ≤ n$; under our assumptions, remark 9.2.43(iii) implies that $v(b_j - a_j) ≤ r^q_v$ for every $j = 1, \ldots, n$. If $r_v = 1$, the ideal $I$ is not contained in the center of $v$ (see remark 9.2.43(v)), and then the same holds for $J$, so that $s_v = 1$ as well. If $r_v = 0$, we get $v(b_j - a_j) = 0$ for every $j ≤ n$, whence $s_v = 0$ as well. Lastly, if $0 < s_v < 1$, we get $s^q_v < s_v$, so that $v(a_i) = v(b_i)$, and thus $s_v ≥ r_v$ again.

Next, suppose that (b) holds, and let $v ∈ \text{Spv } A$ be any valuation; again, we need to show that $s_v ≥ r_v$, and by virtue of proposition 9.2.16(iii) we may assume that the center $p$ of $v$ is a maximal ideal of $A$; especially $I ⊂ p$, in which case $r_v < 1$, and we argue as in the previous case, to conclude. □

We shall continue in section 9.3 the study of the class of ideals considered in remark 9.2.43. We shall be especially interested in the case where $A = B$ is a perfect topological $\mathbb{F}_p$-algebra: see lemma 9.3.75 which in turn shall be useful for our investigation of the finer topological properties of the ring $W(A)$ of Witt vectors over $A$.

### 9.3. Witt vectors

This reviews the ring of $p$-typical Witt vectors associated with an arbitrary ring; the basic reference is [28] Ch.IX. §1, though our treatment is self-contained and pays greater attention to the topological aspects of the theory.

Henceforth we fix a prime number $p$ and we set $\mathbb{F}_p := \mathbb{Z}/p\mathbb{Z}$.

**Definition 9.3.1.** Let $M$ be the free monoid with basis $\{X_i, Y_i \mid i ∈ \mathbb{N}\}$, and consider the morphism of monoids

$$\deg : M → \mathbb{N}^{⊕2} \quad \text{such that} \quad \deg(X_i) := (p^i, 0) \quad \deg(Y_i) := (0, p^i) \quad \text{for every } i ∈ \mathbb{N}.$$ 

Let $P ∈ \mathbb{Z}[M] = \mathbb{Z}[X_i, Y_i \mid i ∈ \mathbb{N}]$ be any polynomial; we can write uniquely $P = \sum_{i=1}^k n_i P_i$ for integers $n_1, \ldots, n_k ∈ \mathbb{Z} \setminus \{0\}$ and distinct monomials $P_1, \ldots, P_k ∈ M$, and we say that:

- $P$ is bihomogeneous of degree $(a, b) ∈ \mathbb{N}^{⊕2}$, if $\deg(P_i) = (a, b)$ for every $i = 1, \ldots, k$
- $P$ is homogeneous of total degree $d ∈ \mathbb{N}$, if $\deg(P_i) = (a_i, b_i)$ with integers $a_i, b_i ∈ \mathbb{N}$ such that $a_i + b_i = d$, for every $i = 1, \ldots, k$. 

9.3.2. Following [28, Ch. IX, §1, n.1] one defines, for every $n \in \mathbb{N}$, the $n$-th Witt polynomial

$$\omega_n(X_0, \ldots, X_n) := \sum_{i=0}^{n} p^i X_i^{p^n-i} \in \mathbb{Z}[X_0, \ldots, X_n].$$

Notice the inductive relations:

$$\omega_{n+1}(X_0, \ldots, X_{n+1}) = \omega_n(X_0^p, \ldots, X_n^p) + p^{n+1}X_{n+1}$$

(9.3.3)

Let $A$ be any ring; for every $n \in \mathbb{N}$, and every $a := (a_n \mid n \in \mathbb{N}) \in A^\mathbb{N}$, the element

$$\omega_n(a) := \omega_n(a_0, \ldots, a_n) \in A$$

is called the $n$-th ghost component of $a$, and we consider the ghost map

$$\omega_A : A^\mathbb{N} \to A^\mathbb{N} \quad a \mapsto (\omega_n(a) \mid n \in \mathbb{N}).$$

**Lemma 9.3.4.** Let $A$ be a ring, $(J_n \mid n \in \mathbb{N})$ a sequence of ideals of $A$, such that

$$pJ_n + J_n^p \subset J_{n+1} \subset J_n$$

for every $n \in \mathbb{N}$.

Let also $x, y \in A$ be any two elements, and $a, b \in A^\mathbb{N}$ any two sequences. The following holds:

(i) If $x \equiv y \pmod{J_0}$, we have $x p^n \equiv y p^n \pmod{J_n}$ for every $n \in \mathbb{N}$.

(ii) If $a_i \equiv b_i \pmod{J_m}$ for every $i = 0, \ldots, n$, then $\omega_i(a) \equiv \omega_i(b) \pmod{J_{m+i}}$ for every $i = 0, \ldots, n$.

**Proof.** (i) is left to the reader, and (ii) follows easily from (i). \qed

**Proposition 9.3.5.** With the notation of (9.3.2), we have:

(i) If $p$ is a regular (resp. invertible) element in $A$, then $\omega_A$ is injective (resp. bijective).

(ii) Suppose that $A$ admits a ring endomorphism $\varphi : A \to A$ such that

$$\varphi(a) \equiv a^p \pmod{pA}$$

for every $a \in A$.

Then $\text{Im} \ \omega_A = \{ b \in A^\mathbb{N} \mid \varphi(b_n) \equiv b_{n+1} \pmod{p^{n+1}A} \text{ for every } n \in \mathbb{N} \}$. Especially, $\text{Im} \ \omega_A$ is a subring of $A^\mathbb{N}$.

**Proof.** (i): Indeed, (9.3.3) shows that the condition $\omega_n(a) = b$ is equivalent to the identities

$$b_0 = a_0$$

and

$$b_n = \omega_n-1(a_0^p, \ldots, a_{n-1}^p) + p^n a_n$$

for every $n \geq 1$

whence the assertion.

(ii): An easy induction argument reduces the assertion to the following:

**Claim 9.3.6.** Let $n > 0$ be any integer, and $a_0, \ldots, a_{n-1}, b_n \in A$ any sequence of elements. Set

$$b_{n-1} := \omega_{n-1}(a_0, \ldots, a_{n-1}).$$

Then the following conditions are equivalent:

(a) There exists $a_n \in A$ such that $b_n = \omega_n(a_0, \ldots, a_n)$.

(b) $\varphi(b_{n-1}) \equiv b_n \pmod{p^nA}$.

**Proof of the claim.** We apply lemma 9.3.4(ii) to the filtration $(p^nA \mid n \in \mathbb{N})$, to deduce that

$$\omega_n(a_0, \ldots, a_{n-1}, x) \equiv \omega_{n-1}(a_0^p, \ldots, a_{n-1}^p) \pmod{p^nA}$$

(by (9.3.3))

$$\equiv \omega_{n-1}(\varphi(a_0), \ldots, \varphi(a_{n-1})) \pmod{p^nA}$$

$$\equiv \varphi(b_{n-1}) \pmod{p^nA}$$

for every $x \in A$. The claim is an immediate consequence. \qed
9.3.7. Take now \( A := \mathbb{Z}[X_i, Y_i \mid i \in \mathbb{N}] \), and let \( \varphi : A \to A \) be the endomorphism such that 
\[ \varphi(X_i) = X_i^p \] \( \varphi(Y_i) = Y_i^p \) for every \( i \in \mathbb{N} \). Clearly \( \varphi \) fulfills the condition of proposition 9.3.5(ii); from proposition 9.3.5 and (9.3.3) we deduce that there exist polynomials 
\[ S_n, P_n \in \mathbb{Z}[X_0, \ldots, X_n, Y_0, \ldots, Y_n] \quad I_n \in \mathbb{Z}[X_0, \ldots, X_n] \quad F_n \in \mathbb{Z}[X_0, \ldots, X_{n+1}] \]
uniquely characterized, for every \( n \in \mathbb{N} \), by the identities:

\[ \omega_n(S_0, \ldots, S_n) = \omega_n(X_0, \ldots, X_n) + \omega_n(Y_0, \ldots, Y_n) \]
\[ \omega_n(P_0, \ldots, P_n) = \omega_n(X_0, \ldots, X_n) \cdot \omega_n(Y_0, \ldots, Y_n) \]
\[ \omega_n(I_0, \ldots, I_n) = -\omega_n(X_0, \ldots, X_n) \]
\[ \omega_n(F_0, \ldots, F_n) = \omega_n+1(X_0, \ldots, X_{n+1}). \]

**Remark 9.3.8.** (i) Notice that for every \( n \in \mathbb{N} \), the polynomial \( \omega_n \) is bihomogeneous of degree \( (p^n, 0) \). By a simple induction argument, it follows easily that \( S_n \) is homogeneous of total degree \( p^n \), and \( P_n \) (resp. \( I_n \), resp. \( F_n \)) is bihomogeneous (resp. homogeneous) of degree \( (p^n, p^n) \) (resp. \( p^n \), resp. \( p^{n+1} \)), for every \( n \in \mathbb{N} \).

(ii) For example, a simple calculation yields the formulae:

\[
S_0 = X_0 + Y_0 \\
S_1 = X_1 + Y_1 - \sum_{i=1}^{p-1} \frac{1}{p} \binom{p}{i} X_0^i Y_0^{p-i} \\
P_0 = X_0 Y_0 \\
P_1 = X_0^p Y_1 + X_1 Y_0^p + p X_1 Y_1 \\
I_0 = -X_0 \\
I_1 = -X_1 - \varepsilon \cdot X_0^p \\
F_0 = X_0^p + pX_1 \\
F_1 = (1 - p^{-1})X_0^p + pX_2 - \sum_{i=1}^{p-1} \frac{1}{p} \binom{p}{i} X_0^i (pX_1)^{p-i}.
\]

where \( \varepsilon = 1 \) if \( p = 2 \), and \( \varepsilon = 0 \) if \( p > 2 \). Also, since \( \omega_n(0, \ldots, 0, X_n) = p^n X_n \), we see that

\[ (9.3.9) \quad S_n(0, \ldots, 0, X_n, 0, \ldots, 0, Y_n) = X_n + Y_n \quad \text{for every } n \in \mathbb{N} \]

(iii) A simple induction shows that:

\[ (9.3.10) \quad F_n \equiv X_n^p \quad \text{(mod } p\mathbb{Z}[X_0, \ldots, X_{n+1}]\text{)} \quad \text{for every } n \in \mathbb{N}. \]

Indeed, for \( n = 0 \) the assertion is clear from (ii). Suppose that \( n > 0 \), and that the assertion is already known for every integer \( < n \), and to ease notation, set \( A := \mathbb{Z}[X_0, \ldots, X_{n+1}] \) and \( \omega_n(F) := \omega_n(F_0, \ldots, F_n) \); from (9.3.3) we get

\[ \omega_n(F) \equiv \omega_n(X_0^p, \ldots, X_n^p) \equiv \omega_{n-1}(X_0^{p^2}, \ldots, X_{n-1}^{p^2}) + p^n X_n^p \quad \text{(mod } p^{n+1}A\text{)} \]

On the other hand, the inductive assumption, together with lemma 9.3.4(i,ii) implies that

\[ \omega_n(F) \equiv \omega_{n-1}(F_0^p, \ldots, F_{n-1}^p) + p^n F_n \equiv \omega_{n-1}(X_0^{p^2}, \ldots, X_{n-1}^{p^2}) + p^n F_n \quad \text{(mod } p^{n+1}A\text{)} \]

therefore \( p^n F_n \equiv p^n X_n^p \) (mod \( p^n A \)), and the assertion follows.

9.3.11. Let now \((A, +, \cdot, \mathcal{T})\) be an arbitrary topological ring (see definition 8.3.1(i)). We endow \( A^\mathbb{N} \) with the topology \( \mathcal{T}_{W(A)} \) defined as the product of the topologies \( \mathcal{T} \) on each copy of \( A \), and for every \( a := (a_n \mid n \in \mathbb{N}), b := (b_n \mid n \in \mathbb{N}) \) in \( A^\mathbb{N} \), we set:

\[ S_A(a, b) := (S_n(a_0, \ldots, a_n, b_0, \ldots, b_n) \mid n \in \mathbb{N}) \]
\[ P_A(a, b) := (P_n(a_0, \ldots, a_n, b_0, \ldots, b_n) \mid n \in \mathbb{N}) \]
\[ I_A(a) := (I_n(a_0, \ldots, a_n) \mid n \in \mathbb{N}) \].
Moreover, the opposite whose zero element and unit element are respectively the sequences
\[(9.3.12)\quad S_A \circ (\psi^N \times \psi^N) = \psi^N \circ S_B \quad P_A \circ (\psi^N \times \psi^N) = \psi^N \circ P_B \quad I_A \circ \psi^N = \psi^N \circ I_B.\]

**Theorem 9.3.13.** With the notation of [9.3.11], the set \(A^n\), endowed with the addition law \(S_A : A^n \times A^n \to A^n\) and product law \(P_A : A^n \times A^n \to A^n\) is a commutative topological ring, whose zero element and unit element are respectively the sequences
\[0_A := (0, 0, \ldots) \quad \text{and} \quad 1_A := (1, 0, 0, \ldots).\]

Moreover, the opposite \(-\bar{a}\) (that is, with respect to the addition law \(S_A\)) of any \(\bar{a} \in A^n\), is the element \(I_A(\bar{a})\).

**Proof.** It is clear that \(S_A, P_A, I_A\) are continuous mapping for the topology \(\mathcal{T}_{W(A)}\), hence it remains only to prove that \((A^n, S_A, P_A)\) is a ring. Pick any surjective ring homomorphism \(\psi : B \to A\), with \(B = \mathbb{Z}[M]\) for some free monoid \(M\), and endow \(B\) with the discrete topology; then \(\psi^N\) is also surjective, and in light of (9.3.12), it suffices to prove the theorem for \(B\). Also, the \(p\)-Frobenius endomorphism of \(M\) induces an endomorphism \(\varphi\) of \(B\) that lifts the Frobenius endomorphism of \(B/pB\). We may then replace \(A\) by \(B\), and assume from start that \(p\) is a regular element of \(A\), and \(\varphi : A \to A\) is a given lift of the Frobenius endomorphism of \(A/pA\). In this case, Proposition 9.3.5(i,ii) implies that \(\omega_A\) maps bijectively \(A^n\) onto a subring of \(A^n\), and the identities of (9.3.7) tell us that the ring structure induced on \(A^n\) via this identification, is precisely the one given by the addition law \(S_A\) and multiplication law \(P_A\), and also the zero element and the unit are the required ones, since \(\omega_A(0_A) = 0 \in A^n\) and \(\omega_A(1_A) = 1 \in A^n\). By the same token, it is clear that \(-\bar{a}\) is computed by \(I_A(\bar{a})\) in the resulting ring.

**Definition 9.3.14.** Let \((A, \mathcal{T})\) be any topological ring. The topological ring
\[(A^n, S_A, P_A, 0_A, 1_A, \mathcal{T}_{W(A)})\]
is called the **ring of Witt vectors associated with** \(A\), and is denoted by \(W(A, \mathcal{T})\). If no ambiguities are likely to arise, we often omit reference to \(\mathcal{T}\), and write simply \(W(A)\).

9.3.15. By construction, the ghost map is a continuous ring homomorphism
\[\omega_A : W(A) \to A^n\]
(where \(A^n\) is endowed with termwise addition and multiplication). Henceforth, the addition and multiplication of elements \(\bar{a}, \bar{b} \in W(A)\) shall be denoted simply in the usual way: \(\bar{a} + \bar{b}\) and \(\bar{a} \cdot \bar{b}\), and the neutral element of addition and multiplication shall be denoted respectively \(0\) and \(1\). The rule \(A \to W(A)\) is a functor from the category of topological rings (and continuous ring homomorphisms) to itself; indeed, if \(\psi : A \to B\) is any continuous ring homomorphism, the map \(\psi^N\) yields a continuous ring homomorphism
\[W(\psi) : W(A) \to W(B)\quad \bar{a} \mapsto (\psi(a_n) \mid n \in \mathbb{N}).\]
and moreover one has the identity:
\[\psi^N \circ \omega_A = \omega_B \circ W(\psi).\]
Remark 9.3.16. (i) More generally, if $A$ is not necessarily unital ring, the proof of theorem 9.3.13 shows that the datum $(A^N, S_A, P_A, Q_A)$ is a non-unital ring $W(A)$, that we shall also call the ring of Witt vectors associated with $A$. Then clearly the rule $A \mapsto W(A)$ extends to an endofunctor of the category of (associative, commutative) non-unital rings.

(ii) If $A$ is a unital ring, and $f : A \rightarrow B, g : A \rightarrow C$ two unital $A$-algebras, the natural ring homomorphisms $B \rightarrow B \otimes_A C \leftarrow C$ induce a map of $W(A)$-algebras

\[ WB \otimes_{WA} WC \rightarrow W(B \otimes_A C). \]

Namely, it is the unique $W(A)$-linear map such that $b \otimes c \mapsto (P_n(b \otimes 1, 1 \otimes c) \mid n \in \mathbb{N})$ for every $b \in W(B)$ and $c \in W(C)$, with $b \otimes 1 := (b_n \otimes 1 \mid n \in \mathbb{N})$, and likewise for $1 \otimes c$.

(iii) More generally, let $A$ be a unital ring; a non-unital right $A$-algebra is the datum of a right $A$-module $B$ and a (commutative, associative) non-unital ring structure on $B$ such that $(bb') \cdot a = b \cdot (b'a)$ for every $a \in A$ and every $b, b' \in B$. Likewise we define non-unital left $A$-algebras. To every left non-unital $A$-algebra $B$, we attach a unital $A$-algebra whose underlying $A$-module is $A \oplus B$, whose structure map $A \rightarrow A \oplus B$ is the natural inclusion, and with

\[ (a, b) \cdot (a', b') := (aa', ab' + a'b + bb') \]

and likewise for right $A$-algebras: the details are left to the reader.

(iv) With this terminology, we may then extend (ii) to the case where $B$ and $C$ are respectively right and left non-unital $A$-algebras: in this case, the homomorphism (9.3.17) of non-unital rings is obtained as follows. Recall that the polynomial $P_n$ is bihomogeneous of degree $(p^n, p^n)$ for every $n \in \mathbb{N}$ (remark 9.3.8(i)); hence there exists $N \in \mathbb{N}$ such that $P_n = \sum_{i=1}^{N} r_i P_{n,i}$, with $r_i \in \mathbb{Z}$, and where each $P_{n,i}$ is a monomial of bidegree $(p^n, p^n)$, i.e. there exists $M_i \in \mathbb{N}$ with $P_{n,i} = \prod_{j=0}^{M_i} X_j^{e_{ij}} Y_j^{f_{ij}}$ and $\sum_{j=0}^{M_i} d_j p^j = \sum_{j=0}^{M_i} e_j p^j = p^n$. Then we set $Q_n(b, c) := \sum_{i=1}^{N} r_i P_{n,i}(b, c)$, with $P_{n,i}(b, c) := \prod_{j=0}^{M_i} b_j^{d_j} \otimes \prod_{j=0}^{M_i} c_j^{e_j}$ for every $i = 1, \ldots, N$ and $b, c$ as in (ii); lastly, (9.3.17) is given by the rule: $b \otimes c \mapsto (Q_n(b, c) \mid n \in \mathbb{N})$. In order to check that (9.3.17) is a map of non-unital rings, endow $B' := A \oplus B$ and $C' := A \oplus C$ of the unital $A$-algebra structures described in (iii), and notice that (9.3.17) is the restriction of the map of unital $W(A)$-algebras $WB' \otimes_{WA} WC' \rightarrow W(B' \otimes_A C')$ of (ii).

9.3.18. Next, one defines two continuous mappings $W(A) \rightarrow W(A)$, by the rule:

\[ F_A(a) := (F_n(a_0, \ldots, a_{n+1}) \mid n \in \mathbb{N}) \]
\[ V_A(a) := (0, a_0, a_1, \ldots). \]

$F_A$ and $V_A$ are often called, respectively, the Frobenius and Verschiebung maps ([28, Ch.IX, §1, n.5]). Consider also the mappings $f_A, v_A : A^N \rightarrow A^N$ such that

\[ f_A(a) := (a_1, a_2, \ldots) \quad v_A(a) := (0, pa_0, pa_1, \ldots) \quad \text{for every } a := (a_0, a_1, \ldots) \in A^N. \]

Then $f_A$ is a continuous ring endomorphism of $A^N$, and $v_A$ is a continuous endomorphism of the additive group of $A^N$, and the basic identity characterizing $(F_n \mid n \in \mathbb{N})$ can be written as:

\[ \omega_A \circ F_A = f_A \circ \omega_A. \]

On the other hand, (9.3.3) yields the identity:

\[ \omega_A \circ V_A = v_A \circ \omega_A. \]

Let $\psi : A \rightarrow B$ be a continuous ring homomorphism; directly from the definitions we obtain:

\[ W(\psi) \circ F_A = F_B \circ W(\psi) \quad W(\psi) \circ V_A = V_B \circ W(\psi). \]

Proposition 9.3.22. With the notation of (9.3.18), we have:

(i) The map $F_A$ is a continuous endomorphism of the ring $W(A)$, and $V_A$ is a continuous endomorphism of the additive group underlying $W(A)$. 

(ii) Moreover one has the identities:

\[ F_A \circ V_A = p \cdot 1_{W(A)} \]

(9.3.23)

\[ V_A(a \cdot F_A(b)) = V_A(a) \cdot b \quad \text{for every } a, b \in W(A). \]

(iii) \( F_A \) is a lifting of the Frobenius endomorphism of \( W(A)/pW(A) \), i.e.:

\[ F_A(a) \equiv a^p \pmod{pW(A)} \quad \text{for every } a \in W(A). \]

Proof. (i): Arguing as in the proof of theorem 9.3.13, we reduce to the case where \( p \) is a regular element in \( A \) and the Frobenius endomorphism of \( A/pA \) lifts to a ring endomorphism \( \varphi : A \to A \), in which case \( \omega_A \) is an injective ring homomorphism (proposition 9.3.5(ii)). Then the assertion follows immediately from (9.3.19) and (9.3.20). By the same token, we also get the identities of (ii). Likewise, (iii) is reduced to the identity

\[ f_A(a) - a^p \in p \cdot \text{Im} \omega_A \]

for every \( a := (a_n \mid n \in \mathbb{N}) \in \text{Im} \omega_A \) (here \( a^p = (a_n^p \mid n \in \mathbb{N}) \) denotes the \( p \)-power map for the ring structure of \( A^n \)). Now, we have

(9.3.24) \( \varphi(a_n) \equiv a_n^p \pmod{pA} \quad \varphi(a_n) \equiv a_{n+1} \pmod{p^{n+1}A} \quad \text{for every } n \in \mathbb{N} \)

by proposition 9.3.5(ii), hence \( a_n^p - a_{n+1} \in pA \) for every \( n \in \mathbb{N} \). Set \( b_n := p^{-1} \cdot (a_n^p - a_{n+1}); \)

again by proposition 9.3.5(ii), it suffices to check that \( \varphi(b_n) \equiv b_{n+1} \pmod{p^{n+1}A} \), that is

\[ \varphi(a_n^p - a_{n+1}) \equiv a_{n+1}^p - a_{n+2} \pmod{p^{n+2}A} \quad \text{for every } n \in \mathbb{N}. \]

However, from (9.3.24) and lemma 9.3.4(i) we deduce that \( \varphi(a_n)^p \equiv a_{n+1}^p \pmod{p^{n+2}A} \), whence the contention: details left to the reader. \( \square \)

9.3.25. Let \( n \in \mathbb{N} \) be any integer; it follows easily from (9.3.23) that

\[ V_n(A) := \text{Im} V^n_A \]

is an ideal of \( W(A) \), and we define the ring of \( n \)-truncated Witt vectors of \( A \) as the quotient

\[ W_n(A) := W(A)/V_n(A) \]

which we endow with the topology \( \mathcal{T}_{W_n(A)} \) induced by the projection \( \pi_n : W(A) \to W_n(A) \).

Remark 9.3.26. (i) More generally, if \( A \) is a not necessarily unital ring, then \( V_n(A) \) is a well-defined ideal of the non-unital ring \( W(A) \) (see remark 9.3.16(i)). Hence, the quotient \( W_n(A) \) is a well-defined non-unital ring in this case, for every \( n \in \mathbb{N} \).

(ii) Likewise, in the situation of remark 9.3.16(iii), we have a well-defined homomorphism of non-unital \( A \)-algebras \( W_nB \otimes_{W_nA} WC \to W_n(B \otimes_A C) \), for every \( n \in \mathbb{N} \).

Lemma 9.3.27. With the notation of (9.3.25), we have:

(i) \( a = (a_0, \ldots, a_{m-1}, 0, \ldots) + V^m_A \circ f^m_A(a) \) for every \( a \in W(A) \) (where the addition is taken in the additive group of \( W(A) \)).

(ii) The projection \( W(A) \to A^n : (a_i \mid i \in \mathbb{N}) \mapsto (a_0, \ldots, a_{n-1}) \) factors through \( \pi_n \) and a bijection \( W_n(A) \to A^n \), and \( \mathcal{T}_{W_n(A)} \) corresponds to the product topology of \( A^n \), under this identification.

Proof. (i): Arguing as in the proof of theorem 9.3.13, we may reduce to the case where \( p \) is a regular element in \( A \), in which case \( \omega_A \) is an injective ring homomorphism, and therefore it suffices to show that

\[ \omega_A(a) = \omega_A(a_0, \ldots, a_{m-1}, 0, \ldots) + \omega_A \circ V^m_A \circ f^m_A(a). \]

The latter follows by a simple inspection: details left to the reader. Assertion (ii) follows easily from (i). \( \square \)
Remark 9.3.28. (i) In view of lemma [9.3.27(ii)], we get therefore an inverse system of topological rings \((W_n(A) \mid n \in \mathbb{N})\), whose limit is \(W(A)\). Clearly the ghost components descend to well-defined continuous ring homomorphisms:

\[
\overline{\omega}_n : W_n(A) \to A \quad \text{for every } m < n.
\]

Especially, the map \(\overline{\omega}_0 : W_1(A) \to A\) is an isomorphism of topological rings.

(ii) A direct inspection of the construction shows that the endofunctor \(\overline{W}\) of the category of topological rings commutes with all limits.

(iii) In the same vein, if the topological ring \(A\) is the limit of a system \((A_i \mid i \in I)\) of topological rings, then \(F_A\) is the limit of the corresponding system of maps \((F_{A_i} \mid i \in I)\), and likewise for \(V_A\).

(iv) Let \(A\) be any topological ring. \(I\) any ideal of the monoid \((A, \cdot)\), and \(r \in \mathbb{N}\) any integer. In light of remark [9.3.28(i)], it is easily seen that the sets

\[
W(I, r) := \{(a_n \mid n \in \mathbb{N}) \in W(A) \mid a_n \in I^n A \text{ for every } n \leq r\} \quad \text{and} \quad W(I) := \bigcap_{n \in \mathbb{N}} W(I, n)
\]

are ideals of \(W(A)\) : details left to the reader. Moreover, we have the inclusions:

\[(9.3.29) \quad W(I^c, r) \subset W(I, r)c \quad \text{and} \quad W(I^c) \subset W(I)c\]

(where, for any topological space \(X\) and every subset \(S \subset X\) we denote by \(S^c\) the topological closure of \(S\) in \(X\)). Indeed, by definition we have \(W(I, r) := \bigcap_{n \in \mathbb{N}} J_n\), with \(J_n := I^n A\) for every \(n \leq r\) and \(J_n := A\) for \(n > r\), so that \(W(I, r)c = \bigcap_{n \in \mathbb{N}} J_n^c\), and it suffices to recall that \((I^c)^n \subset (I^n)^c\) for every \(n \in \mathbb{N}\). The same argument applies to \(W(I)\).

Especially, if \(I^n A\) is a closed ideal in the topology of \(A\) for every \(n \in \mathbb{N}\), then it follows that \(W(I, r)\) is a closed ideal of \(W(A)\), and the same holds also for \(W(I)\).

Furthermore, if \(I, J\) are any two ideals of the monoid \((A, \cdot)\), and \(r \in \mathbb{N}\) is any integer, it follows easily from remark [9.3.28(i)] that

\[
W(I, r) \cdot W(J, r) \subset W(IJ, r) \quad \text{and} \quad W(I) \cdot W(J) \subset W(IJ).
\]

Proposition 9.3.30. Let \(A\) be a topological ring, and \(n \in \mathbb{N}\). We have:

(i) With the notation of remark [9.3.28(i)], the ring homomorphism

\[
\pi_n : W_{n+1}(A) \to A^{n+1} \quad a \mapsto (\overline{\omega}_0(a), \overline{\omega}_1(a), \ldots, \overline{\omega}_n(a))
\]

is integral with nilpotent kernel.

(ii) \(p^n A^{n+1} \subset \text{Im } \pi_n \subset \{ (x_0, \ldots, x_n) \in A^{n+1} \mid x_i \equiv x_0^p \pmod{pA} \text{ for } i = 1, \ldots, n\}\).

Proof. (i): Denote by \(B \subset A^{n+1}\) the integral closure of the image of \(\pi_n\). Clearly \(B\) contains the \(n + 1\) canonical idempotents \(e_0, \ldots, e_n\) of \(A^{n+1}\). Next, a simple inspection shows that

\[
\pi_n(a e_0) = (a, a^p, \ldots, a^{p^n}) \quad \text{for every } a \in A.
\]

It follows that \(a^p e_i = e_i \cdot \pi_n(a e_0) \in B\), and then also \(a e_i \in B\), for every \(a \in A\) and every \(i \leq n\). This implies that \(B = A^{n+1}\), i.e. \(\pi_n\) is integral, as asserted. Next, the sequence of ideals \((W_i(A) \mid i \in \mathbb{N})\) induces a descending filtration \((\overline{V}_i \mid i = 0, \ldots, n)\) on \(W_{n+1}(A)\), and we notice:

Claim 9.3.31. For every \(i = 0, \ldots, n - 1\), we have an isomorphism of \(W_{n+1}(A)\)-modules

\[
A \cong \overline{V}_i/\overline{V}_{i+1} \quad a \mapsto a e_i \pmod{\overline{V}_{i+1}}
\]

for the \(W_{n+1}(A)\)-module structure on \(A\) induced by \(\overline{\omega}_i\).

Proof of the claim. It is clear that this map is bijective. To show that it is also \(W_{n+1}(A)\)-linear, notice that \(P_j(X_0, \ldots, X_j, 0, \ldots, 0) = 0\) for every \(j < i\) (remark [9.3.8(ii)]), so that

\[
\omega_i(0, \ldots, 0, P_i(X_0, \ldots, X_i, 0, \ldots, 0, Y_i)) = \omega_i(X_0, \ldots, X_i) \cdot \omega_i(0, \ldots, 0, Y_i)
\]
by (9.3.7). This translates as the identity
\[ p^i \cdot P_i(X_0, \ldots, X_i, 0, \ldots, 0, Y_i) = \omega_i(X_0, \ldots, X_i) \cdot p^i Y_i \]
whence \( P_i(X_0, \ldots, X_i, 0, \ldots, 0, Y_i) = \omega_i(X_0, \ldots, X_i) \cdot Y_i \), which implies the claim. \( \Diamond \)

Set \( I := \text{Ker } \pi_n \); from claim 9.3.31 we deduce that \( I \cdot V_i \subset V_{i+1} \) for every \( i = 0, \ldots, n \), whence \( I^{n+1} = 0 \) in \( W_{n+1}(A) \), which concludes the proof of (i).

(ii): The second inclusion follows by direct inspection of the Witt polynomials. To show the first inclusion, consider any sequence \( (a_0, \ldots, a_n) \in A^{n+1} \); we need to find a solution \( (x_0, \ldots, x_n) \in W_{n+1} \) for the system of polynomial equations:
\[ x_0^p + px_1^{p-1} + \cdots + p^i x_i = p^n a_i \quad \text{for } i = 0, \ldots, n \]
and we claim that there exists a solution that fulfills as well the further condition: \( x_i \in p^{n-i}A \) for \( i = 0, \ldots, n \). The proof proceeds by a simple induction on \( i \leq n \), which we leave to the reader. \( \square \)

Corollary 9.3.32. Let \( A \) be any topological ring such that \( p^k A = 0 \) for some \( k \in \mathbb{N} \). Then \( \text{Ker } (\overline{\omega}_0 : W_{n+1}A \to A) \) is nilpotent for every \( n \in \mathbb{N} \).

Proof. Let \( \varrho \in W_{n+1}A \) be an element such that \( \overline{\omega}_0(\varrho) = 0 \), and define \( \pi_n \) as in proposition 9.3.30(i): in view of (9.3.3), we see that \( \pi_n(\varrho) = (0, pb_1, \ldots, pb_n) \) for some \( b_1, \ldots, b_n \in A \); hence \( \varrho^k \in \text{Ker } \pi_n \), and it suffices to invoke proposition 9.3.30(i) to conclude. \( \square \)

Lemma 9.3.33. Let \( (A, \mathcal{T}) \) be a topological ring, with separated completion \( (A^\wedge, \mathcal{T}^\wedge) \).

(i) If the topology \( \mathcal{T} \) is discrete, the topology \( \mathcal{T}_{W(A)} \) agrees with the linear topology defined by the filtration \( (V_m(A) \mid m \in \mathbb{N}) \).

(ii) If the topology \( \mathcal{T} \) is separated (resp. and complete), then the same holds for \( \mathcal{T}_{W(A)} \).

(iii) If \( \mathcal{T} \) is a linear topology, then the same holds for \( \mathcal{T}_{W(A)} \).

(iv) Denote also by \( W(A, \mathcal{T})^\wedge \) the separated completion of \( W(A, \mathcal{T}) \). The natural map \( W(A, \mathcal{T}) \to W(A^\wedge, \mathcal{T}^\wedge) \) factors uniquely via an isomorphism of topological rings:
\[ W(A, \mathcal{T})^\wedge \cong W(A^\wedge, \mathcal{T}^\wedge) \]

Proof. (i) follows easily from lemma 9.3.27(ii) : details left to the reader.

(ii): It is clear from the definitions that if \( A \) is separated, then the same holds for \( \mathcal{T}_{W(A)} \). Next, suppose that \( A \) is complete and separated, and for every \( n \in \mathbb{N} \) consider the short exact sequence of topological groups
\[ (9.3.34) \quad 0 \to V_n(A)/V_{n+1}(A) \to W_{n+1}(A) \to W_n(A) \to 0 \]
where \( V_{n+1}(A) \) is endowed with the topology induced by the inclusion into \( W_{n+1}(A) \). Taking into account claim 9.3.31 and proposition 8.2.13(i,v), a simple induction then shows that \( W_n(A) \) is separated and complete for every \( n \in \mathbb{N} \). Then the assertion follows from corollary 8.2.16(i) and remark 9.3.28(i).

(iii): Let \( (I_\lambda \mid \lambda \in \Lambda) \) be a fundamental system of open ideals of \( A \), and for every \( \lambda \in \Lambda \) and every \( r \in \mathbb{N} \), denote by \( \pi_{\lambda, r} : W(A) \to W_r(A/I_\lambda) \) the projection; then it is easily seen that the family of ideals \( (\text{Ker } \pi_{\lambda, r} \mid \lambda \in \Lambda, r \in \mathbb{N}) \) is a fundamental system of open neighborhoods of \( 0 \in W(A) \). The assertion is an immediate consequence.

(iv) is similar to (ii) : in light of corollary 8.2.16(ii), we are reduced to checking that \( W_n(A^\wedge) \) is the separated completion of \( W_n(A) \). The latter is established by induction on \( n \in \mathbb{N} \), by means of the exact sequences (9.3.34) and proposition 8.2.13(i,v). \( \square \)
9.3.35. **Teichmüller mapping.** The projection $\omega_0$ admits a continuous set-theoretic section

$$\tau_A : A \to W(A) \quad a \mapsto (a, 0, 0, \ldots).$$

For every $a \in A$, we call $\tau_A(a)$ the **Teichmüller representative** of $a$. Clearly, for any continuous ring homomorphism $\psi : A \to B$ we have:

$$\tau_B \circ \psi = W(\psi) \circ \tau_A.$$  
(9.3.36)

**Proposition 9.3.37.** With the notation of (9.3.35), we have:

(i) $\tau_A(a) \cdot \underline{b} = (a^n b_n \mid n \in \mathbb{N})$ for every $a \in A$ and $\underline{b} := (b_n \mid n \in \mathbb{N}) \in W(A)$.

(ii) Moreover, $\tau_A$ is a multiplicative map, i.e. the following identity holds:

$$\tau_A(a) \cdot \tau_A(b) = \tau_A(a \cdot b) \quad \text{for every } a, b \in A$$

(iii) $a = \sum_{n=0}^{\infty} V_n^a(\tau_A(a_n))$ for every $a := (a_n \mid n \in \mathbb{N}) \in W(A)$, where the convergence of the series is relative to the topology $\mathcal{T}_{W(A)}$.

**Proof.** (i): Since $P_n$ is bihomogeneous of degree $(p^n, p^n)$ (remark 9.3.38(i)), we have

$$P_n(X_0, 0, \ldots, 0, Y_0, \ldots, Y_n) = X_0^{p^n} \cdot P_n(1, 0, \ldots, 0, Y_0, \ldots, Y_n) = X_0^{p^n} \cdot Y_n$$

where the second identity follows after recalling that $1_A := (1, 0, \ldots)$ is the unit of $W(A)$. The assertion follows immediately. (ii) is a special case of (i), and (iii) follows easily from lemma [9.3.27](i).

**Example 9.3.38.** (i) For any $n \in \mathbb{N}$, let $(a_0, \ldots, a_n) \in W_{n+1}(\mathbb{Z})$ be the sequence that represents the element $p^n$. Since $\omega_i$ is a ring homomorphism, we have

$$p^n = a_0^i + p a_1^i + \cdots + p^i a_i \quad \text{for every } i = 0, \ldots, n.$$  

A simple induction then shows that

$$a_i \equiv p^{n-i} \quad \text{(mod } p^{n-i+1}) \quad \text{for every } i = 0, \ldots, n.$$  

(ii) Let $A$ be any topological ring, $n, i \in \mathbb{N}$ any integers; set

$$k := \min(i, n) \quad \text{and} \quad \nabla_{n,j}(A) := V_j(A)/V_{n+1}(A) \quad \text{for every } j \leq n.$$  

Let also $\nabla : W_n(A) \to W_{n+1}(A)$ be the $\mathbb{Z}$-linear map induced by $V$. We claim that

$$\sum_{j=0}^{k} p^{i-j} \nabla_{n,j}(A) = J_{i,n} := \{(a_0, \ldots, a_n) \in W_{n+1}(A) \mid a_j \in p^{i-j} A \text{ for every } j \leq k\}.$$  

For the proof, we argue by induction on $n$ and $i$, and notice first that $J_{i,n}$ is an ideal of $W_{n+1}(A)$ for every $n$ and $i$, due to remark [9.3.8](i). If $n = 0$ or $i = 0$, there is nothing to prove. Suppose then that $n, i > 0$ and that the assertion is known for all strictly smaller values of $n$ and $i$; from (i) we see that $p^i W_{n+1}(A) \subset J_{i,n}$, and the inductive assumption shows that

$$\sum_{j=1}^{k} p^{i-j} \nabla_j(A) = \nabla\left(\sum_{j=0}^{k-1} p^{i-j-1} \nabla_{n,j}(A)\right) = \nabla(J_{i-1,n-1}) \subset J_{i,n}$$

whence $\sum_{j=0}^{k} p^{i-j} \nabla_{n,j}(A) \subset J_{i,n}$. Conversely, say that $a := (a_0, \ldots, a_n) \in J_{i,n}$, so that $a_0 = p^i b_0$ for some $b_0 \in A$; due to lemma [9.3.27](i) and proposition [9.3.37](i) we may write

$$a = \tau(a_0) + \nabla(a_1, \ldots, a_n) = \tau(b_0) \cdot (p^i, 0, \ldots, 0) + \nabla(a_1, \ldots, a_n)$$

and notice that $\nabla(a_1, \ldots, a_n) \in \nabla(J_{i-1,n-1}) \subset \sum_{j=1}^{k} p^{i-j} \nabla_j(A)$. Also, from (i) we see that $(p^i, 0, \ldots, 0) = p^i + \nabla(b_1, \ldots, b_n)$, where again $(b_1, \ldots, b_n) \in J_{i-1,n-1}$. Summing up, we get $J_{i,n} \subset \sum_{j=0}^{k} p^{i-j} \nabla_j(A)$, as required.
(iii) Especially, (ii) implies that for every ring $A$ we have
\[ p^i W_{n+1}(A) \subset J_{i,n} \subset p^{i-n} W_{n+1}(A) \quad \text{for every } i, n \in \mathbb{N} \text{ with } i \geq n. \]

If $\mathcal{T}_p$ denotes the $p$-adic topology on $A$, it follows that the topology of $W_{n+1}(A, \mathcal{T}_p)$ agrees with the $p$-adic topology of the underlying ring $W_{n+1}(A)$, for every $n \in \mathbb{N}$.

**Example 9.3.39.** (i) Let $S \subset \mathbb{Z}$ be any subset, and $A$ any ring (which we may regard as a discrete topological ring). Then the localization map $j : A \to S^{-1}A$ induces a ring isomorphism
\[ S^{-1}W_{n+1}(A) \xrightarrow{\sim} W_{n+1}(S^{-1}A) \quad \text{for every } n \in \mathbb{N}. \]

Indeed, let us show first that multiplication by every $s \in S$ is a bijection on $W_{n+1}(S^{-1}A)$. To this aim, we consider the descending filtration $(\mathcal{V}_i A \mid i = 0, \ldots, n)$ as in the proof of proposition 9.3.30(i); we are then easily reduced to checking that multiplication by $s$ is bijective on $\mathcal{V}_i(A) / \mathcal{V}_{i+1}(A)$ for $i = 0, \ldots, n-1$. But according to claim 9.3.31, the latter quotient is isomorphic to $S^{-1}A$, for the $W_{n+1}(S^{-1}A)$-module structure induced on $S^{-1}A$ by $\mathcal{V}_i$, whence the contention. Thus, $W_{n+1}(j)$ extends to a well defined ring homomorphism $\lambda : S^{-1}W_{n+1}A \to W_{n+1}(S^{-1}A)$. To see that the latter is an isomorphism, we notice that $\lambda$ is a homomorphism of filtered rings for the filtrations $S^{-1}\mathcal{V}_i A$ on $S^{-1}W_{n+1}A$ and $\mathcal{V}_i(S^{-1}A)$ on $W_{n+1}(S^{-1}A)$; then it suffices to check that the associated graded ring homomorphism $gr \lambda$ is bijective, and the latter assertion follows again from claim 9.3.31.

(ii) If $p \in A^\times$, a simple inspection shows that ghost map $\omega_A : W(A) \to A^N$ is a ring homomorphism, and likewise, $W_{n+1}A \xrightarrow{\sim} A^{n+1}$ in this case, for every $n \in \mathbb{N}$. Combining with (i), we deduce that for every ring $A$, the localization $A \to A[p^{-1}]$ induces a ring isomorphism
\[ W_{n+1}(A)[p^{-1}] \xrightarrow{\sim} (A[p^{-1}])^{n+1} \quad \text{for every } n \in \mathbb{N}. \]

(iii) In the same vein, let $S \subset A$ be any multiplicative subset, and denote by $\tau_A(S) \subset W_{n+1}A$ the image of the subset $\{\tau_A(s) \mid s \in S\} \subset W(A)$ (notation of (9.3.35)). Then the localization map $j : A \to S^{-1}A$ induces a ring isomorphism
\[ \lambda : \tau_A(S)^{-1}W_{n+1}A \xrightarrow{\sim} W_{n+1}(S^{-1}A) \quad \text{for every } n \in \mathbb{N}. \]

Indeed, from proposition 9.3.37(ii) we see that the image of $\tau_A(S)$ is invertible in $W_{n+1}(S^{-1}A)$, so $\lambda$ is well defined. Next, proposition 9.3.37(i) easily implies that $\lambda$ is surjective. Lastly, the kernel of $\lambda$ is $\tau_A(S)^{-1}1Ker W_{n+1}(j)$; but clearly $\text{Ker } W_{n+1}(j)$ is the ideal of all sequences $a := (a_0, \ldots, a_n)$ such that for every $i = 0, \ldots, n$ there exists $s_i \in S$ with $s_ia_i = 0$. Then $\tau_A(s_0 \cdots s_n) \cdot a = 0$ in $W_{n+1}A$; this shows that $\text{Ker } \lambda = 0$, and concludes the proof.

**9.3.40. Let now $A$ be a topological $\mathbb{F}_p$-algebra.** In this case (9.3.10) yields the identity:
\[ F_A(a) = (a^p \mid n \in \mathbb{N}) \quad \text{for every } a := (a_n \mid n \in \mathbb{N}) \in W(A). \]

As an immediate consequence we get:
\[ p \cdot a = V_A \circ F_A(a) = F_A \circ V_A(a) = (0, a^p_0, a^p_1, \ldots) \quad \text{for every } a \in W(A). \]

Especially, we have
\[ p = (0, 1, 0, \ldots) \quad \text{in } W(A). \]

Moreover, let $\Phi_A : A \to A$ be the Frobenius endomorphism; (9.3.41) also implies the identity:
\[ F_A \circ \tau_A = \tau_A \circ \Phi_A. \]

**Proposition 9.3.45. Let $A$ be any $\mathbb{F}_p$-algebra.** We have:

(i) The $p$-adic topology on $W(A)$ agrees with the $V_1(A)$-adic topology, and both are finer than the topology $\mathcal{T}'$ defined by the filtration $(V_n(A) \mid n \in \mathbb{N})$.

(ii) Moreover, $W(A)$ is also complete and separated for the $p$-adic topology.
(iii) \( W(A)^\times = \omega_0^{-1}(A^\times) \).
(iv) \( V^i(\tau_A(b)) \cdot V^j(\tau_A(b)) = V^{i+j}(\tau_A(a^p b^p)) \) for every \( a, b \in A \) and every \( i, j \in \mathbb{N} \).

Proof. (i): It is clear from (9.3.42) that the \( p \)-adic topology on \( W(A) \) is finer than both \( \mathcal{J}' \) and the \( V_1 \)-adic topology. Conversely, for every \( a, b \in W(A) \) we have
\[
V_A(a) \cdot V_A(b) = V_A(a \cdot F_A V_A(b)) = p \cdot V_A(a \cdot b)
\]
whence \( V_1^2 \subset pA \), which says that the \( V_1 \)-adic topology is finer than the \( p \)-adic topology.

(ii): Since \( W(A) \) is complete and separated for the linear topology \( \mathcal{J}' \), the assertion follows from lemma 8.3.12.

(iii): Clearly \( W(A)^\times \subset \omega_0^{-1}(A^\times) \). For the converse, notice that the ideal \( V_1(A) \) is contained in the Jacobson radical ideal of \( W(A) \), due to (i),(ii) and remark 8.3.10(v). Therefore, the induced map \( \text{Spec} \omega_0 : \text{Spec} A \to \text{Spec} W(A) \) restricts to a bijection on the sets of maximal ideals of \( A \) and \( W(A) \), and the assertion follows easily.

(iv): Without loss of generality, we may assume that \( i \leq j \); then we compute
\[
V^i(\tau_A(b)) \cdot V^j(\tau_A(b)) = V^i(\tau_A(a) \cdot F^iV^j(\tau_A(b))) \quad (\text{by } (9.3.23))
\]
\[
= V^i(\tau_A(a) \cdot p^i \cdot V^{j-i}(\tau_A(b))) \quad (\text{again by } (9.3.23))
\]
\[
= p^i \cdot V^i(\tau_A(a) \cdot V^{j-i}(\tau_A(b))) \quad (\text{by proposition } 9.3.22(i))
\]
\[
= p^i \cdot V^j(V^{j-i}(\tau_A(a^{p^i-j}b))) \quad (\text{by proposition } 9.3.37(i))
\]
\[
= p^i \cdot V^j(\tau_A(a^{p^j-i}b)) \quad (\text{by } (9.3.42))
\]
\[
= V^{i+j}(\tau_A(a^{p^i} b^p))
\]
as stated. \( \square \)

9.3.46. Suppose additionally that \( A \) is perfect, i.e. that \( \Phi_A \) is an automorphism of the topological ring \( A \) (especially, it is a homeomorphism). It follows from (9.3.44) that \( F_A \) is an automorphism of \( W(A) \). Hence, in view of (9.3.23) and (9.3.42):
\[
p^n \cdot W(A) = V_n(A) \quad \text{for every } n \in \mathbb{N}.
\]
So, the \( p \)-adic filtration coincides with the filtration \( (V_n(A) \mid n \in \mathbb{N}) \) and with the \( V_1(A) \)-adic filtration. Especially, the 0-th ghost component descends to an isomorphism
\[
\omega_0 : W(A)/pW(A) \cong A.
\]
Also, the identity of proposition 9.3.37(iii) can be written in the form:
\[
(9.3.47) \quad \sum_{n=0}^{\infty} p^n \cdot \tau_A(a^{-n}_{n}) \quad \text{for every } \ a := (a_n \mid n \in \mathbb{N}) \in W(A).
\]

Proposition 9.3.48. Let \( A \) be a reduced \( \mathbb{F}_p \)-algebra, \( a := (a_n \mid n \in \mathbb{N}) \in W(A) \) any element.

(i) Consider the following conditions:
(a) The ideal \( J := \sum_{n \in \mathbb{N}} a_n A \) is not contained in any minimal prime ideal of \( A \).
(b) \( a \) is a regular element of \( W(A) \).
Then (a)\( \Rightarrow \)(b), and if \( A \) has only finitely many minimal prime ideals, (b)\( \Rightarrow \)(a).

(ii) \( W(A) \) is reduced, and if \( A \) is a domain, the same holds for \( W(A) \).

(iii) If \( A \) is a perfect field, then \( W(A) \) is a complete discrete valuation ring of mixed characteristic \( (0, p) \), maximal ideal \( pW(A) \), and residue field \( A \).

(iv) If \( A \subset B \) is an inclusion of perfect \( \mathbb{F}_p \)-algebras, then \( W(A) \subset W(B) \), and
\[
p^n W(A) = W(A) \cap p^n W(B) \quad \text{for every } n \in \mathbb{N}.
\]
(v) If $A$ is perfect, and $\sum_{i=0}^{k}a_i A = A$ for some $k \in \mathbb{N}$, we have

$$aW(A) \cap p^nW(A) = p^{n-k} \cdot (aW(A) \cap p^kW(A))$$

for every $n \in \mathbb{N}$

and moreover, the ideal $aW(A)$ is a closed subset for the $p$-adic topology on $W(A)$.

Proof. Notice that the assertions are independent of the topology of $A$ and $B$, hence we may assume that both these topologies are discrete.

(iii): We know already that $W(A)$ is $p$-adically complete, by proposition 9.3.45(ii). Also, it follows easily from (9.3.42) that $p$ is regular in $W(A)$, and taking into account proposition 9.3.45(iii) we see that every element of $W(A)$ can be written uniquely in the form $p^n \cdot u$, for some $n \in \mathbb{N}$ and an invertible element $u \in W(A)$. The assertion follows immediately.

(ii): Suppose first that $A$ is a domain, and we prove that the same holds for $W(A)$. To this aim, let $B$ be any perfect field containing $A$; since $W(A)$ is a subring of $W(B)$, it suffices to check that $W(B)$ is a domain, which is clear from (iii).

Next, let $\text{Min} A$ be the set of all minimal prime ideals of $A$; if $A$ is reduced, the natural map $j : A \to B := \prod_{p \in \text{Min} A} A_p$ is injective, and therefore $W(A)$ is a subring of $W(B) = \prod_{p \in \text{Min} A} W(A_p)$. To prove that $W(A)$ is reduced, it then suffices to show that the same holds for every factor $W(A_p)$, but this is already known, since each such $A_p$ is a field.

(i): Suppose that (a) holds; arguing as in the proof of (ii), we reduce to checking that the image of $a$ is regular in $W(A_p)$, for every $p \in \text{Min} A$. But under condition (a), it is clear that the image of $a$ does not vanish in $W(A_p)$ for any such $p$. Thus, in this case (ii) implies that (b) holds. Conversely, suppose that $\text{Min} A = \{p_1, \ldots, p_r\}$ is a finite set, and say that $J \subset p_i$. Pick any $f \in \bigcap_{i=2}^r p_i \setminus p_1$; since $j$ is injective, it is easily seen that $\text{Ann}_A(f) = p_1$ (details left to the reader). By proposition 9.3.37(i), we then see that $a \cdot \tau_A(f) = 0$, which contradicts (b).

(iv): It is clear that $W(A) \subset W(B)$, and also that $V_n(A) = W(A) \cap V_n(B)$, so the assertion follows from (9.3.46).

(v): Say that $xa = p^n y$ for some $x, y \in W(A)$; by (i), $p$ is regular in $W(A)$, so for the proof of the stated equality it suffices to show that $x \in p^{n-k}W(A)$. However, we have already noticed that the map $j$ is injective, and therefore $p^k W(A) = W(A) \cap p^k W(B)$, by (iv). Hence, it suffices to show that the image of $x$ lies in $p^{n-k} W(A_p)$ for every such $p$. Moreover, $A_p$ is a perfect field for every $p \in \text{Min} A$, and $\sum_{i=0}^{k}a_i \cdot A_p = A_p$, so we may replace from start $A$ by any $A_p$, in which case $W(A)$ is a discrete valuation ring with $p$ as uniformizer, by (iii), and notice that by assumption the elements $a_0, \ldots, a_k$ cannot all vanish, therefore

$$a \notin p^{k+1}W(A) \quad \text{and} \quad x \cdot a \in p^nW(A)$$

whence the assertion : details left to the reader. Lastly, the foregoing implies that the $p$-adic topology on $aW(A)$ agrees with the topology induced from the $p$-adic topology on $W(A)$. On the other hand, (i) says that $a$ is regular on $W(A)$, hence scalar multiplication by $a$ induces a bijection $W(A) \cong aW(A)$ that identifies the $p$-adic topology of $W(A)$ with the $p$-adic topology of $aW(A)$. Since $W(A)$ is $p$-adically complete and separated (proposition 9.3.45(ii)), it follows that the same holds for $aW(A)$. Summing up, $aW(A)$ is complete and separated for the topology induced from the $p$-adic topology of $W(A)$, and consequently it is a closed subset in $W(A)$, for this topology.

Example 9.3.49. Let $(A, \mathcal{T})$ be a topological $\mathbb{F}_p$-algebra.

(i) If $A$ is perfect and $\mathcal{T}$ is the discrete topology, then it follows from (9.3.46) and proposition 9.3.45(i) that $\mathcal{T}_{W(A)}$ agrees with the $p$-adic topology.

(ii) By inspecting the proof of theorem 8.2.8(ii), it is easily seen that if $(A, \mathcal{T})$ is perfect, the same holds for its separated completion.

(iii) For instance, we have a natural isomorphism of topological rings :

$$\mathbb{Z}_p \cong W(\mathbb{F}_p)$$
(where $\mathbb{F}_p$ is endowed with the discrete topology, and $\mathbb{Z}_p$ with the $p$-adic topology). Indeed, (i) says that the topology of $W(\mathbb{F}_p)$ agrees with the $p$-adic topology, hence the unique ring homomorphism $\mathbb{Z} \to W(\mathbb{F}_p)$ extends to a unique continuous map $\psi : \mathbb{Z}_p \to W(\mathbb{F}_p)$. Since $p$ is a regular element of $W(\mathbb{F}_p)$ (proposition 9.3.48(i)), the map is injective. Moreover, if we endow both rings with their $p$-adic filtrations, the induced map $\text{gr} \cdot \psi : \text{gr} \cdot \mathbb{Z}_p \to \text{gr} \cdot W(\mathbb{F}_p)$ on associated graded rings is easily seen to be an isomorphism. Then the assertion follows from [28 Ch.III, §2, n.8, Cor.2].

(iv) It follows from (iii) that the structure map $\beta : \mathbb{F}_p \to A$ induces a natural structure $W(\beta)$ of topological $\mathbb{Z}_p$-algebra on $W(A)$.

(v) Let $A := \mathbb{F}_p[T^{1/p^\infty}]$, the universal perfect $\mathbb{F}_p$-algebra in one generator (notation of example 4.8.55(iii)), and endow $A$ with its discrete topology. Then $W(A)$ is the $p$-adic completion of $\mathbb{Z}_p[T^{1/p^\infty}]$. The latter can be described as the ring of all power series
\[
\sum_{n\in\mathbb{N}} a_n T^{\lambda_n}
\]
where $(\lambda_n \mid n \in \mathbb{N})$ is any sequence of elements of $\mathbb{N}[1/p]$, and $(a_n \mid n \in \mathbb{N})$ is any sequence of elements of $\mathbb{Z}_p$ that converges $p$-adically to 0. For the proof, we argue as in (iii): we have a unique map of $\mathbb{Z}_p$-algebras $\psi : \mathbb{Z}_p[T^{1/p^\infty}] \to W(A)$ such that $\psi(T^\lambda) := \tau_A(T^\lambda)$ for every $\lambda \in \mathbb{N}[1/p]$ (for the $\mathbb{Z}_p$-algebra structure on $W(A)$ provided by (iv)). Then $\psi$ extends by continuity to a unique map of topological $\mathbb{Z}_p$-algebras $\psi^\wedge : \mathbb{Z}_p\{T^{1/p^\infty}\} \to W(A)$, and if we endow both rings with their $p$-adic filtrations, it is easily seen that the resulting map of associated graded rings $\text{gr} \cdot \psi^\wedge$ is bijective, so the same holds for $\psi^\wedge$, again by [28 Ch.III, §2, n.8, Cor.3].

9.3.51. The lifting property. In the situation of lemma 9.3.4, endow $A$ (resp. $A/J_n$, for every $n \in \mathbb{N}$) with the linear topology $\mathcal{V}$ defined by the system of ideals $(J_n \mid n \in \mathbb{N})$ (resp. with the discrete topology) and let $\pi_n : A \to A/J_n$ and $\pi'_n : A/J_n \to A/J_0$ be the natural projections, for every $n \in \mathbb{N}$. Let also $R$ be a topological $\mathbb{F}_p$-algebra, and $\overline{\mathcal{V}} : R \to A/J_0$ a continuous ring homomorphism. We say that a continuous mapping $\varphi_n : R \to A/J_n$ is a lifting of $\overline{\mathcal{V}}$ if we have:
\[
\varphi_n(x^n) = \varphi_n(x)^n \quad \text{for every } x \in R, \quad \text{and} \quad \pi'_n \circ \varphi_n = \overline{\mathcal{V}}.
\]

Lemma 9.3.52. With the notation of 9.3.51, the following holds:

(i) If $\varphi_n$ and $\varphi'_n$ are two liftings of $\overline{\mathcal{V}}$, then $\varphi_n$ and $\varphi'_n$ agree on $R^p$.

(ii) If $R$ is a perfect topological $\mathbb{F}_p$-algebra, there exists a unique lifting $\varphi_n : R \to A/J_n$ of $\overline{\mathcal{V}}$. We have $\varphi_n(1) = 1$ and $\varphi_n(xy) = \varphi_n(x) \cdot \varphi_n(y)$ for every $x, y \in R$.

(iii) Let $R$ be as in (ii), and suppose that $(A, \mathcal{V})$ is complete and separated. Then :

(a) There exists a unique continuous mapping $\varphi : R \to A$ such that
\[
\pi_0 \circ \varphi = \overline{\mathcal{V}} \quad \text{and} \quad \varphi(x^n) = \varphi(x)^n \quad \text{for every } x \in R.
\]

(b) Moreover, $\varphi(1) = 1$ and $\varphi(xy) = \varphi(x) \cdot \varphi(y)$ for every $x, y \in R$.

(c) If furthermore, $A$ is an $\mathbb{F}_p$-algebra, then $\varphi$ is a homomorphism of topological rings.

Proof. (i) is an easy consequence of lemma 9.3.4(i).

(ii) The uniqueness follows from (i). For the existence, pick any mapping $\sigma : A/J_0 \to A/J_n$ such that $\pi'_n \circ \sigma = 1_{A/J_0}$, and notice that the mapping $\psi := \sigma \circ \overline{\mathcal{V}} : R \to A/J_n$ is continuous, and $\pi'_n \circ \psi = \overline{\mathcal{V}}$. We let :
\[
\varphi_n(x) := \psi(x^{p^{-n}})^n \quad \text{for every } x \in R.
\]

Using lemma 9.3.4(i) one verifies easily that $\varphi_n$ does not depend on the choice of $\psi$. Especially, define $\psi' : R \to A/J_n$ by the rule $x \mapsto \psi(x^{p^{-1}})^n$ for every $x \in R$. Clearly $\pi'_n \circ \psi' = \overline{\mathcal{V}}$ as
well, hence:
\[ \varphi_n(x^p) = \psi(x^{p^1-n})^p = \psi(x^{p-n})^{p^{n+1}} = \varphi_n(x)^p \quad \text{for every } x \in R \]
as claimed. If we choose \( \sigma \) so that \( \sigma(1) = 1 \), we obtain \( \varphi_n(1) = 1 \). Finally, since \( \varphi \) is a ring homomorphism we have \( \psi(x) \cdot \psi(y) \equiv \psi(xy) \pmod{J_0} \) for every \( x, y \in R \). Hence
\[ \psi(x)^{p^n} \cdot \psi(y)^{p^n} \equiv \psi(xy)^{p^n} \pmod{J_0} \]
(again by lemma 9.3.4(i)) and finally \( \varphi_n(x^{p^n}) \cdot \varphi_n(y^{p^n}) = \varphi_n((xy)^{p^n}) \), which implies the last stated identity, since \( R \) is perfect.

(iii): The existence and uniqueness of \( \varphi \) follow from (ii). It remains only to show that \( \varphi(x) + \varphi(y) = \varphi(x + y) \) in case \( A \) is an \( \mathbb{F}_p \)-algebra. It suffices to check the latter identity on the projections onto \( A/J_n \), for every \( n \in \mathbb{N} \), in which case one argues analogously to the foregoing proof of the multiplicative property for \( \varphi_n \): the details shall be left to the reader. \( \square \)

**Proposition 9.3.53.** In the situation of (9.3.51), suppose that \( R \) is a perfect topological \( \mathbb{F}_p \)-algebra and \((A, \mathcal{T})\) is complete and separated. Then we have:

(i) For every \( n \in \mathbb{N} \) there exists a unique ring homomorphism \( v_n : W_{n+1}(A/J_0) \rightarrow A/J_n \) such that the following diagram commutes:

\[
\begin{array}{ccc}
W_{n+1}(A) & \xrightarrow{\omega_n} & A \\
W_{n+1}(A/J_0) & \xrightarrow{\pi_n} & W_{n+1}(A/J_0) \\
\end{array}
\]

(ii) Let \( u_n := v_n \circ W_{n+1}(\varphi) \circ T_R^{\varphi^n} \), where \( T_R : W_{n+1}(R) \rightarrow W_{n+1}(R) \) is induced by the Frobenius automorphism of \( W(R) \). Then we have a commutative diagram:

\[
\begin{array}{ccc}
W_{n+2}(R) & \xrightarrow{u_{n+1}} & A/J_{n+1} \\
W_{n+1}(R) & \xrightarrow{\pi_n} & A/J_n \\
\end{array}
\]

where the vertical maps are the natural projections.

(iii) There exists a unique ring homomorphism \( u \) such that the following diagram commutes:

\[
\begin{array}{ccc}
W(R) & \xrightarrow{u} & A \\
R & \xrightarrow{\varphi} & A/J_0. \\
\end{array}
\]

Furthermore, \( u \) is continuous for the topology \( \mathcal{T}_{W(R)} \), and we have:

\[ u(a) = \sum_{n \in \mathbb{N}} p^n \cdot \varphi(a_n^{p^n}) \quad \text{for every } a := (a_n \mid n \in \mathbb{N}) \in W(R) \]

with \( \varphi : R \rightarrow A \) the unique continuous mapping characterized as in lemma 9.3.52(iii).

**Proof.** (i): We have to check that \( \omega_n(a_0, \ldots, a_n) \in J_n \) whenever \( a_0, \ldots, a_n \in J_0 \), which is clear from lemma 9.3.4(ii).

(ii): Since \( T_R \) is an automorphism, it boils down to verifying:

**Claim 9.3.55.** \( \varphi \circ v_{n+1}(\varphi(a_0), \ldots, \varphi(a_{n+1})) = v_n(\varphi(F_0(a_0, a_1)), \ldots, \varphi(F_n(a_0, \ldots, a_{n+1}))) \) for every \( (a_0, \ldots, a_{n+1}) \in W_{n+1}(A) \).
Proof of the claim. Directly from (9.3.21) we derive:

\((\varphi(F_0(a_0, a_1)), \ldots, \varphi(F_n(a_0, \ldots, a_{n+1}))) = (F_0(\varphi(a_0), \varphi(a_1)), \ldots, F_n(\varphi(a_0), \ldots, \varphi(a_n)))\).

Hence, it suffices to show that

\[ \vartheta \circ v_{n+1}(b_0, \ldots, b_{n+1}) = v_n(F_0(b_0, b_1), \ldots, F_n(b_0, \ldots, b_{n+1})) \]

for every \((b_0, \ldots, b_{n+1}) \in W_{n+1}(A/J_0)\). The latter identity follows from (9.3.19). \(\diamondsuit\)

(iii): We take \(u := \lim_{n \in \mathbb{N}} u_n\), where the maps \(u_n\) are as in (ii), for every \(n \in \mathbb{N}\). With this definition, it is clear that \(u\) is continuous for the topology \(\mathcal{T}_{W(R)}\). Next we remark that \(\pi_0 \circ u \circ \tau_R = \varphi \circ \omega_0 \circ \tau_R = \varphi\), hence:

\[(9.3.56)\quad u \circ \tau_R = \varphi\]

by lemma 9.3.52(iii.a). Now (9.3.54) holds by (9.3.47), (9.3.56) and the continuity of \(u\). \(\square\)

Remark 9.3.57. (i) Let \(\mathcal{A}_p\) be the full subcategory of \(\mathcal{Z}_p\)-TopAlg whose objects are the discrete topological rings in which \(p\) is nilpotent. For every perfect topological \(\mathbb{F}_p\)-algebra \(E\) and every topological ring \(W\), we consider the functors

\[
\overline{\mathcal{H}}_E, H_W : \mathcal{A}_p \to \text{Set}
\]

such that

\[
\overline{\mathcal{H}}_E(A) := \text{Hom}_{\mathcal{Z}_p\text{-TopAlg}}(E, A/pA) \quad H_W(A) := \text{Hom}_{\mathcal{Z}_p\text{-TopAlg}}(W(E), A)
\]

for every \(A \in \text{Ob}(\mathcal{A}_p)\) (where \(A/pA\) is endowed with the discrete topology); to any continuous ring homomorphism \(A \to A'\) of objects of \(\mathcal{A}_p\), the functor \(\overline{\mathcal{H}}_E\) assigns the mapping

\[
\overline{\mathcal{H}}_E(\varphi) : H_E(A) \to H_E(A') \quad (\overline{\psi} : E \to A/pA) \mapsto (\varphi \otimes_{\mathbb{F}_p} \overline{\psi}) \circ \overline{\psi}
\]

and likewise, \(H_W(\varphi) : H_W(A) \to H_W(A')\) assigns to any \(\psi : A \to A'\) the map \(\varphi \circ \psi\). Then proposition 9.3.53(iii) says that we have a natural isomorphism of functors

\[(9.3.58)\quad H_{W(E)} \xrightarrow{\sim} \overline{\mathcal{H}}_E\]

that assigns to every \(A \in \text{Ob}(\mathcal{A}_p)\) the bijection \(H_{W(E)}(A) \xrightarrow{\sim} \overline{\mathcal{H}}_E(A) : \varphi \mapsto \varphi \otimes_{\mathbb{F}_p} \overline{\psi}.

(ii) Suppose that \(E\) is a perfect topological \(\mathbb{F}_p\)-algebra whose topology is linear, complete and separated. Then the existence of an isomorphism of functors (9.3.58) characterizes \(W(E)\) up to natural isomorphism, in the category of complete and separated topological rings whose topology is linear and coarser than the \(p\)-adic topology. Indeed, suppose that \(W'\) is any other such topological ring, endowed with an isomorphism of functors \(H_{W'} \xrightarrow{\sim} \overline{\mathcal{H}}_E\). There follows an isomorphism of functors \(\omega : H_{W(E)} \xrightarrow{\sim} H_{W'}\). Now, let \(I \subset W(E)\) be any open ideal; the quotient \(W(E)/I\) is an object of \(\mathcal{A}_p\), and the projection \(\pi_I : W(E) \to W(E)/I\) is an element of \(H_{W(E)}(W(E)/I)\), so we get a continuous ring homomorphism \(\omega(\pi_I) : W' \to W(E)/I\). Moreover, if \(J \subset I\) is another open ideal, the projection \(\pi_{I,J} : W(E)/J \to W(E)/I\) is a morphism of \(\mathcal{A}_p\), and we have

\[
\pi_{I,J} \circ \omega(\pi_I) = H_{W'}(\pi_{I,J})(\omega(\pi_I)) = \omega(H_{W(E)}(\pi_{I,J})(\pi_I)) = \omega(\pi_I)
\]

by the naturality of \(\omega\). Hence, we have a well defined inverse system \((\omega(\pi_I) \mid I \subset W(E))\) indexed by the cofiltered system of open ideals of \(W(E)\); the limit of this system is a well defined continuous ring homomorphism \(\alpha : W' \to W(E)\). Swapping the roles of \(W'\) and \(W(E)\), the inverse natural transformation \(\omega^{-1} : H_{W(E)} \xrightarrow{\sim} H_{W(E)}\) yields likewise a continuous ring homomorphism \(\beta : W(E) \to W'\), as \(W'\) is complete and separated by assumption.

It remains to check that \(\alpha\) and \(\beta\) are mutually inverse isomorphisms. To this aim, let \(I \subset W(E)\) be any open ideal, \(\pi'_I : W' \to W'/I'\) the projection, and set \(I := \text{Ker}(\omega^{-1}(\pi'_I)) : W(E) \to W(E)/I'\). Then

\[
\pi_I \circ \omega(\pi'_I) = H_{W'}(\pi_I)(\omega(\pi'_I)) = \omega(H_{W(E)}(\pi_I)(\pi'_I)) = \omega(\pi'_I)
\]

by the naturality of \(\omega\). Hence, we have a well defined inverse system \((\omega(\pi'_I) \mid I \subset W(E))\) indexed by the cofiltered system of open ideals of \(W(E)\); the limit of this system is a well defined continuous ring homomorphism \(\alpha : W' \to W(E)\). Swapping the roles of \(W'\) and \(W(E)\), the inverse natural transformation \(\omega^{-1} : H_{W(E)} \xrightarrow{\sim} H_{W(E)}\) yields likewise a continuous ring homomorphism \(\beta : W(E) \to W'\), as \(W'\) is complete and separated by assumption.

It remains to check that \(\alpha\) and \(\beta\) are mutually inverse isomorphisms. To this aim, let \(I \subset W(E)\) be any open ideal, \(\pi'_I : W' \to W'/I'\) the projection, and set \(I := \text{Ker}(\omega^{-1}(\pi'_I)) : W(E) \to W(E)/I'\). Then

\[
\pi_I \circ \omega(\pi'_I) = H_{W'}(\pi_I)(\omega(\pi'_I)) = \omega(H_{W(E)}(\pi_I)(\pi'_I)) = \omega(\pi'_I)
\]

by the naturality of \(\omega\). Hence, we have a well defined inverse system \((\omega(\pi'_I) \mid I \subset W(E))\) indexed by the cofiltered system of open ideals of \(W(E)\); the limit of this system is a well defined continuous ring homomorphism \(\alpha : W' \to W(E)\). Swapping the roles of \(W'\) and \(W(E)\), the inverse natural transformation \(\omega^{-1} : H_{W(E)} \xrightarrow{\sim} H_{W(E)}\) yields likewise a continuous ring homomorphism \(\beta : W(E) \to W'\), as \(W'\) is complete and separated by assumption.

It remains to check that \(\alpha\) and \(\beta\) are mutually inverse isomorphisms. To this aim, let \(I \subset W(E)\) be any open ideal, \(\pi'_I : W' \to W'/I'\) the projection, and set \(I := \text{Ker}(\omega^{-1}(\pi'_I)) : W(E) \to
whence, by (ii), a natural isomorphism of topological rings

$$H_{W(E')} \cong H_{W(E')} \times H_{W(E')} \cong H_{W(E') \otimes W(E')}$$

whence, by (ii), a natural isomorphism of topological rings

$$(9.3.59) \quad W(E') \otimes W(E') \cong W(E') \otimes W(E').$$

**Proposition 9.3.60.** Let $A$ be any discrete $\mathbb{F}_p$-algebra. We have :

(i) $W(A)$, endowed with its $p$-adic topology, is a flat and topologically free $\mathbb{Z}_p$-module.

(ii) If $A$ is perfect, and $(g_\lambda, | \lambda \in \Lambda)$ is any basis of the $\mathbb{F}_p$-vector space underlying $A$, then $(\tau_A(g_\lambda) | \lambda \in \Lambda)$ is a topological basis of the topological $\mathbb{Z}_p$-module underlying $W(A)$.

**Proof.** The element $p$ is regular in $W(A)$, by proposition [9.3.48(i)], so $W(A)$ is torsion-free, hence flat, as a $\mathbb{Z}_p$-module, for its natural $\mathbb{Z}_p$-module structure as in example 9.3.49(iv). In order to check both (i) and (ii), it then suffices to show the following general

**Claim 9.3.61.** Let $R$ be any artinian ring, $\kappa$ (resp. $m$) the residue field (resp. the maximal ideal) of $R$, and $M$ any flat $R$-module. Let also $(\lambda_\kappa | \lambda \in \Lambda)$ be any system of elements of $M$, whose image in $M_0 := M \otimes_R \kappa$ is a basis for the latter $\kappa$-vector space. Then the induced $R$-linear map

$$\psi : R^\oplus \Lambda \to M \quad e_\lambda \mapsto f_\lambda \quad \text{for every } \lambda \in \Lambda$$

is an isomorphism (here $(e_\lambda | \lambda \in \Lambda)$ is the canonical basis of $R^\oplus \Lambda$).

**Proof of the claim.** Endow $R^\oplus \Lambda$ and $M$ with the $m$-adic filtrations, and let $\text{gr}_R R^\oplus \Lambda$ and $\text{gr}_M$ be the associated graded $\kappa$-vector spaces. By virtue of [100, Th.22.3], the natural $\kappa$-linear map

$$m^n/m^{n+1} \otimes_\kappa M_0 \to \text{gr}_n M$$

is an isomorphism for every $n \in \mathbb{N}$. This easily implies that the $\kappa$-linear map $\text{gr}_R : \text{gr}_R R^\oplus \Lambda \to \text{gr}_M$ induced by $\psi$, is an isomorphism for every $n \in \mathbb{N}$. Then the assertion follows from [28 Ch.III, §2, n.8, Cor.3].

**9.3.62. Teichmüller representative of a sum.** We shall need a combinatorial identity expressing the Teichmüller representative of a finite sum of elements of a perfect topological $\mathbb{F}_p$-algebra $A$, as a series of terms, each of which is itself a Teichmüller representative. To state the result, let

$$\Sigma_n^{(k)} := \{(\sigma_0, \ldots, \sigma_k) \in p^{-n-1} A^{k+1} | p^{1-n} \Lambda_{k+1} | \sigma_0 + \cdots + \sigma_k = 1\}$$

for every $k, n \in \mathbb{N}$. and set $\Sigma_n := \bigcup_{k \in \mathbb{N}} \Sigma_n^{(k)}$ for every $k \in \mathbb{N}$. Also for every $a := (a_0, \ldots, a_k) \in A^{k+1}$ and every $\sigma := (\sigma_0, \ldots, \sigma_k) \in \Sigma_n$ set

$$a^\sigma := a_0^{\sigma_0} \cdots a_k^{\sigma_k}$$

(notice that the fractional powers $a_0^\sigma$ are well defined, since $A$ is perfect).

**Proposition 9.3.63.** For every integer $k \in \mathbb{N}$ the following holds :
(i) There exists a mapping \( \Sigma^{(k)} \to \mathbb{Z}_p : \sigma \mapsto c_\sigma \) such that
\[
\tau_A(a_0 + \cdots + a_k) = \sum_{n \in \mathbb{N}} p^n \cdot \sum_{\sigma \in \Sigma^{(k)}_n} c_\sigma \cdot \tau_A(a^\sigma)
\]
for every perfect \( \mathbb{F}_p \)-algebra \( A \) and every \( a := (a_0, \ldots, a_k) \in A^{k+1} \).

(ii) \( c_\sigma = 1 \) for every \( \sigma \in \Sigma^{(k)}_0 \).

Proof. To begin with, let us show the following:

Claim 9.3.64. With the notation of the proposition, for every \( n \in \mathbb{N} \) we have:
\[
(\tau_A(a_0)^{1/p^n} + \cdots + \tau_A(a_k)^{1/p^n})^p^n \equiv \tau_A(a_0 + \cdots + a_k) \quad (\text{mod } p^nW(A)).
\]

Proof of the claim. Since \( \tau_A \) is a splitting of \( \omega_0 \), for every \( n \in \mathbb{N} \) we have
\[
\tau_A(a_0)^{1/p^n} + \cdots + \tau_A(a_k)^{1/p^n} \equiv \tau_A(a_0 + \cdots + a_k)^{1/p^n} \quad (\text{mod } pW(A))
\]
and then the claim follows immediately from lemma 9.3.4(i). \( \Diamond \)

Now, consider first the case where \( A = \mathbb{F}_p[T_0^{1/p^n}, \ldots, T_k^{1/p^\infty}] \) is the universal perfect \( \mathbb{F}_p \)-algebra in the variables \( T_0, \ldots, T_k \) (see example 4.8.55(iii)). We endow \( A \) with the discrete topology. Set \( T_\bullet := (T_0, \ldots, T_k) \), and notice that the system of monomials \( (T_\bullet^\mu \mid \mu \in \mathbb{N}[1/p]^{k+1}) \) is a basis for the \( \mathbb{F}_p \)-vector space underlying \( A \), so the system \( (\tau_A(T_\bullet)^\mu \mid \mu \in \mathbb{N}[1/p]^{k+1}) \) is a topological basis of the topologically free \( \mathbb{Z}_p \)-module underlying \( W(A) \) (proposition 9.3.60(ii)). Hence, the image of the same system in \( W(A)/p^nW(A) \) is a basis for the latter free \( \mathbb{Z}/p^n\mathbb{Z} \)-module, for every \( n \in \mathbb{N} \). Consider the image \( S_n \) of \( S := \tau_A(T_0 + \cdots + T_k) \) in \( W(A)/p^nW(A) \); from claim 9.3.64 we see that \( S_n \) is uniquely a sum of products \( c_\mu(n)T_\bullet^\mu \) with \( c_\mu(n) \in \mathbb{Z}/p^n\mathbb{Z} \) and \( T_\bullet^\mu \) a monomial of the above type, with the further condition that
\[
c_\mu(n) = 0 \quad \text{unless} \quad \mu \in \bigcup_{i=0}^n \Sigma^{(k)}_i.
\]
Moreover, the uniqueness of the resulting expression means that the image of \( c_\mu(m) \) in \( \mathbb{Z}/p^n\mathbb{Z} \) agrees with \( c_\mu(n) \), for every such \( \mu \) and every \( m \geq n \). Summing up, we get the sought identity for \( S \), and (ii) follows as well. Next, if \( A \) is any perfect \( \mathbb{F}_p \)-algebra, there exists a unique (continuous) map of \( \mathbb{F}_p \)-algebras
\[
\psi : \mathbb{F}_p[T_0^{1/p^n}, \ldots, T_k^{1/p^\infty}] \to A \quad \text{such that} \quad \psi(T_i) = a_i \quad \text{for } i = 0, \ldots, k.
\]
Since the sought identity is already known for \( T_\bullet \), we deduce it for \( a \), by virtue of (9.3.36). \( \Box \)

9.3.65. Let \( A \) be any perfect \( \mathbb{F}_p \)-algebra, \( b := (b - n \mid n \in \mathbb{N}) \in W(A) \) any element, and set
\[
\text{Ann}_A(b) := \{a \in A \mid \tau_A(a \cdot b) = 0\}.
\]

Corollary 9.3.66. With the notation of (9.3.65), the subset \( \text{Ann}_A(b) \) is a radical ideal of \( A \).

Proof. Let \( a \in \text{Ann}_A(b) \) for some \( n \in \mathbb{N} \). We show first that \( a^\mu \in \text{Ann}_A(b) \) for every \( \mu \in \mathbb{N}[1/p] \). Indeed, in view of proposition 9.3.37(i), the assumption means that \( a^\mu \cdot b_n = 0 \) for every \( n \in \mathbb{N} \), and therefore \( a^{\mu \cdot n} b_{n^k} = 0 \) for every \( k, n \in \mathbb{N} \), since \( A \) is perfect. Hence \( a^{\mu \cdot n} b_{n^k} = 0 \) as well, for every \( n, k \in \mathbb{N} \), which means that \( \tau_A(a^{\mu \cdot n} \cdot b) = 0 \) for every \( k \in \mathbb{N} \) (again by proposition 9.3.37(i)); the assertion is a straightforward consequence.

It then remains only to check that \( \text{Ann}_A(b) \) is an ideal of \( A \). However, if \( a, a' \in \text{Ann}_A(b) \) and \( x \in A \) is any element, it is clear that \( ax \in \text{Ann}_A(b) \), and proposition 9.3.63 easily implies that \( a + a' \in \text{Ann}_A(b) \) as well, as required. \( \Box \)

In the same vein, though the Teichmüller mapping is not a ring homomorphism, one can attach to it a continuous map on Zariski spectra, as explained in the following proposition.
Proposition 9.3.67. Let $E$ be any perfect $\mathbb{F}_p$-algebra; the following holds:

(i) For every $p \in \text{Spec } W(E)$, the subset $\tau^{-1}_E p$ is a prime ideal of $E$.

(ii) The resulting map

$$\text{Spec } \tau_E : \text{Spec } W(E) \to \text{Spec } E \quad p \mapsto \tau^{-1}_E p$$

is continuous and spectral.

(iii) Let $p \in \text{Spec } W(E)$ be any prime ideal, set $q := \text{Spec } \tau_E(p) \in \text{Spec } E$, and let $\pi_p : W(E) \to \kappa(p), \pi_q : E \to \kappa(q)$ be the projections. If $p$ is a closed subset in the $p$-adic topology of $W(E)$, then $\tau_E$ induces a morphism of multiplicative monoids

$$\tau_p : \kappa(q) \to \kappa(p) \quad \text{such that} \quad \tau_p \circ \pi_q = \pi_p \circ \tau_E.$$ 

(iv) Let $E'$ be any other perfect $\mathbb{F}_p$-algebra, and $\varphi : E \to E'$ any continuous ring homomorphism. Then the resulting diagram commutes:

$$\begin{array}{ccc}
\text{Spec } W(E') & \xrightarrow{\text{Spec } \tau_{E'}} & \text{Spec } E' \\
\text{Spec } W(\varphi) \downarrow & & \downarrow \text{Spec } \varphi \\
\text{Spec } W(E) & \xrightarrow{\text{Spec } \tau_E} & \text{Spec } E.
\end{array}$$

Proof. (i): Say that $x, y \in E$ and $\tau_E(x, y) \in p$; since $\tau_E$ is a multiplicative map, it follows easily that either $x$ or $y$ lies in $\tau^{-1}_E p$. By the same token, if $x \in \tau^{-1}_E p$ and $y \in E$, then $xy \in \tau^{-1}_E p$. Next, suppose that $x, y \in \tau^{-1}_E p$; by proposition 9.3.63, we may write $\tau_E(x, y)$ as a $p$-adically convergent series $\sum_{n \in \mathbb{N}} p^n \cdot z_n$, where each $z_n$ is a finite $\mathbb{Z}_p$-linear combination of terms of the form $\tau_E(x^\alpha y^{1-\alpha})$, with $\alpha, 1 - \alpha \in \mathbb{N}[1/p]$. It follows easily that $z_n = \tau_E(x^{1/p}) \cdot z'_n + \tau_E(y^{1/p}) \cdot z''_n$, for suitable $z'_n, z''_n \in W(E)$. Summing up, we get

$$\tau_E(x + y) = a \cdot \tau_E(x^{1/p}) + b \cdot \tau_E(y^{1/p}) \quad \text{where} \quad a := \sum_{n \in \mathbb{N}} c_n z'_n, \quad b := \sum_{n \in \mathbb{N}} c_n z''_n.$$ 

However, by the foregoing we already know that $x^{1/p}, y^{1/p} \in \tau^{-1}_E p$, so $\tau_E(x + y) \in p$, whence the contention.

(ii): Let $f \in E$ any element; directly from the definition we get

$$(9.3.68) \quad (\text{Spec } \tau_E)^{-1}(\text{Spec } E_f) = \text{Spec } A_{\tau_E(f)}$$

which says that $\text{Spec } \tau_E$ is continuous and spectral.

(iii): We check first that $\tau_E$ descends to a morphism $\overline{\tau} : E/q \to W(E)/p$ of multiplicative monoids. To this aim, let $x \in E$ and $y \in q$ be any two elements; arguing as in the proof of (i), we see that $d := \tau_E(x + y) - \tau_E(x)$ can be written as $p$-adically convergent series $\sum_{n \in \mathbb{N}} d_n$, where $d_n \in p^n \tau_E(y^{1/p^n}) W(E)$ for every $n \in \mathbb{N}$. We have already remarked that $\tau_E(y^{1/p^n}) \in p$ for every $n \in \mathbb{N}$, and since $p$ is $p$-adically closed in $W(E)$, it follows that $d \in p$ as well, whence the claim. Now, by construction $\overline{\tau}^{-1}(0) = \{0\}$, so $\overline{\tau}$ extends uniquely to a morphism of monoids $\tau_p$ as sought.

(iv) follows immediately from (9.3.66). \hfill \Box

9.3.69. Angular powers. For the further investigation of the ring of Witt vectors $W(A)$ of a given perfect topological $\mathbb{F}_p$-algebra $A$, it is useful to consider special types of ideals of $A$ and $W(A)$ defined by certain combinatorial conditions that we proceed to explain.

- First, consider any $p$-perfect monoid $P$, i.e. such that the $p$-Frobenius endomorphism $\Phi_P$ of $P$ is bijective. A basic example of $p$-perfect monoid is $\mathbb{N}[1/p] := S_{p^{-1}} \mathbb{N}$, the localization of $\mathbb{N}$ at its multiplicative subset $S_p := \{p^k \mid k \in \mathbb{N}\}$. Notice that this condition on $P$ means that for every $x \in P$ and every $\lambda \in \mathbb{N}[1/p]$, the fractional power $x^\lambda$ is well defined: indeed, we may
write \( \lambda = p^{-n}a \) for some \( a, n \in \mathbb{N} \) and set \( x^\lambda := \Phi_p^{-n}(x^a) \). It is easily seen that this definition is independent of the choice of \( a \) and \( n \).

- For any ideal \( I \subset P \) and every \( \lambda = p^{-n}a \in \mathbb{Z}[1/p] \) we define the angular power:
  \[
  I^{(\lambda)} := \bigcup_{r \in \mathbb{N}} \Phi_p^{-n-r}(I^{r'\lambda}) \quad \text{if} \; \lambda > 0, \quad \text{and} \quad I^{(\lambda)} := P \quad \text{if} \; \lambda \leq 0.
  \]

Notice that \( I^{(\lambda)} \) is an increasing union of ideals of \( P \), and a simple inspection shows that the definition does not depend on the choice of \( a \) and \( n \). Explicitly, if \( \lambda \geq 0 \), the ideal \( I^{(\lambda)} \) is the subset of all products of the form \( a_1^{\mu_1} \cdots a_k^{\mu_k} \), where \( k \in \mathbb{N} \) is any integer, \( a_1, \ldots, a_k \) are arbitrary elements of \( I \), and \( \mu_1, \ldots, \mu_k \) are arbitrary rational numbers in \( \mathbb{N}[1/p] \) such that \( \sum_{i=1}^{k} \mu_i = \lambda \). Moreover, if \( S \subset I \) is any system of generators for \( I \), then \( I^{(\lambda)} \) is generated by the set of all products as above, where \( a_1, \ldots, a_k \in S \).

**Lemma 9.3.70.** In the situation of (9.3.69), the following holds:

1. If \( (I_j \mid j \in J) \) is any filtered family of ideals of \( P \), we have
   \[
   (\bigcup_{j \in J} I_j)^{(\lambda)} = \bigcup_{j \in J} I_j^{(\lambda)} \quad \text{for every} \; \lambda \in \mathbb{N}[1/p].
   \]

2. For every ideal \( I \subset P \), every \( n \in \mathbb{N} \) and every \( \lambda, \mu \in \mathbb{N}[1/p] \) we have
   
   (a) \( (I^n)^{(\lambda)} = (I^{(\lambda)})^n = I^{(n\lambda)} \).
   
   (b) \( (I^{(\lambda)})^n = I^{(\lambda + \mu)} \).
   
   (c) \( (I^{(\lambda)})^{(\mu)} = I^{(\lambda \mu)} \).

3. If \( I \subset P \) is a non-empty finitely generated ideal generated by \( r \) elements of \( P \), then \( I^{(\lambda)} \subset I^n \) for every \( n \in \mathbb{N} \) such that \( \lambda \geq n + r - 1 \).

**Proof.** (i): This is clear from the explicit description of the angular power furnished in (9.3.69).

(ii): Indeed, say that \( \lambda = p^k a \) for some \( a, n \in \mathbb{N} \); we have
   \[
   (I^n)^{(\lambda)} = \bigcup_{r \in \mathbb{N}} \Phi_p^{-n-r}(I^{n\lambda}) = \bigcup_{r \in \mathbb{N}} \Phi_p^{-n-r}(I^{ap'}) = (I^{(\lambda)})^n.
   \]

(iii): Clearly \( I^{(\lambda)} I^{(\mu)} \subset I^{(\lambda + \mu)} \). For the converse inclusion, say that \( a_1^{t_1} \cdots a_k^{t_k} \in I^{(\lambda + \mu)} \), for given \( a_1, \ldots, a_k \in I \) and rational numbers \( t_1, \ldots, t_k \) in \( \mathbb{N}[1/p] \) such that \( \sum_{i=1}^{k} t_i = \lambda + \mu \). If \( \mu = 0 \), there is nothing to prove; otherwise, let \( j < k \) be the largest integer such that \( s := \sum_{i=0}^{j} t_i \leq \lambda \). Then \( t_{j+1} > t'_{j+1} := \lambda - s \), and if we set \( t'_j = t_{j+1} - t'_{j+1} \) we get
   \[
   a_1^{t_1} \cdots a_j^{t_{j+1}} \cdots a_k^{t_k} \in I^{(\mu)}
   \]

whence the contention.

(iv): Say that \( \lambda = p^{-m}b \) and \( \mu = p^{-m}b \); taking into account (ii.a) we may compute
   \[
   (I^{(\lambda)})^{(\mu)} = \bigcup_{r \in \mathbb{N}} \Phi_p^{-m-r}((I^{\lambda})^{bp'}) = \bigcup_{r \in \mathbb{N}} \Phi_p^{-m-r}((I^{bp'})^{(\lambda)}) = \bigcup_{r \in \mathbb{N}} \Phi_p^{-m-s}(I^{abp^{r+s}}) = (I^{(\lambda)})^{(\mu)}
   \]

whence the sought identity.

(v): Indeed, for \( \lambda = p^{-n}a \) we may compute
   \[
   I^{(\lambda)} J^{(\lambda)} = \bigcup_{r \in \mathbb{N}} \Phi_p^{-n-r}(I^{ap'}) \cdot \bigcup_{r \in \mathbb{N}} \Phi_p^{-n-r}(J^{ap'}) = \bigcup_{r \in \mathbb{N}} \Phi_p^{-n-r}(I^{ap'} J^{ap'})
   \]

whence the contention.
Lemma 9.3.75. Let $t_i \in [a_i, a_i + 1]$, and set $s := a_i + \cdots + a_r$; clearly $x \in I^s$. Suppose now that $\lambda \geq n + r - 1$; if $t_i \in \mathbb{N}$ for every $i = 1, \ldots, r$, it follows that $s = \lambda \geq n$, since $r > 0$. Lastly, if there exists $i \leq r$ such that $t_i \not\in \mathbb{N}$, then $s + r > \lambda$, whence $s \geq n$ again, and the assertion follows. \hfill $\square$

Remark 9.3.71. (i) Let $A$ be a ring, $P$ a $p$-perfect monoid, as defined in (9.3.69), and $u : P \to (A, \cdot)$ a morphism of monoids. Then, for every ideal $I \subset P$ and every $\lambda \in \mathbb{Z}[1/p]$ we may consider the ideal $I^{(\lambda)}A$ of the ring $A$, generated by $u(I^{(\lambda)})$. We also define:

$$I^{[r]}A := \bigcap_{\mu \in \mathbb{Z}[1/p], \mu < r} I^{(\mu)}A, \quad I^{[s]}A := \bigcup_{\mu \in \mathbb{Z}[1/p], \mu > s} I^{(\mu)}A$$

for every $r \in \mathbb{R}$.

From lemma 9.3.70(ii.a,ii.c) we deduce immediately:

$$(I^{(\lambda)}A)^n = (I^{(\lambda)})^n A = I^{(n\lambda)}A \quad I^{(\lambda)}I^{(\mu)}A = I^{(\lambda+\mu)}A \quad I^{(\lambda)}J^{(\lambda)}A = (IJ)^{(\lambda)}A$$

for every ideals $I, J \subset P$ and every $\lambda, \mu \in \mathbb{Z}[1/p]$ and every $n \in \mathbb{N}$.

(ii) If $A$ is a perfect $\mathbb{F}_p$-algebra, we may take for $u$ the identity map of the multiplicative monoid $P := (A, \cdot)$. In this case, notice that every ideal $I$ of the ring $A$ is also an ideal of the underlying monoid $P$, so the angular powers of $I$ are well defined ideals of $P$; moreover:

$$(IA)^{(\lambda)}A = I^{(\lambda)}A \quad \text{for every } \lambda \in \mathbb{Z}[1/p] \text{ and every ideal } I \subset P$$

(details left to the reader). Combining with lemma 9.3.70(ii.c) we get

$$(I^{(\lambda)}A)^{(\mu)}A = I^{(\lambda\mu)}A \quad \text{for every } \lambda \in \mathbb{Z}[1/p] \text{ and every ideal } I \subset P.$$ 

Furthermore, suppose that $I$ is an ideal of the ring $A$ generated (in the usual ring-theoretic sense) by a subset $S \subset A$ consisting of $r$ elements, and let $J_S$ be the ideal of $P$ generated by $S$; then $I^n = J^n_S A$ and $I^{(\lambda)}A = J_S^{(\lambda)}A$ for every $n \in \mathbb{N}$ and $\lambda \in \mathbb{Z}[1/p]$, so lemma 9.3.70(iv) yields

$$I^{(\lambda)}A \subset I^n \quad \text{for every } n \in \mathbb{N} \text{ and every } \lambda \in \mathbb{Z}[1/p] \text{ such that } \lambda \geq n + r - 1.$$ 

(iii) If $A$ is as in (ii), we may also take

$$P := (A, \cdot) \quad \text{and} \quad u := \tau_A : P \to W(A).$$

If $a_* := (a_j \mid j \in J)$ is any system of elements of $A$ generating an ideal $I$ of the monoid $P$, we may regard we shall also use the notation

$$[a_*]^{(\lambda)} := I^{(\lambda)}W(A).$$

(iv) For instance, if $A$ is as in (ii), from lemma 9.3.70(ii.a) and (9.3.47) we see that

$$W(I^{(\lambda)}, r) = \left\{ \sum_{n=0}^{\infty} p^n \cdot \tau_A(b_n) \mid b_n \in I^{(\lambda)}A \text{ for every } n \leq r \right\}$$

for every ideal $I \subset A$, every $\lambda \in \mathbb{Z}[1/p]$ and every $r \in \mathbb{N}$ (notation of remark 9.3.28(iv)), and likewise we can describe $W(I^{(\lambda)})$. Moreover, for every such $I$, notice that

$$p^k W(A) \cap W(I^{(\lambda)}) = p^k W(I^{(\lambda)}) \quad \text{for every } \lambda \in \mathbb{Z}[1/p] \text{ and every } k \in \mathbb{N}.$$ 

Indeed, say that $b := (b_n \mid n \in \mathbb{N}) \in p^k W(A) \cap W(I^{(\lambda)})$; in view of lemma 9.3.70(ii.a), this means that $b_n = 0$ for $n = 0, \ldots, k - 1$, and $b_n \in I^{(p^k\lambda)}$ for every integer $n \geq k$. Clearly $\xi := (b_{n+k}^{1/p}) \mid n \in \mathbb{N}) \in W(I^{(\lambda)})$, and $p^k \cdot \xi = b$, whence the claim. As an immediate consequence, we deduce that the 0-th ghost map $\omega_0$ induces an $A$-linear isomorphism

$$W(I^{(\lambda)})/pW(I^{(\lambda)}) \cong I^{(\lambda)}A \quad \text{for every } \lambda \in \mathbb{Z}[1/p].$$

Lemma 9.3.75. Let $A$ be any perfect $\mathbb{F}_p$-algebra, and $I, J \subset A$ two ideals. We have:

(i) $I^{[r]}A = \overline{c_0}(I, A, r)$ for every $r \in \mathbb{R}_+$ (notation of remark 9.2.43).
(ii) Suppose that $I$ and $J$ are finitely generated, and let $(a_1, \ldots, a_n)$ (resp. $(b_1, \ldots, b_n)$) be a finite system of generators for $I$ (resp. $J$). Let also $q > 1$ be a rational number with $b_i - a_i \in \text{i.c.}(I, A, q)$ for every $i = 1, \ldots, n$

and suppose furthermore that
(a) either, the radical of $I$ equals the radical of $J$
(b) or else, $I$ is contained in the Jacobson radical of $A$.

Then $I^{(1)} A = J^{(1)} A$.

Proof. (i): We are easily reduced to showing that

$I^{(\lambda)} A \subset \text{i.c.}(I, A, \lambda) \subset I^{(\lambda')} A \quad \text{for every } \lambda' \in \mathbb{N}[1/p]$ such that $\lambda' < \lambda$.

To this aim, a direct inspection of the definition shows that

$\Phi_A(\text{i.c.}(I, A, \lambda)) = \text{i.c.}(I, A, p\lambda) \quad \text{and} \quad \Phi_A(I^{(\lambda)} A) = I^{(p\lambda)} A \quad \text{for every } \lambda \in \mathbb{N}[1/p]$,

so that we may replace $\lambda$ by $p^n \lambda$ for a suitable $n \in \mathbb{N}$, after which we may assume that $\lambda \in \mathbb{N}$. Moreover, since the subset $S := \{k\lambda/p^n \mid k, n \in \mathbb{N}\}$ is dense in $\mathbb{N}[1/p]$, we may assume that $\lambda' \in S$. In this case, taking into account (9.2.44) and lemma 9.3.70(ii.a), we may further replace $I$ by $I^{(\lambda)} A$, $\lambda$ by 1, and $\lambda'$ by $\lambda' / \lambda$, so we reduce to checking that

$I^{(1)} A \subset \text{i.c.}(I, A) \subset I^{(\mu)} A \quad \text{for every } \mu \in \mathbb{N}[1/p]$ such that $\mu < 1$.

To this aim, say that $x \in I^{(1)}$; by definition, this means that $x^p^n \in I^{p^n}$ for some $n \in \mathbb{N}$, whence $x \in \text{i.c.}(I, A)$. Next, let $x \in \text{i.c.}(I, A)$, so that $x^p^n \in \sum_{i=0}^{n-1} x^n I^{m-i}$ for some $n \in \mathbb{N}$.

Claim 9.3.76. $x^m \in \sum_{i=0}^{n-1} x^n I^{m-i}$ for every $m \geq n$.

Proof of the claim. We argue by induction on $m - n$. If $m = n$, there is nothing to prove, so assume that the claim is already known for some $m \geq n$. In this case, we get

$x^{m+1} \in \sum_{i=1}^{n} x^n I^{m+1-i} = x^n I^{m+1-n} + \sum_{i=1}^{n-1} x^n I^{m+1-i}$.

Moreover, $x^n I^{m+1-n} \in \sum_{i=0}^{n-1} x^n I^{m+1-i}$, so the claim holds for $m + 1$.

It follows from claim 9.3.76 that $x^p^k \in I^{p^n+1-n}$, whence $x \in I^{(1-(n-1)/p^k)}$ for every $k \in \mathbb{N}$ such that $p^k \geq n$, whence the contention.

(ii): Under the stated conditions, lemma 9.2.47 says that $\text{i.c.}(I, A) = \text{i.c.}(J, A)$. Together with (9.2.45), we deduce that

$\text{i.c.}(I, A, q) = \text{i.c.}(J, A, q)$.

Hence $J \subset I + \text{i.c.}(I, A, q) \subset I^{(1)} A$ and likewise $I \subset J + \text{i.c.}(J, A, q) \subset J^{(1)} A$, whence the assertion.

9.3.77. Let $A$ be a perfect $\mathbb{F}_p$-algebra, $a_\bullet := (a_1, \ldots, a_k)$ a finite system of elements of $A$, and $I \subset A$ (resp. $\mathcal{J} \subset W(A)$) the ideal generated by $a_\bullet$ (resp. by $\tau_A(a_1), \ldots, \tau_A(a_k)$). Set

$\mathcal{J} := pW(A) + \mathcal{J} \quad W(\lambda) := W(I^{(\lambda)}) \quad \text{for every } \lambda \in \mathbb{N}[1/p]$ (notation of remark 9.3.28(iv)). Lastly, denote by $\mathcal{A}_\lambda$ (resp. $\mathcal{A}_{W(A)}$) the topology of $A$ (resp. of $W(A, \mathcal{A}_A)$). We complement the generalities of lemma 9.3.70 with the following:

**Proposition 9.3.78.** In the situation of (9.3.77), the following holds:

(i) $[a_\bullet]^{(\lambda)} \subset W(\lambda) \subset [a_\bullet]^{(\lambda')} \quad \text{for every } \lambda' < \lambda \in \mathbb{N}[1/p]$ (notation of remark 9.3.71(iii)).

(ii) If $\mathcal{A}_A$ agrees with the $I$-adic topology, $\mathcal{A}_{W(A)}$ agrees with the $\mathcal{J}$-adic topology.
Proof. (ii): Notice that $\tau_A(b^\mu) = \tau_A(b^\mu)$ for every $b \in A$ and every $\mu \in \mathbb{N}[1/p]$. Taking into account \[\text{(9.3.70)}\] and proposition \[\text{(9.3.63)}\], we deduce that
\[W(\lambda, r) := W(I(\lambda), r) = p^{r+1}W(A) + [a_\bullet(\lambda)] \quad \text{every } r \in \mathbb{N}\]
which, in light of lemma \[\text{(9.3.70)}\] iv), shows that the linear topology induced by the cofiltered system of ideals $(W(\lambda, r) \mid r \in \mathbb{N}, \lambda \in \mathbb{N}[1/p])$ agrees with the $\mathcal{F}$-adic topology. But by the same token we see that the latter family is a fundamental system of open neighborhoods of zero in $W(A)$, whence the contention.

(i): Since $W(\lambda, r)$ is an open ideal in the $p$-adic topology of $W(A)$ for every $r \in \mathbb{N}$, we see that $W(\lambda)$ is a closed ideal in $W(A)$ for the $p$-adic topology of $W(A)$. On the other hand, from \[\text{(9.3.73)}\] it follows that the $p$-adic topology of $W(\lambda)$ agrees with the topology induced from the $p$-adic topology of $W(A)$. Taking into account proposition \[\text{(9.3.45)}\] ii), we deduce that $W(\lambda)$ is complete and separated for its $p$-adic topology, and then \[\text{(9.3.74)}\] and claim \[\text{(9.3.61)}\] imply that $W(\lambda)$ is a topologically free $\mathbb{Z}_p$-module for this topology, and any lifting of an $\mathbb{F}_p$-basis of $I(\lambda)A$ yields a topological basis. However, clearly we may find:

- a subset $S \subseteq \mathbb{N}[1/p]^{\geq k}$ consisting of sequences $(\mu_1, \ldots, \mu_k)$ such that $\mu_1 + \cdots + \mu_k = \lambda$
- a system of elements $(b_\mu \mid \mu \in S)$ of $A$ such that the family $(b_\mu \cdot a^\mu \mid \mu \in S)$ is an $\mathbb{F}_p$-basis of $I(\lambda)A$, where $a^\mu := a_{\mu_1} \cdots a_{\mu_k}$ for every $\mu \in S$

so that the system $(\tau_A(b_\mu \cdot a^\mu) \mid \mu \in S)$ is a topological $\mathbb{Z}_p$-basis of $W(\lambda)$. Now, clearly $[a_\bullet]^{(\lambda)} \subset W(\lambda)$; to check the second inclusion, let $w \in W(\lambda)$ be any element. By construction, there exists a unique system $(d_\mu \mid \mu \in S)$ of elements of $\mathbb{Z}_p$ such that
\[w = \sum_{\mu \in S} d_\mu \cdot \tau_A(b_\mu \cdot a^\mu)\]
where the series converges in the $p$-adic topology of $W(A)$, and the set $\{\mu \in S \mid d_\mu \notin p^n\mathbb{Z}_p\}$ is finite for every $n \in \mathbb{N}$. Pick any $N \in \mathbb{N}$ such that $\lambda - \lambda' \geq kp^{-N}$, and for every $r \in \mathbb{R}$ define
\[\tau \in p^{-N}\mathbb{Z}, \quad r^* \in [0, p^{-N}] \quad \text{fulfilling the condition:} \quad r = \tau + r^*\]
Then, for every $\mu \in S$ let also $\overline{\mu} := (\overline{\mu}_1, \ldots, \overline{\mu}_k)$, $\mu^* := (\mu_1^*, \ldots, \mu_k^*)$, and set
\[S' := \{\sigma \in p^{-N}\mathbb{N}^{\geq k} \mid \lambda \geq \sigma_1 + \cdots + \sigma_k > \lambda'\} \]
With this notation, it is easily seen that $\overline{\mu} \in S'$ for every $\mu \in S$. Hence, let also
\[c_\sigma := \sum_{\mu \in S \atop \overline{\mu} = \sigma} d_\mu \cdot \tau_A(b_\mu \cdot a^\mu) \quad \text{for every } \sigma \in S'\]
(notice that this series converges $p$-adically in $W(A)$, so $c_\sigma$ is well defined); we get
\[w = \sum_{\sigma \in S'} c_\sigma \cdot \tau_A(a^\sigma)\]
To conclude, it suffices to remark that $S'$ is a finite set, and $a^\sigma \in I(\lambda)A$ for every $\sigma \in S'$.

**Example 9.3.79.** Let $A := \mathbb{F}_p[T^{1/p^\infty}]$, endow $A$ with its $T$-adic topology $\mathcal{F}_T$, and let $(A^\wedge, \mathcal{F}_T^\wedge)$ be the completion of $(A, \mathcal{F}_T)$. According to lemma \[\text{(9.3.33)}\] iv), the topological ring $W(A^\wedge, \mathcal{F}_T^\wedge)$ is the completion of $W(A, \mathcal{F}_T)$. In light of example \[\text{(9.3.49)}\] v) and proposition \[\text{(9.3.78)}\] ii), the latter is naturally isomorphic to the $(p, T)$-adic completion of $\mathbb{Z}_p\{T^{1/p^\infty}\}$, or equivalently, the $(p, T)$-adic completion of $\mathbb{Z}_p[T^{1/p^\infty}]$. Explicitly, this is the ring of all power series \[\text{(9.3.50)}\], where $(\lambda_n \mid n \in \mathbb{N})$ is any sequence of elements of $\mathbb{N}[1/p]$, and $(a_n \mid n \in \mathbb{N})$ is any sequence of elements of $\mathbb{Z}_p$, with the property that
\[\lim_{n \to \infty} v_p(a_n) + \lambda_n = \infty\]
(where $v_p : \mathbb{Z}_p \to \mathbb{N} \cup \{\infty\}$ is the $p$-adic valuation).
9.3.80. Semi-norms on the Witt ring. Let $A$ be any topological ring, $| \cdot |_A$ a real-valued semi-norm on $A$ (see definition \[9.1.3\](v)). For any non-empty subset $S \subset A$ we let
$$|S|_A := \sup_{a \in S} |a|_A \in \mathbb{R}_+ \cup \{+\infty\}.$$ 

Also, for every real number $\rho \in [0, 1]$ we consider the mapping
$$| \cdot |_\rho : W(A) \to \mathbb{R}_+ \cup \{+\infty\} \quad (a_n \mid n \in \mathbb{N}) \mapsto \sup_{n \in \mathbb{N}} |a_n|_A^p^{-n} \cdot \rho^n.$$ 

For instance, notice that $|0|_\rho = 0$ and $|1|_\rho = 1$; more generally, we have $|\tau_A(a)|_\rho = |a|_A$ for every $a \in A$. We let
$$W(A, \rho) := \{a \in W(A) \mid |a|_\rho \in \mathbb{R}_+\}.$$ 

**Lemma 9.3.81.** With the notation of \[9.3.80\], the following holds:

(i) $W(A, \rho)$ is an additive subgroup of $W(A)$ for every $\rho \in [0, 1]$.
(ii) Both $W(A, 0)$ and $W(A, 1)$ are subrings of $W(A)$.
(iii) $|a - b|_\rho \leq \max(|a|_\rho, |b|_\rho)$ for every $a, b \in W(A)$.
(iv) $|a \cdot b|_\rho \leq |a|_\rho \cdot |b|_\rho$ for every $a, b \in W(A)$ and every $\rho_1, \rho_2 \in [0, 1]$.
(v) $\rho^n \cdot |F_A(a)|_\rho \leq |a|_\rho^n$ for every $a \in W(A)$ and every $\rho \in [0, 1]$.
(vi) $|V_A(a)|_{\rho^{1/p}} = \rho^{1/p} \cdot |a|_{\rho^{1/p}}$ for every $a \in W(A)$ and every $\rho \in [0, 1]$.
(vii) $|\tau_A(a) : b|_\rho \leq |a|_A \cdot |b|_\rho$ for every $a \in A$ and every $b \in W(A)$, and if $| \cdot |_A$ is a valuation, this inequality is actually an equality.

**Proof.** Let $a := (a_n \mid n \in \mathbb{N}), b := (b_n \mid n \in \mathbb{N})$ be any two elements of $W(A)$, and suppose that $M := \max(|a|_\rho, |b|_\rho) \in \mathbb{R}_+$. This condition means that
$$|a_n|_A, |b_n|_A \leq (M/\rho^n)^{p^n} \quad \text{for every } n \in \mathbb{N}.$$ 

Set $c := a + b, d := a \cdot b$ and recall that $c = (c_n \mid n \in \mathbb{N})$ (resp. $d = (d_n \mid n \in \mathbb{N})$), where $c_n = S_n(a_0, \ldots, a_{n-1}, b_0, \ldots, b_{n-1})$ (resp. $d_n = P_n(a_0, \ldots, a_{n-1}, b_0, \ldots, b_{n-1})$ : notation of \[9.3.7\]) for every $n \in \mathbb{N}$. By construction, $S_n$ is a $Z$-linear combination of monomials $Q(X_0, \ldots, X_n, Y_0, \ldots, Y_n)$ of total degree $p^n$ (remark \[9.3.8\]); we claim that
$$r := |Q(a_0, \ldots, a_n, b_0, \ldots, b_n)|_A \leq (M/\rho^n)^{p^n} \quad \text{for every such } Q.$$ 

Indeed, say that $Q = \prod_{i=0}^n X_i^{n_i} Y_i^{m_i}$; then
$$\sum_{i=0}^n (n_i + m_i)p^i = p^n, \text{ and therefore}$$
$$r \leq \prod_{i=0}^n (M/\rho^i)^{(n_i + m_i)p^i} = M^{p^n} \cdot \rho^{-t} \quad \text{where } t := \sum_{i=0}^n i \cdot (n_i + m_i)p^i \leq np^n.$$ 

Since $\rho \leq 1$, the claim follows. Lastly, arguing with the polynomials $I_n$ of \[9.3.7\] that are bihomogeneous of degree $(p^n, 0)$, we get as well $| - a|_\rho \leq |a|_\rho$, and therefore $| - a|_\rho = |a|_\rho$ for every $a \in W(A)$. Assertions (i) and (iii) are immediate consequences.

(iv): Likewise, $P_n$ is a $Z$-linear combination of monomials $R$ of bidegree $(p^n, p^n)$, and a similar calculation shows that
$$|R(a_0, \ldots, a_n, b_0, \ldots, b_n)|_A \leq |a|_{\rho_1} \cdot |b|_{\rho_2} \cdot (\rho_1 \rho_2)^{-np^n} \quad \text{for every such } R$$
(details left to the reader), whence the assertion. (ii) now follows from (iii) and (iv).

(v) is proven in the same way : for every $n \in \mathbb{N}$ one estimates $|F_n(a_0, \ldots, a_{n+1})|$ by writing $F_n$ as a sum of bihomogeneous monomials of degree $(p^{n+1}, 0)$ : the details are left to the reader.

(vi): Set $M := |a|_\rho$, fix a real number $\varepsilon > 0$, and pick $n \in \mathbb{N}$ such that $|a_n|_A^{p^{-n}} \cdot \rho^n > M - \varepsilon$. Then we have
$$|a_k|_A \leq (M/\rho^{k-1})^{p^{k-1}} = (M^{1/p})^{p^k} \cdot \rho^{-(k-1)p^{k-1}} \quad \text{for every } k > 0$$
which is equivalent to

\[ |a_{k-1}|_A^{p^{-k}} \cdot \rho^{k/p} \leq (\rho M)^{1/p} \quad \text{for every } k > 0. \]

On the other hand, we have \(|a_n|_A^{p^{-n-1}} \cdot \rho^{(n+1)/p} > (\rho(M - \varepsilon))^{1/p}\) whence the contention.

(vii) follows directly from proposition 9.3.37(i).

**Proposition 9.3.82.** In the situation of (9.3.80), suppose that \(A\) is an \(\mathbb{F}_p\)-algebra. We have:

(i) \(|F_A(a)|_\rho = |a|_\rho^p\) for every \(a \in W(A)\) and every \(\rho \in [0, 1]\).

(ii) \(W(A, \rho)\) is a subring of \(W(A)\), and \(|\cdot|_\rho\) restricts to a semi-norm on \(W(A, \rho)\).

(iii) If moreover \(|\cdot|_A\) is a valuation, the same holds for the restriction of \(|\cdot|_\rho\) to \(W(A, \rho)\).

(iv) If \(A\) is perfect and \(|\cdot|_A\) is a valuation, we have

\[ \sum_{n \in \mathbb{N}} p^n \cdot \tau_A(b_n) \bigg|_\rho = \sup_{n \in \mathbb{N}} |b_n|_A \cdot \rho^n \quad \text{for every sequence } (b_n)_{n \in \mathbb{N}} \text{ of elements of } A. \]

**Proof.** Assertion (i) (resp. (iv)) follows easily from (9.3.41) (resp. from (9.3.47)).

(iii): For \(\rho = 0\), we have \(|a|_\rho = |a_0|_A\) for every \(a := (a_n)_{n \in \mathbb{N}} \in W(A)\), so the assertion is clear in this case. Hence, suppose that \(\rho \in [0, 1]\), and let \(a, a' \in W(A, \rho)\) be any two elements. It is clear that \(a \in W(A, \rho - \varepsilon)\) for every \(\varepsilon \in [0, \rho]\), and moreover

\[ \lim_{\varepsilon \to 0} |a|_{\rho - \varepsilon} = |a|_\rho. \]

Furthermore, it is easily seen that, if \(\varepsilon > 0\), there exist minimal \(N, N' \in \mathbb{N}\) such that

\[ |a_N|_A^{p^{-N}} \cdot (\rho - \varepsilon)^N = |a|_{\rho - \varepsilon} \quad \text{and} \quad |a'_N|_A^{p^{-N'}} \cdot (\rho - \varepsilon)^{N'} < |a'|_{\rho - \varepsilon}. \]

We have to check that \(|a \cdot a'|_\rho = |a|_\rho \cdot |a'|_\rho\), and in light of (9.3.83) it suffices to show that \(|a \cdot a'|_\rho = |a|_{\rho - \varepsilon} \cdot |a'|_{\rho - \varepsilon}\) for every \(\varepsilon \in [0, \rho]\). We may then replace \(\rho\) by \(\rho - \varepsilon\), and assume from start that \(N, N'\) are the minimal integers such that

\[ |a_N|_A^{p^{-N}} \cdot \rho^N = |a|_\rho \quad \text{and} \quad |a'_N|_A^{p^{-N'}} \cdot \rho^{N'} < |a'|_\rho. \]

With this notation, write \(a = b + V_A^N(c)\), with \(b := (a_0, \ldots, a_{N-1}, 0, \ldots), c := (a_N, a_{N+1}, \ldots)\). By remark 9.1.4(iii) we have

\[ |b|_\rho < |a|_\rho \quad \text{and therefore} \quad |a|_\rho = |V_A^N(c)|_\rho \]

from which we deduce that \(|b \cdot a'|_\rho < |a|_\rho \cdot |a'|_\rho|\), so – again by remark 9.1.4(iii) – we are reduced to checking that \(|V_A^N(c)|_\rho \cdot |a'|_\rho = |V_A^N(c \cdot a')|_\rho|\). But proposition 9.3.22(ii) and lemma 9.3.81(v) yield

\[ |V_A^N(c \cdot a')|_\rho = |V_A^N(c \cdot F_A^N(a'))|_\rho = |c \cdot F_A^N(a')|_{\rho N}^{1/pN} \cdot \rho^N \]

and on the other hand

\[ |V_A^N(c)|_\rho = |c|_{\rho N}^{1/pN} \cdot \rho^N \quad \text{and} \quad |F_A^N(a')|_{\rho N}^{1/pN} = |a'|_\rho \]

by lemma 9.3.81(v) and (i). Say that \(a'' := F_A^N(a')\); then notice that – in view of (9.3.41) – the integer \(N'\) is still the smallest one such that

\[ |a''_N|_A^{p^{-N'}} \cdot \rho^{N'} = |a''|_\rho. \]

Summing up, we may replace \(a\) and \(a'\) by \(c\) and respectively \(a''\), and \(\rho\) by \(\rho^N\), and assume from start that \(N = 0\), i.e. that \(|a_0|_A = |a|_\rho\). Likewise, by repeating the same considerations on \(a'\), we may assume that \(|a'_0|_A = |a'|_\rho\). Lastly, notice that

\[ |a \cdot a'|_\rho \geq |a_0 a'_0|_A = |a_0|_A \cdot |a'_0|_A = |a|_\rho \cdot |a'|_\rho \]

and the converse inequality is already known, by (ii), whence the contention.
ii): Let \( \underline{a} := (a_n \mid n \in \mathbb{N}) \) and \( \underline{b} := (b_n \mid n \in \mathbb{N}) \) be any two elements of \( W(A, \rho) \); we have to show that \( |\underline{a} \cdot \underline{b}|_\rho \leq |\underline{a}|_\rho \cdot |\underline{b}|_\rho \). However, from propositions 9.3.77(iii) and 9.3.45(iv) we get
\[
\underline{a} \cdot \underline{b} \equiv \sum_{i+j=n} V^{\gamma+1}(\tau_A(a^p b^p)) \pmod{V^{\gamma+1}} \quad \text{for every } n \in \mathbb{N}
\]
and in view of lemma 9.3.81(iii) we are then easily reduced to the case where \( \underline{a} = V_A^i(\tau_A(x)) \) and \( \underline{b} = V_A^j(\tau_A(y)) \) for some \( i, j \in \mathbb{N} \) and \( x, y \in A \). We compute:
\[
|V_A^{i+j}(\tau_A(x^p y^p))|_\rho \leq |\tau_A(x^p y^p)|_\rho \cdot |\tau_A(x)|_\rho \cdot |\tau_A(y)|_\rho \quad \text{(by lemma 9.3.81(iii))}
\]
\[
= |\tau_A(x^p y^p)|_\rho^{1/p^{i+j}} \leq |\tau_A(x)|_\rho^{1/p^i} \cdot |\tau_A(y)|_\rho^{1/p^j}
\]
\[
= |V_A^i(\tau_A(x))|_\rho \cdot |V_A^j(\tau_A(y))|_\rho \quad \text{(again by lemma 9.3.81(iii))}
\]
as required. \( \square \)

**Remark 9.3.84.** In spite of the inequalities of lemma 9.3.81(vii) and proposition 9.3.82(iv), the map \( \tau_A : A \rightarrow W(A, \rho) \) is not necessarily continuous for the topology on \( W(A, \rho) \) induced by the semi-norm \( | \cdot |_\rho \), unless \( \rho = 0 \).

**Lemma 9.3.85.** Let \( E \) be a perfect topological \( \mathbb{F}_p \)-algebra, \( I \subset E \) any ideal, and denote by \( \mathcal{R}_E \) the set of all real-valued valuations on \( E \) with \( |E| = 1 \) (notation of 9.3.80). For every \( r, r' \in \mathbb{R}_+ \) we have:

(i) \( |I^{|r|}|_E = |I|^{|r|} \) for every \( | \cdot |_E \) in \( \mathcal{R}_E \).

(ii) \( |I^{|r'|}|_E = |I|^{|r'|} \).

(iii) \( |I^{|r|}| = |I^{|r|/2}| \).

(iv) \( W(I^{|r|})E = \{ a \in W(E) \mid |a| \leq |I|^{|r|} \text{ for every } | \cdot |_E \text{ in } \mathcal{R}_E \} \).

**Proof.** (i): Clearly \( |I^{|r|}|_E \leq |I|^{|r|} \). For the converse inequality, fix any real number \( \varepsilon > 0 \), and pick \( y \in I \) such that \( |y|_E > |I|^{|r|} - \varepsilon \). Since \( \mathbb{N}[1/p] \) is dense in \( \mathbb{R}_+ \), we may find \( \lambda \in \mathbb{N}[1/p] \) such that \( \lambda \geq r \) and \( |y^\lambda|_E > |I|^{|r|} - \varepsilon \). It follows that \( |y^\lambda| = |y|^\lambda \leq |I|^{|r|} \) for every \( | \cdot |_E \) in \( \mathcal{R}_E \), and \( |y^\lambda|_E > |I|^{|r|} - \varepsilon \), so that \( |I^{|r|}| \geq |I|^{|r|} - \varepsilon \), as needed.

(ii): Indeed, by lemmas 9.2.46 and 9.3.75(i), the ideal \( (I^{|r|})^{|r'|} \) (resp. \( (I^{|r'|})^{|r|} \)) is the set of all \( x \in E \) such that \( |x| \leq |I^{|r|}|^{|r'|} \) (resp. \( |x| \leq |I^{|r'|}|^{|r|} \)) for every \( | \cdot |_E \) in \( \mathcal{R}_E \). But from (i) we get \( |I^{|r|}|^{|r'|} = |I|^{|r'r'|} \) for every such \( | \cdot |_E \), whence the assertion.

(iii): This is obvious for \( r = 0 \), and for \( r > 0 \), we have \( I^{|r|} \subset (I^{|r|})^{|r'|} \subset (I^{|r'|})^{|r|} \) by lemma 9.3.75(i), and then the assertion follows from (ii).

(iv) follows by combining (iii), 9.3.72 and proposition 9.3.82(iv). \( \square \)

### 9.4. Fontaine rings

In this section we revisit and expand Fontaine and Wintenberger’s theory of the fields of norms of a local field of characteristic zero, which we frame as a special case of a simple and very general construction that endows every topological \( \mathbb{F}_p \)-algebra \( A \) with a universal perfect cover \( E(A) \rightarrow A \); indeed, \( E \) shall be a right adjoint to the inclusion of the subcategory of perfect topological \( \mathbb{F}_p \)-algebras into the category of all topological \( \mathbb{F}_p \)-algebras.

In section [16, ..] this functor will play an important role in the study of perfectoid rings.

**Definition 9.4.1.** (i) A topological monoid is the datum \( (P, \mu, \mathcal{T}) \) of a monoid \( (P, \mu) \) and a topology \( \mathcal{T} \) on the set \( P \), such that the composition law \( \mu : P \times P \rightarrow P \) of \( P \) is continuous (where \( P \times P \) is endowed with the product topology). A morphism of topological monoids \( (P, \mu, \mathcal{T}) \rightarrow (P', \mu', \mathcal{T}') \) is a morphism of monoids \( P \rightarrow P' \) that is continuous for the topologies \( \mathcal{T} \) and \( \mathcal{T}' \). Clearly the topological monoids and their morphisms form a category TopMon.
(ii) Let \( p \) be any prime integer. We say that \((P, \mu, \mathcal{F})\) is a \( p \)-perfect topological monoid if the \( p \)-Frobenius endomorphism \( p_P : P \to P \) is an isomorphism of topological monoids (see definition \[4.8.40\](ii)). This means that \( P \) is uniquely \( p \)-divisible, and \( p_P \) is a homeomorphism for the topology \( \mathcal{F} \). We denote by 

\[ p\text{-}\text{TopMon} \]

the full subcategory of \( \text{TopMon} \) whose objects are the \( p \)-perfect topological monoids.

**Remark 9.4.2.** Using the criterion of proposition \[1.2.22\](i) is easily seen that \( \text{TopMon} \) is a complete category: indeed, any family \( \{ (P_i, \mathcal{F}_i) \mid i \in I \} \) of topological monoids admits a product \( P \), which is just the product \( P \) of the underlying topological spaces, endowed with the unique composition law such that all the projections \( P \to P_i \) are morphisms of monoids. Also, if \( f, g : (P, \mathcal{F}) \to (P', \mathcal{F}') \) is any pair of morphisms in \( \text{TopMon} \), the equalizer of \( f \) and \( g \) is the equalizer of the underlying morphisms of monoids, endowed with the topology induced from \( \mathcal{F} \) : details left to the reader. Likewise, one checks that \( \text{TopMon} \) is also cocomplete.

**Proposition 9.4.3.** The inclusion functor \( p\text{-}\text{TopMon} \to \text{TopMon} \) admits both a right and a left adjoint, denoted respectively

\[ E : \text{TopMon} \to p\text{-}\text{TopMon} \quad \text{and} \quad E^* : \text{TopMon} \to p\text{-}\text{TopMon}. \]

**Proof.** Let \((P, \mathcal{F})\) be any topological monoid; we let \( \{(P_n, \mathcal{F}_n) \mid \varphi_n : P_{n+1} \to P_n \mid n \in \mathbb{N}\} \) be the system of topological monoids such that \((P_n, \mathcal{F}_n) := (P, \mathcal{F}) \) and \( \varphi_n \) is the \( p \)-Frobenius endomorphism of \( P \) for every \( n \in \mathbb{N} \). In light of remark 9.4.2 we may set

\[ (E(P), \mathcal{F}_E(P)) := \lim_{n \in \mathbb{N}} (P_n, \mathcal{F}_n) \quad \text{and} \quad (E^*(P), \mathcal{F}^*_E(P)) := \colim_{n \in \mathbb{N}} (P_n, \mathcal{F}_n). \]

So \( E(P) \) is the set of all sequences \((a_n \mid n \in \mathbb{N})\) of elements \( a_n \in P \) such that \( a_n = a_{n+1}^p \) for every \( n \in \mathbb{N} \). Any morphism of topological monoids \( f : P \to Q \) induces a morphism of topological monoids

\[ E(f) : E(P) \to E(Q) \quad (a_n \mid n \in \mathbb{N}) \mapsto (f(a_n) \mid n \in \mathbb{N}). \]

Moreover, clearly the Frobenius endomorphism \( p_{E(P)} \) is an automorphism of \( E(P) \) with inverse \( f \) given explicitly by the rule:

\[ f(a_n \mid n \in \mathbb{N}) = (a_{n+1} \mid n \in \mathbb{N}) \quad \text{for every} \quad (a_n \mid n \in \mathbb{N}) \in E(P). \]

In other words, \( f \) is the limit of the system of morphisms \( (1_p : P_n \to P_{n+1} \mid n \in \mathbb{N}) \), so it is a continuous map, and therefore \( p_{E(P)} \) is a homeomorphism. Furthermore, the projection to \( P_0 \) defines a natural morphism of topological monoids

\[ (9.4.4) \quad \pi : E(P) \to P \quad (a_n \mid n \in \mathbb{N}) \mapsto a_0 \]

and if \( P \) is already \( p \)-perfect, then clearly \( \pi \) is an isomorphism of topological monoids. Lastly, let \( f : Q \to P \) be any morphism of topological monoids, such that \( Q \) is \( p \)-perfect. There follows a well defined morphism \( f^\dagger := E(f) \circ \pi_Q^{-1} : Q \to E(P) \) of topological monoids. Conversely, to any \( g : Q \to E(P) \) we may attach the morphism \( g^\dagger := \pi_P \circ g : Q \to P \). It is easily seen that the rules \( f \mapsto f^\dagger \) and \( g \mapsto g^\dagger \) are mutually inverse bijections, which concludes the construction of the right adjoint.

Next, let us check that the inverse \( g \) of \( p_{E^*(P)} \) is continuous. Indeed, any element \( \alpha \in E^*(P) \) is the class of a pair \((a, n)\), for some \( n \in \mathbb{N} \) and some \( a \in P_n \), and \( g(\alpha) \) is then the class of \((a, n+1)\); in other words, \( g \) is the colimit of the system of morphisms \((1_p : P_n \to P_{n+1} \mid n \in \mathbb{N}) \), whence the contention. This shows that \( E^*(P) \) is an object of \( p\text{-}\text{TopMon} \), and obviously the rule \( P \mapsto E^*(P) \) yields a well defined functor as sought. Furthermore, the map \( j_0 : P \to E^*(P) \) defines a natural transformation which is an isomorphism in case \( P \) is already \( p \)-perfect. Now, the definition of an adjunction between \( E^* \) and the inclusion functor is, mutatis mutandis, as in the foregoing case: the details shall be left to the reader. \( \square \)
Remark 9.4.5. (i) By construction, the natural transformation $P \mapsto \pi_P$ defined in (9.4.4) is the counit of the adjunction exhibited by proposition 9.4.3. Likewise, the unit of this adjunction is the transformation $Q \mapsto \pi_Q^{-1}$ for every $p$-perfect topological monoid $Q$.

(ii) Taking into account the triangular identities of (1.1.13), we deduce from (i) the identity

$$E(\pi_P) = \pi_{E(P)} : E(E(P)) \to E(P)$$

and this map is an isomorphism of $p$-perfect topological monoids.

(iii) For every topological monoid $P$, we have

$$E(P)^\times = \pi_P^{-1}(P^\times).$$

Indeed, the inclusion $E(P)^\times \subseteq \pi_P^{-1}(P^\times)$ is obvious. For the converse, suppose that $x := (x_n | n \in \mathbb{N}) \in E(P)$ and $\pi_P(x) \in P^\times$. This means that $x_0 \in P^\times$, and since $x_{n+1} = x_n$ for every $n \in \mathbb{N}$, it follows that $x_n \in P^\times$ for every $n \in \mathbb{N}$, so $x \in E(P)^\times$.

(iv) Likewise, it is easily seen that an element $x \in E(P)$ is regular if and only if the same holds for $\pi_P(x)$ (see example 4.8.36(i)).

Example 9.4.6. Endow the abelian group $\mathbb{Q}_p/\mathbb{Z}_p$ (resp. $\mathbb{Q}_p$) with its discrete topology (resp. with its usual $p$-adic topology); then there exists a natural isomorphism $E(\mathbb{Q}_p/\mathbb{Z}_p) \cong \mathbb{Q}_p$, that identifies the map $\pi_{\mathbb{Q}_p/\mathbb{Z}_p}$ with the projection $\mathbb{Q}_p \to \mathbb{Q}_p/\mathbb{Z}_p$ (verification left to the reader).

9.4.7. Consider now the category of topological $\mathbb{F}_p$-algebras

$$\mathbb{F}_p\text{-TopAlg}$$

(whose $\mathbb{F}_p$ is endowed with its discrete topology : see definition 8.3.1(iii)). If $R$ is an object of $\mathbb{F}_p\text{-TopAlg}$, the $p$-Frobenius of the multiplicative monoid $(R, \cdot)$ is the Frobenius endomorphism $\Phi_R$ of the ring $R$, and a simple inspection of the proof of proposition 9.4.3 reveals that the composition law of $E(R, \cdot, \mathcal{T})$ is the multiplication map for a natural structure of topological ring. Moreover, for any morphism of topological $\mathbb{F}_p$-algebras $f : R \to S$, the map $E(f) : E(R) \to E(S)$ is a morphism of topological $\mathbb{F}_p$-algebras. In other words, $E$ lifts to a functor

$$E : \mathbb{F}_p\text{-TopAlg} \to \mathbb{F}_p\text{-TopAlg}_{\text{perf}}$$

(9.4.8)

to the full subcategory of $\mathbb{F}_p\text{-TopAlg}$ whose objects are the perfect topological $\mathbb{F}_p$-algebras (see 9.3.46), and (9.4.8) commutes with the forgetful functors $(R, +, \cdot, \mathcal{T}) \mapsto (R, \cdot, \mathcal{T})$ to topological monoids. Furthermore, the map $\pi_R$ of (9.4.4) is a morphism of topological $\mathbb{F}_p$-algebras, so the adjunction exhibited in the proof of proposition 9.4.3 lifts to an adjunction between the functor $E$ of (9.4.8) and the forgetful functor $\mathbb{F}_p\text{-TopAlg}_{\text{perf}} \to \mathbb{F}_p\text{-TopAlg}$.

The same argument shows that $E^*$ lifts to a left adjoint to the forgetful functor $E^* : \mathbb{F}_p\text{-TopAlg} \to \mathbb{F}_p\text{-TopAlg}_{\text{perf}}$.

Remark 9.4.9. (i) Suppose that $(R, \mathcal{T})$ is a topological $\mathbb{F}_p$-algebra whose topology $\mathcal{T}$ is linear. Then it is easily seen that a fundamental system of open neighborhoods of $0 \in E(R, \mathcal{T})$ is given by the intersections of finitely many elements of the family of ideals

$$\Phi_R^n(\pi_R^{-1}(I))$$

for every $n \in \mathbb{N}$ and every open ideal $I \subset R$.

Especially, the topology $\mathcal{T}_R$ of $E(R)$ is also linear. Moreover, if $\mathcal{T}$ is separated (resp. and complete) then the same holds for the topology of $E(R)$, since the latter is a closed subset of $R^n$, for the product topology : details left to the reader.

(ii) In the situation of (i), suppose moreover that $I \subset R$ is an ideal such that $\mathcal{T}$ agrees with the $I$-adic topology on $R$, and set $\mathcal{I} := \pi_R^{-1}(I)$. Since $\Phi_R^0(\mathcal{I}) \subset \mathcal{I} \subseteq \pi_R^{-1}(P^\times)$, we see that $\mathcal{T}_R$ is the linear topology defined by the system of ideals $\{\Phi_R^n(\mathcal{I}) | n \in \mathbb{N}\}$. Especially, if $\mathcal{I}$ is finitely generated, $\mathcal{T}_R$ agrees with the $\mathcal{I}$-adic topology.
(iii) Suppose that the Frobenius endomorphism $\Phi_R$ of the topological $\mathbb{F}_p$-algebra $R$ is surjective. Then clearly the same holds for $\overline{\pi}_R$. Moreover, if $\Phi_R$ is open and surjective, the same holds for $\overline{\pi}_R$. Indeed, any open subset of $E(R)$ is a union of subsets of the form $U := E(R) \cap \prod_{n \in \mathbb{N}} U_n$, where each $U_n$ is open in $R$ and there exists $k \in \mathbb{N}$ such that $U_n = A$ for every $n > k$; with this notation, since $\Phi_R$ is surjective, we have
$$\overline{\pi}_R(U) = \Phi_R^k(U_k \cap \Phi_R^{-1}U_{k-1} \cap \cdots \cap \Phi_R^{-k}U_0)$$
and this set is open in $R$, when $\Phi_R$ is an open map.

(iv) By virtue of proposition 3.25(iii), both the functor $E$ for topological monoid and the one for topological $\mathbb{F}_p$-algebras commute with all limits. By the same token, the existence of the left adjoint $E^*$ implies that the forgetful functor $p$-TopMon $\rightarrow$ TopMon also commutes with limits, and likewise for perfect topological $\mathbb{F}_p$-algebras.

Let $A$ be any $\mathbb{F}_p$-algebra, $I \subset A$ a finitely generated ideal, and denote by $\mathcal{T}_I$ (resp. $\mathcal{T}_d$) the $I$-adic topology (resp. the discrete topology) on $A$. Then $(A, \mathcal{T}_I)$ is a perfect topological $\mathbb{F}_p$-algebra if and only if the same holds for $(A, \mathcal{T}_d)$. Indeed, suppose that the Frobenius endomorphism $\Phi_A$ is bijective on $A$; in order to show that $\Phi_A$ is an automorphism of $(A, \mathcal{T})$, it suffices to prove that for every $k \in \mathbb{N}$ there exists $n(k) \in \mathbb{N}$ such that $I^{n(k)} \subset \Phi(I^n)$; but the latter is clear, since $I$ is finitely generated (details left to the reader).

**Theorem 9.4.10.** Let $(A, \mathcal{T}_A)$ be any complete and separated topological ring whose topology $\mathcal{T}_A$ is linear and coarser than the $p$-adic topology. Let also $I \subset A$ be a given ideal that is topologically nilpotent for the topology $\mathcal{T}_A$, and $\pi : A \rightarrow A/I$ the projection. Endow $A/I$ with the quotient topology $\mathcal{T}_{A/I}$ induced by $\mathcal{T}_A$ via $\pi$, and denote by $((A/I)^{\wedge}, \mathcal{T}_{A/I}^{\wedge})$ the completion of $(A/I, \mathcal{T}_{A/I})$, and by $j : A \rightarrow (A/I)^{\wedge}$ the completion map. Suppose moreover that:

(a) either, $I$ is a closed subset for the topology $\mathcal{T}_A$

(b) or else, $I$ is finitely generated, and a closed subset for the $p$-adic topology of $A$.

Then the maps
$$E(\pi) : E(A, \mathcal{T}_A) \rightarrow E(A/I, \mathcal{T}_{A/I}) \quad E(j) : E(A/I, \mathcal{T}_{A/I}) \rightarrow E((A/I)^{\wedge}, \mathcal{T}_{A/I}^{\wedge})$$
are isomorphisms of topological monoids.

**Proof.** Let $(J_\lambda | \lambda \in \Lambda)$ be a family of ideals of $A$ which is a fundamental system of open neighborhoods of $0$ for the topology $\mathcal{T}_A$. Suppose first that $I$ is closed for the topology $\mathcal{T}_A$, and set $\pi^{\wedge} := j \circ \pi : A \rightarrow (A/I)^{\wedge}$; in this case, $j$ is injective, so the same holds for $E(j)$, and to prove the theorem it suffices to check that $E(\pi^{\wedge})$ is an isomorphism. However, we have natural isomorphisms
$$A \xrightarrow{\sim} \lim_{\lambda \in \Lambda} A/J_\lambda \quad (A/I)^{\wedge} \xrightarrow{\sim} \lim_{\lambda \in \Lambda} A/(I + J_\lambda)$$
whence, by remark 3.4.9(iv), induced isomorphisms of topological monoids
$$E(A) \xrightarrow{\sim} \lim_{\lambda \in \Lambda} E(A/J_\lambda) \quad E((A/I)^{\wedge}) \xrightarrow{\sim} \lim_{\lambda \in \Lambda} E(A/(I + J_\lambda)).$$
Thus, it suffices to show that the induced map $E(A/J_\lambda) \rightarrow E(A/(I + J_\lambda))$ is an isomorphism of topological monoids for every $\lambda \in \Lambda$. In this case, we may then replace $A$ by $A/J_\lambda$, and assume from start that the topology $\mathcal{T}_A$ is discrete, hence $I$ is a nilpotent ideal.

**Claim 9.4.11.** The theorem holds when the topology $\mathcal{T}_A$ is discrete and $I = pA$.

**Proof of the claim.** In this case, the $p$-adic filtration is finite, hence the homomorphism of topological $\mathbb{F}_p$-algebras $\overline{\pi}_{A/\mathbb{N}} : E(A/pA) \rightarrow A/pA$ lifts to a morphism of monoids $v : E(A/pA) \rightarrow A$ (lemma 3.5.2(iii)). Explicitly, say that $p^kA = 0$ for some $k \in \mathbb{N}$, let $\overline{\pi}_n := (\pi_n | n \in \mathbb{N}) \in E(A/pA)$ be any element, and pick $a_k \in A$ whose image in $A/pA$ equals $\overline{\pi}_k$; then lemma 3.4(i) shows that $v(\overline{\pi}_n) = a_k^n$. This description easily implies that $v$
is continuous (for the discrete topology on $A$). Therefore $v$ corresponds, by adjunction, to a unique morphism $v^\dagger := E(v) \circ \overline{\pi}^{-1}_{E(A/pA)} : E(A/pA) \to E(A)$ of $p$-perfect topological monoids. We have

$$E(\pi) \circ v^\dagger = E(\pi \circ v) \circ \overline{\pi}^{-1}_{E(A/pA)} = E(\overline{\pi}_{A/pA}) \circ \overline{\pi}^{-1}_{E(A/pA)} = 1_{E(A/pA)}$$

by remark 9.4.5(ii). Lastly, the foregoing explicit description of $v$ implies that $v^\dagger \circ E(\pi) = 1_{E(A)}$ (details left to the reader), and the claim follows.

Now, we have a commutative diagram of topological monoids

$$
\begin{array}{ccc}
E(A) & \xrightarrow{E(\pi')} & E(A/pA) \\
E(\pi) \downarrow & & \downarrow E(\pi'') \\
E(A/I) & \xrightarrow{E(\pi''')} & E(A/(pA + I))
\end{array}
$$

where $\pi', \pi'', \pi'''$ are the projections. By claim 9.4.11 we know already that $E(\pi')$ and $E(\pi''')$ are isomorphisms, hence it suffices to show that the same holds for $E(\pi'')$. Thus, we may further replace $A$ by $A/pA$, and assume from start that $A$ is also an $\mathbb{F}_p$-algebra. In this case, the $I$-adic filtration on $A$ fulfills the conditions of lemma 9.3.4 hence lemma 9.3.52(iii) applies and says that the map $\overline{\pi}_{A/I} : E(A/I) \to A/I$ lifts to a morphism of monoids $w : E(A/I) \to A$, and arguing as in the proof of claim 9.4.11 we see that $w$ is continuous, so it yields, again by adjunction, a morphism of topological monoids $w^\dagger : E(A/I) \to E(A)$, which is seen to be an inverse for $E(\pi)$, by the same argument as in the proof of claim 9.4.11. This concludes the proof, in case $I$ is closed for the topology $\mathcal{T}_A$.

For the general case, denote by $\overline{T} \subset A$ the topological closure of $A$ (for the topology $\mathcal{T}_A$), endow $A/\overline{T}$ with the quotient topology $\mathcal{T}_{A/\overline{T}}$ induced by the projection $A \to A/\overline{T}$, and let $((A/\overline{T})^\wedge, \mathcal{T}_{A/\overline{T}}^\wedge)$ be the completion of $(A/\overline{T}, \mathcal{T}_{A/\overline{T}})$; denote also by $\pi' : (A/I)^\wedge \to (A/\overline{T})^\wedge$ and $\pi : A \to (A/\overline{T})^\wedge$ the induced maps; we deduce morphisms of topological monoids $E(A) \to E((A/I)^\wedge) \to E((A/\overline{T})^\wedge)$ whose composition equals $E(\pi)$. Notice that $\overline{T}$ is still topological nilpotent, hence $E(\pi)$ is an isomorphism, by the foregoing case. Also $\pi'$ is an isomorphism, so the same holds for $E(\pi')$ as well. We set $v := E(\pi')^{-1} \circ E(\pi') : E((A/I)^\wedge) \to E(A)$. Clearly $v \circ E(\pi) = 1_{E(A)}$, so it remains only to check that $v$ is bijective, or equivalently, that the same holds for $E(\pi)$. To this aim, let $\mathcal{T}_A'$ be the $(I + pA)$-adic topology on $A$, and notice that $\mathcal{T}_A'$ is still complete and separated (lemma 8.3.12); moreover, clearly both $I$ and $pA$ are topologically nilpotent ideals in $(A, \mathcal{T}_A')$. Furthermore, notice that

$$\bigcap_{n \in \mathbb{N}} (I + (I + pA)^n) = \bigcap_{n \in \mathbb{N}} (I + p^n A) = I$$

since $I$ is closed in the $p$-adic topology of $A$; thus, $I$ is closed in the topology $\mathcal{T}_A'$, so the foregoing case shows that the map $E(\pi) : E(A, \mathcal{T}_A') \to E(A/I)$ is indeed bijective.

**Remark 9.4.12.** Keep the situation of theorem 9.4.10.

(i) For every $(\overline{a}_n \mid n \in \mathbb{N}) \in E(A/I)$ and every $n \in \mathbb{N}$ choose a representative $a_n \in A$ for the class $\overline{a}_n$. By inspecting the proof, we see that the inverse of $E(\pi)$ is given by the rule:

$$\overline{a}_n \mid n \in \mathbb{N} \mapsto \left( \lim_{k \to \infty} a_n^{p_k} \mid n \in \mathbb{N} \right)$$

(9.4.13)

where the convergence is relative to the topology $\mathcal{T}_A$.

(ii) Suppose moreover, that $p \in I$; then $E(A/I)$ is a topological $\mathbb{F}_p$-algebra, and the isomorphism $E(\pi)$ can be used to transfer to $E(A)$ the ring structure of $E(A/I)$. In light of (i), we
get the following expressions for the addition and multiplication laws on \( E(A) \) such that \( E(\pi) \) becomes an isomorphism of topological rings:

\[
\begin{align*}
(a_n \mid n \in \mathbb{N}) + (b_n \mid n \in \mathbb{N}) := & \left( \lim_{k \to +\infty} (a_{n+k} + b_{n+k})^{p^k} \mid n \in \mathbb{N} \right) \\
(a_n \mid n \in \mathbb{N}) \cdot (b_n \mid n \in \mathbb{N}) := & \left( a_nb_n \mid n \in \mathbb{N} \right)
\end{align*}
\]

where the limit is computed in the topology \( \mathcal{T}_A \).

(iii) In the situation of (ii), suppose furthermore that \( A \) is a domain (resp. a field). Then theorem \ref{thm:9.4.10} implies immediately that the same holds for \( E(A/I) \) (and of course also for \( E(\pi) \), for its ring structure as in (ii)).

**Corollary 9.4.14.** Let \((A, \mathcal{T})\) be a perfect topological \( \mathbb{F}_p \)-algebra, \( I \subset A \) an open and topologically nilpotent ideal, and denote by \((A^\wedge, \mathcal{T}^\wedge)\) the separated completion of \((A, \mathcal{T})\). Then there is a natural isomorphism of topological \( \mathbb{F}_p \)-algebras

\[
\omega : (A^\wedge, \mathcal{T}^\wedge) \xrightarrow{\sim} E(A/I) \quad \text{such that} \quad \pi = \omega \circ \pi_{A/I}
\]

where \( \pi : A^\wedge \to A/I \) is the natural map.

**Proof.** Let \( I^\wedge \) be the topological closure of the image of \( I \) in \( A^\wedge \), and endow \( B := A^\wedge/I^\wedge \) with the quotient topology induced by the projection \( \pi : A^\wedge \to B \); notice that the natural map \( A/I \to B \) induces an isomorphism \( \varphi : A/I \xrightarrow{\sim} B^\wedge \) on the respective completed rings. Then example \ref{ex:9.3.49}(iii) and theorem \ref{thm:9.4.10} imply that the composition

\[
A^\wedge \xrightarrow{\pi_{A^\wedge}} E(A^\wedge) \xrightarrow{E(\pi)} E(B) \xrightarrow{E(\varphi)} E(A/I)
\]

is an isomorphism, whence the corollary. \( \square \)

**9.4.15.** Let now \((R, \cdot, | \cdot_R)\) be any valuation ring with value group \( \Gamma_R \) and residue characteristic \( p \). Notice that the \( p \)-Frobenius map of \( \Gamma_R \) is injective, so we may regard \( E(\Gamma_R) \) as a subgroup of \( \Gamma_R \). To ease notation, set \( E := E(R/pR) \); also, let \( \Delta := \Gamma_R \) in case \( R \) is an \( \mathbb{F}_p \)-algebra, and otherwise let \( \Delta := O(|p|_R) \) (notation of remark \ref{rem:9.1.2}(vii)). We define a mapping

\[
| \cdot |_E : E \to \Gamma_E \quad \text{where} \quad \Gamma_E := \Gamma_R \cap \Delta
\]

as follows. Let \( a := (a_n \mid n \in \mathbb{N}) \in E \) be any element, and for every \( n \in \mathbb{N} \) choose a representative \( \tilde{a}_n \in R \) for the class \( a_n \in R/pR \). If \( |\tilde{a}_n|_R \leq |p|_R \) for every \( n \in \mathbb{N} \), then we set \( |a|_E := 0 \); if there exists \( n \in \mathbb{N} \) such that \( |\tilde{a}_n|_R > |p|_R \), then we set \( |a|_E := |\tilde{a}_n|_R^{p^n} \). One verifies easily that the definition is independent of all the choices; the details shall be left to the reader.

**Lemma 9.4.16.** In the situation of \ref{9.4.15}, the pair \((E, | \cdot |_E)\) is a valuation ring.

**Proof.** The bijection of remark \ref{rem:9.1.13}(vii) attaches to \( \Delta \) the prime ideal \( p(\Delta) = \bigcap_{n \in \mathbb{N}} p^n R \), and we set \( R' := R/p(\Delta) \). Since the set of ideals of \( R' \) is naturally identified with the set of those ideals of \( R \) that contain \( p(\Delta) \), it follows easily that \( R' \) is a valuation ring, and then it is clear that its valuation is induced by the primary specialization \( | \cdot |_R \) of \( | \cdot |_E \) (notation of \ref{9.2.10}). Notice moreover that \( R'/pR' = R/pR \), so that \( E(R'/pR') = E \). Summing up, we may replace \( R \) by \( R' \) after which we may assume from start that \( \Gamma_R = \Delta \), and that the \( p \)-adic topology on \( R \) is separated. Moreover, notice that in this case the \( p \)-adic topology on \( R \) agrees with either the valuation topology (see definition \ref{def:9.1.14} or with the discrete topology; hence the \( p \)-adic completion \( R^\wedge \) of \( R \) is still a valuation ring (proposition \ref{prop:9.1.15}(iii)). Then, since \( R^\wedge/pR^\wedge = R/pR \), we may replace \( R \) by \( R^\wedge \), and assume from start that \( R \) is \( p \)-adically complete, in which case remark \ref{rem:9.4.12}(iii) already shows that \( E \) is a domain. Moreover, in this situation the isomorphism \( E(R) \to E \) of theorem \ref{thm:9.4.10} identifies the map \( | \cdot |_E \) with the mapping

\[
| \cdot |_E(R) : E(R) \to \Gamma_{R_0} \quad (a_n \mid n \in \mathbb{N}) \mapsto |a_0|_R.
\]
With this notation, clearly $|x_\bullet \cdot y_\bullet|_{E(R)} = |x_\bullet|_{E(R)} \cdot |y_\bullet|_{E(R)}$ for every $x_\bullet, y_\bullet \in E(R)$. By the same token, it is clear that $x_\bullet$ divides $y_\bullet$ in $E(R)$ if and only if $|x_\bullet|_{E(R)} \geq |y_\bullet|_{E(R)}$ so $(E, \cdot | E)$ is a valuation ring.

The last topics of this section are the graded versions of the functors $W$ and $E$.

9.4.17. Let $(\Gamma, +, 0)$ be a monoid, $p \in \mathbb{N}$ a prime integer, $(A, B)$ a topological ring with $\Gamma$-graded structure, and suppose that the $p$-Frobenius endomorphism of $\Gamma$ is injective. The assumption implies that the natural map $\Gamma \to E^*(\Gamma)$ is injective (notation of proposition 9.4.3), hence we may regard $B$ naturally as an $E^*(\Gamma)$-graded $\mathbb{Z}$-algebra. We define

$$W(B) := \bigoplus_{\gamma \in E^*(\Gamma)} \text{gr}_\gamma W(B) \quad \text{where} \quad \text{gr}_\gamma W(B) := \prod_{n \in \mathbb{N}} \text{gr}_{p^n \gamma} B \quad \text{for every} \quad \gamma \in E^*(\Gamma).$$

From remark 9.3.8(i) it follows easily that, for every $\gamma, \mu \in \Gamma$, the addition and multiplication laws on $W(B)$ restrict respectively to maps

$$\text{gr}_\gamma W(B) \times \text{gr}_\mu W(B) \to \text{gr}_{\gamma + \mu} W(B) \quad \text{gr}_\gamma W(B) \times \text{gr}_\mu W(B) \to \text{gr}_{\gamma + \mu} W(B).$$

We may therefore define an addition law on $W(B)$ by taking the direct sum of the addition laws on each $\Gamma$-graded summand. Likewise, the map $x \mapsto -x$ on $W(B)$ restricts to a map $\text{gr}_\gamma W(B) \to \text{gr}_\gamma W(B)$ for every $\gamma \in \Gamma$, so that $W(B)$ is an abelian group with this addition law. Next, clearly $1 \in \text{gr}_0 W(B)$, so we obtain a ring structure on $W(B)$, by extending linearly the multiplication map already defined on each graded term. Thus, the multiplication map of $W(B)$ agrees with that of $W(B)$ on each pair of homogeneous elements, but it will be usually different, on non-homogeneous elements.

Lemma 9.4.18. With the notation of (9.4.17), the induced map

$$\varphi : W(B) \to W(B) \quad (b_\gamma \in E^*(\Gamma)) \mapsto \sum_{\gamma \in E^*(\Gamma)} b_\gamma$$

is injective (again, notice that $\varphi$ agrees with the inclusion map on homogeneous terms, but it usually differs from it on non-homogeneous elements).

Proof. For every $r \in \mathbb{N}$ and $\gamma \in E^*(\Gamma)$ define $\text{gr}_\gamma W_r(B)$ as the image of $\text{gr}_\gamma W(B)$ into $W_r(B)$, and set

$$W_r(B) := \bigoplus_{\gamma \in E^*(\Gamma)} \text{gr}_\gamma W_r(B).$$

We shall show, more precisely, that the resulting map $\varphi_r : W_r(B) \to W_r(B)$ is a bijection. We argue by induction on $r$. For $r = 1$, the assertion follows by a simple inspection. Next, suppose that $r \geq 0$ and that $\varphi_r$ is bijective; we deduce a commutative ladder with exact rows:

$$0 \to \bigoplus_{\gamma \in E^*(\Gamma)} \text{gr}_{p^r \gamma} B \to W_{r+1}(B) \to W_r(B) \to 0$$

$$\psi_r \downarrow \varphi_{r+1} \downarrow \varphi_r$$

$$0 \to W_{r+1}(B) \cap V_r \to W_{r+1}(B) \to W_r(B) \to 0$$

where $V_r$ denotes the image of $V_r(B)$ in $W_{r+1}(B)$. It then suffices to check that $\psi_r$ is a bijection; but (9.3.3) implies that $\psi_r$ is none else than the restriction of the additive map $V^r$, and since $E^*(\Gamma)$ is $p$-perfect, the source of $\psi_r$ is just $B$, whence the contention. □

Due to lemma 9.4.18, we may regard $W(B)$ as a subring of $W(B)$. We also see that $W_r(B)$ inherits from $B$ a natural $E^*(\Gamma)$-graded $\mathbb{Z}$-algebra structure, for every $r \in \mathbb{N}$. Moreover, $\text{gr}_0 W(B) = W(\text{gr}_0 B)$, so $W(B)$ is an $E^*(\Gamma)$-graded $W(\text{gr}_0 B)$-algebra. Set

$$W(A, B) := (W(A), W(B))$$
and let also $E^*(\Gamma)_{(p)}$ be the object of the category $E^*(\Gamma)/\text{Mnd}$ given by the $p$-Frobenius automorphism $p_{E^*(\Gamma)} : E^*(\Gamma) \to E^*(\Gamma)_{(p)}$.

**Proposition 9.4.19.** With the notation of (9.4.17), the following holds:

(i) The pair $W(A, B)$ is an $E^*(\Gamma)$-graded structure on $W(A)$ (see definition 8.5.1(i)).

(ii) The map $\omega_0$ is a morphism of topological rings with $E^*(\Gamma)$-graded structures

$$\omega_0 : W(A, B) \to (A, B).$$

(iii) The Frobenius and Verschiebung maps of $W(A)$ (see (9.3.18)) induce respectively a morphism of topological rings with $E^*(\Gamma)$-graded structures

$$F_A : W(A, B) \to (W(A), E^*(\Gamma) \times_{E^*(\Gamma)_{(p)}} W(B))$$

and a continuous map of $E^*(\Gamma)$-graded topological abelian groups

$$V_A : E^*(\Gamma) \times_{E^*(\Gamma)_{(p)}} W(B) \to W(B)$$

(notation of definition 7.6.9(iv)).

**Proof.** (i): Indeed, a direct inspection shows that $\text{gr}_\gamma W(B)$ is a closed subset in $W(A, \mathcal{T}_A)$, for every $\gamma \in E^*(\Gamma)$. Next, notice that the topology of $W(B)$ agrees with the topology induced by $W(A)$ via the inclusion map $W(B) \to W(A)$. Hence, in order to check that the topology induced by $W(A)$ on $W(B)$ is linear and defined by a system of open graded ideals, it suffices to show that the same holds for the topology induced by $W(B)$. However, let $(J_\lambda | \lambda \in \Lambda)$ be any fundamental system of open graded ideals of $B$, and set $\mathcal{J}_{\lambda, r} := \text{Ker}(W(B) \to W_r(B/J_\lambda))$ for every $\lambda \in \Lambda$ and $r \in \mathbb{N}$; the proof of lemma 9.3.33(iii) shows that $(\mathcal{J}_{\lambda, r} | \lambda \in \Lambda; r \in \mathbb{N})$ is a fundamental system of open ideals of $W(B)$, and we are reduced to checking that $\mathcal{J}_{\lambda, r} \cap W(B)$ is a graded ideal of $W(B)$, for every $\lambda \in \Lambda$ and $r \in \mathbb{N}$. To this aim, we consider the commutative diagram

$$\begin{array}{ccc}
W(B) & \xrightarrow{\varphi} & W(B) \\
\downarrow & & \downarrow \\
W_r(B/J_\lambda) & \xrightarrow{\varphi_r} & W_r(B/J_\lambda)
\end{array}$$

where $\varphi_r$ is the isomorphism defined as in the proof of lemma 9.4.18 and the vertical arrows are the natural projections. We deduce that $\mathcal{J}_{\lambda, r} \cap W(B)$ is the kernel of the projection $W(B) \to W_r(B/J_\lambda)$, and the assertion follows easily. It remains to check that $W(B)$ is a dense subset of $W(A)$, but this is clear, since $\varphi_r$ is bijective for every $r \in \mathbb{N}$.

(ii) follows by a direct inspection of the construction.

(iii) follows easily from remark 9.3.31. \qed

We have the following graded version of proposition 9.3.53:

**Proposition 9.4.20.** Let $p \in \mathbb{N}$ be a prime integer, $\Gamma$ a monoid whose $p$-Frobenius endomorphism is injective, $(R, S)$ and $(A, B)$ two topological rings with $\Gamma$-structures, and suppose that:

(a) $R$ is a perfect topological $\mathbb{F}_p$-algebra, and $A$ is complete and separated.

(b) $B$ admits a fundamental system $(J_n | n \in \mathbb{N})$ of graded open ideals such that $pJ_n + J_n \subset J_{n+1} \subset J_n$ for every $n \in \mathbb{N}$.

Then, for every morphism $\varphi : (R, S) \to (A, B)$ of topological rings with $\Gamma$-graded structures there exists a unique morphism $u : W(R, S) \to (A, B)$ of topological rings with $\Gamma$-graded
structures that makes commute the diagram

\[
\begin{array}{ccc}
W(R, S) & \xrightarrow{\psi} & (A, B) \\
\omega_0 & & \pi \\
(R, S) & \xrightarrow{\varphi} & (A, B)/J_0
\end{array}
\]

where \( \pi \) is the natural projection.

**Proof.** We have to show that the unique continuous ring homomorphism \( u : W(R) \to A \) provided by proposition [9.3.53](iii) restricts to a map of \( \Gamma \)-graded rings \( W(S) \to B \). However, recall that \( \text{gr}_\gamma B \) is a closed subset of \( A \), so it is complete and separated for the topology induced by \( B \), for every \( \gamma \in \Gamma \), and hence also for the \( p \)-adic topology (lemma [8.3.12](ii)). Then, let \( \varphi : R \to A \) be the unique continuous mapping characterized as in lemma [9.3.52](iii); by inspecting \( [9.3.54] \), we are reduced to checking that \( \varphi(\text{gr}_\gamma S) \subset \text{gr}_\gamma B \) for every \( \gamma \in \Gamma \). To this aim, pick any map \( \psi : R \to A \) such that :

(a) \( \pi \circ \psi = \varphi \)

(b) \( \psi(\text{gr}_\gamma S) \subset \text{gr}_\gamma B \) for every \( \gamma \in \Gamma \)

and recall that \( \varphi(r) = \lim_{n \to +\infty} \psi(r^{p^n})^{p^n} \) for every \( r \in R \). The assertion follows easily. \( \square \)

9.4.21. Let \( \Gamma \) be a monoid, \( P \) a \( \Gamma \)-graded monoid. Clearly \( E(P) \) is naturally an \( E(\Gamma) \)-graded monoid. Moreover, let \( B := (B, \text{gr}_\bullet B) \) be a \( \Gamma \)-graded topological \( \mathbb{Z} \)-algebra; we define the \( \Gamma \)-graded monoid

\[ B^* := \coprod_{\gamma \in \Gamma} \text{gr}_\gamma B \]

whose composition law is induced by the multiplication map of \( B \). The natural morphism of \( \Gamma \)-graded monoids \( B^* \to B \) (which is not injective, unless \( \Gamma = \{ 0 \} \)) induces a morphism of \( E(\Gamma) \)-graded monoids

\[ E(B^*) \to E(B). \]

Furthermore, if \( B \) is an \( \mathbb{F}_p \)-algebra we may define the \( E(\Gamma) \)-graded subring of \( E(B) \)

\[ E(B) := \bigoplus_{\gamma \in E(\Gamma)} \text{gr}_\gamma E(B^*) \]

which we endow with the topology induced from \( E(B) \), via the inclusion map \( E(B) \to E(B) \), and the rule \( B \mapsto E(B) \) defines a functor from the category of \( \Gamma \)-graded topological \( \mathbb{F}_p \)-algebras to the category of perfect \( E(\Gamma) \)-graded topological \( \mathbb{F}_p \)-algebras. It is easily seen that this functor is right adjoint to the forgetful functor \( C^* \mapsto C/\Gamma \) induced by \( \pi_\Gamma : E(\Gamma) \to \Gamma \).

**Proposition 9.4.22.** Let \( (\Gamma, +, 0) \) be a monoid, \( (A, B) \) a topological \( \mathbb{F}_p \)-algebra with \( \Gamma \)-graded structure, such that \( A \) is complete and separated, and the \( p \)-Frobenius endomorphism \( p_\Gamma \) of \( \Gamma \) is injective. We have :

(i) \( E(A, B) := (E(A), E(B)) \) is an \( E(\Gamma) \)-graded structure on \( E(A) \).

(ii) The pair \( (\pi_A, \pi_\Gamma) \) is a morphism of topological \( \mathbb{F}_p \)-algebras with graded structures :

\[ \pi_A : E(A, B) \to (A, B). \]

(iii) Let \( \Gamma' \) be another monoid whose \( p \)-Frobenius endomorphism is injective, and \( \Gamma \to \Gamma' \) any morphism of monoids. Then the identity map of \( E(A) \) induces an isomorphism of topological rings with \( \Gamma' \)-graded structures

\[ E(A, B, \Gamma)/\Gamma' \to E((A, B, \Gamma)/\Gamma'). \]
Proof. Indeed, the definition immediately shows that \( \text{gr}_\gamma E(B) \) is closed in the topology of \( E(A) \) for every \( \gamma \in \Gamma \). Next, notice that – under the current assumptions – we may regard \( E(\Gamma) \) as a submonoid of \( \Gamma \), and for every graded ideal \( J \subset B \) and every \( r \in \mathbb{N} \), set

\[
J^* := \coprod_{\gamma \in \Gamma} \text{gr}_\gamma J \quad \text{and} \quad E(J) := \coprod_{\gamma \in \Gamma} \text{gr}_\gamma E(J^*).
\]

So, \( E(J) \) is a graded ideal of \( E(B) \), and from remark 9.4.9(i) it follows that the topology of \( E(A) \) induces on \( E(B) \) the linear topology defined by the cofiltered system of graded ideals

\[
(\Phi_{E(B)}E(J) \mid J \subset B; \ r \in \mathbb{N}),
\]

where \( J \) ranges over all the open graded ideals of \( B \). It remains to check that \( E(B) \) is dense in \( E(A) \). To this aim, let \( a := (a_n \mid n \in \mathbb{N}) \in E(A) \) be any element, and for every finite subset \( S \subset E(\Gamma) \) and every \( n \in \mathbb{N} \), set \( S(n) := p_n^{-n}(S) \); for every such \( S \), we define the element

\[
a_S := (a_{nS(n)} \mid n \in \mathbb{N}) \in E(B)
\]

where the component \( a_{nS(n)} \in \bigoplus_{\gamma \in S(n)} \text{gr}_\gamma B \) is defined as in remark 8.5.2(iii).

Claim 9.4.23. (i) \( a_{n,\gamma} = 0 \) for every \( \gamma \in \Gamma \setminus E(\Gamma) \) and every \( n \in \mathbb{N} \).

(ii) \( (a_{nS(n)} \mid S \subset E(\Gamma)) \) is a Cauchy net in \( B \) whose limit is \( a_n \), for every \( n \in \mathbb{N} \).

(iii) \( a_{nS(n)} = a_{n+1S(n+1)} \), for every \( n \in \mathbb{N} \) and every finite subset \( S \subset E(\Gamma) \).

Proof of the claim. For every \( n \in \mathbb{N} \), let \( (a_{n,\gamma} \mid \gamma \in \Gamma) \in \prod_{\gamma \in \Gamma} B_\gamma \) be the sequence of canonical projections of \( a_n \) (see remark 8.5.2(iii)); in view of lemma 8.5.6(i) we see that \( a_{n,p\gamma} = a_{n+1,\gamma} \) for every \( \gamma \in \Gamma \), and \( a_{n,\gamma} = 0 \) if \( \gamma \in \Gamma \setminus p\gamma(\Gamma) \). Assertions (i) and (iii) are immediate consequences.

(ii) follows immediately from (i) and proposition 8.5.3(ii).

From claim 9.4.23(ii,iii) we conclude that the system \( (a_S \mid S \subset E(\Gamma)) \) is a Cauchy net in \( E(B) \) whose limit is \( a \), as required.

(iii) is clear by inspecting the constructions.

(iii): Indeed, by example 8.5.7(iii), any such morphism will be necessarily an isomorphism, and conversely, consider the natural morphism \( (A, B, \Gamma) \to (A, B, \Gamma, \Gamma^\prime) \) which induces a morphism \( E(A, B, \Gamma) \to E((A, B, \Gamma, \Gamma^\prime)) \) which in turns factors uniquely through a morphism as sought, again by example 8.5.7(iii).

9.4.24. Let \( (A, B) \) be a complete and separated topological ring with \( \Gamma \)-graded structure, whose topology is linear and coarser than the \( p \)-adic topology. Endow \( A/pA \) with the quotient topology induced by the projection \( \pi_A : A \to A/pA \), and let \( (A/pA)^\wedge \) be the separated completion of \( A/pA \); by theorem 9.4.10, the map \( \pi_A \) induces an isomorphism of topological monoids

\[
E(\pi_A) : E(A) \xrightarrow{\sim} E(A/pA)
\]

and the completion map \( j : A/pA \to (A/pA)^\wedge \) induces an isomorphism of topological rings

\[
E(j) : E(A/pA) \to E((A/pA)^\wedge).
\]

Especially, \( E(A/pA) \) is a complete and separated topological ring whose topology is linear (remark 9.4.9(ii)), and we may transfer the ring structure of \( E(A/pA) \) onto \( E(A) \) (see remark 9.4.12(ii)), after which the latter can also be regarded as a complete and separated topological ring with a linear topology. Furthermore, suppose that the \( p \)-Frobenius map of \( \Gamma \) is injective, so that the topological rings with \( E(\Gamma) \)-structures

\[
((A/pA)^\wedge, B_\emptyset) := ((A, B)/pB)^\wedge \quad \text{and} \quad E((A/pA)^\wedge, B_\emptyset)
\]

are well defined, by proposition 9.4.22(i) (and remark 8.5.2(iv)), and we may transfer as well this graded structure onto \( E(A) \) and \( E(A/pA) \). We denote by

\[
E(A, B) \quad \text{and} \quad E(A/pA, B/pB)
\]
the resulting topological rings with $E(\Gamma)$-graded structures, whose underlying topological rings are respectively $E(A)$ and $E(A/pA)$. Define $B'$ as in remark 8.5.2(ii), and notice that $pB = pB' \cap B$ and $pA \subset A \cap pB'$, so that

\[(9.4.25) \quad pB = pA \cap B\]

and therefore the natural map $E(B/pB) \to E(A/pA)$ is injective.

**Proposition 9.4.26.** In the situation of \((9.4.24)\), let also $C$ (resp. $C_0$) be the $\Gamma$-graded dense subring of $E(A)$ (resp. of $E(A/pA)$). With the notation of \((9.4.21)\) we have:

\[C_0 = E(B/pB) \quad \text{and} \quad C = E(B)\]

**Proof.** Notice that – as explained in remark 8.5.4(ii) – since $A$ is complete and separated, $gr_{\gamma} B_0$ is the maximal separated quotient of $gr_{\gamma}(B/pB)$, for every $\gamma \in \Gamma$; it is also a closed subset of the complete ring $(A/pA)^{\wedge}$, so it is the separated completion of $gr_{\gamma}(B/pB)$.

Now, from \((9.4.25)\) we deduce that the canonical $\gamma$-projection of $(A, B)$ induces a continuous $B_0/pB_0$-linear map $\pi_{\gamma} : A/pA \to gr_{\gamma}(B/pB)$ for every $\gamma \in \Gamma$, and in view of the injectivity of $p\gamma$, proposition 8.5.3(ii) and lemma 8.5.6(i) easily imply that $\pi_{\gamma}(a^p) = \pi_{\gamma}(a)^p$ in the $\Gamma$-graded $\mathbb{Z}$-algebra $B/pB$. To ease notation, set $D_{\gamma} := gr_{\gamma}(E(B))$ and $D_{0,\gamma} := gr_{\gamma}(E(B/pB))$ for every $\gamma \in E(\Gamma)$; there follows, for every such $\gamma$, a continuous $E(gr_{\gamma}B)$-linear map

\[\pi_{E,\gamma} : E(A/pA) \to D_{0,\gamma} \quad (a_n \mid n \in \mathbb{N}) \mapsto (\pi_{\gamma/p^n}(a_n) \mid n \in \mathbb{N})\]

Let also $\pi_{\gamma}^\wedge : (A/pA)^{\wedge} \to gr_{\gamma} B_0$ be the completion of $\pi_{\gamma}$, for every $\gamma \in \Gamma$; we obtain likewise a continuous $E(gr_{\gamma}B_0)$-linear map for every $\gamma \in E(\Gamma)$

\[\pi_{E,\gamma}^\wedge : E((A/pA)^{\wedge}) \to gr_{\gamma} E(B_0) \quad (a_n \mid n \in \mathbb{N}) \mapsto (\pi_{\gamma/p^n}(a_n) \mid n \in \mathbb{N})\]

However, $\pi_{E,\gamma}^\wedge$ is none else than the canonical $\gamma$-projection of $E((A/pA)^{\wedge}, B_0)$; indeed, it is easily seen that it coincides with the latter map on the dense subring $E(B_0)$, and $gr_{\gamma} E(B_0)$ is separated, whence the claim. Moreover, by construction we have a commutative diagram

\[
\begin{array}{ccc}
E(A/pA) & \xrightarrow[\Pi_{\gamma \in E(\Gamma)} \pi_{E,\gamma}]{\Pi_{\gamma \in E(\Gamma)} \pi_{E,\gamma}} & D_{0,\gamma} \\
E(j) & \downarrow & \downarrow i_{\gamma} \\
E((A/pA)^{\wedge}) & \xrightarrow[\Pi_{\gamma \in E(\Gamma)} \pi_{E,\gamma}^\wedge]{\Pi_{\gamma \in E(\Gamma)} \pi_{E,\gamma}^\wedge} & gr_{\gamma} E(B_0)
\end{array}
\]

where $i_{\gamma} : D_{0,\gamma} \to gr_{\gamma} E(B_0)$ is the restriction of $E(j)$, for every $\gamma \in \Gamma$. Then, a simple inspection of this diagram shows that $gr_{\gamma} C_0 \subset D_{0,\gamma}$ for every $\gamma \in \Gamma$, and the converse inclusion is obvious. Lastly, it is clear that $E(\pi \gamma)(D_{\gamma}) \subset D_{0,\gamma}$ for every $\gamma \in E(\Gamma)$. To show the converse inclusion, let $\bar{b}_{\gamma} := (\bar{b}_n \mid n \in \mathbb{N})$ be any element of $D_{0,\gamma}$, and for every $n \in \mathbb{N}$ pick $b_n \in gr_{\gamma/p^n} B$ whose image in $gr_{\gamma/p^n}(B/pB)$ agrees with $\bar{b}_n$; according to remark 9.4.12(i), the element $E(\pi \gamma)^{-1}(\bar{b}_{\gamma})$ is the sequence $(b_n' \mid n \in \mathbb{N})$ with $b_n' := \lim_{k \to \infty} b_{n,k}^p$ for every $n \in \mathbb{N}$, where the convergence is relative to the topology of $A$. But since $gr_{\gamma} B$ is closed in $A$ for every $\gamma \in \Gamma$, we see that $b_n' \in gr_{\gamma/p^n} B$ for every $n \in \mathbb{N}$, whence the claim. \qed

9.5. **Divided power modules and algebras.** This section is a review of the theory of divided power modules and algebras.

**Definition 9.5.1.** Let $A$ be a ring, $k \in \mathbb{N}$ an integer, and $\underline{M} := (M_1, \ldots, M_k)$ an object of the abelian category $(A\text{-Mod})^k$, i.e. any sequence of $A$-modules. Let also $Q$ be another $A$-module, and $\underline{d} := (d_1, \ldots, d_k) \in \mathbb{N}^{\mathbb{N}^k}$ any sequence of $k$ integers.
(i) We denote by $F_M, G_Q : A\text{-Alg} \to \text{Set}$ the functors given respectively by the rules:

\[ B \mapsto (M_1 \times \cdots \times M_k) \otimes_A B \quad \text{and} \quad B \mapsto Q \otimes_A B \quad \text{for every } A\text{-algebra } B. \]

Also, let $M_i : \text{Hom}_A(M_i, A)$ for every $i = 1, \ldots, k$, and set:

\[ \text{Sym}_A^i(M_i^\vee) := \bigotimes_{i=1}^k \text{Sym}_A^i(M_i^\vee) \]

which we view as an $\mathbb{N}^\otimes k$-graded $A$-algebra, with the grading given by the rule:

\[ \text{Sym}_A^n(M_i^\vee) := \bigotimes_{i=1}^k \text{Sym}_A^n(M_i^\vee) \quad \text{for every } n := (n_1, \ldots, n_k) \in \mathbb{N}^\otimes k. \]

(ii) A homogeneous multipolynomial law of degree $d$ on the sequence of $A$-modules $M$ with values in $Q$, is a natural transformation $\lambda : F_M \to G_Q$, which we write also

\[ \lambda : M \rightsquigarrow Q \]

such that for every $A$-algebra $B$ we have:

\[ (9.5.2) \quad \lambda_B(b \cdot x) = b_1^{d_1} \cdots b_k^{d_k} \cdot \lambda_B(x) \quad \text{for every } b \in B^\otimes k \text{ and every } x \in F_M(B) \]

where $b \cdot x := (b_1 \cdot x_1, \ldots, b_k \cdot x_k)$ (and where we let $b^0 := 1$ for every $b \in B$).

(iii) The set of all homogeneous multipolynomial laws $M \rightsquigarrow Q$ of degree $d$ is denoted

\[ \text{Pol}_d^A(M, Q). \]

Remark 9.5.3. (i) Let $f := (f_i : M_i' \to M_i | i = 1, \ldots, k)$ be a sequence of $A$-linear maps, and set $M' := (M_1', \ldots, M_k')$; let also $g : Q \to Q'$ be another $A$-linear map. Suppose that $\lambda : M \rightsquigarrow Q$ is a homogeneous multipolynomial law of degree $d$; then we obtain a law

\[ g \circ \lambda \circ f : M' \rightsquigarrow Q' \]

of the same type, by the rule:

\[ B \mapsto (g \otimes_A B) \circ \lambda_B \circ ((f_1 \times \cdots \times f_k) \otimes_A B) : (M_1' \times \cdots \times M_k') \otimes_A B \to Q' \otimes_A B \]

for every $A$-algebra $B$. This shows that the rule $(M, Q) \mapsto \text{Pol}_d^A(M, Q)$ is functorial in both arguments. However, it is not a priori obvious that this functor takes values in (essentially) small sets. The latter assertion will nevertheless be proven shortly.

(ii) Suppose that $M' := (M_1', \ldots, M_k')$ is another sequence of $A$-modules, $Q'$ another $A$-module, and $d' := (d'_1, \ldots, d'_k) \in \mathbb{N}^\otimes k'$ another sequence of integers. If we have two homogeneous polynomial laws $\lambda : M \rightsquigarrow Q$ and $\lambda' : M' \rightsquigarrow Q'$ of degrees respectively $d$ and $d'$, we can form the tensor product

\[ \lambda \otimes \lambda' : (M, M') \rightsquigarrow Q \otimes_A Q' \]

which is the homogeneous multipolynomial law of degree $(d, d')$ given by the rule:

\[ (\lambda \otimes \lambda')(B)(x_1, \ldots, x_k, x'_1, \ldots, x'_{k'}) := \lambda_B(x_1, \ldots, x_k) \otimes \lambda_B'(x'_1, \ldots, x'_{k'}) \]

for every $A$-algebra $B$ and every $(x_1, \ldots, x_{k'}) \in (M_1 \times \cdots \times M_{k'}') \otimes_A B$.

(iii) Let $B$ be any $A$-algebra, and $Q$ a $B$-module, which we also regard as an $A$-module, by restriction of scalars. Set also $N := M_1 \times \cdots \times M_k$, to ease notation. We have a bijection:

\[ (9.5.4) \quad \text{Pol}_d^B(B \otimes_A M, Q) \xrightarrow{\sim} \text{Pol}_d^A(M, Q) \]
natural with respect to $B$-linear maps $Q \to Q'$ and morphisms $M' \to M$ in $(A\text{-Mod})^k$. Namely, to every homogeneous polynomial law $\lambda : B \otimes_A M \leadsto Q$ of degree $d$, we assign the homogeneous polynomial law $\lambda^! : \underline{M} \leadsto Q$ that makes commute the diagrams:

$$
\begin{array}{ccc}
C \otimes_A N & \xrightarrow{\lambda^!_C} & C \otimes_A Q \\
\varphi \otimes_A N & \downarrow & \downarrow \\
C \otimes_A B \otimes_A N & \xrightarrow{\lambda^!_{C\otimes_A B}} & (C \otimes_A B) \otimes_B (B \otimes_A N)
\end{array}
$$

whose right vertical arrow is the standard isomorphism, and where $\varphi : C \to C \otimes_A B$ is given by the rule : $c \mapsto c \otimes 1$ for every $c \in C$, for all $A$-algebras $C$. Indeed, the inverse of (9.5.4) is the mapping that assigns to every homogeneous polynomial law $\mu : M \leadsto Q$ of degree $d$, the homogeneous polynomial law $\mu^! : B \otimes_A M \leadsto Q$ that makes commute the diagrams:

$$
\begin{array}{ccc}
C \otimes_A N & \xrightarrow{\mu_C} & C \otimes_A Q \\
\downarrow & \downarrow & \downarrow \\
C \otimes_B (B \otimes_A N) & \xrightarrow{\mu^!_C} & C \otimes_B Q
\end{array}
$$

for every $B$-algebra $C$.

whose left vertical arrow is the standard isomorphism, and whose right vertical arrow is the $B$-linear map such that $c \otimes q \mapsto c \otimes q$, for every $c \in C$ and $q \in Q$. We leave to the reader the verification of the identities : $(\lambda^!)^! = \lambda$ and $(\mu^!)^! = \mu$ for every such $\lambda$ and $\mu$.

9.5.5. In the situation of definition [9.5.1] let also $\mathcal{B}$ be any full subcategory of $A\text{-Alg}$ such that $\text{Ob}(\mathcal{B})$ contains all the free polynomial $A$-algebras of finite type, and denote by $j_\mathcal{B} : \mathcal{B} \to A\text{-Alg}$ the inclusion functor. We consider also the set :

$$
\text{Pol}^d_A(M, Q)_\mathcal{B}
$$

of all natural transformations $\lambda : F_M \circ j_\mathcal{B} \Rightarrow G_Q \circ j_\mathcal{B}$ verifying condition (9.5.2) for every $B \in \text{Ob}(\mathcal{B})$.

**Proposition 9.5.6.** With the notation of (9.5.5), the restriction map :

$$
\text{Pol}^d_A(M, Q) \to \text{Pol}^d_A(M, Q)_\mathcal{B} \quad \lambda \mapsto \lambda \ast j_\mathcal{B}
$$

is bijective for every $k \in \mathbb{N}$, every $d \in \mathbb{N}^{\leq k}$, every ring $A$, and all $A$-modules $M_1, \ldots, M_k, Q$.

**Proof.** Let $\mathcal{B}_0$ (resp. $\mathcal{B}_1$) be the full subcategory of $A\text{-Alg}$ whose objects are the free polynomial $A$-algebras of finite type (resp. the free polynomial $A$-algebras on arbitrary sets of indeterminates). To ease notation, set $N := M_1 \times \cdots \times M_k$; we show first :

**Claim 9.5.7.** The proposition holds for $\mathcal{B} = \mathcal{B}_1$.

**Proof of the claim.** Let us consider, for every $A$-algebra $B$, the standard simplicial resolution $P_B[\bullet] \to B$ arising from the cotriple associated to the forgetful functor $A\text{-Alg} \to \text{Set}$ and its left adjoint (see example [7.10.13(i)]); hence the augmentation $\varepsilon_B : P_B[0] \to B$ is a surjective map of $A$-algebras, and the set underlying $B$ is the coequalizer of the maps of $A$-algebras $\partial_0, \partial_1 : P_B[1] \to P_B[0]$. If $\lambda : \underline{M} \leadsto Q$ is any homogeneous polynomial law of degree $d$, the
commutativity of the diagram

\[
\begin{align*}
  P_B[1] \otimes_A N & \xrightarrow{\lambda_{P_B[1]}} P_B[1] \otimes_A Q \\
  \partial_0 \otimes_A N & \xrightarrow{\partial_1 \otimes_A N} \partial_0 \otimes_A Q \xrightarrow{\partial_1 \otimes_A Q} \partial_0 \otimes_A N \\
  P_B[0] \otimes_A N & \xrightarrow{\lambda_{P_B[0]}} P_B[0] \otimes_A Q \\
  \varepsilon_B \otimes_A N & \xrightarrow{\lambda_B} B \otimes_A N \\
  B \otimes_A N & \xrightarrow{\lambda_B} B \otimes_A N
\end{align*}
\]

(9.5.8)

and the surjectivity of \( \varepsilon_B \otimes_A N \), already show that \( \lambda_{P_B[0]} \) determines \( \lambda_B \), whence the injectivity of our restriction map (as \( P_B[0] \) is a free polynomial \( A \)-algebra). Next, let \( \lambda : F_M \circ j_{\mathscr{B}_1} \Rightarrow G_Q \circ j_{\mathscr{B}_1} \) be an element of \( \text{Pol}_A^d(M, Q)_{\mathscr{B}_1} \); since the tensor product is right exact, it is easily seen that the map \( \varepsilon_B \otimes_A N \) identifies the set \( B \otimes_A N \) with the coequalizer (in the category of sets) of the pair of maps \( \partial_0 \otimes_A N, \partial_1 \otimes_A N : P_B[1] \otimes_A N \to P_B[0] \otimes_A N \) (details left to the reader). Since \( P_B[0] \) and \( P_B[1] \) are free polynomial \( A \)-algebras, in this situation the top square subdiagram of (9.5.8) is well defined and commutes, so there exists exactly one map of sets \( \lambda_B \) that makes commute also the bottom square subdiagram. It is easily seen that such \( \lambda_B \) fulfills (9.5.2), since the same holds for \( \lambda_{P_B[0]} \), and since both \( \varepsilon_B \) and \( \varepsilon_B \otimes_A N \) are surjective. Hence, we obtain a well defined map \( \lambda_B \) as required, for every \( A \)-algebra \( B \), and it remains to check that the rule \( B \mapsto \lambda_B \) defines a natural transformation \( F_M \Rightarrow G_Q \), i.e. for every map \( f : B \to B' \) of \( A \)-algebra, we have \((f \otimes_A Q) \circ \lambda_B = \lambda_B \circ (f \otimes_A N)\). To this aim, we are easily reduced to showing the same identity for the map \( g := f \circ \varepsilon_B : P_B[0] \to B' \); but since \( P_B[0] \) is a free polynomial \( A \)-algebra, we may find a map of \( A \)-algebras \( h : P_B[0] \to P_{B'}[0] \) such that \( g = \varepsilon_B \circ h \). Then, by a simple diagram chase, we are further reduced to checking the sought identity for the map \( h \); but the latter holds by assumption, since both \( P_B[0] \) and \( P_B'[0] \) are free polynomial \( A \)-algebras.

Next, we show that the proposition holds for \( \mathscr{B} = \mathscr{B}_0 \). In view of claim [9.5.7], we are reduced to checking that the corresponding restriction map \( \text{Pol}_A^d(M, Q)_{\mathscr{B}_1} \to \text{Pol}_A^d(M, Q)_{\mathscr{B}_0} \) is injective. To this aim, let us fix, for every free polynomial \( A \)-algebra \( B \), a filtered system \( (B_i \mid i \in I_B) \) of free polynomial \( A \)-subalgebras of \( B \) whose colimit is \( B \). Now, if \( \lambda \) is any element of \( \text{Pol}_A^d(M, Q)_{\mathscr{B}_1} \), it is easily seen that \( \lambda_B \) must be the colimit of the induced system of maps of sets \((\lambda_{B_i} \mid i \in I_B)\). This shows already that our restriction map is injective. Lastly, let \( \lambda \) be any element of \( \text{Pol}_A^d(M, Q)_{\mathscr{B}_0} \); then conversely we may define, for every free polynomial \( A \)-algebra \( B \), a map \( \lambda_B : F_M B \to G_Q B \), by taking the colimit of the system of maps \((\lambda_{B_i} \mid i \in I_B)\). It is easily seen that this map \( \lambda_B \) fulfills condition (9.5.2), for every such \( B \) : the details shall be left to the reader. It remains to check that the rule \( B \mapsto \lambda_B \) defines a natural transformation. Hence, let \( f : B \to B' \) be a map of free polynomial \( A \)-algebras; we need to show that \((f \otimes_A Q) \circ \lambda_B = \lambda_B \circ (f \otimes_A N)\). However, let \((g_i : B_i \to B \mid i \in I_B)\) and \((g'_j : B'_j \to B' \mid j \in I_B)\) be the universal cocones; we are easily reduced to checking that the same identity holds for the map \( f \circ g_i : B_i \to B' \), for every \( i \in I_B \). But for every such \( i \) we may find \( j \in I_{B'} \) such that \( f \circ g_i \) factors through \( g'_j \) and a map \( h : B_i \to B'_j \) of \( A \)-algebras, and we are further reduced to checking the sought identity for the map \( h \). The latter holds by assumption, since \( B_i, B'_j \in \text{Ob}(\mathscr{B}_0) \).

Now, let \( \mathscr{B} \) be any full subcategory of \( A \)-Alg containing \( \mathscr{B}_0 \); by the foregoing, it is clear that the restriction map \( \text{Pol}_A^d(M, Q) \to \text{Pol}_A^d(M, Q)_{\mathscr{B}} \) is injective. Lastly, let \( \lambda \) be any element of \( \text{Pol}_A^d(M, Q)_{\mathscr{B}_0} \), and denote by \( \lambda_0 \) its image in \( \text{Pol}_A^d(M, Q)_{\mathscr{B}_1} \); by the foregoing, \( \lambda_0 \) is the restriction of some \( \lambda' \in \text{Pol}_A^d(M, Q) \), and it remains to check that \( \lambda' = \lambda_B \) for every \( B \in \text{Ob}(\mathscr{B}) \). However, for every such \( B \), and every \( x \in F_M B \), we may find \( B_0 \in \text{Ob}(\mathscr{B}_0) \), a
map \( f : B_0 \to B \) of \( A \)-algebras, and \( y \in F_M B_0 \) with \( f \otimes_A M(y) = x \); by construction, 
\( \lambda_B(x) = \lambda_{B_0}(y) = \lambda_{B_0}(y) = \lambda_B(x) \), as required. \( \square \)

**Lemma 9.5.9.** In the situation of definition 9.5.1 suppose that the \( A \)-module \( M_i \) is free of finite rank, for every \( i = 1, \ldots, k \). Then, there exists a natural bijection

\[
\text{Pol}_A^d(M, Q) \sim Q \otimes_A \text{Sym}_A^d(M')
\]

**Proof.** Indeed, fix bases \((e_1, \ldots, e_{ir_i})\) for each \( A \)-module \( M_i \), and denote by \((e_1^*, \ldots, e_{ir_i}^*)\) the dual basis of \( M_i' \). For every \( i = 1, \ldots, k \) there is a natural (injective) map of \( A \)-algebras

\[
\text{Sym}_A^*(M_i') \to \text{Sym}_A^*(M_i') : s \mapsto 1 \otimes \cdots \otimes s \otimes \cdots \otimes 1
\]

allowing to view naturally the \( e_{ij}^* \) as elements of \( \text{Sym}_A^*(M_i') \). Recall also that \( \text{Sym}_A^*(M_i') \) is the free \( A \)-algebra \( A[e_1^*, \ldots, e_{ir_i}^*] \) on the set \( e_{ij}^* \), for every \( i = 1, \ldots, k \). Let now \( \lambda : M \sim Q \) be a given homogeneous multiplication law of degree \( d \), and set

\[
P_\lambda(e_{ij}^*) := \lambda_{\text{Sym}_A^*(M')}(\sum_{j=1}^{r_i} e_{1j}^* \otimes e_{2j}^* \cdots \sum_{j=1}^{r_k} e_{kj}^* \otimes e_{kj}^*) \in Q \otimes_A \text{Sym}_A^*(M')
\]

Notice that the terms in parenthesis are elements of \( M_i \otimes_A M_i' \subset M_i \otimes_A \text{Sym}_A^*(M_i') \) that do not depend on the chosen bases, since they correspond to the identity automorphisms of \( M_i \), under the natural identification \( M_i \otimes_A M_i' \sim \text{End}_A(M_i) \). Now, let \( B \) be any \( A \)-algebra, and \( b_{i*} := (b_{ij} | i = 1, \ldots, k; j = 1, \ldots, r_i) \) any sequence of elements of \( B \). By considering the unique map of \( A \)-algebras \( \varphi_{b_{i*}} : \text{Sym}_A^*(M_i') \to M_i \) given by the rule \( e_{ij}^* \mapsto b_{ij} \) for every \( i = 1, \ldots, k \) and every \( j = 1, \ldots, r_i \), it is easily seen that

\[
\lambda_B(\sum_{j=1}^{r_i} b_{ij} e_{1j}^* \cdots \sum_{j=1}^{r_k} b_{kj} e_{kj}^*) = P_\lambda(b_{i*}) := (Q \otimes_A \varphi_{b_{i*}})(P_\lambda(e_{ij}^*)) \in Q \otimes_A B.
\]

In other words, \( \lambda \) is completely determined by the polynomial \( P_\lambda(e_{ij}^*) \) with coefficients in \( Q \). Next, take \( B := \text{Sym}_A^*(M')[Y_1, \ldots, Y_k] \); the homogeneity condition on \( \lambda \) implies that

\[
P_\lambda(Y_i e_{ij}^* | i = 1, \ldots, k) = \lambda_B(\sum_{j=1}^{r_i} e_{1j}^* \otimes \cdots \sum_{j=1}^{r_k} e_{kj}^* \otimes e_{kj}^*) = Y_1^{d_1} \cdots Y_k^{d_k} \cdot P_\lambda(e_{ij}^*)
\]

which means that \( P_\lambda \in Q \otimes_A \text{Sym}_A^d(M') \). Conversely, it is clear that any element of \( Q \otimes_A \text{Sym}_A^d(M') \) yields a homogeneous law of degree \( d \), whence the lemma. \( \square \)

**Lemma 9.5.10.** Let \( f_*, g_* : M'' \to M' \) be two morphisms of \( (A, \text{-Mod})^k \), and \( p_* : M' \to M \) the projection of \( M' \) onto \( M := \text{Coequal}(f_*, g_*) \). Suppose that for \( i = 1, \ldots, k \), the map

\[
h_i : M'' \to M'_i \times_{(p_i, p_i)} M'_i \quad x \mapsto (f_i(x), g_i(x))
\]

is surjective. Then the induced map of sets

\[
\text{Pol}_A^d(M, Q) \to \text{Equal}(\text{Pol}_A^d(M', Q) \subset \text{Pol}_A^d(M'', Q))
\]

is bijective for every \( A \)-module \( Q \) and every \( d \in \mathbb{N}^k \) (notation of example 1.2.16 ii).

**Proof.** For \( i = 1, \ldots, k \), let \( q_i : M'_i \oplus M'_i \to M_i \) be the map such that \( (x, y) \mapsto p_i(x - y) \) for every \( x, y \in M'_i \). Then \( q_i \) is a surjection with kernel \( M'_i \times_M M'_i \). If \( B \) is any \( A \)-algebra, it follows that the image of \( B \otimes_A (M'_i \times_M M'_i) \) in \( B \otimes_A (M'_i \oplus M'_i) \) is \( (B \otimes_A M'_i) \times_{B \otimes_A M'_i} (B \otimes_A M'_i) \), and on the other hand \( B \otimes_A h_i \) is still surjective for every \( i = 1, \ldots, k \), so the same holds for each of the induced maps \( h_{i*} : B \otimes_A (M'_i \times_M M'_i) \to (B \otimes_A M'_i) \times_{B \otimes_A M'_i} (B \otimes_A M'_i) \), and clearly \( B \otimes_A p_* \) is the projection of \( B \otimes_A M'_i \) onto the coequalizer of \( B \otimes_A f_* \) and \( B \otimes_A g_* \).
Now, let $\lambda : M' \to Q$ be any homogeneous polynomial law of degree $d$, and $B$ any $A$-algebra. Since each $h_{B,i}$ is surjective, it follows that $\lambda_B$ factors through a unique map of sets $\mu_B : F_{MB} \to B \otimes_A Q$, and an easy inspection shows that the resulting rule $B \mapsto \mu_B$ is a homogeneous polynomial law of degree $d$.

**Remark 9.5.11.** (i) Lemma 9.5.9 shows especially that, if $M_1, \ldots, M_k$ are free $A$-modules of finite rank, the rule $Q \mapsto \text{Pol}^d_A(M_i, Q)$ yields a functor with values in essentially small sets, and it is clear that the sum of two homogeneous multipolynomial laws of degree $d$ is still a law of the same type; likewise, if we multiply such a law by an element of $A$, we get a new law of the same type. Up to isomorphism, we may therefore assume that this is a functor $A\text{-Mod} \to A\text{-Mod}$.

(ii) Let $M$ be a free $A$-module of finite rank $r$, and fix any basis $e_1, \ldots, e_r$ of $M$. The symmetric group $S_d$ acts on the set $T := \{1, \ldots, r\}^d$ by permutations:

$$\sigma(i_1, \ldots, i_d) := (i_{\sigma^{-1}(1)}, \ldots, i_{\sigma^{-1}(d)}) \quad \text{for every } \sigma \in S_d \text{ and every } i_\sigma \in T.$$ 

For every such $i_\sigma$, let $[i_\sigma] \in S_d/T$ be the class of $i_\sigma$, and denote by $e_{[i_\sigma]} \in \text{Sym}^i_A M$ be the class of $e_{i_\sigma} := e_{i_1} \otimes \cdots \otimes e_{i_d}$. Clearly, if $i_\sigma, j_\sigma \in T$ and $[i_\sigma] = [j_\sigma]$, then $e_{[i_\sigma]} = e_{[j_\sigma]}$, so this notation is unambiguous, and it is easily seen that the system $(e_{[i_\sigma]} | [i_\sigma] \in S_d/T)$ is a basis of $\text{Sym}^i_A M$ (details left to the reader). Moreover, let $N$ be any other free $A$-module of finite rank $s$, and fix as well a basis $f_1, \ldots, f_s$ of $N$; recall that we have a natural $A$-linear isomorphism

$$(9.5.12) \quad \omega_{M,N} : M^\vee \otimes_A N^\vee \overset{\sim}{\to} (M \otimes_A N)^\vee.$$ 

Namely, denote by $e^*_1, \ldots, e^*_r$ and $f^*_1, \ldots, f^*_s$ the corresponding dual bases; then $(e_i \otimes f_j | i = 1, \ldots, r; j = 1, \ldots, s)$ is a basis of $M \otimes_A N$, and we let likewise $((e_i \otimes f_j^* | i = 1, \ldots, r; j = 1, \ldots, s)$ be its dual basis. With this notation, we have

$$\omega_{M,N}(e^*_i \otimes f^*_j) = (e_i \otimes f_j)^* \quad \text{for every } i = 1, \ldots, r \text{ and } j = 1, \ldots, s.$$ 

It is easily seen that this isomorphism is independent of the choice of bases $e_\sigma$ and $f_\sigma$.

(iii) The lemma can be rephrased by saying that, under the stated assumptions, the $A$-module

$$\Gamma^d_A(M) := (\text{Sym}^d_A M^\vee)^\vee$$

represents the functor $A\text{-Mod} \to A\text{-Mod}$ such that $Q \mapsto \text{Pol}^d_A(M_i, Q)$ for every $A$-module $Q$.

(iv) The rule $(A, M) \mapsto \Gamma^d_A(M)$ is functorial for sequences $\underline{M}$ of free $A$-modules of finite rank. Indeed, let $\varphi : \underline{M} \to \underline{N}$ be a morphism of such sequences. For every degree $d$ of length $k$, the induced map $\text{Pol}^d_A(N, Q) \to \text{Pol}^d_A(M, Q)$ corresponds to a map

$$(9.5.13) \quad \text{Sym}^d_A(N^\vee) \otimes A Q \to \text{Sym}^d_A(M^\vee) \otimes A Q$$

that can be worked out as follows. Pick bases $(e_{ij} | j = 1, \ldots, r_i)$ for $N_i$ and $(f_{ij} | j = 1, \ldots, s_i)$ for $M_i$, for every $i = 1, \ldots, k$, and denote as usual by $(e^*_{ij} | j = 1, \ldots, r_i), (f^*_{ij} | j = 1, \ldots, s_i)$ the respective dual bases. Say that $\lambda : N \sim Q$ is a given homogeneous law of degree $d$, and let $P_\lambda(e^*_{i\bullet}) \in \text{Sym}^d_A(N^\vee) \otimes A Q$ be the corresponding homogeneous polynomial. By construction,
the polynomial $P_{\lambda \circ \varphi} \in \text{Sym}_A^d(M^\vee) \otimes_A Q$ corresponding to $\lambda \circ \varphi$ is calculated as

$$P_{\lambda \circ \varphi}(f_{ij}^*) := (\lambda \circ \varphi)_\text{Sym}_A^*(M^\vee)\left(\sum_{j=1}^{s_i} f_{ij} \otimes f_{ij}^* \mid i = 1, \ldots, k\right)$$

$$= \lambda_{\text{Sym}_A^*(M^\vee)}\left(\sum_{j=1}^{s_i} \varphi_i(f_{ij}) \otimes f_{ij}^* \mid i = 1, \ldots, k\right)$$

$$= \lambda_{\text{Sym}_A^*(M^\vee)}\left(\sum_{j=1}^{r_i} e_{ij} \otimes \varphi_i^*(e_{ij}^*) \mid i = 1, \ldots, k\right)$$

$$= P_A(\varphi_i^*(e_{ij}^*) \mid i = 1, \ldots, k)).$$

In other words, (9.5.13) equals $\text{Sym}_A^d(\varphi^\vee) \otimes_A 1_Q$, so if we let

$$\Gamma_A^d := \text{Sym}_A^d(\varphi^\vee)$$

we obtain:

- a functor $\Gamma^d_A(-)$ from the full subcategory $(A_{\text{Mod}})^k_{\text{ff}}$ of $(A_{\text{Mod}})^k$ consisting of all sequences of free $A$-modules of finite rank, into the category of $A$-modules
- for every $A$-module $Q$, a well defined isomorphism of functors on this subcategory

$$(Q, M) \mapsto (\text{Pol}_A^d(M, Q)) \sim \text{Hom}_A(\Gamma_A^d(M), Q) : A_{\text{Mod}} \times (A_{\text{Mod}})^k_{\text{ff}} \to A_{\text{Mod}}$$

(v) Notice that for every sequence of $A$-modules $M := (M_1, \ldots, M_k)$, every $A$-multilinear map $\varphi : M_1 \times \cdots \times M_k \to Q$ induces, for every $A$-algebra $B$, a $B$-multilinear map $\varphi_B : (B \otimes_A M_1) \times \cdots \times (B \otimes_A M_k) \to B \otimes_A Q$, and the rule $B \mapsto \varphi_B$ for every such $B$ is obviously a homogeneous polynomial law of degree $1_k := (1, \ldots, 1)$. We obtain therefore a natural transformation of functors:

$$\text{Hom}_A(M_1 \otimes_A \cdots \otimes_A M_k, Q) \to \text{Pol}_A^d(M, Q)$$

for every $A$-module $Q$.

In case each $M_i$ is free of finite rank, this transformation must come from an $A$-linear map

$$\Gamma_A^1(M) \to M_1 \otimes_A \cdots \otimes_A M_k.$$

On the other hand, by construction, and in view of (9.5.12), we have a natural identification

$$\Gamma_A^1(M) = (M_1^\vee \otimes_A \cdots \otimes_A M_k^\vee) \sim M_1 \otimes_A \cdots \otimes_A M_k$$

and by inspecting the proof of lemma 9.5.9 it is easily seen that this latter map coincides with (9.5.15) : the detailed verification shall be left to the reader.

The following result extends the above observations to arbitrary sequences $M$ of $A$-modules.

**Theorem 9.5.16.** Let $M$ be any sequence as in definition (9.5.1)(i). We have:

(i) $\text{Pol}_A^d(M, Q)$ is an essentially small set, for every $A$-module $Q$.

(ii) There exists a functor

$$\Gamma^d_A : (A_{\text{Mod}})^k \to A_{\text{Mod}}$$

with a natural isomorphism of $A$-module valued functors

$$\text{Pol}_A^d(-, Q) \sim \text{Hom}_A(\Gamma_A^d(-), Q)$$

for every $A$-module $Q$.

**Proof.** Suppose first that the $A$-modules $M_1, \ldots, M_k$ are finitely presented, and for $i = 1, \ldots, k$, pick an $A$-linear surjection $f_i : L_i \to M_i$, with $L_i$ free of finite rank. Let $g_i : L_i \oplus L_i \to M_i$ be the map given by the rule $((l, l')) \mapsto f_i(l - l')$ for every $(l, l') \in L_i \oplus L_i$; since $M_i$ is finitely presented, $\text{Ker} \ g_i$ is finitely generated, for every $i = 1, \ldots, k$, so we may find a free $A$-module
$L'_i$ of finite rank, and a surjective $A$-linear map $L'_i \rightarrow \text{Ker } g_i$. By composing with the inclusion \(\text{Ker } g_i \rightarrow L_i \oplus L_i\) and the two projections $L_i \oplus L_i \rightarrow L_i$, we deduce a presentation of $M_i$:

\[
(9.5.18) \quad \text{Coker } (h^1_i, h^2_i : L'_i \rightarrow L_i) \cong M_i
\]

such that the induced map $L'_i \rightarrow L_i \times_M L_i$ is surjective. Set $L := (L_1, \ldots, L_k)$, $L' := (L'_1, \ldots, L'_k)$ and $h^j := (h^j_1, \ldots, h^j_k)$ for $j = 1, 2$. By lemma [9.5.10], the presentations (9.5.18) induce a presentation of sets:

\[
\text{Pol}^d_A(M, Q) \cong \text{Equal}(\text{Pol}^d_A(L, Q) \supseteq \text{Pol}^d_A(L', Q)) \quad \text{for every } A\text{-module } Q.
\]

Combining with lemma [9.5.9] it follows easily that the theorem holds for $M$, with

\[
\Gamma^d_A(M) := \text{Coequal}(\Gamma^d_A(h^1), \Gamma^d_A(h^2) : \Gamma^d_A(L') \supseteq \Gamma^d_A(L))
\]

(details left to the reader). Lastly, let $M$ be an arbitrary sequence. We may then find a filtered system of sequences $(M_\sigma \mid \sigma \in \Sigma)$ consisting of finitely presented $A$-modules and with $A$-linear transition maps, whose colimit is isomorphic to $M$. Since such colimits are preserved by arbitrary base changes, and commute with the forgetful functor to sets, it follows easily that the system induces an isomorphism of sets:

\[
\text{Pol}^d_A(M, Q) \cong \lim_{\sigma \in \Sigma} \text{Pol}^d_A(M_\sigma, Q) \quad \text{for every } A\text{-module } Q
\]

(details left to the reader). In view of the foregoing, the theorem then holds for $M$, with

\[
\Gamma^d_A(M) := \operatorname{colim}_{\sigma \in \Sigma} \Gamma^d_A(M_\sigma).
\]

Again, we invite the reader to spell out the details. \hfill \Box

9.5.19. The identity map of $\Gamma^d_A M$ corresponds to a homogeneous multipolynomial law

\[
\lambda^d_M : M \rightarrow \Gamma^d_A M
\]

such that every other law $\widetilde{M} \sim Q$ homogeneous of the same degree, factors uniquely through $\lambda^d_M$ and an $A$-linear map $\Gamma^d_A M \rightarrow Q$ (in the sense explained in remark [9.5.3(i)]. Especially, if $M \in \text{Ob}((A\text{-Mod})^k)$ is another sequence, and $d' \in \mathbb{N}^{d_k}$ any sequence of integers, the tensor product $\lambda^d_M \otimes \lambda^{d'}_{M'}$ (remark [9.5.3(ii)]) factors uniquely through $\lambda^{d + d'}_{M \otimes M'}$ and an $A$-linear map

\[
(9.5.20) \quad \Gamma^{d + d'}_A (M, M') \rightarrow \Gamma^d_A(M) \otimes_A \Gamma^{d'}_A(M')
\]

Furthermore, in the situation of remark [9.5.3(iii)], the bijection (9.5.4) translates as a bijection:

\[
\text{Hom}_B(\Gamma^d_B(\otimes A M), Q) \cong \text{Hom}_A(\Gamma^d_A M, Q) \cong \text{Hom}_B(B \otimes A \Gamma^d_A M, Q)
\]

natural with respect to $B$-linear maps $Q \rightarrow Q'$ and morphisms $M' \rightarrow M$ in $(A\text{-Mod})^k$. Such a natural bijection then must come from an isomorphism of $B$-modules

\[
(9.5.21) \quad B \otimes A \Gamma^d_A(M) \cong \Gamma^d_B(B \otimes A M) \quad 1 \otimes \lambda^d_M(m) \mapsto \lambda^{d}_{B \otimes A M}(1 \otimes m)
\]

which is natural with respect to morphisms in $(A\text{-Mod})^k$ and maps $B \rightarrow B'$ of $A$-algebras.

**Corollary 9.5.22.** With the notation of (9.5.19), we have:

(i) The functor (9.5.17) commutes with all filtered colimits.

(ii) The map (9.5.20) is an isomorphism of $A$-modules, for every $M, M', d$ and $d'$.

(iii) If the $A$-modules $M_1, \ldots, M_k$ are all free (resp. finitely presented, resp. finitely generated, resp. flat), then the same holds for $\Gamma^d_A(M)$. 
(iv) In the situation of lemma 9.5.10, the induced map
\[ \text{Coequal}(\Gamma^d_A(f_\flat), \Gamma^d_A(g_\sharp)) : \Gamma^d_A(M^n) \xrightarrow{\sim} \Gamma^d_A(M') \xrightarrow{\sim} \Gamma^d_A(M) \]
is an isomorphism of \( A \)-modules.

(v) For every \( M_k := (M_1, \ldots, M_k) \in \text{Ob}((A-\text{Mod})^k) \), the natural transformation (9.5.14) is an isomorphism of functors, and therefore it induces a natural \( A \)-linear isomorphism:
\[ \omega^{\circ}_k : \Gamma^d_A(M) \xrightarrow{\sim} M_1 \otimes_A \cdots \otimes_A M_k. \]

(vi) Set \( 0_k := (0, \ldots, 0) \in \mathbb{N}^\oplus ; \) we have a natural isomorphism of functors:
\[ \Gamma^0_A(M) \xrightarrow{\sim} A \text{ for every } M \in \text{Ob}((A-\text{Mod})^k) \]
that identifies \( \lambda^0_k \) with the polynomial law \( M \leadsto A = x_\bullet \mapsto 1 \) for all \( B \in \text{Ob}(A-\text{Alg}) \) and all \( x_\bullet \in F_M(B) \), and identifies \( \Gamma^0_A f \) with \( 1_A \), for every morphism \( f \) of \( (A-\text{Mod})^k \).

**Proof.** (i): It suffices to check that the natural map
\[ \text{Pol}^d_A(\text{colim}_{\sigma \in \Sigma} M_\sigma, Q) \rightarrow \lim_{\sigma \in \Sigma} \text{Pol}^d_A(M_\sigma, Q) \]
is an isomorphism, for every filtered system of \( A \)-modules \( (M_\sigma \mid \sigma \in \Sigma) \) and every \( A \)-module \( Q \); the latter assertion is obvious (details left to the reader).

(iii): The assertion concerning free modules of finite rank, and finitely generated or finitely presented modules follows directly from the explicit construction in lemma 9.5.9 and theorem 9.5.16. The assertion for flat modules follows from the assertion for free modules of finite rank and from (i), by means of Lazard’s theorem [95, Ch.I, Th.1.2]. Moreover, from remark 9.5.11(iv), we see that if \( \varphi : M \rightarrow N \) is a morphism of sequences of free \( A \)-modules of finite rank, such that \( \varphi_i \) is a split injection for every \( i = 1, \ldots, n \), then \( \Gamma^d_A(\varphi) \) is also a split injective map of free \( A \)-modules; from this, and from (i), it follows easily that \( \Gamma^d_A \) transforms sequences of free \( A \)-modules (of possibly infinite rank) into free \( A \)-modules : details left to the reader.

(iv) follows formally from lemma 9.5.10: details left to the reader.

(ii): Let \( t : \Gamma^d_A(M, M') \rightarrow Q \) be an \( A \)-linear map. To \( t \) we attach an \( A \)-linear map
\[ t^* : \Gamma^d_A(M) \otimes_A \Gamma^d_A(M') \rightarrow Q \]
as follows. Set \( \tau := t \circ \Delta^{d,d}_A \Gamma A (M, M') : (M, M') \leadsto Q \) (notation of remark 9.5.3(i)). To every \( A \)-algebra \( B \), the law \( \tau \) attaches the mapping
\[ B \otimes A M \rightarrow \text{Pol}^d_B(B \otimes A M', B \otimes A Q) \quad x \mapsto \tau_{B,x} \]
where \( (\tau_{B,x})c(y) := \tau_{C}((1 \otimes x_\bullet, y) \) for every \( x \in B \otimes A M \), every \( B \)-algebra \( C \) and every \( y \in C \otimes A M' \). In light of (iii), the latter is the same as a mapping
\[ B \otimes A M \rightarrow \text{Hom}_B(B \otimes A \Gamma^d_A(M'), B \otimes A Q) \quad x \mapsto t_{B,x} \]
and notice that, for every \( x \in B \otimes A M \), the \( B \)-linear map \( t_{B,x} \) is characterized by the identity
\[ t_{B,x}(\lambda^{d}_A, y) = (\tau_{B,x})B(y) \quad \text{for every } y \in B \otimes A M'. \]

We deduce a compatible system of mappings
\[ B \otimes A \Gamma^d_A(M') \rightarrow \text{Pol}^d_B(B \otimes A M, B \otimes A Q) : y \mapsto \tau_{B,y}^* \quad \text{for every } A \text{-algebra } B \]
where \( (\tau_{B,y})c(x) := t_{C,x}(1 \otimes y) \) for every \( B \)-algebra \( C \), every \( x \in C \otimes A M \), and every \( y \in B \otimes A \Gamma^d_A(M') \). The \( C \)-linearity of \( t_{C,x} \) implies that these latter mappings are \( B \)-linear (for every \( A \)-algebra \( B \)), and then they are the same as a compatible system of \( B \)-linear maps
\[ B \otimes A \Gamma^d_A(M') \rightarrow \text{Hom}_B(B \otimes A \Gamma^d_A(M), B \otimes A Q) : y \mapsto t_{B,y}^* \]
for every $A$-algebra $B$. Notice that, for every $y \in B \otimes_A \Gamma^d_A(M')$, the $B$-linear map $t^*_{B,y}$ is characterized by the identity:

\[(9.5.25) \quad t^*_{B,y}(\lambda^d_M(x)) = (\tau_{B,y})_B(x) \quad \text{for every } x \in B \otimes_A M.\]

Obviously, the datum of a compatible system \((9.5.24)\) is the same as that of a map $t^*$ as sought.

**Claim 9.5.26.** $t^* \circ (9.5.20) = t$.

*Proof of the claim.* It suffices to show that $t^* \circ (9.5.20) \circ \lambda^d_{M,M'} = \tau$. However, recall that $(9.5.20) \circ \lambda^d_{M,M'} = \lambda^d_M \otimes \lambda^d_{M'}$, so we are reduced to checking that $t^* \circ (\lambda^d_M \otimes \lambda^d_{M'}) = \tau$. Hence, let $B$ be any $A$-algebra, and $m \in B \otimes_A M$, $m' \in B \otimes_A M'$ any two elements. To ease notation, set $x := \lambda^d_M(m)$ and $y := \lambda^d_{M'}(m')$. We compute:

\[
(t^* \circ (\lambda^d_M \otimes \lambda^d_{M'}))_B(m, m') = (B \otimes_A t^*)(x \otimes y)
\]

\[
= t^*_{B,y}(x) = (\tau_{B,y})_B(m) \quad \text{(by } (9.5.25))
\]

\[
= t_{B,m}(y) = (\tau_{B,m})_B(m') \quad \text{(by } (9.5.23))
\]

\[
= \tau_B(m, m')
\]

as claimed. \(\diamondsuit\)

Especially, if we let $t$ be the identity map of $\Gamma^d_A(M, M')$, claim 9.5.26 shows that the resulting $t^*$ is a left inverse for $(9.5.20)$. Now, if all the modules $M_1, \ldots, M'_k$ are free of finite rank, then lemma 9.5.9 shows that both of the $A$-modules appearing in $(9.5.20)$ are free and have the same rank, so the assertion follows, in this case.

Next, suppose that each $A$-module $M_i$ and $M'_i$ is finitely presented; pick for $i = 1, \ldots, k$ a finite presentation for $M_i$ as in $(9.5.18)$, and let $L_i := (L_{1i}, \ldots, L_{ki})$ and $L'_i := (L'_{1i}, \ldots, L'_{ki})$. By (iv) and naturality of $(9.5.20)$, we get an induced commutative diagram with exact rows:

\[
\begin{array}{ccccccc}
\Gamma^d_A(L', M') & \longrightarrow & \Gamma^d_A(L, M') & \longrightarrow & \Gamma^d_A(M, M') & \longrightarrow & 0 \\
\downarrow & & \downarrow & & \downarrow & & \\
\Gamma^d_A(L') \otimes_A & \longrightarrow & \Gamma^d_A(L) \otimes_A & \longrightarrow & \Gamma^d_A(M) \otimes_A & \longrightarrow & 0
\end{array}
\]

so it suffices to prove the assertion for $(L, M')$ and $(L', M')$. Arguing likewise with a presentation for $M'$, we reduce to the case where $M$ and $M'$ consist of free $A$-modules of finite rank, which has already been treated. Lastly, if $M$ and $N$ are arbitrary sequences, we may present them as filtered colimits of sequences of finitely presented $A$-modules; since tensor products commute with such colimits, we are done, by the foregoing case (details left to the reader).

(v): First, by a direct inspection of the constructions we get a commutative diagram:

\[
\begin{array}{ccc}
\Gamma^1_A(M) & \longrightarrow & \Gamma^1_A(M_1 \otimes_A \cdots \otimes_A M_k) \\
\omega^1_{M_1} & \downarrow & \omega^1_{M_1 \otimes_A \cdots \otimes_A M_k} \\
M_1 \otimes_A \cdots \otimes_A M_k & \longrightarrow & \Gamma^1_A(M_1 \otimes_A \cdots \otimes_A M_k)
\end{array}
\]

whose top horizontal arrow is obtained from the isomorphisms $(9.5.20)$ provided by (ii). Hence, we are reduced to the case where $k = 1$, so $M$ is a single $A$-module $M$. Next, by virtue of (i), we may assume that $M$ is an $A$-module of finite presentation, in which case we may pick a presentation $(9.5.18)$ of $M$ by free $A$-modules of finite rank, and by virtue of (iv) we are then
further reduced to the case where \(M\) is free of finite rank, in which case the assertion is already known by remark 9.5.11(v).

(vi): Let \(\lambda : M \rightarrow Q\) be any homogeneous polynomial law of degree \(0\); then:
\[
\lambda_B(x_\bullet) = 0^0 \cdots 0^0 \cdot \lambda_B(x_\bullet) = \lambda_B(0x_1, \ldots, 0x_k) = \lambda_B(0, \ldots, 0)
\]
for every \(A\)-algebra \(B\) and every \(x_\bullet \in F_M(B)\). In other words, \(\lambda_B\) is the constant map with value \(\lambda_A(0, \ldots, 0)\) for every such \(B\). We have then a natural isomorphism of functors:
\[
\text{Pol}^0_A(M, Q) \overset{\sim}{\rightarrow} Q \overset{\sim}{\rightarrow} \text{Hom}_A(A, Q)
\]
which must come from an isomorphism \(\Gamma^0_A(M) \overset{\sim}{\rightarrow} A\), and the stated identifications of \(\lambda^0_A\) and \(\Gamma^0_A f\) follow by direct inspection. \(\square\)

**Remark 9.5.27.** (i) Let \(M\) and \(d\) be as in (9.5.19), suppose that all the \(A\)-modules \(M_i\) are free of finite rank, and set \(S(M) := \text{Sym}_A(M^\vee)\). Let \(Q\) be another \(A\)-module, and \(\lambda : M \rightarrow Q\) a homogeneous multipolynomial law of degree \(d\). From lemma 9.5.9 we may extract the following calculation for the \(A\)-linear map \(\lambda^\dagger : \Gamma^d_A(M) \rightarrow Q\) corresponding to \(\lambda\). Set
\[
P_{\lambda} := \lambda_{S(M)}(1_{M_1}, \ldots, 1_{M_k}) \in \Gamma^d_A(M^\vee) \otimes_A Q.
\]
Then \(\lambda^\dagger\) is the image of \(P_{\lambda}\) under the natural identification \(\Gamma^d_A(M^\vee) \otimes_A Q \overset{\sim}{\rightarrow} \text{Hom}_A(\Gamma^d_A(M), Q)\).

(ii) Let \(M, M', d\) and \(d'\) be as in (9.5.19), suppose that all the \(A\)-modules \(M_i\) and \(M'_i\) are free of finite rank, and to ease notation let
\[
\lambda := \lambda^d_M\quad \lambda' := \lambda_{M'}^d\quad \lambda := \lambda \otimes \lambda'.
\]
By (i), we compute
\[
P_{\lambda} = \lambda_{S(M,M')}(1_{M_1}, \ldots, 1_{M_k}) \otimes \lambda'_{S(M,M')}(1_{M'_1}, \ldots, 1_{M'_{k'}}).
\]
However, \(\lambda_{S(M,M')}(1_{M_1}, \ldots, 1_{M_k})\) is the image of \(P_{\lambda}\) under the \(A\)-linear map induced by the \(A\)-algebra homomorphism \(S(M) \rightarrow S(M, M') = S(M) \otimes_A S(M')\) given by the rule \(s \mapsto s \otimes 1\), for every \(s \in S(M)\). Likewise we determine \(\lambda'_{S(M,M')}(1_{M'_1}, \ldots, 1_{M'_{k'}})\), and we conclude that \(P_{\lambda} = P_{\lambda} \otimes P_{\lambda'},\) whence \(\lambda^\dagger = \lambda^\dagger \otimes \lambda'^\dagger\), under the natural identification
\[
\text{End}_A(\Gamma^d_A(M)) \overset{\sim}{\rightarrow} \text{End}_A(\Gamma^d_A(M^\vee)) \otimes_A \text{End}_A(\Gamma^d_A(M')^\vee).
\]
But by definition, \((\lambda^d_M)^\dagger\) is the identity automorphism of \(\Gamma^d_A(M)\), for every sequence \(M\), and every degree \(d\). We see therefore that:
\[
(\lambda^d_M \otimes \lambda^d_{M'})^\dagger = (\lambda^d_{M,M'})^\dagger
\]
which translates as saying that the \(A\)-linear map (9.5.20) is none else than the transpose of the natural isomorphism
\[
\text{Sym}_A^d(M^\vee) \otimes_A \text{Sym}_A^d(M'^\vee) \overset{\sim}{\rightarrow} \text{Sym}_A^{dd}(M^\vee, M'^\vee).
\]
This gives an alternative proof of corollary 9.5.22(ii), in the case of free \(A\)-modules.

9.5.28. Let \(A\) be a ring, and \(d \in \mathbb{N}\). For every \(A\)-module \(M\), the symmetric group \(S_d\) acts on \(\otimes^d_A M\) by permuting the tensor factors:
\[
\sigma(m_1 \otimes \cdots \otimes m_d) := m_{\sigma^{-1}(1)} \otimes \cdots \otimes m_{\sigma^{-1}(d)}\quad \text{for every } \sigma \in S_d\text{ and every } m_1, \ldots, m_d \in M
\]
(here \(\otimes^0_A M = A\) for every such \(M\), and \(S_0\) is the trivial group with one element). We set:
\[
TS^d_A M := (\otimes^d_A M)^{S_d}.
\]
Clearly every $A$-linear map $f : M \to M'$ induces an $A$-linear map $\otimes_A^d(f) : \otimes_A^d M \to \otimes_A^d M'$ such that $m_1 \otimes \cdots \otimes m_d \mapsto f(m_1) \otimes \cdots \otimes f(m_d)$ for every $m_1, \ldots, m_d \in M$, and $\otimes_A^d(f)$ restricts to a map $TS_A^d(f) : TS_A^d M \to TS_A^{d'} M'$, so we get a well defined functor

$$TS_A^d : A\text{-Mod} \to A\text{-Mod}$$

for every $d \in \mathbb{N}$ and every ring $A$.

Moreover, notice that the $A$-linear map

$$\otimes_A^d M \to TS_A^d M \quad x \mapsto \sum_{\sigma \in S_d} \sigma(x)$$

factors through an $A$-linear map

$$\alpha_M^d : \text{Sym}_A^d M \to TS_A^d M.$$ Let furthermore $\beta_M^d : TS_A^d M \to \text{Sym}_A^d M$ be the restriction of the projection $\otimes_A^d M \to \text{Sym}_A^d M$.

**Lemma 9.5.29.** (i) For every flat $A$-algebra $B$, the natural map

$$B \otimes_A TS_A^d M \to TS_B(B \otimes_A M)$$

is an isomorphism.

(ii) If $M$ is free of finite rank $r$, then $TS_A^d M$ is a free direct factor of $\otimes_A^d M$ of rank $\binom{r + d - 1}{d}$.

(iii) $\alpha_M^d \circ \beta_M^d = d! \cdot 1_{TS_A^d M}$ and $\beta_M^d \circ \alpha_M^d = d! \cdot 1_{\text{Sym}_A^d M}$.

(iv) Let $e \in \mathbb{N}$ be another integer; if $M$ is a flat $A$-module, the same holds for $TS_A^d M$, and there exists a subgroup $W \subset S_{de}$ such that the natural map

$$TS_A^d(TS_A^d M) \to \otimes_A^d(\otimes_A^d M) \sim \otimes_A^{de} M$$

identifies $TS_A^e(TS_A^d M)$ with the submodule $(\otimes_A^{de} M)^W$ of $\otimes_A^{de} M$.

**Proof.** (i) and (iii) shall be left to the reader.

(ii): Fix a basis $e_1, \ldots, e_r$ of $M$; then $\otimes_A^d M$ is free with basis $(e_{i_1} \otimes \cdots \otimes e_{i_d} | i_1, \ldots, i_d \in \{1, \ldots, r\})$. For every $i_\bullet \in T := \{1, \ldots, r\}^d$, let also $S_d(i_\bullet) \subset T$ be the orbit of $i_\bullet$ under the $S_d$-action defined as in remark 9.5.1(ii); moreover, set $e_{i_\bullet} := e_{i_1} \otimes \cdots \otimes e_{i_d}$ for every such $i_\bullet$. Choose a set of representatives $\Delta$ for the quotient $S_d \setminus T$; it is then easily seen that $TS_A^d M$ is free with basis:

$$[e_{i_\bullet}] := \sum_{j_\bullet \in S_d(i_\bullet)} e_{j_\bullet} \quad \text{for all } i_\bullet \in \Delta$$

and the assertion follows by a direct computation that we leave to the reader.

(iv): In order to check that $TS_A^d M$ is a flat $A$-module, since the functor $TS_A^d$ commutes with filtered colimits, by Lazard’s theorem ([155, Ch.I, Th.1.2]) we are reduced to the case where $M$ is a free $A$-module of finite rank, in which case the assertion follows from (ii). Let $S_{d,e}$ be the group of permutations of $\Sigma := \{1, \ldots, d\} \times \{1, \ldots, e\}$ (of course, this is isomorphic to $S_{de}$). We have injective group homomorphisms:

$$S_d^e \xrightarrow{f} S_{d,e} \xleftarrow{g} S_e$$

where $f$ assigns to every $(\sigma_1, \ldots, \sigma_e) \in S_d^e$ the permutation such that $(a, b) \mapsto (\sigma_b(a), b)$ for every $(a, b) \in \Sigma$, and $g$ assigns to every $\psi \in S_e$ the permutation such that $(\sigma, b) \mapsto (\sigma, \psi(b))$ for every such $(\sigma, b)$. Clearly $\text{Im}(f) \cap \text{Im}(g) = \{1_{\Sigma}\}$, and for every $\psi \in S_e$, the inner automorphism of $S_{d,e}$ given by conjugation by $g(\psi)$ leaves $\text{Im}(f)$ invariant. Thus, we can combine $f$ and $g$ into an injective group homomorphism

$$W := S_d^e \times S_e \to S_{d,e} \quad (\sigma, \psi) \mapsto f(\sigma) \circ g(\psi).$$
Claim 9.5.30. For \( i = 1, 2 \), let \( M_i \) be an \( A \)-module with a finite group \( \Gamma_i \) of \( A \)-linear automorphisms. If \( M_1 \) and \( M_{3-i}^{\Gamma_3} \) are flat \( A \)-modules for either \( i = 1 \) or \( i = 2 \), the natural map
\[
M_1^{\Gamma_1} \otimes_A M_2^{\Gamma_2} \to (M_1 \otimes_A M_2)^{\Gamma_1 \times \Gamma_2}
\]
is an isomorphism.

Proof of the claim. Say that \( M_2 \) and \( M_1^{\Gamma_1} \) are flat \( A \)-modules. We have:
\[
(M_1 \otimes_A M_2)^{\Gamma_1 \times \Gamma_2} = ((M_1 \otimes_A M_2)^{\Gamma_1 \times 1_{\Gamma_2}})^{1_{\Gamma_1} \times \Gamma_2}
\]
and the natural map \((M_1 \otimes_A M_2)^{\Gamma_1 \times 1_{\Gamma_2}} \to M_1^{\Gamma_1} \otimes_A M_2 \) (resp. \((M_1^{\Gamma_1} \otimes_A M_2)^{1_{\Gamma_1} \times \Gamma_2} \to M_1^{\Gamma_1} \otimes_A M_2^{\Gamma_2}\)) is an isomorphism, since \( M_2 \) (resp. \( M_1^{\Gamma_1} \)) is a flat \( A \)-module. The assertion follows in this case; one argues likewise in case \( M_1 \) and \( M_2^{\Gamma_2} \) are flat \( A \)-modules.

Since \( \text{TS}^d_A M \) is a flat \( A \)-module, by claim 9.5.30 and a simple induction on \( e \), we compute:
\[
\text{TS}^d_A(\text{TS}^d_A M) = (\otimes^e_A (\otimes^d_A M)^{S^d_e})^{S^d_e} = ((\otimes^e_A (\otimes^d_A M))^{S^d_e})^{S^d_e} = ((\otimes^e_A (\otimes^d_A M))^W
\]
as stated. \( \square \)

9.5.31. For every \( d > 0 \) and every \( A \)-module \( M \) set \( M^{(d)} := (M, \ldots, M) \in \text{Ob}((A \text{-Mod})^d) \), and for every \( e \in \mathbb{N}^d \) let \( \sigma := e_1 + \cdots e_k \); we have a natural transformation of functors:
\[
\text{Pol}_A^d(M^{(d)}, Q) \to \text{Pol}_A^d(M, Q)
\]
that assigns to every homogeneous polynomial law \( \lambda : M^{(d)} \rightsquigarrow Q \) of degree \( e \) the polynomial law \( \lambda^e : M \rightsquigarrow Q \) such that
\[
\lambda^e_B(x) = \lambda_B(x, \ldots, x) \quad \text{for every } A \text{-algebra } B \text{ and every } x \in B \otimes_A M.
\]
In view of corollary 9.5.22(ii), this transformation then comes from an \( A \)-linear map
\[
\Gamma_A^e M \to \Gamma_A^e M^{(d)} \cong \Gamma_A^e M \otimes_A \cdots \otimes_A \Gamma_A^e M
\]
which is characterized as the unique \( A \)-linear map such that
\[
(\lambda^e_{M^{(d)}})_B(x) \mapsto (\lambda^e_{M})_B(x) \otimes \cdots \otimes (\lambda^e_{M})_B(x)
\]
for every \( A \)-algebra \( B \) and every \( x \in B \otimes_A M \).

9.5.33. Consider next the special case where \( e = (e_1, \ldots, e_k) \) for some \( e \in \mathbb{N} \); then, every \( \sigma \in S_d \) determines a natural isomorphism of functors:
\[
\text{Pol}_A^d(M^{(d)}, Q) \cong \text{Pol}_A^d(M, Q)
\]
that assigns to every \( \lambda \) as in the foregoing, the polynomial law \( \sigma(\lambda) : M^{(d)} \rightsquigarrow Q \) such that
\[
\sigma(\lambda)_B(x_\bullet) = \lambda_B(x_{\sigma(1)}, \ldots, x_{\sigma(d)}) \quad \text{for every } A \text{-algebra } B \text{ and every } x_\bullet \in (B \otimes_A M)^{\otimes d}.
\]
We obtain in this fashion a natural \( S_d \)-action on the functor \( \text{Pol}_A^d(M^{(d)}, -) \), which clearly translates as the permutation action on \( \Gamma_A^e(M^{(d)} \equiv \otimes^d(\Gamma_A^e M) \), as defined in (9.5.28). Now, obviously for every homogeneous polynomial law \( \lambda : M^{(d)} \rightsquigarrow Q \) and every \( \sigma \in S_d \) we have \( \sigma(\lambda)^{\otimes} = \lambda^{\otimes} \). This implies that (9.5.32) factors through an \( A \)-linear map:
\[
t^{d,e}_M : \Gamma_A^e M \to \text{TS}^d_A(\Gamma_A^e M) \quad \text{for every } e \in \mathbb{N} \text{ and every } d > 0.
\]
By corollary 9.5.22(v), the map \( t^{d,1}_M \) can be regarded as an \( A \)-linear map
\[
t^{d,1}_M : \Gamma_A^e M \to \text{TS}^d_A M
\]
and in view of lemma 9.5.29(i) and proposition 9.5.6 the corresponding homogeneous polynomial law \( \tau^d_M : M \rightsquigarrow \text{TS}^d_A M \) of degree \( d \) is characterized by the identities:
\[
(\tau^d_M)_B(x) = x \otimes \cdots \otimes x \in \text{TS}^d_A(B \otimes_A M) \quad \text{for every flat } A \text{-algebra } B \text{ and every } x \in B \otimes_A M.
Proposition 9.5.34. Let $e, d \in \mathbb{N}$ with $d > 0$, and $M$ a flat $A$-module.

(i) The map $t^d_{de} M$ is an isomorphism.

(ii) We have a commutative diagram:

$$
\begin{array}{ccc}
\Gamma^d e_M & \xrightarrow{t^d_{de}} & TS^d_A(\Gamma^e A) \\
\downarrow t^d_{de} & & \downarrow TS^d_A(t^d_{de}) \\
TS^d e_M & \xrightarrow{j} & TS^d_A(\Gamma^e A) \\
\end{array}
$$

where $j$ is the inclusion map (we identify $TS^d_A(\Gamma^e A)$ with $(\otimes^d e_M)^W$ as in lemma 9.5.29(iv)).

(iii) There exists a natural $A$-linear map $\alpha^{d,e}_{M}$ : $TS^d_A(\Gamma^e A) \rightarrow \Gamma^d e_M$ such that:

$$
\alpha^{d,e}_{M} \circ t^d_{de} = \frac{(de)!}{(e!)^d \cdot d!} \cdot 1_{\Gamma^d e_M}.
$$

Proof. (i): Since both $\Gamma^d e_M$ and $TS^d_A(\Gamma^e A)$ commute with filtered colimits of $A$-modules, Lazard’s theorem ([95, Ch. I, Th. 2]) reduces to the case where $M$ is free of finite rank $r$; fix a basis $e_1, \ldots, e_r$ of $M$. By (9.5.12) and a simple induction, we obtain a natural $A$-linear isomorphism:

$$
\otimes^d_A(M^r) \cong (\otimes^d_A(M))^r.
$$

For such $M$, the split inclusion map $TS^d_A M \rightarrow \otimes^d_A M$ induces a surjection

$$
(\otimes^d_A(M))^r \rightarrow (TS^d_A M)^r
$$

and taking into account remark 9.5.11(iii), it is easily seen that the composition of (9.5.35) and (9.5.36) factors through an $A$-linear surjection

$$
(\Gamma^d e_M)^r \rightarrow \text{Sym}_A^d(M^r) \rightarrow (TS^d_A M)^r.
$$

By lemma 9.5.29(ii), the $A$-modules $\text{Sym}_A^d(M^r)$ and $(TS^d_A M)^r$ are free of the same rank, so (9.5.37) is an isomorphism, and it suffices to check that the transpose of $t^d_M$ is an inverse of (9.5.37). However, set $B := \text{Sym}_A^d(M^r)$, and recall that $t^d_M$ is the image of $P(e^\ast) := (\tau^d_M)B(1_M) \in \text{Sym}_A^d(M^r) \otimes_A TS^d_A M$ under the natural identification:

$$
\text{Sym}_A^d(M^r) \otimes_A TS^d_A M \cong \text{Hom}_A(\text{Sym}_A^d(M^r), TS^d_A M).
$$

Set $T := \{1, \ldots, r\}^d$, and fix a set of representatives $\Delta$ for $S_d \setminus T$; we compute:

$$
P(e^\ast) = (\tau^d_M)B\left(\sum_{i=1}^{r} e^\ast_i \otimes e_i^\ast\right) = \sum_{i^\ast \in \Delta} e^\ast_{i^\ast} \otimes e_{i^\ast} = \sum_{i^\ast \in \Delta} e^\ast_{i^\ast} \otimes [e_{i^\ast}]
$$

where $([e_{i^\ast}])_{i^\ast \in \Delta}$ is the basis of $TS^d_A M$ exhibited in the proof of lemma 9.5.29(ii), and $e^\ast_{i^\ast} \in \text{Sym}_A^d(M^r)$ is defined as in remark 9.5.11(ii), for every $i^\ast \in \Delta$. Hence, $P(e^\ast)$ corresponds to the $A$-linear map $t^d_{de} : \text{Sym}_A^d(M^r) \rightarrow TS^d_A M$ such that $t^d_{de}(l) = \sum_{i^\ast \in \Delta} l(e_{i^\ast}) \cdot [e_{i^\ast}]$ for every $A$-linear form $l : \text{Sym}_A^d(M^r) \rightarrow A$. Consequently, $(t^d_M)^r : (TS^d_A M)^r \rightarrow \text{Sym}_A^d(M^r)$ is the map such that $(t^d_M)^r(l^r) = \sum_{i^\ast \in \Delta} l^r(e_{i^\ast}) \cdot e^\ast_{i^\ast}$ for every $A$-linear form $l^r : TS^d_A M \rightarrow A$. Lastly, let $([e_{i^\ast}]) = \text{be the dual of the basis ([e_{i^\ast}])_{i^\ast \in \Delta}}$; a simple inspection shows that (9.5.37) is given by the rule $e_{i^\ast}^\ast \mapsto [e_{i^\ast}^\ast]$ for every $i^\ast \in \Delta$, and on the other hand $(t^d_M)^r([e_{i^\ast}]) = e_{i^\ast}^\ast$ for every such $i^\ast$, as required.

(ii): It suffices to compare the corresponding homogeneous polynomial laws $M \sim \rightarrow TS^d_A(\Gamma^e A)$; which amounts to showing that $j \circ \tau^d_{de} = TS^e(t^d_M) \circ \tau^d_{de}$, where $\tau^d_{de} : M \sim \rightarrow TS^d_A(\Gamma^e A)$ is the homogeneous polynomial law corresponding to $t^d_M$. Then the assertion follows by inspecting the characterizations of $t^d_{de}$, $t^d_{de}$ and $t^e_M$ given in (9.5.31) and (9.5.33).
(iii): Let \( a^{d,e}_M : (\otimes A M)^W \to TS_A^d M \) be the A-linear map such that : \( x \mapsto \sum_{\sigma \in W \setminus S_d} \sigma(x) \) for every \( x \in (\otimes A M)^W \). It is easily seen that \( a^{d,e}_M \circ j = \frac{(de)!}{(e)!d!} \cdot 1_{TS_A^d M} \), where \( j : TS_A^d M \to (\otimes A M)^W \) is the inclusion map. By virtue of lemma 9.5.29(iv), the maps \( TS_A^d (e_M) \) and \( e^{d,e}_M \) identify \( a^{d,e}_M \) with an A-linear map \( \alpha^{d,e}_M : TS_A (\Gamma_A M) \to \Gamma_A^d M \), and the sought identity follows directly from (ii).

### 9.5.38

Let \( M \) and \( M' \) be two sequences of A-modules, of the same length \( k \). We set

\[ M \otimes_A M' := (M_1 \otimes_A M'_1, \ldots, M_k \otimes_A M'_k) \]

For every \( d \in \mathbb{N}^k \) we have a natural transformation of functors

\[ \text{Pol}^d_A (M \otimes_A M', Q) \to \text{Pol}^d_A ((M, M'), Q) \quad \text{for every } A \text{-module } Q \]

that assigns to every homogeneous polynomial law \( \lambda : M \otimes_A M' \hookrightarrow Q \) of degree \( d \) the law \( \lambda_T : (M, M') \hookrightarrow Q \) given by the rule:

\[ \lambda_T^B (m_\bullet, m'_\bullet) := \lambda_B (m_1 \otimes m'_1, \ldots, m_k \otimes m'_k) \]

for every A-algebra \( B \) and every \( (m_\bullet, m'_\bullet) \in F_{M \otimes M'}(B) \). This natural transformation must come from a map of A-modules \( \Gamma_A^d (M \otimes M') \to \Gamma_A^d (M \otimes M') \) which, by virtue of corollary 9.5.22(ii), is the same as a map natural in both \( M \) and \( M' \):

\[ \varphi^d_{M, M'} : \Gamma_A^d (M) \otimes_A \Gamma_A^d (M') \to \Gamma_A^d (M \otimes M'). \]

### Remark 9.5.39

(i) By direct inspection, we see that the map \( B \otimes_A \varphi^d_{M, M'} \) is identified with \( \varphi^d_{B \otimes A M, B \otimes A M'} \) for every A-algebra \( B \), under the natural isomorphisms (9.5.21).

(ii) Under the identifications of (i), the map \( \varphi^d_{M, M'} \) is characterized as the unique A-linear map such that

\[ (\lambda_T^B (m) \otimes (\lambda_T^B (m'))) B (m) \otimes (\lambda_T^B (m'))) B (m') \mapsto (\lambda_T^B (m \otimes m')) B (m \otimes m') \]

for every A-algebras \( B \), every \( m \in B \otimes_A (M_1 \times \cdots \times M_k) \) and every \( m' \in B \otimes_A (M'_1 \times \cdots \times M'_k) \).

### 9.5.40

Let \( M \) and \( M' \) be two sequences of A-modules, of the same length \( k \), and \( e, e' \) two degrees of length \( k \). If \( \lambda : (M, M') \hookrightarrow Q \) is any homogeneous law of degree \( (e, e') \), then we can also regard \( \lambda \) as a homogeneous multipolynomial law of degree \( e + e' \) on the sequence \( M \oplus M' \) of length \( k \). In this way, we obtain a natural mapping

\[ \text{Pol}^e_A ((M, M'), Q) \to \text{Pol}^{e+e'}_A (M \oplus M', Q) \quad \text{for every } A \text{-module } Q \]

which, by transposition, corresponds to a unique A-linear map

\[ \Gamma_A^{e+e'} (M \oplus M') \to \Gamma_A^{e+e'} (M, M'). \]

Fix \( d \in \mathbb{N}^k \); in view of corollary 9.5.22(ii), we see that the sum of the maps (9.5.42) for all pairs \((e, e')\) with \( e + e' = d \), is a well defined A-linear map

\[ \Delta^d_{M, M'} := \bigoplus_{e+e'=d} \Delta^{e+e'}_{M, M'} : \Gamma_A^d (M \oplus M') \to \bigoplus_{e+e'=d} \Gamma_A^e (M) \otimes_A \Gamma_A^{e'} (M'). \]

### Proposition 9.5.43

The map \( \Delta^d_{M, M'} \) is an isomorphism, for every \( M, M' \), and every degree \( d \).

**Proof.** Arguing as in the proof of corollary 9.5.22(ii), we are easily reduced to the case where \( M \) and \( M' \) are sequences of free A-modules of finite rank. In this case, (9.5.42) can be computed as in remark 9.5.27(i); namely, it corresponds to the element

\[ P \in \text{Sym}^{e+e'}_A ((M \oplus M')^\vee) \otimes_A \text{Sym}^{e+e'}_A (M^\vee, M'^\vee)^\vee \]
determined as follows. Take \( Q := \Gamma^e_{\mathcal{M}, M'}(M, M') \), and let \( \lambda : M \oplus M' \to \Gamma^e_{\mathcal{M}}(M, M') \) be the image of \( \lambda^\mathcal{M}_{\mathcal{M}, M'} \) under (9.5.41). To ease notation, for every sequence \( N \) of \( A \)-modules, let \( S(N) := \text{Sym}_A(N) \); then
\[
P = \lambda_{S(M \oplus M')}(1_{M_1 \oplus M'_1}, \ldots, 1_{M_k \oplus M'_k}).
\]
Thus, we come down to evaluating the image of \( 1_{M_i \oplus M'_i} \) under the natural identification
\[
(M_i \oplus M'_i) \otimes_A S(M_i \oplus M'_i) \cong (M_i \otimes_A S(M_i \oplus M'_i)) \times (M'_i \otimes_A S(M_i \oplus M'_i)).
\]
for every \( i = 1, \ldots, k \). We easily find that \( 1_{M_i \oplus M'_i} \mapsto (p_i, p'_i) \) under this identification, where \( p_i : M_i \oplus M'_i \to M_i \) and \( p'_i : M_i \oplus M'_i \to M'_i \) are the natural projections; so finally
\[
P = (\lambda_{M \oplus M'}^e S(M \oplus M'))(p_1, \ldots, p_k, p'_1, \ldots, p'_k).
\]
Pick a basis \((e_{i1}, \ldots, e_{ir_i})\) (resp. \((e'_{i1}, \ldots, e'_{ir'_i})\)) for each \( M_i \) (resp. \( M'_i \)), let \((e^*_{i1}, \ldots, e^*_{ir_i})\) (resp. \((e'^*_{i1}, \ldots, e'^*_{ir'_i})\)) be the dual basis, and for every \( i = 1, \ldots, k \) and every \( j = 1, \ldots, r_i \) (resp. \( j = 1, \ldots, r'_i \)) denote by \( \varepsilon_{ij} \) (resp. \( \varepsilon'_{ij} \)) the element of \((M_i \oplus M'_i)^\vee\) that agrees with \( e^*_{ij} \) on \( M_i \) and that vanishes on \( M'_i \) (resp. that agrees with \( e'^*_{ij} \) on \( M'_i \) and vanishes on \( M_i \)). Notice that
\[
p_i = \sum_{j=1}^{r_i} \varepsilon^*_{ij} \otimes e_{ij} \quad p'_i = \sum_{j=1}^{r'_i} \varepsilon'^*_{ij} \otimes e'_{ij}
\]
for every \( i = 1, \ldots, k \).

With this notation, it follows that the right-hand side of (9.5.44) is the image of
\[
(\lambda_{M \oplus M'}^e S(M \oplus M'))(1_{M_1}, \ldots, 1_{M_k}, 1_{M'_1}, \ldots, 1_{M'_k}) = 1_{\text{Sym}_A^e(M \oplus M')}
\]
under the natural map
\[
S(M, M') \to S(M \oplus M') : e_{ij} \mapsto \varepsilon^*_{ij} \quad e'_{ij} \mapsto \varepsilon'^*_{ij}.
\]
In other words, the sought \( P \) is none else than the restriction of (9.5.45) to the direct factor \( \text{Sym}_A^e(M \oplus M') \), and this restriction is an isomorphism onto a direct factor of the \( A \)-module \( \text{Sym}_A^e(M \oplus M') \). By transposition, we see that (9.5.42) is identified with the projection onto a natural direct factor of \( \Gamma^e_{\mathcal{M}}(M \oplus M') \), and a simple inspection shows that the sum of all these projections is the identity map of the latter \( A \)-module, whence the proposition. \( \square \)

**Remark 9.5.46.** (i) Let \( M, M' \), \( Q \) and \( \lambda \) be as in (9.5.40). The image of \( \lambda \) under (9.5.41) is characterized as the unique law \( \varphi : M \oplus M' \to Q \) of degree \( e + e' \) such that \( \varphi(m, m') = \lambda_B(m, m') \) for every \( A \)-algebra \( B \) and every \( (m, m') \in B \otimes_A (M \oplus M') \). In turns, \( \varphi \) corresponds to the unique \( A \)-linear map \( f : \Gamma^e_{\mathcal{M}}(M \oplus M') \to Q \) such that \( (B \otimes_A f)(\lambda^e_{\mathcal{M}, B}(m, m')) = \lambda_B(m, m') \) for every \( B \) and \( (m, m') \) as above. Especially, if we take \( \lambda := \lambda^e_{\mathcal{M}, B} \), we see that (9.5.42) is characterized as the unique \( A \)-linear map such that
\[
(\lambda^e_{\mathcal{M}, B}^e)(B(m, m') \mapsto (\lambda^e_{\mathcal{M}})(B)(m, m')
\]
for every \( B \) and \( (m, m') \) as above. Lastly, it follows that \( \Delta^e_{\mathcal{M}, B} \) is characterized as the unique \( A \)-linear map such that
\[
(\lambda^e_{\mathcal{M}, B})(B)(m, m') \mapsto (\lambda^e_{\mathcal{M}})(B)(m) \otimes (\lambda^e_{\mathcal{M}})(B)(m')
\]
for every \( A \)-algebra \( B \) and every \( (m, m') \in B \otimes_A (M \oplus M') \).

(ii) In the same vein, let \( f : M \to N \) be any morphism in \((A\text{-Mod})^k \), and \( d \in \mathbb{N}^k \) any degree. Then we see that the induced map
\[
\Gamma^d_{\mathcal{M}}(f) : \Gamma^e_{\mathcal{M}}(M) \to \Gamma^d_{\mathcal{M}}(N)
\]
is characterized as the unique \( A \)-linear map such that
\[
(\lambda^d_M)_B(m) \mapsto (\lambda^{d'}_M)_B(f(m))
\]
for every \( A \)-algebra \( B \), and every \( m \in B \otimes_A M \) (details left to the reader).

9.5.47. Let \( M, M', M'' \) be three sequences of \( A \)-modules of length \( k \), and \( d, d', d'' \) three degrees, also of lengths \( k \). We obtain a diagram of \( A \)-linear maps:

\[
\begin{array}{c}
\Gamma_A^{\circ}e+e''(M \oplus M' \oplus M'') \arrow[dd]_{\Delta^e_{M, M', M''}} \rightarrow \Gamma_A^{e}(M) \otimes_A \Gamma_A^{e''}(M') \otimes_A \Gamma_A^{e''}(M'') \\
| \downarrow_{\Delta^e_{M, M', M''}} \\
\Gamma_A^{e'}(M) \otimes A \Gamma_A^{e''}(M') \otimes A \Gamma_A^{e''}(M'') \arrow[rr] \rightarrow \Gamma_A^{e'}(M) \otimes A \Gamma_A^{e''}(M') \otimes A \Gamma_A^{e''}(M'').
\end{array}
\]

**Proposition 9.5.48.** The diagram of (9.5.47) commutes.

**Proof.** By remark 9.5.46(i), the map \( \Delta^e_{M, M', M''} \) is characterized as the unique one such that
\[
(\lambda^e_{M, M', M''})_B(m, m', m'') \mapsto (\lambda^e_M)_B(m) \otimes (\lambda^{e'}_{M'})_B(m') \otimes (\lambda^{e''}_{M''})_B(m'')
\]
for every \( A \)-algebra \( B \) and every \( (m, m', m'') \in B \otimes_A (M \oplus M' \oplus M'') \), and \( \Delta^e_{M, M', M''} \) is the unique \( A \)-linear map such that
\[
(\lambda^e_{M, M', M''})_B(m', m'') \mapsto (\lambda^e_{M'})_B(m') \otimes (\lambda^{e''}_{M''})_B(m'')
\]
for every \( A \)-algebra \( B \) and every \( (m', m'') \in B \otimes_A (M' \oplus M'') \). Therefore, the composition of the top horizontal and right vertical arrows in the diagram is the unique \( A \)-linear map such that
\[
(\lambda^e_{M, M', M''})_B(m, m', m'') \mapsto (\lambda^e_M)_B(m) \otimes (\lambda^{e'}_{M'})_B(m') \otimes (\lambda^{e''}_{M''})_B(m'')
\]
for every \( B \) and \( (m, m', m'') \) as above. The same calculation can be carried out for the composition of the other two arrows, and clearly one obtains the same result. \( \square \)

9.5.49. Let \( M \) be any sequence of \( A \)-modules of length \( k \), and denote by \( s : M \oplus M \rightarrow M \) the addition map : \( (m, m') \mapsto m + m' \) for every \( m, m' \in M \). By proposition 9.5.43 we have a unique system of \( A \)-linear maps
\[
\mu^e_{M} : \Gamma_A^e(M) \otimes_A \Gamma_A^{e'}(M) \rightarrow \Gamma_A^{e+e'}(M) \quad \text{for every } e, e' \in \mathbb{N}^{\leq k}
\]
such that, for every \( d \in \mathbb{N}^{\leq k} \), the resulting diagram :

\[
\begin{array}{c}
\Gamma_A^d(M) \otimes \Delta^e_{M, M''} \rightarrow \bigoplus_{e+e'=d} \Gamma_A^e(M) \otimes \Gamma_A^{e'}(M) \\
| \downarrow_{\Theta_{e+e'=d} \mu^e_{M}} \\
\Gamma_A^d(M)
\end{array}
\]
commutes. Consider now, for every $e, e', e'' \in \mathbb{N}^{\oplus k}$ the diagram of $A$-linear maps:

\[
\begin{array}{c}
\Gamma^d_A(M^{\oplus 3}) \xrightarrow{\Delta^d_M \otimes \Delta^d_M} \bigoplus \Gamma^d_A(M^{\oplus 2}) \otimes_A \Gamma^{e''}_M \\
\Gamma^d_A(M^{\oplus 2}) \xrightarrow{\Delta^d_M \otimes \Delta^d_M} \bigoplus \Gamma^d_A(M \otimes_A \Gamma^{e''}_M) \\
\Gamma^d_A(M) \xrightarrow{\Delta^d_M} \Gamma^d_A(M)
\end{array}
\]

whose top left square subdiagram commutes by naturality of $\Delta^d$, and whose other three square subdiagrams commute by definition. We also have a similar diagram, whose two top horizontal arrows are $\Delta^d_{M^{\oplus 2}}$ and $\bigoplus_{e+e''=d} \Gamma^{e, e''}_A M \otimes_A \Delta^d_{M^{\oplus 2}}$, and whose two left (resp. right) vertical arrows are $\Gamma^d_A(1_M \oplus s)$ and $\Gamma^d_A(s)$ (resp. $\bigoplus_{e+e''=d} \Gamma^{e, e''}_A M \otimes_A \mu^{e, e''}_M$ and $\bigoplus_{e+e''=d} \mu^{e, e''}_M$). On the other hand, clearly $s \circ (s \oplus 1_M) = s \circ (1_M \oplus s)$; combining with proposition \[9.5.48\] we finally conclude that the diagram

\[
\begin{array}{c}
\Gamma^e_A(M) \otimes_A \Gamma^{e'}_A(M) \otimes_A \Gamma^{e''}_A(M) \xrightarrow{\mu^{e, e', e''}_M \otimes_A \mu^{e, e', e''}_M} \Gamma^{e+e', e''}_A(M) \otimes_A \Gamma^{e+e', e''}_A(M) \\
\Gamma^e_A(M) \otimes_A \Gamma^{e'}_A(M) \otimes_A \Gamma^{e''}_A(M) \xrightarrow{\mu^{e, e', e''}_M} \Gamma^{e+e', e''}_A(M) \otimes_A \Gamma^{e+e', e''}_A(M)
\end{array}
\]

commutes, for every $e, e', e'' \in \mathbb{N}^{\oplus k}$. The foregoing shows that the maps $\mu^{e, e', e''}_M$ define on

\[\Gamma^*_A(M) := \bigoplus_{d \in \mathbb{N}^{\oplus k}} \Gamma^d_A(M),\]

a natural structure of associative $\mathbb{N}^{\oplus k}$-graded $A$-algebra. We call $\Gamma^*_A(M)$ the divided power envelope of $M$. Moreover, let $\sigma : M \oplus M \to M \oplus M$ be the map such that $\sigma(m, m') := (m', m)$ for all $m, m' \in M$; remark \[9.5.46(i)\] yields a commutative diagram:

\[
\begin{array}{c}
\Gamma^{e+e'}_A(M \oplus M) \xrightarrow{\Delta^{e+e'}_M} \Gamma^e_A(M) \otimes_A \Gamma^{e'}_A(M) \\
\Gamma^{e+e'}_A(M \oplus M) \xrightarrow{\Delta^{e+e'}_M} \Gamma^e_A(M) \otimes_A \Gamma^{e'}_A(M)
\end{array}
\]

for every $e, e' \in \mathbb{N}^{\oplus k}$, where $\omega^{e, e'}_M$ is the isomorphism that swaps the two tensor factors. Since obviously $s \circ \sigma = s$, it follows easily that:

\[\mu^{e, e', e'}_M \circ \omega^{e, e'}_M = \mu^{e, e', e'}_M\]

for every $e, e' \in \mathbb{N}^{\oplus k}$ which means that the algebra $\Gamma^*_A(M)$ is commutative. It is customary to use the notation

\[m[d] := (\lambda^d_M)_B(m) \in B \otimes_A M\]
for every $A$-algebra $B$, every $m \in B \otimes_A M$, and every $d \in \mathbb{N}^{\oplus k}$. With this notation, the commutativity of (9.5.50) amounts to the identity

$$\sum_{e \leq \epsilon = d} a^{|\epsilon|} \cdot b^{e}$$

for every $A$-algebra $B$, every $a, b \in B \otimes_A M$, and every $d \in \mathbb{N}^{\oplus k}$. Clearly, the above construction yields a well defined functor

$$(A-\text{Mod})^k \rightarrow A-\text{Alg} : M \mapsto \Gamma^*_A(M)$$

and notice that, for every morphism $f : M \rightarrow N$ of sequences, we have

$$(\Gamma^*_A f)(a^{|\epsilon|}) = (fa)^{|\epsilon|} = (\Gamma^*_A f(a))^{|\epsilon|}$$

for every $d$, every $A$-algebra $B$, and every $a \in B \otimes_A M$.

**Theorem 9.5.53.** With the notation of (9.5.49), we have :

1. For every $A$-algebra $B$, there exists a natural isomorphism of $\mathbb{N}^{\oplus k}$-graded algebras :
   $$B \otimes_A \Gamma^*_A(M) \cong \Gamma^*_{B}(B \otimes_A M)$$

2. The functor (9.5.52) commutes with filtered colimits.

3. For any two sequences of $A$-modules $M$ and $M'$ of the same length $k$, there exists a natural isomorphism of $\mathbb{N}^{\oplus k}$-graded $A$-algebras :
   $$\Gamma^*_A(M \oplus M') \cong \Gamma^*_A(M) \otimes_A \Gamma^*_A(M')$$
   (with the $\mathbb{N}^{\oplus k}$-grading of the tensor product defined in the obvious way).

**Proof.** (i) and (ii) follow immediately from the natural isomorphisms (9.5.21) and corollary 9.5.22(i), and (iii) follows directly from proposition 9.5.43.

9.5.54. Consider the special case of a sequence $M$ consisting of a single $A$-module $M$. From (9.5.51), by evaluating the expression $(2m)^{|d|} = 2^d \cdot m^{|d|}$, a simple induction on $d$ shows that

$$d! \cdot m^{|d|} = m^d \quad \text{in} \ \Gamma^*_A(M), \text{for every} \ m \in M.$$  

**Corollary 9.5.56.** In the situation of (9.5.54), we have in $\Gamma^*_A(M)$ the identity :

$$m^{|i|} \cdot m^{|j|} = \binom{i+j}{i} \cdot m^{|i+j|} \quad \text{for every} \ m \in M \text{ and every} \ i, j \in \mathbb{N}. $$

**Proof.** By considering the $A$-linear map $f : A \rightarrow M$ such that $f(1) = m$, we reduce to the case where $M = A$ and $m = 1$. By considering the unique ring homomorphism $\mathbb{Z} \rightarrow A$ we reduce further – in light of theorem 9.5.53(i) – to the case where $A = M = \mathbb{Z}$. However, $\Gamma^*_A(\mathbb{Z})$ is a torsion-free $\mathbb{Z}$-module, by lemma 9.5.9, so the identity follows easily from (9.5.55).

**Corollary 9.5.57.** Let $M$ be an $A$-module, and $N \subset M$ any submodule. The induced map

$$\Gamma^*_A M \rightarrow \Gamma^*_A(M/N)$$

is surjection of $A$-algebras, with kernel generated by the image of $\Gamma^*_A N := \bigoplus_{d > 0} \Gamma^d_A N$.

**Proof.** From corollary 9.5.22(iv) we get an isomorphism of $A$-algebras

$$\text{Coequal}(\Gamma^*_A(j_1), \Gamma^*_A(j_2) : \Gamma^*_A(M \times_{M/N} M) \xrightarrow{\sim} \Gamma^*_A(M)) \rightarrow \Gamma^*_A(M/N)$$

where $j_1, j_2 : M \times_{M/N} M \rightarrow M$ are the natural maps. However, the isomorphism of $A$-modules $M \otimes N \xrightarrow{\sim} M \times_{M/N} M : (x, y) \mapsto x + y$ identifies $j_1$ (resp. $j_2$) with the map $M \otimes N \rightarrow M$ such that $(x, y) \mapsto x + y$ (resp. $(x, y) \mapsto x$). Let also $i_1 : M \rightarrow M \oplus N$ and $i_2 : N \rightarrow M \oplus N$ be the inclusion maps to the first and respectively second direct summand, so that $j_2 \circ i_1 = j_1 \circ i_1 = 1_M$, $j_2 \circ i_2 = 0$, and $l := j_1 \circ i_2 : N \rightarrow M$ is the inclusion map. Now, by direct inspection we
see that $\Gamma^d_A(i_1)$ maps $\Gamma^d_A M$ to the direct summand $\Gamma^d_A M \otimes_A \Gamma^0_A N \to \Gamma^{(d,0)}_A (M, N)$, for every $d \in \mathbb{N}$, and the resulting map $\Gamma^d_A M \to \Gamma^{(d,0)}_A (M, N)$ is characterized as the unique such that $x[0] \mapsto (x, 0)[0]$ for every $A$-algebra $B$ and every $x \in B \otimes_A M$. On the other hand, by construction we have $(x, y)[0] = [x[0] \otimes 1]$ for every $A$-algebra $B$ and every $(x, y) \in B \otimes_A (M \oplus N)$, under the natural identification $B \otimes_A \Gamma^0_A N \to B$ (corollary 9.5.22 vii) and remark 9.5.46 vii). Likewise we may characterize $\Gamma^d_A(i_2)$ for every $d \in \mathbb{N}$; hence, $\Gamma^d_A(i_1)$ and $\Gamma^d_A(i_2)$ are the maps of $A$-algebras:

$$
\Gamma^d_A M \to \Gamma^d_A M \otimes_A \Gamma^0_A N \quad x \mapsto x \otimes 1.
$$

Thus, let $d \in \mathbb{N}$ and $z \in \Gamma^d_A(M \oplus N)$, and write $z = \sum_{i=0}^d x_i \otimes y_{d-i}$ with $x_i \in \Gamma^i_A M$ and $y_i \in \Gamma^0_A N$ for $i = 0, \ldots, d$. It follows that

$$
\Gamma^d_A(j_1)(z) = \sum_{i=0}^d x_i \cdot \Gamma^d_A(l)(y_{d-i})
$$

and

$$
\Gamma^d_A(j_2)(z) = x_d \cdot \Gamma^0_A(l)(y_0)
$$

so finally, the kernel of the projection onto $\Gamma^d_A(M/N)$ is the $A$-module generated by all products $x \cdot \Gamma^i_A(l)(y)$, for every $i \in \mathbb{N}$, every $j \in \mathbb{N} \setminus \{0\}$, every $x \in \Gamma^i_A M$ and every $y \in \Gamma^j_A N$.

9.5.58. For every $d, e \in \mathbb{N}$ with $d > 0$, we have a natural triangle of $A$-linear maps:

$$
\begin{array}{ccc}
\Gamma^d_A M & \xrightarrow{\gamma^d_{M,e}} & TS^d_A(\Gamma^e_A M) \\
\downarrow \gamma^d_{M,e} & & \downarrow \beta^d_{M,e} \\
\text{Sym}^d_A(\Gamma^e_A M) & & \\
\end{array}
$$

for every $A$-module $M$.

where $\beta^d_{M,e}$ is the restriction of the projection $\otimes^d_A(\Gamma^e_A M) \to \text{Sym}^d_A(\Gamma^e_A M)$, the map $\gamma^d_{M,e}$ is induced by the multiplication map of the $A$-algebra $\Gamma^e_A M$, and $t^d_{M,e}$ is defined as in (9.5.33).

Remark 9.5.59. If $e = 1$, the diagram of (9.5.58) becomes the triangle of $A$-linear maps:

$$
\begin{array}{ccc}
\Gamma^d_A M & \xrightarrow{t^d_{M}} & TS^d_A M \\
\downarrow \gamma^d_{M} & & \downarrow \beta^d_{M} \\
\text{Sym}^d_A M & & \\
\end{array}
$$

where $t^d_{M}$ and $\beta^d_{M}$ are defined as in (9.5.33) and (9.5.28), and with $\gamma^d_{M} := \gamma^d_{M,1}$.

Proposition 9.5.60. (i) With the notation of (9.5.58), we have:

$$
\gamma^d_{M,e} \circ \beta^d_{M,e} \circ t^d_{M} = \frac{(de)!}{(e!)^d} \cdot 1_{\Gamma^d_A M}.
$$

(ii) If $M$ is a flat $A$-module, let $\alpha^d_{M,e}$ be the map of proposition 9.5.34 iii; we have:

$$
\gamma^d_{M,e} \circ \beta^d_{M,e} = d! \cdot \alpha^d_{M,e}.
$$

(iii) Define the map $\alpha^d_{M}$ as in (9.5.28); with the notation of remark 9.5.59 we have:

$$
\gamma^d_{M} \circ \beta^d_{M} \circ t^d_{M} = d! \cdot 1_{\Gamma^d_A M},
$$

and

$$
\alpha^d_{M} = \gamma^d_{M} \circ \beta^d_{M} \circ t^d_{M} = d! \cdot 1_{\text{Sym}^d_A M}.
$$

Proof. (i): It suffices to check that the homogeneous polynomial law $M \leadsto \Gamma^d_A M$ corresponding to $\gamma^d_{M,e} \circ \beta^d_{M,e} \circ t^d_{M}$ equals $\frac{(de)!}{(e!)^d} \cdot \lambda^d_{M,e}$, i.e. that for every $A$-algebra $B$ we have:

$$
\gamma^d_{M,e} \circ \beta^d_{M,e} \circ t^d_{M}((\lambda^d_{M,e} B)(m)) = \frac{(de)!}{(e!)^d} \cdot (\lambda^d_{M,e} B)(m)
$$

for every $m \in B \otimes_A M$. 

By proposition 9.5.6 it even suffices to check the above identity for all flat A-algebras B; then, by considering the A-linear map $A \to M$ such that $1 \mapsto m$, and by invoking the naturality of the maps of (9.5.58), and their compatibility with the flat base change $A \to B$ (9.5.21) and lemma 9.5.29 (i)) we are then reduced to the case where $M = A = B$ and $m = 1$. However, recall that if M is a flat A-module, the isomorphisms $t_M^e$ and $t_M^e$ identify $t_M^e$ with the inclusion map $\text{TS}_A^e M \to (\otimes_A^e M)^W$ (where $W \subset S_d$ is the subgroup $(S_d)^e \times S_r$), and $\beta_{M}^{d,e}$ with the restriction $\text{TS}_A^d (\text{TS}_A^e M) \to \text{Sym}^d_A (\text{TS}_A^e M)$ of the projection map $\otimes^d_A (\text{TS}_A^e M) \to \text{Sym}^d_A (\text{TS}_A^e M)$ (proposition 9.5.34); hence, we are reduced to checking that:

\[(9.5.61) \quad t_M^e \circ \gamma_M^{d,e} \circ \text{Sym}^d_A (t_M^e)^{-1} (1 \otimes \cdots \otimes 1) = \frac{(de)!}{(e!)^d} (1 \otimes \cdots \otimes 1).\]

Now, let $M$ be more generally a free $A$-module of rank $r$, fix a basis $e_1, \ldots, e_r$ of $M$, and let $\epsilon_1^*, \ldots, \epsilon_r^*$ be the dual basis. Let also $p_1, p_2 : M \oplus M \to M$ be the two projections, and set $\epsilon_{j,i} := \epsilon_i^* \circ p_j : M \oplus M \to A$ for $j = 1, 2$ and $i = 1, \ldots, r$. Moreover, set:

\[l(i_\bullet) := k \quad \text{for every } k \in \mathbb{N} \text{ and every } i_\bullet \in T_k := \{1, \ldots, r\}^k.\]

Let $\epsilon_{j,i}^* \in \text{Sym}^1_A (M^\vee)$ be the class of $\epsilon_{i_1}^* \otimes \cdots \otimes \epsilon_{i_j}^*$, for every $i_\bullet \in T_k$, and define likewise $\epsilon_{[j,i]}^* \in \text{Sym}^2_A ((M \oplus M)^\vee)$ for $j = 1, 2$. Notice that $\text{Sym}^d_A ((M \oplus M)^\vee)$ admits the basis:

\[(\epsilon_{[1,i]}^* \otimes \epsilon_{[2,j]}^*) \mid l(i_\bullet) + l(j_\bullet) = d \quad \text{for every } d \in \mathbb{N}.\]

The proof of proposition 9.5.43 identifies $\Delta_{M,M}^{k,k'} : \Gamma^k_A (M \oplus M) \to \Gamma_{A}^{k,k'} (M, M)$ with the transpose of the $A$-linear map

\[\text{Sym}^1_A (M^\vee, M^\vee) \to \text{Sym}^1_A (M^\vee, M^\vee) \quad \epsilon_{j,i}^* \otimes \epsilon_{j,i}^* \mapsto \epsilon_{[1,i]}^* \otimes \epsilon_{[2,j]}^*\]

for every $k, k' \in \mathbb{N}$. Furthermore, for every $d \in \mathbb{N}$ choose a set of representatives $\Delta_d$ for the quotient $S_d \backslash T_d$, define the basis $\{[\epsilon_{i}] \mid i_\bullet \in \Delta_d\}$ of $\text{TS}_A^d M$ as in the proof of lemma 9.5.29 (ii), and let $\{[\epsilon_{i}]^* \mid i_\bullet \in \Delta_d\}$ be its dual basis. The proof of proposition 9.5.34 shows that the transpose of $t_M^d$ is the $A$-linear map

\[(\text{TS}_A^d M)^\vee \cong \text{Sym}^d_A (M^\vee) \quad [\epsilon_{i}]^* \mapsto \epsilon_{i}^*\quad \text{for every } i_\bullet \in \Delta_d.\]

Notice as well that $([\epsilon_{i}]^*, [\epsilon_{j}]^*) \mid i = 1, \ldots, r\}$ is a basis of $(M \oplus M)^\vee$, and let $([\epsilon_1, i], [\epsilon_2, j] \mid i = 1, \ldots, r\}$ be the dual basis of $M \oplus M$; for every $d \in \mathbb{N}$ and every $\alpha_\bullet \in T_d := \{1, 2\} \times \{1, \ldots, r\}^d$ we set $\epsilon_{\alpha_\bullet} := \epsilon_{\alpha_1} \otimes \cdots \otimes \epsilon_{\alpha_d} \in \otimes^d_A (M \oplus M)$. Then, for every $k, k' \in \mathbb{N}$ with $d = k + k'$, and every pair of sequences $i_\bullet, j_\bullet \in T_k, j_\bullet \in T_{k'}$, let $\langle i_\bullet, j_\bullet \rangle \in T_d$ be the sequence $((1, i_1), \ldots, (1, i_k), (2, j_1), \ldots, (2, j_{k'}))$; we may choose a set of representatives $\Delta_d'$ for the quotient $S_d \backslash T_d'$ consisting of sequences of this form, and we obtain as in the proof of lemma 9.5.29 (ii), a basis $\{[\epsilon_{\langle i_\bullet, j_\bullet \rangle}] \mid \langle i_\bullet, j_\bullet \rangle \in \Delta_d\}$ of $\text{TS}_A^d (M \oplus M)$. Summing up, we conclude that the isomorphisms $t_M^d, t_M^k$ and $t_M^k$ identify $\Delta_{M,M}^{k,k'}$ with the $A$-linear map

\[\text{TS}_A^d (M \oplus M) \to \text{TS}_A^d (M \oplus M) \quad [\epsilon_{\langle i_\bullet, j_\bullet \rangle}] \mapsto \begin{cases} [\epsilon_{i_\bullet}] \otimes [\epsilon_{j_\bullet}] & \text{if } l(i_\bullet) = k \\ 0 & \text{otherwise.} \end{cases}\]

Next, let $s : M \oplus M \to M$ be the addition map; by naturality of the maps $t_M^d$, we get a commutative diagram:

$$
\begin{array}{ccc}
\Gamma^d_A (M \oplus M) & \xrightarrow{\epsilon_M^d} & \text{TS}_A^d (M \oplus M) \\
\gamma_M^d (\cdot) & \downarrow & \downarrow \text{TS}_A^d (s) \quad \otimes_A^d (\cdot) \\
\Gamma^d_A M & \xrightarrow{\epsilon_M^d} & \text{TS}_A^d M \\
\end{array}
$$
whose unlabeled horizontal arrows are the inclusion maps. It is easily seen that \( \otimes^d_A(s) \) is given by the rule : 
\[ \varepsilon_{(i_1, j_1, \ldots, i_d, j_d)} \mapsto e_{(i_1, j_1, \ldots, i_d, j_d)} \] for every \( (i_1, j_1, \ldots, i_d, j_d) \in T'^d_d \), with \( (i_k, j_k) := (i_1, \ldots, i_k, j_1, \ldots, j_d) \) (where \( k := \ell(i_k) \) and \( k' := \ell(j_k) \)). Then, for every \( k \in \mathbb{N} \) and every sequence \( i_* \in T_k \), set

\[ X(i_*, u) := \{ t \in \{ 1, \ldots, k \} | i_t = u \} \quad \text{for every } u = 1, \ldots, r. \]

Let \( N_u(i_*) \) be the cardinality of \( X(i_*, u) \), and for every \( i_* \in T_k \) and \( j_* \in T_{k'} \), define

\[ C(i_*, j_*) := \prod_{u=1}^r \left( \frac{N_u(i_*) + N_u(j_*)}{N_u(i_*)} \right). \]

A direct calculation that we leave to the reader then shows that \( TS_A^d(s) \) is given by the rule :

\[ [\varepsilon_{(i_1, j_1)}] \mapsto C(i_*, j_*) \cdot [e_{(i_1, j_1)}] \quad \text{for every } (i_*, j_*) \in \Delta^d_d. \]

In view of the foregoing, we deduce that the isomorphisms \( t^d_M, t^k_M \) and \( t^d_{M'} \) identify the map \( \mu^d_{M'} \) of (9.5.49) with the map

\[ \text{TS}_A^d M \otimes_A \text{TS}_A^d M \to \text{TS}_A^{d^2} M \quad \text{such that } \quad [e_{i_*}] \otimes [e_{j_*}] \mapsto C(i_*, j_*) \cdot [e_{(i_1, j_1)}] \]

for every \( i_* \in \Delta_k \) and \( j_* \in \Delta_{k'} \). Notice also that

\[ N_u(i_*) + N_u(j_*) = N_u(i_*, j_*) \quad \text{for every } u = 1, \ldots, r. \]

Hence, for every \( d, e \in \mathbb{N} \) with \( d \geq 2 \), let \( i_1, \ldots, i_d, c_* \in T_e \), and set

\[ \left( \begin{array}{c} a \\ b_1, \ldots, b_d \end{array} \right) := \frac{a!}{b_1! \cdots b_d!} \quad \text{for every } a, b_1, \ldots, b_d \in \mathbb{N}. \]

Define also inductively the sequence \( (i_1, \ldots, i_k, c_*) \in T_{ke} \) for every \( k = 2, \ldots, d \) as follows. For \( k = 2 \) it is already defined; for \( k > 2 \), we set \( (i_1, \ldots, i_k, c_*) := ((i_1, \ldots, i_{k-1}, c_*), i_k, c_*) \). With this notation, we conclude that the map \( t^d_M \circ \beta^d_M \circ \text{Sym}^d_M \) is given by the rule :

\[ (\otimes^d_A M)^W \cong \text{TS}_A^d(\text{TS}_A^d M) \to \text{Sym}^d_A(\text{TS}_A^d M). \]

Now, fix again a basis \( e_1, \ldots, e_r \) of \( M \); for every \( i_* := (i_1, \ldots, i_d, c_*) \in T_e^d = T_{de} \), let \( W(i_*) \) be the orbit of \( i_* \) under the natural \( W \)-action on \( T_{de} \), and set

\[ [e_{i_*}] : = \sum_{j_* \in W(i_*)} e_{j_*} \]

(\where, as usual, \( e_{j_*} := e_{j_1,1} \otimes \cdots \otimes e_{j_d,e} \in \otimes^d_A M \) for every \( j_* \in T_{e}^d \)). Fix also a set \( \Delta_{de} \) of representatives for the quotient \( W/t_{de}^d \); it is easily seen that \( (\otimes^d_A M)^W \) admits the basis \( \{ [e_{i_*}] | i_* \in \Delta_{de} \} \). Moreover, let \( [i_1], \ldots, [i_d] \in S_d(T_e) \) be the classes of the sequences \( i_1, \ldots, i_d, c_* \), and for every set \( \Sigma \), let \( c(\Sigma) \) be the cardinality of \( \Sigma \). With this notation, a simple inspection shows that (9.5.63) is given by the rule :

\[ [e_{(i_1, \ldots, i_d, c_*)}] \mapsto c(S_d([i_1], \ldots, [i_d, c_*])) \cdot e_{(i_1, \ldots, i_d, c_*)} \\otimes \cdots \otimes e_{(i_d, c_*)} \quad \text{for every } i_* \in \Delta_{de} \]

where \( S_d([i_1], \ldots, [i_d, c_*]) \) denotes the orbit of \( ([i_1], \ldots, [i_d, c_*]) \in (S_d(T_e))^d \) under the natural \( S_d \)-action. Combining with (9.5.62), we see that \( \otimes^d_A M \) is naturally identified with the A-linear map

\[ (\otimes^d_A M)^W \to \text{TS}_A^{de} M \]
given by the rule:
\[ [e_{i\bullet}]_W \mapsto c(S_d([i_1, \ldots, i_d])) \cdot \prod_{u=1}^r \left( N_u(i_1), \ldots, N_u(i_d) \right) \cdot [e_{i\bullet}] \quad \text{for every } i\bullet \in \Delta_{d,e}. \]

Let \( S_{de}(i\bullet) \) be the orbit of \( i\bullet \) under the natural \( S_{de} \)-action on \( T_{de} \), and notice that:
\[ [e_{i\bullet}] = \sum_{j\bullet \in W\backslash S_{de}(i\bullet)} [e_{j\bullet}]_W \quad \text{for every } i\bullet \in T_{de}^e \]
where \( W\backslash S_{de}(i\bullet) \) is the quotient of \( S_{de}(i\bullet) \) under the natural \( W \)-action. Notice as well that the cardinalities of the stabilizers of \( i\bullet \) under the \( S_{de} \)-action and the \( S_{de}^d \)-action are respectively:
\[ \frac{(de)!}{c(S_{de}(i\bullet))} = \prod_{u=1}^r N_u(i\bullet)_! \quad \text{and} \quad \frac{(e)!^d}{c(S_{de}^d(i\bullet))} = \prod_{u=1}^r \prod_{j=1}^d N_u(i_{j\bullet})! \]
whence:
\[ \frac{(de)!}{c(S_{de}(i\bullet))} \cdot \frac{c(S_{de}^d(i\bullet))}{(e)!^d} = \prod_{u=1}^r \left( N_u(i\bullet), \ldots, N_u(i_d) \right). \]

On the other hand, we have:
\[ S_d([i_1, \ldots, i_d]) = S_{de}^d \backslash W(i\bullet), \]
whence:
\[ c(S_d([i_1, \ldots, i_d])) = \frac{c(W(i\bullet))}{c(S_{de}^d(i\bullet))}. \]

Summing up, we see that (9.5.64) is given by the rule:
\[ [e_{i\bullet}]_W \mapsto \frac{(de)!}{(e)!^d} \cdot \frac{c(W(i\bullet))}{c(S_{de}(i\bullet))} \cdot \sum_{j\bullet \in W\backslash S_{de}(i\bullet)} [e_{j\bullet}]_W \quad \text{for every } i\bullet \in \Delta_{d,e}. \]

However, for every \( i\bullet \in T_{de} \) we may compute:
\[ \frac{c(W(i\bullet))}{c(S_{de}(i\bullet))} \cdot \sum_{j\bullet \in W\backslash S_{de}(i\bullet)} [e_{j\bullet}]_W = \frac{1}{c(S_{de}(i\bullet))} \cdot \sum_{j\bullet \in S_{de}(i\bullet)} [e_{j\bullet}]_W = \frac{1}{c(S_{de})} \cdot \sum_{\sigma \in S_{de}} [e_{\sigma(i\bullet)}]_W \]
\[ = \frac{c(W)}{c(S_{de})} \cdot \sum_{\sigma \in W\backslash S_{de}} [e_{\sigma(i\bullet)}]_W \]
and notice that \( c(W)/c(S_{de}) = \frac{(e)!^d}{(de)!} \). The sought identity now follows by a direct inspection of the definition of \( \alpha_{de} \).

(iii): The first stated identity is a special case of (i). Next, recall that \( \beta_{de}^d \) is the restriction of the projection \( \pi_{A}^d : \otimes^d M \rightarrow \text{Sym}^d_M \); the second identity will follow immediately from:

**Claim 9.5.65.** \( t_{de}^d \circ \gamma_{M}^d \circ \pi_{A}^d(x) = \sum_{\sigma \in S_d} \sigma(x) \) for every \( x \in \otimes^d A M \).

**Proof of the claim.** We are easily reduced to the case where \( M \) is free of some finite rank \( r \), and as usual we fix a basis \( e_1, \ldots, e_r \). In this case, \( \pi_{A}^d \) is the \( A \)-linear map such that \( e_{i\bullet} \mapsto e_{i\bullet} \) for every \( i\bullet \in T_{de} \). Moreover, by the foregoing, the map \( t_{de}^d \circ \gamma_{M}^d \) is given by the rule:
\[ e_{i\bullet} \mapsto \prod_{u=1}^r N_u(i\bullet)_! \cdot [e_{i\bullet}] = \sum_{\sigma \in S_d} e_{\sigma(i\bullet)} \quad \text{for every } i\bullet \in T_{de}. \]

The claim follows at once.

The third stated identity follows from the second one and lemma 9.5.29(iii).
9.5.66. Let now $A$ be a ring, $d \in \mathbb{N}$, and for every $A$-algebra $B$ and every $B$-module $M$, let $\mu_{B,M} : B \otimes_A M \to B$ be the scalar multiplication map, i.e. the $A$-linear map such that $b \otimes m \mapsto bm$ for every $b \in B$ and every $m \in M$. We deduce an $A$-linear map

$$\mu^d_{B,M} : \Gamma^d_A(B) \otimes_A \Gamma^d_A(M) \xrightarrow{\varphi^d_{B,M}} \Gamma^d_A(B \otimes_A M) \xrightarrow{\Gamma^d_A(\mu_{B,M})} \Gamma^d_A(M)$$

for every such $B$ and $M$, where $\varphi^d_{B,M}$ is defined as in (9.5.38). By virtue of remarks 9.5.39(ii) and 9.5.46(ii), the system of such maps is uniquely characterized by the identities:

$$(9.5.67) \quad \mu^d_{B,M}(b[d] \otimes m[d]) = (bm)[d]$$

for every $A$-algebra $B$, every $B$-module $M$, and every $b \in B$ and $m \in M$. Especially, taking $M := B$, it follows easily that $\mu^d_{B,B}$ furnishes the multiplication map for a well defined $A$-algebra structure on $\Gamma^d_A B$, for every such $B$ and $d$. Moreover, $\mu^d_{B,M}$ is the scalar multiplication map for a well defined $\Gamma^d_A B$-module structure on $\Gamma^d_A M$, for every $B$-module $M$. Furthermore, if $f : B \to C$ is any map of $A$-algebras, then clearly the same holds for $\Gamma^d_A(f)$, and if $g : M \to N$ is any morphism of $B$-modules, then $\Gamma^d_A(g)$ is a $\Gamma^d_A B$-linear map. Summing up, we obtain for every $d \in \mathbb{N}$, every ring $A$, and every $A$-algebra $B$, natural functors:

$$\Gamma^d_A : A\text{-Alg} \to A\text{-Alg} \quad \Gamma^d_A : B\text{-Mod} \to \Gamma^d_A B\text{-Mod}.$$ 

Notice also that $TS^d_A B$ is an $A$-subalgebra of the $A$-algebra $\otimes^d_A B$.

**Proposition 9.5.68.** (i) The natural bijection $9.5.21$ is an isomorphism of $C$-algebras

$$C \otimes_A \Gamma^d_A B \xrightarrow{\sim} \Gamma^d_C(C \otimes_A B)$$

for every $A$-algebra $C$.

(ii) The map $t^d_B : \Gamma^d_A B \to TS^d_A B$ of $9.5.33$ is an integral radicial morphism of $A$-algebras, and $\text{Ker}(t^d_B)$ lies in the nilradical of $\Gamma^d_A B$, for every $d \in \mathbb{N}$ and every $A$-algebra $B$.

(iii) If $B$ is an $A$-algebra of finite type, the same holds for $\Gamma^d_A B$.

(iv) Let $f : B_1 \to B_2$ be an integral map of $A$-algebras; we have:

(a) The maps $TS^d_A f$ and $\Gamma^d_A f$ are integral.

(b) If moreover $f$ is radicial, the same holds for $\Gamma^d_A f$.

(c) If $\text{Ker} f$ lies in the nilradical of $B_1$, then $\text{Ker}(\Gamma^d_A f)$ lies in the nilradical of $\Gamma^d_A B_1$.

**Proof.** (i) follows easily from the characterization $(9.5.67)$ of the map $\mu^d_{B,B}$.

(ii): Again, the characterization $(9.5.67)$ of $\mu^d_{B,B}$ easily implies that $t^d_B$ is a map of $A$-algebras.

Next, let us check that for every algebraically closed field $K$ and every ring homomorphism $A \to K$, the map $t^d_K$ induces a bijection:

$$\text{Hom}_{A\text{-Alg}}(TS^d_A B, K) \xrightarrow{\sim} \text{Hom}_{A\text{-Alg}}(\Gamma^d_A B, K).$$

To this aim, set $B_K := K \otimes_A B$, and consider the commutative diagram

$$
\begin{array}{ccc}
K \otimes_A \Gamma^d_A B & \xrightarrow{K \otimes_A t^d_B} & K \otimes_A TS^d_A B \\
\downarrow & & \downarrow \varphi \\
\Gamma^d_K(B_K) & \xrightarrow{t^d_{B_K}} & TS^d_K B_K
\end{array}
$$

whose left vertical arrow is the isomorphism of (i), and where $\varphi$ is the restriction of the natural isomorphism $K \otimes_A (\otimes^d_A B) \xrightarrow{\sim} \otimes^d_K B_K$. On the one hand, $(9.5.69)$ is naturally identified with the analogous map $\text{Hom}_{K\text{-Alg}}(TS^d_K B_K, K) \xrightarrow{\sim} \text{Hom}_{K\text{-Alg}}(\Gamma^d_K B_K, K)$ induced by $K \otimes_A t_B$, and on the other hand, $t^d_{B_K}$ is an isomorphism, by proposition 9.5.34(i); hence, we are reduced to checking that $\varphi$ induces a bijection

$$\text{Hom}_{K\text{-Alg}}(TS^d_K B_K, K) \xrightarrow{\sim} \text{Hom}_{K\text{-Alg}}(K \otimes_A TS^d_A B, K) \xrightarrow{\sim} \text{Hom}_{A\text{-Alg}}(TS^d_A B, K).$$
To this aim, we consider the commutative diagram:

\[
\begin{array}{ccc}
TS_A^d B & \xrightarrow{j_B} & \otimes_A^d B \\
\downarrow & & \downarrow \\
TS_K^d B_K & \xrightarrow{j_{B_K}} & \otimes_K^d B_K
\end{array}
\]

where \(j_B\) and \(j_{B_K}\) are the inclusion maps, which are integral, and according to [28, Ch.5, §2, n.2, Cor. of Th.2] induce bijections

\[
\text{Hom}_{A,\text{Alg}}(\otimes_A^d B, K) / G \xrightarrow{\sim} \text{Hom}_{A,\text{Alg}}(TS_A^d B, K)
\]

\[
\text{Hom}_{K,\text{Alg}}(\otimes_K^d B_K, K) / G \xrightarrow{\sim} \text{Hom}_{K,\text{Alg}}(TS_K^d B_K, K)
\]

for the \(S_d\)-actions on \(\otimes_A^d B\) and on \(\otimes_K^d B_K\) as in (9.5.28). It then suffices to remark that the natural map \(\otimes_A^d B \to \otimes_K^d B_K\) induces a bijection \(\text{Hom}_{K,\text{Alg}}(\otimes_K^d B_K, K) \xrightarrow{\sim} \text{Hom}_{A,\text{Alg}}(\otimes_A^d B, K)\). This shows already that \(t_B^d\) is radicial and that \(\text{Ker} t_B^d\) lies in the nilradical of \(\Gamma^d_A B\). To conclude, it suffices to check that \(j_B \circ t_B^d\) is integral. To this aim, choose a surjective map of \(A\)-algebras \(P \to B\) from a free polynomial \(A\)-algebra; since the induced map \(\otimes_A^d P \to \otimes_A^d B\) is surjective, it suffices to check the assertion for \(t_B^d\) and the inclusion map \(TS_A^d P \to \otimes_A^d P\). But the latter is integral, and \(t_B^d\) is an isomorphism, by proposition 9.5.34(i).

(iii): Let \(f : A[T^*_x] \to B\) be a surjection of \(A\)-algebras, from a free polynomial \(A\)-algebra \(A[T^*_x]\) of finite type. As \(\Gamma^d_A f\) is surjective (corollary 9.5.22(iv)), it suffices to check the assertion for \(\Gamma^d_A A[T^*_x]\). Next, the isomorphism \(A \otimes_Z \Gamma^d_Z Z[T^*_x] \to \Gamma^d_A A[T^*_x]\) of lemma 9.5.29(i) reduces to the case where \(A = Z\), and especially, \(A\) is noetherian. Then, notice that \(\otimes_Z^d Z[T^*_x]\) is a \(Z\)-algebra of finite type, and by (ii) and proposition 9.5.34(i), \(\Gamma^d_Z Z[T^*_x]\) is isomorphic to \(TS^d_T Z[T^*_x]\). Since the \(\otimes^d_Z Z[T^*_x]\) is integral over \(TS^d_T Z[T^*_x]\), the assertion follows from [10, Prop.7.8].

(iv): In light of (ii) we have a commutative diagram of \(A\)-algebras:

\[
\begin{array}{ccc}
\Gamma^d_A B_1 & \xrightarrow{t^d_{B_1}} & TS_A^d B_1 & \xrightarrow{j_1} & \otimes_A^d B_1 \\
\downarrow & & \downarrow & & \downarrow \\
\Gamma^d_A B_2 & \xrightarrow{t^d_{B_2}} & TS_A^d B_2 & \xrightarrow{j_2} & \otimes_A^d B_2
\end{array}
\]

where \(j_1\) and \(j_2\) are the inclusion maps. In order to check that \(TS_A^d f\) is integral, it suffices then to show that the same holds for \((\otimes_A^d f) \circ j_1\); however, \(j_1\) is integral, and the same holds for \(\otimes_A^d f\), since \(f\) is integral, whence the assertion. Combining with (ii), we deduce that \((TS_A^d f) \circ t_{B_1}^d\) is integral; hence, let \(x \in \Gamma^d_A B_2\) be any element, and pick a monic polynomial \(P \in (\Gamma^d_A B_1)[T]\) such that \(P(t_{B_2} x) = 0\). Set \(Q := P - T\), and notice that \(Q(x) \in \text{Ker}(t_{B_2}^d)\); by (ii), it follows that \(Q(x)^n = 0\) for some \(n \in \mathbb{N}\), so \(x\) is integral over \(\Gamma^d_A B_1\). This completes the proof of (iv.a).

Next, recall that \(f\) is radicial (resp. that \(\text{Ker} f\) lies in the nilradical \(\mathcal{N}\) of \(B_1\) if and only if, for every algebraically closed field \(K\), the induced map \(\text{Hom}_{Z,\text{Alg}}(B_2, K) \to \text{Hom}_{Z,\text{Alg}}(B_1, K)\) is injective (resp. surjective). It follows easily that if \(f\) is radicial (resp. if \(\text{Ker} f \subset \mathcal{N}\)), then the same holds for \(\otimes_A^d f\), and arguing as in the proof of (ii), we deduce that the same holds also for \(TS_A^d f\). By the same token, (ii) implies that \(t_{B_1}^d\) induces a bijection \(\text{Hom}_{Z,\text{Alg}}(TS_A^d B_1, K) \xrightarrow{\sim} \text{Hom}_{Z,\text{Alg}}(\Gamma^d_A B_i, K)\) for \(i = 1, 2\) and every algebraically closed field \(K\). Assertions (iv.b) and (iv.c) follow immediately.

\[\square\]

**Definition 9.5.70.** With the notation of (9.5.66), we call a **norm map of degree \(d\)** for the \(A\)-algebra \(B\), any map of \(A\)-algebras

\[\Gamma^d_A B \to A.\]
Remark 9.5.71. Let $B$ be any $A$-algebra, $d \in \mathbb{N}$, and $\nu : \Gamma^d_A B \to A$ a norm map of degree $d$.

(i) In light of Remark 9.5.71(i), we see that the datum of $\nu$ is equivalent to that of a system of morphisms of multiplicative monoids

$$N_C : C \otimes_A B \to C$$

natural with respect to maps of $A$-algebras $C \to C'$, and such that

$$N_C(c \otimes b) = c^d \cdot N_C(1 \otimes b)$$

for every $c \in C$ and $b \in B$.

Indeed, from $\nu$ we obtain such a compatible system $N_\bullet$ by the rule:

$$N_C := (C \otimes_A \nu) \circ (\chi^d_B)_C$$

and conversely, every such compatible system $N_\bullet$ yields an $A$-linear map $\nu : \Gamma^d_A B \to A$, by the universal property of $\Gamma^d_A B$, and the condition that $N_C$ is a map of multiplicative monoids implies easily that $\nu$ is a map of $A$-algebras (details left to the reader).

(ii) The isomorphism of proposition 9.5.68(i) identifies naturally $C \otimes_A \nu$ with a norm map $\nu_C : \Gamma^d_C (C \otimes_A B) \to C$ of degree $d$. Indeed, if $N_\bullet$ (resp. $N_\bullet^0$) is the compatible system of morphisms of multiplicative monoids associated with $\nu$ (resp. with $\nu_C$), then $N_C$ is the just the restriction of $N_\bullet$ to the category of $C$-algebras.

Example 9.5.72. (i) Let $A$ be a ring, $B$ an $A$-algebra whose underlying $A$-module is projective of constant finite rank $d$. Then, for every other $A$-algebra $C$, the $C$-module underlying the $C$-algebra $C \otimes_A B$ is projective of constant finite rank $d$. Every $x \in C \otimes_A B$ induces a $C$-linear endomorphism $\mu_x : C \otimes_A B \to C \otimes_A B$ such that $x \cdot x' \mapsto xx'$ for every $x' \in C \otimes_A B$. The determinant $N_C(x) := \det(\mu_x)$ is an element of $C$, and the construction of $N_C : C \otimes_A B \to C$ is natural for maps $C \to C'$ of $A$-algebras, so we get a compatible system $N_\bullet$ of maps of sets for every $A$-algebra $C$. In view of remark 9.5.71(i), $N_\bullet$ corresponds to a unique norm map

$$\nu_{B/A} : \Gamma^d_A B \to A$$

such that $$(C \otimes_A \nu_{B/A})(x^d) = \det(\mu_x)$$

for every $A$-algebra $C$ and every $x \in C \otimes_A B$.

(ii) Let $A$ be a normal domain, $K$ its field of fractions, and $B$ the integral closure of $A$ in a finite field extension $E$ of $K$, of degree $d$. Then, every free polynomial $A$-algebra $A[T]$ is again a normal domain, and $B[T] = B \otimes_A A[T]$ is the integral closure of $A[T]$ in the finite field extension $E(T)$ of $K(T)$. With this notation, the norm map $N_{K[T]} : E[T] = K[T] \otimes_K E \to K[T]$ is well defined as in (i), and we claim that $N_{K[T]}(B[T]) \subset A[T]$. Indeed, recall that $\det(\mu_x) = (-1)^d \cdot \chi_x(0)$, where $\chi_x \in K(T)[X]$ is the characteristic polynomial of the endomorphism $\mu_x$ of $E(T)$, for every $x \in E(T)$; let also $m_x \in K(T)[X]$ be the minimal polynomial of $x$ over $K(T)$. Since $\chi_x$ and $m_x$ have the same set of roots $\Sigma$, it suffices to check that every root of $m_x$ is integral over $A[T]$, when $x \in B[T]$. However, let $L$ be any normal extension of $K(T)$ containing $E(T)$; then $\Sigma$ is the orbit of $x$ under the action of the Galois group $\text{Gal}(L/K(T))$, whence the assertion. Thus, for every free polynomial $A$-algebra $A[T]$ the restriction of $N_{K[T]}$ is a well defined morphism of multiplicative monoids

and it is clear that the rule $A[T] \ni \nu_{A[T]} \mapsto N'_{A[T]}$ is natural for maps of free polynomial $A$-algebras, since the same holds for the rule $K[T] \ni \nu_{K[T]} \mapsto N_{K[T]}$. By virtue of proposition 9.5.68 it follows that $N'_A$ extends uniquely to a well defined homogeneous polynomial law $N' : B \xrightarrow{\sim} A$ of degree $d$, and it is easily seen that $N'_A$ still satisfies Remark 9.5.71, for every $A$-algebra $C$ (details left to the reader); whence finally, a norm map of degree $d$ for the $A$-algebra $B$:

$$\nu_{B/A} : \Gamma^d_A B \to A.$$
(iii) Let \( A \) be a ring, \( G \) a finite group of automorphisms of \( A \), and \( H \subset G \) a subgroup with \([G:H]=d\). For every \( A^G \)-algebra \( B \), we get an induced action of \( G \) on \( B \otimes_A^G A \), and if \( B \) is a flat \( A^G \)-algebra, the natural maps:

\[
B \rightarrow (B \otimes_A^G A)^G \quad \text{and} \quad B \otimes_A^G A^H \rightarrow (B \otimes_A^G A)^H
\]

are isomorphisms (details left to the reader). Fix a system of representatives \( \Sigma \subset G \) for the classes of \( G/H \); for every flat \( A^G \)-algebra \( B \), we then get a map of multiplicative monoids:

\[
N_B'' : B \otimes_A^G A^H \rightarrow B \quad x \mapsto \prod_{g \in \Sigma} g(x)
\]

which is clearly natural for every map of flat \( A^G \)-algebras. By proposition 9.5.6, the rule \( B \mapsto N_B'' \) then extends uniquely to a well defined homogeneous polynomial law \( N'' : A^H \rightarrow A^G \) of degree \( d \), whence again a norm map of degree \( d \) for the \( A^G \)-algebra \( A^H \):

\[
\nu''_{A^H/A^G} : \Gamma_A^G A^H \rightarrow A^G.
\]

(iv) The following example generalizes all the previous ones. Consider a ring \( A \), an injective ring homomorphism \( A \rightarrow A' \), a projective \( A' \)-module \( P \) of constant rank \( d \), and a map of associative \( A \)-algebras \( \rho : B \rightarrow \text{End}_{A'}(P') \). For every flat \( A \)-algebra \( C \), let moreover

\[
\rho_C := C \otimes_A \rho : C \otimes_A B \rightarrow C \otimes_A \text{End}_{A'}(P') \rightarrow \text{End}_{C \otimes_A A'}(C \otimes_A P')
\]

and suppose that \( N''_C(b) := \det(\rho_C(b)) \in C \) for every such \( C \) and every \( b \in C \otimes_A B \). By proposition 9.5.6, the rule \( C \mapsto N''_C \) for every such \( C \) extends uniquely to a homogeneous polynomial law \( N'' : B \rightarrow A \) of degree \( d \), and clearly \( N_C \) is a morphism of multiplicative monoids for every flat \( A \)-algebra \( C \), hence also for any \( A \)-algebra \( C \) (details left to the reader); whence finally a norm map of degree \( d \)

\[
\nu''_{P,P'} : \Gamma_A^d B \rightarrow A.
\]

9.5.73. Let \( A \) be a ring, \( B \) an \( A \)-algebra, \( d \in \mathbb{N} \), and \( \nu : \Gamma_A^d B \rightarrow A \) a norm map of degree \( d \). Let also \( N : B \rightarrow A \) be the homogeneous polynomial law of degree \( d \) associated with \( \nu \), as in remark 9.5.71(i). We set

\[
\chi_b(T) := N_{C[T]}(T - b) \in C[T] \quad \text{for every} \ A\text{-algebra}\ C \quad \text{and every} \ b \in C \otimes_A B.
\]

Let moreover \( \nu_{C[T]} : C[T] \otimes_A \Gamma_A^d B \rightarrow C[T] \) for every such \( C \), and notice that

\[
\chi_b(T) = \nu_{C[T]}((T - b)^d)
\]

and \((T - b)^d = \sum_{i=0}^d T^i \cdot (-b)^{d-i} = \sum_{i=0}^d T^i \cdot 1^i \cdot (-b)^{d-i} \) in \( C[T] \otimes_A \Gamma_A^d B \), by virtue of (9.5.51). Since \((-b)^0 = 1\), and \( \nu_{C[T]}(1^d) = N_{C[T]}(1) = 1 \), we may compute:

\[
\chi_b(T) = \sum_{i=0}^d T^i \cdot \nu_{C[T]}(1^i) \cdot (-b)^{d-i} = T^d + \sum_{i=0}^{d-1} T^i \cdot \nu_{C[T]}(1^i) \cdot (-b)^{d-i}.
\]

We get therefore a well defined homogeneous polynomial law of degree \( d \):

\[
B \nrightarrow B \quad b \mapsto \chi_b(b) \in C \otimes_A B \quad \text{for every} \ A\text{-algebra}\ C \quad \text{and every} \ b \in C \otimes_A B
\]

and we define the characteristic map of \( \nu \) as the associated \( A \)-linear map \( \chi^\dagger : \Gamma_A^d B \rightarrow B \).

**Definition 9.5.74.** With the notation of (9.5.73), we say that \( \nu \) is a Cayley-Hamilton norm map if \( \chi^\dagger = 0 \), i.e. if \( \chi_b(b) = 0 \) for every \( A \)-algebra \( C \) and every \( b \in C \otimes_A B \).
**Example 9.5.75.** (i) In the situation of example 9.5.72(iv), notice that, by the theorem of Cayley-Hamilton, we have $\rho_C(\chi(b)) = 0$ for every flat $A$-algebra $C$ and every $b \in C \otimes_A B$. Thus, if $\rho_C$ is injective for every such $C$, the norm map $\nu_{B,\rho}$ is Cayley-Hamilton.

(ii) Especially, the norm maps $\nu_{B/A}, \nu'_{B/A}$ and $\nu''_{A/H/AC}$ of example 9.5.72(i,ii,iii) are Cayley-Hamilton.

**Remark 9.5.76.** (i) Let $\varphi : B' \to B$ be a map of $A$-algebras, $\nu : \Gamma^d_A B \to A$ a norm map of degree $d$, and set $\nu' := \nu \circ \Gamma^d_A(\varphi)$. Let also $\chi^\dagger$ and $\chi'^\dagger$ be the characteristic maps of $\nu$, respectively $\nu'$. By a direct inspection of the constructions we get a commutative diagram:

$$
\begin{array}{ccc}
\Gamma^d_A B' & \xrightarrow{\chi'^\dagger} & B' \\
\varphi \downarrow & & \downarrow \\
\Gamma^d_A B & \xrightarrow{\chi^\dagger} & B \\
\end{array}
$$

(details left to the reader). In particular, if $\varphi$ is surjective and $\nu'$ is Cayley-Hamilton, the same holds for $\nu$, since $\Gamma^d_A(\varphi)$ is surjective (corollary 9.5.22(iv)).

(ii) In particular, let $\nu : \Gamma^d_A B \to A$ be a norm map of degree $d$, and $I \subset B$ the ideal generated by the image of the characteristic map $\chi^\dagger$ of $\nu$; let also $\pi : B \to B/I$ be the projection, and suppose that $\nu$ factors through $\Gamma^d_A(\pi)$ and a norm map $\overline{\nu} : \Gamma^d_A(B/I) \to A$. Then, if $\chi^\dagger$ denotes the characteristic map of $\overline{\nu}$, we have $\chi^\dagger \circ \Gamma^d_A(\pi) = \pi \circ \chi^\dagger = 0$, by (i), whence $\chi^\dagger = 0$, since $\Gamma^d_A(\pi)$ is a surjection (corollary 9.5.22(iv)). In other words, in this situation, $\overline{\nu}$ is Cayley-Hamilton.

(iii) In the situation of (i), let also $C$ be any $A$-algebra, and $\nu_C : \Gamma^d_C(C \otimes_A B) \to C$ the norm map induced by $\nu$ as in remark 9.5.71(ii). Then we get a commutative diagram of $C$-modules:

$$
\begin{array}{ccc}
C \otimes_A \Gamma^d_A B & \xrightarrow{\sim} & \Gamma^d_C(C \otimes_A B) \\
\chi^\dagger \circ \otimes_A & & \chi^\dagger \\
C \otimes_A B & \xrightarrow{\sim} & C \otimes_A B \\
\end{array}
$$

where $\chi^\dagger$ is the characteristic map of $\nu_C$, and the top horizontal arrow is the isomorphism of proposition 9.5.68(i). Especially, if $\nu$ is a Cayley-Hamilton norm map, the same holds for $\nu_C$.

**Theorem 9.5.77.** Let $\nu : \Gamma^d_A B \to A$ be a norm map of degree $d$, and $I \subset B$ the ideal generated by the image of the characteristic map $\chi^\dagger$ of $\nu$. Then $\nu$ is the composition of the projection $\Gamma^d_A B \to \Gamma^d_A(B/I)$ and a Cayley-Hamilton norm map $\overline{\nu} : \Gamma^d_A(B/I) \to A$.

**Proof.** By remark 9.5.76(ii), it suffices to show that $\nu$ factors through the projection onto $\Gamma^d_A(B/I)$ and a norm map $\overline{\nu} : \Gamma^d_A(B/I) \to A$. We first deal with the following special case:

**Claim 9.5.78.** The theorem holds if $A$ is an algebraically closed field.

**Proof of the claim.** In this case, $B$ is trivially a flat $A$-algebra, so $\nu$ is naturally identified with a map of $A$-algebras $TS^d_A B \to A$ (propositions 9.5.68(ii) and 9.5.34(iii)). The latter extends to a map of $A$-algebras $\otimes_A B \to A$, which is the same as a system of $d$ maps of $A$-algebras $\nu_1, \ldots, \nu_d : B \to A$. Let $\rho : B \to \text{End}_A(A^{\otimes d})$ be the morphism of associative $A$-algebras that maps each $b \in B$ to the diagonal $d \times d$ matrix $\rho(b)$ with $\rho(b)_{ii} = \nu_i(b)$ for $i = 1, \ldots, d$. Working out the definitions, we see that $\nu$ corresponds to the homogeneous polynomial law $B \rightsquigarrow A$ arising from $\rho$, as in example 9.5.72(iv). Let $J := \text{Ker} \rho$, so that $\rho$ factors through the projection $\pi : B \to B/J$ and a map of associative $A$-algebras $\rho' : B/J \to \text{End}_A(A^{\otimes d})$; then $\rho'$ induces, again by example 9.5.72(iv), a norm map $\nu' : \Gamma^d_A(B/J) \to A$ such that $\nu = \nu' \circ \Gamma^d_A(\pi)$, and $\nu'$ is Cayley-Hamilton, by virtue of example 9.5.75(i). By remark 9.5.76(i), it follows that $I \subset J$, whence the required factorization of $\nu$. \qed
Now, choose a free polynomial $A$-algebra $P$, a surjective map $\varphi : P \to B$ of $A$-algebras, and set $\nu^P := \nu \circ \Gamma^d_A(\varphi) : \Gamma^d_A P \to A$; remark 9.5.76(ii) yields the identity:

$$\varphi \circ \chi^P = \chi^1 \circ \Gamma^d_A(\varphi)$$

where $\chi^1 : \Gamma^d_A B \to B$ and $\chi^P : \Gamma^d_A P \to P$ are the characteristic maps of $\nu$ and $\nu^P$. Let $J \subset P$ be the ideal generated by the image of $\chi^P$; since $\Gamma^d_A(\varphi)$ is surjective (corollary 9.5.22(iv)), it follows that $\varphi(J) = I$. Let $\overline{\varphi} : P/J \to B/J$ be the map induced by $\varphi$, and $\pi : P \to P/J$ the projection; it follows easily from corollary 9.5.57 that $\text{Ker} \, \pi$ is the image of $\text{Ker} \, \Gamma^d_A(\varphi)$, under the map $\Gamma^d_A(\pi) : \Gamma^d_A P \to \Gamma^d_A(P/J)$. Now, suppose that $\nu^P$ factors through $\Gamma^d_A(\pi)$ and a norm map $\overline{\nu} : \Gamma^d_A(P/J) \to A$; then we deduce that $\nu$ factors through the projection $\Gamma^d_A B \to \Gamma^d_A(B/I)$ and a norm map $\overline{\nu} : \Gamma^d_A(B/I) \to A$.

Thus, it suffices to show the theorem for $P$, and we may assume from start that $B = A[T_\bullet]$ is a free polynomial $A$-algebra. In this case, set $A_0 := \Gamma^d_A(\mathbb{Z}[T_\bullet])$; taking into account the isomorphism of proposition 9.5.68(i), we get a norm map of degree $d$:

$$\nu_0 : \Gamma^d_A(A_0[T_\bullet]) \iso A_0 \otimes_{\mathbb{Z}} \Gamma^d_A(\mathbb{Z}[T_\bullet]) = A_0 \otimes_{\mathbb{Z}} A_0 \xrightarrow{\mu_A} A_0$$

where $\mu_A$ is the multiplication map of the ring $A_0$. By the same token, $\nu$ is naturally identified with a map of $A$-algebras $A \otimes_{\mathbb{Z}} A_0 \to A$ and we get therefore an induced $A_0$-algebra structure on $A$ (indeed, the set of norm maps of degree $d$ of the $A$-algebra $A[T_\bullet]_A$ is in natural bijection with the set of all such $A_0$-algebra structures). Then, a simple inspection yields a commutative diagram of $A$-algebras:

$$
\begin{array}{ccc}
A \otimes_{A_0} \Gamma^d_A(A_0[T_\bullet]) & \xrightarrow{\omega} & \Gamma^d_A(A[T_\bullet]) \\
\downarrow{A \otimes_{A_0} \nu_0} & & \downarrow{\nu} \\
A & & \\
\end{array}
$$

where $\omega$ is again the natural isomorphism of proposition 9.5.68(i). Let $\chi^1_A : \Gamma^d_A(A_0[T_\bullet]) \to A_0$ be the characteristic map of $\nu_0$, and $I_0 \subset A_0[T_\bullet]$ the ideal generated by the image of $\chi^1_A$; from remark 9.5.76(iii) we see that the image of $A \otimes_{A_0} I_0$ in $A[T_\bullet]$ is the ideal $I$. Let $\pi_0 : A_0[T_\bullet] \to A_0[T_\bullet]/I_0$ be the projection; by corollary 9.5.57 the kernel of $\Gamma^d_A(\pi_0)$ is the image of $\Gamma^d_A(I_0)$, so the kernel of $\nu$ is the image of $A \otimes_{A_0} \Gamma^d_A(I_0) \iso \Gamma^d_A(A \otimes_{A_0} I_0)$, and the latter is also the kernel of the projection $\Gamma^d_A(A[T_\bullet]) \to \Gamma^d_A(A[T_\bullet]/I)$, again by corollary 9.5.57. Summing up, we see that if $\nu_0$ factors through $\Gamma^d_A(\pi_0)$ and a norm map $\overline{\nu}_0 : \Gamma^d_A(A_0[T_\bullet]/I_0) \to A_0$, then $\nu$ is the composition of the projection onto $\Gamma^d_A(A[T_\bullet]/I)$ and a norm map $\overline{\nu} : \Gamma^d_A(A[T_\bullet]/I) \to A$.

Thus, we are further reduced to the case where $A = A_0$, and in particular $A$ is a domain, since the same clearly holds for $TS^d_A(A_0[T_\bullet])$ (propositions 9.5.68(ii) and 9.5.34(i)). Next, let $K$ be an algebraic closure of the field of fractions of $A$, and set $B_K := K \otimes_A B$ and $\nu_K := K \otimes_A \nu$. Since $\Gamma^d_A B$ is a flat $A$-module (corollary 9.5.22(iii)), the induced map $\Gamma^d_A B \to K \otimes_A \Gamma^d_A B \iso \Gamma^d_K B_K$ is injective, and $\nu_K$ is naturally identified with a norm map $\Gamma^d_K B_K \to K$. Let $\chi^1_K$ be the characteristic map of $\nu_K$; arguing as in the foregoing, we see that the ideal of $B_K$ generated by the image of $\chi^1_K$ is $I_K := K \otimes_A I$. Hence, if $\nu_K$ is the composition of the projection $\Gamma^d_K B_K \to \Gamma^d_K(B_K/I_K)$ and a norm map $\overline{\nu}_0 : \Gamma^d_K(B_K/I_K) \to K$, then $\nu$ factors through the projection onto $\Gamma^d_A(B/I)$ and a norm map $\Gamma^d_A(B/I) \to A$. Thus, it suffices to show the theorem for the norm map $\overline{\nu}_K$, and this is already known by claim 9.5.78.

9.6. Regular rings. In a later section, we shall need a criterion for the regularity of a certain type of extensions of regular local rings. Such a criterion is stated incorrectly in [48, Ch.0, Th.22.5.4]; our first task is to supply a corrected version of loc. cit.

**Proposition 9.6.1.** Let $K$ be a field, and $L$ a field extension of $K$. We have:

(i) $H_i^L \mathbb{L}_{L/K} = 0$ for every $i > 1$.
(ii) If $L$ is a separable extension of $K$, then $H_i^L \mathbb{L}_{L/K} = 0$ for every $i > 0$.
(iii) (Cartier’s equality). If $L$ is an extension of finite type of $K$, then
\[
\dim_L H_1^L \mathbb{L}_{L/K} < +\infty \quad \text{and} \quad \dim_L \Omega^1_{L/K} - \dim_L H_1^L \mathbb{L}_{L/K} = \text{tr.} \deg[L : K].
\]

**Proof.** (ii): By [82, Ch.II, (1.2.3.4)], we may assume that $L$ is an extension of $K$ of finite type, in which case $L$ is a separable algebraic extension of a subfield $L_0 \subset L$, which is a purely transcendental extension of $K$ of finite type. Since $L$ is an étale $L_0$-algebra, and since $L_0$ is a localization of a smooth $K$-algebra, we then have

(9.6.2) $L_{L/L_0} \Rightarrow 0$ and $L_{L_0/K} \Rightarrow \Omega^1_{L/K_0}[0]$ in $\text{D}(L-\text{Mod})$  

([82, Ch.III, Prop.3.1.1 and Prop.3.1.2] and [82, Ch.II, Cor.2.3.1.1]). However, the tower of field extensions $K \subset L_0 \subset L$ yields a distinguished triangle:

(9.6.3) $\mathbb{L}_{L/L_0}[1] \rightarrow \mathbb{L}_{L_0/K} \otimes_{L_0} L \rightarrow \mathbb{L}_{L/K} \rightarrow \mathbb{L}_{L/L_0}$ in $\text{D}(L-\text{Mod})$  

([82, Ch.II, Prop.2.1.2]) whence the assertion.

(i): Let $K_0$ be the smallest subfield of $K$; so $K_0$ is either $\mathbb{Q}$ or $\mathbb{F}_p$, for some prime integer $p$, and in either case, it is a perfect field. By (i), we then have $H_i^L \mathbb{L}_{K_0/K} = H_i^L \mathbb{L}_{L_0/K_0} = 0$ for every $i > 0$. However, the tower of field extensions $K_0 \subset K \subset L$ yields a distinguished triangle:

$$L_{L/K} \rightarrow L_{L/K_0} \otimes K L \rightarrow L_{L/K_0} \rightarrow L_{L/K}$$

([82, Ch.II, Prop.2.1.2]) whence the assertion.

(iii): Suppose first that $L$ is a separable extension of $K$, and pick $L_0 \subset L$ as in the proof of (ii), so $L_0 = \text{Frac} K[T_1, \ldots, T_r]$, with $r := \text{tr.} \deg[L : K]$. From (9.6.2) and (9.6.2), we get:

$$\dim_L \Omega^1_{L/K} = \dim_L H_0^L \mathbb{L}_{L/K} = \dim_{L_0} \Omega^1_{L_0/K} = \dim_{L_0} L_0 \otimes_{K[T_1, \ldots, T_r]} \Omega^1_{K[T_1, \ldots, T_r]/K} = r$$

which establishes the sought identity, as in this case we have $H_i^L \mathbb{L}_{L/K} = 0$, by (ii).

Next, suppose that $K$ is of finite type over its smallest subfield $K_0$. We have $H_i^L \mathbb{L}_{L/K_0} = 0$, by (ii); then the tower of field extensions $K_0 \rightarrow K \rightarrow L$ yields an exact sequence

$$0 \rightarrow H_1^L \mathbb{L}_{L/K} \rightarrow \Omega^1_{K/K_0} \otimes K L \rightarrow \Omega^1_{L/K_0} \otimes K \Omega^1_{K/K_0} \rightarrow 0$$

([82, Ch.II, Prop.2.1.2]), and on the other hand:

$$\dim_K \Omega^1_{K/K_0} = \text{tr.} \deg[K : K_0] \quad \text{and} \quad \dim_L \Omega^1_{L/K_0} = \text{tr.} \deg[L : K_0]$$

by the foregoing case. The assertion follows straightforwardly, in this case.

Lastly, let $K$ be an arbitrary field, and write $K$ as the union of the filtered family $(K_\lambda \mid \lambda \in \Lambda)$ of its subfields that are finitely generated over $K_0$. Choose $x_1, \ldots, x_t \in L$ such that $K(x_1, \ldots, x_t) = L$. Let $\varphi : K[X_1, \ldots, X_t] \rightarrow L$ be the map of $K$-algebras given by the rule: $X_i \mapsto x_i$ for $i = 1, \ldots, t$. Then $I := \text{Ker} \varphi$ is a finitely generated ideal, so we may find $\lambda \in \Lambda$ and an ideal $I_\lambda \subset K_\lambda[X_1, \ldots, X_t]$ such that $I = I_\lambda \otimes_{K_\lambda} K$ (details left to the reader). Denote by $L_\lambda$ the field of fractions of $K_\lambda[T_1, \ldots, T_t]/I_\lambda$; it is easily seen that $L_\lambda \otimes_{K_\lambda} K$ is a domain, and its field of fractions is a $K$-algebra naturally isomorphic to $L$. Especially, we have $\text{tr.} \deg[L_\lambda : K_\lambda] = \text{tr.} \deg[L : K]$; and on the other hand, there is a natural isomorphism:

$$\mathbb{L}_{L_\lambda/K_\lambda} \otimes_{L_\lambda} L \sim \mathbb{L}_{L/K} \quad \text{in} \quad \text{D}^{-}(L-\text{Mod})$$

([82, Ch.II, Prop.2.2.1, Cor.2.3.1.1]). Then the sought identity for the extension $K \subset L$ follows from the same identity for the extension $K_\lambda \subset L_\lambda$. The latter is already known, by the previous case. Likewise, the argument shows that $\dim_L H_1^L \mathbb{L}_{L/K} < +\infty$.  

$\square$
9.6.4. Consider a local ring \( A \), with maximal ideal \( m_A \), and residue field \( k_A := A/m_A \) of characteristic \( p > 0 \). From [48, Ch.0, Th.20.5.12(i)] we get a complex of \( k_A \)-vector spaces
\[
0 \to m_A/(m_A^2 + pA) \xrightarrow{d_A} \Omega^1_{A/Z} \otimes_A k_A \to \Omega^1_{k_A/Z} \to 0.
\]

**Lemma 9.6.6.** The complex \((9.6.5)\) is exact.

**Proof.** Set \((A_0, m_{A_0}) := (A/pA, m_A/pA)\) and \( \mathbb{F}_p := \mathbb{Z}/p\mathbb{Z} \); the induced sequence of ring homomorphisms \( \mathbb{F}_p \to A_0 \to k_A \) yields a distinguished triangle ([82, Ch.II, \S2.1.2.1]):
\[
\mathbb{L}_{A_0/\mathbb{F}_p} \otimes_{A_0} k_A \to \mathbb{L}_{k_A/\mathbb{F}_p} \to \mathbb{L}_{k_A/A_0} \to \mathbb{L}_{A_0/\mathbb{F}_p} \otimes_{A_0} k_A[1].
\]

However, we have \( H_i \mathbb{L}_{k_A/\mathbb{F}_p} = 0 \) for every \( i > 0 \), by proposition [9.6.1(ii)]. We deduce a short exact sequence
\[
0 \to H_1 \mathbb{L}_{k_A/A_0} \to \Omega^1_{A_0/\mathbb{F}_p} \otimes_{A_0} k_A \to \Omega^1_{k_A/\mathbb{F}_p} \to 0
\]
which, under the natural identifications
\[
\Omega^1_{k_A/Z} \sim \Omega^1_{k_A/\mathbb{F}_p}, \quad \Omega^1_{A_0/Z} \otimes_A k_A \sim \Omega^1_{A_0/\mathbb{F}_p} \otimes_{A_0} k_A, \quad H_1 \mathbb{L}_{k_A/A_0} \sim m_{A_0}/m_{A_0}^2
\]
([82, Ch.III, Cor.1.2.8.1]) becomes \((9.6.5)\), up to replacing \( d_A \) by \(-d_A\) ([82, Ch.III, Prop.1.2.9]; details left to the reader). \( \square \)

9.6.7. Keep the situation of \((9.6.4)\), and define
\[
A_2 := A \times_{k_A} W_2(k_A)
\]
where \( W_2(k_A) \) is the ring of 2-truncated Witt vectors of \( k_A \), as in \((9.3.25)\), which is augmented over \( k_A \), via the ghost component map \( \overline{w}_0 : W_2(k_A) \to k_A \). Notice that
\[
V_1(k_A) := \text{Ker } \overline{w}_0
\]
is an ideal of \( W_2(k_A) \) such that \( V_1(k_A)^2 = 0 \); especially, it is naturally a \( k_A \)-vector space, with addition and scalar multiplication given respectively by the rules:
\[
(0, a) + (0, b) := (0, a + b), \quad x \cdot (0, a) := (x, 0) \cdot (0, a) = (0, x^p \cdot a)
\]
for every \( a, b, x \in k_A \). In other words, the map
\[
(9.6.8) \quad V_1(k_A) \to k_A^{1/p}, \quad (0, a) \mapsto a^{1/p}
\]
is an isomorphism of \( k_A \)-vector spaces, and we also see that \( V_1(k_A) \) is a one-dimensional \( k_A^{1/p} \)-vector space, with scalar multiplication given by the rule: \( a \cdot (0, b) := (0, a^p b) \) for every \( a \in k_A^{1/p} \) and \( b \in k_A \). By construction, we have a natural exact sequence of \( A_2 \)-modules:
\[
(9.6.9) \quad 0 \to V_1(k_A) \to A_2 \xrightarrow{\pi} A \to 0.
\]
Especially, \( A_2 \) is a local ring, and \( \pi \) is a local ring homomorphism inducing an isomorphism on residue fields.

9.6.10. It is easily seen that the rule \((A, m_A) \mapsto A_2\) defines a functor on the category \( p\text{-Local} \) of local rings with residue field of characteristic \( p > 0 \), and local ring homomorphisms, to the category of (commutative, unital) rings. Hence, let us set
\[
(A, m_A) \mapsto \overline{\Omega}_A := \Omega^1_{A_2/Z} \otimes_{A_2} A.
\]
It follows that the rule \((A, m_A) \mapsto (A, \overline{\Omega}_A)\) yields a functor
\[
p\text{-Local} \to \text{Alg.Mod}
\]
to the category whose objects are the pairs \((B, M)\) where \( B \) is a ring, and \( M \) is a \( B \)-module (the morphisms \((B, M) \to (B', M')\) are the pairs \((\varphi, \psi)\) where \( \varphi : B \to B' \) is a ring homomorphism, and \( \psi : B' \otimes_B M \to M \) is a \( B' \)-linear map: cp. [59, Def.2.5.22(ii)]).
In view of (9.6.9) and [48, Ch.0, Th.20.5.12(i)] we get an exact sequence of $A$-modules
\[ V_1(k_A) \to \Omega_A \to \Omega^1_{A/Z} \to 0 \]
whence, after tensoring with $k_A$, a sequence of $k_A$-vector spaces
\[ 0 \to V_1(k_A) \xrightarrow{j_A} \Omega_A \otimes_A k_A \xrightarrow{\rho} \Omega^1_{A/Z} \otimes_A k_A \to 0 \]
which is right exact by construction.

**Proposition 9.6.12.** With the notation of (9.6.10), we have:

(i) If $p \notin m_A^2$, then the sequence (9.6.11) is exact.

(ii) If $p \in m_A^2$, then $\ker j_A = \{(0, a^p) \mid a \in k_A\}$. Especially, the isomorphism (9.6.8) identifies $\ker j_A$ with the subfield $k_A$ of $k_A^{1/p}$.

**Proof.** In view of lemma 9.6.6, the kernel of $\rho$ is naturally identified with the kernel of the natural map
\[ m_{A^2}/(m_{A^2} + pA_2) \to m_A/(m_A^2 + pA). \]
On the other hand, it is easily seen that $m_{A^2} = m_A \oplus V_1(k_A)$, and under this identification, the multiplication law of $A_2$ restricts on $m_{A^2}$ to the mapping given by the rule : $(a, b) \cdot (a', b') := (aa', 0)$ for every $a, a' \in m_A$ and $b, b' \in V_1(k_A)$. There follows a natural isomorphism
\[ m_{A^2}/m_A^2 \cong (m_A/m_A^2) \oplus V_1(k_A) \]
which identifies the map $m_{A^2}/m_A^2 \to m_A/m_A^2$ deduced from $\pi$ (notation of (9.6.9)), with the projection on the first factor. Moreover, by inspecting the definitions, we easily get a commutative diagram
\[
\begin{array}{ccc}
V_1(k_A) & \xrightarrow{j_A} & \Omega_A \otimes_A k_A \\
\downarrow & & \downarrow d_{A_2} \\
m_{A^2}/m_A^2 & \xrightarrow{t_{A_2}} & m_{A^2}/(m_A^2 + pA_2)
\end{array}
\]
whose bottom horizontal arrow is the quotient map, and whose left vertical arrow is the inclusion map of the direct summand $V_1(k_A)$ resulting from (9.6.13).

The map $A_2 \to m_{A^2}/m_A^2$ given by the rule : $a \mapsto pa \mod m_A^2$ factors (uniquely) through a $k_A$-linear map
\[ t_{A_2} : k_A \to m_{A^2}/m_A^2 \quad a \mod m_A \mapsto pa \mod m_A^2 \]
and likewise we may define a map $t_A : k_A \to m_A/m_A^2$. The snake lemma then gives an induced map $\partial : \ker t_A \to V_1(k_A)$, and in view of the foregoing, the proposition follows from :

**Claim 9.6.14.** (i) If $p \notin m_A^2$, then $t_A$ is injective.

(ii) If $p \in m_A^2$, then $\text{Im} \partial = \{(0, a^p) \mid a \in k_A\}$.

**Proof of the claim.** (i) is obvious.

(ii) By virtue of (9.3.23), we have $p = (p, (0, 1))$ in $A_2$, and if $(a, y) \in A_2$ is any element, then $p \cdot (a, y) = (pa, (0, a^p))$, so in case $p \in m_A^2$, the map $t_{A_2}$ is given by the rule :
\[ a \mapsto (pa, (0, a^p)) = (0, (0, a^p)) \in (m_A/m_A^2) \oplus V_1(k_A) \quad \text{for every } a \in A. \]
By the same token, in this case $t_A$ is the zero map. The claim follows straightforwardly. \qed
9.6.15. Keep the notation of (9.6.10), and assume that $p \notin m_A^3$, so (9.6.11) is a $k_A$-extension of $\Omega_{A/Z}^1 \otimes_A k_A$ by $V_1(k_A)$, by virtue of proposition 9.6.12 hence, (9.6.11) $\otimes_{k_A} k_{A}^{1/p}$ is a $k_{A}^{1/p}$-extension of the corresponding $k_{A}^{1/p}$-vector spaces. Recall now that $V_1(k_A)$ is naturally a $k_{A}^{1/p}$-vector space of dimension one, and let $\psi_A : V_1(k_A) \otimes_{k_A} k_{A}^{1/p} \to V_1(k_A)$ be the scalar multiplication. By push out along $\psi_A$, we obtain therefore an extension $\psi_A * (9.6.11) \otimes_{k_A} k_{A}^{1/p}$ fitting into a commutative ladder with exact rows:

\[
\begin{array}{ccccccc}
0 & \longrightarrow & V_1(k_A) \otimes_{k_A} k_{A}^{1/p} & \longrightarrow & \Omega_{A}^{1} \otimes_{A} k_{A}^{1/p} & \longrightarrow & 0 \\
\psi_A & & \downarrow & \psi_A & & \downarrow & \\
0 & \longrightarrow & V_1(k_A) & \longrightarrow & \Omega_{A}^{1} \otimes_{A} k_{A}^{1/p} & \longrightarrow & 0
\end{array}
\]

(see [59 $\S$2.5.5]). We consider now the mapping:

$$d_A : A \to \Omega_A \quad a \mapsto \psi_A(d(a, \tau_{k_A}(\bar{a})) \otimes 1) \quad \text{for every } a \in A$$

where:

- $\bar{a} \in k_A$ is the image of $a$ in $k_A$
- $\tau_{k_A}$ is the Teichmüller mapping (see (9.3.35)), so $\tau_{k_A}(\bar{a}) = (\bar{a}, 0) \in W_2(k_A)$
- $d : A_2 \to \Omega_{A_2/Z}$ is the universal derivation of $A_2$.

Since $\tau_{k_A}$ is multiplicative, the map $d_A$ satisfies Leibniz’s rule, i.e. we have

$$d_A(ab) = \bar{a} \cdot d_A(b) + \bar{b} \cdot d_A(a) \quad \text{for every } a, b \in A.$$ 

However, $d_A$ is not quite a derivation, since additivity fails for $\tau_{k_A}$, hence also for $d_A$. Instead, from remark 9.3.8(ii), and recalling that $(p - 1)! = -1$ in $\mathbb{F}_p$, we get the identity:

$$
\tau_{k_A}(\bar{a} + \bar{b}) = \tau_{k_A}(\bar{a}) + \tau_{k_A}(\bar{b}) - \sum_{i=1}^{p-1} \left( \frac{\bar{a}^i}{i!} \cdot \frac{\bar{b}^{p-i}}{(p - i)!} \right) \\
= \tau_{k_A}(\bar{a}) + \tau_{k_A}(\bar{b}) - \sum_{i=1}^{p-1} \frac{\bar{a}^{i/p}}{i!} \cdot \frac{\bar{b}^{1-i/p}}{(p - i)!} \cdot p
$$

for every $\bar{a}, \bar{b} \in k_A$. On the other hand, notice that

$$\psi_A(d(0, x \cdot p) \otimes 1) = j_A \circ \psi_A(x \cdot p \otimes 1)$$

$$= x \cdot j_A \circ \psi_A(p \otimes 1)$$

$$= x \cdot \psi_A(d(0, p) \otimes 1)$$

$$= x \cdot \psi_A(d(p - (p, 0)) \otimes 1)$$

$$= - x \cdot d_A(p)$$

for every $x \in k_{A}^{1/p}$, whence:

$$d_A(a + b) = d_A(a) + d_A(b) + \sum_{i=1}^{p-1} \frac{\bar{a}^{i/p}}{i!} \cdot \frac{\bar{b}^{1-i/p}}{(p - i)!} \cdot d_A(p) \quad \text{for every } a, b \in A.$$ 

9.6.16. Especially, notice we do have $d_A(a + b) = d_A(a) + d_A(b)$ in case either $a$ or $b$ lies in $m_A$. Hence, $d_A$ restricts to an additive map $m_A \to \Omega_A$, and Leibniz’s rule implies that the latter descends to a $k_A$-linear map

$$\bar{d}_A : m_A/m_A^2 \to \Omega_A.$$
Proposition 9.6.17. Let \((A, m_A)\) be a local ring with residue field \(k_A := A/m_A\) of characteristic \(p > 0\), and such that \(p \notin m_A^2\). Then there exists a natural exact sequence of \(k_A^{1/p}\)-vector spaces:

\[
0 \to m_A/m_A^2 \otimes_{k_A} k_A^{1/p} \rightarrow \frac{m_A}{m_A^2 \cap pA} \otimes_{k_A} k_A^{1/p} \rightarrow \frac{m_A}{m_A^2 + pA} \otimes_{k_A} k_A^{1/p} \to 0.
\]

**Proof.** By inspecting the constructions in (9.6.15), we obtain a commutative ladder of \(k_A\)-vector spaces, with exact rows:

\[
\begin{array}{ccccccc}
0 & \to & \frac{pA}{m_A^2 \cap pA} & \to & \frac{m_A}{m_A^2} & \otimes_{k_A} k_A^{1/p} & \to & \frac{m_A}{m_A^2 + pA} & \otimes_{k_A} k_A^{1/p} & \to & 0 \\
& & i & \downarrow & j & \downarrow & & & & & \\
0 & \to & V_1(k_A) & \to & \Omega_A & \to & \Omega_A^{1/A/Z} & \otimes_{A} k_A^{1/p} & \to & 0 \\
\end{array}
\]

such that \(d_A \otimes_{k_A} k_A^{1/p}\) is injective with cokernel naturally isomorphic to \(\Omega_A^{1/A/Z} \otimes_{k_A} k_A^{1/p}\) (lemma 9.6.6). By the snake lemma, it then suffices to show that \(i\) is an isomorphism; but since both the source and target of the latter map are one-dimensional \(k_A^{1/p}\)-vector spaces, we come down to checking that \(i\) is not the zero map. But a simple inspection yields \(i(p \otimes 1) = (0, 1)\). \(\square\)

9.6.18. We wish next to show how the rule \(A \mapsto \Omega_A\) extends to a functor

\[
p\text{-Local} \to \text{Alg.Mod} \quad (A, m_A) \mapsto (k_A^{1/p}, \Omega_A).
\]

Namely, if \(p \notin m_A^2\), we let \(\Omega_A\) be the \(k_A^{1/p}\)-module introduced in (9.6.15), and if \(p \in m_A^2\), we set

\[
\Omega_A := \Omega_A^{1/A/Z} \otimes_{A} k_A^{1/p}.
\]

To any local ring homomorphism \(\varphi : A \to B\) we attach the \(k_A^{1/p}\)-linear map

\[
\Omega_\varphi : \Omega_A \to \Omega_B
\]

defined as follows:

- In case \(p \notin m_B^2\), then obviously \(p \notin m_A^2\). Denote by \(\overline{\varphi} : k_A^{1/p} \to k_B^{1/p}\) the map induced by \(\varphi\). By (9.6.10), we have an induced \(A\)-linear map \(\overline{\Omega}_\varphi \otimes_A \overline{\varphi} : \overline{\Omega}_A \otimes_A k_A^{1/p} \to \overline{\Omega}_B \otimes_B k_B^{1/p}\). Also, the naturality of the ghost component map \(\overline{\Omega}_0\) yields a \(k_A\)-linear map \(V_1(\varphi) : V_1(k_A) \to V_1(k_B)\), and indeed, \(V_1(\varphi)\) is even \(k_A^{1/p}\)-linear. Moreover, for every \(a \in k_A\) and \(b \in k_B^{1/p}\) we may compute

\[
\psi_B(\overline{\Omega}_\varphi(j_A(0, a)) \otimes \overline{\varphi}(b)) = \psi_B(j_B(V_1(\varphi)(0, a)) \otimes \overline{\varphi}(b))
\]

\[
= j_B \circ \psi_B(V_1(\varphi)(0, a) \otimes \overline{\varphi}(b))
\]

\[
= j_B \circ V_1(\varphi) \circ \psi_A((0, a) \otimes b)
\]

so the pair \((\psi_B \circ (\overline{\Omega}_\varphi \otimes \overline{\varphi}), j_B \circ V_1(\varphi))\) determines a unique \(k_A^{1/p}\)-linear map \(\Omega_\varphi : \Omega_A \to \Omega_B\) as required.

- In case \(p \in m_A^2\), then \(p \in m_B^2\), and we set \(\Omega_\varphi := \Omega_\varphi^{1/A} \otimes_A \overline{\varphi}\), where \(\Omega_\varphi^{1/A} : \Omega_A^{1/A/Z} \to \Omega_B^{1/B/Z}\) is the natural \(A\)-linear map.

- Lastly, if \(p \notin m_A^2\) but \(p \in m_B^2\), we let \(\Omega_\varphi\) be the composition of the natural projection \(\Omega_A \to \Omega_A^{1/A} \otimes_A k_A^{1/p}\) and \(\Omega_\varphi^{1/A} \otimes_A \overline{\varphi}\).

If \(\varphi' : B \to C\) is another morphism in \(p\text{-Local}\), it is easy to verify that \(\Omega_{\varphi' \circ \varphi} = \Omega_{\varphi'} \circ \Omega_\varphi\), so we do get a functor as sought (details left to the reader).
9.6.19. In the same vein, we may extend the map $d_A$ to a natural transformation of functors. Namely, if $p \notin m_A^2$, we let $d_A$ be the map introduced in (9.6.15), and if $p \in m_A^2$, we let $d_A : A \to \Omega A$ be the map induced by the universal derivation $A \to \Omega A$. Then it is easily seen that every local ring homomorphism $\varphi : A \to B$ induces a commutative diagram

$$
\begin{array}{ccc}
A & \xrightarrow{d_A} & \Omega A \\
\varphi \downarrow & & \downarrow \Omega \varphi \\
B & \xrightarrow{d_B} & \Omega B.
\end{array}
$$

**Proposition 9.6.20.** Let $(A, m_A), (B, m_B)$ be two local rings with residue characteristic $p > 0$, and $\varphi : A \to B$ a local ring homomorphism. We have:

(i) Suppose that $\varphi$ is formally smooth for the $m_A$-adic topology on $A$ and the $m_B$-adic topology on $B$. Then $\varphi$ and $\Omega \varphi$ induce injective maps

$$(m_A/m_A^2) \otimes_{k_A} k_B \to m_B/m_B^2 \quad \Omega A \otimes_{k_A^1} k_B^{1/p} \to \Omega B.$$  

(ii) Suppose that

(a) $m_A \cdot B = m_B$.
(b) The induced residue field extension $k_A \to k_B$ is algebraic and separable.
(c) $\varphi$ is flat.

Then $\Omega \varphi$ induces an isomorphism of $k_B^{1/p}$-vector spaces:

$$\Omega A \otimes A B \sim \Omega B.$$  

(iii) If $B = A/m_A^2$ and $\varphi$ is the natural projection, then $\Omega \varphi$ is an isomorphism.

(iv) The functor $\Omega \varphi$ and the natural transformation $d_A$ commute with all filtered colimits.

**Proof.** (ii): Assumption (a) and the flatness of $\varphi$ imply that the induced map

$$(m_A/m_A^2) \otimes_{k_A} k_B \to m_B/m_B^2$$

is an isomorphism ([100], Th.22.3), so $p \in m_A$ if and only if $p \in m_B$. On the other hand, under assumption (b), we have

$$(9.6.21) \quad k_B^{1/p} = k_A^{1/p} \cdot k_B.$$  

Now, consider first the case where $p \in m_A^2$; then $\Omega \varphi = \Omega A^{1/p} \otimes_{A} \varphi$ (notation of (9.6.18)), so the assertion follows from (9.6.21) together with the following

**Claim 9.6.22.** If $p \in m_A^2$, then $\Omega_A^{1/p}$ induces a $k_B$-linear isomorphism

$$\Omega_A^{1/p} \otimes_{A} k_B \to \Omega_B.$$  

**Proof of the claim.** Under the standing assumptions, (9.6.4) gives a commutative ladder with short exact rows

$$
\begin{array}{c}
0 \longrightarrow (m_A/m_A^2) \otimes_{k_A} k_B \longrightarrow \Omega A^{1/p} \otimes_{A} k_B \longrightarrow \Omega_{k_A}^{1/p} \otimes_{k_A} k_B \longrightarrow 0 \\
0 \longrightarrow m_B/m_B^2 \longrightarrow \Omega B \otimes_{k_B} k_B \longrightarrow \Omega_{k_B} \longrightarrow 0
\end{array}
$$

(9.6.23)

and we have already remarked that the left vertical arrow is an isomorphism; the same holds for the right vertical arrow, due to assumption (b). The claim follows.

The case where $p \notin m_A^2$ is treated likewise: one argues as in the proof of claim 9.6.22 except that, instead of appealing to (9.6.5), one invokes proposition 9.6.17 and the naturality of $d_A$ established in (9.6.19): the details shall be left to the reader.

$\Diamond$
(iii): For the case where $p \in \mathfrak{m}_A^2$, we consider again the induced ladder (9.6.23) : under the standing assumptions, clearly the first and third vertical arrows are isomorphisms, so the same holds for the middle one.

For the case where $p \notin \mathfrak{m}_A^2$, one argues again likewise : the ladder (9.6.23) is replaced by the corresponding ladder for $\Omega_\bullet$, provided by proposition [9.6.17] and the naturality of $d_\bullet$ : the details shall be left to the reader.

(iv): Let $((A_\lambda, \mathfrak{m}_\lambda) \mid \lambda \in \Lambda)$ be a filtered system of local rings and local ring homomorphisms. Notice that if $p \in \mathfrak{m}_\lambda^2$ for some $\lambda \in \Lambda$, then $p \in \mathfrak{m}_\mu^2$ for every $\mu \geq \lambda$ in $\Lambda$, and since $\Lambda$ is filtered, we may then replace $\Lambda$ with $\Lambda/\lambda$, and assume that $p \notin \mathfrak{m}_\mu$ for every $\mu \in \Lambda$. In this case, the contention follows straightforwardly from the corresponding assertion for the functor $\Omega^1$ and the universal derivation $d_\bullet$.

It remains to consider the case where $p \notin \mathfrak{m}_\lambda$ for every $\lambda \in \Lambda$. For this, one applies proposition [9.6.17] which reduces again the contention to the previous case (details left to the reader).

(i): We consider first the following special case :

Claim 9.6.24. Let $n \in \mathbb{N}$ be any integer, and $q \subset A[T_1, \ldots, T_n]$ any prime ideal such that $q \cap A = \mathfrak{m}_A$. Set $R := A[T_1, \ldots, T_n]_q$ and denote by $m_R$ and $k_R$ respectively the maximal ideal and the residue field of $R$. Then :

(i) $\dim_{k_R} m_R/m_R^2 = n + \dim_{k_A} m_A/m_A^2$.

(ii) The natural map $\gamma : (m_A/m_A^2) \otimes_{k_A} k_R = m_R/m_R^2$ is injective.

(iii) The natural map $\Omega^1_{A/Z} \otimes_A R \to \Omega^1_{R/Z}$ is injective, and its image is a direct summand of $\Omega^1_{R/Z}$.

(iv) The natural map $\Omega_A \otimes_{k_A} k_R^{1/p} \to \Omega_R$ is injective.

Proof of the claim. (i): By proposition [9.6.1(i)], we have $H_i \mathbb{L}_{k_R/k_A} = 0$ for every $i > 1$; then the transitivity triangle for the cotangent complex relative to the maps $A \to k_A \to k_R$ yields a short exact sequence of $k_R$-vector spaces :

$$0 \to H_1 \mathbb{L}_{k_R/k_A} \otimes_{k_A} k_R \xrightarrow{\alpha} H_1 \mathbb{L}_{k_R/A} \to H_1 \mathbb{L}_{k_R/k_A} \to 0$$

([82] Ch.II, §2.1.2.1)). Likewise, since $H_i \mathbb{L}_{R/A} = 0$ for every $i > 0$ ([82] Ch.II, Cor.1.2.6.3]), the sequence of maps $A \to R \to k_R$ yields an exact sequence of $k_R$-vector spaces :

$$0 \to H_1 \mathbb{L}_{k_R/A} \xrightarrow{\beta} H_1 \mathbb{L}_{k_R/R} \to \Omega^1_{R/A} \otimes_R k_R \to \Omega_{k_R/A} \to 0.$$  

However, we have natural isomorphisms

$$H_1 \mathbb{L}_{k_R/k_A} \cong m_A/m_A^2 \quad H_1 \mathbb{L}_{k_R/R} \cong m_R/m_R^2$$

([82] Ch.III, Cor.1.2.8.1]), and clearly $\dim_{k_R} \Omega_{R/A} \otimes_R k_R = n$. Thus :

$$\dim_{k_A} m_A/m_A^2 = \dim_{k_R} H_1 \mathbb{L}_{k_R/A} - \dim_{k_R} H_1 \mathbb{L}_{k_R/k_A}$$

$$\dim_{k_R} m_R/m_R^2 = \dim_{k_R} H_1 \mathbb{L}_{k_R/A} + n - \dim_{k_R} \Omega_{k_R/k_A}.$$  

Taking into account the identity

$$\dim_{k_R} H_1 \mathbb{L}_{k_R/k_A} = \dim_{k_R} \Omega_{k_R/k_A}$$

provided by proposition [9.6.1(iii)], the assertion follows.

(ii): Notice that the composition of $\alpha$ and $\beta$ yields an injective map $(m_A/m_A^2) \otimes_{k_A} k_R \to m_R/m_R^2$ so it suffices to check that this composition equals $\gamma$. However, let

$$\Sigma : H_1 \mathbb{L}_{k_R/k_A} \xrightarrow{d} H_0 k_R \otimes_R \mathbb{L}_{R/A}$$

be the boundary map of the transitivity triangle

$$(9.6.25) \quad k_R \otimes_R \mathbb{L}_{R/A} \to \mathbb{L}_{k_R/A} \to \mathbb{L}_{k_R/R} \to k_R \otimes_R \sigma \mathbb{L}_{R/A}$$
arising from the sequence \( A \to R \to k_R \); we regard \( \Sigma \) as a complex placed in degrees \([-1, 0]\). Then, clearly, the triangle \( \tau^{-1} \) \((9.6.25)\) is naturally isomorphic in \( D(k_R\text{-Mod}) \) to the triangle
\[
(9.6.26) \quad k_R \otimes_R H_0 \mathbb{L}_{k_R/A}[0] \to \Sigma \to H_1 \mathbb{L}_{k_R/R}[1] \to k_R \otimes_R H_0 \mathbb{L}_{k_R/A}[1].
\]
According to \([82\text{ III.1.2.9.1}]\), the complex \( \Sigma \) is naturally isomorphic to the complex
\[
\Theta : \quad m_R/m_R^2 \xrightarrow{-d_{R/A}} k_R \otimes_R \Omega^1_{R/A}
\]
(placed in degrees \([-1, 0]\)) where \( d_{R/A} \) is induced by the universal derivation \( R \to \Omega^1_{R/A} \). Likewise, we have natural isomorphisms
\[
(9.6.27) \quad \tau^{-1} \mathbb{L}_{k_R/R} \sim m_R/m_R^2[1] \quad \tau^{-1} \mathbb{L}_{R/A} \sim \Omega^1_{R/A}[0]
\]
and under these identifications, \((9.6.26)\) is the obvious triangle deduced from \( \Theta \). Especially, the map \( \beta \) is naturally identified with the inclusion map \( \text{Ker} d_{R/A} \to m_R/m_R^2 \).

Likewise, there exists a natural identification
\[
(9.6.28) \quad \tau^{-1} \mathbb{L}_{k_A/A} \sim m_A/m_A^2[1] \quad \text{in} \ D(k_A\text{-Mod})
\]
as well as a natural map of complexes
\[
(9.6.29) \quad k_R \otimes_{k_A} (m_A/m_A^2)[1] \to \Theta
\]
deduced from \( \gamma \). To conclude, it suffices to check that the map
\[
(9.6.30) \quad \tau^{-1} k_R \otimes_{k_A} \mathbb{L}_{k_A/A} \to \tau^{-1} \mathbb{L}_{k_R/A}
\]
coming from the transitivity triangle for the sequence \( A \to k_A \to k_R \), corresponds to the morphism \((9.6.29)\), under the identification \((9.6.28)\) and the previous identification of \( \tau^{-1} \mathbb{L}_{k_R/A} \) with \( \Theta \). To this aim, it suffices to compare the maps obtained by applying to these two morphisms the functor \( \text{Ext}^1_{k_A}(-, M[0]) \), for arbitrary \( k_R\text{-modules} \ M \). Now, recall that there exists a natural isomorphism
\[
\text{Ext}^1_{k_A}(\tau^{-1} \mathbb{L}_{k_R/R}, M[0]) \sim \text{Exal}_R(k_R, M) \quad \text{for every} \ k_R\text{-module} \ M.
\]
As explained in \([82\text{ III.1.2.8}]\), under the identification \((9.6.27)\), this becomes the following \( k_R\text{-linear isomorphism} \)
\[
(9.6.31) \quad \text{Hom}_{k_R}(m_R/m_R^2, M) \sim \text{Exal}_R(k_R, M) \quad \varphi \mapsto \varphi \ast U
\]
(notation of \([59\text{ §2.5.5}]\)), where
\[
U : \quad 0 \to m_R/m_R^2 \to R/m_R^2 \to k_R \to 0
\]
is the natural extension. There is a natural surjection
\[
\text{Hom}_{k_R}(m_R/m_R^2, M) \to \text{Ext}^1_{k_R}(\Theta, M[0])
\]
and the foregoing implies that the natural isomorphism
\[
\text{Ext}^1_{k_R}(\tau^{-1} \mathbb{L}_{k_R/A}, M[0]) \sim \text{Exal}_A(k_R, M)
\]
is also realized as in \((9.6.31)\) : given a class \( c \) in \( \text{Ext}^1_{k_R}(\Theta, M[0]) \), take an arbitrary representative \( \varphi : m_R/m_R^2 \to M \), and the correspondence associates with \( c \) the class of the push out \( \varphi \ast U \).

By the same token, we have a natural isomorphism
\[
\text{Ext}^1_{k_R}(\tau^{-1} k_R \otimes_{k_A} \mathbb{L}_{k_A/A}, M[0]) \sim \text{Exal}_A(k_A, M) \quad \text{for every} \ k_R\text{-module} \ M
\]
and on the one hand, the map \( \text{Ext}^1_{k_R}(\Theta, M[0]) \) is identified naturally with the map
\[
\text{Exal}_A(k_R, M) \to \text{Exal}_A(k_A, M)
\]
the constructions, we get a natural commutative ladder of
view of (iii), there follow commutative diagrams of
free $R$-module generated by $dT_i$ is formally smooth over $B$
for every $k_B$-module $M$ and every $\varphi : m_R/m_R^2 \to M$. We leave the verification as an exercise
for the reader.

(iii) is a standard calculation (more precisely, the complement of $\Omega^1_{A/Z} \otimes_A R$ in $\Omega^1_{R/Z}$ is the
free $R$-module generated by $dT_1, \ldots, dT_n$).

(iv): If $p \in m_A^2$, the assertion follows from (iii). Suppose then that $p \notin m_A^2$. By inspecting
the constructions, we get a natural commutative ladder of $k_B^{1/p}$-vector spaces
\[
\begin{array}{cccccc}
0 & \longrightarrow & V_1(k_A) \otimes_{k_A^{1/p}} k_B^{1/p} & \longrightarrow & \Omega_A \otimes_{k_A^{1/p}} k_B^{1/p} & \longrightarrow & \Omega^1_{A/Z} \otimes_A k_B^{1/p} & \longrightarrow & 0 \\
0 & \longrightarrow & V_1(k_R) & \longrightarrow & \Omega_R & \longrightarrow & \Omega^1_{R/Z} \otimes_R k_B^{1/p} & \longrightarrow & 0 \\
\end{array}
\]
whose central vertical arrow is the map of the claim. However, it is easily seen that the left
vertical arrow is an isomorphism, so the assertion follows from (iii).

Now, pick a free polynomial $A$-algebra $C$ and a surjective map $C \to B$ of $A$-algebras; let $q \subset C$
be the preimage of $m_B$, set $R := C_q$, and let $m_R$ be the maximal ideal of $R$. Since $B$ is formally smooth over $A$
for the topologies of the maximal ideals, the induced surjection $R/m_R^2 \to B/m_B^2$ admits a section
$B/m_B^2 \to R/m_R^2$ which is also a local map of $A$-algebras. In view of (iii), there follow commutative diagrams of $k_B$-linear and respectively $k_B^{1/p}$-linear maps
\[
\begin{array}{cccccc}
(m_A/m_A^2) \otimes_{k_A} k_B & \longrightarrow & m_B/m_B^2 & \longrightarrow & \Omega_A \otimes_{k_A} k_B^{1/p} & \longrightarrow & \Omega_B \\
\end{array}
\]
which reduce the assertion to the case where $B = R$. In this case, write $C$ as the filtered colimit of
the system $(C_\lambda | \lambda \in \Lambda)$ of its free polynomial $A$-subalgebras of finite type; for each $\lambda \in \Lambda$, let $q_\lambda := q \cap C_\lambda$ and $R_\lambda := (C_\lambda)_{q_\lambda}$. Clearly $R$ is the filtered colimit of the system $(R_\lambda | \lambda \in \Lambda)$, so the assertion follows from (iv) and claim \[9.6.24\](ii).

9.6.32. Let $(A, m_A)$ be any object of $p$-Local, and $k_A := A/m_A$. Consider a finite sequence
$f_1, \ldots, f_n$ of elements of $A$, and $e_1, \ldots, e_n \in \mathbb{N}$ with $e_i > 1$ for every $i = 1, \ldots, n$. Set
\[
C := A[T_1, \ldots, T_n]/(T_1^{e_1} - f_1, \ldots, T_n^{e_n} - f_n).
\]
Fix a prime ideal $n \subset C$ such that $n \cap A = m_A$, and let $B := C_n$. So the induced map $A \to B$
is a local ring homomorphism; we denote by $m_B$ the maximal ideal of $B$, and set $k_B := B/m_B$.
Also, let $\nu := \dim_k_{k_A} E$, where $E \subset \Omega_A$ is the $k_A^{1/p}$-vector space spanned by $d_A f_1, \ldots, d_A f_n$.

\textbf{Theorem 9.6.33.} In the situation of (9.6.32), suppose moreover that :
(a) $f_i \in m_A$, for every $i \leq n$ such that $p$ does not divide $e_i$,
(b) $m_A/m_A^2$ is a finite dimensional $k_A$-vector space.
Then $m_B/m_B^2$ is a finite dimensional $k_B$-vector space, and we have :

$$\dim_{k_B} m_B/m_B^2 = n + \dim_{k_A} m_A/m_A^2 - \nu.$$  

Proof. Let $q \subset A[T_1, \ldots, T_n]$ be the preimage of $n$, set $R := A[T_1, \ldots, T_n]_q$, and denote by $p$ the maximal ideal of $R$, and by $F \subset p/p^2$ the $k_B$-vector space spanned by $T_1^{e_1} - f_1, \ldots, T_n^{e_n} - f_n$. Clearly, we have a short exact sequence

$$0 \to F \to p/p^2 \to m_B/m_B^2 \to 0.$$  

Suppose first that $p \notin m_A^3$, in which case $p \notin p^3$, by claim 9.6.24(ii), hence $\Omega_R$ is defined by (9.6.15). On the other hand, notice that $d(T_i^{e_i}) = d(T_i^{e_i} - f_i) + d(f_i)$ in $\Omega_R$, since $T_i^{e_i} - f_i \in p$. Now, if $e_i$ is a multiple of $p$, Leibniz’s rule yields $d(T_i^{e_i}) = e_i \cdot T_i^{e_i-1} d(T_i) = 0$. If $e_i$ is not a multiple of $p$, we have $f_i \in m_A$ by assumption; hence $T_i \in p$ and therefore $d(T_i^{e_i}) = 0$ again, since $e_i > 1$. In either case, we find

$$d(f_i) = -\bar{d}(T_i^{e_i} - f_i) \quad \text{in } \Omega_R, \text{ for every } i = 1, \ldots, n.$$  

In view of proposition 9.6.17 it follows that

$$\dim_{k_B} m_B/m_B^2 = \dim_{k_B} p/p^2 - \dim_{k_B} E'$$  

where $E' \subset \Omega_R$ is the $k_B^{1/p}$-vector space spanned by $d(f_1), \ldots, d(f_n)$. Then the assertion follows from claim 9.6.24(iv).

Lastly, suppose $p \in m_A^3$, so that $p \notin p^3$ as well. Arguing as in the foregoing case, we see that $\dim_{k_B} F$ equals the dimension of the $k_B$-vector subspace of $\Omega^{1}_{R/Z} \otimes_R k_B$ spanned by $df_1, \ldots, df_n$, and in view of claim 9.6.24(iii), the latter equals $\nu$, whence the contention. □

Corollary 9.6.34. In the situation of theorem 9.6.33 the following conditions are equivalent :

(a) $A$ is a regular local ring, and $\nu = n$.

(b) $B$ is a regular local ring.

Proof. Suppose first that (b) holds. Since the map $A \to B$ is faithfully flat, it is easily seen that $A$ is noetherian, and then [48] Ch.0, Prop.17.3.3(i)] shows already that $A$ is a regular local ring. Moreover, $C$ is clearly a finite $A$-algebra, therefore $\dim_{k_B} m_B/m_B^2 = \dim B \leq \dim A = \dim_{k_A} m_A/m_A^2$. Theorem 9.6.33 then implies that $\nu = n$, so (a) holds.

Next, suppose that (a) holds. We apply theorem 9.6.33 as in the foregoing, to deduce that $\dim B = \dim A = \dim_{k_B} m_B/m_B^2$, whence (b) : details left to the reader. □

Remark 9.6.35. (i) Keep the notation of corollary 9.6.34. In [48] Ch.0, Th.22.5.4] it is asserted that condition (b) is equivalent to the following :

(a') $A$ is regular and the space $E \subset \Omega^{1}_{A/Z} \otimes_A k_A$ spanned by $df_1, \ldots, df_n$ has dimension $n$.

When $p \in m_A^3$, this condition (a’) agrees with our condition (a), so in this case of course we do have (a’)⇒(b). However, the latter equivalence fails in general, in case $p \notin m_A^3$ : the mistake is found in [48] Ch.0, Rem.22.4.8], which is false. The implication (a’)⇒(b) does remain true in all cases : this is easily deduced from theorem 9.6.33 since the image of $d_A(f)$ in $\Omega^{1}_{A/Z} \otimes_{k_A} k_A^{1/p}$ agrees with $df \otimes 1$, for every $f \in A$. The proof of loc.cit. is correct for $p \in m_A^3$, which is the only case that is used in the proof of corollary 9.6.34.

(ii) Moreover, in the situation of corollary 9.6.34 suppose that $B$ is a regular local ring. Then the sequence

$$(d_B f_1^{1/e_1}, \ldots, d_B f_n^{1/e_n})$$  

spans a $k_B^{1/p}$-vector subspace of $\Omega_B$ of dimension $n$. Indeed, consider the ring

$$C := B[T_1, \ldots, T_n]/(T_1^p - f_1^{1/e_1}, \ldots, T_n^p - f_n^{1/e_n}).$$
Corollary 9.6.34 applies to the extension $A \subset C$, the sequence $(f_1, \ldots, f_n)$, and the sequence of integers $(pe_1, \ldots, pe_n)$, so $C$ is a regular local ring. But the same corollary applies as well to the extension $B \subset C$, the sequence $(f_1^{1/e_1}, \ldots, f_n^{1/e_n})$, and the sequence of integers $(p, \ldots, p)$, and yields the assertion.

(iii) Let us say that the sequence $(f_1, \ldots, f_n)$ is maximal in $A$ if

$$(d_Af_1, \ldots, d_Af_n)$$

is a basis of the $k_A^{1/p}$-vector space $\Omega_A$. Then, in the situation of (ii), we claim that the sequence $(f_1, \ldots, f_n)$ is maximal in $A$ if and only if the sequence $(f_1^{1/e_1}, \ldots, f_n^{1/e_n})$ is maximal in $B$. Indeed, under the current assumptions we have $\dim_{k_A} \Omega_A^{1/p} = \dim_{k_B} \Omega_B^{1/p}$, since these integers are equal to the transcendence degree of $k_A$ (and $k_B$) over $\mathbb{F}_p$, and on the other hand $\dim_{k_A} m_A/m_A^2 = \dim_{k_B} m_B/m_B^2$, since $A$ and $B$ are regular local rings of the same dimension; then the assertion follows from (ii), lemma 9.6.6, and proposition 9.6.17 (details left to the reader).

(iv) Likewise, consider any morphism $\varphi : A \to B$ in Local fulfilling conditions (a),(b) and (c) of proposition 9.6.20 (ii). Then clearly the sequence $(f_1, \ldots, f_n)$ is maximal in $A$ if and only if the sequence $(\varphi(f_1), \ldots, \varphi(f_n))$ is maximal in $B$.

9.6.36. Let $p > 0$ be a prime integer, and $A$ an $\mathbb{F}_p$-algebra. Denote by $\Phi_A : A \to A$ the Frobenius endomorphism of $A$, given by the rule : $a \mapsto a^p$ for every $a \in A$. For every $A$-module $M$, we let $M(\Phi)$ be the $A$-module obtained from $M$ via restriction of scalars along the map $\Phi_A$ (that is, $a \cdot m := a^m n$ for every $a \in A$ and $m \in M$). Notice that $\Phi_A$ is an $A$-linear map $A \to A(\Phi)$. Theorem 9.6.37, and part (i) of the following theorem 9.7.26 are due to E.Kunz.

Theorem 9.6.37. Let $A$ be a noetherian local $\mathbb{F}_p$-algebra. Then the following conditions are equivalent :

(i) $A$ is regular.

(ii) $\Phi_A$ is a flat ring homomorphism.

(iii) There exists $n > 0$ such that $\Phi_A^n$ is a flat ring homomorphism.

Proof. (i)$\Rightarrow$(ii): Let $A^\wedge$ be the completion of $A$, and $f : A \to A^\wedge$ the natural map. Clearly

$$f \circ \Phi_A = \Phi_{A^\wedge} \circ f.$$ 

Since $f$ is faithfully flat, it follows that $\Phi_A$ is flat if and only if the same holds for $\Phi_{A^\wedge}$, so we may replace $A$ by $A^\wedge$, and assume from start that $A$ is complete, hence $A = k[[T_1, \ldots, T_d]]$, for a field $k$ of characteristic $p$, and $d = \dim A$ (48, Ch.0, Th.19.6.4)). Then, it is easily seen that

$$\Phi_A(A) = A^p = k^p[[T_1^p, \ldots, T_d^p]].$$

Set $B := k[[T_1^p, \ldots, T_d^p]]$; the ring $A$ is a free $B$-module (of rank $p^d$), hence it suffices to check that the inclusion map $A^p \to B$ is flat. However, denote by $m$ the maximal ideal of $A^p$; clearly $B$ is an $m$-adically ideal-separated $A$-module (see [100] p.174, Def.), hence it suffices to check that $B/m^kB$ is a flat $A^p/m^k$-module for every $k > 0$ ([100] Th.22.3)). The latter is clear, since $k[T_1^p, \ldots, T_d^p]$ is a flat $k^p[T_1^p, \ldots, T_d^p]$-module.

(ii)$\Rightarrow$(iii) is obvious.

(iii)$\Rightarrow$(i): Notice first that $\text{Spec } \Phi_A^n$ is the identity map on the topological space underlying $\text{Spec } A$; especially, $\Phi_A^n$ is flat if and only if it is faithfully flat, and the latter condition implies that $\Phi_A^n$ is injective. We easily deduce that if (iii) holds, then $A$ is reduced. Now, consider quite generally, any finite system $x_* := (x_1, \ldots, x_i)$ of elements of $A$, and let $I \subset A$ be the ideal generated by $x_*$. we shall say that $x_*$ is a system of independent elements, if $I/I^2$ is a free $A/I$-module of rank $n$. We show first the following :
Claim 9.6.38. Let \( y, z, x_2, \ldots, x_t \) be a family of elements of \( A \), such that \( x_\bullet := (yz, x_2, \ldots, x_t) \) is a system of independent elements, and denote by \( J \subset A \) the ideal generated by \( x_\bullet \). We have:

(i) \( (y, x_2, \ldots, x_t) \) is a system of independent elements of \( A \).
(ii) If \( \text{length}_A A/J \) is finite, then

\[
\text{length}_A A/J = \text{length}_A A/(y, x_2, \ldots, x_t) + \text{length}_A A/(z, x_2, \ldots, x_t).
\]

Proof of the claim. (i): Suppose \( a_1y + a_2x_2 + \cdots + a_t x_t = 0 \) is a linear relation with \( a_1, \ldots, a_t \in A \), and let \( I \subset A \) be the ideal generated by \( y, x_2, \ldots, x_t \). We have to show that \( a_1, \ldots, a_t \in I \). However, as \( a_1yz + a_2xz_2 + \cdots + a_t x_t = 0 \), it follows by assumption, that \( a_1 \) lies in \( J \subset I \).

Write \( a_1 = b_1yz + b_2x_2 + \cdots + b_t x_t \); then

\[
b_1 yz + (a_2 + b_2) x_2 + \cdots + (a_t + b_t) x_t = 0.
\]

Therefore \( a_i + b_i y \in J \) for \( i = 2, \ldots, t \), and therefore \( a_2, \ldots, a_t \in I \), as required.

(ii): It suffices to show that the natural map of \( A \)-modules:

\[
A/(z, x_2, \ldots, x_t) \rightarrow I/J \quad a \mapsto ay + J
\]

is an isomorphism. However, the surjectivity is immediate. To show the injectivity, suppose that \( ay \in J \), i.e. \( ay = b_1yz + b_2x_2 + \cdots + b_t x_t \) for some \( b_1, \ldots, b_t \in A \); we deduce that \( (b_1z - a)yz + b_2x_2 + \cdots + b_t x_t = 0 \), hence \( a - b_1z \in J \) by assumption, so \( a \) lies in the ideal generated by \( z, x_2, \ldots, x_t \), as required.

Now, set \( q := p^n \), and \( A_\nu := A^{p^n} \subset A \) for every integer \( \nu > 0 \); pick a minimal system \( x_\bullet := (x_1, \ldots, x_t) \) of generators of the maximal ideal \( m_A \) of \( A \), and notice that, since \( A \) is reduced, \( \Phi_A^{p^n} \) induces an isomorphism \( A \rightarrow A_\nu \), hence \( x_\bullet^{(\nu)} := (x_1^{(\nu)}, \ldots, x_t^{(\nu)}) \) is a minimal system of generators for the maximal ideal \( m_\nu \) of \( A_\nu \). Set as well \( I_\nu := m_\nu A \); since the inclusion map \( A_\nu \rightarrow A \) is flat by assumption for every \( \nu > 0 \), we have a natural isomorphism of \( A \)-modules

\[
(m_\nu/m_\nu^2) \otimes_{A_\nu} A \cong I_\nu/I_\nu^2.
\]

On the other hand, set \( k_\nu := A_\nu/m_\nu \); by Nakayama’s lemma, \( \text{dim}_{k_\nu} m_\nu/m_\nu^2 = t \), so \( I_\nu/I_\nu^2 \) is a free \( A \)-module of rank \( t \), i.e. \( x_\bullet^{(\nu)} \) is an independent system of elements of \( A \). From claim 9.6.38(ii) and a simple induction, we deduce that

\[
\text{length}_A A/I_\nu = \text{length}_A A^{\nu}/I_\nu A^{\nu} = q^{\nu t} \quad \text{for every } \nu > 0
\]

(9.6.39)

(where the first equality holds, since \( I_\nu \) is an open ideal in the \( m_\nu \)-adic topology of \( A \)). According to [43] Ch.0, Th.19.9.8] (and its proof), \( A^\nu \) contains a field isomorphic to \( k_0 := A/m_A \), and the inclusion map \( k_0 \rightarrow A^\nu \) extends to a surjective ring homomorphism \( k_0[[X_1, \ldots, X_t]] \rightarrow A^\nu \), such that \( X_i \mapsto x_i \) for \( i = 1, \ldots, t \). Denote by \( J \) the kernel of this surjection; in view of (9.6.39), we have

\[
\text{length}_A A, k_0[[X_1, \ldots, X_t]]/(J, X_1^{\nu t}, \ldots, X_t^{\nu t}) = q^{\nu t}
\]

which means that \( J \subset (X_1^{\nu t}, \ldots, X_t^{\nu t}) \) for every \( \nu > 0 \). We conclude that \( J = 0 \), and \( A^\nu = k_0[[X_1, \ldots, X_t]] \) is regular, so the same holds for \( A \).

As an application, let us point out the following combinatorial version of Kunz’s theorem:

**Theorem 9.6.40.** Let \( P \) be a monoid and \( k > 1 \) an integer; suppose that \( P^k \) is fine and the Frobenius endomorphism \( k_P : P \rightarrow P \) is flat (definition 4.8.40(ii)). Then \( P^k \) is a free monoid.

**Proof.** First, we remark that \( k_P^k : P^k \rightarrow P^k \) is still flat (corollary 6.1.50(i)). Moreover, \( k_P^k \) is injective. Indeed, suppose that \( x^k = y^k \cdot u \) for some \( x, y \in P \) and \( u \in P^k \); from theorem 6.1.43 we deduce that there exist \( b_1, b_2, t \in P \) such that

\[
b_1 x = b_2 y \quad 1 = b_1^k t \quad u = b_2^k t.
\]
Especially, \(b_1, b_2 \in P^\times\), so the images of \(x\) and \(y\) agree in \(P^2\). Hence, we may replace \(P\) by \(P^2\), and assume that \(k_P\) is flat and injective, in which case \(\mathbb{Z}[k_P] : \mathbb{Z}[P] \to \mathbb{Z}[P]\) is flat (theorem 6.2.3), integral and injective, hence it is faithfully flat. Now, let \(R\) be the colimit of the system of rings \((R_n \mid n \in \mathbb{N})\), where \(R_n := \mathbb{Z}[P]\), and the transition map \(R_n \to R_{n+1}\) is \(\mathbb{Z}[k_P]\) for every \(n \in \mathbb{N}\). The induced map \(j : R_0 \to R\) is still faithfully flat; moreover, let \(p\) be any prime divisor of \(k\), and notice that \(j \circ p_P = j\) (where \(p_P\) is the \(p\)-Frobenius map). It follows that \(p_P\) is flat and injective as well, so \(\mathbb{F}_p[p_P] : \mathbb{F}_p[P] \to \mathbb{F}_p[P]\) is a flat ring homomorphism (again, by theorem 6.2.3), and then the same holds for the induced map \(\mathbb{F}_p[[p_P]] : \mathbb{F}_p[[P]] \to \mathbb{F}_p[[P]]\). By theorem 6.3.17, we deduce that \(\mathbb{F}_p[[P]]\) is a regular local ring, with maximal ideal \(m := \mathbb{F}_p[[m_P]]\); notice that the images of the elements of \(m_P \setminus m_P^2\) yield a basis for the \(\mathbb{F}_p\)-vector space \(m/m^2\). Say that \(m_P \setminus m_P^2 = \{x_1, \ldots, x_s\}\); it follows that the continuous ring homomorphism
\[
\mathbb{F}_p[[T_1, \ldots, T_s]] \to \mathbb{F}_p[[P]] \quad T_i \mapsto x_i \quad \text{for } i = 1, \ldots, s
\]
is an isomorphism. From the discussion of (6.4.23), we immediately deduce that \(P \simeq \mathbb{N}^{\leq s}\), as required.

Next, we wish to present a characterization of regular local rings via the cotangent complex, borrowed from [3], which shall be used in the following section on excellent rings.

**Lemma 9.6.41.** Let \(A\) be a ring, \(f := (f_1, \ldots, f_n)\) a completely secant sequence of elements of \(A\), that generates an ideal \(I \subset A\), and set \(A_0 := A/I\). Then there is a natural isomorphism
\[
\mathbb{L}_{A_0/A} \simto I/I^2[1] \quad \text{in } D(A_0\text{-Mod})
\]
and \(I/I^2\) is a free \(A_0\)-module of rank \(n\).

**Proof.** The sequence \(f\) is quasi-regular, by proposition 7.8.15 so the second assertion follows from remark 7.8.16 ii). Next, set \(R := \mathbb{Z}[T_1, \ldots, T_n]\), and let \(u : R \to A\) be the unique ring homomorphism such that \(u(T_i) = a_i\) for \(i = 1, \ldots, n\). We get a coterminal diagram of rings:
\[
\begin{array}{ccc}
R & \xrightarrow{u} & A \\
p \downarrow & & \downarrow \\
\mathbb{Z} & \to & A_0
\end{array}
\]
with \(p\) the standard augmentation such that \(p(T_1) = \cdots = p(T_n) = 0\); also, \(\text{Tor}_1^R(\mathbb{Z}, A_0) = 0\) for every \(i > 0\), by lemma 7.8.14 i). By [82, Ch.II, Prop.2.2.1] there follows a natural isomorphism:
\[
A_0 \otimes_{\mathbb{Z}} \mathbb{L}_{\mathbb{Z}/R} \simto \mathbb{L}_{A_0/A} \quad \text{in } D(A_0\text{-Mod}).
\]
Thus, we are reduced to prove the sought isomorphism for the ring \(R\) and the regular sequence \((T_1, \ldots, T_n)\), in which case \(I = \text{Ker} p\), and \(R/I = \mathbb{Z}\). However, by [82, Ch.II, Prop.2.1.2], the sequence of ring homomorphisms \(\mathbb{Z} \to R \to \mathbb{Z}\) induces a distinguished triangle
\[
\mathbb{L}_{\mathbb{Z}/R}[-1] \to \mathbb{L}_{R/Z} \otimes \mathbb{Z} R \to \mathbb{L}_{\mathbb{Z}/Z} \to \mathbb{L}_{\mathbb{Z}/R} \quad \text{in } D(\mathbb{Z}\text{-Mod})
\]
and to conclude, it suffices to recall that \(\mathbb{L}_{\mathbb{Z}/Z} \simto 0\), and \(\mathbb{L}_{R/Z} \simto \Omega^1_{R/Z}[0]\), by virtue of [82, Ch.II, Prop.1.2.4.4].

**Proposition 9.6.42.** Let \((A, m)\) be a local noetherian ring, \(a \in m\), and \(A_0 := A/aA\). The following conditions are equivalent:

(a) \(a\) is a regular element of \(A\).

(b) \(H_2^a\mathbb{L}_{A_0/A} = 0\), and \(aA/a^2A\) is a free \(A_0\)-module of rank one.
Proof. For any ring \( R \), any non-invertible element \( x \in R \), and any \( n \in \mathbb{N} \), set \( R_n := R/xa^{n+1}R \), and consider the \( R_0 \)-linear map
\[
\beta_{x,n} : R_0 \to x^nR/xa^{n+1}R \quad (a \mod xR) \mapsto (x^n a \mod xa^{n+1}R).
\]
Notice that the sequence \((x)\) is \( R \)-quasi-regular if and only if \( \beta_{x,n} \) is an isomorphism for every \( n \in \mathbb{N} \) (see definition 7.8.13). We remark:

Claim 9.6.43. Suppose that \( R \) is a noetherian local ring, denote by \( \kappa_R \) the residue field of \( R \), and let \( n > 0 \) be any given integer. The following conditions are equivalent:

1. \( \beta_{x,n} \) is an isomorphism.
2. \( x^n \neq 0 \) and \( \text{Tor}_1^{R_0} (x^nR/xa^{n+1}R, \kappa_R) = 0 \).
3. \( x^n \neq 0 \) and the surjection \( R_0 \to \kappa_R \) induces a surjective map
\[
H_2(\mathbb{L}_{R_{n-1}/R} \otimes_{R_{n-1}} R_0) \to H_2(\mathbb{L}_{R_{n-1}/R} \otimes_{R_{n-1}} \kappa_R).
\]

Proof of the claim. It is easily seen that (c) \( \Leftrightarrow \) (d).

Conversely, if (d) holds, notice that \( x^nR/xa^{n+1}R \neq 0 \), as \( \bigcap_{n \in \mathbb{N}} x^nR = 0 \) ([100, Th.8.10(ii)]). Hence \( \kappa_R \otimes_R \beta_{x,n} \) is an isomorphism of one-dimensional \( \kappa_R \)-vector spaces. On the other hand, under assumption (d), the natural map \( \kappa_R \otimes_R \text{Ker} \beta_{x,n} \to \text{Ker}(\kappa_R \otimes_R \beta_{x,n}) \) is an isomorphism. By Nakayama’s lemma, we conclude that \( \text{Ker} \beta_{x,n} = 0 \), i.e. (c) holds.

Next, recall that \( H_0(\mathbb{L}_{R_{n-1}/R}) = 0 \) for every \( n \in \mathbb{N} \) ([82, Ch.II, Prop.1.2.4.2]); then the Künneth spectral sequence ([123, Th.5.6.4]) yields natural isomorphisms of \( R_0 \)-modules
\[
H_1(\mathbb{L}_{R_{n-1}/R} \otimes_{R_{n-1}} M) \cong x^nR/x^{2n}R \otimes_{R_{n-1}} M \cong x^nR/xa^{n+1}R \otimes R_0 M
\]
for every \( R_0 \)-module \( M \) ([82, Ch.III, Cor.1.2.8.1]). Denote by \( m_0 \subset R_0 \) the maximal ideal; there follows a left exact sequence
\[
0 \to \text{Tor}_1^{R_0} (x^nR/xa^{n+1}R, \kappa_R) \to H_1(\mathbb{L}_{R_{n-1}/R} \otimes_{R_{n-1}} m_0) \to H_1(\mathbb{L}_{R_{n-1}/R} \otimes_{R_{n-1}} R_0) \to 0
\]
which shows that (d) \( \Leftrightarrow \) (e) (details left to the reader). \( \diamond \)

Claim 9.6.44. Let \( f : R \to R' \) be a ring homomorphism, and \( x' := f(x) \). Suppose that \( \beta_{x,n} \) and \( \beta_{x',n} \) are bijections, for some \( n \in \mathbb{N} \), and set \( R'_n := R'/xa^{n+1}R' \). Then the induced morphism
\[
\mathbb{L}_{R_0/\mathbb{R}} \otimes_{R_0} R'_0 \to \mathbb{L}_{R_0/R_0} R'_n
\]
is an isomorphism in \( D(R'_0 \text{-Mod}) \).

Proof of the claim. If \( n = 0 \), there is nothing to prove, hence assume that \( n > 0 \). We remark that, for every \( i = 0, \ldots, n \), we have an exact complex
\[
R_n \xrightarrow{x^{i+1}} R_n \xrightarrow{x^{i}} R_n.
\]
Indeed, for \( i = 0 \), this results immediately from the assumption that \( \text{Ker} \beta_{n,x} = 0 \). Suppose that \( i > 0 \), and that the assertion is known for \( i = 1 \); then, if \( yx^{n-i} = x^{n+1}z \) for some \( y, z \in R \), the inductive hypothesis implies that \( y = x'u \) for some \( u \in R \). It follows that \( x^n(u - zx) = 0 \), and since \( \text{Ker} \beta_{n,x} = 0 \), thus, \( u \in xR \), and \( y \in x^{i+1}R \), as asserted.

We deduce that the \( R_n \)-module \( R_0 \) admits a free resolution
\[
\Sigma : \cdots \to R_n \xrightarrow{x} R_n \xrightarrow{x^n} R_n \xrightarrow{x} R_n \to R_0.
\]
The same argument applies to \( R' \) and its element \( x' \), and yields a corresponding free resolution \( \Sigma' \) of the \( R'_n \)-module \( R'_0 \). Clearly \( \Sigma' \otimes_{R_n} R'_0 = \Sigma \), i.e. the natural morphism \( R_0 \otimes_{R_n} R'_n \to R'_0 \) is an isomorphism in \( D(R'_0 \text{-Mod}) \). The claim then follows from [82, Ch.II, Prop.2.2.1]. \( \diamond \)

With these preliminaries, we may now return to the situation of the proposition: first, lemma 9.6.41 says that (a) \( \Rightarrow \) (b). For the converse, in light of proposition 7.8.15, it suffices to show that \( \beta_{a,n} : A_0 \to a^n A/a^{n+1}A \) is bijective for every \( n \in \mathbb{N} \). We shall argue by induction on \( n \).
For \( n = 0 \), there is nothing to prove. Assume that \( n > 0 \), and that the assertion is known for \( n - 1 \). Let \( n \subset A[T] \) be the (unique) maximal ideal containing \( T \), and set \( B := A[T]_n \).

We let \( B_n := B/T^{n+1}B \) and \( A_n := A/a^{n+1}A \) for every \( n \in \mathbb{N} \). Clearly \( \beta_{T,n-1} : B_0 \to T^{n-1}B/T^nB \) is bijective, and the same holds for \( \beta_{a,n-1} \), by inductive assumption. Then, claim \( 9.6.44 \) says that the induced morphism \( \mathbb{L}_{B_n/B_{n-1}} \otimes_{B_0} A_0 \to \mathbb{L}_{A_0/A_{n-1}} \) is an isomorphism in \( D(A_0\text{-Mod}) \).

Denote by \( \kappa \) the residue field of \( A \) and \( B \); by considering the Künneth spectral sequence

\[
E^2_{pq} := \text{Tor}^A_{p}(H_q\mathbb{L}_{A_0/A}, \kappa) \Rightarrow H_{p+q}(\mathbb{L}_{A_0/A} \otimes A_0, \kappa)
\]

\(([\text{125}} \text{ Ch.5.6.4})\) we get \( H_2(\mathbb{L}_{A_0/A} \otimes A_0, \kappa) = 0 \), by virtue of (b). Consequently, the commutative diagram of ring homomorphisms

\[
\begin{array}{ccc}
B & \longrightarrow & B_{n-1} \longrightarrow B_0 \\
\downarrow & & \downarrow \\
A & \longrightarrow & A_{n-1} \longrightarrow A_0
\end{array}
\]

induces a commutative ladder with exact rows \(([\text{82}} \text{ Ch.II, Prop.2.1.2})\) :

\[
\begin{array}{ccc}
H_3(\mathbb{L}_{B_0/B_{n-1}} \otimes B_0, \kappa) & \longrightarrow & H_2(\mathbb{L}_{B_{n-1}/B} \otimes B_{n-1}, \kappa) \longrightarrow H_2(\mathbb{L}_{B_0/B} \otimes B_0, \kappa) \\
\downarrow & & \downarrow \\
H_3(\mathbb{L}_{A_0/A_{n-1}} \otimes A_0, \kappa) & \longrightarrow & H_2(\mathbb{L}_{A_{n-1}/A} \otimes A_{n-1}, \kappa) \longrightarrow 0
\end{array}
\]

whose left vertical arrow is an isomorphism. It follows that the central vertical arrow is surjective. Consider now the commutative diagram induced by the maps \( B_0 \to A_0 \to \kappa \):

\[
\begin{array}{ccc}
H_2(\mathbb{L}_{B_{n-1}/B} \otimes B_{n-1}, B_0) & \longrightarrow & H_2(\mathbb{L}_{B_{n-1}/B} \otimes B_{n-1}, \kappa) \\
\downarrow & & \downarrow \\
H_2(\mathbb{L}_{A_{n-1}/A} \otimes A_{n-1}, A_0) & \longrightarrow & H_2(\mathbb{L}_{A_{n-1}/A} \otimes A_{n-1}, \kappa)
\end{array}
\]

\((9.6.45)\)

We have just seen that the right vertical arrow of \((9.6.45)\) is surjective, and the same holds for its top horizontal arrow, in light of claim \( 9.6.43 \). Thus, finally, the bottom horizontal arrow is surjective as well, so \( \beta_{a,n} \) is an isomorphism (claim \( 9.6.43 \)), and the proposition is proved. \( \square \)

**Theorem 9.6.46.** Let \((A, \mathfrak{m})\) be a local ring, and \( I \subset \mathfrak{m} \) an ideal; denote by \( \kappa \) the residue field of \( A \), and set \( A_0 := A/I \). Consider the following conditions :

(a) Every minimal system of generators of \( I \) is a regular sequence of elements of \( A \).

(b) \( I \) is generated by a regular sequence of \( A \).

(c) The natural morphism \( \mathbb{L}_{A_0/A} \to I/I^2[1] \) is an isomorphism in \( D(A_0\text{-Mod}) \), and \( I/I^2 \) is a flat \( A_0 \)-module.

(d) \( H_n(\mathbb{L}_{A_0/A} \otimes A_0, \kappa) = 0 \) for every \( n \geq 2 \).

(e) \( H_2(\mathbb{L}_{A_0/A} \otimes A_0, \kappa) = 0 \).

Then (a)\( \Rightarrow \) (b)\( \Rightarrow \) (c)\( \Rightarrow \) (d) \( \Rightarrow \) (e), and if \( A \) is noetherian, (e)\( \Rightarrow \) (a).

**Proof.** Clearly \( (a) \Rightarrow (b) \) and \( (d) \Rightarrow (e) \); moreover, \( (b) \Rightarrow (c) \), by lemma \( 9.6.41 \) and proposition \( 7.8.15 \) To see that \( (c) \Rightarrow (d) \), we invoke the Künneth spectral sequence \(([\text{125}} \text{ Th.5.6.4})\) :

\[
E^2_{pq} := \text{Tor}^A_{p}(H_q\mathbb{L}_{A_0/A}, \kappa) \Rightarrow H_{p+q}(\mathbb{L}_{A_0/A} \otimes A_0, \kappa)
\]

\((9.6.47)\)

Lastly, let us check that \( (e) \Rightarrow (a) \) when \( A \) is noetherian. Thus, let \((a_1, \ldots, a_n)\) be a minimal system of generators for \( I \); recall that \( n = \dim_\kappa I \otimes_A \kappa \). We argue by induction on \( n \). If \( n = 0 \),
there is nothing to show. If \( n = 1 \), recall that \( H_0 \mathbb{L}_{A_0/A_1} = 0 \) and \( H_1 \mathbb{L}_{A_0/A_1} = I/I^2 \) \(^{(82)}\) Ch.II, Prop.1.2.4.2 and Ch.III, Cor.1.2.8.1\)); then from the spectral sequence \((9.6.47)\) we deduce that
\[
\text{Tor}^1_{A_0}(I/I^2, \kappa) = E^2_{1,1} = E^\infty_{1,1} = 0
\]
so \( I/I^2 \) is a flat \( A_0 \)-module, by the local flatness criterion \((100)\) Th.22.3\). Then, again from \((9.6.47)\) it follows easily that
\[
H_2(\mathbb{L}_{A_0/A_0}) \otimes A_0 \kappa = E^2_{0,2} = E^\infty_{0,2} = 0
\]
and by \(^{(82)}\) Ch.II, Cor.2.3.7\], the \( A_0 \)-module \( H_2 \mathbb{L}_{A_0/A_0} \) is of finite type, so that \( H_2 \mathbb{L}_{A_0/A_0} = 0 \), by Nakayama’s lemma; we may then conclude with proposition \((9.6.42)\).

Next, suppose that \( n > 1 \), and that the assertion is already known when \( \dim_n I \otimes_A \kappa < n \). Set \( B := A/a_1 A \) and \( J := IB \). The ring homomorphisms \( A \to B \to A_0 \) induce exact sequences
\[
0 \to H_2(\mathbb{L}_{A_0/B} \otimes A_0 \kappa) \to H_1(\mathbb{L}_{B/A} \otimes B \kappa) \to I \otimes_A \kappa \to J \otimes_B \kappa \to 0
\]
\((82)\) Ch.II, Prop.2.1.2 and Ch.III, Cor.1.2.8.1\]). However, clearly \( J \) admits a generating system of length \( n - 1 \), hence \( n' := \dim_n J \otimes_B \kappa < n \). But \( \dim_n H_1(\mathbb{L}_{B/A} \otimes B \kappa) = 1 \), so we have necessarily \( n' = n - 1 \) and \( H_2(\mathbb{L}_{A_0/B} \otimes A_0 \kappa) = 0 \). By inductive assumption, the sequence \( (\overline{a}_2, \ldots, \overline{a}_n) \) of the images in \( B \) of \( (a_2, \ldots, a_n) \), is then regular. By virtue of lemma \((9.6.41)\) and proposition \((7.8.15)\) it follows that \( H_3(\mathbb{L}_{A_0/B} \otimes A_0 \kappa) = 0 \), whence, \( H_3(\mathbb{L}_{B/A} \otimes B \kappa) = 0 \), so \( a_1 \) is a regular element in \( A \), and finally, \( (a_1, \ldots, a_n) \) is a regular sequence, as stated. \(\Box\)

**Corollary 9.6.48.** Let \((A, m)\) be a local noetherian ring, with residue field \( \kappa \). The following conditions are equivalent:

(a) \( A \) is regular.

(b) The natural morphism \( \mathbb{L}_m/A \to m/m^2[1] \) is an isomorphism in \( \text{D}(\kappa\text{-Mod}) \).

(c) \( H_2 \mathbb{L}_m/A = 0 \).

**Proof.** It follows immediately, by invoking theorem \((9.6.46)\) with \( I := m \). \(\Box\)

We conclude this section with a desingularization result that can also be found in \((93)\) Lemma 3.10, and is closely related to \((97)\) Prop.1.2.8\).

**9.6.49.** Let \((A, m)\) be a local noetherian domain, \( p \subset A \) a prime ideal with \( \dim A/p = 1 \). We define inductively as follows, an inverse system of \( A \)-schemes:
\[
\cdots \to X_2 \xrightarrow{i_1} X_1 \xrightarrow{i_0} X_0
\]
and for every \( n \in \mathbb{N} \) a reduced subscheme \( C_n \subset X_n \), with \( \pi_n(C_{n+1}) = C_n \). Set \( X_0 := \text{Spec } A \) and \( C_0 := \text{Spec } A/p \). For every \( n \in \mathbb{N} \), let \( Z_n \subset C_n \) be the pre-image of \( m \), endowed with its reduced subscheme structure, and \( J_n \subset \mathcal{O}_{X_n} \) the ideal defining \( Z_n \); we let \( \pi_n : X_{n+1} \to X_n \) be the blow-up of \( J_n \), and \( C_{n+1} \subset X_{n+1} \) the strict transform of \( C_n \). For every \( n \in \mathbb{N} \), let also \( i_n : C_n \to X_n \) be the closed immersion, and set \( \mathcal{J}_n := \text{Ker}(\mathcal{O}_{X_n} \to i_n^* \mathcal{O}_{C_n}) \).

**Proposition 9.6.50.** In the situation of \((9.6.49)\), suppose that the normalization \((A/p)^e \) of \( A/p \) is a finite \( A/p \)-algebra. Then there exists \( n_0 \in \mathbb{N} \) such that for every \( n \geq n_0 \) we have:

(i) \( C_n \) is a regular scheme.

(ii) \( \mathcal{J}_n^{m} / \mathcal{J}_n^{m+1} \) is a torsion-free \( \mathcal{O}_{C_n, z} \)-module, for every \( z \in Z_n \) and every \( m \in \mathbb{N} \).

(iii) If moreover, \( A_q \) is a regular ring, the same holds for \( \mathcal{O}_{X_n, z} \), for every \( z \in Z_n \).

**Proof.** (i) Recall that the restriction \( \pi_n : C_{n+1} \to C_n \) of \( \pi_n \) is the blowup of the ideal \( \mathcal{J}_n \subset \mathcal{O}_{C_n} \) defining \( Z_n \), for every \( n \in \mathbb{N} \); we notice:

**Claim 9.6.51.** \( \pi_n \) is a finite morphism, for every \( n \in \mathbb{N} \).

Proof of the claim. Clearly, $C_{n+1}$ is an integral scheme, and $\pi_n$ is projective and induces an isomorphism $\pi_n^{-1}(C_n \setminus Z_n) \xrightarrow{\sim} C_n \setminus Z_n$. Let $y \in C_{n+1}$ be any point with $z := \pi_n(y) \in Z_n$; the induced map $\Theta_{C_n,z} \to \Theta_{C_{n+1},y}$ is injective, and induces an isomorphism of the respective fields of fractions. Moreover, dim $\Theta_{C_{n+1},y} \geq 1$, hence the transcendence degree of the residue field extension $\kappa(z) \to \kappa(y)$ is 0, by [100, Th.15.5]. By [100, Th.5.6], this implies that $\pi_n^{-1}(z)$ is a $\kappa(z)$-scheme of dimension 0 and of finite type, for every $z \in Z_n$, so $\pi_n^{-1}(x)$ is a finite set, for every $x \in C_n$. Then the claim follows from [50, Ch.IV, Th.8.11.1].

From claim [9.6.51] we have $C_n = \text{Spec } R_n$, for some finite $A/p$-algebra $R_n$ lying in the normalization $(A/p)^\nu$ of $A/p$. Since $A/p$ is noetherian and $(A/p)^\nu$ is a finite $A/p$-algebra, it follows that there exists $n_0 \in \mathbb{N}$ such that $\pi_n$ is an isomorphism for every $n \geq n_0$. The latter means that $\mathcal{F}_n$ is an invertible ideal for every such $n$, whence the assertion.

(ii,iii): By (i) we find $k \in \mathbb{N}$ such that $C_k = \text{Spec } (A/p)^\nu$. We then get an inverse system

$$\cdots \to X_k(z) \times_{X_k} X_{k+2} \to X_k(z) \times_{X_k} X_{k+1} \to X_k(z)$$

for every $z \in Z_k$

(notation of definition [4.9.17](iii)) whose transition morphism $X_k(z) \times_{X_k} \pi_{k+1}$ is the blow-up of the restriction of $\pi_{k+1}$, for every $n \in \mathbb{N}$. Since $Z_k$ has finitely many points, it suffices therefore to prove the assertions for $A$ replaced by $A_z := \Theta_{X_k,z}$ and $p$ replaced by the prime ideal $p_z \subset A_z$ such that $\text{Spec } A_z/p_z = C_k(z)$, for every $z \in Z_k$. Thus, we may assume that $A/p$ is regular, and $\pi_n$ is an isomorphism $C_{n+1} \xrightarrow{\sim} C_n$, so that $Z_n$ has a unique point $z_n$, for every $n \in \mathbb{N}$. Let

$$A_n := \Theta_{X_n,z_n} \quad m_n := \mathcal{I}_{n,z_n} \quad p_n := \mathcal{I}_{n,z_n}$$

for every $n \in \mathbb{N}$

so that $X_n(z_n) = \text{Spec } A_n$. For given $n \in \mathbb{N}$, let $x_1, \ldots, x_k$ be a finite system of generators of $p_n$, and $x_0 \in m_n$ any element whose image in $A_n/p_n$ generates the ideal $m_n/p_n$, so that the system $x_0, \ldots, x_k$ generates the ideal $m_n$. We have already remarked that $X_n(z_n) \times_{X_n} \pi_n$ is the blow-up of the ideal $(\mathcal{I}_{n,z_n})_{X_n(z_n)}$; hence, $X_n(z_n) \times_{X_n} X_{n+1}$ admits the affine open covering $U_0 \cup \cdots \cup U_k$, where $U_i := \text{Spec } B_i$, with $B_i := A_n[x_i/z_i, \ldots, x_k/z_i]$ for every $i = 0, \ldots, k$.

Claim 9.6.52. (i) $C_{n+1} \subset U_0$.

(ii) $x_1/x_0, \ldots, x_k/x_0$ generate a prime ideal $q_n \subset B_0$.

(iii) $m_n := B_0x_0 + q_n$ is a maximal ideal of $B_0$.

(iv) The induced maps $A_n/p_n \to B_0/q_n \to A_{n+1}/p_{n+1}$ are isomorphisms.

Proof of the claim. (i): The universal property of the blow-up $X_n(z_n) \times_{X_n} \pi_n$ says that for $i = 0, \ldots, k$, every morphism of schemes $f : T \to X_n(z_n)$ such that $f^{-1}(\mathcal{I}_{n,z_n}) \cdot \Theta_T$ is invertible and generated by the image of $x_i$, factors uniquely through $U_i$. Especially, the projection $X_n(z_n) \times_{X_n} C_{n+1} \to X_n(z_n)$ factors through $U_0$, whence (i).

(ii,iv): From (i) we get a commutative diagram of schemes

$$\begin{array}{ccc}
X_n(z_n) \times_{X_n} C_{n+1} & \longrightarrow & U_0 \\
\downarrow & & \downarrow \\
X_n(z_n) \times_{X_n} C_n & \longrightarrow & X_n(z_n)
\end{array}$$

whose horizontal arrows are closed immersions, and whose left vertical arrow is an isomorphism. Hence, the induced morphism

(9.6.53) $X_n(z_n) \times_{X_n} C_{n+1} \to U_0 \times_X C_n = \text{Spec } B_0/p_n B_0$

is a closed immersion. However, $X_n(z_n) \times_{X_n} C_{n+1} = \text{Spec } A_{n+1}/p_{n+1}$, and notice that $x_0$ annihilates the ideal $q_n/p_n B_0$ of $B_0/p_n B_0$, since $x_0$ is a regular element of $A_{n+1}/p_{n+1}$, it follows that the map $B_0/p_n B_0 \to A_{n+1}/p_{n+1}$ corresponding to (9.6.53) factors through a surjection $f : B_0/q_n \to A_{n+1}/p_{n+1}$. On the other hand, the unique map of $A_n$-algebras $A_n \to B_0/q_n$
factors through a surjection \( g : A_n/p_n \to B_0/q_n \), and by assumption \( f \circ g \) is an isomorphism, whence both (ii) and (iv).

(iii): From (iv) we get surjections \( A_n/m_n \to B_0/n_{n+1} \to A_{n+1}/m_{n+1} \), whence the claim. ◊

In light of claim [9.6.52](ii,iv), and since \( A_{n+1} \) is a localization of \( B_0, \) we see that \( p_{n+1} \) is generated by the images of \( x_1/x_0, \ldots, x_k/x_0; \) whence, for every \( m \in \mathbb{N}, \) an \( A_n/p_n \)-linear map

\[
\varphi_{n,m} : p_n^m/p_n^{m+1} \to p_{n+1}^m/p_{n+1}^{m+1} \quad (y \mod p_n^{m+1}) \mapsto (x_0^{-m}y \mod p_{n+1}^{m+1})
\]

whose image contains a set of generators for the \( A_{n+1}/p_{n+1} \)-module \( p_{n+1}^m/p_{n+1}^{m+1}. \) Since the natural map \( A_n/p \to A_{n+1}/p_{n+1} \) is an isomorphism, it follows that \( \varphi_{n,m} \) is surjective, for every \( m \in \mathbb{N}. \) Moreover, set \( R_n := \bigoplus_{m \in \mathbb{N}} p_n^m/p_n^{m+1} \) for every \( n \in \mathbb{N}; \) it is easily seen that the direct sum of the maps \( \varphi_{n,m} \) yields a surjective map of graded \( A_n/p_n \)-algebras:

\[
\varphi_n : R_n \to R_{n+1}.
\]

Claim 9.6.54. (i) \( A_n[x_0^{-1}] \otimes A_n \varphi_n \) is an isomorphism.

(ii) \( \text{Ann}_{R_n}(m_n) \subset \text{Ker} \varphi_n. \)

Proof of the claim. (i): We have already remarked that \( A_{n+1} \) is a localization of \( B_0, \) and \( p_{n+1} = q_n A_{n+1}; \) hence \( p_{n+1}^m/p_n^{m+1} = A_n \otimes B_0 q_n^m/q_n^{m+1}, \) so that \( \varphi_{n,m} \) is a composition:

\[
p_n^m/p_n^{m+1} \xrightarrow{\alpha_m} q_n^m/q_n^{m+1} \xrightarrow{\beta_m} p_{n+1}^m/p_{n+1}^{m+1}
\]

where \( \alpha_m \) is given by the rule \((y \mod p_n^{m+1}) \mapsto (x_0^{-m}y \mod q_n^{m+1}), \) for every \( y \in p_n^m, \) and \( \beta_m \) is the localization. Since the localization \( B_0 \to A_{n+1} \) induces an isomorphism \( B_0/q_n \xrightarrow{\sim} A_{n+1}/p_{n+1} \) (claim [9.6.52](iii)), the map \( \beta_m \) is bijective for every \( m \in \mathbb{N}. \) Thus, we need to check that \( A_n[x_0^{-1}] \otimes A_n \alpha_m \) is bijective for every \( m \in \mathbb{N}. \) However, clearly \( A_n[1/x_0] = B_0[1/x_0], \) and \( p_n[1/x_0] = q_n[1/x_0] \) in \( B_0[1/x_0], \) whence the assertion.

(ii): We come down to checking that the annihilator of \( x_0 \) in \( p_n^m/p_n^{m+1} \) lies in \( \text{Ker} \varphi_{n,m}, \) for every \( m \in \mathbb{N}. \) Hence, let \( y \in p_n^m \) whose class \( \overline{y} \) is annihilated by \( x_0; \) the latter means that there exist polynomials \( P,Q \in A_n[X_1, \ldots, X_k] \) homogeneous of degree \( n \) and respectively \( n + 1, \) such that \( y = P(x_1, \ldots, x_k), \) and \( x_0y = Q(x_1, \ldots, x_k). \) It follows that

\[
x_0^{m+1}P(x_1/x_0, \ldots, x_k/x_0) = x_0^{m+1}Q(x_1/x_0, \ldots, x_k/x_0)
\]

whence \( t := P(x_1/x_0, \ldots, x_k/x_0) = Q(x_1/x_0, \ldots, x_k/x_0) \) in \( B_0, \) since \( x_0 \) is regular in this ring. But \( \alpha_m(\overline{y}) \) is precisely the class of \( t \) in \( q_n^m/q_n^{m+1}, \) so \( \alpha_m(\overline{y}) = 0, \) whence the assertion. ◊

Now, set \( J_r := \text{Ann}_{R_0}(m_0^r) \) for every \( r \in \mathbb{N}; \) since \( R_0 \) is noetherian, there exists \( r \in \mathbb{N} \) such that \( J_r = J_{r+1}. \) Also, clearly \( \text{Ann}_{R_n}(m_n^r) = \text{Ann}_{R_{n+1}}(m_n^r). \) In light of claim [9.6.54] it then follows easily that \( \text{Ker} (\varphi_n \circ \cdots \circ \varphi_0) = J_r \) for every \( n \geq r, \) and \( R_0/J_r \xrightarrow{\sim} R_n \) is then a torsion-free \( A_0/p_0 \)-algebra for every \( n \geq r, \) whence (ii).

It follows in particular that \( p_n^m/p_n^{m+1} \) is a free \( A_n/p_n \)-module of finite rank for every \( n \geq r \) and every \( m \in \mathbb{N}, \) since it is torsion-free, and since \( A_n/p_n \) is a discrete valuation ring. According to [51], Ch.IV, Cor.19.1.2, proposition 7.8.15 and remark 7.8.1(i,ii), in order to show (iii) it then suffices to check that the natural map of graded \( A_n/p_n \)-algebras

\[
\psi : \text{Sym}_{A_n}^*(p_n/p_n^2) \to R_n
\]

is an isomorphism for every \( n \geq r. \) Now, by the same token, \( \text{Sym}_{A_n}^*(p_n/p_n^2) \) is a free \( A_n/p_n \)-module of finite rank, for every \( n \geq r \) and every \( m \in \mathbb{N}; \) Since \( \psi \) is surjective, it then suffices to check that these modules have the same rank, for every such \( n \) and \( m. \) However, notice that the structure map \( A \to A_n \) induces an isomorphism \( A_p \xrightarrow{\sim} (A_n)_{p_n}, \) for every \( n \in \mathbb{N}, \) hence \( (A_n)_{p_n} \) is a regular ring for each such \( n, \) under the assumptions of (iii). Invoking again [51] Ch.IV, Cor.19.1.2, proposition 7.8.15 and remark 7.8.16 we deduce that the localization \( \psi_{p_n} \) of \( \psi \) is an isomorphism for every \( n \geq r, \) whence the contention. ◊
Definition 9.6.55. Let $A$ be a noetherian ring. We say that $A$ is a Nagata ring, if for every $p \in \text{Spec } A$ and every finite field extension $\kappa(p) \subset L$, the integral closure of $A/p$ in $L$ is a finite $A$-module. (Such rings are called universally japanese in [48, Ch.0, Déf.23.1.1].)

Corollary 9.6.56. Let $(A, m)$ be a Nagata local domain such that the regular locus of $\text{Spec } A$ is an open subset. Then there exist a regular local domain $(A', m')$ and an injective local ring homomorphism $A \to A'$ of essentially finite type, such that :

(i) The induced map $\text{Frac}(A) \to \text{Frac}(A')$ is an isomorphism.
(ii) The induced map $A/m \to A'/m'$ is a finite field extension.

Proof. Recall that the regular locus $U$ of $X := \text{Spec } A$ is the set of all $p \in X$ such that $A_p$ is a regular ring. If $U = \text{Spec } A$, we may take $A' = A$; hence, suppose that $U$ is a proper subset of $X$. Since $A$ is noetherian, we may find $p \in U$ such that $U \cap \text{Spec } A/p = \{ p \}$. Especially, $\{ p \}$ is an open subset of $\text{Spec } A/p$, hence there exists $f \in A \setminus p$ such that $\text{Spec } (A/p)_f = \{ p \}$, so that $(A/p)_f$ is a field. By [48, Ch.0, Cor.16.3.3], it follows that dim $A/p = 1$. Then the assertion follows immediately from proposition 9.6.50(iii) and claim 9.6.51.

9.7. Regular morphisms and excellent rings. Recall that a morphism of schemes $f : X \to Y$ is called regular, if it is flat, and for every $y \in Y$, the fibre $f^{-1}(y)$ is locally noetherian and geometrically regular ([49, Ch.IV, Déf.6.8.1]).

Lemma 9.7.1. Let $f : X \to Y$ and $g : Y \to Z$ be two morphisms of locally noetherian schemes. We have :

(i) If $f$ and $g$ are regular, then the same holds for $g \circ f$.
(ii) If $g \circ f$ is regular, and $f$ is faithfully flat, then $g$ is regular.

Proof. (i): Clearly $h := g \circ f$ is flat. Let $z \in Z$ be any point, and $K$ any finite extension of $\kappa(z)$. Set

$$X' := h^{-1}(z) \times_{K} K$$

and

$$Y' := g^{-1}(z) \times_{K} K.$$

It is easily seen that the induced morphism $f' : X' \to Y'$ is regular. Moreover, for every $y \in Y'$, the local ring $\mathcal{O}_{Y', y'}$ is regular, since $g$ is regular. Then the assertion follows from :

Claim 9.7.2. Let $A \to B$ be a flat and local ring homomorphism of local noetherian rings. Denote by $m_A \subset A$ the maximal ideal, and suppose that both $A$ and $B_0 := B/m_A B$ are regular. Then $B$ is regular.

Proof of the claim. On the one hand, $\text{dim } B = \text{dim } A + \text{dim } B_0$ ([48, Ch.IV, Cor.6.1.2]). On the other hand, let $a_1, \ldots, a_n$ be a minimal generating system for $m_A$, and $b_1, \ldots, b_m$ a system of elements of the maximal ideal $m_B$ of $B$, whose images in $B_0$ is a minimal generating system for $m_B/m_A B$. By Nakayama’s lemma, it is easily seen that the system $a_1, \ldots, a_n, b_1, \ldots, b_m$ generates the ideal $m_B$. Since $A$ and $B_0$ are regular, $n = \text{dim } A$ and $m = \text{dim } B$, so $n + m = \text{dim } B$, and the claim follows.

(ii): Clearly $g$ is flat. Then the assertion follows easily from [48, Ch.0, Prop.17.3.3(i)] : details left to the reader.

Definition 9.7.3. Let $A$ be a noetherian ring.

(i) We say that $A$ is a $G$-ring, if the formal fibres of $\text{Spec } A$ are geometrically regular, i.e. for every $p \in \text{Spec } A$, the natural morphism $\text{Spec } A_p^\wedge \to \text{Spec } A_p$ from the spectrum of the $p$-adic completion of $A$, is regular : see [49, Ch.IV, §7.3.13].

(ii) We say that $A$ is quasi-excellent, if $A$ is a $G$-ring, and moreover the following holds. For every prime ideal $p \subset A$, and every finite radical extension $K'$ of the field of fractions $K$ of $B := A/p$, there exists a finite $B$-subalgebra $B'$ of $K'$ such that the field of fractions of $B'$ is $K'$, and the regular locus of $\text{Spec } B'$ is an open subset (the latter is the set of all prime ideals $q \subset B'$ such that $B'_q$ is a regular ring).
(iii) We say that $A$ is c \textit{catenarian} if any two saturated chains $(p_0 \subset \cdots \subset p_n)$, $(q_0 \subset \cdots \subset q_m)$ of prime ideals of $A$, with $p_0 = q_0$ and $p_n = q_m$, have the same length (so $n = m$) ([49, Ch.IV, D\textsuperscript{é}f.5.6.2]). We say that $A$ is \textit{universally catenarian} if every $A$-algebra $B$ of finite type is catenarian.

(iv) We say that $A$ is \textit{excellent}, if it is quasi-excellent and universally catenarian ([49, Ch.IV, D\textsuperscript{é}f.7.8.2]).

\textbf{Lemma 9.7.4.} Let $A$ be a noetherian ring.

(i) If $A$ is quasi-excellent, then $A$ is a Nagata ring (see definition 9.6.55).

(ii) If $A$ is a G-ring, then every quotient and every localization of $A$ is a G-ring.

(iii) Suppose that the natural morphism $\text{Spec } A_\mathfrak{m}^\wedge \rightarrow \text{Spec } A_\mathfrak{m}$ is regular for every maximal ideal $\mathfrak{m} \subset A$. Then $A$ is a G-ring.

(iv) If $A$ is a local G-ring, then $A$ is quasi-excellent.

(v) If $A$ is a complete local ring, then $A$ is excellent.

\textbf{Proof.} (i): This is [49, Ch.IV, Cor.7.7.3].

(ii): The assertion for localizations is obvious. Next, if $I \subset A$ is any ideal, and $\mathfrak{p} \subset A$ any prime ideal containing $I$, then $(A/I)^\wedge_\mathfrak{p}_{} = A_\mathfrak{p}^\wedge_{} / IA_\mathfrak{p}^\wedge_{}$, from which it is immediate that $A/I$ is a G-ring, if the same holds for $A$.

(iv) follows from [49, Ch.IV, Th.6.12.7, Prop.7.3.18, Th.7.4.4(ii)].

(v): In light of (iv), it suffices to remark that every complete noetherian local ring is universally catenarian ([49, Ch.IV, Prop.5.6.4] and [48, Ch.0, Th.19.8.8(i)]) and is a G-ring ([48 Ch.0, Th.22.3.3, Th.22.5.8, and Prop.19.3.5(iii)]).

(iii): Let us remark, more generally:

\textbf{Claim 9.7.5.} Let $\varphi : A \rightarrow B$ be a faithfully flat ring homomorphism of noetherian rings, such that $f := \text{Spec } \varphi$ is regular. If $B$ is a G-ring, the same holds for $A$.

\textbf{Proof of the claim.} In light of (ii), we easily reduce to the case where both $A$ and $B$ are local, $\varphi$ is a local ring homomorphism, and it suffices to show that the natural morphism $\pi_A : \text{Spec } A^\wedge \rightarrow \text{Spec } A$ is regular (where $A^\wedge$ is the completion of $A$). Consider the commutative diagram:

$$
\begin{array}{ccc}
\text{Spec } B^\wedge & \xrightarrow{f^\wedge} & \text{Spec } A^\wedge \\
\pi_B \downarrow & & \downarrow \pi_A \\
\text{Spec } B & \xrightarrow{f} & \text{Spec } A.
\end{array}
$$

(9.7.6)

By assumption, $\pi_B$ is a regular morphism; Then the same holds for $f \circ \pi_B = \pi_A \circ f^\wedge$ (lemma 9.7.1(i)). However, it is easily seen that the induced map $\varphi^\wedge : A^\wedge \rightarrow B^\wedge$ is still a local ring homomorphism, hence $f^\wedge$ is faithfully flat, so the claim follows from lemma 9.7.1(ii). \hfill \Diamond

Now, in order to prove (iii), it suffices to check that $A_\mathfrak{m}$ is a G-ring for every maximal ideal $\mathfrak{m} \subset A$. In view of our assumption, the latter assertion follows from claim 9.7.5 and (v). \hfill \Box

\textbf{Proposition 9.7.7.} Let $A$ be a ring, $B$ a noetherian $A$-algebra of finite (Krull) dimension, $n \in \mathbb{N}$ an integer, and suppose that $H_k(L_{B/A} \otimes_B \kappa(p)) = 0$ for every prime ideal $\mathfrak{p} \subset B$ and every $k = n_1, \ldots, n + \dim B$. Then $H_n(L_{B/A} \otimes_B M) = 0$ for every $B$-module $M$.

\textbf{Proof.} Let us start out with the following more general:

\textbf{Claim 9.7.8.} Let $A$ be a ring, $B$ a noetherian $A$-algebra, $\mathfrak{p} \in \text{Spec } B$ a prime ideal, $n \in \mathbb{N}$ an integer, and suppose that the following two conditions hold:

(a) $H_n(L_{B/A} \otimes_B \kappa(p)) = 0$.

(b) $H_{n+1}(L_{B/A} \otimes_B B/q) = 0$ for every proper specialization $q$ of $\mathfrak{p}$ in $\text{Spec } B$. 
Then, \( H_n(\mathbb{L}_{B/A} \otimes_B B/p) = 0 \).

**Proof of the claim.** Let \( b \in B \setminus p \) be any element, and set \( M := B/(p + BB) \). Since \( B \) is noetherian, \( M \) admits a finite filtration \( M_0 \subset M_1 \subset \cdots \subset M_n := M \) such that, for every \( i = 0, \ldots, n - 1 \), the subquotient \( M_{i+1}/M_i \) is isomorphic to \( B/q \), for some proper specialization \( q \) of \( p \) ([100, Th.6.4]). From (b), and a simple induction, we deduce that \( H_n+1(\mathbb{L}_{B/A} \otimes_B M) = 0 \). Whence, by considering the short exact sequence of modules

\[
0 \to B/p \to B/p \to M \to 0
\]

we see that scalar multiplication by \( b \) is an injective map on the \( B \)-module \( H_n(\mathbb{L}_{B/A} \otimes_B B/p) \). Since this holds for every \( b \in B \setminus p \), we conclude that the natural map

\[
H_n(\mathbb{L}_{B/A} \otimes_B B/p) \to H_n(\mathbb{L}_{B/A} \otimes_B B/p) \otimes_B B_p = H_n(\mathbb{L}_{B/A} \otimes_B \kappa(p))
\]

is injective. Then the assertion follows from (a).

Now, let \( p \subset B \) be any prime ideal; the assumption, together with claim 9.7.8 and a simple induction on \( d := \dim B/p \), shows that

\[
H_k(\mathbb{L}_{B/A} \otimes_B B/p) = 0 \quad \text{for every } k = n, \ldots, n + \dim B - d.
\]

For any \( B \)-module \( M \), set \( H(M) := H_n(\mathbb{L}_{B/A} \otimes_B M) \). Especially, we get \( H(B/p) = 0 \), for any prime ideal \( p \subset B \). Since \( B \) is noetherian, it follows easily that \( H(M) = 0 \) for any \( B \)-module \( M \) of finite type (details left to the reader). Next, if \( M \) is arbitrary, we may write it as the union of the filtered family \( (M_i \mid i \in I) \) of its submodules of finite type; since \( H(M) \) is the colimit of the induced system \( (H(M_i) \mid i \in I) \), we see that \( H(M) = 0 \), as sought.

**Corollary 9.7.9.** Let \( A \to B \) be a homomorphism of noetherian rings. Then the following conditions are equivalent:

(a) \( \Omega_{B/A}^1 \) is a flat \( B \)-module, and \( H_i \mathbb{L}_{B/A} = 0 \) for every \( i > 0 \).

(b) \( \Omega_{B/A}^1 \) is a flat \( B \)-module, and \( H_1 \mathbb{L}_{B/A} = 0 \).

(c) The induced morphism of schemes \( f : \text{Spec } B \to \text{Spec } A \) is regular.

(d) \( H_1(\mathbb{L}_{B/A} \otimes_B \kappa(x)) = 0 \) for every \( x \in \text{Spec } B \).

**Proof.** Set \( X := \text{Spec } B \) and \( Y := \text{Spec } A \); let \( x \in X \), and \( y := f(x) \). We remark :

Claim 9.7.10. The following conditions are equivalent :

(e) the map on stalks \( \mathcal{O}_{Y,y} \to \mathcal{O}_{X,x} \) is formally smooth for the preadic topologies defined by the maximal ideals.

(f) \( f \) is flat at the point \( x \), and the \( \kappa(y) \)-algebra \( \mathcal{O}_{f^{-1}(y),x} \) is geometrically regular.

(g) \( H_i(\mathbb{L}_{B/A} \otimes_B \kappa(x)) = 0 \).

(h) \( H_i(\mathbb{L}_{B/A} \otimes_B \kappa(x)) = 0 \) for every \( i > 0 \).

**Proof of the claim.** The equivalence (e)⇔(f) follows from [43, Ch.0, Th.19.7.1]. Next, to ease notation, set \( A' := \mathcal{O}_{X,x} \) and \( B' := \mathcal{O}_{Y,y} \); we have a natural identification

\[
\mathbb{L}_{B/A} \otimes_B \kappa(x) \xrightarrow{} \mathbb{L}_{B'/A'} \otimes_{B'} \kappa(x)
\]

([82, Ch.II, Cor.2.3.1.1]) from which we get (e)⇔(g), by virtue of proposition 8.6.30. Obviously, (h)⇔(g). Conversely, suppose that (g) holds, and set \( A'' := \kappa(x) \) and \( B'' := A'' \otimes_{A'} B' \); by the foregoing, we know already that \( B' \) is a flat \( A' \)-algebra, so we get an isomorphism

\[
\mathbb{L}_{B'/A'} \otimes_{B'} \kappa(x) \xrightarrow{} \mathbb{L}_{B''/A''} \otimes_{B''} \kappa(x)
\]

([82, Ch.II, Prop.2.2.1]). Moreover, \( B'' \) is a regular local ring; in view of corollary 9.6.48, the sequence of ring homomorphisms \( A'' \to B'' \to \kappa(x) \) then yields an isomorphism

\[
H_i(\mathbb{L}_{B''/A''} \otimes_{B''} \kappa(x)) \xrightarrow{} H_i \mathbb{L}_{\kappa(x)/A''} \quad \text{for every } i > 1
\]
Combining with proposition 9.6.1(i), we get (h).  

From claims 9.7.10 we already see that (a) \(\Rightarrow\)(b) \(\Rightarrow\)(c) \(\Rightarrow\)(d). Lastly, suppose that (d) holds; in order to show that \(\Omega_{B/A}^1\) is a flat \(B\)-module, it suffices to check that \(\text{Tor}_1^B(H_0 \mathcal{L}_{B/A}, M) = 0\) for every \(B\)-module \(M\). To this aim, recall the Künneth spectral sequence

\[
E_{p,q}^2 := \text{Tor}_p^B(H_0 \mathcal{L}_{B/A}, M) \Rightarrow H_{p+q}(\mathcal{L}_{B/A} \otimes_B M). 
\]

It is easily seen that \(E_{0,0}^2 = E_{1,0}^\infty\), so we are reduced to proving that \(H_1(\mathcal{L}_{B/A} \otimes_B M) = 0\) for every such \(M\). Then, proposition 9.7.7 further reduces to checking that \(H_i(\mathcal{L}_{B/A} \otimes_B \kappa(x)) = 0\) for every \(i > 0\). The latter follows from (d) and claim 9.7.10. Likewise, taking \(M := B\), and arguing with proposition 9.7.7 and claim 9.7.10, we also deduce that \(H_i \mathcal{L}_{B/A} = 0\) for every \(i > 0\), whence (a).

**Corollary 9.7.11.** Let \(A\) be a local noetherian ring, \(A^\wedge\) the completion of \(A\). Then the following conditions are equivalent:

(a) \(A\) is quasi-excellent.
(b) \(\Omega_{A^\wedge/A}^1\) is a flat \(A^\wedge\)-module, and \(H_1 \mathcal{L}_{A^\wedge/A} = 0\).
(c) \(\Omega_{A^\wedge/A}^1\) is a flat \(A^\wedge\)-module, and \(H_i \mathcal{L}_{A^\wedge/A} = 0\) for every \(i > 0\).

**Proof.** Taking into account lemma 9.7.4(iii), this is a special case of corollary 9.7.9.

**Proposition 9.7.12.** Let \(p > 0\) be a prime integer, \(A\) a regular local and excellent \(\mathbb{F}_p\)-algebra, \(B\) a local noetherian \(A\)-algebra, \(m_B\) the maximal ideal of \(B\), and \(M\) a \(B\)-module of finite type. Then the \(B\)-module \(\Omega_{A^\wedge/F_p}^1 \otimes_A M\) is separated for the \(m_B\)-adic topology.

**Proof.** Let \(\varphi : A \rightarrow B\) be the structure morphism, and set \(p := \varphi^{-1}m_B\); the localization \(A_p\) is still excellent (lemma 9.7.4(ii,iv)) and regular, and clearly \(\Omega_{A_p/F_p}^1 \otimes_{A_p} M = \Omega_{A^\wedge/F_p}^1 \otimes_A M\), hence we may replace \(A\) by \(A_p\), and assume that \(\varphi\) is local. Let \(A^\wedge\) and \(B^\wedge\) be the completions of \(A\) and \(B\), set \(M^\wedge := B^\wedge \otimes_B M\), and notice that both of the natural maps \(\mathbb{F}_p \rightarrow A\) and \(A \rightarrow A^\wedge\) are regular. In view of corollary 9.7.9, it follows that both of the natural \(B\)-linear maps

\[
\Omega_{A^\wedge/F_p}^1 \otimes_A M \rightarrow \Omega_{B^\wedge/F_p}^1 \otimes_B M^\wedge
\]

\[
\Omega_{A^\wedge/F_p}^1 \otimes_A M \rightarrow \Omega_{A^\wedge/F_p}^1 \otimes_A M^\wedge
\]

are injective (to see the injectivity of the second map, one applies the transitivity triangle arising from the sequence of ring homomorphisms \(\mathbb{F}_p \rightarrow A \rightarrow A^\wedge\) : details left to the reader). Thus, we may assume that \(A\) is complete. Now, for every ring \(R\), and every integer \(m \in \mathbb{N}\), set

\[
R_{(m)} := R[[T_1, \ldots, T_m]] \quad R_{(m)} := R[[T_1^p, \ldots, T_m^p]] \subset R_{(m)}.
\]

With this notation, we have an isomorphism \(A \cong \kappa(d)\) of \(\mathbb{F}_p\)-algebras, where \(\kappa\) is the residue field of \(A\), and \(d := \text{dim} \ A\) (48 Ch.0, Th.19.6.4).

**Claim 9.7.14.** Let \(K\) be any field of characteristic \(p\), and \(m \in \mathbb{N}\) any integer. We have:

(i) There exists a cofiltered system \((K^\lambda \mid \lambda \in \Lambda)\) of subfields of \(K\) such that \([K : K^\lambda]\) is finite for every \(\lambda \in \Lambda\), and \(\cap_{\lambda \in \Lambda} K^\lambda = K^p\).

(ii) For every system \((K^\lambda \mid \lambda \in \Lambda)\) fulfilling the condition of (i), the following holds:

(a) \(\Omega_{K_{(m)}^\wedge/K_{(m)}^\lambda}^1\) is a free \(K_{(m)}\)-module of finite rank, for every \(\lambda \in \Lambda\), and the rule

\[
M \mapsto \Omega_{m}(M) := \lim_{\lambda \in \Lambda} (\Omega_{K_{(m)}^\wedge/K_{(m)}^\lambda}^1 \otimes_{K_{(m)}^\wedge} M)
\]

defines an exact functor \(K_{(m)}^\wedge\text{-Mod} \rightarrow K_{(m)}^\wedge\text{-Mod} \).

(b) The natural map

\[
\eta_{m}(M) : \Omega_{K_{(m)}^\wedge/K_{(m)}^\lambda}^1 \otimes_{K_{(m)}^\wedge} M \rightarrow \Omega_{m}(M)
\]

is injective for every \(K_{(m)}\)-module \(M\).
(c) Let $F$ (resp. $F^\lambda$) denote the field of fractions of $K_{(m)}$ (resp. of $K^\lambda_{(m)}$), for every $\lambda \in \Lambda$; then $\bigcap_{\lambda \in \Lambda} F^\lambda = F^p$.

Proof of the claim. (i) and (ii.c) follow from [48] Ch.0, Prop.21.8.8 (and its proof).

(ii.a): For given $\lambda \in \Lambda$, say that $x_1, \ldots, x_r$ is a $p$-basis of $K$ over $K^\lambda$; then it is easily seen that $x_1, \ldots, x_r, T_1, \ldots, T_m$ is a $p$-basis of $K_{(m)}$ over $K^\lambda_{(m)}$ (see [48] Ch.0, Déf.21.1.9). According to [48] Ch.0, Cor.21.2.5], it follows that $\Omega^1_{K_{(m)}/K^\lambda_{(m)}}$ is the free $(K_{(m)})^\cdot$-module of finite type with basis $dx_1, \ldots, dx_r, dT_1, \ldots, dT_m$. Moreover, say that $K^\mu \subset K^\lambda$, and let $x_{r+1}, \ldots, x_s$ be a $p$-basis of $K^\lambda$ over $K^\mu$; then $x_1, \ldots, x_s$ is a $p$-basis of $K$ over $K^\mu$ ([48] Ch.0, Lemme 21.1.10]), so the induced map

$$\Omega^1_{K_{(m)}/K^\lambda_{(m)}} \to \Omega^1_{K_{(m)}/K^\lambda_{(m)}}$$

is a projection onto a direct factor, and the assertion follows easily.

(ii.b): We are easily reduced to the case where $M$ is a $K_{(m)}$-module of finite type, and in light of (ii.a), may further assume that $M$ is a cyclic $K_{(m)}$-module. Next, we remark that, due to (ii.c), the natural map

$$\Omega^1_{F/F_p} \to \lim_{\lambda \in \Lambda} \Omega^1_{F/F^\lambda}$$

is injective ([48] Ch.0, Th.21.8.3]) in other words, $\eta_{m}(F)$ is injective. In order to show the injectivity of $\eta_{m}(M)$, it then suffices to check that the functor $M \mapsto \Omega^1_{K_{(m)}/F_p} \otimes K_{(m)} M$ is exact. The latter holds by virtue of corollary [9,7.9] since the (unique) morphism of schemes $\text{Spec } K_{(m)} \to \text{Spec } F_p$ is obviously regular. This completes the proof for $m = 0$. Suppose now that $m > 0$, and that the injectivity of $\eta_{m}(M)$ is already known for every $n < m$ and every $K_{(n)}$-module $M$. By the foregoing, it remains to check that $\eta_{m}(K_{(m)}/I)$ is injective, for every non-zero ideal $I \subset K_{(m)}$. Pick any non-zero $f \in I$, and set $R := K_{(m-1)}$; according to [28] Ch.VII, n.7, Lemme 3 and [28] Ch.VII, n.8, Prop.6], there exist an automorphism $\sigma$ of the ring $K_{(m)}$, and elements $g \in R[T], u \in K_{(m)}^\times$ such that $\sigma(f) = u \cdot g$, and $g = T_m^d + a_1 T_m^{d-1} + \cdots + a_d$ for some $d \geq 0$ and certain elements $a_1, \ldots, a_d$ of the maximal ideal of $R$. However, set $M' := K_{(m)}/\sigma(I)$; in view of the commutative diagram of $F_p$-modules:

$$\begin{array}{ccc}
\Omega^1_{K_{(m)}/F_p} \otimes K_{(m)} M & \xrightarrow{\eta_{m}(M)} & \Omega_{m}(M) \\
\downarrow & & \downarrow \\
\Omega^1_{K_{(m)}/F_p} \otimes K_{(m)} M' & \xrightarrow{\eta_{m}(M')} & \Omega_{m}(M')
\end{array}$$

(whose vertical arrows are induced by $\sigma$) we see that $\eta_{m}(M)$ is injective, if and only if the same holds for $\eta_{m}(M')$. Hence, we may replace $I$ by $\sigma(I)$, and assume that $g \in I$. In this case, set also $R^\lambda := K^\lambda_{(m-1)}$ for every $\lambda \in \Lambda$, and notice that the natural maps

$$R[T]/g^p R[T] \to K_{(m)}/g^p K_{(m)} \quad R^\lambda[T]/g^p R^\lambda[T] \to K^\lambda_{(m)}/g^p K^\lambda_{(m)}$$

are bijective; there follows a commutative diagram of $K_{(m)}$-modules:

$$\begin{array}{ccc}
\Omega^1_{R[T]/F_p} \otimes R[T] M & \xrightarrow{\alpha^\lambda \otimes R[T]} & \Omega^1_{K_{(m)}/F_p} \otimes K_{(m)} M \\
\downarrow & & \downarrow \\
\Omega^1_{R[T]/R^\lambda} \otimes R[T] M & \xrightarrow{\eta_{m}^\lambda \otimes K_{(m)}} & \Omega^1_{K_{(m)}/K^\lambda_{(m)}} \otimes K_{(m)} M
\end{array}$$
whose horizontal arrows are isomorphisms, and \( \eta_m(M) = \lim_{\lambda \in \Lambda} \eta_{m-1}^{\lambda} \otimes_{K_{(m)}} M \). On the other hand, for every \( \lambda \in \Lambda \) we have a commutative ladder of \( R[T_m] \)-modules with exact rows:

\[
\begin{array}{cccccc}
0 & \longrightarrow & \Omega^1_{R/\mathbb{F}_p} \otimes_R R[T_m] & \longrightarrow & \Omega^1_{R[T_m]/\mathbb{F}_p} & \longrightarrow & \Omega^1_{R[T_m]/R} & \longrightarrow & 0 \\
\sum_{\lambda} & & \eta_{m-1}^{\lambda} \otimes_R R[T_m] & & \alpha^\lambda & & 1 & & 1 \\
0 & \longrightarrow & \Omega^1_{R/R^\lambda} \otimes_R R[T_m] & \longrightarrow & \Omega^1_{R[T_m]/R^\lambda} & \longrightarrow & \Omega^1_{R[T_m]/R} & \longrightarrow & 0
\end{array}
\]

and notice that the rows of \( \sum_{\lambda} \otimes_R R[T_m] \) are still short exact, for every \( \lambda \in \Lambda \). By inductive assumption, \( \lim_{\lambda \in \Lambda} \eta_m^{\lambda - 1} \otimes_R M \) is an injective map; we deduce that the same holds for \( \lim_{\lambda \in \Lambda} \alpha^\lambda \otimes_{R[T]} M \), and the claim follows.

Take \( K := \kappa \), and pick any cofiltered system \( (K_\lambda | \lambda \in \Lambda) \) as provided by claim [9.7.14](i); in light of claim [9.7.14](ii,b), it now suffices to show that the resulting \( \Omega_d(M) \) is a separated \( B \)-module, for every noetherian \( \kappa_{(d)} \)-algebra \( B \) and every \( B \)-module \( M \) of finite type. However, \( \Omega_d(M) \) is a submodule of \( \prod_{\lambda \in \Lambda} (\Omega_{K_{(m)}}^{\lambda} \otimes_{K_{(m)}} M) \), hence we are reduced to checking that each direct factor of the latter \( B \)-module is separated. But in view of claim [9.7.14](ii,a), we see that each such factor is a finite direct sum of copies of \( M \), so finally we come down to the assertion that \( M \) is separated for the \( m_R \)-adic topology, which is well known.

\[ \square \]

**Theorem 9.7.15.** Let \( \varphi : A \rightarrow B \) be a local ring homomorphism of local noetherian rings. Suppose that \( A \) is quasi-excellent, and \( \varphi \) is formally smooth for the preadic topologies defined by the maximal ideals. Then \( \text{Spec} \, \varphi \) is regular.

**Proof.** This is the main result of [4]. We begin with the following general remark:

**Claim 9.7.16.** Let \( R \) be a local noetherian ring, \( m_R \subset R \) the maximal ideal, \( H : R\text{-Mod} \rightarrow R\text{-Mod} \) an additive functor, and suppose that

(a) \( H \) is \( R \)-linear, i.e. \( H(t \cdot 1_M) = t \cdot H(1_M) \) for every \( R \)-module \( M \), and every \( t \in R \).
(b) \( H \) is semi-exact, i.e. for any short exact sequence \( 0 \rightarrow M' \rightarrow M \rightarrow M'' \rightarrow 0 \) of \( R \)-modules, the induced sequence \( H(M') \rightarrow H(M) \rightarrow H(M'') \) is exact.
(c) \( H \) commutes with filtered colimits.
(d) \( H(M) \) is separated for the \( m_R \)-adic topology, for every \( R \)-module \( M \) of finite type.
(e) \( H(R/m_R) = 0 \).

Then \( H(M) = 0 \) for every \( R \)-module \( M \).

**Proof of the claim.** Since \( H \) commutes with filtered colimits, it suffices to show that \( H(M) = 0 \) for every finitely generated \( R \)-module \( M \), and since \( H \) is semi-exact, a simple induction reduces further to the case where \( M \) is a cyclic \( R \)-module. Let now \( \mathcal{F} \) be the family of all ideals \( I \) of \( R \) such that \( H(R/I) \neq 0 \), and suppose, by way of contradiction, that \( \mathcal{F} \neq \emptyset \); pick a maximal element \( J \) of \( \mathcal{F} \), and set \( M := R/J \). By assumption, \( J \neq m_R \); thus, let \( t \in R \) be a non-invertible element with \( t \notin J \); we get an exact sequence

\[ H(M) \xrightarrow{t \cdot} H(M) \rightarrow H(B_{(m+n)}/(J + tB_{(m+n)})) \]

whose third term vanishes, by the maximality of \( J \). On the other hand, \( \bigcap_{n \in \mathbb{N}} t^nH(M) = 0 \), since \( H(M) \) is separated. Thus \( H(M) = 0 \), contradicting the choice of \( J \), and the claim follows.

\[ \diamond \]

Denote by \( \kappa \) the residue field of \( A \), and for every \( m, n \in \mathbb{N} \), let \( \varphi_{m,n} : A_{(m)} \rightarrow B_{(m+n)} \) be the composition of \( \varphi_{(m)} : A_{(m)} \rightarrow B_{(m)} \) (the \( T \)-adic completion of \( \varphi \otimes_A A[T_1, \ldots, T_m] \)) with the natural inclusion map \( B_{(m)} \rightarrow B_{(m+n)} \) (notation of [9.7.13]).
Claim 9.7.17. In the situation of the theorem, suppose furthermore that \( A \) is either a field or a complete discrete valuation ring of mixed characteristic. Then, the morphism \( \text{Spec} \, \varphi_{m,n} \) is regular for every \( m, n \in \mathbb{N} \).

**Proof of the claim.** Set

\[
H(M) := H_1(\mathbb{L}_{B(m+n)/A(m)} \otimes B(m+n), M).
\]

We shall consider separately three different cases:

- Suppose first that \( A \) is a field of characteristic \( p > 0 \). According to corollary 9.7.9, it suffices to show that \( H(M) \) vanishes for every \( B(m+n) \)-module \( M \). Notice that the natural map \( \mathbb{F}_p \to B(m+n) \) is regular; from the distinguished triangle ([28, Ch.VII, n.7, Lemme 3])

\[
\mathbb{L}_{A(m)/\mathbb{F}_p} \otimes A(m) B(m+n) \to \mathbb{L}_{B(m+n)/\mathbb{F}_p} \to \mathbb{L}_{B(m+n)/A(m)} \to \mathbb{L}_{A(m)/\mathbb{F}_p} \otimes A(m) B(m+n)[1]
\]

and corollary 9.7.9, we deduce an injective \( B(m+n) \)-linear map

\[
H(M) \to \Omega^1_{A(m)/\mathbb{F}_p} \otimes A(m) M
\]

from which it follows that if \( M \) is a \( B(m+n) \)-module of finite type, \( H(M) \) is a separated \( B(m+n) \)-module, for the preadic topology defined by the maximal ideal of \( B(m+n) \) (proposition 9.7.12). Since \( \varphi \) is formally smooth, \( \varphi_{m,n} \) is also formally smooth for the preadic topologies defined by the maximal ideals of \( A(m) \) and \( B(m+n) \); from proposition 8.6.30, we see that \( H(M) = 0 \), if \( M \) is the residue field of \( B(m+n) \). Then the assertion follows from claim 9.7.16.

- Next, suppose that \( A \) is either a field of characteristic zero, or a complete discrete valuation ring of mixed characteristic (so either \( \kappa = A \), or else \( \kappa \) is a field of positive characteristic). According to corollary 9.7.9, it suffices to show that \( H(M) \) vanishes for \( M = \kappa(q) \), where \( q \subset B(m+n) \) is any prime ideal. Fix such \( q \), and set \( p := q \cap A(m) \); if \( p = 0 \), then \( M \) is a \( K \)-algebra, where \( K \) is the field of fractions of \( A(m) \); now, \( K \) is a field of characteristic zero, and \( B' := B(m+n) \otimes A(m) K \) is a regular local \( K \)-algebra, so the induced morphism \( \text{Spec} B' \to \text{Spec} K \) is regular; since \( H(M) = H_1(\mathbb{L}_{B'/K} \otimes_{B'} M) \), the assertion follows from corollary 9.7.9.

Notice that this argument applies especially to the case where \( m = 0 \); for the general case, we argue by induction on \( m \). Hence, suppose that \( n \in \mathbb{N} \), \( m > 0 \), and that the assertion is already known for \( \varphi_{n,m-1} \).

Consider first the case where \( A \) is a discrete valuation ring, and \( p \) contains the maximal ideal of \( A \), and set \( \overline{B} := B \otimes_A \kappa \). Since \( \varphi_{m,n} \) is flat, and since \( M \) is a \( B(m+n) \)-module, we have a natural isomorphism

\[
H(M) \cong H_1(\mathbb{L}_{\overline{B}(m+n)/\kappa(m)} \otimes_{\overline{B}(m+n)} M).
\]

Then the sought vanishing follows from the foregoing, since \( \overline{B} \) is a formally smooth \( \kappa \)-algebra (for the preadic topology of its maximal ideal).

Lastly, suppose that either \( A \) is a field, or \( p \) does not contain the maximal ideal of \( A \) (and \( p \neq 0 \)). In either of these two cases, we may find \( f \in p \) whose image in \( \kappa(m) \) is not zero. According to [28, Ch.VII, n.7, Lemme 3] and [28, Ch.VII, n.8, Prop.6], we may find an automorphism \( \sigma \) of the \( A \)-algebra \( A(m) \) and elements \( g \in A(m)[T_m] \), \( u \in A(m)^x \) such that \( \sigma(f) = u \cdot g \), and \( g = T_m^d + a_1 T_m^{d-1} + \cdots + a_d \) for some \( d \geq 0 \) and certain elements \( a_1, \ldots, a_d \) of the maximal ideal of \( A(m-1) \). Denote by \( \sigma' : B(m) \to B(m) \) the \( T \)-adic completion of \( \sigma \otimes_A B \), and let \( \sigma_B : B(m+n) \to B(m+n) \) be the \( T \)-adically continuous automorphism that restricts to \( \sigma' \) on \( B(m) \), and such that \( \sigma_B(T_i) = T_i \) for \( i = m+1, \ldots, m+n \). Set \( M' := B(m+n)/\sigma_B(q) \); by construction,
we have a commutative diagram of $A$-algebras

$$
\begin{array}{ccc}
A_{(m)} & \xrightarrow{\varphi_{m,n}} & B_{(m+n)} \\
\sigma & \downarrow & \sigma_B \\
A_{(m)} & \xrightarrow{\varphi_{m,n}} & B_{(m+n)}
\end{array}
$$

inducing an isomorphism

$$
\mathbb{L}_{B_{(m+n)}/A_{(n)}} \otimes_{B_{(m+n)}} M \sim \mathbb{L}_{B_{(m+n)}/A_{(n)}} \otimes_{B_{(m+n)}} M' \quad \text{in } D(A\text{-Mod}).
$$

Thus, we may replace $M$ by $M'$, and assume from start that $g \in \mathfrak{p}$. In this case, set $B' := B[[T_{m+1}, \ldots, T_{m+n}]]$, and notice that both of the natural maps

$$
A_{(m-1)}[T_m]/gA_{(m-1)}[T_m] \rightarrow A_{(m)}/gA_{(m)} \quad B'_{(m-1)}[T_m]/gB'_{(m-1)}[T_m] \rightarrow B_{(m+n)}/gB_{(m+n)}
$$

are isomorphisms. Since both $\varphi_{m,n}$ and the map $A_{(m-1)}[T_m] \rightarrow B'_{(m-1)}[T_m]$ induced by $\varphi$ are flat ring homomorphisms, there follows a natural isomorphism of $B_{(m+n)}$-modules :

$$
\mathbb{L}_{B_{(m+n)}/A_{(n)}} \otimes_{B_{(m+n)}} M \sim \mathbb{L}_{B'_{(m-1)}/A_{(m-1)}/T_m/[A_{(m-1)}][T_m] \otimes_{B'_{(m-1)}/T_m][A_{(m-1)}][T_m]} M
$$

([82, Ch.II, Prop.2.2.1]). However, the resulting map $A_{(m-1)} \rightarrow B'_{(m-1)}$ is none else than $\varphi_{m-1,n}$, up to a relabeling of the variables; the vanishing of $H(M)$ then follows from the inductive assumption (and from corollary 9.7.9).

\begin{proof}[Claim 9.7.18]
In the situation of the theorem, suppose furthermore that $A$ and $B$ are complete, and let $M$ be a $B$-module of finite type. Then $H_1(\mathbb{L}_{B/A} \otimes_B M)$ is a $B$-module of finite type.

Let $\overline{f} : A_0 \rightarrow \kappa$ be a surjective ring homomorphism, with $A_0$ a Cohen ring ([48, Ch.0, Th.19.8.6(ii)]), and set $\overline{B} := B \otimes_A \kappa$; in light of [48, Ch.0, Lemme 19.7.1.3], there exists a flat local, complete and noetherian $A_0$-algebra $B_0$ fitting into a cocartesian diagram :

$$
\begin{array}{ccc}
A_0 & \xrightarrow{\psi} & B_0 \\
\overline{f} & \downarrow & \overline{f}_B \\
\kappa & \xrightarrow{\kappa_B} & \overline{B}.
\end{array}
$$

Denote by $\kappa_B$ the residue field of $B$; there follow natural isomorphisms of $B$-modules :

$$
H_1(\mathbb{L}_{B/A} \otimes_B \kappa_B) \sim H_1(\mathbb{L}_{\overline{B}/\kappa} \otimes_{\overline{B}} \kappa_B) \sim H_1(\mathbb{L}_{B_0/A_0} \otimes_{B_0} \kappa_B)
$$

([82, Ch.II, Prop.2.2.1]) which, according to proposition 8.6.30 imply that $\psi$ is formally smooth (for the preadic topologies defined by the maximal ideals). By [48, Ch.0, Th.19.8.6(i)], $\overline{f}$ lifts to a ring homomorphism $f : A_0 \rightarrow A$, whence a commutative diagram

$$
\begin{array}{ccc}
A_0 & \xrightarrow{\psi} & B_0 \\
\varphi \circ f & \downarrow & \overline{f}_B \\
B & \xrightarrow{} & \overline{B}.
\end{array}
$$

Then, by [48, Ch.0, Cor.19.3.11], the map $\overline{f}_B$ lifts to a ring homomorphism $f_B : B_0 \rightarrow B$. Notice now that both $f$ and $f_B$ are local maps and induce isomorphisms on the residue fields; it
follows easily that, for suitable \( m, n \in \mathbb{N} \), they extend to surjective \( g \) and \( g_B \) fitting into a commutative diagram

\[
\begin{array}{ccc}
A_{0,(m)} & \xrightarrow{\psi_{(m,n)}} & B_{0,(m+n)} \\
g & \downarrow & g_B \\
A & \xrightarrow{\varphi} & B
\end{array}
\]

whence exact sequences ([82 Ch.II, Prop.2.1.2])

\[
H_1(\mathbb{L}_{B_{0,(m+n)}/A_{0,(m)}} \otimes B_{0,(m+n)} M) \rightarrow H_1(\mathbb{L}_{B/A_{0,(m)}} \otimes B M) \rightarrow H_1(\mathbb{L}_{B_{0,(m+n)}/B \otimes B_{0,(m+n)}} M)
\]

However, claim [9.7.17] applies to \( \psi \), and together with corollary [9.7.9] it implies that the first module of the first of these sequences vanishes; on the other hand, it is easily seen that the third \( B \)-module of the same sequence is finitely generated, so the same holds for the middle term. By inspecting the second exact sequence, the claim follows.

We may now conclude the proof of the theorem: let \( A^\wedge \) and \( B^\wedge \) be the completions of \( A \) and \( B \); since \( \varphi \) is formally smooth, the same holds for its completion \( \varphi^\wedge : A^\wedge \rightarrow B^\wedge \). First, we show that \( \text{Spec } \varphi^\wedge \) is regular; to this aim, it suffices to check that \( H^\wedge(M) := H_1(\mathbb{L}_{B^\wedge/A^\wedge} \otimes M) \) vanishes for every \( B^\wedge \)-module \( M \) (corollary [9.7.9]). However, we know already that \( H^\wedge(M) \) is a \( B^\wedge \)-module of finite type, if the same holds for \( M \) (claim [9.7.18]); especially, for such \( M \), \( H^\wedge(M) \) is separated for the adic topology of \( B^\wedge \) defined by the maximal ideal. Moreover, \( H^\wedge(M) = 0 \), if \( M \) is the residue field of \( B^\wedge \) (proposition [8.6.30]). Then the assertion follows from claim [9.7.16]. Lastly, the natural morphism \( \text{Spec } A^\wedge \rightarrow \text{Spec } A \) is regular by assumption, hence the same holds for the induced morphism \( \text{Spec } B^\wedge \rightarrow \text{Spec } A \) (lemma [9.7.1(i)]). Finally, since \( B^\wedge \) is a faithfully flat \( B \)-algebra, we conclude that \( \text{Spec } \varphi \) is regular, by virtue of lemma [9.7.1(ii)].

\begin{proposition}
Let \( A \) be a noetherian local ring, and \( \varphi : A \rightarrow B \) an ind-étale local ring homomorphism. Then:

(i) \( A \) is quasi-excellent if and only if the same holds for \( B \).

(ii) If \( A \) is excellent, the same holds for \( B \).
\end{proposition}

\begin{proof}
Set \( f := \text{Spec } \varphi \), and \( f^\wedge := \text{Spec } \varphi^\wedge \), where \( \varphi^\wedge : A^\wedge \rightarrow B^\wedge \) is the map of complete local rings obtained from \( \varphi \). Notice first that, for every \( y \in \text{Spec } A \), and every \( x \in f^{-1}(y) \), the stalk \( \mathcal{O}_{f^{-1}(y),x} \) is an ind-étale \( \kappa(y) \)-algebra, i.e. a separable algebraic extension of \( \kappa(y) \), hence \( f^{-1}(y) \) is geometrically regular, and therefore \( f \) is regular and faithfully flat. Moreover, \( f \) is the limit of a cofiltered system of formally étale morphisms, hence it is formally étale; \textit{a fortiori}, \( B \) is also formally smooth over \( A \) for the preadic topologies, so \( B^\wedge \) is formally smooth over \( A^\wedge \) for the preadic topologies, and consequently \( f^\wedge \) is a regular morphism (theorem [9.7.15]).

(i): If \( B \) is quasi-excellent, claim [9.7.5] and lemma [9.7.4(iv)] imply that \( A \) is quasi-excellent. Next, assume that \( A \) is quasi-excellent; we have a commutative diagram [9.7.6], in which \( \pi_A \) is a regular morphism, and then the same holds for \( \pi_A \circ f^\wedge = f \circ \pi_B \) (lemma [9.7.1(i)]). Now, let \( y \in \text{Spec } B \) be any point, and set \( z := f(y) \); we know that \( (f \circ \pi_B)^{-1}(z) \) is a geometrically regular affine scheme, so write it as the spectrum of a noetherian ring \( C \). The stalk \( E := \mathcal{O}_{f^{-1}(z),y} \) is a separable algebraic field extension of \( \kappa(z) \), hence \( \pi_B^{-1}(y) \simeq \text{Spec } C \otimes_B E \), the spectrum of a localization of \( C \), so it is again geometrically regular, i.e. \( \pi_B \) is a regular morphism, and we conclude by lemma [9.7.4(iii, iv)].

(ii): By (i), it remains only to show that \( B \) is universally catenarian, provided the same holds for \( A \). To this aim, it suffices to apply [51 Ch.IV, Lemma 18.7.5.1].
\end{proof}
Proposition 9.7.20. Let $p > 0$ be a prime integer, and $A$ a noetherian $\mathbb{F}_p$-algebra whose Frobenius endomorphism $\Phi_A$ is a finite map (see (9.6.36)), and for every prime ideal $p \subset A$, set $\kappa(p) := A_p/pA_p$ (the residue field of the point $p \in \text{Spec } A$). Then
\[
\dim A_p/qA_p = \dim_{\kappa(p)} \Omega^1_{A_p/qA_p} = \dim_{\kappa(p)/\mathbb{F}_p} - \dim_{\kappa(p)} \Omega^1_{A_p/qA_p}
\]
for every pair of prime ideals $q \subset p \subset A$.

Proof. For every $\mathbb{F}_p$-algebra $R$, let $\Phi_R : R \to R$ be the Frobenius endomorphism. We notice :

Claim 9.7.21. Let $A$ be an $\mathbb{F}_p$-algebra such that $\Phi_A$ is a finite map. We have :

(i) For every $A$-algebra $B$ of essentially finite type, $\Phi_B$ is finite as well.
(ii) Suppose moreover that $A$ is noetherian, $I \subset A$ is any ideal, and let $A^\wedge_I$ be the $I$-adic completion of $A$. Then :
\begin{enumerate}
    \item[(a)] $\Phi A^\wedge_I = 1_{A^\wedge_I} \otimes_A \Phi A$ is finite, and $\Omega^1_{A^\wedge_I/\mathbb{F}_p} = A^\wedge_I \otimes_A \Omega^1_{A/\mathbb{F}_p}$.
    \item[(b)] If $A$ is reduced, the same holds for $A^\wedge_I$.
\end{enumerate}
(iii) Suppose that $(A, m_A)$ is a local noetherian domain, and denote by $K$ (resp. $\kappa$) the field of fractions (resp. the residue field) of $A$. Then
\[
\dim_K \Omega^1_{K/\mathbb{F}_p} = \dim_{\kappa} \Omega^1_{\kappa/\mathbb{F}_p} + \dim A.
\]

Proof of the claim. (i): Suppose first that $B = A[X]$; then it is easily seen that $\Phi_B = \Phi_A \otimes_{\mathbb{F}_p} \Phi_{\mathbb{F}_p[X]}$, and by (ii) we deduce that the claim holds as well for any free polynomial $A$-algebra of finite type. Next, let $I \subset A$ be any ideal; since $\Phi_A(I) \subset I$, it is easily seen that $\Phi A/I = \Phi_A \otimes_A A/I$, so $\Phi A/I$ is finite, and therefore the assertion holds for any $A$-algebra of finite type. Lastly, let $S \subset A$ be any multiplicative subset; then it is easily seen that
\[
\dim_{S^{-1}A} = S^{-1} \Phi_A
\]
and the assertion follows.

(ii.a): Set $B := A(\Phi)$; by assumption, $\Phi_A : A \to B$ is a finite $A$-linear map, hence its $I$-adic completion $(\Phi_A)^\wedge_I : A^\wedge_I \to B^\wedge_I$ equals $1_{A^\wedge_I} \otimes_A \Phi A$ ([100, Th.8.7]). Say that $I$ is generated by $r$ elements of $A$; then it is easily seen that $I^{(p-1)r+1} \subset \Phi_A(I) \subset I$, so we have a natural $A^\wedge_I$-linear identification on $I$-adic completions :
\[
B^\wedge_I \overset{\sim}{\rightarrow} (A^\wedge_I)_{(\Phi)}
\]
and under this identification, $(\Phi_A)^\wedge_I = \Phi A^\wedge_I$, whence the first assertion of (ii.a). Next, we notice that ([7.24]) yields a natural identification $\Omega^1_{A^\wedge_I/\mathbb{F}_p} = \Omega^1_{B^\wedge_I/\mathbb{F}_p}$, and on the other hand, the sequence of ring homomorphisms
\[
\mathbb{F}_p \to A^\wedge_I \overset{\Phi A^\wedge_I}{\longrightarrow} B^\wedge_I
\]
yields natural identifications :
\[
\Omega^1_{B^\wedge_I/\mathbb{F}_p} = \Omega^1_{B^\wedge_I/A^\wedge_I} = A^\wedge_I \otimes_{A^\wedge_I} \Omega^1_{B/A^\wedge_I} = A^\wedge_I \otimes_{A^\wedge_I} \Omega^1_{B^\wedge_I/\mathbb{F}_p} = B^\wedge_I \otimes_{B^\wedge_I} \Omega^1_{B^\wedge_I/\mathbb{F}_p} = A^\wedge_I \otimes_{A^\wedge_I} \Omega^1_{B^\wedge_I/\mathbb{F}_p}
\]
where the last equality is induced by (9.7.24) and the identity map $A \overset{\sim}{\rightarrow} B$. This completes the proof of the second assertion.

(ii.b): Since $A$ is reduced, $\Phi_A$ is injective, and then the same holds for its completion $(\Phi_A)^\wedge_I$. But we have seen that the latter is naturally identified with $\Phi A^\wedge_I$, whence the claim.

(iii): Notice that $\Omega^1_{K/\mathbb{F}_p}$ is a $K$-vector space of finite dimension, since its dimension equals $[K : K^p]$ ([48, Ch.0, Th.21.4.5]), and the latter is finite, by (i); the same argument applies to the $\kappa$-vector space $\Omega^1_{\kappa/\mathbb{F}_p}$. Denote by $\delta(A)$ the difference between the left and right hand-side of (9.7.22); we have to show that $\delta(A) = 0$. Let $A^\wedge$ be the $m_A$-adic completion of $A$, and $p \subset A^\wedge$
any minimal prime ideal such that \( \dim A^\wedge/p = d := \dim A \). In view of (ii.b), \( L := (A^\wedge)_p \) is a field; taking into account (ii.a), we get

\[
\Omega^1_{L/p} = L \otimes A^\wedge \Omega^1_{A^\wedge/p} = L \otimes_A \Omega^1_{A/p} = L \otimes_K \Omega^1_{K/\mathcal{F}_p}.
\]

Hence \( \dim_L \Omega^1_{L/p} = \dim_K \Omega^1_{K/\mathcal{F}_p} \), so we see that

\[
(9.7.25) \quad \delta(A) = \delta(A^\wedge/p)
\]

for any prime ideal \( p \subset A^\wedge \) such that \( \dim A^\wedge/p = d \).

We may then replace \( A \) by \( A^\wedge/p \), after which we may assume that \( A \) is a complete local domain. In this case, \( A \) contains a field mapping isomorphically onto \( \kappa \), and there is a finite map of \( \kappa \)-algebras \( A' := \kappa[[T_1, \ldots, T_d]] \to A \) \((100\text{ Th.29.4}(iii))\). Denote by \( K' \) the field of fractions of \( A' \), and notice that \( [K : K'] = [K : K^p] \cdot [K^p : K'] = [K : K^p] \cdot [K^p : K'^p] \); on the other hand, \( \Phi_K \) induces an isomorphism \( K \xrightarrow{\sim} K' \), hence have as well \( [K : K'] = [K^p : K'^p] \), so \( [K : K^p] = [K' : K'^p] \) and finally:

\[
\dim_K \Omega^1_{K'/\mathcal{F}_p} = \dim_K \Omega^1_{K/\mathcal{F}_p}
\]

\((48\text{ Ch.0, Cor.21.2.5})\). Since \( \dim A' = \dim A \), we conclude that \( \delta(A) = \delta(A') \). Hence, it suffices to check that \( \delta(A') = 0 \). Furthermore, set \( B := \kappa[[T_1, \ldots, T_d]] \), and let \( m \subset B \) be the maximal ideal generated by \( T_1, \ldots, T_d \); we have \( A' = B^\wedge_m \), so \( (9.7.25) \) further reduces to showing that \( \delta(B^\wedge_m) = 0 \), which shall be left as an exercise for the reader.

Now, in view of claim \ref{9.7.21}(i), we may replace \( A \) by \( A_p/q.A_p \), and assume from start that \( A \) is a local domain, that \( q = 0 \) and that \( p \) is the maximal ideal; in this case, the sought identity is given by claim \ref{9.7.21}(iii).

\[\square\]

**Theorem 9.7.26.** Let \( p > 0 \) be a prime integer, and \( A \) a noetherian \( \mathcal{F}_p \)-algebra. We have:

(i) If the Frobenius endomorphism \( \Phi_A \) of \( A \) is a finite map, then \( A \) is excellent.

(ii) Conversely, suppose that \( A \) is a local Nagata ring, with residue field \( k \), and that \( [k : k^p] \) is finite. Then \( \Phi_A \) is a finite ring homomorphism.

**Proof.** (i): We reproduce the proof from \cite{99} Appendix, Th.108.

**Claim 9.7.27.** If \( \Phi_A \) is finite, then \( A \) is quasi-excellent.

**Proof of the claim.** We check first the openness condition for the regular loci. To this aim, in light of claim \ref{9.7.21}(i), we may assume that \( A \) is an integral domain, and it suffices to prove that the regular locus of \( \text{Spec} A \) is an open subset. Set \( B := A_{(\Phi)} \) (notation of \ref{9.6.36}), and let \( p \subset A \) be any prime ideal; by theorem \ref{9.6.37} and \ref{9.7.23}, the ring \( A_p \) is regular if and only if \( (\Phi_A)_p \) is a flat ring homomorphism, if and only if \( B_p \) is a flat \( A_p \)-module. Since, by assumption, \( B \) is a finite \( A \)-module, the latter holds if and only if \( B_p \) is a free \( A_p \)-module. Then, the assertion follows from \cite{100} Th.4.10.

Next, we show that \( A \) is a G-ring. By claim \ref{9.7.21}(i), we may assume that \( A \) is local, and we let \( A^\wedge \) be the completion of \( A \). From claim \ref{9.7.21}(ii.a) we see that the natural map

\[
A_{(\Phi)} \otimes_A A^\wedge \to (A^\wedge)_{(\Phi)}
\]

is an isomorphism in \( \text{D}(A\text{-Mod}) \). Then the assertion follows from \cite{59} Lemma 6.5.13(i)] and corollary \ref{9.7.11}.

Now, it follows easily from proposition \ref{9.7.20} and claim \ref{9.7.21}(i), that \( A \) is universally catenarian; combining with claim \ref{9.7.27}, we obtain (i).

(ii): The assertion to prove is that \( A_{(\Phi)} \) is a finite \( A \)-module. To this aim, denote by \( I \subset A \) the nilradical ideal; we remark :

**Claim 9.7.28.** It suffices to show that \( (A/I)_{(\Phi)} \) is a finite \( A \)-module.
Proof of the claim. Indeed, suppose that \((A/I)(\phi)\) is a finite \(A\)-module; we shall deduce, by induction on \(s\), that \((A/I^s)(\phi)\) is a finite \(A\)-module, for every \(s > 0\). Since \(A\) is noetherian, we have \(I^t = 0\) for \(t > 0\) large enough, so the claim will follow. The assertion for \(s = 1\) is our assumption. Suppose therefore that \(s > 1\), and that we already know the assertion for \(s - 1\). Notice that \(I^s/I^{s-1}\) is a finite \(A/I\)-module, hence a finite \((A/I)(\phi)\)-module, by our assumption. Since \((A/I^{s-1})(\phi)\) is a finite \(A\)-module, we deduce easily that the assertion holds for \(s\), as required.

In view of claim \(9.7.28\), we may replace \(A\) by \(A/I\) (which is obviously still a Nagata ring), and assume from start that \(A\) is reduced. In this case, let \(\{p_1, \ldots, p_t\}\) be the set of minimal prime ideals of \(A\); we have a commutative diagram of ring homomorphisms:

\[
\begin{array}{ccc}
A & \xrightarrow{\Phi_A} & A \\
\downarrow & & \downarrow \\
\prod_{i=1}^t A/p_i & \xrightarrow{\prod_{i=1}^t \Phi_{A/p_i}} & \prod_{i=1}^t A/p_i
\end{array}
\]

whose vertical arrows are injective and finite maps. Suppose now that \((A/p_i)(\phi)\) is a finite \(A/p_i\)-module for every \(i = 1, \ldots, t\). Then \(\prod_{i=1}^t (A/p_i)(\phi)\) is a finite \(A\)-module, and therefore the same holds for its \(A\)-submodule \(A(\phi)\). Thus, we are reduced to checking the sought assertion for each of the quotients \(A/p_i\) (which are still Nagata rings), and hence we may assume from start that \(A\) is a domain. In this case, denote by \(K\) the field of fractions of \(A\); by the definition of Nagata ring, we are further reduced to checking that \(\Phi_K : K \to K\) is a finite field extension, i.e. that \([K : K^p]\) is finite. Denote \(A^\wedge\) the completion of \(A\); we remark:

Claim 9.7.29. (i) The endomorphism \(\Phi_{A^\wedge}\) is a finite map.

(ii) \(\text{Spec } K \otimes_A A^\wedge\) is a geometrically reduced \(K\)-scheme.

Proof of the claim. (i): Indeed, \(A^\wedge\) is a quotient of a power series ring \(B := k[[T_1, \ldots, T_r]]\) (48 Ch.0, Th.19.8.8(i)), hence it suffices to show that \(\Phi_B\) is finite. However, \(B^p = k^p[[T_1^p, \ldots, T_r^p]]\), and \([k : k^p]\) is finite by assumption, whence the claim.

(ii): This is [49 Ch.IV, Th.7.6.4].

Let \(p \subset A^\wedge\) be any minimal prime ideal; it follows from claim \(9.7.29\) that \(L := (A^\wedge)_p\) is a separable field extension of \(K\) (49 Ch.IV, Prop.4.6.1), so the natural map

\[
\Omega^1_{K/F_p} \otimes_K L \to \Omega^1_{L/E}
\]

is injective (48 Ch.0, Cor.20.6.19(iii)); on the other hand, claim \(9.7.29\) implies that \([L : L^p]\) is finite, i.e. \(\Omega^1_{L/F_p}\) is a finite-dimensional \(L\)-vector space (48 Ch.0, Th.21.4.5). We conclude that \(\Omega^1_{K/F_p}\) is a finite-dimensional \(K\)-vector space, whence the contention, again by loc.cit.

Part (i) of proposition \(9.7.31\) was first observed in [12 Th.1.1]. Also, the class of ring homomorphisms introduced by definition \(9.7.30\) has been extensively studied in [11], in which one can find most of the results that follow, and much more.

Definition 9.7.30. Let \(f : (A, \mathfrak{m}_A) \to (B, \mathfrak{m}_B)\) be a local ring homomorphism of local noetherian rings, and denote by \(B^\wedge\) the \(\mathfrak{m}_B\)-adic completion of \(B\).

(i) A Cohen factorization of \(f\) is the datum of a complete local noetherian ring \((C, \mathfrak{m}_C)\) and ring homomorphisms \(g : A \to C, h : C \to B^\wedge\) such that \(C/\mathfrak{m}_AC\) is a regular ring, \(g\) is faithfully flat, \(h\) is surjective, and \(f = h \circ g\).

(ii) We say that \(f\) is a homomorphism of complete intersection if it admits a Cohen factorization as in (i), such that \(\text{Ker } h\) is generated by a regular sequence of elements of \(\mathfrak{m}_C\).
Proposition 9.7.31. Let $f : (A, \mathfrak{m}_A) \to (B, \mathfrak{m}_B)$ be a local homomorphism of complete local noetherian rings, and denote by $\kappa_A$ and $\kappa_B$ the residue fields of $A$ and $B$. The following holds:

(i) $f$ admits a Cohen factorization.

(ii) If $H^1_{\mathfrak{n}_B/\kappa_A}$ is a finite dimensional $\kappa_B$-vector space, we may find a Cohen factorization $A \xrightarrow{g} (C, \mathfrak{m}_C) \xrightarrow{h} B$ of $f$, where $g$ is formally smooth for the $\mathfrak{m}_A$-adic and $\mathfrak{m}_C$-adic topologies.

Proof. (i): Let $p$ be the characteristic of $\kappa_A$ and $\kappa_B$. If $p = 0$, we have fields $k_A \subset A, k_B \subset B$ such that the induced maps $k_A \to \kappa_A$ and $k_B \to \kappa_B$ are isomorphisms ([100] Th.28.3); if $p > 0$, we have complete discrete valuation rings $V_A, V_B$ and local ring homomorphisms $V_A \to A, V_B \to B$ inducing isomorphisms $V_A/pV_A \cong \kappa_A, V_B/pV_B \cong \kappa_B$ ([100] Th.29.2). In the first case, set $R_0 := \mathbb{Q}, R_A := k_A$ and $R_B := k_B$; in the second case, set $R_0 := \mathbb{Z}_{p\mathbb{Z}}, R_A := V_A$, and $R_B := V_B$. In either case, let $k_A$ and $k_B$ be the residue fields of $R_A$ and $R_B$, and notice that $R_A$ and $R_B$ are formally smooth $R_0$-algebras for the $p$-adic topologies ([100] Th.26.9 and Th.28.10). Fix finite systems of generators $x_1, \ldots, x_n$ for $A_m$, and $y_1, \ldots, y_m$ for $B_m$; we may assume that $m \ge n$, and $f(x_i) = y_i$ for $i = 1, \ldots, n$. Set

$$A_0 := R_A[[X_1, \ldots, X_n]] \quad B_0 := R_B[[Y_1, \ldots, Y_m]]$$

and let $m_{A_0} \subset A_0, m_{B_0} \subset B_0$ be the maximal ideals; we deduce surjective maps

$$\varphi_A : A_0 \to A \quad \varphi_B : B_0 \to B$$

such that $\varphi_A(X_i) = x_i$ and $\varphi_B(Y_j) = y_j$ for every $i = 1, \ldots, n$ and $j = 1, \ldots, m$. Obviously $J := \ker \varphi_B \subset m_{B_0}$, and $B_0$ is a complete local ring, so that $B_0$ is $J$-adically complete and separated (Lemma 8.3.12). We then get a commutative diagram of rings:

$$\begin{array}{ccc}
R_0 & \xrightarrow{i_B} & R_B \\
\downarrow{i_A} & & \downarrow{j_B} \\
R_A & \xrightarrow{j_A} & A \\
\downarrow{\varphi_B} & & \downarrow{f} \\
B & & B
\end{array}$$

and by [48] Ch.0, Cor.19.3.11] there exists a local ring homomorphism

$$\psi : R_A \to B_0$$

such that $\psi \circ i_A = j_B \circ i_B$ and $\varphi_B \circ \psi = f \circ j_A$.

Then $\psi$ extends uniquely to a local ring homomorphism

$$g_0 : A_0 \to B_0$$

such that $g_0(X_1) = Y_1, \ldots, g_0(X_n) = Y_n$.

As $f$ is continuous for the $m_A$-adic and $m_B$-adic topologies, the resulting diagram commutes:

$$\begin{array}{ccc}
A_0 & \xrightarrow{\varphi_A} & A \\
\downarrow{g_0} & & \downarrow{f} \\
B_0 & \xrightarrow{\varphi_B} & B
\end{array}$$

Set $C := B_0 \otimes_{A_0} A$; then $f$ factors through $g := g_0 \otimes_{A_0} A : A \to C$ and a map $h : C \to B$.

Claim 9.7.32. $g_0$ is a flat ring homomorphism.

Proof of the claim. Set $X_* := (X_1, \ldots, X_n)$ and $Y_* := (Y_1, \ldots, Y_m)$; as $X_*$ is a regular sequence in $A_0$, the Koszul complex $K(X_*, A_0)$ is a resolution of the quotient $R_A$ of $A_0$ (proposition 7.8.7); by the same token, $B_0 \otimes_{A_0} K_*(X_*, A_0) = K_*(Y_*, B_0)$ is a resolution of $B_0 \otimes_{A_0} R_A$, since $Y_*$ is a regular sequence in $B_0$. This shows that $\text{Tor}^1_{A_0}(B_0, R_A) = 0$, and clearly $B_0 \otimes_{A_0} R_A$ is a flat $R_A$-algebra; then the assertion follows from the local flatness criterion ([100] Th.22.3). $\Diamond$

Clearly $g_0$ is a local map, hence it is faithfully flat, by claim 9.7.32 so the same holds for $g$. Moreover, $C/m_A C = B_0 \otimes_{A_0} k_A = k_B[[Y_{n+1}, \ldots, Y_m]]$ is a regular ring, and clearly $h$ is surjective, as the same holds for $\varphi_B$. Then $A \xrightarrow{g} C \xrightarrow{h} B$ is the sought Cohen factorization of $f$. 

Proof. Obviously \( \beta \) is a homomorphism of complete intersection.

Let \( \pi_B : B \to \kappa_B \) and \( \pi_{C_0} : C \to \kappa_B \) be the natural projections; we obtain a commutative diagram:

\[
\begin{array}{ccc}
A & \overset{f}{\longrightarrow} & B \\
\downarrow{g_0} & & \downarrow{\pi_B} \\
C_0 & \overset{\pi_{C_0}}{\longrightarrow} & \kappa_B
\end{array}
\]

and by [48, Ch.0, Cor.19.3.11] there exists a ring homomorphism \( h_0 : C_0 \to B \) such that \( \pi_B \circ h_0 = \pi_{C_0} \) and \( h_0 \circ g_0 = f \). Pick \( y_1, \ldots, y_m \) as in the proof of (i), set \( C := C_0[[Y_1, \ldots, Y_m]] \), and let \( \mathfrak{m}_C \subset C \) be the maximal ideal, and \( h : C \to B \) the unique continuous ring homomorphism such that \( h|_{C_0} = h_0 \) and \( h(Y_i) = y_i \) for \( i = 1, \ldots, m \). Then \( h \) is surjective, and \( C \) is a formally smooth \( A \)-algebra ([48, Prop.19.3.5(i)]), for the \( A \)-adic and \( C \)-adic topologies.

Proposition 9.7.33. Let \( f : (A, m_A) \to (B, m_B) \) be a local ring homomorphism of local noetherian rings, and \( k_B \) the residue field of \( B \). The following conditions are equivalent:

(a) For every Cohen factorization \( A \overset{g}{\to} C \overset{h}{\to} B^\wedge \) of \( f \), the kernel of \( h \) is generated by a regular sequence.

(b) \( f \) is a homomorphism of complete intersection.

(c) \( H_i(\mathbb{L}_{B/A} \otimes_B k_B) = 0 \) for every \( i > 1 \).

(d) \( H_2(\mathbb{L}_{B/A} \otimes_B k_B) = 0 \).

Proof. Obviously (a) \( \implies \) (b) and (c) \( \implies \) (d).

(b) \( \implies \) (c): First, since \( B^\wedge \) is a flat \( B \)-algebra, by [82, Ch.II, Prop.2.2.1] we have:

\[
\mathbb{L}_{B/A} \otimes_B k_B \xrightarrow{\sim} \mathbb{L}_{k_B/k_B} \xrightarrow{\sim} 0 \quad \text{in } D(k_B{-}\text{Mod}).
\]

Next, from the sequence of maps \( A \xrightarrow{f} B \to B^\wedge \) we get a distinguished triangle:

\[
\mathbb{L}_{B/A} \otimes_B k_B \xrightarrow{\beta} \mathbb{L}_{B^\wedge/A} \otimes_B k_B \to \mathbb{L}_{B^\wedge/B} \otimes_B k_B = 0
\]

([82, Ch.II, Prop.2.1.2]), so \( \beta \) is an isomorphism in \( D(k_B{-}\text{Mod}) \). We may therefore replace \( B \) by \( B^\wedge \), and assume from start that \( B \) is complete and separated. In this case, from a given Cohen factorization \( A \overset{g}{\to} C \overset{h}{\to} B \), we get a distinguished triangle

\[
\mathbb{L}_{C/A} \otimes_C k_B \to \mathbb{L}_{B/A} \otimes_B k_B \to \mathbb{L}_{B/C} \otimes_B k_B
\]

and if \( \text{Ker } h \) is generated by a regular sequence, we have as well \( H_i(\mathbb{L}_{B/C} \otimes_B k_B) = 0 \) for every \( i > 1 \), by theorem 9.6.46. We are thus reduced to checking that \( H_i(\mathbb{L}_{C/A} \otimes_C k_B) = 0 \) for every \( i > 1 \). Let also \( k_A \) be the residue field of \( A \), and set \( C^\prime := k_A \otimes_A C \); since \( C \) is a flat \( A \)-algebra, invoking again [82, Ch.II, Prop.2.2.1] we get a natural identification:

\[
H_i(\mathbb{L}_{C'/k_A} \otimes_{C'} k_B) = 0 \quad \text{for every } i > 0
\]

(claim 9.7.10). By the same token, we have \( H_i(\mathbb{L}_{k_A/k_0}) = 0 \) for every \( i > 0 \). Lastly, the sequence of ring homomorphisms \( k_0 \to k_A \to C^\prime \) yields a distinguished triangle:

\[
\mathbb{L}_{k_A/k_0} \otimes_{k_A} k_B \to \mathbb{L}_{C'/k_0} \otimes_{C'} k_B \to \mathbb{L}_{C'/k_A} \otimes_{C'} k_B
\]

from which, combining with the foregoing, we get the sought vanishing.
(d)⇒(a): Arguing as in the foregoing, we may assume that $B = B^\wedge$; then, a given Cohen factorization $A \to C \to B$ yields an exact sequence

$$H_2(L_{B/A} \otimes_B k_B) \to H_2(L_{B/C} \otimes_B k_B) \xrightarrow{\partial} H_1(L_{C/A} \otimes_C k_B)$$

([82] Ch.II, Prop.2.1.2) and in view of theorem [9.6.46], we are reduced to checking that the boundary map $\partial$ is the zero map. To this aim, we consider the commutative diagram of rings:

$$\begin{array}{ccc}
Z & \longrightarrow & C \\
\downarrow & & \downarrow \\
A & \longrightarrow & C \\
\end{array}$$

from which, by the functoriality property of the transitivity triangle ([82] Ch.II, (2.1.1)), we deduce a commutative diagram of $k_B$-modules:

$$\begin{array}{ccc}
H_2(L_{B/C} \otimes_B k_B) & \xrightarrow{\partial} & H_1(L_{C/Z} \otimes_C k_B) \\
\downarrow & & \downarrow \\
H_2(L_{B/C} \otimes_B k_B) & \xrightarrow{\partial} & H_1(L_{C/A} \otimes_C k_B)
\end{array}$$

which further reduces to checking that $\varphi$ is the zero map. Now, define $k_A, k_0$ and $C'$ as in the foregoing; we get a commutative diagram of $k_B$-modules:

$$\begin{array}{ccc}
H_1(L_{C/Z} \otimes_C k_B) & \longrightarrow & H_1(L_{C'/k_0} \otimes_C k_B) \\
\varphi & & \\
H_1(L_{C/A} \otimes_C k_B) & \longrightarrow & H_1(L_{C'/k_A} \otimes_C k_B)
\end{array}$$

whose bottom horizontal arrow is bijective, by virtue of the natural identification ([9.7.34]), and whose top horizontal arrow is the zero map, by ([9.7.35]), whence the assertion.

**Corollary 9.7.36.** Let $(A, m_A) \xrightarrow{f} (B, m_B) \xrightarrow{g} (C, m_C)$ be two local homomorphisms of noetherian local rings. The following holds:

(i) If $f$ and $g$ are of complete intersection, the same holds for $g \circ f$.

(ii) If $g$ and $g \circ f$ are of complete intersection, the same holds for $f$.

(iii) If $f$ is formally smooth for the $m_A$-adic and $m_B$-adic topologies, and $g \circ f$ is of complete intersection, then $g$ is of complete intersection.

(iv) If $f$ is formally smooth for the $m_A$-adic and $m_B$-adic topologies, or else surjective with kernel generated by a regular sequence of $m_A$, then $f$ is of complete intersection.

**Proof.** (i): Let $k_C$ be the residue field of $C$; we consider the induced distinguished triangle:

$$L_{B/A} \otimes_B k_C \to L_{C/A} \otimes_C k_C \to L_{C/B} \otimes_C k_C$$

([82] Ch.II, Prop.2.1.2). By proposition 9.7.33, the assumptions of (i) amount to the vanishing of $H_2(L_{B/A} \otimes_B k_C)$ and $H_2(L_{C/B} \otimes_C k_C)$, whence the vanishing of $H_2(L_{C/A} \otimes C k_C)$, which yields the assertion, again by proposition 9.7.33.

(ii): We argue likewise with (9.7.37): by proposition 9.7.33, the assumptions imply that $H_2(L_{C/A} \otimes C k_C) = H_2(L_{C/B} \otimes C k_C) = 0$, whence $H_2(L_{B/A} \otimes_B k_C) = 0$, which yields the assertion, again by proposition 9.7.33.

(iii): By proposition 9.7.33, the assumption on $g \circ f$ yields $H_2(L_{C/A} \otimes C k_C) = 0$, and by claim 9.7.10, the assumption on $f$ yields $H_1(L_{B/A} \otimes_B k_C) = 0$. Then, from (9.7.37) we get $H_2(L_{C/B} \otimes C k_C) = 0$, which yields the assertion, as usual by proposition 9.7.33.

(iv): It follows immediately from theorem 9.6.46, claim 9.7.10 and proposition 9.7.33. \qed
Lemma 9.7.38. Let \( f : (A, \mathfrak{m}_A) \to (B, \mathfrak{m}_B) \) be a local ring homomorphism of complete intersection of local noetherian rings, \( M \) an \( A \)-module of finite type, and \( L_* \) a complex of free \( A \)-modules of finite rank. The following holds:

(i) If \( H_n(B \otimes_A L_*) = 0 \) for some \( n \in \mathbb{Z} \), then \( H_n(L_*) = 0 \).

(ii) If \( \text{Tor}_i^A(M, B) = 0 \) for every \( i \geq 0 \), then \( \text{Tor}_i^A(M, B) = 0 \) for every \( i \in \mathbb{N} \).

Proof. (i): Pick a Cohen factorization \( A \xrightarrow{g} C \xrightarrow{h} B^n \) of \( f \), so that \( \text{Ker} \, h \) is generated by a regular sequence of \( C \); since \( g \) is faithfully flat, it suffices to check that \( H_n(C \otimes_A L_*) = 0 \), and since \( B^n \) is a flat \( B \)-algebra, we have \( H_n(B^n \otimes_A L_*) = 0 \). Thus, we may replace \( A \) by \( C \), \( B \) by \( B^n \), and \( L_* \) by \( C \otimes_A L_* \), and assume from start that \( f \) is surjective, and its kernel is generated by a regular sequence \( x_* := (x_1, \ldots, x_k) \) of \( A \). Next, arguing by induction on the length \( k \) of \( x_* \), we are easily reduced to showing the following. If \( x \in \mathfrak{m}_A \) is a regular element, and \( H_n(L_* / xL_*) = 0 \), then \( H_n(L_*) = 0 \). However, since \( L_i \) is a free \( A \)-module for every \( i \in \mathbb{Z} \), we have a short exact sequence of complexes:

\[
0 \to L_* \xrightarrow{x^{-1}1_*} L_* \to L_*/xL_* \to 0
\]

whence a short exact sequence of \( A \)-modules:

\[
H_n(L_*) \xrightarrow{x^{-1}H_n(L_*)} H_n(L_*) \to H_n(L_*/xL_*) = 0.
\]

But \( H_n(L_*) \) is an \( A \)-module of finite type, so \( H_n(L_*) = 0 \), by Nakayama’s lemma.

(ii): Since \( B^n \) is a faithfully flat \( B \)-algebra, we have a natural identification

\[
B^n \otimes_B \text{Tor}_i^A(M, B) \xrightarrow{\sim} \text{Tor}_i^A(M, B^n) \quad \text{for every } i \in \mathbb{N}
\]

and it suffices to check that \( B^n \otimes_B \text{Tor}_i^A(M, B) = 0 \) for every \( i > 0 \). Moreover, the induced map \( A \to B^n \) is still of complete intersection, by corollary 9.7.36(i,iv). Thus, we may replace \( B \) by \( B^n \), and assume that \( B \) is \( m_B \)-adically complete, in which case \( f \) admits a Cohen factorization \( (A, \mathfrak{m}_A) \xrightarrow{g} (C, \mathfrak{m}_C) \xrightarrow{h} (B, \mathfrak{m}_B) \) such that \( \text{Ker} \, h \) is generated by a regular sequence of \( m_C \), and since \( g \) is faithfully flat, we have a natural identification

\[
C \otimes_A \text{Tor}_i^A(M, B) \xrightarrow{\sim} \text{Tor}_i^C(C \otimes_A M, B) \quad \text{for every } i \in \mathbb{N}.
\]

Again, it suffices to check that \( C \otimes_A \text{Tor}_i^A(M, B) = 0 \) for every \( i > 0 \) and \( h \) is of complete intersection, by corollary 9.7.36(iv). Thus, we may replace \( f \) by \( h \) and \( M \) by \( A^n \otimes_A M \), and assume that \( f \) is surjective, with kernel generated by a regular sequence \( x_* := (x_1, \ldots, x_k) \) of \( \mathfrak{m}_A \). Now, in view of lemma 7.8.14(ii), proposition 7.8.15, and remark 7.8.16(i), the assumption of (ii) is equivalent to the vanishing of \( H_i(x_*, M) \). By the same token, the latter implies that \( x_* \) is completely secant on \( M \). Then the assertion follows, by invoking again lemma 7.8.14(ii).

Theorem 9.7.39. Let \( (A, \mathfrak{m}_A) \) be a quasi-excellent local ring, \( (B, \mathfrak{m}_B) \) a complete local noetherian ring, and \( f : A \to B \) a local ring homomorphism. Let \( k_A \) and \( k_B \) be the residue fields of \( A \) and \( B \), and suppose that \( H_1(L_{k_B/k_A}) \) is a finite dimensional \( k_B \)-vector space. Then \( B \) is the colimit of a filtered system \( (B_\lambda \mid \lambda \in \Lambda) \) of local \( A \)-algebras of essentially finite type, such that:

(i) the transition map \( B_\lambda \to B_\mu \) is local of complete intersection, for every \( \mu \geq \lambda \) in \( \Lambda \)

(ii) the universal cocone \( (B_\lambda \to B \mid \lambda \in \Lambda) \) consists of local maps of complete intersection.

Moreover, if \( B \) is a domain, then \( B_\lambda \) is a domain for every \( \lambda \in \Lambda \).

Proof. Let \( \hat{A} \) be the \( \mathfrak{m}_A \)-adic completion of \( A \), and \( j : A \to \hat{A} \) the completion map; by proposition 9.7.31(ii), the completion \( f^\wedge : \hat{A} \to B \) of \( f \) admits a Cohen factorization \( \hat{A} \xrightarrow{g^\wedge} (C, \mathfrak{m}_C) \xrightarrow{h} B \), where \( g^\wedge \) is formally smooth for the \( \mathfrak{m}_A \)-adic and \( \mathfrak{m}_C \)-adic topologies. Then the same holds for \( g : = g^\wedge \circ j : A \to C \), and since \( f \) is quasi-excellent, the induced morphism \( \text{Spec} \, C \to \text{Spec} \, A \) is regular (theorem 9.7.15). Then, by a theorem of Popescu ([108]), \( C \) is
the colimit of a filtered system \((C_\lambda \mid \lambda \in \Lambda)\) of smooth \(A\)-algebras. For every \(\lambda \in \Lambda\), let \(p_\lambda \subset C_\lambda\) be the preimage of \(m_C\); clearly \(C\) is also the filtered colimit of the induced system of local \(A\)-algebras of essentially finite type \((D_\lambda := C_{\lambda p_\lambda} \mid \lambda \in \Lambda)\), with local transition maps. By corollary \[9.7.36\] (iv), the map \(g\) is of complete intersection, and by corollary \[9.7.36\] (iii), the same then holds for each map \(D_\lambda \to C\) of the universal cocone. Now, let us pick an exact complex of \(C\)-modules of finite type

\[\Sigma_\bullet : \quad C^\oplus m \xrightarrow{u} C^\oplus n \xrightarrow{v} C \xrightarrow{h} B.\]

We may then find \(\lambda \in \Lambda\), and \(D_\lambda\)-linear maps

\[D_\lambda^\oplus m \xrightarrow{u_\lambda} D_\lambda^\oplus n \xrightarrow{v_\lambda} D_\lambda \quad \text{such that} \quad C \otimes_{D_\lambda} u_\lambda = u \quad \text{and} \quad C \otimes_{D_\lambda} v_\lambda = v\]

and we set \(u_\mu := D_\mu \otimes_{D_\lambda} u_\lambda, v_\mu := D_\mu \otimes_{D_\lambda} v_\lambda,\) and \(B_\lambda := \text{Coker} v_\lambda\) for every \(\mu \in \Lambda\) with \(\mu \geq \lambda\). Since \(v \circ u = 0\), we may find then also find \(\mu \geq \lambda\) such that \(v_\mu \circ u_\mu = 0\). After replacing \(\Lambda\) by a cofinal subset, we thus obtain a compatible system of complexes :

\[\Sigma_{\lambda, \bullet} : \quad D_\lambda^\oplus m \xrightarrow{u_\lambda} D_\lambda^\oplus n \xrightarrow{v_\lambda} D_\lambda \xrightarrow{h_\lambda} B_\lambda \quad \text{for every \(\lambda \in \Lambda\)}\]

whose colimit is \(\Sigma_\bullet\), and clearly the induced filtered system \((B_\lambda \mid \lambda \in \Lambda)\), whose colimit is \(B\), consists of local \(A\)-algebras, and its transition maps are local homomorphisms of \(A\)-algebras. By construction, \(\Sigma_\bullet = C \otimes_{D_\lambda} \Sigma_{\lambda, \bullet}\), so \(\Sigma_{\lambda, \bullet}\) is exact for every \(\lambda \in \Lambda\), by lemma \[9.7.38\] (i). It follows easily that :

\[\text{Tor}_i^{D_\lambda}(B_\lambda, C) = 0 \quad \text{for every \(\lambda \in \Lambda\)}\]

and then we have \(\text{Tor}_i^{D_\lambda}(B_\lambda, C) = 0\) for every \(\lambda \in \Lambda\) and every \(i > 0\) (lemma \[9.7.38\] (ii)). By \[82\] Ch.II, Prop.2.2.1] we deduce, for every \(\lambda \in \Lambda\), a natural identification

\[\mathbb{L}_{B/B_\lambda} \otimes_B k_B \xymatrix{\sim & \mathbb{L}_{C/D_\lambda} \otimes_C k_B} \quad \text{in} \quad \text{D}(k_B\text{-Mod})\]

and taking into account proposition \[9.7.33\] we finally obtain (ii). Assertion (i) follows from (ii) and corollary \[9.7.36\] (ii). Lastly, suppose that \(B\) is a domain, and for any given \(\lambda \in \Lambda\), choose a Cohen factorization \(B_\lambda \xrightarrow{2_\lambda} B'_\lambda \xrightarrow{h_\lambda} B\), with \(I := \text{Ker} h_\lambda\) generated by a regular sequence; thus, the graded ring \(\text{gr}_{\lambda} B'_\lambda\) associated with the \(I\)-adic filtration on \(B'_\lambda\) is isomorphic to a polynomial algebra \(B[T_1, \ldots, T_n]\) (proposition \[7.8.15\]). Hence \(\text{gr}_{\lambda} B'_\lambda\) is a domain, and since the \(I\)-adic filtration is separated on \(B'_\lambda\) (\[100\] Th.8.10(iii))), \(B'_\lambda\) is a domain; on the other hand, \(g_\lambda\) is faithfully flat, hence injective, so \(B_\lambda\) is a domain. \(\square\)

9.8. **Normalization, weak normalization and \(p\)-integral closure.** Recall that for an inclusion of rings \(A \subset B\), we denote by \(\text{i.c.}(A, B)\) the integral closure of \(A\) into \(B\) (see definition \[7.6.13\] (i)); recall moreover that

\[(9.8.1) \quad \text{i.c.}(S^{-1}A, S^{-1}B) = S^{-1}\text{i.c.}(A, B) \quad \text{for every subset} \ S \subset A.\]

More generally, let \(X\) be a scheme, \(\mathcal{O} \subset \mathcal{B}\) an inclusion of quasi-coherent \(\mathcal{O}_X\)-algebras; then the rule : \(U \mapsto \mathcal{C}(U) := \text{i.c.}(\mathcal{O}(U), \mathcal{B}(U))\) for every affine open subset \(U \subset X\) defines a subpresheaf \(\mathcal{C} \subset \mathcal{B}\) on the site of affine open subsets of \(X\), and \[9.8.1\] easily implies that \(\mathcal{C}\) is a sheaf on this site, so it extend uniquely on the Zariski site of \(X\) to a quasi-coherent \(\mathcal{O}_X\)-subalgebra of \(\mathcal{B}\), which we call the **integral closure of** \(\mathcal{O}\), **in** \(\mathcal{B}\), and denote

\[\text{i.c.}(\mathcal{O}, \mathcal{B}).\]

Also, for every ring \(A\), we let \(\mathcal{N}_A\) be the nilradical of \(A\), and set \(A_\text{red} := A/\mathcal{N}_A\), the maximal reduced quotient of \(A\). Every ring homomorphism \(f : A \to A'\) induces a ring homomorphism

\[f_\text{red} : A_\text{red} \to A'_\text{red}.\]

Recall that

\[\mathcal{N}_{S^{-1}A} = S^{-1}A; \quad \text{and} \quad S^{-1}(A_\text{red}) = (S^{-1}A)_\text{red}; \quad \text{for every subset} \ S \subset A.\]
Arguing as in the foregoing, we deduce that for every quasi-coherent \( \mathcal{O}_X \)-algebra \( \mathcal{A} \), the rule : 
\( U \mapsto \mathcal{N}_{\mathcal{A}}(U) \) for every affine open subset \( U \subset X \) extends uniquely to a quasi-coherent ideal 
\( \mathcal{N}_{\mathcal{A}} \subset \mathcal{A} \) 

called the nilradical of \( \mathcal{A} \). The \( \mathcal{O}_X \)-algebra \( \mathcal{A}_{\text{red}} := \mathcal{A}/\mathcal{N}_{\mathcal{A}} \) is quasi-coherent, and every morphism \( \varphi : \mathcal{A} \to \mathcal{A}' \) of quasi-coherent \( \mathcal{O}_X \)-algebras induces a morphism \( \varphi_{\text{red}} : \mathcal{A}_{\text{red}} \to \mathcal{A}'_{\text{red}} \).

**Lemma 9.8.2.** Let \( A \) be a Krull domain, \( F \) the field of fractions of \( A \), \( B \) a flat \( A \)-algebra, and suppose that \( B \otimes_A \kappa(p) \) is reduced, for every prime ideal \( p \in \text{Spec} \ A \) of height one. Then \( B \) is integrally closed in \( B \otimes_A F \).

**Proof.** See [100, §12] for the basic generalities on Krull domains; especially, [100, Th.12.6] asserts that if \( A \) is a Krull domain, the natural sequence of \( A \)-modules :
\[
\mathcal{E} : 0 \to A \to F \to \bigoplus_{ht \, p=1} F/A_p \to 0
\]
is short exact, where \( p \in \text{Spec} \ A \) ranges over the prime ideals of height one. By flatness, \( \mathcal{E} \otimes_A \mathcal{B} \) is still exact, hence \( B = \bigcap_{ht \, p=1} B \otimes_A A_p \) (where the intersection takes place in \( B \otimes_A F \)). We are therefore reduced to the case where \( A \) is a discrete valuation ring. Let \( t \) denote a chosen generator of the maximal ideal of \( A \), and suppose that \( x \in B \otimes_A F \) is integral over \( B \), so that \( x^n + b_1x^{n-1} + \cdots + b_n = 0 \) in \( B \otimes_A F \), for some \( b_1, \ldots, b_n \in B \); let also \( r \in \mathbb{N} \) be the minimal integer such that we have \( x = t^{-r}b \) for some \( b \in B \). We have to show that \( r = 0 \); to this aim, notice that \( b^n + t^{r-1}b_1b^{n-1} + \cdots + t^{rn}b_n = 0 \) in \( B \); if \( r > 0 \), it follows that the image \( \bar{b} \) of \( b \) in \( B/tB \) satisfies the identity : \( \bar{b}^n = 0 \), therefore \( \bar{b} = 0 \), since by assumption, \( B/tB \) is reduced. Thus \( b = t^{r}b' \) for some \( b' \in B \), and \( x = t^1b' \), contradicting the minimality of \( r \).

The following proposition generalizes [49, Ch.IV, Prop.6.14.4].

**Proposition 9.8.3.** Let \( f : X \to S \) be a flat morphism of schemes with geometrically reduced fibres, \( B_1 \subset B_2 \) two quasi-coherent \( \mathcal{O}_S \)-algebras, and \( B_3 := \text{i.c.}(B_1, B_2) \). Suppose that :

(a) either \( f \) is locally finitely presented,

(b) or else, \( S \) is locally noetherian.

Then \( f^* B_3 = \text{i.c.}(f^* B_1, f^* B_2) \) and \( f^*(B_1)_{\text{red}} = f^*(B_1, \text{red}) \).

**Proof.** The assertion is local on both \( S \) and \( X \), hence we may assume that \( S = \text{Spec} \ A \) and \( X = \text{Spec} \ A' \), for a ring \( A \) and an \( A \)-algebra \( A' \). Then also \( B_1 \) and \( B_2 \) are the quasi-coherent algebras associated with \( A \)-algebras \( B_1 \subset B_2 \), and \( B_3 \) is the quasi-coherent algebra associated with \( B_3 := \text{i.c.}(B_1, B_2) \). Suppose first that condition (a) holds, and write \( A \) as the colimit of a filtered system \( (A_\lambda | \lambda \in \Lambda) \) of noetherian subrings; we remark :

**Claim 9.8.4.** Let \( A_\lambda := (A_\lambda \mid \lambda \in \Lambda) \) be a filtered system of rings, \( A \) the colimit of \( A_\lambda \), and \( X \to S := \text{Spec} \ A \) a flat morphism of schemes of finite presentation, with geometrically reduced fibres. Then for some \( \lambda \in \Lambda \) there exists a flat morphism of schemes with geometrically reduced fibres \( X_\lambda \to S_\lambda \), and an isomorphism of \( S \)-schemes \( S \times_{S_\lambda} X_\lambda \to X \).

**Proof of the claim.** By [50, Ch.IV, Th.8.8.2(ii)], we may find \( \lambda \in \Lambda \), a finitely presented morphism \( f_\lambda : X_\lambda \to S_\lambda \), and an isomorphism of \( S \)-schemes : \( X \to X_\lambda \times_{S_\lambda} S \). We set \( S_\mu := \text{Spec} \ A_\mu \), \( X_\mu := X_\lambda \times_{S_\lambda} S_\mu \), and \( f_\mu := S_\mu \times_{S_\lambda} f_\lambda : X_\mu \to S_\mu \) for every \( \mu \in \Lambda \) with \( \mu \geq \lambda \); after replacing \( \Lambda \) by a cofinal subset, we may then assume that \( f_\mu \) is defined for every \( \mu \in \Lambda \), and moreover that each such \( f_\mu \) is flat ([50, Ch.IV, Cor.11.2.6.1]). For every \( \mu \in \Lambda \), let \( Z_\mu \subset S_\mu \) be the subset of all \( s \in S_\mu \) such that the fibre \( f_\mu^{-1}(s) \) is not geometrically reduced; by [50, Ch.IV, Th.9.7.7], \( Z_\mu \) is a constructible subset of \( S_\mu \). By assumption, we have 
\[
\bigcap_{\mu \in \Lambda} p_\mu^{-1} Z_\mu = \emptyset
\]
and it is clear that \( p^{-1}_\mu \Lambda \subset p^{-1}_\lambda \Lambda \) whenever \( \mu \geq \lambda \). Then, \( \Lambda = \emptyset \) for some \( \mu \in \Lambda \) ([48 Ch.IV, Prop.1.8.2, Cor.1.9.8]), hence we may replace \( \Lambda \) by a still smaller cofinal subset, and achieve that all the \( f_\lambda \) have geometrically reduced fibres.

By claim [9.8.4] we find \( \lambda \in \Lambda \) and a flat ring homomorphism \( \varphi_0 : A_\lambda \to A'_0 \) such that:

- all the fibres of \( \text{Spec}(\varphi_0) \) are geometrically reduced
- there exists an isomorphism of \( A \)-algebras \( A' \cong A \otimes_{A_\lambda} A'_0 \).

We need to show that \( A' \otimes_A B_3 = \text{i.c.}(A' \otimes_A B_1, A' \otimes_A B_2) \) and \( A' \otimes_A B_1_{\text{red}} = (A' \otimes_A B_1)_{\text{red}} \). However, in view of the natural identifications : \( A' \otimes_A B_i \cong A'_0 \otimes_{A'_0} B_i \) for \( i = 1, 2, 3 \), we may replace \( A \) and \( A' \) by \( A_\lambda \) and \( A'_0 \), and assume that \( A \) is noetherian, \( i.e. \) that condition (b) holds. For the first identity, arguing as in the proof of [49 Ch.IV, Prop.6.14.4 and Cor.6.14.5], we reduce to the following two separate cases:

(a') \( B_1 \) is a domain of finite type over \( A \) and \( B_2 \) is a finite extension of \( \text{Frac}(B_1) \), \( B_1 \) and \( B_2 \) are fields, and \( B_1 \) is algebraically closed in \( B_2 \) (so \( B_3 = B_1 \) in this case).

In case (a') holds, \( B_3 \) is a Krull domain ([103 Th.33.10]), and the assertion follows from lemma [9.8.2]. In case (b'), we may replace \( A \) by \( B_1 \) and \( A' \) by \( A' \otimes_A B_1 \), and assume that \( A \) is a field, \( A' \) is a geometrically reduced \( A \)-algebra, \( B := B_2 \) is a field extension of \( A \) such that \( A \) is algebraically closed in \( B \), and we need to check that \( A' \) is integrally closed in \( A' \otimes_A B \). Now, pick a basis \( (b_i \mid i \in I) \) for the \( A \)-vector space \( B \), with \( b_{i_0} = 1 \) for some \( i_0 \in I \), and say that \( \sum_{i \in J} a_i \otimes b_i \in A' \otimes_A B \) is integral over \( A' \) (for some finite subset \( J \subset I \)); we need to check that \( a_i = 0 \) for every \( i \in J \setminus \{i_0\} \). However, since \( A' \) is reduced, it suffices to check that the image of \( a_i \) vanishes in \( \kappa(p) \), for every minimal prime ideal \( p \) of \( A' \). Thus, we may further assume that \( A' \) is a field, in which case it is a separable (not necessarily algebraic) extension of \( A \), since it is a geometrically reduced \( A \)-algebra. Then, \( A' \otimes_A B \) is a domain, according to [32 Ch.V, §17, n.2, Cor.], and \( A' \) is algebraically closed in \( \text{Frac}(A' \otimes_A B) \), by [32 Ch.V, §17, Exerc.2(b)].

For the second identity, notice that \( A' \otimes_A \mathcal{M}_B \subset \mathcal{M}_{A' \otimes_A B_1} \); hence it suffices to check that if \( B_1 \) is reduced, the same holds for \( A' \otimes_A B_1 \). Moreover, we may assume that \( B_1 \) is an \( A \)-algebra of finite type, in which case \( B_1 \) is noetherian, and it has finitely many minimal prime ideals \( q_1, \ldots, q_m \), and since \( B_1 \) is reduced, the natural map \( B_1 \to \prod_{i=1}^m B_{q_i} \), is injective. Then, the same holds for the induced map \( A' \otimes_A B_1 \to \prod_{i=1}^n A' \otimes_A B_{q_i} \). However, \( B_{q_i} \) is a field, and \( A' \otimes_A B_{q_i} \) is reduced for every \( i = 1, \ldots, n \), since \( A' \) has geometrically reduced fibres over \( A \); the assertion follows.

**Definition 9.8.5.** Let \( f : X' \to X \) be a morphism of schemes, \( \xi' \) a geometric point of \( X' \) localized at \( x' \in X' \), and set \( \xi := f(\xi') \). We shall say that \( f \) is **pro-smooth at the point** \( x' \) if the induced map of strictly henselian local rings

\[
\mathcal{O}_{X(\xi), x} \to \mathcal{O}_{X'(\xi'), x'}
\]

is ind-smooth (\( i.e. \) a filtered colimit of smooth ring homomorphisms).

**Corollary 9.8.6.** Let \( f : X' \to X \) be a morphism of schemes, \( \xi' \) a geometric point of \( X' \), \( \mathcal{R} \subset \mathcal{S} \) a monomorphism of quasi-coherent \( \mathcal{O}_X \)-algebras, and

\[
\varphi : f^* \text{i.c.}(\mathcal{R}, \mathcal{S}) \to \text{i.c.}(f^* \mathcal{R}, f^* \mathcal{S})
\]

the induced morphism. Suppose that \( f \) is pro-smooth at the support \( x' \) of \( \xi' \); then we have:

(i) \( f \) is flat at the point \( x' \).

(ii) \( \varphi_{\xi'} \) is an isomorphism.
Proof. (i): Set \( x := f(x'), \xi := f(\xi') \). We have a commutative diagram of local \( S \)-schemes

\[
\begin{array}{ccc}
X'(\xi') \ar[r]^{f(\xi')} & X(\xi) \ar[d]^{\psi} \\
X'(x') \ar[r]_{f(x')} & X(x) \ar[u]^{\psi}
\end{array}
\]

whose vertical arrows are ind-étale morphisms, and whose top horizontal arrow is ind-smooth by assumption. Especially, since \( \psi' \) is faithfully flat, the same holds for \( f(x') \), i.e. \( f \) is flat at \( x' \).

(ii): We may assume that \( X = \text{Spec} \ A \) for some ring \( A \). Let \( g : X'(\xi') \to X' \) be the natural morphism. It suffices to show that \( g^* \varphi \) is an isomorphism. However, \( g^* i.c.(f^* \mathcal{R}, f^* \mathcal{F}) = i.c.(g^* f^* \mathcal{R}, g^* f^* \mathcal{F}) \) by proposition 9.8.3 and \( g^* \varphi \) is the induced morphism

\[
(f \circ g)^* i.c.(\mathcal{R}, \mathcal{F}) \to i.c.(f \circ g)^* \mathcal{R}, (f \circ g)^* \mathcal{F}).
\]

Notice that \( f \circ g \) is induced by an ind-smooth ring homomorphism \( A \to \mathcal{O}_{X', \xi'} \), so we may invoke again proposition 9.8.3 to conclude. \( \square \)

9.8.7. Recall that a morphism of schemes \( \varphi : X \to Y \) is called universally injective or radical if for every field \( K \), the induced map on \( K \)-valued points \( X(K) \to Y(K) \) is injective ([44, Ch.I, Def.3.5.4]). It is easily seen that the latter holds if and only if \( \varphi \) is injective and the residue field extension \( \kappa(x) \to \kappa(\varphi(x)) \) is purely inseparable for every \( x \in X \). In the rest of this section we study certain classes of ring homomorphisms \( f : A \to B \) such that \( \text{Spec} f \) is radical, in which case we just say that \( f \) is radial. We shall see that \( f \) is radical if and only if the kernel \( I_f \) of the multiplication law \( B \otimes_A B \to B \) lies in the nilradical \( \mathcal{N}_{B \otimes_A B} \) (corollary 9.8.13(i)).

Lemma 9.8.8. (i) Let \( S \) be a scheme, and \( \varphi : Y \to X \) and \( \varphi' : Y' \to X' \) two surjective morphisms of \( S \)-schemes. Then \( \varphi \times_S \varphi' : Y \times_S Y' \to X \times_S X' \) is surjective.

(ii) Let \( f : A \to B \) be a ring homomorphism such that \( \text{Spec} f \) is surjective; then \( \text{Ker} f \subset \mathcal{N}_A \).

(iii) Let \( A \) be a ring, \( f : B \to C \) and \( f' : B' \to C' \) two integral homomorphisms of \( A \)-algebras with \( \text{Ker} f \subset \mathcal{N}_B \) and \( \text{Ker} f' \subset \mathcal{N}_{B'} \). Then \( f \otimes_A f' : B \otimes_A B' \to C \otimes_A C' \) is integral and its kernel lies in \( \mathcal{N}_{B \otimes_A B'} \).

Proof. (i): (See [44, Ch.I, Prop.3.5.2(i)])]. We have \( \varphi \times_S \varphi' = (\varphi \times_S X') \circ (Y \times_S \varphi') \), so it suffices to show that both \( \varphi \times_S X' \) and \( Y \times_S \varphi' \) are surjective. But notice that the natural isomorphism \( Y \times_S X' \to Y \times_X (X \times_S X') \) identifies \( \varphi \times_S X' \) with \( \varphi \times_X (X \times_S X') \), and similarly for \( Y \times_S \varphi' \); hence, we are reduced to checking if \( \varphi : Y \to X \) is a surjective morphism of schemes, and \( \psi : Z \to X \) is any \( X \)-scheme, then the base change \( \varphi \times_Y Z : Y \times_X Z \to Z \) is surjective. Thus, let \( y \in Y \) and \( z \in Z \) with \( x := \varphi(y) = \psi(z) \), and let \( \kappa(z) \to \kappa(x) \to \kappa(y) \) be the induced residue field extensions; it suffices to check that \( \text{Spec} \kappa(y) \times_{\text{Spec} \kappa(x)} \text{Spec} \kappa(z) \neq \emptyset \), which is clear, since \( \kappa(y) \cong_{\kappa(z)} \kappa(z) \neq 0 \).

(ii): Let \( a \in \text{Ker} f \), and \( p \in \text{Spec} A \); by assumption there exists \( q \in \text{Spec} B \) with \( p = f^{-1}q \), so that \( a \in p \), whence the assertion.

(iii): Obviously \( f \otimes_A f' \) is integral. Since \( (B \otimes_A B')_{\text{red}} = (B_{\text{red}} \otimes_{A_{\text{red}}} B'_{\text{red}})_{\text{red}} \), and similarly for \( (C \otimes_A C')_{\text{red}} \), we may replace \( f \) and \( f' \) by \( f_{\text{red}} \) and \( f'_{\text{red}} \), and assume from start that \( f \) and \( f' \) are injective. Then, by the going up theorem, both \( \text{Spec} f \) and \( \text{Spec} f' \) are surjective, hence the same holds for \( \text{Spec} f \otimes_A f' \), by (i), and then the assertion follows from (ii). \( \square \)

The following proposition 9.8.9 is borrowed from [16, Exp.XII, Lemma 2.6], and its corollary 9.8.13(ii) can also be easily deduced from [124, Th.1].

Proposition 9.8.9. Let \( f : A \to B \) be an injective and finite ring homomorphism of noetherian rings. Then \( f \) is the composition of a finite sequence of injective ring homomorphisms

\[
B_n := A \xrightarrow{f_n} B_{n-1} \xrightarrow{f_{n-1}} B_{n-2} \to \cdots \to B_0 := B
\]
such that the induced morphism of schemes \( \text{Spec} f_i : \text{Spec} B_i \to B_{i+1} \) is an effective epimorphism in the category of schemes, for every \( i = 1, \ldots, n \).

**Proof.** The assertion means that \( f_i \) identifies \( B_{i+1} \) with the equalizer of the two natural ring homomorphisms \( (g_{i,k} : B_i \to B_i \otimes_{B_{i+1}} B_i \mid k = 1, 2) \), with \( g_{i,1}(b) := b \otimes 1 \) and \( g_{i,2}(b) := 1 \otimes b \) for \( i = 1, \ldots, n \) and every \( b \in B_{i+1} \). Then let us define inductively \( B_0 := B \), and \( B_{i+1} := \ker(h_{i,1} - h_{i,2}) \) for every \( i \in \mathbb{N} \), where \( h_{i,1}, h_{i,2} : B_i \to B_i \otimes_A B_i \) are the analogous maps.

**Claim 9.8.10.** For every \( i \in \mathbb{N} \), the induced map \( B_i \otimes_A B_i \to B_i \otimes_{B_{i+1}} B_i \) is an isomorphism.

**Proof of the claim.** The map in question is clearly surjective. We compute in \( B_i \otimes_A B_i \):

\[
    cb \otimes b' = (c \otimes 1) \cdot (b \otimes b') = (1 \otimes c) \cdot (b \otimes b') = b \otimes cb'
\]

for every \( b, b' \in B_i \) and \( c \in B_{i+1} \) which easily implies that the map in question is also injective. \( \Diamond \)

Due to claim 9.8.10 it remains only to check that \( B_n = A \) for sufficiently large \( n \in \mathbb{N} \). To this aim, set \( M_i := B_i/A \), and let \( S_i \subset \text{Spec} A \) be the support of \( M_i \), for every \( i \in \mathbb{N} \). Then \( S_{i+1} \subset S_i \), for every \( i \in \mathbb{N} \), and since \( A \) is noetherian, there exists \( n \in \mathbb{N} \) such that \( S := S_n = S_i \) for every \( i \geq n \). Thus, it suffices to check that \( S = \emptyset \). If the latter fails, let \( p \) be a maximal point of the closed subset \( S \); a simple induction on \( i \in \mathbb{N} \) shows that \( (B_{i+1})_{p} \) is the equalizer of the localizations \( h_{i,1})_{p}, (h_{i,2})_{p} : B_{i+1} \otimes_A B_{i+1} \), for every \( i \in \mathbb{N} \). Hence, we may replace \( f \) by its localization \( f_{p} : A_{p} \to B_{p} \), and assume from start that \( (A, p) \) is local, and the support of \( M_n \) is the maximal ideal of \( A \), hence the \( A \)-module \( M_n \) has finite length, so there exists \( i \geq n \) such that \( M_i = M_{i+1} \), i.e. \( B_i = B_{i+1} \). Set \( \kappa(p) := A/p \) and \( B_i(p) := B_i/pB_i \); it follows that each of the maps \( B_i \to B_i \otimes_A B_i \) is an isomorphism, hence the same holds for the induced maps \( B_i(p) \to B_i(p) \otimes_{\kappa(p)} B_i(p) \), so \( \dim_{\kappa(p)} B_i(p) = 1 \), and therefore \( f : A \to B \) induces an isomorphism \( \kappa(p) \cong B_i(p) \). By Nakayama’s lemma, we conclude that \( A = B_i \), whence \( M_i = 0 \) and \( S_i = \emptyset \), a contradiction. \( \square \)

9.8.11. Let \( p \in \mathbb{Z} \) be a prime integer. For every \( \mathbb{F}_p \)-algebra \( R \), we let \( R^{\text{perf}} \) be the inductive limit of the system of \( \mathbb{F}_p \)-algebras \( (R_n \mid n \in \mathbb{N}) \) with \( R_n := R \) for every \( n \in \mathbb{N} \), and with transition map given by the Frobenius endomorphism \( \Phi_R : R_n \to R_{n+1} \) of \( R \), for every such \( n \). The rule \( R \mapsto R^{\text{perf}} \) yields a left adjoint for the forgetful functor from the category of perfect \( \mathbb{F}_p \)-algebras to the category of all \( \mathbb{F}_p \)-algebras. Moreover, by virtue of [59 Th.3.5.13(ii)], any étale homomorphism \( R \to S \) of \( \mathbb{F}_p \)-algebras induces an isomorphism

\[
    R^{\text{perf}} \otimes_R S \cong S^{\text{perf}}.
\]

Especially, for every subset \( \Sigma \subset R \), we have

\[
    (\Sigma^{-1} R)^{\text{perf}} = \Sigma^{-1} R^{\text{perf}}.
\]

**Corollary 9.8.13.** Let \( f : A \to B \) be a ring homomorphism.

(i) The following conditions are equivalent:

(a) \( f \) is a radical homomorphism,

(b) \( I_f \subset \mathcal{M}_{B \otimes_A B} \) (notation of (9.8.7)).

(ii) Let moreover \( \rho \in \mathbb{N} \) be a prime integer, and suppose that \( A \) and \( B \) are \( \mathbb{F}_p \)-algebras, and \( f \) is integral and injective. Then (a) and (b) are also equivalent to:

(c) \( f \) induces an isomorphism \( f^{\text{perf}} : A^{\text{perf}} \cong B^{\text{perf}} \).

**Proof.** (a)\( \Leftrightarrow \)(b): Set \( X := \text{Spec} A, Y := \text{Spec} B \), and let \( \pi : Y \times_X Y \to X \) be the projection.

With this notation, \( \text{Spec} B \otimes_A B/I_f \) is the diagonal closed subset \( \Delta_{Y/X} \subset Y \times_X Y \). Suppose then that (b) holds; it follows already that \( \Delta_{Y/X} = Y \times_X Y \), so \( \varphi := \text{Spec} f : Y \to X \) is injective. Moreover, let \( y \in Y \) be any point, set \( x := \varphi(y) \), and let \( \kappa(x) \) and \( \kappa(y) \) be the residue fields of \( x \) and respectively \( y \); then \( Z(y) := \text{Spec} \kappa(y) \otimes_{\kappa(x)} \kappa(y) = \pi^{-1}(y) \) consists of a unique
point of $Y \times_X Y$, which means that the field extension $κ(x) \subset κ(y)$ is algebraic and purely inseparable, therefore (a) holds. Conversely, if (a) holds, then $φ$ is injective, and $Z(y)$ consists of a unique point, so that $Δ_{Y/X} = Y \times_X Y$, whence (b).

(b)$\Leftrightarrow$(c): Since the natural map $R^{perf} \to (R_{red})^{perf}$ is an isomorphism for every $\mathbb{F}_p$-algebra $R$, and since $f$ is radical if and only if the same holds for the induced map $f_{red} : A_{red} \to B_{red}$, we may assume that $A$ and $B$ are reduced, in which case (c) means that for every $b \in B$ there exists $n \in \mathbb{N}$ with $b^{p^n} \in A$. Now, let us write $B$ as the filtered colimit of the system $(f_\lambda : A \to B_\lambda | \lambda \in Λ)$ of its finite $A$-subalgebras. It follows easily that (c) holds for $f$ if and only if it holds for every $f_\lambda$. On the other hand, $Spec f$ is the limit of the system of maps $(Spec f_\lambda | \lambda \in Λ)$, and each $Spec f_\lambda$ is surjective; it follows easily that $Spec f$ is injective if and only if the same holds for each $Spec f_\lambda$. Moreover, it is clear that for any field $K$, and any filtered system $E_* := (E_\lambda | \lambda \in Λ)$ of field extension of $K$, the colimit of $E_*$ is algebraic and purely inseparable over $K$ if and only if the same holds for every $E_\lambda$; summing up, we see that $f$ is radical if and only if the same holds for every $f_\lambda$, hence, in view of (i), it suffices to show the equivalence (b)$\Leftrightarrow$(c) for each $f_\lambda$, and we may assume that $f$ is a finite ring homomorphism.

Next, let $(A_\lambda | \lambda \in Λ)$ be the filtered system of all $\mathbb{Z}$-subalgebras of $A$ of finite type; also, choose any finite subset $Σ \subset B$ such that $B = A[Σ]$. Notice that (c) holds if and only if for every $b \in Σ$ there exists $n \in \mathbb{N}$ such that $b^{p^n} \in A$; then the latter condition holds if and only if there exists $λ \in Λ$ and $n \in \mathbb{N}$ such that $b^{p^n} \in A_λ$ for every $b \in Σ$. Moreover, there exists a cofinal subset $Λ' \subset Λ$ such that the restriction $f_λ : A_λ \to B_λ := A_λ[Σ]$ is a finite ring homomorphism for every $λ \in Λ'$. Furthermore, recall that $I_λ$ is the ideal generated by $(b \otimes 1 - 1 \otimes b | b \in Σ)$, and likewise for the ideal $I_{f_λ}$, for every $λ \in Λ$. It follows that $I_λ \subset J_{B \otimes A}$ if and only if $I_{f_\lambda} \subset J_{B_\lambda \otimes A_\lambda \cdot B_\lambda}$ for some $λ \in Λ'$. Summing up, it then suffices to check the equivalence (b)$\Leftrightarrow$(c) for each $f_\lambda$, and therefore we may assume that $A$ and $B$ are noetherian.

Next, pick a decomposition $f = f_1 \circ \cdots \circ f_n$ as in proposition [9.8.9] since $Spec f_i$ is a surjection for each $i = 1, \ldots, n$, clearly $f$ is radical if and only if the same holds for each $f_i$. Similarly, $f^{perf} = f_1^{perf} \circ \cdots \circ f_n^{perf}$ is an isomorphism if and only if $f_i^{perf}$ is an isomorphism for every $i = 1, \ldots, n$. Thus, it suffices to show the equivalence (b)$\Leftrightarrow$(c) for each $f_i$, and therefore we may assume that $Spec f$ is an effective epimorphism of schemes. Now, (b) says that for every $b \in B$ there exists $n \in \mathbb{N}$ with

$$(b \otimes 1 - 1 \otimes b)^{p^n} = b^{p^n} \otimes 1 - 1 \otimes b^{p^n} = 0.$$ 

By assumption, the latter holds if and only if $b^{p^n} \in A$, whence the contention. □

**Remark 9.8.14.** (i) Let $f : A \to B$ an injective ring homomorphism, and denote by $\mathcal{E}$ the set of all $A$-subalgebras $B' \subset B$ such that the induced map $f' : A \to B'$ is integral and radical; recall that if $B' = A[Σ]$ for a subset $Σ \subset B'$, then $I_{f'}$ is generated by the system $(b \otimes 1 - 1 \otimes b | b \in Σ)$.

(ii) In view of corollary [9.8.13](i), it follows easily that if $B', B'' \in \mathcal{E}$, then also $B' \cdot B'' \in \mathcal{E}$.

(iii) Moreover, for every system $(B_λ | λ \in Λ)$ of elements of $\mathcal{E}$ filtered by inclusion, we have $\bigcup_{λ \in Λ} B_λ \in \mathcal{E}$.

(iv) Furthermore, if $B' \in \mathcal{E}$, and $B'' \subset B'$ is any $A$-subalgebra, then $B'' \in \mathcal{E}$ as well.

**Definition 9.8.15.** From remark [9.8.14](ii,iii), it follows that $\mathcal{E}$ is a filtered set, and the subring $C := \bigcup_{B' \in \mathcal{E}} B'$ is the largest element of $\mathcal{E}$; we call $C$ the weak normalization of $A$ in $B$.

**Remark 9.8.16.** (i) Consider a commutative diagram of rings:

$$
\begin{array}{ccc}
A & \xrightarrow{i} & B \\
\downarrow{g_λ} & & \downarrow{g_B} \\
A' & \xrightarrow{i'} & B'
\end{array}
$$
where \(i\) and \(i'\) are injective ring homomorphisms. Denote by \(C\) (resp. \(C'\)) the weak normalization of \(A\) in \(B\) (resp. of \(A'\) in \(B'\)). Then \(g_B(C) \subseteq C'\). Indeed, let \(x \in C\); by remark 9.8.14(iv), the induced map \(A \to A[x]\) is radical, hence \(x \otimes 1 - 1 \otimes x\) is nilpotent in \(A[x] \otimes_A A[x]\), so that its image \(g_B(x) \otimes 1 - 1 \otimes g_B(x)\) is nilpotent in \(A'[x] \otimes_{A'} A'[x]\), and therefore the induced map \(A' \to A'[x]\) is radical, whence the claim.

(ii) Let \(f : A \to B\) be an injective and integral ring homomorphism; let \(j_i\) (resp. \(j_2\)) be the ring homomorphism \(B \to B \otimes_A B\) given by the rule \(b \mapsto b \otimes 1\) (resp. \(b \mapsto 1 \otimes b\)) for every \(b \in B\). For \(i = 1, 2\) let also \(j'_i : B \to (B \otimes_A B)_{red}\) be the composition of \(j_i\) with the projection \(B \otimes_A B \to (B \otimes_A B)_{red}\). Then the weak normalization of \(A\) in \(B\) is the equalizer of \(j'_1\) and \(j'_2\). Indeed, if \(b \in B\) and \(A[b]\) is a radical \(A\)-algebra, then \(b \otimes 1 - 1 \otimes b\) is nilpotent in \(A[b] \otimes_A A[b]\), hence also in \(B \otimes_A B\), so \(j'_1(b) = j'_2(b)\). Conversely, if the latter identity holds, \(b \otimes 1 - 1 \otimes b\) is nilpotent in \(B \otimes_A B\); but notice that the map \(A[b] \to B\) is still injective and integral, so the kernel of the induced map \(A[b] \otimes_A A[b] \to B \otimes_A B\) lies in the nilradical (lemma 9.8.8(iii)). It follows that \(b \otimes 1 - 1 \otimes b\) is nilpotent in \(A[b] \otimes_A A[b]\), so \(A[b]\) is a radical \(A\)-algebra, as required.

**Lemma 9.8.17.** Let \(f_* : (A_\lambda : A \to B_\lambda \mid \lambda \in \Lambda)\) be a filtered system of injective ring homomorphisms; denote by \(f : A \to B\) the colimit of \(f_*\), and for every \(\lambda \in \Lambda\) let \(C_\lambda\) be the weak normalization of \(A_\lambda\) in \(B_\lambda\). Then, the system of rings \((B_\lambda \mid \lambda \in \Lambda)\) restricts to a filtered system of rings \(C_* : (C_\lambda \mid \lambda \in \Lambda)\), whose colimit \(C\) is the weak normalization of \(A\) in \(B\).

**Proof.** Let \(f' : A \to C\) be the map induced by \(f\), and for every \(\lambda \in \Lambda\), let \(f'_\lambda : A_\lambda \to C_\lambda\) be the map induced by \(f_\lambda\). By corollary 9.8.13(i) we know that \(I_{f'_\lambda} \subseteq C_\lambda \otimes_{A_\lambda} C_\lambda\); on the other hand, it is easily seen that \(I_{f'}\) is the colimit of the system of ideals \((I_{f_\lambda} \mid \lambda \in \Lambda)\), hence \(I_{f'} \subseteq C_\lambda \otimes_{A_\lambda} C_\lambda\). Moreover, since \(C_\lambda\) is an integral \(A_\lambda\)-algebra for every \(\lambda \in \Lambda\), it is easily seen that \(C\) is an integral \(A\)-algebra. Invoking again corollary 9.8.13(i), we deduce that \(C\) lies in the weak normalization \(C'\) of \(A\) in \(B\). Conversely, if \(x \in C'\), then in particular \(x\) lies in the integral closure \(C''\) of \(A\) in \(B\), hence we find \(\lambda \in \Lambda\) and \(x_\lambda \in B_\lambda\) whose class in \(B\) agrees with \(x\), and such that \(x_\lambda\) is integral over \(A_\lambda\); by corollary 9.8.13(i), we have \(x_\lambda \otimes 1 - 1 \otimes x_\lambda \in C_\lambda \otimes_{A_\lambda} C_\lambda\), and therefore \(x \otimes 1 - 1 \otimes x \in C'\) as well. Hence, after replacing \(\lambda\) by some \(\lambda' \geq \lambda\), we may assume that \(x_\lambda \otimes 1 - 1 \otimes x_\lambda \in C_\lambda'' \otimes_{A_\lambda} C_\lambda''\), where \(C_\lambda''\) denotes the integral closure of \(A_\lambda\) in \(B_\lambda\). Now, the inclusion \(A_\lambda[x] \to C_\lambda''\) is integral and injective, hence the kernel of the induced ring homomorphism \(A_\lambda[x] \otimes_{A_\lambda} A_\lambda[x] \to C_\lambda'' \otimes_{A_\lambda} A_\lambda[x]\) lies in the nilradical (lemma 9.8.8(iii)). Summing up, we conclude that \(x_\lambda \otimes 1 - 1 \otimes x_\lambda\) is already nilpotent in \(A_\lambda[x] \otimes_{A_\lambda} A_\lambda[x]\), so \(x_\lambda \in C_\lambda\), and finally \(x \in C\). This shows that \(C' = C\), as required.

**Proposition 9.8.18.** Let \(f : A \to B\) be an injective ring homomorphism, \(C\) the weak normalization of \(A\) in \(B\), and \(A'\) a flat \(A\)-algebra such that the induced morphism \(\text{Spec } A' \to \text{Spec } A\) has geometrically reduced fibres. Suppose that:

- either \(A'\) is a finitely presented \(A\)-algebra
- or else, \(A\) is noetherian.

Then \(A' \otimes_A f : A' \to B' := A' \otimes_A B\) is an injective ring homomorphism, and the weak normalization of \(A'\) in \(B'\) is \(A' \otimes_A C\).

**Proof.** Since \(A'\) is a flat \(A\)-algebra, \(A' \otimes_A f\) is still injective, as stated. Now, let \(A''\) (resp. \(A''_0\)) be the integral closure of \(A\) in \(B\) (resp. of \(A'\) in \(B'\)); then \(A'' = A' \otimes_A A''\) (proposition 9.8.3). We may then replace \(B\) by \(A''\), and assume that \(B\) is an integral \(A\)-algebra. In this case, notice that for every \(A\)-algebra \(R\) we have \((A' \otimes_A R)_{red} = A' \otimes_A R_{red}\) (proposition 9.8.3); then the assertion follows easily from remark 9.8.16(ii).

9.8.19. Let \(f : A \to B\) be an injective and injective ring homomorphism, \(I \subseteq A\) an ideal; set \(X := \text{Spec } A, Y := \text{Spec } B, Z := \text{Spec } A/I, U := X \setminus Z,\) and notice that \(\varphi := \text{Spec } f : Y \to X\) is surjective by the going up theorem, hence the same holds for its restriction \(\varphi^{-1}Z \to Z,\)
and therefore the kernel of \( A/I \otimes_A f : A/I \to B/IB \) lies in the nilradical (lemma 9.8.8(ii)), i.e. the induced map \((A/I)_{\text{red}} \to (B/IB)_{\text{red}}\) is injective and integral as well.

**Lemma 9.8.20.** In the situation of (9.8.19), suppose that \( \varphi \) restricts to a radicial morphism of schemes \( \varphi|_U : \varphi^{-1}U \to U \), and let \( C \) (resp. \( \overline{C} \)) be the weak normalization of \( A \) in \( B \) (resp. of \((A/I)_{\text{red}} \) in \((B/IB)_{\text{red}}\)). Then we have:

\[
C = B \times_{(B/IB)_{\text{red}}} \overline{C}.
\]

**Proof.** By remark 9.8.16(i), the projection \( B \to (B/IB)_{\text{red}} \) maps \( C \) into \( \overline{C} \), whence the inclusion \( C \subset C' := B \times_{(B/IB)_{\text{red}}} \overline{C} \). For the converse inclusion, we need to show that the induced map \( g : A \to C' \) is radicial. To this aim, it suffices to check that the same holds for \( A/I \otimes_A g : A/I \to C'/IC \) and for \( A[a^{-1}] \otimes_A g : A[a^{-1}] \to C'[a^{-1}] \), for every \( a \in I \). However, for any such \( a \), the localization \( C'[a^{-1}] = \frac{B[a^{-1}]}{\varphi[A[a^{-1}]]} \), and since \((B/IB)_{\text{red}}[a^{-1}] = \overline{C}[a^{-1}] = 0 \), we see that \( C'[a^{-1}] = B[a^{-1}] \); but \( \varphi \) is radicial. It remains thus only to check that \( C/IC \) is a radicial \( A/I \)-algebra; to this aim, notice that the kernel of the surjection \( B \to (B/IB)_{\text{red}} \) is the radical \( J \) of the ideal \( IB \subset B \). Then \( J \) is also the kernel of the surjection \( C' \to \overline{C} \); on the other hand, since \( IB \subset J \subset C \), we have \( J^2 \subset IC \subset IB \subset J \), and clearly \( J \) is also the radical of the ideal \( I^2 B \) of \( C \). Hence, \( C/IC \) is a radicial \( A/I \)-algebra if and only if the same holds for the \( A/I \)-algebra \( C/J \); but \( C/J = \overline{C} \), whence the contention. \( \square \)

**Proposition 9.8.21.** Let \( B \) be a ring, \( A \subset B \) a subring, and \( G \) a finite group of automorphisms of \( B \) such that \( g(A) = A \) for every \( g \in G \). Denote by \( C \) (resp. \( D \)) the integral closure (resp. the weak normalization) of \( A \) in \( B \). Then we have:

(i) \( C^G \) is the integral closure of \( A^G \) in \( B^G \).

(ii) \( D^G \) is the weak normalization of \( A^G \) in \( B^G \).

**Proof.** (i): Clearly \( \text{i.c.}(A^G, B^G) \subset C^G \). To show the reverse inclusion, let \( x \in C^G \), so that \( x \in B^G \) and \( x \) is integral over \( A \); but since \( G \) is a finite group, \( A \) is integral over \( A^G \) (details left to the reader), hence \( x \) is integral over \( A^G \), as required.

(ii): Let \( D' \) be the weak normalization of \( A^G \) in \( B^G \); we have \( D' \subset D \) by remark 9.8.16(i), and then obviously \( D' \subset D^G \). For the reverse inclusion, we come down to checking that the inclusion map \( A^G \to D^G \) is radicial. To this aim, notice first:

**Claim 9.8.22.** (i) \( \varphi(D) = D \) for every \( g \in G \).

(ii) Let \( K \) be any algebraically closed field, and \( E \subset B \) any subring such that \( g(E) = E \) for every \( g \in G \). Then the set \( \text{Hom}_{\text{Alg}}(E, K) \) inherits from \( E \) a natural \( G \)-action, and the map \( \text{Hom}_{\text{Alg}}(E, K) \to \text{Hom}_{\text{Alg}}(E^G, K) : \varphi \mapsto \varphi|_{A^G} \) factors through a bijection

\[
\text{Hom}_{\text{Alg}}(E, K)/G \sim \text{Hom}_{\text{Alg}}(E^G, K).
\]

**Proof of the claim.** (i): We apply remark 9.8.16(i) with \( A' := A, B' := B, g_B := g, g_A := g|_A, \) and with \( i \) and \( i' \) the inclusion maps; then we get \( \varphi(D) \subset D \), and similarly \( g^{-1}(D) \subset D \), whence the claim.

(ii): The injectivity follows easily from [28, Ch.5, §2, n.2, Cor. of Th.2], and the surjectivity is clear, since the inclusion map \( E^G \to E \) is integral.

Now, the radicial map \( A \to D \) induces a bijection \( \text{Hom}_{\text{Alg}}(D, K) \sim \text{Hom}_{\text{Alg}}(A, D) \) for every algebraically closed field \( K \); in view of claim 9.8.22(i), this map is obviously \( G \)-equivariant, hence it induces a bijection on the quotients by the respective \( G \)-actions. Then, claim 9.8.22(ii) implies that the map \( A^G \to D^G \) also induces a bijection \( \text{Hom}_{\text{Alg}}(D^G, K) \sim \text{Hom}_{\text{Alg}}(A^G, D) \) for every such \( K \), whence the contention. \( \square \)
**Proposition 9.8.23.** In the situation of remark 9.8.16(i), let \( D \) (resp. \( D' \)) be the integral closure of \( A \) in \( B \) (resp. of \( A' \) in \( B' \)), and suppose that we have norm maps \( \nu_A : \Gamma_A^d A' \to A \) and \( \nu_B : \Gamma_B^d B' \to B \) of some degree \( d \in \mathbb{N} \), that make commute the induced diagram:

\[
\begin{array}{ccc}
\Gamma_A^d A' & \longrightarrow & \Gamma_B^d B' \\
\nu_A & & \nu_B \\
A & \downarrow i & B
\end{array}
\]

(see definition 9.5.70). Then there exist unique norm maps \( \nu_C : \Gamma_C^d C' \to C \) and \( \nu_D : \Gamma_D^d D' \to D \) of degree \( d \), that make commute the resulting diagram:

\[
\begin{array}{ccc}
\Gamma_A^d A' & \longrightarrow & \Gamma_C^d C' & \longrightarrow & \Gamma_D^d D' & \longrightarrow & \Gamma_B^d B' \\
\nu_A & & \nu_C & & \nu_D & & \nu_B \\
A & \downarrow & C & \downarrow & D & \downarrow & B
\end{array}
\]

Moreover, if \( \nu_B \) is Cayley-Hamilton, the same holds for \( \nu_C \) and \( \nu_D \) (see definition 9.5.74).

**Proof.** We need to show that the image of the composition of \( \nu_B \) with the natural map \( \Gamma_D^d D' \to \Gamma_B^d B' \) lies in \( D \); to this aim, it suffices to check that the natural map \( \Gamma_A^d A' \to \Gamma_D^d D' \) is integral. However, the latter is the composition of the integral map \( \Gamma_A^d A' \to D \otimes_A \Gamma_D^d D' \) (proposition 9.5.68(iv.a)), the isomorphism \( D \otimes_A \Gamma_A^d A' \cong \Gamma_D^d (D \otimes_A D') \) (proposition 9.5.68(i)) and the surjection \( \Gamma_D^d (D \otimes_A D') \to \Gamma_B^d B' \) (corollary 9.5.22(iv)), whence the contention.

Likewise, we need to check that the image of the composition of \( \nu_D \) with the natural map \( \Gamma_C^d C' \to \Gamma_B^d B' \) lies in \( C \). To this aim, notice that the natural map \( \Gamma_A^d A' \to \Gamma_A^d C' \) is integral, radial, and its kernel lies in the nilradical of \( \Gamma_A^d A' \) (proposition 9.5.68(iv.b,iv.c)); the same holds for the natural map \( \Gamma_A^d C' \to C \otimes_A \Gamma_A^d C' \cong \Gamma_A^d (C \otimes_A C') \). By the same token, since the natural map \( C \otimes_A C' \to C' \) is surjective, and its kernel lies in the nilradical of \( C \otimes_A C' \), then the same holds for the induced map \( \Gamma_A^d (C \otimes_A C') \to \Gamma_A^d C' \). Summing up, we conclude that the natural map \( \Gamma_A^d A' \to \Gamma_A^d C' \) is integral, radial, and its kernel \( J \) lies in the nilradical of \( \Gamma_A^d A' \); we have therefore a commutative diagram of rings:

\[
\begin{array}{ccc}
\Gamma_A^d (A')/J & \longrightarrow & \Gamma_A^d C' \\
& \downarrow & \\
A & \longrightarrow & B
\end{array}
\]

whose top horizontal arrow is integral, radial and injective. Then the contention follows from remark 9.8.16(i). Lastly, let \( \chi_B^\dagger, \chi_C^\dagger, \chi_D^\dagger \) be the characteristic maps of \( \nu_B, \nu_C \) and \( \nu_D \) (see 9.5.73); by inspecting the definitions, we get a commutative diagram:

\[
\begin{array}{ccc}
\Gamma_C^d C' & \longrightarrow & \Gamma_D^d D' & \longrightarrow & \Gamma_B^d B' \\
\chi_C^\dagger & & \chi_D^\dagger & & \chi_B^\dagger \\
C' & \longrightarrow & D' & \longrightarrow & B'
\end{array}
\]

whence the last assertion of the proposition. \( \square \)

**Definition 9.8.24.** (i) Let \( R \) be a ring, \( S \subset R \) a subring, and \( p > 0 \) a prime integer. We say that \( S \) is \( p \)-integrally closed in \( R \), if for every \( x \in R \) such that \( x^p \in S \), we have \( x \in S \).

(ii) Let \( R \) be a ring and \( p > 0 \) a prime integer; if \( (S_\lambda : \lambda \in \Lambda) \) is any family of \( p \)-integrally closed subrings of \( R \), then clearly \( \bigcap_{\lambda \in \Lambda} S_\lambda \) is also \( p \)-integrally closed in \( R \). Hence, for every subring \( S \subset R \) there exists a smallest \( p \)-integrally closed subring \( S' \) of \( R \) containing \( S \). We say that \( S' \) is the \( p \)-integral closure of \( S \) in \( R \).
Remark 9.8.25. (i) Let $R$ be a ring, $S \subset R$ a subring; consider the increasing countable system $(S_n \mid n \in \mathbb{N})$ of subrings of $R$ defined inductively as follows: $S_0 := S$, and $S_{n+1} := S_n[S_n]$ for every $n \in \mathbb{N}$, where $\Sigma_n := \{ x \in R \mid x^p \in S_n \}$. Then it is easily seen that $\bigcup_{n \in \mathbb{N}} S_n$ is the $p$-integral closure of $S$ in $R$.

(ii) In the situation of remark 9.8.16(i), let $D$ (resp. $D'$) be the $p$-integral closure of $A$ in $B$ (resp. of $A'$ in $B'$). Define the system of subrings $(A_n \mid n \in \mathbb{N})$ of $B$ (resp. $(A'_n \mid n \in \mathbb{N})$ of $B'$) as in (i); a simple induction shows that $g_B(A_n) \subset A'_n$ for every $n \in \mathbb{N}$, so $g_B$ restricts to a ring homomorphism $D \to D'$.

Lemma 9.8.26. (i) Let $R$ be a ring, $a \in R$ a regular element such that $pR \subset a^pR$. Then $R$ is $p$-integrally closed in $R[a^{-1}]$ if and only if the Frobenius endomorphism of $R/a^pR$ induces an injective ring homomorphism $\overline{\Phi} : R/aR \to R/a^pR$.

(ii) Let $R$ be a topological ring, $S \subset R$ an open subring, $T$ the $p$-integral closure of $S$ in $R$; endow $S$ and $T$ with the topologies induced by $R$, and denote by $R^\wedge$, $S^\wedge$ and $T^\wedge$ the respective completions. Then $T^\wedge$ is the $p$-integral closure in $R^\wedge$ of $S^\wedge$.

(iii) Let $R_\lambda := (R_\lambda \mid \lambda \in \Lambda)$ be a system of rings, with transition morphisms $f_{\lambda\mu} : R_\lambda \to R_\mu$ for every $\lambda, \mu \in \Lambda$ with $\mu \geq \lambda$. For every $\lambda \in \Lambda$, let also $S_\lambda \subset R_\lambda$ be a subring, such that $f_{\lambda\mu}(S_\lambda) \subset S_\mu$ for every such $\lambda, \mu$. Denote by $D_\lambda \subset R_\lambda$ the $p$-integral closure of $S_\lambda$ in $R_\lambda$, for every $\lambda \in \Lambda$. The following holds:

(a) Let $R$ and $S$ be the limits of $R_\lambda$ and respectively of $S_\lambda := (S_\lambda \mid \lambda \in \Lambda)$. Then the limit of the induced system $D_\lambda := (D_\lambda \mid \lambda \in \Lambda)$ is the $p$-integral closure of $S$ in $R$.

(b) Suppose moreover that $\Lambda$ is filtered, and let $R'$ and $S'$ be the colimits of $R_\lambda$ and respectively of $S_\lambda$. Then the colimit of $D_\lambda$ is the $p$-integral closure of $S'$ in $R'$.

(iv) Let $B$ be a ring, $A \subset B$ a subring, $C$ the $p$-integral closure of $A$ in $B$, and $S \subset A$ a multiplicative subset. Then $S^{-1}C$ is the $p$-integral closure of $S^{-1}A$ in $S^{-1}B$.

Proof. (i): Suppose first that $\overline{\Phi}$ is injective; let $x \in R[a^{-1}]$ be any element such that $x^p \in R$, and suppose, by way of contradiction, that $x \notin R$. There exists a smallest $m \in \mathbb{N}$ such that $y := a^m x \notin R$ and $a^{m+1} x \in R$. Hence, $y^p = a^{mp} x^p \in R$, and therefore $(a^{m+1} x)^p = a^p y^p \in a^p R$. Thus, the class of $a^{m+1} x$ lies in $\text{Ker} \overline{\Phi}$, i.e. $a^{m+1} x = az$ for some $z \in R$; since $a$ is regular, it follows that $z = a^m x$, contradicting the choice of $m$.

Conversely, suppose that $R$ is integrally closed in $R[a^{-1}]$, and let $x \in R$ be an element whose class $\overline{x} \in R/aR$ lies in $\text{Ker} \overline{\Phi}$; this means that there exists $y \in R$ such that $x^p = a^p y$. Hence, $(x/a)^p \in R$, so that $x/a \in R$, and therefore $x = 0$.

(ii): Notice that $S^\wedge\cdot T = T^\wedge$, hence $T^\wedge$ lies in the $p$-integral closure of $S^\wedge$ in $R^\wedge$. Hence, we are reduced to checking that $S$ is $p$-integrally closed in $R$ if and only if $S^\wedge$ is $p$-integrally closed in $R^\wedge$. Suppose first that $S$ is $p$-integrally closed in $R$, and let $x \in R^\wedge$ be any element such that $x^p \in S^\wedge$. Denote by $j : R \to R^\wedge$ the completion map. Pick a Cauchy net $(x_\lambda \mid \lambda \in \Lambda)$ in $R$ whose limit is $x$; then $(x_\lambda^p \mid \lambda \in \Lambda)$ is a Cauchy net converging to $x^p$, and since $S^\wedge$ is open in $R^\wedge$ (corollary 8.2.17(i)), we may replace $\Lambda$ by a cofinal subset, and assume that $j(x_\lambda)^p \in S^\wedge$ for every $\lambda \in \Lambda$. Then $x_\lambda^p \in S$ (corollary 8.2.17(ii)), whence $x_\lambda \in S$ for every $\lambda \in \Lambda$, and finally $x \in S^\wedge$, as required. Conversely, if $S^\wedge$ is $p$-integrally closed in $R^\wedge$, and $x \in R$ is any element with $x^p \in S$, we have $j(x)^p \in S^\wedge$, so $j(x) \in S$, whence $x \in S$, again by corollary 8.2.17(ii).

The proof of (iii) shall be left to the reader. (iv): Let $b \in B$, $s \in S$ such that $(b/s)^p \in S^{-1}C$; it follows easily that $t^p b^p \in C$ for some $t \in S$, hence $tb \in C$, and consequently $b/s \in S^{-1}C$. This shows that $S^{-1}C$ is $p$-integrally closed in $S^{-1}B$, hence it contains the $p$-integral closure $C'$ of $S^{-1}A$ in $S^{-1}B$. On the other hand, by remark 9.8.25, the localization $B \to S^{-1}B$ restricts to a ring homomorphism $C \to C'$; since $C'$ is an $S^{-1}A$-algebra, we must then have $S^{-1}C' \subset C'$.

□
9.8.27. Let $X$ be a scheme, $\mathcal{A} \to \mathcal{B}$ a monomorphism of quasi-coherent $\mathcal{O}_X$-algebras; for every affine open subset $U \subset X$, let $\mathcal{C}(U)$ (resp. $\mathcal{D}(U)$) be the weak normalization (resp. the $p$-integral closure) of $\mathcal{A}(U)$ in $\mathcal{B}(U)$; by remark 9.8.16(i), the rule $U \mapsto \mathcal{C}(U)$ (resp. $U \mapsto \mathcal{D}(U)$) defines a subsheaf of $\mathcal{O}_X$-algebras $\mathcal{C} \subset \mathcal{B}$ (resp. $\mathcal{D} \subset \mathcal{B}$) on the site of affine open subsets of $X$, and it follows easily from proposition 9.8.18 (resp. from lemma 9.8.26(iv)) that $\mathcal{C}$ (resp. $\mathcal{D}$) is a sheaf on this site, so it extends uniquely to a subsheaf of $\mathcal{B}$ on the Zariski site of $X$; moreover, $\mathcal{C}$ and $\mathcal{D}$ are quasi-coherent $\mathcal{O}_X$-algebras. We call $\mathcal{C}$ and $\mathcal{D}$ respectively the weak normalization and the $p$-integral closure of $\mathcal{A}$ in $\mathcal{B}$.

**Proposition 9.8.28.** Let $f : A \to B$ be an injective ring homomorphism, $\mathfrak{p} \in \mathbb{N}$ a prime integer, and suppose that $f$ induces an isomorphism $A[1/\mathfrak{p}] \xrightarrow{\sim} B[1/\mathfrak{p}]$. Let $A^\nu$ (resp. $C_0$, resp. $C_1$) be the integral closure (resp. the weak normalization, resp. the $p$-integral closure) of $A$ in $B$; denote by $(A/pA)_{\text{red}} \xrightarrow{\sim} (A^\nu/pA^\nu)_{\text{red}} \xrightarrow{\iota} A^\nu$ the natural maps, and set

$$ C_2 := \{b \in B \mathrel{|} \text{there exists } n \in \mathbb{N} \text{ such that } b^{\nu n} \in A\} $$

$$ D := \{x \in (A^\nu/pA^\nu)_{\text{red}} \mathrel{|} \text{there exists } n \in \mathbb{N} \text{ such that } x^{\nu n} \in \text{Im}(j)\}. $$

Then $j$ is injective, and $C_0 = C_1 = C_2 = \pi^{-1}D$.

**Proof.** One argues as in (9.8.19) to see that $j$ is injective.

Now, the inclusion $C_2 \subset C_1$ is obvious, and the identity $C_0 = \pi^{-1}D$ follows easily from lemma 9.8.20. By remark 9.8.25 we may write $C_1$ as the increasing union of the family $A_0 \subset A_1 \subset A_2 \subset \cdots$ of subrings of $B$, defined inductively by $A_0 := A$, and $A_{i+1} := A_i[\Sigma_i]$ for every $i \in \mathbb{N}$, where $\Sigma_i := \{b \in B \mathrel{|} b^{\nu n} \not\in A_i\}$. By remark 9.8.14(iii), in order to check that $C_1 \subset C_0$, it will therefore suffice to show that the inclusion map $A_i \to A_{i+1}$ is radical for every $i \in \mathbb{N}$. However, notice that $A_i[1/\mathfrak{p}] = A_{i+1}[1/\mathfrak{p}]$ for every such $i$, hence we are reduced to checking that the induced map $A_i/pA_i \to A_{i+1}/pA_{i+1}$ is radical, which is clear by construction.

Lastly, let us show that $C_0 \subset C_2$. To this aim, let us write $f$ as the colimit of a filtered system of injective ring homomorphisms $(f_\lambda : A_\lambda \to B_\lambda \mathrel{|} \lambda \in \Delta)$, where $A_\lambda$ and $B_\lambda$ are $\mathbb{Z}$-subalgebras of finite type of $A$ and respectively $B$, for every $\lambda \in \Delta$; since $f$ induces an isomorphism $A[1/\mathfrak{p}] \xrightarrow{\sim} B[1/\mathfrak{p}]$, we may also assume that $f_\lambda$ induces an isomorphism $A_\lambda[1/\mathfrak{p}] \xrightarrow{\sim} B_\lambda[1/\mathfrak{p}]$ for every $\lambda \in \Delta$ (details left to the reader). For every such $\lambda$, let $C_{2,\lambda}$ be the subset of all $b \in B_\lambda$ such that $b^{\nu n} \in A_\lambda$ for some $n \in \mathbb{N}$, and let $C_{0,\lambda}$ be the weak normalization of $A_\lambda$ in $B_\lambda$. Clearly $C_2$ is the filtered union of the resulting system $(C_{2,\lambda} \mathrel{|} \lambda \in \Delta)$; on the other hand, $C_0$ is the colimit of the system of subrings $(C_{0,\lambda} \mathrel{|} \lambda \in \Delta)$, by lemma 9.8.17. Hence, we are reduced to checking that $C_{0,\lambda} \subset C_{2,\lambda}$ for every $\lambda \in \Delta$, and we may assume that $A$ and $B$ are noetherian.

Let now $b \in C_0$, and set $B' := A[b]$; we have to check that $b^{\nu n} \in A$ for some $n \in \mathbb{N}$, and obviously $A[1/\mathfrak{p}] = B'[1/\mathfrak{p}]$, so we may replace $B$ by $B'$ and suppose that $f$ is finite and radical. In this case, pick a decomposition $f = f_1 \circ \cdots \circ f_n$ as in proposition 9.8.9 again, it suffices to check the assertion for each $f_i$, hence we may assume that $\text{Spec } f$ is an effective epimorphism of schemes (and still radical). Thus, for every $b \in B$ the element $c := b \otimes 1 - 1 \otimes b$ is nilpotent in $B \otimes_A B$ (corollary 9.8.13(i)), and moreover notice that the two natural maps $B[1/\mathfrak{p}] \to B \otimes_A B[1/\mathfrak{p}]$ are isomorphisms, since $A[1/\mathfrak{p}] = B[1/\mathfrak{p}]$, hence the same holds for the multiplication law $B \otimes_A B[1/\mathfrak{p}] \to B[1/\mathfrak{p}]$, and the therefore image of $c$ vanishes in $B \otimes_A B[1/\mathfrak{p}]$, i.e. $p^k c = 0$ in $B \otimes_A B$ for some $k \in \mathbb{N}$, and after replacing $k$ by a larger integer, we may assume that $c^k = 0$. We write

$$ b^{\nu n} \otimes 1 = 1 \otimes b^{\nu n} + \sum_{j=1}^{\nu n} \binom{\nu n}{j} (1 \otimes b^{\nu n-j}) \cdot c^j = 1 \otimes b^{\nu n} + \sum_{j=1}^{k-1} \binom{\nu n}{j} (1 \otimes b^{\nu n-j}) \cdot c^j $$

and recall that the $p$-adic valuation of $\binom{\nu n}{j}$ equals $n - v_p(j)$ for $j = 1, \ldots, \nu n$, where $v_p(j)$ denotes the $p$-adic valuation of $j$. In particular, with $n := 2k$, we see that $\binom{\nu n}{j}$ is divisible by $p^k$.
for every \( j = 1, \ldots, k - 1 \), so finally \( b^n \otimes 1 = 1 \otimes b^n \) in \( B \otimes A B \), and consequently \( b^n \in A \), since Spec \( f \) is an effective epimorphism.

**Proposition 9.8.29.** Let us resume the situation of remark \( \ref{9.8.16} \)(i), and let \( a \in A \) be any element and \( n \in \mathbb{N} \) any integer; also, denote by \( A^n \) (resp. \( A^n' \)) the integral closure of \( A \) in \( B \) (resp. of \( A' \) in \( B' \)). The following holds:

(i) If \( g_A \) and \( g_B \) are injective, \( aB' \subset \text{Im} \ g_B \) and \( a^n A' \subset \text{Im} \ g_A \), then:

\[
aA^n \subset g_B(A^n) \quad \text{and} \quad aC' \subset g_B(C).
\]

(ii) If \( g_A \) and \( g_B \) are surjective, and \( a\ker g_B = 0 \), then:

\[
a \cdot g_B^{-1} A^n \subset A^n \quad \text{and} \quad a \cdot g_B^{-1} C' \subset C.
\]

(iii) If \( g_A \) and \( g_B \) are surjective, and \( \ker g_B \subset \mathcal{N}_B \) (notation of \( \ref{9.8.7} \)), then:

\[
g_B^{-1} A^n = A^n \quad \text{and} \quad g_B^{-1} C' = C.
\]

**Proof.** (i): Let \( b \in A^n \), and pick any monic polynomial \( P := X^m + a'_1 X^{m-1} + \cdots + a'_m \in A[X] \) such that \( P(b^n) = 0 \). Hence \( a'^m \cdot P(b^n) = 0 = (ab)^m + a^m a'_1 (ab)^{m-1} + \cdots + a^m a'_{m-1} = 0 \), and by assumption \( a^n a'_1, a^n a'_2, \ldots, a^n a'_m \in g_A(A) \) and \( ab \in g_B(B) \), so \( ab \in g_B(A^n) \), whence the first stated inclusion. Next, set \( C_0 := g_A(A) + aC' \); clearly \( C_0 \) is an \( A \)-subalgebra of \( g_B(B) \), and we need to check that the induced map \( A \rightarrow C_0 \) is radical.

**Claim 9.8.30.** The kernel and cokernel of the induced map \( C_0 \otimes_A C_0 \rightarrow C' \otimes A' C' \) are annihilated by \( a^{n+2} \).

**Proof of the claim.** By construction, the cokernel of the induced injection \( j : C_0 \rightarrow C' \) is annihilated by \( a \); since the kernel of \( C' \otimes_A j \) is a quotient of \( \text{Tor}^A_1(C', C'/C_0) \), it follows that both the kernel and cokernel of \( C' \otimes_A j \) are annihilated by \( a \). By the same token, the kernel and cokernel of \( C' \otimes_A C_0 \otimes_A j : C_0 \otimes_A C_0 \rightarrow C' \otimes_A C' \) are annihilated by \( a \) as well. Lastly, the natural map \( \pi : C' \otimes_A C' \rightarrow C'' \otimes_A C'' \) is clearly surjective, and its kernel is generated by the elements of the form \( a'(x \otimes y - x \otimes a'y) \), for all \( a' \in A' \) and all \( x, y \in C' \). By assumption, \( a^n(a'x \otimes y - x \otimes a'y) = 0 \) in \( C' \otimes_A C' \), so \( a^n \ker \pi = 0 \). The claim follows easily.

Let \( c \in aC'' \) be an element; then \( c \otimes 1 - 1 \otimes c \) is nilpotent in \( C' \otimes A' C' \) (corollary \( \ref{9.8.13} \)(ii)), by claim \( \ref{9.8.30} \); it follows that there exists \( N \in \mathbb{N} \) with \( a^{n+2}(c \otimes 1 - 1 \otimes c)^N = 0 \) in \( C_0 \otimes_A C_0 \). Then, say that \( c = ad \) for some \( d \in C' \); it follows that \( (c \otimes 1 - 1 \otimes c)^N = a^N d^N = 1 - 3a^2 d^2 \otimes ad + 3ad \otimes a^2 d^2 + 1 \otimes a^2 d^3 \) is divisible by \( a \) in \( C_0 \otimes_A C_0 \), and finally \( (c \otimes 1 - 1 \otimes c)^N = 0 \) in \( C_0 \otimes_A C_0 \), whence the contention.

(ii): Let \( b \) and \( P \) be as in the foregoing; suppose that \( b = g_B(c) \) for some \( c \in B \), and pick \( a_1, \ldots, a_m \in A \) with \( g_A(a_i) = a'_i \) for \( i = 1, \ldots, m \). Set \( Q := X^n + a_1 X^{n-1} + \cdots + a_m \in A[X] \); then \( aQ(c) = 0 \), and it follows easily that \( ac \in A^n \), whence the first inclusion of (ii). Next, set \( C_0 := A + a \cdot g_B^{-1} C' \); we need to show that the resulting ring homomorphism \( A \rightarrow C_0 \) is radical. However, notice that the restriction \( g_C : C_0 \rightarrow C \) of \( g_B \) has both kernel and cokernel annihilated by \( a \); then by lemma \( \ref{14.1.55} \) we find an \( A \)-linear map \( h : C \rightarrow C_0 \) with \( h \circ g_C = a^2 1_{C_0} \) and \( g_C \circ h = a^2 \cdot 1_C \). Hence \( (h \otimes A) h \circ (g_C \otimes_A g_C) = a^2 1_{C_0} \) and \( (g_C \otimes_A g_C) \circ (h \otimes A) h = a^2 1_C \), so both the kernel and cokernel of \( g_C \otimes_A g_C : C_0 \otimes_A C_0 \rightarrow C \otimes A C = C \otimes A' C \) are annihilated by \( a^4 \). We may now argue as in the proof of (i), to conclude that \( c \otimes 1 - 1 \otimes c \) is nilpotent in \( C_0 \otimes_A C_0 \), for every \( c \in a \cdot g_B^{-1} C' \), whence the contention.

(iii): Let \( b, c, P \) and \( Q \) be as in the proof of (ii); since \( \ker g_B \subset \mathcal{N}_B \), we have \( Q(c)^n = 0 \) for some \( n \in \mathbb{N} \), so \( c \in A^n \), whence the first identity of (iii). Next, set \( C_0 := g_B^{-1} C' \); we need to check that the map \( A \rightarrow C_0 \) is radical, or equivalently, that the same holds the induced map on reduced quotients \( A_{\text{red}} \rightarrow (C_0)_{\text{red}} \). However, \( g_B \) induces an isomorphism \( (C_0)_{\text{red}} \cong (C')_{\text{red}} \), and by definition the map \( A_{\text{red}} \rightarrow (C')_{\text{red}} \) is radical; since \( g_A \) induces a surjection \( A_{\text{red}} \rightarrow A'_{\text{red}} \), the assertion follows easily.
10. Cohomology and Local Cohomology of Sheaves

**Definition 10.1.1.** Let $X$ be a topological space, $\mathcal{F}$ a sheaf on $X$.

(i) We say that $\mathcal{F}$ is flabby if the restriction map $\mathcal{F}(X) \to \mathcal{F}(U)$ is surjective for every open subset $U \subset X$.

(ii) We say that $\mathcal{F}$ is qc-flabby if the restriction map $\mathcal{F}(V) \to \mathcal{F}(U)$ is a surjection whenever $U \subset V$ are quasi-compact open subsets of $X$.

(iii) The support of $\mathcal{F}$ is the subset:

$$\text{Supp}\mathcal{F} := \{x \in X \mid \mathcal{F}_x \neq \emptyset\} \subset X.$$ 

Lemma 10.1.2. Let $X$ be a topological space, $(X_\lambda \mid \lambda \in \Lambda)$ a family of open subsets of $X$ with $X = \bigcup_{\lambda \in \Lambda} X_\lambda$, and $\mathcal{F}$ a sheaf on $X$. For every $\lambda \in \Lambda$, let $\mathcal{F}_\lambda$ be the restriction of $\mathcal{F}$ to $X_\lambda$. Then $\mathcal{F}$ is flabby if and only if $\mathcal{F}_\lambda$ is flabby for every $\lambda \in \Lambda$.

**Proof.** It is easily seen that if $\mathcal{F}$ is flabby, the same holds for every $\mathcal{F}_\lambda$. Conversely, suppose that $\mathcal{F}_\lambda$ is flabby for every $\lambda \in \Lambda$; let $U \subset X$ be any open subset, and $\sigma \in \mathcal{F}(U)$. For every subset $\Lambda' \subset \Lambda$ set $X_{\Lambda'} := \bigcup_{\lambda \in \Lambda'} X_\lambda$, and denote by $\mathcal{P}$ the set of all pairs $(\Lambda', \sigma')$ where $\Lambda'$ is a subset of $\Lambda$, and $\sigma' \in \mathcal{F}(U \cup X_{\Lambda'})$ is any section whose restriction to $U$ agrees with $\sigma$. We endow $\mathcal{P}$ with the partial order such that $(\Lambda', \sigma') \leq (\Lambda'', \sigma'')$ if and only if $\Lambda' \subset \Lambda''$ and the restriction of $\sigma''$ to $U \cup X_{\Lambda''}$ agrees with $\sigma'$. It is clear that if $(\Lambda_i, \sigma_i) \mid i \in I$ is any totally ordered subset in $\mathcal{P}$, then there exists $(\Lambda', \sigma')$ in $\mathcal{P}$ with $\Lambda' = \bigcup_{i \in I} \Lambda_i$ and such that $(\Lambda_i, \sigma_i) \leq (\Lambda', \sigma')$ for every $i \in I$. Also, $(\emptyset, \sigma) \in \mathcal{P}$. By Zorn's lemma, $\mathcal{P}$ admits then a maximal element $(\Lambda', \sigma')$, and it suffices to check that $\Lambda' = \Lambda$. Thus, suppose that $\lambda \in \Lambda \setminus \Lambda'$; set $\Lambda'':= \Lambda' \cup \{\lambda\}$, and let $\sigma''$ be the restriction of $\sigma'$ to $U_\lambda := X_\lambda \cap (U \cup X_{\Lambda'})$. Since $\mathcal{F}_\lambda$ is flabby, there exists $\sigma_\lambda \in X_\lambda$ whose restriction to $U_\lambda$ agrees with $\sigma''$. Then there exists $\tau \in \mathcal{F}(U \cup X_{\Lambda''})$ whose restriction to $U \cup X_{\Lambda''}$ agrees with $\sigma'$ and whose restriction to $X_\lambda$ agrees with $\sigma_\lambda$. By construction, we have $(\Lambda'', \tau) > (\Lambda', \sigma')$, a contradiction.

10.1.3. Let $X$ be a topological space, and consider a short exact sequence

$$\Sigma : 0 \to \mathcal{F}' \to \mathcal{F} \to \mathcal{F}'' \to 0$$

of abelian sheaves on $X$. For every open subset $U \subset X$, the sequence $\Sigma$ induces a complex :

$$\Sigma(U) : 0 \to \mathcal{F}'(U) \to \mathcal{F}(U) \to \mathcal{F}''(U) \to 0.$$

**Lemma 10.1.4.** In the situation of (10.1.3), the following holds :

(i) If $\mathcal{F}'$ is flabby, the sequence $\Sigma(U)$ is short exact.

(ii) If both $\mathcal{F}$ and $\mathcal{F}'$ are flabby, the same holds for $\mathcal{F}''$.

(iii) Suppose that $X$ is locally coherent and quasi-separated. Then :

(a) If $\mathcal{F}'$ is qc-flabby and $U$ is quasi-compact, the sequence $\Sigma(U)$ is short exact.

(b) If both $\mathcal{F}$ and $\mathcal{F}'$ are qc-flabby, the same holds for $\mathcal{F}''$.

**Proof.** (i): Let $s'' \in \mathcal{F}''(U)$ be any section; we need to show that $s''$ is the image of an element of $\mathcal{F}(U)$. To this aim, let $\mathcal{P}$ be the set of all pairs $(V, t)$, where $V \subset U$ is an open subset, and $t \in \mathcal{F}(V)$ is a section whose image in $\mathcal{F}''(V)$ agrees with the restriction of $s''$. Then $\mathcal{P}$ is partially ordered by declaring that $(V, t) \leq (V', t')$ if and only if $V \subset V'$ and $t$ is the restriction of $t'$ to $V$. Clearly, if $((V_\lambda, t_\lambda) \mid \lambda \in \Lambda)$ is a totally ordered subset of $\mathcal{P}$, then there exists a unique section $t$ on $V := \bigcup_{\lambda \in \Lambda} V_\lambda$ such that $(V, t) \in \mathcal{P}$ and $(V_\lambda, t_\lambda) \leq (V, t)$ for every $\lambda \in \Lambda$. Moreover, $\mathcal{P} \neq \emptyset$, since $(\emptyset, 0) \in \mathcal{P}$. By Zorn's lemma, $\mathcal{P}$ admits
By construction, we have $u$(lemma 10.1.2), hence we find $s$. Y reduce to showing that, for every short exact sequence $Y$ separated, and then $x \in (\text{the induced sequence is short exact, for every } k \text{ consisting of quasi-compact open subsets, such that whence, by the snake lemma, a surjection}: Coker \imath \in (u) \text{ image of an element of } X \text{ is the image of a section } s_i \in (F(U_i)).$

For every $k \leq n$, let $V_k := U_1 \cup \ldots \cup U_k$; we show by induction on $k$ that $s''_{V_k}$ is in the image of $E(V_k)$; the lemma will follow for $k = n$. For $k = 1$ there is nothing to prove. Suppose that $k > 1$ and that the assertion is known for all $j < k$; hence we can find $t \in (E(V_{k-1})$ whose image is $s''_{V_{k-1}}$. The difference $u := ((t - s_k)|_{U_k})$ lies in the image of $E(U_k \cap V_{k-1})$; since $U_k \cap V_{k-1}$ is quasi-compact and $E'$ is qc-flabby, $u$ extends to a section of $E'(U_k)$. We can then replace $s_k$ by $s_k + u$, and assume that $s_k$ and $t$ agree on $U_k \cap V_{k-1}$, whence a section on $V_k = U_k \cup V_{k-1}$ with the sought property. Assertion (iii.a) is proved as (ii).

\begin{lemma}
Let $f : Y \to X$ be a continuous map of topological spaces, $F$ a sheaf on $X$, and $G$ a sheaf on $Y$. We have:

(i) If $f$ is an open immersion and $F$ is qc-flabby on $X$, then $f^* F$ is qc-flabby on $Y$.
(ii) If $G$ is flabby on $Y$, then $f_* G$ is flabby on $X$, and $R^p f_* G = 0$ for every $p > 0$.
(iii) If $f$ is quasi-compact and $G$ is qc-flabby on $Y$, then $f_* G$ is qc-flabby on $X$.
(iv) If $X$ and $Y$ are locally coherent, $f$ is quasi-compact and quasi-separated, and $G$ is abelian and qc-flabby, then $R^p f_* G = 0$ for every $p > 0$.
(v) Let $A$ be any sheaf of rings on $X$. Every injective $A$-module is flabby.
(vi) If $X$ is locally noetherian, every qc-flabby sheaf on $X$ is flabby.
\end{lemma}

\textbf{Proof.} (i) and (iii) are trivial.

(ii): Clearly $f^* F$ is flabby, and it remains to check that $R^p f_* G = 0$ for every $p > 0$. To this aim, in view of remark 7.3.29(iv,v,vi) and lemma 10.1.4(ii), it suffices to show that for every short exact sequence $0 \to G' \to G \to G'' \to 0$ of flabby abelian sheaves on $Y$, the resulting sequence $0 \to f_* G' \to f_* G \to f_* G'' \to 0$ is still short exact; the latter follows from 10.1.4(i).

(iv): The assertion is local on $X$, so we may assume that $X$ is quasi-compact and quasi-separated, and then $Y$ is also quasi-compact. Remark 7.3.29(iv,v,vi) and lemma 10.1.4(iii.b) reduce to showing that, for every short exact sequence $0 \to G' \to G \to G'' \to 0$ of qc-flabby abelian sheaves on $Y$, the resulting sequence $0 \to (f_* G')_x \to (f_* G)_x \to (f_* G'')_x \to 0$ is short exact, for every $x \in X$. However, every such $x$ has a fundamental system of open neighborhoods consisting of coherent open subsets of $X$, so we come down to checking that the induced sequence $0 \to G'(f^{-1} U) \to G(f^{-1} U) \to G''(f^{-1} U) \to 0$ is short exact, for every
coherent open neighborhood \(U\) of \(x\). But under the current assumptions, \(f^{-1}U\) is quasi-compact and quasi-separated, so we conclude by lemma 10.1.4 iii.a.

(v): Let \(j : U \to X\) be an open immersion, and \(\mathcal{F}\) any injective \(\mathcal{A}\)-module; the counit of adjunction \(\mathcal{F} \dashv \mathcal{A}\) is a monomorphism of \(\mathcal{A}\)-modules, so it induces a surjection

\[
\varphi : \text{Hom}_\mathcal{A}(\mathcal{A}, \mathcal{F}) \to \text{Hom}_\mathcal{A}(j^j_\ast \mathcal{A}, \mathcal{F}).
\]

We have a natural identification: \(\text{Hom}_\mathcal{A}(\mathcal{A}, \mathcal{F}) \to \mathcal{F}(X)\); by adjunction, we have also a natural identification: \(\text{Hom}_\mathcal{A}(j^j_\ast \mathcal{A}, \mathcal{F}) \to \text{Hom}_\mathcal{A}(j^j_\ast \mathcal{A}, j^\ast \mathcal{F}) \to \mathcal{F}(U)\). Under these identifications, \(\varphi\) corresponds to the restriction map \(\mathcal{F}(X) \to \mathcal{F}(U)\), whence the contention.

(vi): Let \(U \subset X\) be any open subset; we have to check that the restriction map \(\mathcal{F}(X) \to \mathcal{F}(U)\) is surjective. To this aim, fix \(s \in \mathcal{F}(U)\), and let \(S\) be the set of all pairs \((V, s_V)\) where \(V \subset X\) is an open subset containing \(U\), and \(s_V \in \mathcal{F}(V)\) is a section whose restriction to \(U\) agrees with \(s\). We endow \(S\) with a partial ordering, by declaring that \((V, s_V)\) \(\leq\) \((V', s_{V'})\) if \(V \subset V'\) and the restriction of \(s_{V'}\) to \(V\) agrees with \(s_V\). A standard application of Zorn’s lemma shows that \(S\) admits a maximal element \((V, s_V)\), and it suffices to show that \(V = X\). However, if the latter fails, there exists a noetherian open subset \(U' \subset X\) which does not lie in \(V\), and \(U' \cap V\) is quasi-compact (remark 8.1.6 iv); since \(\mathcal{F}\) is qc-flabby, we may then find \(s_{U'} \in \mathcal{F}(U')\) whose restriction to \(U' \cap V\) agrees with the restriction of \(s_V\). Then there exists a unique \(s_{U' \cup V} \in \mathcal{F}(U' \cap V)\) whose restriction to \(U'\) and \(V\) agrees with \(s_{U'}\) and respectively \(s_V\); the pair \((U' \cup V, s_{U' \cup V})\) lies in \(S\), contradicting the maximality of \((V, s_V)\). \(\square\)

10.1.6. Let \(\Lambda\) be a small cofiltered category. We call a system of topological spaces indexed by \(\Lambda\), any functor (notation of \((8.1.1)\))

\[
X_\bullet : \Lambda \to \text{Top} \quad \lambda \mapsto X_\lambda \quad (\lambda \xrightarrow{u} \mu) \mapsto (\varphi_u : X_\lambda \to X_\mu)
\]

We also call a compatible system of sheaves on \(X_\bullet\), the datum of a family \((\mathcal{F}_\lambda \mid \lambda \in \text{Ob}(\Lambda))\), where \(\mathcal{F}_\lambda\) is a sheaf on \(X_\lambda\) for every \(\lambda \in \text{Ob}(\Lambda)\), together with transition maps:

\[
\beta_u : \varphi_u^{-1} \mathcal{F}_\lambda \to \mathcal{F}_\mu \quad \text{for every morphism } u : \mu \to \lambda \in \Lambda
\]

such that \(\beta_{1_\lambda} = 1_{\mathcal{F}_\lambda}\) for every \(\lambda \in \text{Ob}(\Lambda)\), and for any two morphisms \(\nu \xrightarrow{v} \mu \xrightarrow{u} \lambda\) of \(\Lambda\), the following diagram commutes:

\[
\begin{array}{ccc}
\varphi_\nu^{-1} \circ \varphi_u^{-1} \mathcal{F}_\lambda & \xrightarrow{\sim} & \varphi_{uv}^{-1} \mathcal{F}_\lambda \\
\varphi_\nu^{-1} \beta_u & & \beta_{uv} \\
\varphi_\nu^{-1} \mathcal{F}_\mu & \xrightarrow{\beta_v} & \mathcal{F}_\nu
\end{array}
\]

Lemma 10.1.7. With the notation of \((10.1.6)\), let \(X\) be the limit of \(X_\bullet\), and \((\varphi_\lambda : X \to X_\lambda \mid \lambda \in \Lambda)\) a universal cone. Suppose that either one of the following conditions holds:

(a) \(X_\bullet\) is a constant functor with value \(X\) so \(X_\lambda = X\) for every \(\lambda \in \text{Ob}(\Lambda)\), and \(\varphi_u = 1_X\) for every morphism \(u\) of \(\Lambda\), and \(X\) is quasi-compact.

(b) \(X_\lambda\) is a sober and quasi-compact topological space, for every \(\lambda \in \Lambda\).

Then the natural map

\[
\text{colim}_{\lambda \in \text{Ob}(\Lambda)} \Gamma(X_\lambda, \mathcal{F}_\lambda) \to \Gamma(X, \mathcal{F}) \quad \text{with} \quad \mathcal{F} := \text{colim}_{\lambda \in \text{Ob}(\Lambda)} \varphi_\lambda^* \mathcal{F}_\lambda
\]

is injective.

Proof. By virtue of proposition 1.5.20, we may assume that \(\Lambda\) is a cofiltered partially ordered set, and we let \((\Lambda^\circ, \leq)\) be the opposite ordering on \(\Lambda\) (see example 1.1.6 iii)). We then come down to proving the following assertion. Let \(\lambda \in \Lambda\) be any index, \(s, s' \in \Gamma(X_\lambda, \mathcal{F}_\lambda)\) two sections whose images agree in \(\Gamma(X, \mathcal{F})\), and for every \(\mu \in \Lambda\) such that \(\mu \geq \lambda\), denote by \(s\mu\)
and \(s'_\mu\) the images of \(s\) and \(s'\) in \(\Gamma(X_\mu, F_\mu)\); then there exists an index \(\mu \geq \lambda\), such that \(s_\mu = s'_\mu\). However, set

\[ Z_\mu := \{ x \in X_\mu \mid s_{\mu, x} \neq s'_{\mu, x}\} \quad \text{for every } \mu \in \Lambda^o \text{ such that } \mu \geq \lambda \]

and endow \(Z_\mu\) with the topology induced from \(X_\mu\). Now \(Z_\mu\) is a closed subset of \(X_\mu\) for every \(\mu \geq \lambda\), and it is easily seen that \(\psi_\mu(Z_\mu) \subset Z_\nu\) for every morphism \(u : \mu \to \nu\). Thus, \((Z_\mu \mid \mu \geq \lambda)\) is a cofiltered system of topological spaces, and the assumption on \(s\) and \(s'\) implies that the limit of this system is empty. If condition (a) holds, each \(Z_\mu\) is a closed subset of the quasi-compact space \(X\), so we deduce that \(Z_\mu = \emptyset\) for some \(\mu \geq \lambda\), whence \(s_\mu = s'_\mu\) for such index \(\mu\). If (b) holds, each \(Z_\mu\) is a sober space (lemma 8.1.3(iii)), and we conclude again that \(Z_\mu = \emptyset\) for some \(\mu \geq \lambda\), due to proposition 8.1.13(ii.a).

10.1.8. Let \(\Lambda\) be a small cofiltered category; we consider the datum consisting of:

- Two systems \(X_\mu\) and \(Y_\mu\) of topological spaces indexed by \(\Lambda\), such that \(X_\lambda\) and \(Y_\lambda\) are locally spectral for every \(\lambda \in \Lambda\), with quasi-compact and quasi-separated transition maps :

\[(X, Y) \mapsto \varphi_\mu : X_\mu \to X_\lambda, \quad \psi_\mu : Y_\mu \to Y_\lambda \quad \text{for every morphism } u : \mu \to \lambda \text{ in } \Lambda\]

- A compatible system of sheaves \(F_\mu\) on \(Y_\mu\), as defined in (10.1.6).

- A natural transformation \(g_\mu : X_\mu \to Y_\mu\), i.e. a system \(g : \lambda \mapsto (g_\lambda) : X_\lambda \to Y_\lambda \mid \lambda \in \text{Ob}(\Lambda)\) of quasi-compact and quasi-separated continuous maps, such that

\[\varphi_\lambda \circ \psi_\mu = \varphi_\mu \circ g_\mu \quad \text{for every morphism } u : \mu \to \lambda\]

The limits of \(X_\mu\), \(Y_\mu\) and \(g_\mu\) are representable by topological spaces and continuous maps

\[X := \lim_{\Lambda} X_\lambda, \quad Y := \lim_{\Lambda} Y_\lambda, \quad g := \lim_{\Lambda} g_\lambda : Y \to X\]

and the universal cones consist of continuous spectral maps

\[\varphi_\lambda : X \to X_\lambda, \quad \psi_\lambda : Y \to Y_\lambda \quad \text{for every } \lambda \in \Lambda\]

Proposition 10.1.10. In the situation of (10.1.8), the following holds:

(i) If \(Y_\lambda\) is spectral for every \(\lambda \in \text{Ob}(\Lambda)\), the natural map

\[\colim_{\lambda \in \text{Ob}(\Lambda^o)} \Gamma(Y_\lambda, F_\lambda) \to \Gamma(Y, F) \quad \text{with } F := \colim_{\lambda \in \text{Ob}(\Lambda^o)} \psi_\lambda^* F_\lambda\]

is a bijection.

(ii) If \(F_\mu\) is a system of abelian sheaves, then the natural morphisms :

\[\colim_{\lambda \in \text{Ob}(\Lambda^o)} \varphi_\lambda^* R^ig_\lambda^*. F_\lambda \to R^ig_\lambda^*. F\]

are isomorphisms for every \(i \in \mathbb{N}\).

Proof. By virtue of proposition 1.5.20, we may assume that \(\Lambda\) is a cofiltered partially ordered set, and we let \((\Lambda^o, \leq)\) be the opposite ordering on \(\Lambda\) (see example 1.1.6(iii)). The injectivity of the map in (i) is already known, by lemma 10.1.7. Let us then verify the surjectivity. In case \(Y = \emptyset\), we know that \(Y_\lambda = \emptyset\) for some \(\lambda \in \Lambda^o\), so the assertion holds. Hence, we may assume that \(Y\) is not empty. Now, let \(s \in \Gamma(Y, F)\) be any section; since

\[F_y = \colim_{\lambda \in \Lambda^o} F_{\lambda, \psi_\lambda(y)} \quad \text{for every } y \in Y\]

we may find, for every \(y \in Y\), an index \(\lambda(y) \in \Lambda^o\), a quasi-compact open neighborhood \(U_\mu\) of \(\psi_\lambda(y)(y)\) in \(Y_{\lambda(y)}\) and a section \(s(y) \in \Gamma(U_\mu, F_\lambda)\) such that the image of \(s(y)\) in \(F_y\) equals \(s_y\). Then, for each \(y \in Y\), we may find a quasi-compact open neighborhood \(U'_y\) of \(y\) in \(\psi_{\lambda(y)}^{-1}(U_\mu)\) such that the image of \(s(y)\) in \(U'_y\) agrees with the restriction of \(s\). The family \((U'_y \mid y \in Y)\) is an open covering of \(Y\), and since \(Y\) is quasi-compact (theorem 8.1.32(i)), we may find a finite (non-empty) subset \(S \subset Y\) such that \((U'_y \mid y \in S)\) already covers \(Y\). Then, for each \(y \in S\) we
may find an index \(\mu(y) \geq \lambda(y)\) and a quasi-compact open subset \(U'_y\) of \(\psi^{-1}_{\mu(y)\lambda(y)}U_\lambda(y)\) such that \(\psi^{-1}_{\mu(y)}U'_y = U'_y\) (corollary \ref{8.1.38}(ii.a)). Next, since \(\Lambda\) is cofiltered, we may find \(\mu \in \Lambda^o\) such that \(\mu \geq \mu(y)\) for every \(y \in S\), and after replacing \(U'_y\) by \(\psi^{-1}_{\mu(y)\lambda(y)}U'_y\), and \(s(y)\) by its image in \(\Gamma(\psi^{-1}_{\mu(y)\lambda(y)}U'_y, \mathcal{F}_\mu)\) for every \(y \in S\), we may assume that \(\mu(y)\) is a single index \(\mu\), independent of \(y \in S\). Now, since \(\bigcup_{y \in S} \psi^{-1}_{\mu(y)}U'_y = Y\), there exists \(\nu \geq \mu\) such that \(\bigcup_{y \in S} \psi^{-1}_{\nu(y)}U'_y = Y_\nu\) (corollary \ref{8.1.38}(ii.b)), so we may replace \(\mu\) by \(\nu\), each \(U'_y\) by its preimage in \(Y_\nu\), and \(s(y)\) by its image in \(\Gamma(\psi^{-1}_{\nu(y)\lambda(y)}U'_y, \mathcal{F}_\nu)\), and further assume that \((U'_y \mid y \in S)\) is a covering of \(Y_\nu\).

Lastly, notice that – by construction – for every \(y, y' \in S\), the images of \(s(y)\) and \(s(y')\) agree in \(\Gamma(\psi^{-1}_{\nu(y)\lambda(y)}U'_y \cap U'_y, \mathcal{F}_{\nu(y)\lambda(y)})\). Since \(\Lambda\) is cofiltered, we may then find \(\lambda \in \Lambda^o\) such that \(\lambda \geq \nu(y, y')\) for every \(y, y' \in S\). Now, let \(V_y := \psi^{-1}_{\lambda(y)}U'_y\) and denote by \(s'(y)\) the image of \(s(y)\) in \((\Gamma(V_y, \mathcal{F}_\lambda), \mathcal{F}_\lambda)\), for every \(y \in S\); by construction we have \(s'(y)|_{V_{y'} \cap V_{y'}} = s'(y)|_{V_{y'} \cap V_{y'}}\) for every \(y, y' \in S\), so the system \((s'(y) \mid y \in S)\) corresponds to a well defined section \(s' \in \Gamma(Y_\lambda, \mathcal{F}_\lambda)\), whose image in \(\Gamma(Y, \mathcal{F})\) is finally the original section \(s\).

(ii): We notice:

Claim 10.1.11. Suppose that \(\mathcal{F}_\lambda\) is qc-flabby for every \(\lambda \in \Lambda^o\). Then the same holds for \(\mathcal{F}\).

Proof of the claim. Indeed, let \(U \subset V\) be any two quasi-compact open subsets of \(V\); we need to show that the restriction map

\[\Gamma(V, \mathcal{F}) \to \Gamma(U, \mathcal{F})\]

is onto. By corollary \ref{8.1.38} ii) we can find \(\lambda \in \Lambda^o\) and quasi-compact open subsets \(U_\lambda \subset V_\lambda \subset Y_\lambda\) such that \(U = \psi^{-1}_\lambda U_\lambda\), and likewise for \(V\). Let us set \(U_\mu := \psi^{-1}_\mu U_\lambda\) for every \(\mu \in \Lambda^o\) such that \(\mu \geq \lambda\), and likewise define \(V_\mu\). Then, up to replacing \(\Lambda^o\) by the cofinal subset \(\{\mu \in \Lambda^o \mid \mu \geq \lambda\}\), we may assume that \(U_\mu \subset V_\mu\) are defined for every \(\mu \in \Lambda^o\). By (i) the natural map

\[\colim_{\lambda \in \Lambda^o} \Gamma(U_\lambda, \mathcal{F}_\lambda) \to \Gamma(U, \mathcal{F})\]

is bijective for every \(n \in \mathbb{N}\), and likewise for \(V\), whence the claim.

Now, we pick for each \(\lambda \in \Lambda^o\) an injective resolution \(\mathcal{F}_\lambda \to \mathcal{K}_\lambda\), having care to construct \(\mathcal{K}_\lambda\) functorially, so that \(\mathcal{K}_\lambda\) extends to a compatible system of complexes \((\mathcal{F}_\lambda \to \mathcal{K}_\lambda \mid \lambda \in \Lambda^o)\).

From claim \ref{10.1.11} we know that \(\mathcal{K}_\lambda := \colim_{\lambda \in \Lambda^o} \psi^{-1}_\lambda \mathcal{F}_\lambda\) is a complex of qc-flabby sheaves; then lemma \ref{10.1.5}(iv) and remark \ref{7.3.29}(iv) yield a natural isomorphism :

\[g_* \mathcal{K} \cong Rg_* \mathcal{F}\]

in \(\mathbf{D}(\mathbb{Z}_X, \mathbf{Mod})\).

To conclude, let \(V \to X\) be any quasi-compact open immersion, which as usual we see as the limit of a system \((V_\lambda \to X_\lambda \mid \lambda \in \Lambda)\) of quasi-compact open immersions; we come down to checking that the natural map

\[\Gamma(V, \colim_{\lambda \in \Lambda^o} \varphi_*^{\lambda} \mathcal{K}_\lambda) \to \Gamma(V, g_{\infty*} \mathcal{K}_\lambda\] \[= \Gamma(g^{-1}V, \mathcal{K}_\lambda)\]

is an isomorphism of complexes. However, \(g^{-1}V\) is the limit of the system \((g^{-1}_*V_\lambda \mid \lambda \in \Lambda)\) of spectral topological spaces and quasi-compact quasi-separated maps, so (i) naturally identifies both complexes with

\[\colim_{\lambda \in \Lambda^o} \Gamma(g^{-1}_*V_\lambda, \mathcal{K}_\lambda)\]

whence the contention.

\[\square\]

Remark 10.1.12. In the situation of (10.1.8), suppose that \(X_*\) and \(Y_*\) are two systems of schemes, that the systems \(\varphi_*\) and \(\psi_*\) of (10.1.9) consist of affine morphisms of schemes, and \(g_*\) is a system of quasi-compact and quasi-separated morphisms of schemes. By [50] Ch.IV,
Prop.8.2.3] the limits (in the category of schemes) of the systems $X_\bullet, Y_\bullet$ (resp. $g_\bullet$) are representable by schemes (resp. by a morphism of schemes) whose underlying topological spaces (resp. continuous map) agrees with $X$ and $Y$ (resp. $g$), and the resulting $\varphi_\lambda, \psi_\lambda$ are affine morphisms of schemes, for every $\lambda \in \text{Ob}(\Lambda)$. Hence, proposition 10.1.10 applies especially to such inverse systems.

10.1.13. Let $(X, \mathcal{A})$ be a ringed space, and denote by $\mathbb{Z}_X$ the sheaf of rings associated with the constant presheaf with values $\mathbb{Z}$; then $\mathbb{Z}_X\text{-Mod}$ is the category of abelian sheaves on $X$, and the natural morphism $\mathbb{Z}_X \to \mathcal{A}$ induces a forgetful functor

$$\varphi_\mathcal{A} : D(\mathcal{A}\text{-Mod}) \to D(\mathbb{Z}_X\text{-Mod}).$$

Furthermore, let $f : (Y, \mathcal{B}) \to (X, \mathcal{A})$ be a morphism of ringed spaces. For every $\mathcal{B}$-module $\mathcal{F}$, the direct image $f_*\mathcal{F}$ is naturally an $\mathcal{A}$-module, and we notice that the derived functor $Rf_* : D^+(\mathcal{B}\text{-Mod}) \to D^+(\mathcal{A}\text{-Mod})$ commutes with the forgetful functors $\varphi_\mathcal{A}, \varphi_\mathcal{B}$; indeed, every injective $\mathcal{B}$-module is a flabby $\mathcal{Z}_Y$-module (lemma 10.1.5(v)), and the latter are acyclic for the functor $I_* : \mathbb{Z}_Y\text{-Mod} \to \mathbb{Z}_X\text{-Mod}$ (lemma 10.1.5(ii)), so the assertion follows easily.

One defines as in example 7.1.16 a total Hom cochain complex, which is a functor:

$$\bigoplus_{\mathcal{A}\text{-modules}}^\bullet : C(\mathcal{A}\text{-Mod}) \times C(\mathcal{A}\text{-Mod}) \to C(\mathcal{A}\text{-Mod})$$

on the category of complexes of $\mathcal{A}$-modules. Recall that, for any two complexes $M_\bullet, N_\bullet$, and any object $U$ of $X$, the group of $n$-cocycles in $\bigoplus_{\mathcal{A}\text{-modules}}^\bullet(M_\bullet, N_\bullet)(U)$ is naturally isomorphic to $\text{Hom}_{C(\mathcal{A}\text{-Mod})}(M_\bullet|_U, N_\bullet|_U[n])$, and $H^n\bigoplus_{\mathcal{A}\text{-modules}}^\bullet(M_\bullet, N_\bullet)(U)$ is naturally isomorphic to the group of homotopy classes of maps $M_\bullet|_U \to N_\bullet|_U[n]$ (see example 7.1.15(i)). We also set:

$$\text{Hom}_\mathcal{A}^\bullet := \Gamma \circ \bigoplus_{\mathcal{A}\text{-modules}}^\bullet : C(\mathcal{A}\text{-Mod}) \times C(\mathcal{A}\text{-Mod}) \to C(\Gamma(\mathcal{A})\text{-Mod}).$$

The bifunctor $\bigoplus_{\mathcal{A}\text{-modules}}^\bullet$ admits a right derived functor:

$$R\bigoplus_{\mathcal{A}\text{-modules}}^\bullet : D^+(\mathcal{A}\text{-Mod}) \times D(\mathcal{A}\text{-Mod}) \to D(\mathcal{A}\text{-Mod})$$

for whose construction we refer to [125 §10.7]. Likewise, one has a derived functor $R\text{Hom}_\mathcal{A}^\bullet$ for (10.1.14), and there are natural isomorphisms of $\mathcal{A}$-modules:

$$H^i R\text{Hom}_\mathcal{A}^\bullet(M_\bullet, N_\bullet) \cong \text{Hom}_{D^+(\mathcal{A}\text{-Mod})}(M_\bullet, N_\bullet[i])$$

for every $i \in \mathbb{Z}$, and every bounded below complexes $M_\bullet$ and $N_\bullet$ of $\mathcal{A}$-modules.

**Lemma 10.1.16.** Let $(X, \mathcal{A})$ be a ringed space, $\mathcal{B}$ an $\mathcal{A}$-algebra. Then :

(i) If $\mathcal{I}$ is an injective $\mathcal{A}$-module, $\bigoplus_{\mathcal{A}\text{-modules}}(\mathcal{F}, \mathcal{I})$ is flabby for every $\mathcal{A}$-module $\mathcal{F}$, and $\bigoplus_{\mathcal{A}\text{-modules}}(\mathcal{B}, \mathcal{I})$ is an injective $\mathcal{B}$-module.

(ii) There is a natural isomorphism of bifunctors :

$$R \Gamma \circ R\bigoplus_{\mathcal{A}\text{-modules}}^\bullet \cong R\text{Hom}_\mathcal{A}^\bullet.$$

(iii) The forgetful functor $D^+(\mathcal{B}\text{-Mod}) \to D^+(\mathcal{A}\text{-Mod})$ admits the right adjoint :

$$D^+(\mathcal{A}\text{-Mod}) \to D^+(\mathcal{B}\text{-Mod}) : K_\bullet \mapsto R\text{Hom}_\mathcal{A}^\bullet(\mathcal{B}, K_\bullet).$$

**Proof.** (i): Let $j : U \subset X$ be any open immersion; a section $s \in \bigoplus_{\mathcal{A}\text{-modules}}(\mathcal{F}, \mathcal{I})(U)$ is a map of $\mathcal{A}_U$-modules $s : \mathcal{F}_U \to \mathcal{I}_U$. We deduce a map of $\mathcal{A}$-modules $j_!s : j_!\mathcal{F}_U \to j_!\mathcal{I}_U$; since $\mathcal{I}$ is injective, $j_!s$ extends to a map $\mathcal{F} \to \mathcal{I}$, as required. Next, let $\mathcal{B}$ be an $\mathcal{A}$-algebra; we recall the following :

**Claim 10.1.17.** The functor

$$\mathcal{A}\text{-Mod} \to \mathcal{B}\text{-Mod} : \mathcal{F} \mapsto \mathcal{Hom}_{\mathcal{A}\text{-modules}}(\mathcal{B}, \mathcal{F})$$

is right adjoint to the forgetful functor.
Proof of the claim. We have to exhibit a natural bijection
\[ \text{Hom}_{\mathcal{A}}(N, M) \xrightarrow{\sim} \text{Hom}_{\mathcal{A}}(N, \text{Hom}_{\mathcal{B}}(B, M)) \]
for every \( \mathcal{A} \)-module \( M \) and \( \mathcal{B} \)-module \( N \). This is given by the following rule. To an \( \mathcal{A} \)-linear map \( t : N \to M \) one assigns the \( \mathcal{B} \)-linear map \( t' : N \to \text{Hom}_{\mathcal{B}}(B, M) \) such that \( t'(x)(b) = t(x \cdot b) \) for every \( x \in N(U) \) and \( b \in B(V) \), where \( V \subset U \) are any two open subsets of \( X \). To describe the inverse of this transformation, it suffices to remark that \( t(x) = t'(x)(1) \) for every local section \( x \) of \( N \).

Since the forgetful functor is exact, the second assertion of (i) follows immediately from claim 10.1.17. Assertion (ii) follows from (i) and [125, Th.10.8.2].

(10.1.19) Let \( \mathcal{B} \)-module \( M \) be a morphism of ringed spaces. For every \( M \in \text{Ob}(\mathcal{B}) \text{-Mod}) \) and \( N \in \text{Ob}(\mathcal{B})\text{-Mod}) \), there are natural isomorphisms:
\[ \text{(i)} \quad R\text{Hom}^\bullet_{\mathcal{A}}(M, Rf_*N) \xrightarrow{\sim} R\text{Hom}^\bullet_{\mathcal{B}}(Lf^*M, N) \text{ in } \mathcal{D}^+(\mathcal{A}(X))\text{-Mod}).
\]
\[ \text{(ii)} \quad R\mathcal{H}om^\bullet_{\mathcal{A}}(M, Rf_*N) \xrightarrow{\sim} Rf_*R\mathcal{H}om^\bullet_{\mathcal{B}}(Lf^*M, N) \text{ in } \mathcal{D}^+(\mathcal{A})\text{-Mod}).
\]
Proof. One applies lemma 10.1.16 ii) to deduce (i) from (ii).

(ii) By standard adjunctions, for any two complexes \( M \) and \( N \) as in the proposition, we have a natural isomorphism of total Hom cochain complexes:
\[ \mathcal{H}om^\bullet_{\mathcal{A}}(M, f_*N) \xrightarrow{\sim} f_*\mathcal{H}om^\bullet_{\mathcal{A}}(f_*M, N).
\]

Now, let us choose a flat resolution \( P_* \xrightarrow{\sim} M_* \) of \( \mathcal{A} \)-modules, and an injective resolution \( N_* \xrightarrow{\sim} I_* \) of \( \mathcal{B} \)-modules. In view of (10.1.19) and lemma 10.1.16 i) we have natural isomorphisms:
\[ Rf_*R\mathcal{H}om^\bullet_{\mathcal{A}}(Lf^*M, N) \xrightarrow{\sim} f_*\mathcal{H}om^\bullet_{\mathcal{A}}(f_*P, I) \xrightarrow{\sim} \mathcal{H}om^\bullet_{\mathcal{A}}(P, f_*I)
\]
in \( \mathcal{D}^+(\mathcal{A})\text{-Mod}). It remains to show that the natural map
\[ \mathcal{H}om^\bullet_{\mathcal{A}}(P, f_*I) \xrightarrow{\sim} R\mathcal{H}om^\bullet_{\mathcal{A}}(P, f_*I)
\]
is an isomorphism. However, we have two spectral sequences:
\[ E^1_{pq} = H_p\mathcal{H}om^\bullet_{\mathcal{A}}(P, f_*I) \xrightarrow{\sim} H_{p+q}\mathcal{H}om^\bullet_{\mathcal{A}}(P, f_*I)
\]
\[ F^1_{pq} = H_pR\mathcal{H}om^\bullet_{\mathcal{A}}(P, f_*I) \xrightarrow{\sim} H_{p+q}R\mathcal{H}om^\bullet_{\mathcal{A}}(P, f_*I)
\]
and (10.1.20) induces a natural map of spectral sequences:
\[ E^1_{pq} \xrightarrow{\sim} F^1_{pq}
\]
Consequently, it suffices to show that (10.1.21) is an isomorphism for every \( p, q \in \mathbb{N} \), and therefore we may assume that \( P_* \) consists of a single flat \( \mathcal{A} \)-module placed in degree zero. A similar argument reduces to the case where \( I_* \) consists of a single injective \( \mathcal{B} \)-module sitting in degree zero. To conclude, it suffices to show:

Claim 10.1.22. Let \( P \) be a flat \( \mathcal{A} \)-module, \( I \) an injective \( \mathcal{B} \)-module. Then the natural map:
\[ \mathcal{H}om_{\mathcal{A}}(P, f_*I)[0] \xrightarrow{\sim} R\mathcal{H}om^\bullet_{\mathcal{A}}(P, f_*I)
\]
is an isomorphism.
Proof of the claim. $R^i \mathcal{H}om^*_\mathcal{A}(P, f_* I)$ is the sheaf associated with the presheaf on $X$:
$$U \mapsto R^i \mathcal{H}om^*_\mathcal{A}(P_U, f_! I_U).$$
Since $I_U$ is an injective $\mathcal{B}_U$-module, it suffices therefore to show that $R^i \mathcal{H}om^*_\mathcal{A}(P, f_* I) = 0$ for $i > 0$. However, recall that there is a natural isomorphism:
$$R^i \mathcal{H}om^*_\mathcal{A}(P, f_* I) \simeq \mathcal{H}om_{\mathcal{D}(\mathcal{A} \text{-Mod})}(P, f_* I[-i]).$$

Since the homotopy category $\text{Hot}(\mathcal{A} \text{-Mod})$ admits a left calculus of fractions, we deduce a natural isomorphism:

\begin{equation}
R^i \mathcal{H}om^*_\mathcal{A}(P, f_* I) \simeq \colim_{E_\bullet \rightarrow P} \mathcal{H}om_{\mathcal{D}(\mathcal{A} \text{-Mod})}(E_\bullet, f_* I[-i])
\end{equation}

where the colimit ranges over the family of quasi-isomorphisms $E_\bullet \rightarrow P$. We may furthermore restrict the colimit in (10.1.23) to the subfamily of all such $E_\bullet \rightarrow P$ where $E_\bullet$ is a bounded above complex of flat $\mathcal{A}$-modules, since this subfamily is cofinal. Every such map $E_\bullet \rightarrow P$ induces a commutative diagram:

\[
\begin{array}{ccc}
\text{Hom}_\mathcal{A}(P, f_* I[-i]) & \longrightarrow & \mathcal{H}om_{\mathcal{D}(\mathcal{A} \text{-Mod})}(E_\bullet, f_* I[-i]) \\
\downarrow & & \downarrow \\
\text{Hom}_\mathcal{A}(f^* P, I[-i]) & \longrightarrow & \mathcal{H}om_{\mathcal{D}(\mathcal{A} \text{-Mod})}(f^* E_\bullet, I[-i])
\end{array}
\]

whose vertical arrows are isomorphisms. Since $E_\bullet$ and $P$ are complexes of flat $\mathcal{A}$-modules, the induced map $f^* E_\bullet \rightarrow f^* P$ is again a quasi-isomorphism; therefore, since $I$ is injective, the bottom horizontal arrow is an isomorphism, hence the same holds for the top horizontal one, and the claim follows easily. \hfill \square

10.1.24. Suppose that $\mathcal{F}$ is an abelian group object in a given topos $X$, and let $(\text{Fil}^n \mathcal{F} \mid n \in \mathbb{N})$ be a descending filtration by abelian subobjects of $\mathcal{F}$, such that $\text{Fil}^0 \mathcal{F} = \mathcal{F}$. Set $\mathcal{F}^n := \mathcal{F}/\text{Fil}^{n+1} \mathcal{F}$ for every $n \in \mathbb{N}$, and denote by $\text{gr}^n \mathcal{F}$ the graded abelian object associated with the filtered object $\text{Fil}^* \mathcal{F}$; then we have:

**Lemma 10.1.25.** In the situation of [10.1.24], fix $q \in \mathbb{N}$ and suppose that the natural map:
$$\mathcal{F} \rightarrow R \lim_{k \in \mathbb{N}} \mathcal{F}^k$$
is an isomorphism in $\mathcal{D}(\mathbb{Z}_X \text{-Mod})$. Then, the following conditions are equivalent:

(a) $H^q(X, \text{Fil}^n \mathcal{F}) = 0$ for every $n \in \mathbb{N}$.

(b) The natural map $H^q(X, \text{Fil}^n \mathcal{F}) \rightarrow H^q(X, \text{gr}^n \mathcal{F})$ vanishes for every $n \in \mathbb{N}$.

**Proof.** Obviously we have only to show that (b) implies (a). Moreover, let us set:
$$\text{Fil}^n \mathcal{F}^k := \text{Fil}^n \mathcal{F}/\text{Fil}^{k+1} \mathcal{F} \quad \text{for every } n, k \in \mathbb{N} \text{ with } k \geq n.$$  

There follows, for every $n \in \mathbb{N}$, a short exact sequence of inverse systems of sheaves:
$$0 \rightarrow ((\text{Fil}^n \mathcal{F}^k \mid k \geq n) \rightarrow (\mathcal{F}^k \mid k \geq n) \rightarrow \mathcal{F}^{n-1} \rightarrow 0$$

(where the right-most term is the constant inverse system which equals $\mathcal{F}^{n-1}$ in all degrees, with transition maps given by the identity morphisms); whence a distinguished triangle:
$$R \lim_{k \in \mathbb{N}} (\text{Fil}^n \mathcal{F}^k) \rightarrow R \lim_{k \in \mathbb{N}} \mathcal{F}^k \rightarrow \mathcal{F}^{n-1}[0] \rightarrow R \lim_{k \in \mathbb{N}} (\text{Fil}^n \mathcal{F}^k)[1]$$

which, together with our assumption on $\mathcal{F}$, easily implies that the natural map $\text{Fil}^n \mathcal{F} \rightarrow R \lim_{k \in \mathbb{N}} (\text{Fil}^n \mathcal{F}^k)$ is an isomorphism in $\mathcal{D}(\mathbb{Z}_X \text{-Mod})$. Summing up, we may replace the datum $(\mathcal{F}, \text{Fil}^* \mathcal{F})$ by $(\text{Fil}^n \mathcal{F}, \text{Fil}^{n+1} \mathcal{F})$, and reduce to the case where $n = 0$.  \hfill $\square$
The inverse system \((\mathcal{F}_n \mid n \in \mathbb{N})\) defines an abelian group object of the topos \(X^\mathbb{N}\) (see [59 §7.3.4]); whence a spectral sequence:

\[(10.1.26) \quad E_2^{pq} := \lim_{n \in \mathbb{N}}^p H^q(X, \mathcal{F}_n) \Rightarrow H^{p+q}(X^\mathbb{N}, \mathcal{F}) \simeq H^{p+q}(X, \lim_{n \in \mathbb{N}} \mathcal{F}_n).\]

By [125, Cor.3.5.4] we have \(E_2^{pq} = 0\) whenever \(p > 1\), and, in view of our assumptions, \([10.1.26]\) decomposes into short exact sequences:

\[0 \to \lim_{n \in \mathbb{N}}^1 H^{q-1}(X, \mathcal{F}_n) \xrightarrow{\alpha_q} H^q(X, \mathcal{F}) \xrightarrow{\beta_q} \lim_{n \in \mathbb{N}} H^q(X, \mathcal{F}_n) \to 0 \quad \text{for every} \ q \in \mathbb{N}\]

where \(\beta_q\) is induced by the natural system of maps \((\beta_{q,n} : H^q(X, \mathcal{F}) \to H^q(X, \mathcal{F}_n) \mid n \in \mathbb{N})\).

Claim 10.1.27. If (b) holds, then \(\beta_q = 0\).

Proof of the claim. Suppose that (b) holds; we consider the long exact cohomology sequence associated with the short exact sequence:

\[0 \to \Fil^{n+1} \mathcal{F} \to \Fil^n \mathcal{F} \to \gr^n \mathcal{F} \to 0\]

to deduce that the natural map \(H^q(X, \Fil^{n+1} \mathcal{F}) \to H^q(X, \Fil^n \mathcal{F})\) is onto for every \(n \in \mathbb{N}\); hence the same holds for the natural map \(H^q(X, \Fil^n \mathcal{F}) \to H^q(X, \mathcal{F})\). By considering the long exact cohomology sequence attached to the short exact sequence:

\[(10.1.28) \quad 0 \to \Fil^n \mathcal{F} \to \mathcal{F} \to \mathcal{F}_n \to 0\]

we then deduce that \(\beta_{q,n}\) vanishes for every \(n \in \mathbb{N}\), which implies the claim.

\[\Box\]

Claim 10.1.29. If (b) holds, then the inverse system \((H^{n-1}(X, \mathcal{F}_n) \mid n \in \mathbb{N})\) has surjective transition maps.

Proof of the claim. By considering the long exact cohomology sequence associated with the short exact sequence:

\[0 \to \gr^n \mathcal{F} \to \mathcal{F}_n+1 \to \mathcal{F}_n \to 0\]

we are reduced to showing that the boundary map \(\partial_{q-1} : H^{q-1}(X, \mathcal{F}_n) \to H^q(X, \gr^n \mathcal{F})\) vanishes for every \(n \in \mathbb{N}\). However, comparing with \([10.1.28]\), we find that \(\partial_{q-1}\) factors through the natural map \(H^q(X, \Fil^n \mathcal{F}) \to H^q(X, \mathcal{F}_n)\), which vanishes if (b) holds.

\[\Box\]

The lemma follows from claims \([10.1.27]\) and \([10.1.29]\) and [125, Lemma 3.5.3].

Our next result generalizes to arbitrary coherent spaces a classical theorem from [67], where it was stated only for noetherian spaces. We need first to introduce a general truncation construction for abelian sheaves, that shall be useful also in section 11.2.

10.1.30. Let \((X, \mathcal{A})\) be a ringed topological space, \(\varphi : V \to X\) a locally closed immersion, denote by \(\bar{V}\) the topological closure of \(V\) in \(X\), and set \(\partial V := \bar{V} \setminus V\), which is also a closed subset of \(X\). Let also \(i : \bar{V} \to X\) and \(j : V \to \bar{V}\) be the induced closed and respectively open immersions. We set

\[\varphi_1 := i_* \circ j_! : \mathcal{A}^\mathcal{A} \to \mathcal{A}\]

and we call \(\varphi_1\) (resp. \(t_V\)) the functor of extension by zero from \(V\) to \(X\) (resp. of truncation outside \(V\)). Notice that we have natural identifications

\[(10.1.31) \quad t_V \mathcal{F}_x \simeq \begin{cases} \mathcal{F}_x & \text{if } x \in V \\ 0 & \text{otherwise.} \end{cases}\]

Lemma 10.1.32. In the situation of \([10.1.30]\), set \(W := X \setminus V\), denote by \(\psi : W \to X\) the resulting locally closed immersion, and let \(\mathcal{F}\) be an \(\mathcal{A}\)-module such that \(\psi^* \mathcal{F} = 0\). Then there exists a unique natural isomorphism

\[f_\mathcal{F} : t_V \mathcal{F} \simeq \mathcal{F}\]

such that \(f_{\mathcal{F},x}\) is the natural identification \([10.1.31]\), for every \(x \in V\).
Proof. The uniqueness of \( f_{\mathcal{F}} \) is clear. For the existence, set \( \mathcal{G} := i^* \mathcal{F} \); it suffices to exhibit natural isomorphisms

\[
\mathcal{F} \overset{\sim}{\to} i_* \mathcal{G} \quad \text{and} \quad j_! \varphi^* \mathcal{F} \overset{\sim}{\to} \mathcal{G}
\]

which induce the corresponding natural identifications on the stalks. So we may assume that \( \varphi \) is either an open or closed immersion. In case \( \varphi \) is open, we obtain a natural map \( f : \varphi^! \mathcal{F} \to \mathcal{F} \) as follows. Recall that \( \varphi^! \mathcal{F} \) is the sheaf associated with the presheaf \( \mathcal{H} \) such that \( \mathcal{H}(U) = \mathcal{F}(U) \) for \( U \subset V \), and \( \mathcal{H}(U) = 0 \) otherwise; then clearly there is a natural monomorphism \( \mathcal{H} \to \mathcal{F} \) in the category of presheaves on \( X \), and the latter factors uniquely through a map as sought. By construction, \( f_x \) is the identity endomorphism of \( \mathcal{F}_x \), for every \( x \in V \), and \( f_x \) is also trivially an isomorphism for \( x \notin V \), since in this case the stalks of both source and target of \( f_x \) vanish. So \( f \) is indeed an isomorphism with the required properties.

Lastly, suppose \( \varphi \) is a closed immersion; for any open subset \( T \) of \( V \), let \( C_T \) be the cofiltered set of all open subsets \( U \) of \( X \) such that \( U \cap V = T \), and set

\[
\varphi^{-1}(\mathcal{H})(T) := \text{colim}_{U \in C_T} \mathcal{H}(U) \quad \text{for every presheaf of abelian groups} \, \mathcal{H} \, \text{on} \, X.
\]

The rule \( T \mapsto \varphi^{-1}(\mathcal{H})(T) \) for every open subset \( T \) of \( V \) yields a well-defined abelian presheaf on \( V \), functorial in \( \mathcal{H} \) (the resulting functor \( \varphi^{-1} \) from abelian presheaves on \( X \) to abelian presheaves on \( V \) is left adjoint to the direct image functor \( \varphi_* : \text{cp. remark} \, 1.3.6(i) \)). Now, suppose that \( \mathcal{H} \) is a \( \mathcal{A} \)-module such that \( \mathcal{H}|_{X \setminus V} = 0 \); in this case, it is easily seen that \( \varphi^{-1} \mathcal{H} \) is a \( \varphi^* \mathcal{A} \)-module, and moreover the transition map \( \mathcal{H}(U) \to \mathcal{H}(U') \) is an isomorphism, for every \( U, U' \subset C_T \) such that \( U' \subset U \). Especially, this applies with \( \mathcal{H} := \mathcal{F} \), so we get a natural isomorphism

\[
f_U : \mathcal{F}(U) \overset{\sim}{\to} i^{-1} \mathcal{F}(U \cap V) = i_* i^{-1} \mathcal{F}(U) \quad \text{for every open subset} \, U \subset X
\]

and the system of such maps \( f_U \) is the sought isomorphism \( \mathcal{F} \overset{\sim}{\to} i_* i^* \mathcal{F} \).

Proposition 10.1.33. Let \( V \) and \( V' \) be two locally closed subsets of \( X \). The following holds:

(i) We have a unique isomorphism of functors:

\[
\tau_{V,V'} : t_V \circ t_{V'} \overset{\sim}{\to} t_{V \cap V'}
\]

which induces, for every \( \mathcal{A} \)-module \( \mathcal{F} \) and every \( x \in V \cap V' \) a commutative diagram

\[
t_V \circ t_{V'} \mathcal{F}_x \xrightarrow{\tau_{V,V'}^x} t_{V \cap V'} \mathcal{F}_x
\]

(10.1.34)

where \( \alpha, \beta \) and \( \gamma \) are the natural identifications of \( (10.1.31) \).

(ii) Let \( V'' \subset X \) be a third locally closed subset. Then the diagram

\[
t_V \circ t_{V'} \circ t_{V''} \xrightarrow{t_V \circ \tau_{V'^{V''},V''}} t_V \circ t_{V \cap V''} \xrightarrow{\tau_{V,V'' \cap V''}} t_{V \cap V'' \cap V''}
\]

commutes.

(iii) Suppose that:

(a) either \( V \subset V' \) and the resulting immersion \( V \to V' \) is closed

(b) or else \( V' \subset V \) and the resulting immersion \( V' \to V \) is open.
Then there exists a unique morphism of functors

$$c^{V,V'} : t_{V'} \to t_V$$

which induces, for every $\mathcal{A}$-module $\mathcal{F}$ and every $x \in V \cap V'$, a commutative diagram

$$
\begin{array}{c}
\xymatrix{
t_V \circ t_{V'} & t_V \circ t_{V'} \\
t_V \circ t_{V'} & t_{V'} \circ t_V \\
\tau^{V',V} & \tau^{V'',V'} \\\n\tau^{V'',V'} & \tau^{V''} \\\n}\end{array}
$$

whose downward arrows are the natural identifications \(10.1.31\).

(iv) In the situation of (iii), let $V''$ be a third locally closed subset of $X$. Then the resulting diagram

$$
\begin{array}{c}
\xymatrix{t_{V''} \circ t_{V'} & t_{V''} \circ t_V \\
t_{V''} \circ t_{V'} & t_{V'} \circ t_{V''} \\
\tau^{V''} & \tau^{V'} \\\n\tau^{V'} & \tau^{V''} \\\n}\end{array}
$$

commutes.

(v) Let $V \subset V' \subset V''$ (resp. $V'' \subset V' \subset V$) be a chain of closed (resp. open) immersions of locally closed subsets of $X$. Then

$$c^{V,V'} \circ c^{V'',V'} = c^{V,V''}.$$

**Proof.** (i): The uniqueness is clear. For the existence, set $W := V \cap V''$, and let $\varphi : W \to X$ and $\psi : X \setminus W \to X$ be the locally closed immersions; by inspecting the definition, we find natural isomorphisms

$$\varphi^* \circ t_V \circ t_{V'} \cong \varphi^* \mathcal{F} \cong \varphi^* t_W \mathcal{F} \quad \text{for every } \mathcal{A}\text{-module } \mathcal{F}$$

which induce on stalks the isomorphisms $\varphi^*(\gamma \circ \alpha)$ and respectively $\varphi^* \beta$. There follows an isomorphism $\varphi f : t_W \circ t_V \circ t_{V'} \mathcal{F} \to t_{V''} \circ t_{V'} \mathcal{F}$. On the other hand, it is easily seen that $\psi^* \circ t_V \circ t_{V'} \mathcal{F}$ and $\psi^* \circ t_W \mathcal{F}$ both vanish, so lemma \(10.1.32\) naturally identifies $\varphi f$ with an isomorphism $t_V \circ t_{V'} \mathcal{F} \cong t_W \mathcal{F}$ with the sought property.

(ii): The commutativity of the diagram can be checked on stalks, and then it follows easily from the commutativity of \(10.1.34\); details left to the reader.

(iii): Again, the uniqueness of $c^{V,V'}$ is clear. For the existence, consider first case (a), and write $V = V'' \cap Z$ for some closed immersion $\varphi : Z \to X$. The unit of the adjunction $(\varphi^*, \varphi_*)$ yields a natural morphism $\eta : \mathcal{F} \to t_Z \mathcal{F}$, whence a morphism $t_V \eta : t_V \mathcal{F} \to t_V \circ t_Z \mathcal{F}$, which, by (i) is naturally identified with a morphism $t_{V'} \mathcal{F} \to t_{V'} \mathcal{F}$ fulfilling the stated condition. A similar argument works in case (b): we write $V' = V \cap U$ for some open immersion $\psi : U \subset X$ and we consider the counit $\varepsilon : t_U \mathcal{F} \to \mathcal{F}$ of the adjunction $(\psi_!, \psi^*)$; then (i) naturally identifies $t_V \varepsilon$ with a morphism with the sought properties.

(iv) and (v) can be checked on the stalks: the details shall be left to the reader. \(\square\)

**Theorem 10.1.35.** Let $X$ be any coherent space, $\mathcal{F}$ any abelian sheaf on $X$. Then:

(i) $H^i(X, \mathcal{F}) = 0$ for every $i > \dim X$.

(ii) If $X$ is spectral, we have more precisely

$$H^i(X, \mathcal{F}) = 0 \quad \text{for every } i > d_\mathcal{F} := \sup \{\dim \{x\} \mid x \in \text{Supp} \mathcal{F}\}.$$  

**Proof.** (Here, for any subset $T \subset X$, we denote by $\overline{T}$ the topological closure of $T$ in $X$).
Suppose, by way of contradiction, that $\mathcal{S}$ is an isomorphism as well; thus, we may replace $X$ by $\mathcal{S}$, and we let $
abla_{\mathcal{S}} := \text{Im } \varphi_{\mathcal{S}},$ for $S$ ranging over all finite subsets of $\mathcal{S}$. By proposition 10.1.10(i) we deduce that $H^i(\mathcal{X}, \mathcal{F})$ is the filtered colimit of the system of abelian groups $(H^i(\mathcal{X}, \mathcal{F}_S) | S \subset \mathcal{S})$; it then suffices to show the assertion for each subsheaf $\mathcal{F}_S$. Thus, we may assume from start that there exists a finite subset $S \subset \mathcal{S}$ with $\mathcal{F} = \mathcal{F}_S$. In this case, we set

$$Z := \text{Supp } \mathcal{F} = \bigcup_{(U, s) \in S} \text{Supp}(s)$$

and we let $i_Z : Z \rightarrow X$ be the closed immersion. Clearly we have a natural isomorphism

$$H^i(\mathcal{X}, \mathcal{F}) \cong H^i(Z, i_Z^* \mathcal{F}) \quad \text{for every } i \in \mathbb{N}$$

and $Z$ is still a spectral space, by corollary 8.1.40. Hence, we may replace $X$ by $Z$ and $\mathcal{F}$ by $i_Z^* \mathcal{F}$, and assume from start that $Z = X$ (and clearly, we still have $\mathcal{F} = \mathcal{F}_S$). In view of our assumption, it then suffices to show that

$$\dim Z = \sup \left( \dim \{x\} \mid x \in \bigcup_{(U, s) \in S} \text{Supp}(s) \right).$$

To this aim, in light of remark 8.1.2(v), we are reduced to checking that $\dim \text{Supp}(s) = \sup(\dim \{x\} \mid x \in \text{Supp}(s))$ for every $(U, s) \in S$. However, notice that $\text{Supp}(s)$ is pro-constructible in $X$, hence $\text{Supp}(s)$ is the set of all specializations in $X$ of the points of $\text{Supp}(s)$ (proposition 8.1.44(i)). Now the contention follows from remark 8.1.43(iii).

(i): Let $S_X$ be the sober space associated with $X$, and $f_X : X \rightarrow S_X$ the unit of adjunction (proposition 8.1.8); by remark 8.1.11 the space $S_X$ is spectral; moreover the functor

$$f_X^* : \mathbb{Z}_{S_X} \text{-Mod} \rightarrow \mathbb{Z}_X \text{-Mod}$$

is an equivalence of categories, and the induced map $\Gamma(S_X, \mathcal{F}) \rightarrow \Gamma(X, f_X^* \mathcal{F})$ is a bijection for every $\mathbb{Z}_{S_X}$-module $\mathcal{F}$. It follows easily that the induced map

$$H^i(S_X, \mathcal{F}) \rightarrow H^i(X, f_X^* \mathcal{F})$$

is an isomorphism as well; thus, we may replace $X$ by $S_X$, and assume from start that $X$ is spectral.

We argue by induction on $d := \dim X$. If $d = 0$, $X$ is a boolean space (see example 8.1.45), so every sheaf on $X$ is qc-flabby, and the assertion follows from lemma 10.1.5(iv). We may then assume that $d > 0$ and that (i) is already known for every spectral space of dimension $< d$. Suppose, by way of contradiction, that $H^{d+1}(X, \mathcal{F}) \neq 0$ for some $\mathbb{Z}_X$-module $\mathcal{F}$, and pick any element $c \neq 0$ in this cohomology group. For any closed subset $Z \subset X$, let $i_Z : Z \rightarrow X$ be the
corresponding closed immersion, denote by $\mathcal{Z}$ the system of all closed subsets $Z \subset X$ such that the image of $c$ does not vanish in $H^{d+1}(Z, i_Z^* \mathcal{F})$, and endow $\mathcal{Z}$ with the partial ordering given by inclusion. Notice that each $Z \in \mathcal{Z}$ is also a spectral space (corollary 8.1.40), so we must have $\dim Z = d$, by inductive assumption.

Claim 10.1.37. (i) The partially ordered set $\mathcal{Z}$ admits minimal elements.

(ii) Every minimal element of $\mathcal{Z}$ is an irreducible closed subset of $X$.

Proof of the claim. (i): Let $(Z_i \mid i \in I)$ be any totally ordered non-empty subset of $\mathcal{Z}$; by Zorn’s lemma, it suffices to check that $\bigcap_{i \in I} Z_i \in \mathcal{Z}$. However, notice that the inclusion maps $Z_i \to Z_j$ are spectral for every $i, j \in I$ with $Z_i \subset Z_j$ (lemma 8.1.25(x,e) and remark 8.1.26(iv)), so the latter assertion follows directly from proposition 10.1.10(i).

(ii): Let $Z$ be any minimal element of $\mathcal{Z}$, and suppose, by way of contradiction, that $Z = Z_1 \cup Z_2$ for two non-empty closed subsets $Z_1, Z_2$ strictly contained in $Z$; notice that $Z_1$ and $Z_2$ are also spectral spaces (corollary 8.1.40). Pick any non-empty quasi-compact open subset $U \subset Z \setminus Z_1$, and set $Z'_1 := Z \setminus U, Z'_2 := U$. Since $U \subset Z_2$, we have $Z'_2 \subset Z_2$ and $Z_1 \subset Z'_1$. Moreover, both $Z'_1$ (resp. $Z'_2$) is the set of all specializations of the points of $Z \setminus U$ (resp. of $U$); it follows that $Z'_1 := Z'_1 \cap Z'_2$ has dimension $< d$; indeed, any totally ordered sequence $x_1 < \cdots < x_d$ of elements of $(Z'_1, \leq)$ (with ordering given by specialization) can be extended to a totally ordered sequence of $(Z'_2, \leq)$, by adding a generalization $x_{k+1}$ of $x_k$ with $x_{k+1} \in U$. On the other hand, consider the sequence

$$0 \to t_{Z'_1} \mathcal{F} \to t_{Z'_1} \mathcal{F} \oplus t_{Z'_2} \mathcal{F} \to t_Z \mathcal{F} \to 0.$$  \hspace{1cm} (10.1.38)

whose second and third arrows are given by the natural transformations provided by proposition 10.1.33(iii); by considering the stalks over the points of $Z$, it is easily seen that (10.1.38) is short exact, whence an exact sequence of abelian groups

$$H^d(Z'_3, i_{Z'_3}^* \mathcal{F}) \to H^{d+1}(Z, i_Z^* \mathcal{F}) \xrightarrow{\beta} H^{d+1}(Z'_1, i_{Z'_1}^* \mathcal{F}) \oplus H^{d+1}(Z'_2, i_{Z'_2}^* \mathcal{F}).$$  \hspace{1cm} (10.1.39)

However, the first term of (10.1.39) vanishes by inductive assumption, hence $\beta$ is injective; especially the image of $c$ cannot vanish in both $H^{d+1}(Z'_1, i_{Z'_1}^* \mathcal{F})$ and $H^{d+1}(Z'_2, i_{Z'_2}^* \mathcal{F})$, contradicting the minimality of $Z$.

By claim 10.1.37 we may replace $X$ by a minimal element of $\mathcal{Z}$, and assume from start that $X$ is irreducible. In this case, denote by $\eta \in X$ the maximal point, and let $j_\eta : \{\eta\} \to X$ be the inclusion map; there follows a natural map of $\mathbb{Z}_X$-modules $f : \mathcal{F} \to j_\eta^* j_\eta^* \mathcal{F}$ such that $f_\eta$ is an isomorphism. Since $j_\eta^* \mathcal{F}$ is obviously qc-flabby on $\{\eta\}$, lemma 10.1.5(iii,iv) implies that $H^i(X, j_\eta^* j_\eta^* \mathcal{F}) = 0$ for every $i > 0$. We deduce an exact sequence of abelian groups

$$H^{d+1}(X, \text{Ker } f) \to H^{d+1}(X, \mathcal{F}) \to H^{d+1}(X, \text{Im } f)$$  \hspace{1cm} (10.1.40)

as well as an isomorphism of abelian groups

$$H^d(X, \text{Coker } f) \xrightarrow{\sim} H^{d+1}(X, \text{Im } f)$$

and by construction we have $d_{\text{Ker }, f}, d_{\text{Coker }, f} < d$. From the inductive assumption and claim 10.1.36, it follows that the first and third terms of (10.1.40) vanish, so the same holds for the middle one, and the proof is concluded.

Remark 10.1.41. A different proof of (a slight improvement of) theorem 10.1.35 is found in [114]. See also proposition 10.4.7(ii).

10.2. Čech cohomology. This section is a review of the standard constructions of resolutions via Čech complexes, for general topoi. We also include two classical applications to the cohomology of quasi-coherent modules on a scheme.
10.2.1. Let $T$ be a topos, and $\mathfrak{U} := (U_i \mid i \in I)$ a family of objects of $T$; pick any final object $1_T$ of $T$, and set as well (notation of example [4.7.8](iii))

\[
Y := \coprod_{i \in I} U_i \quad U := \bigcup_{i \in I} \text{Im}(U_i \to 1_T) \quad Z := \text{CU}.
\]

According to example [4.7.8](i,iii) there exist natural morphisms of topoi

\[
j_U : T/U \to T \quad \pi : T/Y \to T \quad i : Z \to T.
\]

Moreover, the functor $\pi^*: T \to T/Y$ admits a left adjoint $\pi_!: T/Y \to T$. Furthermore, let $\mathbb{Z}_T$ (resp. $\mathbb{Z}_X$, for every object $X$ of $T$) be the constant ring object of $T$ (resp. of $T/X$) associated with the ring $\mathbb{Z}$. The functor $\pi^*: \text{Z}_T\text{-Mod} \to \text{Z}_Y\text{-Mod}$ admits a left adjoint $\pi_! : \text{Z}_Y\text{-Mod} \to \text{Z}_T\text{-Mod}$.

Then, according to (7.10.3), the adjoint pair $(\pi_!, \pi^*)$ determines a cotriple $(\perp^\mathfrak{U}, \eta, \mu)$, which in turns yields a functor

\[
\text{Z}_T\text{-Mod} \to \mathcal{S}_\mathbb{Z}_T\text{-Mod} \quad \mathcal{F} \mapsto \perp^\mathfrak{U}_\mathbb{Z} \mathcal{F}.
\]

(Notation of definition [7.4.1](iv)). This construction can be described explicitly as follows. We attach to $I$ the simplicial set $I^*$ which, in every degree $n \in \mathbb{N}$ consists of the set of all mappings $[n] \to I$, where $[n] := \{0, \ldots, n\}$; i.e., this is the cartesian power $I^{n+1}$ of $I$, whose elements are all the ordered sequences $t := (t_0, \ldots, t_n)$ of elements of $I$. Every morphism $\varphi : [n] \to [m]$ in the simplicial category $\Delta$ induces a map $\varphi^* : I^{m+1} \to I^{n+1}$ by the rule:

\[
\varphi^*(t) := (t_{\varphi 0}, \ldots, t_{\varphi n}) \quad \text{for every } t \in I^{m+1}
\]

and it is clear that the rules $[n] \to I^{n+1}$ and $\varphi \mapsto \varphi^*$ yield a well defined functor $\Delta^o \to \text{Set}$. For every $t \in I^{n+1}$, we fix as well an object $U_t$ of $T$ that represents the product $U_{t_0} \times \cdots \times U_{t_n}$, and denote by $j_t : T/U_t \to T$ the induced morphism. Notice that every $\varphi : [n] \to [m]$ in $\Delta$ and every $\varphi^* : I^{m+1} \to I^{n+1}$ induces a well defined morphism in $T$:

\[
u_{\varphi(t)}^\mathfrak{U}_\mathbb{Z} : U_t \to U_{\varphi^*(t)}
\]

namely, the unique morphism whose composition with the projection on the $i$-th factor of $U_{\varphi^*(t)}$ agrees with the projection onto the $\varphi(i)$-th factor of $U_t$, for every $i = 0, \ldots, n$. Then $\nu_{\varphi(t)}^\mathfrak{U}_\mathbb{Z}$ in turns induces a morphism

\[
u_{\varphi(t)} : j_t j_t^* \mathcal{F} \to j_{\varphi^*(t)} j_{\varphi^*(t)}^* \mathcal{F}.
\]

With this notation, we have

\[
\perp^\mathfrak{U}_n \mathcal{F} := \bigoplus_{t \in I^{n+1}} j_t j_t^* \mathcal{F} \quad \text{for every } n \in \mathbb{N}
\]

and every morphism $\varphi : [n] \to [m]$ in $\Delta$ corresponds to the unique morphism of $\text{Z}_T$-modules $u_\varphi : \perp^\mathfrak{U}_m \mathcal{F} \to \perp^\mathfrak{U}_n \mathcal{F}$ that makes commute the diagram

\[
j_t j_t^* \mathcal{F} \quad \mathcal{F} \quad \mathcal{F}
\]

\[
\perp^\mathfrak{U}_m \mathcal{F} \quad \perp^\mathfrak{U}_n \mathcal{F}
\]

where the vertical arrows are the inclusion maps. Moreover, $\perp^\mathfrak{U}_1 \mathcal{F} = \mathcal{F}$, and the augmentation $\varepsilon : \perp^\mathfrak{U}_0 \mathcal{F} \to \perp^\mathfrak{U}_1 \mathcal{(U)}$ is the sum of the natural morphisms $j_i j_i^* \mathcal{F} \to \mathcal{F}$ given by the counit for the adjunction $(j_i, j_i^*)$, for every $i \in I$.
Definition 10.2.2. (i) With the notation of §10.2.1, the augmented Čech resolution associated with $\mathcal{U}$ and the $\mathbb{Z}_T$-module $\mathcal{F}$ is the unnormalized chain complex of $\mathbb{Z}_T$-modules

$$(R_\bullet(\mathcal{U}, \mathcal{F}), d_\bullet)$$

obtained from the augmented simplicial complex $\bigoplus^n_1 H_\bullet(\mathcal{U}, \mathbb{Z}_T)$ (see definition 7.4.23(i)).

(ii) To ease notation, we shall set also $R_\bullet(\mathcal{U}) := R_\bullet(\mathcal{U}, \mathbb{Z}_T)$ and $\overline{R}_\bullet(\mathcal{U}) := \tau_{\leq 0} R_\bullet(\mathcal{U})$.

Then the augmented Čech complex of $\mathcal{F}$ relative to the covering $\mathcal{U}$ of $U$ is the cochain complex

$$C^\bullet(\mathcal{U}_\bullet, \mathcal{F}) := \text{Hom}_{\mathbb{Z}_T}(R_\bullet(\mathcal{U}), \mathcal{F}[0]).$$

Hence, $R_\bullet(\mathcal{U})$ is an object of $C^{-1}(\mathbb{Z}_T\text{-Mod})$, and $C^\bullet(\mathcal{U}_\bullet, \mathcal{F})$ is an object of $C^{\geq -1}(\mathbb{Z}\text{-Mod})$.

Lemma 10.2.3. With the notation of definition §10.2.2 we have:

(i) For every $\mathbb{Z}_T$-module $\mathcal{F}$, the complex of $\mathbb{Z}_U$-modules $j_U^* R_\bullet(\mathcal{U}, \mathcal{F})$ is acyclic.

(ii) The natural projection $\mathbb{Z}_T \to i_* \mathbb{Z}_Z$ induces a quasi-isomorphism:

$$R_\bullet(\mathcal{U}) \xrightarrow{\sim} i_* \mathbb{Z}_Z[-1] \quad \text{in } C^-(\mathbb{Z}_T\text{-Mod}).$$

(iii) Suppose that $\mathcal{U}$ is a covering of $T$ (i.e. that $U = 1_T$ and $Z = \varnothing_T$). Then the differential $d_0$ of $R_\bullet(\mathcal{U})$ induces a quasi-isomorphism

$$\overline{R}_\bullet(\mathcal{U}) \xrightarrow{\sim} \mathbb{Z}_T[0] \quad \text{in } C^-(\mathbb{Z}_T\text{-Mod}).$$

Proof. (i): The natural morphism $Y \to U$ is an epimorphism, hence it is a covering in the canonical topology of $T$, and therefore it suffices to check that $\pi^* R_\bullet(\mathcal{U}, \mathcal{F})$ is acyclic. But proposition 7.10.4(ii) says that $\pi^*(\bigoplus_1^n \mathcal{F})$ is homotopically trivial. Then the assertion follows from corollary 7.4.66(ii).

Assertions (ii) and (iii) are immediate consequences of (i). \(\square\)

10.2.4. Keep the notation of §10.2.1, and choose any total ordering on $I$. We let $I_{alt}^{n+1} \subset I^{n+1}$ be the subset of all injective order-preserving mappings $[n] \to I$, for every $n \in \mathbb{N}$, and we set

$$R_{-1}^{alt}(\mathcal{U}, \mathcal{F}) := \mathcal{F} \quad R_n^{alt}(\mathcal{U}, \mathcal{F}) := \bigoplus_{t \in I_{alt}^{n+1}} j_U^{alt t} \mathcal{F} \quad \text{for every } n \in \mathbb{N}.$$
10.2.5. For every \( n \in \mathbb{N} \), denote by \( S_{n+1} \) the permutation group of \([n]\); then, for any \( t \in I_{alt}^{n+1} \), and any \( \sigma \in S_{n+1} \), the sequence \( t \circ \sigma \) is an element of \( I^{n+1} \) such that \( U_{t\circ\sigma} = U_t \), and there exists a unique isomorphism \( \mu_t : U_{t\circ\sigma} \cong U_t \) whose composition with the projection on the \( i \)-th factor of \( U_t \) agrees with the projection on the \( \sigma(i) \)-th factor of \( U_{t\circ\sigma} \), for every \( i \in [n] \). We set
\[
\text{Alt}^{(t\circ\sigma)} := \text{sign}(\sigma) \cdot v_t : j_{t\circ\sigma} \mathbb{Z} \rightarrow j_t \mathbb{Z}
\]
where \( v_t \) is the isomorphism induced by \( \mu_t \), and where \( \text{sign}(\sigma) \) denotes the signature of \( \sigma \). Then, for every \( n \in \mathbb{N} \) there exists a unique morphism of \( \mathbb{Z}_T \)-modules
\[
\text{Alt}_n : R_n(\Omega) \rightarrow R_n^{alt}(\Omega)
\]
whose kernel contains the direct summands \( j_t \mathbb{Z} \) such that the mapping \( t : [n] \rightarrow I \) is not injective, and that makes commute the diagram
\[
\begin{array}{ccc}
j_{t\circ\sigma} : U_{t\circ\sigma} & \xrightarrow{\text{Alt}^{(t\circ\sigma)}} & j_t \mathbb{Z} \\
\downarrow d_{t\circ\sigma} & & \downarrow d_t \\
R_{n-1}(\Omega) & \xrightarrow{\text{Alt}_{n-1}} & R_{n-1}(\Omega')
\end{array}
\]
for every \( t \in I_{alt}^{n+1} \)

(where the vertical arrows are the inclusion maps).

**Proposition 10.2.6.** In the situation of \( \text{(10.2.5)} \), denote by \( \text{Alt}_n : R_n^{alt}(\Omega) \rightarrow R_n(\Omega) \) the inclusion map, and suppose that \( U_t \) is a subobject of \( 1_T \), for every \( i \in I \). Then the following holds :

(i) The system \( (\text{Alt}_{n-1} : n \in \mathbb{N}) \) defines an epimorphism of chain complexes
\[
\text{Alt}_n : R_n(\Omega) \rightarrow R_n^{alt}(\Omega)
\]
whose kernel is independent of the choice of ordering on \( I \).

(ii) \( \text{Alt}_n \circ \text{Alt}_n^{(1)} = 1_R^{alt}(\Omega) \), and \( \text{Alt}_n \circ \text{Alt}_n^{(1)} \) is homotopically equivalent to \( 1_R(\Omega) \).

(iii) Especially, \( \text{Alt}_n \) and \( \text{Alt}_n^{(1)} \) are mutually inverse isomorphisms in \( \mathcal{D}(\mathbb{Z}_T, \text{Mod}) \).

(iv) The natural projection \( \mathbb{Z}_T \rightarrow i_* \mathbb{Z}[-1] \) induces a quasi-isomorphism:
\[
R_n^{alt}(\Omega) \rightarrow i_* \mathbb{Z}[-1] \quad \text{in} \quad \mathcal{C}^-(\mathbb{Z}_T, \text{Mod}).
\]

(v) Suppose that \( \Omega \) is a covering of \( T \) (i.e. that \( U = 1_T \) and \( Z = \emptyset_T \)). Then the differential \( d_0 \) of \( R_n^{alt}(\Omega) \) induces a quasi-isomorphism
\[
\tilde{R}_n^{alt}(\Omega) \rightarrow \mathbb{Z}_T[0] \quad \text{in} \quad \mathcal{C}^-(\mathbb{Z}_T, \text{Mod}).
\]

**Proof.** (i): Fix an integer \( n > 0 \), a sequence \( s \in I^{n+1} \), and let \( c \leq n + 1 \) be the cardinality of \( \{s_0, \ldots, s_n\} \). It suffices to check that the compositions \( d_n \circ \text{Alt}_n^{(1)} \) and \( \text{Alt}_n^{(1)} \circ d_n \) agree on \( j_t \mathbb{Z} \). In case \( c < n \), it is easily seen that both these compositions vanish on such direct summand. In case \( c = 1 \) and \( n = 0 \), the assertion follows by a direct inspection. In case \( c = n + 1 > 1 \), we may find a unique permutation \( \sigma \in S_{n+1} \) and a unique \( t \in I_{alt}^{n+1} \) such that \( s = t \circ \sigma \), and we have to show that we have a commutative diagram
\[
\begin{array}{ccc}
j_t(\sigma) : U_t \mathbb{Z} & \xrightarrow{\text{Alt}^{(t \circ \sigma)}} & j_t \mathbb{Z} \\
\downarrow d_t & & \downarrow d_t \\
R_{n-1}(\Omega) & \xrightarrow{\text{Alt}_{n-1}^{(1)}} & R_{n-1}(\Omega')
\end{array}
\]
where \( d_t \) and \( d_{t \circ \sigma} \) denote the restrictions of the differentials of \( R_n^{alt}(\Omega) \) and respectively \( R_n(\Omega) \).

To this aim, for every \( i = 0, \ldots, n \) denote by \( \beta_1^{(i)} \) the unique permutation of \([n]\) such that
\[
\beta_1^{(i)}(\sigma(i)) = \sigma(i) \quad \text{and} \quad \beta_1^{(j)}(\sigma(j)) < \beta_1^{(i)}(\sigma(k)) \quad \text{for every} \quad j, k \in [n] \setminus \{i\} \quad \text{with} \quad j < k.
\]

Also, we define a third permutation as follows :
• If \( \sigma(i) < i \), let \( \beta_{2}^{(i)} \) be the cycle \( (i, i - 1, \ldots, \sigma(i)) \) of length \( i - \beta(i) + 1 \)
• If \( \sigma(i) > i \), let \( \beta_{2}^{(i)} \) be the cycle \( (i, i + 1, \ldots, \sigma(i)) \) of length \( \sigma(i) - i + 1 \)
• If \( \sigma(i) = i \), let \( \beta_{2}^{(i)} \) be the identity map of \([n] \).

It is easily seen that in either cases

\[
\sigma^{-1} = \beta_{2}^{(i)} \circ \beta_{1}^{(i)} \quad \text{and} \quad \text{sign}(\beta_{2}^{(i)}) = (-1)^{i - \sigma(i)} \quad \text{for every } i = 0, \ldots, n.
\]

Now, for every \( i = 0, \ldots, n \) let \( \varepsilon_{i} : [n - 1] \rightarrow [n] \) be the \( i \)-th face map (see (7.4.6)); we compute:

\[
\text{Alt_{n-1}^U} \circ d_{\alt^\sigma} \circ \text{Alt_{n-1}^U} = \text{Alt_{n-1}^U} \circ \left( \sum_{i=0}^{n} (-1)^{i} \cdot u_{\varepsilon_{i}^{(\alt^\sigma)}} \right)
\]

\[
= \sum_{i=0}^{n} (-1)^{i} \cdot \text{sign}(\beta_{1}^{(i)}) \cdot u_{\varepsilon_{i}^{(\alt^\sigma)}}
= \sum_{i=0}^{n} (-1)^{\sigma(i)} \cdot \text{sign}(\sigma) \cdot u_{\varepsilon_{i}^{(\alt^\sigma)}}
= \sum_{i=0}^{n} (-1)^{i} \cdot \text{sign}(\sigma) \cdot u_{\varepsilon_{i}^{(\alt^\sigma)}}
= \text{sign}(\sigma) \cdot d_{\alt}
\]

as required. Lastly, if \( c = n \), the morphism \( d_{c} \circ \text{Alt}^{(\alt^\sigma)} \) vanishes, and it remains to check that \( \text{Alt}_{n-1}^U \circ d_{\alt} = 0 \) as well. However, in this situation there exist exactly two distinct indices \( i, j \in [n] \) such that \( s_{i} = s_{j} \), and it follows already that \( \text{Alt}_{n-1}^U \circ u_{\varepsilon_{k}^{(\alt^\sigma)}} = 0 \) for every \( k \neq i, j \). Moreover, clearly there exists a unique \( \underline{t} \in T_{\alt}^{n} \) such that \( \{t_{0}, \ldots, t_{n-1}\} = \{s_{0}, \ldots, s_{n}\} \), and notice that the diagram:

\[
\begin{array}{ccc}
U_{\underline{t}} & \xrightarrow{\nu_{\varepsilon_{i}^{(\alt^\sigma)}}^{(\underline{t})}} & U_{\varepsilon_{i}^{(\alt^\sigma)}} \\
\nu_{\varepsilon_{j}^{(\underline{t})}} & & \mu_{\varepsilon_{i}^{(\underline{t})}} \\
U_{\varepsilon_{i}^{(\underline{t})}} & \xrightarrow{\mu_{\varepsilon_{i}^{(\underline{t})}}} & U_{\underline{t}}
\end{array}
\]

commutes (this is the only place where we use our assumption on the objects \( U_{\chi} \)). There follows a commutative diagram

\[
\begin{array}{ccc}
\text{\underline{Z}U_{\underline{t}}} & \xrightarrow{u_{\varepsilon_{i}^{(\underline{Z})}}^{(\underline{t})}} & \text{\underline{Z}U_{\varepsilon_{i}^{(\underline{Z})}}} \\
\nu_{\varepsilon_{j}^{(\underline{Z})}} & & \nu_{\varepsilon_{i}^{(\underline{Z})}} \\
\text{\underline{Z}U_{\varepsilon_{i}^{(\underline{Z})}}} & \xrightarrow{\nu_{\varepsilon_{i}^{(\underline{Z})}}} & \text{\underline{Z}U_{\underline{t}}}
\end{array}
\]

Now, let \( \beta_{i} \) (resp. \( \beta_{j} \)) be the unique permutation of \([n]\) that fixes \( i \) (resp. \( j \)) and such that \( \underline{s} \circ \beta_{i} \) (resp. \( \underline{s} \circ \beta_{j} \)) restricts to an order-preserving map on \([n] \setminus \{i\}\) (resp. on \([n] \setminus \{j\}\)). Arguing as in the foregoing, we see that \( \beta_{i} = \gamma \circ \beta_{j} \) for a cyclic permutation \( \gamma \) of length \( |j - i| \), so that

\[
\rho := (-1)^{i} \cdot \text{sign}(\beta_{i}) = (-1)^{j+1} \cdot \text{sign}(\beta_{j}).
\]
Denote by $1_{U}$ the identity automorphism of $j_{U!}Z_{U_{1}}$. Summing up, we get
\[
\text{Alt}_{n-1}^{\mu} \circ d_{2} = (-1)^{i} \cdot \text{Alt}_{n-1}^{\mu} \circ u_{2}(s) + (-1)^{j} \cdot \text{Alt}_{n-1}^{\mu} \circ u_{2}(s)
\]
\[
= (-1)^{i} \cdot \text{sign}(\beta_{i}) \cdot v_{\epsilon_{i}^{*}}(s) \circ u_{2}(s) + (-1)^{j} \cdot \text{sign}(\beta_{j}) \cdot v_{\epsilon_{j}^{*}}(s) \circ u_{2}(s)
\]
\[
= \rho \cdot (v_{\epsilon_{i}^{*}}(s) \circ u_{2}(s) - v_{\epsilon_{j}^{*}}(s) \circ u_{2}(s))
\]
\[
= 0
\]
and the proof of (i) is concluded.

(ii): Let $V$ be a universe such that $T$ is $V$-small, and set $T'' := T_{V}$; also, let $J$ be the canonical topology on $T$. Then $T'$ is a $V$-topos, and the Yoneda imbedding $h : T \to T'$ factors through an equivalence $T \sim (T, J)_{U}$ and the inclusion functor $(T, J)_{U} \to T'$. Set $U_{i}^{J} := h_{U_{i}} \in \text{Ob}(T')$ for every $i \in I$, $U' := \bigcup_{i \in I} \text{Im}(U_{i}^{J} \to 1_{T'})$, and $\mathcal{U} := (U'_{i} \mid i \in I)$. Hence $U'$ is a presheaf on $T$ whose associated sheaf is isomorphic to $h_{U}$. Let $j_{UV} : T'/U' \to T'$ be the induced morphism of topos; according to lemma [10.2.3], the chain complex $j_{UV}^{*}R_{*}(\mathcal{U})$ is acyclic, hence the same holds for $j_{UV}^{*}R_{*}^{alt}(\mathcal{U})$, and there follows a commutative diagram of complexes of $Z_{T}$-modules:
\[
\begin{array}{ccc}
\overline{R}_{*}(\mathcal{U}) & \longrightarrow & j_{UV}^{*}Z_{U_{1}}[0] \\
\tau_{\leq 0}(\iota_{\mathcal{U}}^{*} \circ \text{Alt}_{\mathcal{U}}^{*}) & & \downarrow \\
\overline{R}_{*}(\mathcal{U}) & \longrightarrow & j_{UV}^{*}Z_{U_{1}}[0]
\end{array}
\]
whose horizontal arrows are induced by the differential $d_{0}$ of $R_{*}(\mathcal{U})$, and therefore are isomorphisms in the category $\text{D}(Z_{T}, \text{Mod})$, so that
\[
\tau_{\leq 0}(\iota_{\mathcal{U}}^{*} \circ \text{Alt}_{\mathcal{U}}^{*}) = 1_{\pi_{*}(\mathcal{U})} \quad \text{in} \quad \text{D}(Z_{T}, \text{Mod}).
\]
However, from the explicit description of (10.2.1) it is easily seen that $\overline{R}_{*}(\mathcal{U})$ is a complex of projective $Z_{T}$-modules, hence we have as well $\tau_{\leq 0}(\iota_{\mathcal{U}}^{*} \circ \text{Alt}_{\mathcal{U}}^{*}) = 1_{\pi_{*}(\mathcal{U})}$ in $\text{Hot}(Z_{T}, \text{Mod})$, by theorem [7.3.23](iii), and then it follows as well that $\iota_{\mathcal{U}}^{*} \circ \text{Alt}_{\mathcal{U}}^{*} = 1_{R_{*}^{alt}(\mathcal{U})}$ in $\text{Hot}(Z_{T}, \text{Mod})$.
Next, notice that $R_{*}(\mathcal{U})$ is a complex of abelian presheaves on $T$, whose associated complex of sheaves agrees with $R_{*}(\mathcal{U})$, and likewise the morphism of abelian sheaves associated with $\iota_{\mathcal{U}}^{*} \circ \text{Alt}_{\mathcal{U}}^{*}$ agrees with $\iota_{\mathcal{U}}^{*} \circ \text{Alt}_{\mathcal{U}}^{*}$. The assertion follows.

(iii) follows directly from (ii). Likewise, (iv) and (v) are immediate from (iii) and lemma [10.2.3](ii,iii).

Remark 10.2.7. (i) In light of proposition [10.2.6](iv) we shall call $R_{*}^{alt}(\mathcal{U})$ the alternating augmented Čech resolution associated with $\mathcal{U}$. This name can be justified as follows. Notice that for every $Z_{T}$-module $\mathcal{F}$ we have natural identifications
\[
(10.2.8) \quad C^{n}(\mathcal{U}, \mathcal{F}) \xrightarrow{\sim} \prod_{i \in I^{n+1}} \mathcal{F}(U_{i}) \quad C_{alt}^{n}(\mathcal{U}, \mathcal{F}) \xrightarrow{\sim} \prod_{i \in I_{alt}^{n+1}} \mathcal{F}(U_{i})
\]
for every $n \in \mathbb{N}$ (notation of definition [10.2.2](ii)). Under these identifications, $C^{*}(\mathcal{U}, \mathcal{F})$ becomes the cochain complex
\[
(10.2.9) \quad 0 \to \Gamma(\mathcal{F}) \to \prod_{i \in I} \mathcal{F}(U_{i}) \to \cdots \to \prod_{i \in I^{n+1}} \mathcal{F}(U_{i}) \to \cdots
\]
whose differential $d^{n}$ is given by the following rule. First, $d^{-1}$ assigns to each global section $s \in \Gamma(\mathcal{F})$ the system of its restrictions $(s_{|U_{i}} \mid t \in I)$. In case $n \geq 0$, we have
\[
d^{n}(s_{\bullet})_{U_{\beta}} := \sum_{k=0}^{n+1} (-1)^{k+n+1} \cdot (s_{\beta \epsilon_{k}})_{U_{\beta}} \quad \text{for every} \quad t \in I^{n+2} \text{and every} \quad s_{\bullet} \in C^{n}(\mathcal{U}, \mathcal{F}).
\]
(ii) Likewise, under the natural identifications of (i), the alternating augmented Čech complex $C^\bullet_{\text{alt}}(\mathcal{U}, \mathcal{F})$ becomes the cochain complex
\[
0 \to \Gamma(\mathcal{F}) \to \prod_{t \in I} \mathcal{F}(U_t) \to \cdots \to \prod_{t \in I_{\text{alt}}^{n+1}} \mathcal{F}(U_t) \to \cdots
\]
whose differentials are given by the same expressions as in (i).

(iii) Under the identification of (i), the morphisms $R_n(\mathcal{U}) \to \mathcal{F}$ that factor through $\text{Alt}_n^\mathcal{U}$ correspond to the system of sections $f_\ast := (f_t : [n] \to I)$ with the following properties:

- $f_t = 0$ whenever the map $t : [n] \to I$ is not injective.
- $f_{t \circ \sigma} = \text{sign}(\sigma) \cdot f_t$ for every injective map $t : [n] \to I$ and every $\sigma \in S_{n+1}$.

Thus, under the identification (10.2.8), the submodule $\text{Hom}_{\mathcal{F}}(R^\bullet_{\text{alt}}(\mathcal{U}), \mathcal{F})$ corresponds to the subgroup of all alternating systems $f_\ast$ of sections of $\mathcal{F}$.

10.2.10. In the situation of (10.2.1), consider another family $\mathcal{U}' := (U'_t \mid t \in I')$ of objects of $\mathcal{T}$, indexed by a totally ordered set $I'$, and set $U' := \bigsqcup_{t \in I'} \text{Im}(U'_t \to 1_\mathcal{T})$ and $Z' := \text{CU}'$. Also, for every $n \in \mathbb{N}$, and every $\underline{z} \in I_{n+1}$ set as usual $U'_{\underline{z}} := U'_{t_0} \times \cdots \times U'_{t_n}$, and denote by $j'_\underline{z} : T/U'_{\underline{z}} \to T$ the induced functor. Suppose that $\mathcal{U}$ is a refinement of $\mathcal{U}'$, i.e. there exists a mapping (that does not necessarily respect the orderings)
\[
\tau : I \to I'
\]
and pick a morphism $\vartheta_i : U_i \to U'_{\tau(i)}$ for every $i \in I$. Then, for every $n \in \mathbb{N}$ and every $\underline{t} := (t_0, \ldots, t_n) \in I_{n+1}$, we set $\tau(\underline{t}) := (\tau(t_0), \ldots, \tau(t_n)) \in I_{n+1}$, and notice that the morphism $\vartheta_{\underline{t}} := \vartheta_{t_0} \times \cdots \times \vartheta_{t_n} : U_\underline{t} \to U'_{\tau(\underline{t})}$ induces a morphism of $\mathbb{Z}_T$-modules
\[
\varphi_{\underline{t}} : j_U \mathbb{Z} U_\underline{t} \to j'_{\tau(\underline{t})} \mathbb{Z} U'_{\tau(\underline{t})}.
\]
For every $n \in \mathbb{N}$, denote by $\varphi_n : R_n(\mathcal{U}) \to R_n(\mathcal{U}')$ the unique morphism of $\mathbb{Z}_T$-modules that makes commute the diagram
\[
\begin{array}{ccc}
j_U \mathbb{Z} U_\underline{t} & \xrightarrow{\varphi_{\underline{t}}} & j'_{\tau(\underline{t})} \mathbb{Z} U'_{\tau(\underline{t})} \\
\downarrow & & \downarrow \\
R_n(\mathcal{U}) & \xrightarrow{\varphi_n} & R_n(\mathcal{U}')
\end{array}
\]
whose vertical arrows are the inclusion maps. Let as well $\varphi_{-1} := 1_{\mathbb{Z}_T}$. With this notation, it is clear that the system $(\varphi_n \mid n \in \mathbb{N})$ is a morphism of augmented simplicial complexes $R_\bullet(\mathcal{U}) \to R_\bullet(\mathcal{U}')$, and we denote
\[
\varphi_\bullet : R_\bullet(\mathcal{U}) \to R_\bullet(\mathcal{U}')
\]
the associated morphism of chain complexes.

10.2.11. Suppose next that $U'_t$ is a subobject of $1_\mathcal{T}$, for every $i' \in I'$; then, on account of proposition [10.2.6(ii)] we may define
\[
\varphi_\bullet^{\text{alt}} := \text{Alt}_n^{\mathcal{U}'} \circ \varphi_\bullet \circ i_{\mathcal{U}}^{\mathcal{U}'} : R^\bullet_{\text{alt}}(\mathcal{U}) \to R^\bullet_{\text{alt}}(\mathcal{U}')
\]
The terms $\varphi_n^{\text{alt}}$ can be described explicitly: first, it is clear that $\varphi_{-1}^{\text{alt}} := 1_{\mathbb{Z}_T}$. Next, if $n \in \mathbb{N}$ and $\underline{t} \in I_{\text{alt}}^{n+1}$ is any sequence, let
\[
\varphi_\underline{t}^{\text{alt}} : j_U \mathbb{Z} U_\underline{t} \to R_n^{\text{alt}}(\mathcal{U}')
\]
be the map given by the following rule. If $\tau(\underline{t})$ is also an injective sequence $[n] \to I'$, let $\sigma \in S_{n+1}$ be the unique permutation such that $\tau(\underline{t}) \circ \sigma \in I_{\text{alt}}^{n+1}$, and set $\varphi_\underline{t}^{\text{alt}} := \text{sign}(\sigma) \cdot \varphi(\underline{t}) : j_U \mathbb{Z} U_\underline{t} \to \mathbb{Z} U'_{\tau(\underline{t}) \circ \sigma} \subset R_n^{\text{alt}}(\mathcal{U}')$. In case $\tau(\underline{t})$ is not injective, we let $\varphi_\underline{t}^{\text{alt}}$ be the zero morphism.
Then \( \varphi^\text{alt} \) is the sum of the \( \varphi^\text{alt}_i \), for \( i \) ranging over all elements of \( I_i \). In case also \( U_i \) is a subobject of \( 1_T \) for every \( i \in I \), it is easily seen that we get a commutative diagram

\[
\begin{array}{ccc}
R_\bullet(\Omega) & \xrightarrow{\text{Alt}_U} & R^\text{alt}_\bullet(\Omega) \\
\varphi \downarrow & & \varphi^\text{alt} \downarrow \\
R_\bullet(\Omega') & \xrightarrow{\text{Alt}'_U} & R^\text{alt}_\bullet(\Omega').
\end{array}
\]

**Lemma 10.2.12.** In the situation of (10.2.10), suppose that \( \tau' : I \to I' \) is another mapping with \( \text{Hom}_T(U_i, U'_\tau(i)) \neq \emptyset \) for every \( i \in I \). Pick a system of morphisms \( (\vartheta'_i : U_i \to U'_{\tau'(i)} \mid i \in I) \), and denote by \( \varphi' : R_\bullet(\Omega) \to R_\bullet(\Omega') \) the associated morphisms of chain complexes. We have:

(i) There exists a homotopy from \( \varphi' \) to \( \varphi \).
(ii) If \( U'_i \) is a subobject of \( 1_T \) for every \( i' \in I' \), there is also a homotopy from \( \varphi^\text{alt} \) to \( \varphi'^\text{alt} \).

**Proof.** Clearly it suffices to show (i). To this aim, for every \( i \in I \) let \( \vartheta_i, \vartheta'_i : U_i \to U'_\tau(i) \times U'_{\tau'(i)} \) be the unique morphism whose composition with the projection on the first (resp. second) factor equals \( \vartheta_i \) (resp. \( \vartheta'_i \)), and for every \( n \in \mathbb{N} \), every \( k = 0, \ldots, n \), and every \( t \in I^{n+1} \), set

\[
\tau(k, t) := (\tau(t_0), \ldots, \tau(t_k), \tau'(t_k), \ldots, \tau'(t_n)) \in I^{n+2}
\]

\[
\vartheta^{(k)}_t := \vartheta_{t_0} \times \cdots \times \vartheta_{t_{k-1}} \times (\vartheta_{t_k}, \vartheta'_{t_k}) \times \vartheta'_{t_{k+1}} \times \cdots \times \vartheta'_{t_n} : U_L \to U'_{\tau(k, t)}.
\]

Then \( \vartheta^{(k)}_t \) induces a natural morphism \( h^{(k)}_L : j_! \mathbb{Z}_{U_L} \to j_\tau(k, t) \mathbb{Z}_{U'_{\tau'(k, t)}} \), and we set

\[
h_L := \sum_{k=0}^n (-1)^k \cdot h^{(k)}_L : j_! \mathbb{Z}_{U_L} \to R_{n+1}(\Omega').
\]

Clearly there exists a unique morphism of \( \mathbb{Z}_T \)-modules \( h_n : R_n(\Omega) \to R_{n+1}(\Omega') \) whose restriction to \( j_! \mathbb{Z}_{U_L} \) agrees with \( h_L \) for every \( t \in I^{n+1} \). Let also \( h_{-1} : R_{-1}(\Omega) \to R_0(\Omega') \) be the zero morphism; a direct calculation shows that the system \( (h_{n-1} \mid n \in \mathbb{N}) \) yields the sought homotopy: the details shall be left to the reader. \( \square \)

**Remark 10.2.13.** (i) In the situation of (10.2.11), consider the case where \( U_{i_0} = 1_T \) for some \( i_0 \in I \). Then \( \Omega \) can be refined by itself in two different ways: we may take for \( \tau : I \to I \) the identity map (with \( \vartheta_i := 1_{U_i} \) for every \( i \in I \)), and we have also the map \( \tau' : I \to I \) such that \( \tau'(i) = i_0 \) for every \( i \in I \) (and then there is a unique choice of \( \vartheta_i \)). Obviously, the morphism \( \varphi : R^\text{alt}_\bullet(\Omega) \to R^\text{alt}_\bullet(\Omega) \) associated with \( \tau \) is the identity map. For the morphism \( \varphi' : R^\text{alt}_\bullet(\Omega) \to R^\text{alt}_\bullet(\Omega) \) associated with \( \tau' \) it is easily seen that

\[
\varphi'_{-1} = 1_{\mathbb{Z}_T} \text{ and } \varphi'_n = 0 \text{ for every } n > 0
\]

and \( \varphi'_0 \) is the sum of the natural morphisms \( j_0 ! \mathbb{Z}_{U_i} \to j_{0, i} ! \mathbb{Z}_{U_{i_0}} = \mathbb{Z}_T \). The homotopy \( h_\bullet \) from \( \varphi \) to \( \varphi' \) furnished by lemma 10.2.12 can be described as follows. First, we may suppose that \( i_0 \) is the maximal element of \( I \). A simple inspection shows that \( h_{-1} : R^\text{alt}_{-1}(\Omega) \to R^\text{alt}_0(\Omega) \) is the zero map. Next, for every \( n \in \mathbb{N} \) and every \( t \in I^{n+1} \), notice that \( U_L = U_{(t, i_0)} \), where \( (t, i_0) \) denotes the sequence \( (t_0, \ldots, t_n, i_0) \); it follows that we may write

\[
h_n = \sum_{t \in I^{n+1}} \rho(t) \cdot h_L
\]

where \( h_L : j_! \mathbb{Z}_{U_L} \to j_{(t, i_0)} ! \mathbb{Z}_{U_{(t, i_0)}} \) is the identity map, and \( \rho(t) \) equals 0 if \( t_n = i_0 \), and equals 1 otherwise.
(ii) In the situation of (i), we deduce a homotopy from $1_{R^\ast_{\bullet}(\mathcal{U})}$ to the zero map. Indeed, let $h'_{n-1}: \mathcal{T}_n \to R_0(\mathcal{U})$ be the composition of the identity map $\mathbb{Z}_n \to j_{i_0}!\mathcal{U}_{i_0}$ and the inclusion map $j_{i_0}!\mathcal{U}_{i_0} \to R_0(\mathcal{U})$. Let also $h'_n := h_n$ for every $n \in \mathbb{N}$. A simple inspection shows that

$$\varphi'_n = h'_{n-1} \circ d_0$$

(where $d_0 : R_0(\mathcal{U}) \to \mathbb{Z}_n$ is the differential of $R(\mathcal{U})$). It follows easily that $(h'_{n-1} \mid n \in \mathbb{N})$ is the sought homotopy.

(iii) Let $\mathcal{F}$ be any $\mathbb{Z}_n$-module. The homotopy $h'_{\ast}$ of (i) induces a homotopy from the identity automorphism of the augmented Čech complex $C_{\cdot}(\mathcal{U}, \mathcal{F})$ to its zero endomorphism. Under the natural identifications of remark 10.2.7(ii), this homotopy $h'_{\ast}$ can be described as follows.

- $h^0 : C^0(\mathcal{U}, \mathcal{F}) \to \Gamma(\mathcal{F})$ is the projection onto the factor $\mathcal{F}(U_{i_0}) = \Gamma(\mathcal{F})$.
- For every $n \geq 0$, the map $h^{n+1} : C^{n+1}(\mathcal{U}, \mathcal{F}) \to C^n(\mathcal{U}, \mathcal{F})$ is the projection that sends to zero every factor $\mathcal{F}(U_{t_1, \ldots, t_n})$ with $t_k < i_0$, and whose restriction to every factor $\mathcal{F}(U_{i_0, \ldots, t_n})$ is the identity map $\mathcal{F}(U_{i_0, \ldots, t_n}) \to \mathcal{F}(U_{i_0, \ldots, t_{n-1}})$.

**Remark 10.2.14.** (i) In the situation of (10.2.4), it is clear that the rule $\mathcal{F} \mapsto R^\ast_{\bullet}(\mathcal{U}, \mathcal{F})$ defines a functor from $\mathbb{Z}_n$-modules to chain complexes of $\mathbb{Z}_n$-modules. The latter then extends naturally to a functor from the category of chain complexes of $\mathbb{Z}_n$-modules to the category of double complexes of $\mathbb{Z}_n$-modules:

$$C(\mathbb{Z}_n\text{-Mod}) \to C_2(\mathbb{Z}_n\text{-Mod}) \quad \mathcal{F} \mapsto R^\ast_{\bullet}(\mathcal{U}, \mathcal{F}).$$

Likewise, $\perp_{\bullet}$ extends to a functor from augmented simplicial $\mathbb{Z}_n$-modules to augmented bisimplicial $\mathbb{Z}_n$-modules:

$$\hat{s}(\mathbb{Z}_n\text{-Mod}) \to \hat{s}(\hat{s}(\mathbb{Z}_n\text{-Mod})) \quad \mathcal{F} \mapsto \perp_{\bullet} \mathcal{F}.$$

(ii) Let now $\mathcal{U}' := (U'_i \mid i' \in I')$ be another family of objects of $\mathcal{T}$. Then we may consider the augmented bisimplicial $\mathbb{Z}_n$-module

$$\perp_{\bullet} : = \perp_{\bullet}(\hat{s}(\mathbb{Z}_n))$$

and we notice that

$$(\perp_{\bullet})^\Delta = \perp_{\bullet} \times \perp_{\bullet}$$

where $\perp_{\bullet}(\hat{I}) := (U_i \times U'_i \mid (i, i') \in \hat{I} \times \hat{I}')$.

In case both $U_i$ and $U'_i$ are subobjects of $1_T$ for every $i \in I$ and $i' \in I'$, we may also define the chain double complex

$$R^\ast_{\bullet}(\mathcal{U}, \mathcal{U}') := R^\ast_{\bullet}(\mathcal{U}', (R^\ast_{\bullet}(\mathcal{U}))$$

and we notice that (notation of example 7.1.16(i))

$$R^\ast_{\bullet}(\mathcal{U}, \mathcal{U}') = R^\ast_{\bullet}(\mathcal{T}) \boxtimes \mathcal{R}^\ast_{\bullet}(\mathcal{U}).$$

**10.2.15.** In the situation of (10.2.1), let $\mathcal{A}$ be any $T$-ring; we consider the functor

$$\mathcal{A}\text{-Mod} \to C(\Gamma(\mathcal{A})\text{-Mod}) \quad \mathcal{F} \mapsto \mathcal{C}(\mathcal{U}, \mathcal{F}) := \text{Hom}_\mathcal{A}(\mathcal{R}_{\bullet}(\mathcal{U}), \mathcal{F}[0])$$

that assigns to every $\mathcal{A}$-module $\mathcal{F}$ its Čech complex, and we define as well the Čech cohomology functor of $\mathcal{F}$ relative to the covering $\mathcal{U}$, by setting:

$$H^i(\mathcal{U}, \mathcal{F}) := H^i\mathcal{C}(\mathcal{U}, \mathcal{F})$$

for every $i \in \mathbb{N}$.

Suppose now that $\mathcal{U}$ is a covering of $T$; since $\mathcal{F}$ represents a sheaf for the canonical topology on $T$, we easily see that the system of restriction maps $(\Gamma(\mathcal{F}) \to \mathcal{F}(U_i) \mid i \in I)$ induces a natural isomorphism

(10.2.16)

$$\Gamma(\mathcal{F}) \sim H^0(\mathcal{U}, \mathcal{F}).$$
On the other hand, let $K^\bullet$ be any bounded below complex of $\mathcal{A}$-modules; lemma 10.2.3(iii) yields natural isomorphisms in $D^+(\mathcal{A}\text{-Mod})$ and in $D^+(\Gamma(\mathcal{A})\text{-Mod})$

\[ R\mathcal{H}om^\bullet_\mathcal{A}(\mathcal{R}_\bullet(\mathcal{U}), K^\bullet) \cong R\Gamma K^\bullet \quad \text{and} \quad R\mathcal{H}om^\bullet_\mathcal{A}(\mathcal{R}_\bullet(\mathcal{U}), K^\bullet) \cong R\Gamma K^\bullet. \]

Hence, after fixing an injective resolution $K^\bullet \xrightarrow{\sim} \mathcal{I}^\bullet$ we get a natural isomorphism

\[ R\Gamma K^\bullet \cong \text{Tot} C^\bullet(\mathcal{U}, \mathcal{I}^\bullet) \quad \text{in } D^+(\Gamma(\mathcal{A})\text{-Mod}). \]

Thus, for every $p \in \mathbb{Z}$ let also define a presheaf $\mathcal{H}^p(K^\bullet)$ on $T$ by the rule

\[ \mathcal{H}^p(K^\bullet)(U) := R^p\Gamma(U, K^\bullet) \quad \text{for every object } U \text{ of } T. \]

We may regard $\mathcal{H}^p(K^\bullet)$ as an object of the $V$-topos $T^\wedge_V$, for some universe $V$ such that $T$ is $V$-small, and the family $\mathcal{I}^\bullet$ can be regarded as a system of objects of $T^\wedge_V$, via the Yoneda imbedding $T \to T^\wedge_V$. Then, the Čech cohomology functors of $\mathcal{H}^p(K^\bullet)$ relative to the covering $\mathcal{U}$ are also well defined, and we deduce a 2-spectral sequence

\[ E^1_{pq} := H^p(\mathcal{U}, \mathcal{H}^q(K^\bullet)) \Rightarrow R^{p+q}\Gamma K^\bullet. \]

Notice also that

\[ \mathcal{H}^0(\mathcal{F}[0]) = \mathcal{F} \quad \text{for every } \mathbb{Z}_T\text{-module } \mathcal{F}. \]

whence, natural maps

\[ \Psi^p(\mathcal{U}, \mathcal{F}) : H^p(\mathcal{U}, \mathcal{F}) \to R^p\Gamma \mathcal{F} \quad \text{for every } p \in \mathbb{N} \]

such that $\Psi^0(\mathcal{U}, \mathcal{F})$ is always an isomorphism (in fact, it is the inverse of the isomorphism 10.2.16), and $\Psi^1(\mathcal{U}, \mathcal{F})$ is always an injective map.

10.2.18. In case $U_i$ is a subobject of $1_T$ for every $i \in I$, we may repeat the considerations of 10.2.15 with the alternating Čech complex

\[ C^\bullet(\mathcal{U}, \mathcal{F}) := \text{Hom}_{\mathcal{Z}}(\mathcal{R}_\bullet^{alt}(\mathcal{U}), \mathcal{F}[0]). \]

Namely, let us set

\[ H^i_{\text{alt}}(\mathcal{U}, \mathcal{F}) := H^i C^\bullet(\mathcal{U}, \mathcal{F}) \quad \text{for every } i \in \mathbb{N}. \]

Then, proposition 10.2.6(ii) (together with example 7.1.25(ii)) yields a natural isomorphism

\[ H^i_{\text{alt}}(\mathcal{U}, \mathcal{F}) \cong H^i(\mathcal{U}, \mathcal{F}) \quad \text{for every } i \in \mathbb{N} \]

and if $\mathcal{U}$ is a covering of $T$, obviously we get therefore a natural isomorphism

\[ R\Gamma K^\bullet \cong \text{Tot} C^\bullet_{\text{alt}}(\mathcal{U}, \mathcal{I}^\bullet) \quad \text{in } D^+(\Gamma(\mathcal{A})\text{-Mod}). \]

for any injective resolution $K^\bullet \xrightarrow{\sim} \mathcal{I}^\bullet$, and a 2-spectral sequence

\[ E^1_{pq} := H^p_{\text{alt}}(\mathcal{U}, \mathcal{H}^q(K^\bullet)) \Rightarrow R^{p+q}\Gamma K^\bullet. \]

Taking $K^\bullet := \mathcal{F}[0]$, there follows a natural map

\[ \Psi^p_{\text{alt}}(\mathcal{U}, \mathcal{F}) : H^p_{\text{alt}}(\mathcal{U}, \mathcal{F}) \to R^p\Gamma \mathcal{F} \quad \text{for every } p \in \mathbb{N} \]

and again, $\Psi^0_{\text{alt}}(\mathcal{U}, \mathcal{F})$ is an isomorphism, whereas $\Psi^1_{\text{alt}}(\mathcal{U}, \mathcal{F})$ is always an injective map. The following immediate corollary is often useful:

**Corollary 10.2.21.** In the situation of 10.2.15, suppose furthermore that

\[ \mathcal{H}^q(\mathcal{F}[0])(U_1) = 0 \quad \text{for every integer } q > 0 \text{ and every } t \in T^q. \]

Then we have:

(i) The map $\Psi^p(\mathcal{U}, \mathcal{F})$ is an isomorphism for every $p \in \mathbb{N}$.

(ii) If $U_i$ is a subobject of $1_T$ for every $i \in \mathbb{N}$, then the map $\Psi^p_{\text{alt}}(\mathcal{U}, \mathcal{F})$ is an isomorphism for every $p \in \mathbb{N}$. 

10.2.22. Let now $C := (\mathcal{C}, J)$ be a small site whose finite non-empty products and fibre products are representable. Then, the finite products of $\mathcal{C}/X$ are representable, for every $X \in \text{Ob}(\mathcal{C})$; for every such $X$, we denote by $J_X$ the topology on $\mathcal{C}/X$ induced by $J$ (see (4.7.2)).

Now, let $S$ be either $C$ or $(\mathcal{C}/X, J_X)$ for some $X \in \text{Ob}(\mathcal{C})$, and denote by $\mathcal{J}(S)$ the set of all families of objects of $S$ that generate a sieve covering the final object of $T := S^\to$, for the canonical topology on $T$. Then $\mathcal{J}(S)$ is endowed with a partial ordering, by declaring that $\mathfrak{U} \leq \mathfrak{U}'$ if and only if the sieve generated by $\mathfrak{U}$ contains the sieve generated by $\mathfrak{U}'$, for every $\mathfrak{U}, \mathfrak{U}' \in \mathcal{J}(S)$. Notice that this is equivalent to saying that the family $\mathfrak{U}'$ is a refinement of $\mathfrak{U}$, when we regard $\mathfrak{U}$ and $\mathfrak{U}'$ as families of objects of the topos $S$. Especially, when $\mathfrak{U} \leq \mathfrak{U}'$, the discussion of (10.2.10) yields a map of complexes $\varphi_{\mathfrak{U}, \mathfrak{U}'} : R_\bullet(\mathfrak{U}') \to R_\bullet(\mathfrak{U})$, and lemma 10.2.12 says that the homotopy class of $\varphi_{\mathfrak{U}, \mathfrak{U}'}$ depends only on $\mathfrak{U}$ and $\mathfrak{U}'$, so we get a well defined functor

$$R_\bullet : \mathcal{J}(S)^\to \to \text{Hot}(\mathcal{Z}_T^{\text{-Mod}}) \quad \mathfrak{U} \mapsto R_\bullet(\mathfrak{U}).$$

Now, let $\mathcal{F}$ be any abelian sheaf on $S$. We then get, for every $i \in \mathbb{N}$, an induced functor

$$H^i(-, \mathcal{F}) : \mathcal{J}(S) \to \mathbb{Z}\text{-Mod} \quad \mathfrak{U} \mapsto H^i(\mathfrak{U}, \mathcal{F}).$$

Notice now that $\mathcal{J}(S)$ is a small and filtered category; we may then define

$$\tilde{H}^i(S, \mathcal{F}) := \text{colim}_{\mathfrak{U} \in \mathcal{J}(S)} H^i(\mathfrak{U}, \mathcal{F})$$

and clearly the rule $\mathcal{F} \mapsto \tilde{H}^i(S, \mathcal{F})$ yields a well defined functor

$$\tilde{H}^i(S, -) : \mathcal{Z}_T^{\text{-Mod}} \to \mathbb{Z}\text{-Mod} \quad \mathfrak{U} \mapsto \tilde{H}^i(\mathfrak{U}, \mathcal{F})$$

for every bounded below complex $K^\bullet$ of $\mathbb{Z}_T$-modules whence, after taking colimits, a 2-spectral sequence

$$E_2^{p,q} := \tilde{H}^p(S, H^q(K^\bullet)) \Rightarrow R^{p+q} \Gamma K^\bullet$$

that, in turn, gives us again natural maps, for every $\mathcal{Z}_T$-module $\mathcal{F}$

$$\Psi^p(S, \mathcal{F}) : \tilde{H}^p(S, \mathcal{F}) \to R^p \Gamma \mathcal{F} \quad \text{for every } p \in \mathbb{N}$$

which, in case $S = (\mathcal{C}/X, J_X)$, shall be denoted simply $\Psi^p(X, \mathcal{F})$.

Lemma 10.2.23. In the situation of (10.2.22), let $\mathcal{F}$ be any $\mathcal{Z}_T$-module, and take $K^\bullet := \mathcal{F}[0]$. Then we have:

(i) $E_2^{0,q} = 0$ for every $q > 0$.

(ii) Both $\Psi^0(S, \mathcal{F})$ and $\tilde{H}^1(S, \mathcal{F})$ are isomorphisms, and $\Psi^2(S, \mathcal{F})$ is injective.

Proof. (i): Fix any injective resolution $\mathcal{F} \to \mathcal{F}^\bullet$, and let $\pi \in E_2^{0,q}$ be any element; by definition, there exists a family $(U_i | i \in I)$ of objects of $S$ that generates a sieve covering the final object of $S^\to$, such that $\pi$ is represented by an element

$$\pi_\bullet \in \text{Ker} \left( \prod_{i \in I} H^q(\mathcal{F}^\bullet(U_i)) \to \prod_{i,j \in I^2} H^q(\mathcal{F}^\bullet(U_{(i,j)})) \right)$$

where $d^{0,q}_v$ is the differential of the Čech complex in degree 0, as in remark (10.2.7) i). In turn, the class $\pi_i \in H^q(\mathcal{F}^\bullet(U_i))$ is represented by a section $s_i \in \mathcal{F}^q(U_i)$ for every $i \in I$, such that $d^{0,q}_v(s_i) = 0$, where $d^{0,q}_v : \mathcal{F}^q(U_i) \to \mathcal{F}^{q+1}(U_i)$ denotes the differential in degree $q$ of the
complex $\mathcal{F}^\bullet$. Since the latter is exact in every degree $q > 0$, it follows that for every $i \in I$ there exist a family $(U_{i,\lambda} \to U_i \mid \lambda \in \Lambda_i)$ of objects of $\mathcal{C}/U_i$ that generates a sieve covering the final object of $(\mathcal{C}/U_i, J_{U_i})$, and for every $\lambda \in \Lambda_i$ a section $s_{i,\lambda} \in \mathcal{F}^{q-1}(U_{i,\lambda})$ such that $d_{i}^{q-1}(s_{i,\lambda}) = s_{i|U_{i,\lambda}}$. Set $\mathfrak{U} := \bigcup_{i \in I} \{U_{i,\lambda} \mid \lambda \in \Lambda_i\}$; then $\mathfrak{U}$ lies in $\mathcal{F}(S)$, and it is easily seen that the image of $\mathfrak{U}$ vanishes in $H^0(\mathfrak{U}, \mathcal{H}^q(\mathcal{F}))$, whence the contention. (ii) is an immediate consequence of (i).

**Theorem 10.2.24** (Cartan). *In the situation of (10.2.22), let $\mathcal{F}$ be any $\mathbb{Z}/\Lambda$-module such that $H^i(X, \mathcal{F}) = 0$ for every $X \in \text{Ob}(\mathcal{C})$ and every $i > 0$. Then we have:

(i) The map $\check{\Psi}^q(C, \mathcal{F})$ is an isomorphism for every $q \in \mathbb{N}$.

(ii) More precisely, the map $\check{\Psi}^q(\mathfrak{U}, \mathcal{F})$ is an isomorphism for every $q \in \mathbb{N}$ and every family $\mathfrak{U}$ of objects of $\mathcal{C}$ that covers the final object of $T$.

**Proof.** (i): We argue by induction on $q \in \mathbb{N}$, and notice that the assertion for $q \leq 1$ is already known without any assumption on $\mathcal{F}$, by lemma [10.2.22](ii). Thus, let $i \geq 2$ and suppose that the assertion of the theorem is already known for every $q < i$, every site $C$ and every abelian sheaf $\mathcal{F}$ on $C$. Notice that if $X \in \text{Ob}(\mathcal{C})$ and $\varphi : Y \to X$ is any object of $\mathcal{C}/X$, we have a natural isomorphism of categories

$$((\mathcal{C}/X)/\varphi \sim \mathcal{C}/Y)$$

and the topology $J_\varphi$ induced on $(\mathcal{C}/X)/\varphi$ by $J_X$ agrees, under this identification, with the topology $J_Y$. Therefore, the site $\mathcal{C}/X$ fulfills the assumptions of the theorem, and by inductive assumption we deduce that $\check{\Psi}^q(X, \mathcal{F})$ is an isomorphism for every $q < i$, and therefore $R^q\Gamma(X, \mathcal{F}) = 0$ for every $X \in \text{Ob}(\mathcal{C})$ and every $q = 1, \ldots, i - 1$. Summing up, we get $\mathcal{H}^q(\mathcal{F}) = 0$ whenever $1 \leq q < i$, whence $E_2^{pq} = 0$ for every $q = 1, \ldots, i - 1$ (notation of (10.2.22)). We also know that $E_2^{0q} = 0$ for every $q > 0$, by lemma [10.2.23](i); in this situation, it is easily seen that $E_2^{10} = E_\infty^{00}$ and $E_\infty^{0p} = 0$ for every $p > 0$, and then $\check{\Psi}^i(X, \mathcal{F})$ is indeed an isomorphism.

(ii) is an immediate consequence of (i) and corollary [10.2.21](i). \qed

10.2.25. We wish now to apply the foregoing results to the cohomology of quasi-coherent modules on a scheme. To begin with, let $A$ be a ring, $M$ an $A$-module; set $X := \text{Spec} A$ and denote by $\mathcal{M}$ the quasi-coherent $\mathcal{O}_X$-module arising from $M$. Let also $f := (f_1, \ldots, f_r)$ be a sequence of elements of $A$, and for every integer $n \geq -1$ and every injective order-preserving map

$$\xi : [n] \to \Sigma := \{1, \ldots, r\} \quad \xi(k) \to t_k$$

let $A_\xi := A[f_{t_0}^{-1} \cdots f_{t_n}^{-1}]$ and $U_\xi := \text{Spec} A_\xi$; we can describe as follows the $A_\xi$-module $\mathcal{M}(U_\xi)$. For every such $\xi$, consider the system of $A$-modules $\{(M_{\xi}^{(k)}, \varphi_k) \mid k \in \mathbb{N}\}$ such that $M_{\xi}^{(k)} := M$ for every $k \in \mathbb{N}$, and the map $\varphi_k : M_{\xi}^{(k)} \to M_{\xi}^{(k+1)}$ is the scalar multiplication by $f_{t_0} \cdots f_{t_n}$ if $n \geq 0$, and it is $1_M$ when $n = -1$. Then we have a natural identification

$$\mathcal{M}(U_\xi) \sim \underset{k \in \mathbb{N}}{\text{colim}} \ M_{\xi}^{(k)}$$

for every $n \geq -1$ and every $\xi : [n] \to \Sigma$.

Moreover, for every face map $\varepsilon_i : [n - 1] \to [n]$ in $\Delta$, we can describe as follows the restriction map $\rho_{i,\xi} : \mathcal{M}(U_{\xi\varepsilon_i}) \to \mathcal{M}(U_\xi)$. We consider the morphism of directed systems

$$\rho_i : \mathcal{M}_{\xi}(\Delta) \to \mathcal{M}_{\xi}(\mathbb{N})$$

such that $\rho_i^{(k)} := f^{(k)}_{t_i} : 1_M$ for every $k \in \mathbb{N}$.

Then, under the identifications (10.2.26), the map $\rho_{i,\xi}$ corresponds to the map

$$\underset{k \in \mathbb{N}}{\text{colim}} \ \rho_{i,\xi}^{(k)} : \underset{k \in \mathbb{N}}{\text{colim}} \ M_{\xi\varepsilon_i}^{(k)} \to \underset{k \in \mathbb{N}}{\text{colim}} M_{\xi}^{(k)}.$$
For every $n \geq -1$ let $\Sigma_{\text{alt}}^{n+1}$ be the set of all injective order-preserving maps $[n] \to \Sigma$, and set
\[ D^k_{(k)} := \text{Hom}_{\text{Set}}(\Sigma_{\text{alt}}^{n+1}, M) \quad \text{for every } k \in \mathbb{N} \]
which we endow with the $A$-module structure inherited from $M$; consider also the map
\[ d^m_k : D^m_{(k)} \to D^{m+1}_{(k)} \quad (\mu : \Sigma_{\text{alt}}^{n+1} \to M) \mapsto \left( t \mapsto \sum_{i=0}^{n+1} (-1)^i \cdot f^k_i \cdot \mu(t \circ e_i) \right) \]
for every $k \in \mathbb{N}$. Then the system $(D^*_{(k)}, d^*_k)$ is a well defined complex of $A$-modules, for every $k \in \mathbb{N}$. Lastly, for every $k \in \mathbb{N}$ we consider the morphism of complexes
\[ D^*_{(k)} \to D^*_{(k+1)} \quad (\mu : \Sigma_{\text{alt}}^{n+1} \to M) \mapsto (t \mapsto f_{t_0} \cdots f_{t_n} \cdot \mu(t)). \]

Summing up, and comparing with remark [10.2.7(i)] we obtain a natural identification
\[ C^*_{\text{alt}}(\mathcal{U}, \mathcal{M}) \sim \text{colim}_{k \in \mathbb{N}} D^*_{(k)} \quad \text{where } \mathcal{U} := (U_1, \ldots, U_r). \]

On the other hand, notice that, for every $n \geq -1$, the free $A$-module $A_{\mathcal{A}}^{n+1}A^{\oplus r}$ admits the standard basis $(e_{t_0} \wedge \cdots \wedge e_{t_n} | t \in \Sigma_{\text{alt}}^{n+1})$, so we have as well a natural identification
\[ \text{Hom}_A(A^{\mathcal{A}}_{\mathcal{A}}^{n+1}A^{\oplus r}, M) \sim D^m_{(k)} \quad \text{for every } n \geq -1 \]
and a direct inspection reveals that, under this latter identification, the differential $d^m_k$ of $D^*_{(k)}$ corresponds to the differential $\text{Hom}_A(d_{(k),n}, M)$, where $f^k := (f^k_1, \ldots, f^k_r)$, and $d_{(k),n}$ is the differential in degree $n$ of the Koszul complex of the sequence $f^k$ (see remark [7.8.1(ii)]). Thus, we get finally a natural isomorphism of complexes of $A$-modules
\[ (10.2.27) \quad C^*_{\text{alt}}(\mathcal{U}, \mathcal{M}) \sim \text{colim}_{k \in \mathbb{N}} K^*_{\text{alt}}(f^k, M)[1] \]
where the transition maps $K^*_{\text{alt}}(f^k, M) \to K^*_{\text{alt}}(f^{k+1}, M)$ are the morphisms $\varphi_f$ of (7.8.20). As a corollary, we get the following classical result of Grothendieck:

**Theorem 10.2.28.** In the situation of (10.2.25), the following holds:

(i) The natural map $M[0] \to R\Gamma \mathcal{M}$ is an isomorphism in $D(\mathcal{O}_\mathcal{X} \text{-Mod})$.

(ii) Let $Y$ be any separated scheme, $\mathcal{F}^*$ a bounded below complex of quasi-coherent $\mathcal{O}_Y$-modules, and $\mathcal{U}$ any affine open covering of $Y$. Then the natural map
\[ \text{Tot} C^*_{\text{alt}}(\mathcal{U}, \mathcal{F}^*) \to R\Gamma \mathcal{F}^* \]
is an isomorphism in $D^+(\mathcal{O}_\mathcal{Y}(Y) \text{-Mod})$.

(iii) Especially, if $Y$ is a separated scheme that can be covered by $r$ affine open subsets, then $H^i(Y, \mathcal{F}) = 0$ for every $i \geq r$, and every quasi-coherent $\mathcal{O}_\mathcal{Y}$-module $\mathcal{F}$.

**Proof.** (i): Since the affine open subsets of $X$ of the form $\text{Spec } A[f^{-1}]$ for $f \in A$ are a basis of the topology of $X$ that is closed under finite intersections, theorem [10.2.24] reduces to showing that
\[ H^0(\mathcal{U}, \mathcal{M}) = M \quad \text{and} \quad H^i(\mathcal{U}, \mathcal{M}) = 0 \quad \text{for every } i > 0 \]
where $\mathcal{U} := (U_1, \ldots, U_r)$ is the finite affine open covering of $X$ associated with a sequence $f := (f_1, \ldots, f_r)$ as in (10.2.25). However, the condition $X = \bigcup_{i=1}^r U_i$ is equivalent to saying that the ideal generated by the system $f$ is $A$, in which case the same holds for the ideal generated by $f^k$, for every $k \in \mathbb{N}$, and then lemma [7.8.2](iii) says that the complex $H^*(f^k, M)$ is homotopically trivial for every $k \in \mathbb{N}$. Taking into account (10.2.27), the contention follows.

(ii): Pick any resolution $\mathcal{F}^* \to \mathcal{F}^*$ by a bounded below complex of injective $\mathcal{O}_Y$-modules; in view of (10.2.19), it suffices to show that the natural map of double complexes
\[ C^*_{\text{alt}}(\mathcal{U}, \mathcal{F}^*) \to C^*_{\text{alt}}(\mathcal{U}, \mathcal{F}^*) \]
induces a quasi-isomorphism on total complexes. However, notice that the open subset $U \subset Y$ is affine, for every $n \in \mathbb{N}$ and every $t \in I_{alt}^{n+1}$ (notation of (10.2.4)); hence, it suffices to check that the induced map $\mathcal{F}^\bullet(V) \to \mathcal{F}^\bullet(V)$ is a quasi-isomorphism, for every affine open subset $V \subset Y$. To this aim, consider the spectral sequence

$$E_1^{p,q} := H^p(V, \mathcal{F}^q) \Rightarrow H^{p+q}(\mathcal{F}^\bullet(V)).$$

Since $V$ is affine, we have $E_1^{p,q} = 0$ for every $p > 0$, due to (i); on the other hand, the differential $d_1^{0,q} : E_1^{0,q} \to E_1^{0,q+1}$ is nothing else than the differential $d^q(V) : \mathcal{F}^q(V) \to \mathcal{F}^{q+1}(V)$, for every $q \in \mathbb{Z}$, whence the claim.

(iii): Indeed, if $\mathcal{U}$ is such a covering, then the complex $\mathcal{C}^\bullet_{alt}(\mathcal{U}, \mathcal{F})$ is an object of the category $C^{[0,r-1]}(\mathcal{O}_Y(Y)\text{-Mod})$, so the assertion follows from (ii).

We conclude this section with an application of Čech cohomology to the computation of sheaf cohomology after change of base scheme; much more can be found in [47, Ch.III, §6].

10.2.29. Namely, consider a diagram of schemes

$$
\begin{array}{ccc}
X_2 & \longrightarrow & X_1 & \longrightarrow & X_0 \\
\pi_2 & \downarrow & \pi_1 & \downarrow & \pi_0 \\
S_2 & \longrightarrow & S_1 & \longrightarrow & S_0
\end{array}
$$

whose two square subdiagram are cartesian, and bounded above complexes of quasi-coherent $\mathcal{O}_{X_0}$-modules $\mathcal{F}_0^\bullet$ and quasi-coherent $\mathcal{O}_{S_1}$-modules $\mathcal{G}_i^\bullet$ for $i = 1, 2$. Then, for every $q \in \mathbb{N}$ there exists a quasi-coherent $\mathcal{O}_{X_1}$-module

$$\text{Tor}_{q}^{\mathcal{S}_0}(\mathcal{G}_1^\bullet, \mathcal{F}_0^\bullet)$$

characterized, up to unique isomorphism, by the following properties ([47, Ch.III, §6.5]):

(a) For every affine open subsets $V_0 \subset S_0$, $V \subset S_1 \times_{S_0} V_0$, and $U \subset X_0 \times_{S_0} V_0$, there exists an isomorphism of $\mathcal{O}_{X_1}(V \times_{S_0} U)$-modules

$$\omega_{V,U} : \Gamma(V \times_{S_0} U, \text{Tor}_{q}^{\mathcal{S}_0}(\mathcal{G}_1^\bullet, \mathcal{F}_0^\bullet)) \xrightarrow{\sim} H_q(\mathcal{F}_0^\bullet(U)) \otimes_{\mathcal{O}_{S_0}(V_0)} \mathcal{F}_0^\bullet(U)).$$

(b) For every $V_0$, $V$, $U$ as in (a) and every inclusion of affine open subsets $V'_0 \subset V_0$, $V' \subset V \cap (S_1 \times_{S_0} V'_0)$ and $U' \subset U \cap (X_0 \times_{S_0} V'_0)$, the resulting diagram commutes:

$$
\begin{array}{ccc}
\Gamma(V \times_{S_0} U, \text{Tor}_{q}^{\mathcal{S}_0}(\mathcal{G}_1^\bullet, \mathcal{F}_0^\bullet)) & \xrightarrow{\omega_{V,U}} & H_q(\mathcal{F}_0^\bullet(U)) \\
\downarrow & & \downarrow \\
\Gamma(V' \times_{S_0} U', \text{Tor}_{q}^{\mathcal{S}_0}(\mathcal{G}_1^\bullet, \mathcal{F}_0^\bullet)) & \xrightarrow{\omega_{V',U'}} & H_q(\mathcal{F}_0^\bullet(U'))
\end{array}
$$

whose left vertical arrow is the restriction map of the sheaf $\text{Tor}_{q}^{\mathcal{S}_0}(\mathcal{G}_1^\bullet, \mathcal{F}_0^\bullet)$, and whose right vertical arrow is the map $H_q(\rho' \otimes_{\rho} \rho'')$ associated with the restriction maps $\rho : \mathcal{O}_{S_0}(V_0) \to \mathcal{O}_{S_0}(V'_0)$, $\rho' : \mathcal{G}_1^\bullet(V) \to \mathcal{G}_1^\bullet(V')$ and $\rho'' : \mathcal{F}_0^\bullet(U) \to \mathcal{F}_0^\bullet(U')$.

**Proposition 10.2.30.** In the situation of (10.2.29), the following holds:

(i) There exists a natural (homological) 2-spectral sequence

$$\text{Tor}_{p+q}^{\mathcal{S}_1}(\mathcal{G}_2^\bullet, \text{Tor}_{q}^{\mathcal{S}_0}(\mathcal{G}_1^\bullet, \mathcal{F}_0^\bullet)) \Rightarrow \text{Tor}_{p+q}^{\mathcal{S}_0}(\mathcal{G}_2^\bullet, \mathcal{F}_0^\bullet).$$
(ii) Suppose that \( \pi_0 \) is quasi-compact and separated, \( \mathcal{F}_0 \) is a bounded complex, and both \( S_1 \) and \( S_0 \) are affine. Set \( A_i := \mathcal{O}_{S_i}(S_i) \) for \( i = 0, 1 \). Then there exist two natural spectral sequences:

\[
E_2^{pq} := H^{-p}(X, \text{For}, \mathcal{O}_{S_0}^q(\mathcal{G}, \mathcal{F}_0^*)) \Rightarrow H_{p+q}(R\Gamma \mathcal{G}^* \otimes_{A_0} R\Gamma \mathcal{F}_0^*)
\]

\[
E_2^{pq} := H_p(R\Gamma \mathcal{G}^* \otimes_{A_0} H^{-q}(X_0, \mathcal{F}_0^*)[0]) \Rightarrow H_{p+q}(R\Gamma \mathcal{G}^* \otimes_{A_0} R\Gamma \mathcal{F}_0^*).
\]

**Proof.** (i): This is obtained from the standard change of base ring spectral sequence, which is natural in all arguments, and therefore globalizes immediately to the sheaf-theoretic situation considered here : the details shall be left to the reader.

(ii): Under our assumptions, \( X_0 \) is quasi-compact and separated, hence we may find a finite affine covering \( \mathcal{U} \) of \( X_0 \), and by theorem 10.2.28(ii), the alternating \( \check{\text{C}} \text{ech} \) complex for \( \mathcal{U} \) computes the cohomology of \( \mathcal{F}_0^* \); especially the complex \( R\Gamma \mathcal{F}_0^* \) is bounded. Moreover, we may find a bounded above Cartan-Eilenberg resolution \( \mathcal{L}^* \xrightarrow{\varphi} \mathcal{G}^* \) consisting of quasi-coherent flat \( \mathcal{O}_{S_i} \)-modules, and \( H_i(R\Gamma \mathcal{G}^* \otimes_{A_0} R\Gamma \mathcal{F}_0^*) \) is naturally isomorphic to the quasi-coherent \( \mathcal{O}_{S_i} \)-module associated with the \( A_i \)-module

\[
H_i((\text{Tot } \mathcal{C}_m^*(\mathcal{U}, \mathcal{F}_0^*)) \otimes_{A_0} \mathcal{L}^*(S_0))
\]

for every \( i \in \mathbb{Z} \). Then the first spectral sequence is the standard spectral sequence attached to the double complex \( \text{Tot } \mathcal{C}_m^*(\mathcal{U}, \mathcal{F}_0^*) \otimes_{A_0} \mathcal{L}^*(S_0) \); similarly one obtains the second spectral sequence : details left to the reader. \( \square \)

10.3. **Quasi-coherent modules.** For any scheme \( X \), we denote by

\[
\mathcal{O}_X\text{-Mod} \quad \mathcal{O}_X\text{-Mod}_{\text{qcoh}} \quad \mathcal{O}_X\text{-Mod}_{\text{coh}} \quad \mathcal{O}_X\text{-Mod}_{\text{lift}}
\]

the category of all (resp. of quasi-coherent, resp. of coherent, resp. of locally free of finite type) \( \mathcal{O}_X \)-modules. Recall that there is a natural functor

\[
(\text{10.3.1}) \quad \mathcal{O}_X(X)\text{-Mod} \rightarrow \mathcal{O}_X\text{-Mod}_{\text{qcoh}} \quad M \mapsto M^\sim
\]

that assigns to every \( \mathcal{O}_X(X) \)-module the quasi-coherent module \( M^\sim \) such that

\[
M^\sim(U) := M \otimes_{\mathcal{O}_X(X)} \mathcal{O}_X(U) \quad \text{for every affine open subset } U \subset X.
\]

This functor is an equivalence, if \( X \) is affine. We notice :

**Corollary 10.3.2.** Let \( A \) be a ring, \( M^* \) (resp. \( N_* \)) a bounded below (resp. above) complex of \( A \)-modules. Set \( X := \text{Spec } A \) and denote by \( M_*^\sim \) (resp. \( N_*^\sim \)) the associated complex of quasi-coherent \( \mathcal{O}_X \)-modules. We have :

(i) The natural map

\[
R\text{Hom}^*_A(N_*, M^*) \rightarrow R\text{Hom}^*_X(N_*^\sim, M_*^\sim)
\]

is an isomorphism in \( D^+(A\text{-Mod}) \).

(ii) If \( A \) is coherent and \( N_* \) is a complex of finitely presented \( A \)-modules, then the natural morphism

\[
R\text{Hom}^*_A(N_*, M^*)^\sim \rightarrow R\text{Hom}^*_X(N_*^\sim, M_*^\sim)
\]

is an isomorphism in \( D(\mathcal{O}_X\text{-Mod}) \).

**Proof.** (i): We apply the trivial duality theorem 10.1.18 to the unique morphism

\[
f : (X, \mathcal{O}_X) \rightarrow (\{\text{pt}\}, A)
\]

of ringed spaces, where \( \{\text{pt}\} \) denotes the one-point space. Since \( f \) is flat and all quasi-coherent \( \mathcal{O}_X \)-modules are \( f_* \)-acyclic, the assertion follows easily.
(ii): Due to (i), it suffices to show the following assertion. For every \( f \in A \), the natural map
\[
R\text{Hom}^*_A(N_i, M^*) \otimes_A A_f \to R\text{Hom}^*_A(N_i, M^*_f)
\]
is an isomorphism in \( D(A_f\text{-Mod}) \). To this aim, notice that, since \( A \) is coherent, we may find a resolution \( P_\bullet \) of \( N_\bullet \) consisting of free \( A \)-modules of finite type (details left to the reader); then we come down to checking that the natural map \( \text{Hom}_A(P_i, M^j) \otimes_A A_f \to \text{Hom}_A(P_i, f_\ast M^j_f) \) is an isomorphism, which is obvious.

We denote by
\[
D(\mathcal{O}_X\text{-Mod})_{\text{qc}} \quad D(\mathcal{O}_X\text{-Mod})_{\text{coh}}
\]
the full triangulated subcategory of \( D(\mathcal{O}_X\text{-Mod}) \) consisting of the complexes \( K^\bullet \) such that \( H^i K^\bullet \) is a quasi-coherent (resp. coherent) \( \mathcal{O}_X \)-module for every \( i \in \mathbb{Z} \). As usual, we shall use also the variants \( D^+(\mathcal{O}_X\text{-Mod})_{\text{qc}} \) (resp. \( D^+(\mathcal{O}_X\text{-Mod})_{\text{coh}} \)) of \( D^+ \) (resp. \( D^+_{\text{qc}} \)) consisting of all objects of \( D(\mathcal{O}_X\text{-Mod})_{\text{qc}} \), resp. \( D^+(\mathcal{O}_X\text{-Mod})_{\text{coh}} \), whose cohomology vanishes in sufficiently large negative degree (resp. sufficiently large positive degree, resp. outside a bounded interval, resp. outside the interval \([a, b])\), and likewise for the corresponding subcategories of \( D(\mathcal{O}_X\text{-Mod})_{\text{coh}} \). Obviously, \((10.3.1)\) induces a natural functor
\[
D(\mathcal{O}_X(X)\text{-Mod}) \to D(\mathcal{O}_X\text{-Mod})_{\text{qc}} \quad M^\bullet \mapsto M^\bullet^\ast.
\]

**Proposition 10.3.3.** Let \( f : Y \to X \) be a flat morphism of schemes, with \( X \) locally coherent (see definition \cite{8.1.55}(i)), and \( K_\bullet \in \text{Ob}(D^-(\mathcal{O}_X\text{-Mod})_{\text{coh}}) \) any complex. We have :

(i) \( R\text{Hom}^*_\mathcal{O}_X(K_\bullet, L^\bullet) \in \text{Ob}(D^+(\mathcal{O}_X\text{-Mod})_{\text{coh}}) \) for every \( L^\bullet \in \text{Ob}(D^+(\mathcal{O}_X\text{-Mod})_{\text{coh}}) \).

(ii) For every \( L^\bullet \in \text{Ob}(D^+(\mathcal{O}_X\text{-Mod})) \) the natural morphism
\[
(10.3.4) \quad f^\ast R\text{Hom}^*_\mathcal{O}_X(K_\bullet, L^\bullet) \to R\text{Hom}^*_\mathcal{O}_X(f^\ast K_\bullet, f^\ast L^\bullet)
\]
is an isomorphism in \( D^+(\mathcal{O}_X\text{-Mod}) \).

**Proof.** (i): The assertion is local on \( X \), so we may assume that \( X = \text{Spec} A \), for some coherent ring \( A \). In this case, we may find a bounded below (resp. above) complex \( M^\bullet \) (resp. \( N_\bullet \)) of finitely presented \( A \)-modules, with isomorphisms \( K^\bullet \cong M^\ast \), \( L^\bullet \cong N^\ast \) in \( D(\mathcal{O}_X\text{-Mod}) \). By virtue of corollary \[(10.3.2)(ii)\], we are then reduced to checking that \( R\text{Hom}^*_A(N_i, M^\ast) \) lies in \( D(\mathcal{O}_X\text{-Mod})_{\text{coh}} \). But this is easily seen, since we may find a resolution of \( N_\bullet \) by a bounded above complex of free \( A \)-modules of finite type (details left to the reader).

(ii): Again, the question is local on \( X \), so we may assume that \( K_\bullet \) admits a resolution by a bounded above complex \( P_\bullet \) of free \( \mathcal{O}_X \)-modules of finite type. Since \( f \) is flat, we have natural convergent spectral sequences
\[
E_1^{pq} := f^\ast R^p R\text{Hom}^*_\mathcal{O}_X(P_q, L^\bullet) \Rightarrow f^\ast R^{p+q} R\text{Hom}^*_\mathcal{O}_X(K_\bullet, L^\bullet)
\]
\[
F_1^{pq} := R^p R\text{Hom}^*_\mathcal{O}_X(f^\ast P_q, f^\ast L^\bullet) \Rightarrow R^{p+q} R\text{Hom}^*_\mathcal{O}_X(f^\ast K_\bullet, f^\ast L^\bullet)
\]
as well as a morphism of spectral sequences \( E_\bullet^{\bullet} \to F_\bullet^{\bullet} \), such that \( H^i(10.3.4) \) is a morphism of filtered \( \mathcal{O}_Y \)-modules, for the two finite filtrations induced by these spectral sequences on their abutments. It then suffices to check that the induced morphism \( E_\infty^{pq} \to F_\infty^{pq} \) is an isomorphism for every \( p, q \in \mathbb{Z} \), and this in turn will follow, if we show that the morphism \( E_1^{pq} \to F_1^{pq} \) is an isomorphism; but the latter assertion is obvious.

**Corollary 10.3.5.** Let \( f : Y \to X \) be a quasi-compact and quasi-separated morphism of schemes, \( \mathcal{F} \) a flat quasi-coherent \( \mathcal{O}_X \)-module, and \( \mathcal{G} \) any \( \mathcal{O}_Y \)-module. Then the natural map
\[
(10.3.6) \quad \mathcal{F} \otimes_{\mathcal{O}_X} Rf_*\mathcal{G} \to Rf_*(f^* \mathcal{F} \otimes_{\mathcal{O}_Y} \mathcal{G})
\]
is an isomorphism in \( D(\mathcal{O}_X\text{-Mod}) \).
Proof. The assertion is local on $X$, hence we may assume that $X = \text{Spec } A$ for some ring $A$, and $\mathcal{F} = M^\sim$ for some flat $A$-module $M$. By [95, Ch.I, Th.1.2], $M$ is the colimit of a filtered family of free $A$-modules of finite rank; in view of proposition [10.1.10(ii)], we may then assume that $M = A^\oplus n$ for some $n \geq 0$, in which case the assertion is obvious. \hfill $\square$

Remark 10.3.7. Notice that, for an affine morphism $f : Y \to X$, the map (10.3.6) is an isomorphism for any quasi-coherent $\mathcal{O}_X$-module $\mathcal{F}$ and any quasi-coherent $\mathcal{O}_Y$-module $\mathcal{G}$. The details shall be left to the reader.

Corollary 10.3.8. Consider a cartesian diagram of schemes

$$
\begin{array}{ccc}
Y' & \xrightarrow{g'} & Y \\
\downarrow f' & & \downarrow f \\
X' & \xleftarrow{g} & X
\end{array}
$$

such that $f$ is quasi-compact and quasi-separated, and $g$ is flat. Then the natural map

(10.3.9) \[ g^* Rf_* \mathcal{G} \to Rf'_* g'^* \mathcal{G} \]

is an isomorphism in $D(\mathcal{O}_X, \text{-Mod})_{qcoh}$, for every quasi-coherent $\mathcal{O}_Y$-module $\mathcal{G}$.

Proof. We easily reduce to the case where both $X$ and $X'$ are affine, hence $g$ is an affine morphism. In this case, it suffices to show that $g_*(10.3.9)$ is an isomorphism, since $Rf_* \mathcal{G}$ lies in $D(\mathcal{O}_X, \text{-Mod})_{qcoh}$ and $Rf'_* g'^* \mathcal{G}$ lies in $D(\mathcal{O}_X, \text{-Mod})_{qcoh}$ ([2, Th.5.6]). However, we have a commutative diagram

$$
\begin{array}{ccc}
g_* (g^* Rf_* \mathcal{G}) & \xrightarrow{\alpha} & Rf_* \mathcal{G} \otimes \mathcal{O}_X g_* \mathcal{O}_X' \\
\downarrow & & \downarrow \\
g_* (Rf'_* g'^* \mathcal{G}) & \xrightarrow{\beta} & Rf_* (\mathcal{G} \otimes \mathcal{O}_Y g'_* \mathcal{O}_Y')
\end{array}
$$

whose left vertical arrow is $g_*(10.3.9)$ and whose right vertical arrow is the natural isomorphism provided by corollary [10.3.5](applied to the flat $\mathcal{O}_Y$-module $\mathcal{F} := g'_* \mathcal{O}_Y$). Also, $\alpha$ and $\beta$ are the natural maps obtained as in [44, Ch.0, (5.4.10)]; it is easily seen that these are isomorphisms, for all affine morphisms $g$ and $g'$. The assertion follows. \hfill $\square$

Remark 10.3.10. Corollary [10.3.8] is also proved in [2, Th.6.7]. Notice that the corollary fails if $\mathcal{G}$ is not quasi-coherent. For a counterexample, let $R := k[x, y]/m$, where $k$ is a field and $m \subset k[x, y]$ is the maximal ideal generated by $x$ and $y$; i.e. $R$ is the local ring at the origin of the affine plane over $k$. Let $R^\wedge$ be the completion of $R$, $X := \text{Spec } R$, $X' := \text{Spec } R^\wedge$, and set $Y := X \setminus \{mR\}$ and $Y' := Y \times_X X'$. Let moreover $p \in Y$ be the prime ideal generated by $x$, and $p'$ its inverse image in $Y'$; take for $\mathcal{O}_Y$ the $\mathcal{O}_Y$-module obtained by extension by zero of the restriction to $\{p\}$ of the structure sheaf of $\mathcal{O}_Y$. With this notation, suppose that the map (10.3.9) induces an isomorphism on the stalks at the closed points; in cohomological degree zero, this comes down to saying that the natural map $f : (R^\wedge)_p \to (R^\wedge)_{p'}$ is an isomorphism. However, notice that the restriction $R_p \to (R^\wedge)_{p'}$ of $f$ induces a homeomorphism $\text{Spec } (R^\wedge)_{p'} \sim \text{Spec } R_p$. On the other hand, we can exhibit a height one prime ideal $q \in \text{Spec } (R^\wedge)_p$ whose image in $\text{Spec } R_p$ is the generic point. Indeed, let $a(X) \in x \cdot k[[x]]$ be a power series that is transcendental over $k(x)$; the kernel of the surjective continuous map of $k[[x]]$-algebras $g : R^\wedge = k[[x, y]] \to k[[x]]$ such that $g(y) := a(x)$ is the ideal $I$ generated by $y - a(x)$, hence the latter is a prime ideal of $R^\wedge$, and we take $q := I_p$. To see that the preimage of $q$ in $\text{Spec } R_p$ is the generic point, it suffices to notice that the restriction $R_p \to k[[x]]$ of $g$ is injective, as $a(x)$ is transcendental over $k(x)$.
10.3.11. There are obvious forgetful functors:
\[ \iota_X : \mathcal{O}_X\text{-Mod}_{\text{qcoh}} \to \mathcal{O}_X\text{-Mod} \]
\[ R \iota_X : \mathcal{D}(\mathcal{O}_X\text{-Mod}_{\text{qcoh}}) \to \mathcal{D}(\mathcal{O}_X\text{-Mod})_{\text{qcoh}} \]
and we wish to exhibit right adjoints to these functors. To this aim, suppose first that \( X \) is affine; then we may consider the functor:
\[ \text{qcoh}_X : \mathcal{O}_X\text{-Mod} \to \mathcal{O}_X\text{-Mod}_{\text{qcoh}} \quad \mathcal{F} \mapsto \mathcal{F}(X) \]
If \( \mathcal{G} \) is a quasi-coherent \( \mathcal{O}_X \)-module, then clearly \( \text{qcoh}_X \mathcal{G} \simeq \mathcal{G} \); moreover, for any other \( \mathcal{O}_X \)-module \( \mathcal{F} \), there is a natural bijection:
\[ \text{Hom}_{\mathcal{O}_X}(\mathcal{G}, \mathcal{F}) \simeq \text{Hom}_{\mathcal{O}_X(X)}(\mathcal{G}(X), \mathcal{F}(X)). \]
It follows easily that \( \text{qcoh}_X \) is the sought right adjoint.

10.3.12. Slightly more generally, let \( U \) be quasi-affine, i.e. a quasi-compact open subset of an affine scheme, and choose a quasi-compact open immersion \( j : U \to X \) into an affine scheme \( X \). In this case, we may define
\[ \text{qcoh}_U : \mathcal{O}_U\text{-Mod} \to \mathcal{O}_X\text{-Mod} \quad \mathcal{F} \mapsto (\text{qcoh}_Xj_*)\mathcal{F}|_U. \]
Since \( j_* : \mathcal{O}_U\text{-Mod} \to \mathcal{O}_X\text{-Mod} \) is right adjoint to \( j^* : \mathcal{O}_X\text{-Mod} \to \mathcal{O}_U\text{-Mod} \), we have a natural isomorphism:
\[ \text{Hom}_{\mathcal{O}_U}(\mathcal{G}, \mathcal{F}) \simeq \text{Hom}_{\mathcal{O}_U}(j_*\mathcal{G}, j_*\mathcal{F}) \]
for every \( \mathcal{O}_U \)-modules \( \mathcal{G} \) and \( \mathcal{F} \). Moreover, if \( \mathcal{G} \) is quasi-coherent, the same holds for \( j_*\mathcal{G} \) ([44 Ch.I, Cor.9.2.2]), whence a natural isomorphism \( \mathcal{G} \simeq j_!\mathcal{G} \), by the foregoing discussion for the affine case. Summing up, this shows that \( \text{qcoh}_U \) is a right adjoint to \( \iota_U \), and especially it is independent, up to unique isomorphism, of the choice of \( j \).

10.3.13. Next, suppose that \( X \) is quasi-compact and quasi-separated. We choose a finite covering \( \mathfrak{U} := (U_i \mid i \in I) \) of \( X \), consisting of affine open subsets, and set \( U := \coprod_{i \in I} U_i \), the \( X \)-scheme which is the disjoint union (i.e. categorical coproduct) of the schemes \( U_i \). We denote by \( \mathfrak{U}_\bullet \) the simplicial covering such that \( \mathfrak{U}_n := U \times_X \cdots \times_X U \), the \( (n+1) \)-th power of \( U \), with the face maps given by the natural projections, and degeneracies induced by the diagonal map \( U \to U \times_X U \); let also \( \pi_n : \mathfrak{U}_n \to X \) be the natural morphism, for every \( n \in \mathbb{N} \). Clearly we have \( \pi_{n-1} \circ \partial_i = \pi_n \) for every face morphism \( \partial_i : \mathfrak{U}_n \to \mathfrak{U}_{n-1} \). The simplicial scheme \( \mathfrak{U}_\bullet \) (with the Zariski topology on each scheme \( \mathfrak{U}_n \)) can also be regarded as a fibré topos over the category \( \Delta^o \) (notation of [59 §2.2]); then the datum \( \mathcal{O}_{\mathfrak{U}_\bullet} := (\mathcal{O}_{\mathfrak{U}_n} \mid n \in \mathbb{N}) \) consisting of the structure sheaves on each \( \mathfrak{U}_n \) and the natural maps \( \partial_i^* \mathcal{O}_{\mathfrak{U}_{n-1}} \to \mathcal{O}_{\mathfrak{U}_n} \) for every \( n > 0 \) and every \( i = 0, \ldots, n \) (and similarly for the degeneracy maps), defines a ring in the associated topos \( \text{Top}(\mathfrak{U}_\bullet) \) (see [59 §3.3.15]). We denote by \( \mathcal{O}_{\mathfrak{U}_\bullet}\text{-Mod} \) the category of \( \mathcal{O}_{\mathfrak{U}_\bullet} \)-modules in the topos \( \text{Top}(\mathfrak{U}_\bullet) \). The family \( (\pi_n \mid n \in \mathbb{N}) \) induces a morphism of topoi
\[ \pi_* : \text{Top}(\mathfrak{U}_\bullet) \to s.X \]
where \( s.X \) is the topos \( \text{Top}(X_\bullet) \) associated with the constant simplicial scheme \( X_\bullet \) (with its Zariski topology) such that \( X_n := X \) for every \( n \in \mathbb{N} \) and such that all the face and degeneracy maps are \( 1_X \). Clearly the objects of \( s.X \) are nothing else than the cosimplicial Zariski sheaves on \( X \). Especially, if we view a \( \mathcal{O}_X \)-module \( \mathcal{F} \) as a constant cosimplicial \( \mathcal{O}_X \)-module, we may define the augmented cosimplicial Čech \( \mathcal{O}_X \)-module
\[ \mathcal{F} 
\]
\[ \mathcal{C}^n(\mathfrak{U}, \mathcal{F}) := \pi_* \circ \pi_n^* \mathcal{F} \]
associated with \( \mathcal{F} \) and the covering \( \mathfrak{U} \); in every degree \( n \in \mathbb{N} \) this is defined by the rule:
\[ \mathcal{C}^n(\mathfrak{U}, \mathcal{F}) := \pi_n \circ \pi_n^* \mathcal{F} \]
and the coface operators \( \partial^i \) are induced by the face morphisms \( \partial_i \) in the obvious way.

**Lemma 10.3.15.** (i) The augmented complex (10.3.14) is aspherical for every \( \mathcal{O}_X \)-module \( \mathcal{F} \).
(ii) If $\mathcal{F}$ is an injective $\mathcal{O}_X$-module, then (10.3.14) is homotopically trivial.

Proof. (See also e.g. [62, Th.5.2.1].) The proof relies on the following alternative description of the cosimplicial Čech $\mathcal{O}_X$-module. Consider the adjoint pair:

$$(\pi^*, \pi_\ast) : \mathcal{O}_I\text{-Mod} \rightleftarrows \mathcal{O}_X\text{-Mod}$$

arising from our covering $\pi : \mathcal{U} \to X$. Let $(\mathcal{T} := \pi_\ast \circ \pi^*, \eta, \mu)$ be the associated triple (see (7.10.3)), $\mathcal{F}$ any $\mathcal{O}_X$-module; we leave to the reader the verification that the resulting augmented cosimplicial complex $\mathcal{F} \to \mathcal{T}^*\mathcal{F}$ as defined in (7.10.2) – is none else than the augmented Čech complex (10.3.14). Thus, for every $\mathcal{O}_X$-module $\mathcal{F}$, the augmented complex $\pi^*\mathcal{F} \to \pi^*\mathcal{C}^\bullet(\mathcal{U}, \mathcal{F})$ is homotopically trivial (proposition 7.10.4); since $\pi$ is a covering morphism, (i) follows. Furthermore, by the same token, the augmented complex $\pi_\ast\mathcal{F} \to \mathcal{C}^\bullet(\mathcal{U}, \mathcal{F})$ is homotopically trivial for every $\mathcal{O}_I$-module $\mathcal{F}$; especially we may take $\mathcal{I} := \pi^*\mathcal{I}$, where $\mathcal{I}$ is an injective $\mathcal{O}_X$-module. On the other hand, when $\mathcal{I}$ is injective, the unit of adjunction $\mathcal{I} \to \mathcal{T}\mathcal{I}$ is split injective; hence the augmented complex $\mathcal{I} \to \mathcal{C}^\bullet(\mathcal{U}, \mathcal{I})$ is a direct summand of the homotopically trivial complex $\mathcal{T}\mathcal{I} \to \mathcal{C}^\bullet(\mathcal{U}, \mathcal{T}\mathcal{I})$, and (ii) follows. \hfill $\Box$

Notice now that the schemes $\mathcal{U}_n$ are quasi-affine for every $n \in \mathbb{N}$, hence the functors $\text{qcoh}_{\mathcal{U}_n}$ are well defined as in (10.3.12), and indeed, the rule : $(\mathcal{F}_n \mid n \in \mathbb{N}) \mapsto (\text{qcoh}_{\mathcal{U}_n}\mathcal{F}_n \mid n \in \mathbb{N})$ yields a functor:

$$\text{qcoh}_{\mathcal{U}_n} : \mathcal{O}_{\mathcal{U}_n}\text{-Mod} \to \mathcal{O}_{\mathcal{U}_n}\text{-Mod}.$$ 

This suggests to introduce a quasi-coherent cosimplicial Čech $\mathcal{O}_X$-module:

$$\mathcal{q}\mathcal{C}^\bullet(\mathcal{U}, \mathcal{F}) := \pi_\ast \circ \text{qcoh}_{\mathcal{U}_n} \circ \pi^*\mathcal{F}$$

for every $\mathcal{O}_X$-module $\mathcal{F}$ (regarded as a constant cosimplicial module in the usual way). More plainly, this is the cosimplicial $\mathcal{O}_X$-module such that :

$$\mathcal{q}\mathcal{C}^n(\mathcal{U}, \mathcal{F}) := \pi_\ast \circ \text{qcoh}_{\mathcal{U}_n} \circ \pi^*\mathcal{F} \quad \text{for every } n \in \mathbb{N}.$$ 

According to [44, Ch.I, Cor.9.2.2], the $\mathcal{O}_X$-modules $\mathcal{q}\mathcal{C}^n(\mathcal{U}, \mathcal{F})$ are quasi-coherent for all $n \in \mathbb{N}$. Finally, we define the functor :

$$\text{qcoh}_X : \mathcal{O}_X\text{-Mod} \to \mathcal{O}_X\text{-Mod}_{\text{qcoh}} \quad \mathcal{F} \mapsto \text{Equal}(\mathcal{q}\mathcal{C}^0(\mathcal{U}, \mathcal{F}) \xrightarrow{\partial^0} \mathcal{q}\mathcal{C}^1(\mathcal{U}, \mathcal{F}))$$

**Proposition 10.3.16.** (i) In the situation of (10.3.13), the functor $\text{qcoh}_X$ is right adjoint to $\iota_X$.

(ii) Let $Y$ be any other quasi-compact and quasi-separated scheme, $f : X \to Y$ any morphism. Then the induced diagram of functors:

$$\begin{array}{ccc}
\mathcal{O}_X\text{-Mod} & \xrightarrow{f_*} & \mathcal{O}_Y\text{-Mod} \\
\text{qcoh}_X \downarrow & & \downarrow \text{qcoh}_Y \\
\mathcal{O}_X\text{-Mod}_{\text{qcoh}} & \xrightarrow{f_*} & \mathcal{O}_Y\text{-Mod}_{\text{qcoh}}
\end{array}$$

commutes up to a natural isomorphism of functors.

**Proof.** For every $n \in \mathbb{N}$ and every $\mathcal{O}_{\mathcal{U}_n}$-module $\mathcal{H}$, the counit of the adjunction yields a natural map of $\mathcal{O}_{\mathcal{U}_n}$-modules: $\text{qcoh}_{\mathcal{U}_n}\mathcal{H} \to \mathcal{H}$. Taking $\mathcal{H}$ to be $\pi_\ast\mathcal{F}$ on $\mathcal{U}_n$ (for a given $\mathcal{O}_X$-module $\mathcal{F}$), these maps assemble to a morphism of cosimplicial $\mathcal{O}_X$-modules :

(10.3.17) $$\mathcal{q}\mathcal{C}^\bullet(\mathcal{U}, \mathcal{F}) \to \mathcal{C}^\bullet(\mathcal{U}, \mathcal{F})$$
and it is clear that (10.3.17) is an isomorphism whenever \( \mathcal{F} \) is quasi-coherent. Let now \( \varphi : \mathcal{G} \to \mathcal{F} \) be a map of \( \mathcal{O}_X \)-modules, with \( \mathcal{G} \) quasi-coherent; after applying the natural transformation (10.3.17) and forming equalizers, we obtain a commutative diagram:

\[
\begin{array}{ccc}
\text{qcoh}_X \mathcal{G} & \xrightarrow{\sim} & \mathcal{G} \\
\text{qcoh}_X \varphi \downarrow & & \downarrow \varphi \\
\text{qcoh}_X \mathcal{F} & \xrightarrow{\sim} & \mathcal{F}
\end{array}
\]

from which we see that the rule: \( \varphi \mapsto \text{qcoh}_X \varphi \) establishes a natural injection:

(10.3.18) \[ \text{Hom}_{\mathcal{O}_X}(\mathcal{G}, \mathcal{F}) \to \text{Hom}_{\mathcal{O}_X}(\mathcal{G}, \text{qcoh}_X \mathcal{F}) \]

and since \( \text{Hom}_{\mathcal{O}_X}(\mathcal{G}, \mathcal{F}) \tag{10.3.17} \) is an isomorphism of cosimplicial \( \mathcal{O}_X \)-modules, (10.3.18) is actually a bijection, whence (i).

(ii) is obvious, since both \( \text{qcoh}_Y \circ f_* \) and \( f_* \circ \text{qcoh}_X \) are right adjoint to \( f^* \circ \iota_Y = \iota_X \circ f^* \).

10.3.19. In the situation of (10.3.13), the functor \( \text{qcoh}_X \) is left exact, since it is a right adjoint, hence it gives rise to a left derived functor:

\[ \text{Rqcoh}_X : \text{D}^+(\mathcal{O}_X\text{-Mod}) \to \text{D}^+(\mathcal{O}_X\text{-Mod}_{\text{qcoh}}). \]

**Proposition 10.3.20.** Let \( X \) be a quasi-compact and quasi-separated scheme. Then:

(i) \( \text{Rqcoh}_X \) is right adjoint to \( \text{Ri}_X \).

(ii) Suppose moreover, that \( X \) is semi-separated, i.e. such that the intersection of any two affine open subsets of \( X \), is still affine. Then the unit of the adjunction \( (\text{Ri}_X, \text{Rqcoh}_X) \) is an isomorphism of functors.

**Proof.** (i): The exactness of the functor \( \iota_X \) implies that \( \text{qcoh}_X \) preserves injectives; the assertion is a formal consequence: the details shall be left to the reader.

(ii): Let \( \mathcal{F}^\bullet \) be any complex of quasi-coherent \( \mathcal{O}_X \)-modules; we have to show that the natural map \( \mathcal{F}^\bullet \to \text{Rqcoh}_X \mathcal{F}^\bullet \) is an isomorphism. Using a Cartan-Eilenberg resolution \( \mathcal{F}^\bullet \xrightarrow{\sim} \mathcal{J}^\bullet \) we deduce a spectral sequence ([125, §5.7])

\[ E_1^{pq} := \text{R}^p \text{qcoh}_X H^q \mathcal{F}^\bullet \Rightarrow \text{R}^{p+q} \text{qcoh}_X \mathcal{F}^\bullet \]

which easily reduces to checking the assertion for the cohomology of \( \mathcal{F}^\bullet \), so we may assume from start that \( \mathcal{F}^\bullet \) is a single \( \mathcal{O}_X \)-module placed in degree zero. Let us then choose an injective resolution \( \mathcal{F}^\bullet \xrightarrow{\sim} \mathcal{J}^\bullet \) (that is, in the category of all \( \mathcal{O}_X \)-modules); we have to show that \( H^p \text{qcoh}_X \mathcal{J}^\bullet = 0 \) for \( p > 0 \). We deal first with the following special case:

**Claim 10.3.21.** Assertion (i) holds if \( X \) is affine.

**Proof of the claim.** Indeed, in this case, the chosen injective resolution of \( \mathcal{F} \) yields a long exact sequence \( 0 \to \mathcal{F}(X) \to \mathcal{J}^\bullet(X) \), and therefore a resolution \( \text{qcoh}_X \mathcal{F} := \mathcal{F}(X)^\sim \to \text{qcoh}_X \mathcal{J}^\bullet := \mathcal{J}^\bullet(X)^\sim \). \( \Box \)

For the general case, we choose any affine covering \( \mathcal{U} \) of \( X \) and we consider the cochain complex of cosimplicial complexes \( q^\mathcal{E}^\bullet(\mathcal{U}, \mathcal{J}^\bullet) \).

**Claim 10.3.22.** For any injective \( \mathcal{O}_X \)-module \( \mathcal{I} \), the augmented complex:

\[ \text{qcoh}_X \mathcal{I} \to q^\mathcal{E}^\bullet(\mathcal{U}, \mathcal{I}) \]

is homotopically trivial.

**Proof of the claim.** It follows easily from proposition [10.3.16](ii) that

\[ q^\mathcal{E}^\bullet(\mathcal{U}, \mathcal{I}) \simeq \text{qcoh}_X (\mathcal{E}^\bullet(\mathcal{U}, \mathcal{F})) \]

for any \( \mathcal{O}_X \)-module \( \mathcal{F} \). Then the claim follows from lemma [10.3.15](ii). \( \Box \)
We have a spectral sequence:

\[ E_1^{pq} := H^p q^* \mathcal{F}^q(\mathcal{U}, \mathcal{I}) \Rightarrow \text{Tot}^{p+q}(q^* \mathcal{F}(\mathcal{U}, \mathcal{I})) \]

and it follows from claim 10.3.22 that \( E_1^{pq} = 0 \) whenever \( p > 0 \), and \( E_0^{0q} = \text{qcoh}_{\mathcal{X}} \mathcal{I}^q \) for every \( q \in \mathbb{N} \), so the spectral sequence \( E^{**} \) degenerates, and we deduce a quasi-isomorphism

\[ (10.3.23) \quad \text{qcoh}_{\mathcal{X}} \mathcal{F}^* \sim \text{Tot}^* (q^* \mathcal{F}(\mathcal{U}, \mathcal{I}^*)) . \]

On the other hand, for fixed \( q \in \mathbb{N} \), we have \( q^* \mathcal{F}(\mathcal{U}, \mathcal{I}^*) = \pi_n q^* \text{coh}_{\mathcal{U}_n} \mathcal{I}^* \); since \( \mathcal{X} \) is semi-separated, \( \mathcal{U}_n \) is affine, so the complex \( q^* \text{coh}_{\mathcal{U}_n} \mathcal{I}^* \) is a resolution of \( \text{qcoh}_{\mathcal{U}_n} \mathcal{I}^* = \mathcal{I}^* \mathcal{F} \), by claim 10.3.21. Furthermore, \( \pi_n : \mathcal{U}_n \rightarrow X \) is an affine morphism, so \( q^* (\mathcal{U}, \mathcal{I}^*) \) is a resolution of \( \pi_n^* \mathcal{F} \). Summing up, we see that \( \text{Tot}^* (q^* \mathcal{F}(\mathcal{U}, \mathcal{I}^*)) \) is quasi-isomorphic to \( \mathcal{F}(\mathcal{U}, \mathcal{F}) \), which is a resolution by lemma 10.3.15(i). Combining with (10.3.23), we deduce (ii).

**Theorem 10.3.24.** Let \( X \) be a quasi-compact semi-separated scheme. The forgetful functor

\[ R\text{L}_X : D^+ (\mathcal{O}_X \cdot \text{Mod}_{\text{qcoh}}) \rightarrow D^+ (\mathcal{O}_X \cdot \text{Mod})_{\text{qcoh}} \]

is an equivalence of categories, whose quasi-inverse is the restriction of \( R\text{qcoh}_X \).

**Proof.** By proposition 10.3.20(ii) we know already that the composition \( R\text{qcoh}_X \circ R\text{L}_X \) is a self-equivalence of \( D^+ (\mathcal{O}_X \cdot \text{Mod}_{\text{qcoh}}) \). For every complex \( \mathcal{F}^* \) in \( D^+ (\mathcal{O}_X \cdot \text{Mod}) \), the counit of adjunction \( \varepsilon_{\mathcal{F}^*} : R\text{L}_X \circ R\text{qcoh}_X \mathcal{F}^* \rightarrow \mathcal{F}^* \) can be described as follows. Pick an injective resolution \( \alpha : \mathcal{F}^* \rightarrow \mathcal{F}^* ; \) then \( \varepsilon_{\mathcal{F}^*} \) is defined by the diagram:

\[ \begin{array}{ccc}
\text{qcoh}_X \mathcal{F}^* & \xrightarrow{\varepsilon} & \mathcal{F}^* \\
\downarrow & & \downarrow \\
\mathcal{F}^* & \xleftarrow{\alpha} & \mathcal{F}^* 
\end{array} \]

where, for each \( n \in \mathbb{N} \), the map \( \varepsilon^n : \text{qcoh}_X \mathcal{F}^n \rightarrow \mathcal{F}^n \) is the counit of the adjoint pair \((\iota_X, \text{qcoh}_X)\). It suffices then to show that \( \varepsilon^* \) is a quasi-isomorphism, when \( \mathcal{F}^* \) is an object of \( D^+ (\mathcal{O}_X \cdot \text{Mod})_{\text{qcoh}} \). To this aim, we may further choose \( \mathcal{F}^* \) of the form \( \text{Tot}^*(\mathcal{F}^{**}) \), where \( \mathcal{F}^{**} \) is a Cartan-Eilenberg resolution of \( \mathcal{F}^* \) (see [123, §5.7]). We then deduce a spectral sequence:

\[ E_2^{pq} := R^p \text{qcoh}_X H^q \mathcal{F}^* \Rightarrow R^{p+q} \text{qcoh}_X \mathcal{F}^* . \]

The double complex \( \mathcal{F}^{**} \) also gives rise to a similar spectral sequence \( F_2^{pq} \), and clearly \( F_2^{pq} = 0 \) whenever \( p > 0 \), and \( F_0^{0q} = H^q \mathcal{F}^* \). Furthermore, the counit of adjunction \( \varepsilon^{**} : \text{qcoh}_X \mathcal{F}^{**} \rightarrow \mathcal{F}^{**} \) induces a morphism of spectral sequences \( \omega^{pq} : E_2^{pq} \rightarrow F_2^{pq} \). Consequently, in order to prove that the \( \varepsilon_{\mathcal{F}^*} \) is a quasi-isomorphism, it suffices to show that \( \omega^{pq} \) is an isomorphism for every \( p, q \in \mathbb{N} \). This comes down to the assertion that \( R^p \text{qcoh}_X \mathcal{F} = 0 \) for every quasi-coherent \( \mathcal{O}_X \)-module \( \mathcal{F} \), and every \( p > 0 \). However, we have \( \mathcal{F} = R\text{L}_X \mathcal{F} \), so that \( R\text{qcoh}_X \mathcal{F} = R\text{qcoh}_X \circ R\text{L}_X \mathcal{F} \), and then the contention follows from proposition 10.3.20(ii).

**Lemma 10.3.25.** Let \( X \) be a quasi-compact and quasi-separated scheme, \( U \) a quasi-compact open subset of \( X \), \( \mathcal{H} \) a quasi-coherent \( \mathcal{O}_X \)-module, \( \mathcal{G} \) a finitely presented quasi-coherent \( \mathcal{O}_U \)-module, and \( \varphi : \mathcal{G} \rightarrow \mathcal{H}|_U \) an \( \mathcal{O}_U \)-linear map. Then:

(i) There exist a finitely presented quasi-coherent \( \mathcal{O}_X \)-module \( \mathcal{F} \) on \( X \), and an \( \mathcal{O}_X \)-linear map \( \psi : \mathcal{F} \rightarrow \mathcal{H} \), such that \( \mathcal{F}|_U = \mathcal{G} \) and \( \psi|_U = \varphi \).

(ii) Especially, every finitely presented quasi-coherent \( \mathcal{O}_U \)-module extends to a finitely presented quasi-coherent \( \mathcal{O}_X \)-module.

**Proof.** (i): Let \( (V_i \mid i = 1, \ldots, n) \) be a finite affine open covering of \( X \). For every \( i = 0, \ldots, n \), let us set \( U_i := U \cup V_i \cup \cdots \cup V_i \); we construct, by induction on \( i \), a family of finitely presented quasi-coherent \( \mathcal{O}_{U_i} \)-modules \( \mathcal{F}_i \), and morphisms \( \psi_i : \mathcal{F}_i \rightarrow \mathcal{H}|_{U_i} \) such that \( \mathcal{F}_{i+1}|_{U_i} = \mathcal{F}_i \) and \( \psi_{i+1}|_{U_{i+1}} = \psi_i \) for every \( i < n \). For \( i = 0 \) we have \( U_0 = U \), and we set \( \mathcal{F}_0 := \mathcal{G} \), \( \psi_0 := \varphi \). Suppose that \( \mathcal{F}_i \) and \( \psi_i \) have already been given. Since \( X \) is quasi-separated, the same holds
for $U_{i+1}$, and the immersion $j : U_i \to U_{i+1}$ is quasi-compact; it follows that $j_*\mathcal{F}_i$ and $j_*\mathcal{H}_{U_i}$ are quasi-coherent $\mathcal{O}_{U_i}$-modules (\cite[Ch.I, Prop.9.4.2(i)]{44}). We let

$$\mathcal{M} := j_*\mathcal{F}_i \times_{j_*\mathcal{H}_{U_i}} \mathcal{H}_{U_{i+1}}.$$ 

Then $\mathcal{M}$ is a quasi-coherent $\mathcal{O}_{U_{i+1}}$-module admitting a map $\mathcal{M} \to \mathcal{H}_{U_{i+1}}$, and such that $\mathcal{M}_{U_i} = \mathcal{F}_i$. We can then find a filtered family of quasi-coherent $\mathcal{O}_{V_{i+1}}$-modules of finite presentation $(\mathcal{M}_\lambda \mid \lambda \in \Lambda)$, whose colimit is $\mathcal{M}_{|V_{i+1}}$. Since $\mathcal{F}_i$ is finitely presented and $U_i \cap V_{i+1}$ is quasi-compact, there exists $\lambda \in \Lambda$ such that the induced morphism $\beta : \mathcal{M}_{X(U_i \cap V_{i+1})} \to \mathcal{F}_{i(U_i \cap V_{i+1})}$ is an isomorphism. We can thus define $\mathcal{F}_{i+1}$ by gluing $\mathcal{F}_i$ and $\mathcal{M}_\lambda$ along $\beta$; likewise, $\psi_i$ and the induced map $\mathcal{M}_\lambda \to \mathcal{M}_{V_{i+1}} \to \mathcal{H}_{V_{i+1}}$ glue to a map $\psi_{i+1}$ as required. Clearly the pair $(\mathcal{F}_n \coloneqq \mathcal{F}_n, \psi_n \coloneqq \psi_n)$ is the sought extension of $(\mathcal{G}, \varphi)$.

(ii): Let $0_X$ be the final object in the category of $\mathcal{O}_X$-modules; to extend a finitely presented quasi-coherent $\mathcal{O}_U$-module $\mathcal{G}$, it suffices to apply (i) to the unique map $\mathcal{G} \to 0_{X|U}$. □

For ease of reference, we point out the following simple consequence of lemma \ref{10.3.25}

**Corollary 10.3.26.** Let $U$ be a quasi-affine scheme, $\mathcal{E}$ a locally free $\mathcal{O}_U$-module of finite type. Then we may find integers $n, m \in \mathbb{N}$ and a left exact sequence of $\mathcal{O}_U$-modules:

$$0 \to \mathcal{E} \to \mathcal{O}_U^{\oplus m} \to \mathcal{O}_U^{\oplus n}.$$ 

**Proof.** Set $\mathcal{E}' := \mathcal{H}om_{\mathcal{O}_U}(\mathcal{E}, \mathcal{O}_U)$, and notice that $\mathcal{E}'$ is a locally free $\mathcal{O}_U$-module of finite type, especially it is quasi-coherent and of finite presentation. By assumption, $U$ is a quasi-compact open subset of an affine scheme $X$, hence $\mathcal{E}'$ extends to a quasi-coherent $\mathcal{O}_X$-module $\mathcal{F}$ of finite presentation (lemma \ref{10.3.25}(ii)); we have $\mathcal{F} = F'$, for some finitely presented $\mathcal{A}$-module $F'$; we choose a presentation of $F'$ as the cokernel of an $\mathcal{A}$-linear map $A^{\oplus m} \to A^{\oplus n}$, for some $m, n \in \mathbb{N}$, whence a presentation of $\mathcal{E}'$ as the cokernel of a morphism $\mathcal{O}_U^{\oplus m} \to \mathcal{O}_U^{\oplus n}$, and after dualizing again, we get the sought left exact sequence. □

10.3.27. Let $X$ be a scheme; for any quasi-coherent $\mathcal{O}_X$-module $\mathcal{F}$, we consider the full subcategory $C/\mathcal{F}$ of the category $\mathcal{O}_X$-$\mathcal{M}od_{qcoh}/\mathcal{F}$ whose objects are all the maps $\varphi : \mathcal{G} \to \mathcal{F}$ such that $\mathcal{G}$ is a finitely presented $\mathcal{O}_X$-module (notation of \ref{1.1.24}). We denote by

$$t_\mathcal{F} : C/\mathcal{F} \to \mathcal{O}_X$-$\mathcal{M}od_{qcoh}$ 

the restriction of the source functor. The first observation is:

**Lemma 10.3.28.** $C/\mathcal{F}$ is a filtered category.

**Proof.** Since $C/\mathcal{F}$ always admits the initial object $0 \to \mathcal{F}$, its set of objects is non-empty. Thus, according to remark \ref{1.2.21}(i), it suffices to check that $C/\mathcal{F}$ is directed and satisfies the coequalizing condition. However, say that $\varphi_i : \mathcal{G}_i \to \mathcal{F}$ ($i = 1, 2$) are any two objects of $C/\mathcal{F}$; then obviously there is a unique morphism $\mathcal{G}_1 \oplus \mathcal{G}_2 \to \mathcal{F}$ whose restriction to $\mathcal{G}_i$ agrees with $\varphi_i$ for $i = 1, 2$.

Next, suppose that $\beta_1, \beta_2 : \mathcal{G} \to \mathcal{G}'$ are two morphisms of finitely presented $\mathcal{O}_X$-modules and $\psi : \mathcal{G}' \to \mathcal{F}$ an object of $C/\mathcal{F}$ such that $\psi \circ \beta_1 = \psi \circ \beta_2$. Set $\mathcal{G}'' := \text{Coker} (\beta_1 - \beta_2)$; it is easily seen that $\mathcal{G}''$ is a finitely presented $\mathcal{O}_X$-module and $\psi$ factors through a unique morphism $\mathcal{G}'' \to \mathcal{F}$, whence the lemma. □

**Proposition 10.3.29.** With the notation of \ref{10.3.27}, suppose that $X$ is quasi-compact and quasi-separated. Then, for any quasi-coherent $\mathcal{O}_X$-module $\mathcal{F}$, the induced map

$$\colim \ t_\mathcal{F} \to \mathcal{F}$$ 

is an isomorphism.
Proof. Let \( \mathcal{F}' \) be such colimit; clearly there is a natural map \( \mathcal{F}' \to \mathcal{F} \), and we have to show that it is an isomorphism. To this aim, we can check on the stalk over the points \( x \in X \), hence we come down to showing:

**Claim 10.3.30.** Let \( \mathcal{F} \) be any quasi-coherent \( \mathcal{O}_X \)-module. Then:

(i) For every \( s \in \mathcal{F}_x \) there exist a finitely presented quasi-coherent \( \mathcal{O}_X \)-module \( \mathcal{G} \), a morphism \( \varphi : \mathcal{G} \to \mathcal{F} \) and \( t \in \mathcal{G}_x \) such that \( \varphi_x(t) = s \).

(ii) For every map \( \varphi : \mathcal{G} \to \mathcal{F} \) with \( \mathcal{G} \) finitely presented and quasi-coherent, and every \( s \in \ker \varphi \), there exists a commutative diagram of quasi-coherent \( \mathcal{O}_X \)-modules:

\[
\begin{array}{ccc}
\mathcal{G} & \xrightarrow{\varphi} & \mathcal{F} \\
\downarrow{\psi} & & \downarrow{\psi} \\
\mathcal{H} & \xrightarrow{\varphi} & \mathcal{F}
\end{array}
\]

with \( \mathcal{H} \) finitely presented and \( \psi_x(s) = 0 \).

**Proof of the claim.** (i): Let \( U \subset X \) be an open subset such that \( s \) extends to a section \( s_U \in \mathcal{F}(U) \); we deduce a map \( \varphi_U : \mathcal{G}_U \to \mathcal{F}_U \) by the rule \( a \mapsto a \cdot s_U \) for every \( a \in \mathcal{G}(U) \). In view of lemma \([10.3.25]^{(i)}\), the pair \((\varphi_U, \mathcal{G}_U)\) extends to a pair \((\varphi, \mathcal{G})\) with the sought properties.

(ii): We apply (i) to the quasi-coherent \( \mathcal{O}_X \)-module \( \ker \varphi \), to find a finitely presented quasi-coherent \( \mathcal{O}_X \)-module \( \mathcal{G}' \), a morphism \( \beta : \mathcal{G}' \to \ker \varphi \) and \( t \in \mathcal{H}_x \) such that \( \beta_x(t) = s \). Then we let \( \psi : \mathcal{G} \to \mathcal{H} := \text{Coker}(\beta) \to \ker \varphi \to \mathcal{G} \) be the natural map. By construction, \( \mathcal{H} \) is finitely presented, \( \psi_x(s) = 0 \) and clearly \( \psi \) factors through \( \psi \).

**10.3.31.** Let \( X \) be a coherent scheme, \( U \subset X \) a quasi-compact open subset, \( a, b \in \mathbb{Z} \) any two integers with \( a \leq b \), and \( \mathcal{H}^* \) any object of \( D^{[a,b]}(\mathcal{O}_X, \text{Mod})_{\text{coh}} \) such that \( \mathcal{H}^*_U \) lies in \( D^{[a,b]}(\mathcal{O}_U, \text{Mod})_{\text{coh}} \). Let also \( \mathcal{I}_i \subset H^i \mathcal{H}^* \) be a quasi-coherent \( \mathcal{O}_X \)-submodule of finite type, for every \( i = a, \ldots, b \).

**Proposition 10.3.32.** In the situation of \([10.3.31]^{(i)}\), the following holds:

(i) There exists an object \( \mathcal{G}^* \) of \( D^{[a,b]}(\mathcal{O}_X, \text{Mod})_{\text{coh}} \) with a morphism \( \varphi^* : \mathcal{G}^* \to \mathcal{H}^* \) in \( D(\mathcal{O}_X, \text{Mod})_{\text{coh}} \) such that:

(a) \( \varphi^*_U \) is an isomorphism.

(b) \( \mathcal{I}_i \subset \text{Im} H^i \varphi^* \) for every \( i = a, \ldots, b \).

(ii) If \( X \) is noetherian, we can find \( \varphi^* \) as in (i) such that \( H^i \varphi^* \) is a monomorphism, for every \( i = a, \ldots, b \).

**Proof.** To start out, for any quasi-coherent \( \mathcal{O}_X \)-module \( \mathcal{F} \) such that \( \mathcal{F}_U \) is a coherent \( \mathcal{O}_U \)-module, define the category \( C/\mathcal{F} \) as in \([10.3.27]^{(i)}\), and consider the full subcategory \( C'/\mathcal{F} \) (resp. \( C''/\mathcal{F} \)) of \( C/\mathcal{F} \) whose objects are all the maps \( \varphi : \mathcal{G} \to \mathcal{F} \) such that \( \varphi_U \) is an isomorphism (resp. an epimorphism).

**Claim 10.3.33.** \( C'/\mathcal{F} \) and \( C''/\mathcal{F} \) are filtered categories.

**Proof of the claim.** The proof of lemma \([10.3.28]^{(i)}\) applies verbatim to show that both \( C'/\mathcal{F} \) and \( C''/\mathcal{F} \) satisfy the coequalizing condition of definition \([1.2.19]^{(i)}\), and it also proves that \( C''/\mathcal{F} \) is directed. Moreover, lemma \([10.3.25]^{(i)}\) says that the sets of objects of these two categories are non-empty, which already implies that \( C''/\mathcal{F} \) is filtered, by remark \([1.2.21]^{(i)}\). By the same token, it remains only to check that \( C'/\mathcal{F} \) satisfies the coequalizing condition. Hence, let \( \varphi_i : \mathcal{G}_i \to \mathcal{F} \) (i = 1, 2) be any two objects of \( C'/\mathcal{F} \), and set \( \mathcal{G}' := \mathcal{G}_1 \times_{\mathcal{F}} \mathcal{G}_2 \); then \( \mathcal{G}' \) is a quasi-coherent \( \mathcal{O}_X \)-module, and \( \mathcal{G}'_U \) is isomorphic to \( \mathcal{F}_U \), especially it is coherent. Then pick any object \( \psi : \mathcal{G}'' \to \mathcal{G}' \) of the category \( C''/\mathcal{F} \), and denote by \( \psi_1 : \mathcal{G}'' \to \mathcal{G}_1 \) (i = 1, 2) the two morphisms induced by \( \psi \); by construction we have \( \varphi_1 \circ \psi_1 = \varphi_2 \circ \psi_2 \). Hence, set \( \mathcal{G} := \mathcal{G}_1 \amalg \mathcal{G}_2 ;\)
we get a unique morphism \( \varphi : \mathcal{G} \to \mathcal{F} \) such that both \( \varphi_1 \) and \( \varphi_2 \) factor through \( \varphi \) and \( \varphi|_U \) is an isomorphism. Since \( \mathcal{G} \) is a finitely presented \( \mathcal{O}_X \)-module, we are done.

\( \boxdot \)

**Claim 10.3.34.** With the foregoing notation, the following holds:

(i) \( C''/\mathcal{F} \) is a cofinal subcategory of \( C/\mathcal{F} \).

(ii) For every object \( K^\bullet \) of \( D^b(\mathcal{O}_X\text{-Mod})_{\text{coh}} \) and every \( c \in \mathbb{Z} \), the natural map

\[
\colim_{C/\mathcal{F}} \text{Hom}_D(\mathcal{O}_X\text{-Mod})(K^\bullet, \mathcal{I}_c) \to \text{Hom}_D(\mathcal{O}_X\text{-Mod})(K^\bullet, \mathcal{F}[c])
\]

is an isomorphism (notation of (10.3.27)).

**Proof of the claim.** (i): Since \( U \) is quasi-compact, it is easily seen that \( C''/\mathcal{F} \) is cofinal in \( C/\mathcal{F} \), so we are reduced to checking that \( C'/\mathcal{F} \) is cofinal in \( C''/\mathcal{F} \). Hence, let \( \psi : \mathcal{G}' \to \mathcal{F} \) be any object of \( C''/\mathcal{F} \); since \( \mathcal{O}_X \) is coherent, \( \mathcal{K} := \text{Ker} \psi|_U \) is a coherent \( \mathcal{O}_U \)-module, therefore we may extend \( \mathcal{K} \) to a coherent \( \mathcal{O}_X \)-module \( \mathcal{K}' \) and the identity map of \( \mathcal{K} \) to a morphism \( \psi' : \mathcal{K}' \to \text{Ker} \psi \) of \( \mathcal{O}_X \)-modules (lemma [10.3.25](i)). Set \( \mathcal{G} := \mathcal{G}'/\psi'((\mathcal{K}')') \); the induced map \( \mathcal{G} \to \mathcal{F} \) is an object of \( C/\mathcal{F} \), whence the contention.

(ii): We have two spectral sequences

\[
E_2^{pq} := \colim_{C/\mathcal{F}} R^p \Gamma \circ R^q \mathcal{H}om_{\mathcal{O}_X}(K^\bullet, \mathcal{I}_c) \Rightarrow \colim_{C/\mathcal{F}} \text{Hom}_D(\mathcal{O}_X\text{-Mod})(K^\bullet, \mathcal{I}_c[p+q])
\]

and a morphism of spectral sequences \( E^{pq}_{2\bullet} \to F^{pq}_{2\bullet} \), such that (10.3.35) is a isomorphism of filtered abelian groups, for the two finite filtrations induced by these spectral sequences on their abutments. Since the functors \( R^p \Gamma \) commute with filtered colimits, we deduce that it suffices to show that the natural morphism

\[
\colim_{C/\mathcal{F}} R^q \mathcal{H}om_{\mathcal{O}_X}(K^\bullet, \mathcal{I}_c) \to R^q \mathcal{H}om_{\mathcal{O}_X}(K^\bullet, \mathcal{F}[c])
\]

is an isomorphism for every \( q \in \mathbb{Z} \). Then, a standard d\'evissage argument further reduces to the case where \( K^\bullet \) is concentrated in a single degree, so we come down to checking that the functor \( \mathcal{F} \to R^q \mathcal{H}om_{\mathcal{O}_X}(\mathcal{G}, \mathcal{F}) \) commutes with filtered colimits of quasi-coherent \( \mathcal{O}_X \)-modules, for every such \( \mathcal{O}_X \)-module \( \mathcal{G} \) and every \( q \in \mathbb{Z} \). To this aim we may assume that \( X \) is affine, in which case – since \( \mathcal{O}_X \) is coherent – \( \mathcal{G} \) admits a resolution \( \mathcal{L}^\bullet \) consisting of free \( \mathcal{O}_X \)-modules of finite rank; the latter are acyclic for the functor \( \mathcal{H}om_{\mathcal{O}_X} \), so we are left with the assertion that the functor \( \mathcal{F} \to H^q \mathcal{H}om_{\mathcal{O}_X}(\mathcal{L}^\bullet, \mathcal{F}) \) commutes with filtered colimits, which is clear. \( \boxdot \)

**Claim 10.3.36.** The proposition holds if \( a = b \).

**Proof of the claim.** From proposition [10.3.29] and claim [10.3.34](i) we deduce that, for every \( x \in X \) we may find an object \( \varphi : \mathcal{G} \to H^a \mathcal{H} \) such that \( \mathcal{F}_{a,x} \subset \text{Im} \varphi_x \), and therefore \( \mathcal{F}_{a|U_x} \subset \text{Im} \varphi|_{U_x} \) for some open neighborhood \( U_x \) of \( x \) in \( X \). Since \( X \) is quasi-compact and \( C/\mathcal{F} \) is filtered, assertion (i) follows easily. Next, suppose that a morphism \( \varphi : \mathcal{G} \to H^a \mathcal{H} \) has already been exhibited that fulfills conditions (i.a) and (i.b), and set \( \mathcal{G}' := \text{Im} \varphi ; \) to show assertion (ii), it suffices to remark that if \( X \) is noetherian, \( \mathcal{G}' \) is still a coherent \( \mathcal{O}_X \)-module.

We proceed now by induction on \( b - a \), the case where \( a = b \) having been covered by claim [10.3.36]. Thus, suppose that \( a < b \), and that the proposition is already known for every object of \( D^{[a+1,b]}(\mathcal{O}_X\text{-Mod})_{\text{coh}} \) fulfilling the stated condition. We have a distinguished triangle

\[
\mathcal{F}[-a] \to \mathcal{H} \to \tau^{2a+1} \mathcal{H}^\bullet \xrightarrow{\varphi^\bullet} \mathcal{F}[1-a] \quad \text{with} \quad \mathcal{F} := H^a \mathcal{H}^\bullet
\]

in \( D(\mathcal{O}_X\text{-Mod})_{\text{coh}} \) (where \( \tau^{2a+1} \) denotes the truncation functor : see remark [7.3.14](iv)). By inductive assumption, we may find an object \( \mathcal{G}^\bullet \) of \( D^{[a+1,b]}(\mathcal{O}_X\text{-Mod})_{\text{coh}} \) and a morphism \( \varphi^\bullet : \mathcal{G}^\bullet \to \tau^{2a+1} \mathcal{H}^\bullet \) in \( D(\mathcal{O}_X\text{-Mod})_{\text{coh}} \) which restricts to an isomorphism on \( U \) and such
that $\mathcal{F}_i \subset \text{Im } H^i \varphi^\bullet$ for every $i = a + 1, \ldots, b$. There follows a morphism of distinguished triangles:

$$
\begin{array}{c}
\mathcal{F}[-a] \longrightarrow \mathcal{H}^\bullet \longrightarrow \mathcal{G}^\bullet \longrightarrow \mathcal{F} [1 - a] \\
\bigg\| \bigg\| \bigg\|
\mathcal{F}[-a] \longrightarrow \mathcal{H}^\bullet \longrightarrow \tau^{\geq a+1} \mathcal{H}^\bullet \longrightarrow \mathcal{F} [1 - a]
\end{array}
$$

for some object $\mathcal{H}^\bullet$ of $D^{[a,b]}(\mathcal{O}_X-\text{Mod})_{\text{coh}}$, and clearly $\beta^\bullet$ restricts to an isomorphism on $U$ and $H^a \beta^\bullet$ is an isomorphism. We may then replace $\mathcal{H}^\bullet$ by $\mathcal{H}^\bullet$, and assume that $\tau^{\geq a+1} \mathcal{H}^\bullet$ lies in $D^{[a+1,b]}(\mathcal{O}_X-\text{Mod})_{\text{coh}}$.

By claim 10.3.34, we may find an object $\psi : \mathcal{G} \to \mathcal{F}$ of $\mathcal{C} / \mathcal{F}$ such that $\alpha^\bullet$ factors through $\psi[1 - a]$ and a morphism $\omega^\bullet : \tau^{\geq a+1} \mathcal{H}^\bullet \to \mathcal{G}[1 - a]$ in $D(\mathcal{O}_X-\text{Mod})_{\text{coh}}$. Moreover, by claim 10.3.36, we may assume that $\mathcal{F}_a \subset \text{Im } \psi$, and also that $\psi$ is a monomorphism, if $X$ is noetherian. Then $\text{Cone } \omega^\bullet[-1]$ lies in $D^{[a,b]}(\mathcal{O}_X-\text{Mod})_{\text{coh}}$, and the induced morphism $\text{Cone } \omega^\bullet[-1] \to \mathcal{H}^\bullet$ will do.

**Corollary 10.3.37.** Let $X$ be a coherent scheme, $U \subset X$ a quasi-compact open subset. Then the induced functor

$$D^{[a,b]}(\mathcal{O}_X-\text{Mod})_{\text{coh}} \to D^{[a,b]}(\mathcal{O}_U-\text{Mod})_{\text{coh}}$$

is essentially surjective, for every $a, b \in \mathbb{Z}$ with $a \leq b$.

**Proof.** Let $j : U \to X$ be the open immersion, $\mathcal{F}^\bullet$ an object of $D^{[a,b]}(\mathcal{O}_U-\text{Mod})_{\text{coh}}$. By [46 Ch.III, Prop.1.4.10, Cor.1.4.12] and a standard spectral sequence argument, it is easily seen that

$$\mathcal{H}^\bullet := \tau^{\geq a} \circ \tau^{\leq b} Rj_* \mathcal{F}^\bullet$$

lies in $D^{[a,b]}(\mathcal{O}_X-\text{Mod})_{\text{coh}}$ and $\mathcal{H}^\bullet|_U = \mathcal{F}^\bullet$. Then the assertion follows immediately from proposition 10.3.32(i). \qed

### 10.4. Depth and cohomology with supports.

This section introduces and studies local cohomology and the closely related notion of depth, in the context of arbitrary schemes (whereas the usual references restrict to the case of locally noetherian schemes).

#### 10.4.1. To begin with, let $(X, \mathcal{O})$ be any ringed topological space, $i : Z \to X$ a closed immersion, set $U := X \setminus Z$ and denote by $j : U \to X$ the resulting open immersion. One defines the functor

$$\Gamma_Z : \mathcal{A}-\text{Mod} \to \mathcal{A}_Z-\text{Mod} \quad \mathcal{F} \mapsto \text{Ker } (\mathcal{F} \to j_* j^* \mathcal{F})$$

as well as its composition with the global section functor

$$\Gamma_Z : \mathcal{A}-\text{Mod} \to \mathcal{A}(X)-\text{Mod} \quad \mathcal{F} \mapsto \Gamma_X(\mathcal{F}, \Gamma_Z \mathcal{F})$$.

It is clear that $\Gamma_Z$ and $\Gamma_Z$ are left exact functors, hence they give rise to right derived functors

$$R\Gamma_Z : D^+(\mathcal{A}-\text{Mod}) \to D^+(\mathcal{A}_Z-\text{Mod}) \quad R\Gamma_Z : D^+(\mathcal{A}-\text{Mod}) \to D^+(\mathcal{A}(X)-\text{Mod})$$

such that the natural morphism $\Gamma_Z \mathcal{F} \to R^d \Gamma_Z \mathcal{F}$ is an isomorphism, for every $\mathcal{A}$-module $\mathcal{F}$ (and likewise for $R^d \Gamma_Z$). Moreover, suppose that $\mathcal{F} \to \mathcal{F}^\bullet$ is a resolution of $\mathcal{F}$ by a complex of injective $\mathcal{A}$-modules; since injective sheaves are flabby (lemma 10.1.15(v)), we obtain a short exact sequence of complexes

$$0 \to \Gamma_Z \mathcal{F}^\bullet \to \mathcal{F}^\bullet \to j_* j^* \mathcal{F}^\bullet \to 0$$

whence a natural exact sequence of $\mathcal{A}$-modules:

$$0 \to \Gamma_Z \mathcal{F} \to \mathcal{F} \to j_* j^* \mathcal{F} \to R^d \Gamma_Z \mathcal{F} \to 0 \quad \text{for every } \mathcal{A}-\text{module } \mathcal{F}$$
and natural isomorphisms:

\[(10.4.3) \quad R^{q-1} j_* j^* \mathcal{F} \cong R^q \mathcal{F} \quad \text{for all } q > 1.\]

**Lemma 10.4.4.** In the situation of (10.4.1), let \( \mathcal{B} \to \mathcal{A} \) be any morphism of sheaves of rings on \( X \). The following holds:

(i) Every flabby \( \mathcal{A} \)-module is \( \Gamma_Z \)-acyclic.

(ii) The functor \( R^q \mathcal{F} \) commutes with the forgetful functor \( \mathcal{D}^+(\mathcal{A}\text{-Mod}) \to \mathcal{D}^+(\mathcal{B}\text{-Mod}) \).

(iii) Suppose that \( X \) is locally coherent and quasi-separated, and that \( Z \) is a constructible closed subset of \( X \). Then:

(a) Every qc-flabby \( \mathcal{A} \)-module is \( \Gamma_Z \)-acyclic.

(b) For every \( i \in \mathbb{N} \) the functor \( R^i \mathcal{F} \) commutes with filtered colimits of \( \mathcal{A} \)-modules.

**Proof.**

(i): First of all, if \( \mathcal{F} \) is flabby on \( X \), the natural morphism \( \mathcal{F} \to j_* j^* \mathcal{F} \) is obviously an epimorphism; together with (10.4.2), this implies that \( R^1 \Gamma_Z \mathcal{F} = 0 \) when \( \mathcal{F} \) is flabby. Next, (10.4.3), together with the fact that flabby \( \mathcal{A} \)-modules are acyclic for direct image functors such as \( j_* \) (lemma [10.1.5](ii)), implies that \( R^i \Gamma_Z \mathcal{F} = 0 \) also for \( i > 1 \), whence the contention.

Assertion (iii.a) is checked in the same way: first one notices that, under the stated assumptions, the morphism \( \mathcal{F} \to j_* j^* \mathcal{F} \) is an epimorphism also for all qc-flabby sheaves on \( X \), which again gives the vanishing of \( R^i \Gamma_Z \mathcal{F} \); for the higher derived functors one then appeals to (10.4.3) and lemma [10.1.5](iv).

(iii.b): Suppose first that \( i > 1 \); in this case, the assertion follows from (10.4.3) and the following more general:

**Claim 10.4.5.** In the situation of (iii), the functor \( R^i j_* \) commutes with filtered colimits, for every \( i \in \mathbb{N} \).

**Proof of the claim.** The claim can be checked at the stalks at the points \( x \in X \), hence we may assume that \( X \) is quasi-compact, in which case the same holds for \( U \). Now, on the one hand, \( R^i j_* \mathcal{F} \) is the sheaf associated with the presheaf given by the rule: \( U' \mapsto H^i(U \cap U', \mathcal{F}) \) for every open subset \( U' \subset X \), so \( (R^i j_* \mathcal{F})_x \) is also the stalk at \( x \) of this presheaf. On the other hand, \( x \) admits a fundamental system of open neighborhoods consisting of quasi-compact open subsets, and if \( U' \) is such a neighborhood of \( x \), the subset \( U' \cap U \) is also quasi-compact, and the functor \( \mathcal{F} \to H^i(U \cap U', \mathcal{F}) \) commutes with filtered colimits, by proposition [10.1.10](ii). The claim follows by combining these two observations.

In case \( i \leq 1 \), we argue similarly with (10.4.2), which reduces to checking that both functors \( \mathcal{F} \to \mathcal{F}_x \) and \( \mathcal{F} \to (j_*)^* \mathcal{F} \) commute with filtered colimits; this is trivial for the former functor, and for the latter it is a special case of claim [10.4.5].

Lastly, (ii) is an immediate consequence of (i) and remark [7.3.29](iv), since any injective \( \mathcal{A} \)-module is a flabby \( \mathcal{B} \)-module (lemma [10.1.5](v)).

**Proposition 10.4.7.** In the situation of (10.4.1), let \( X' \) be the amalgamated sum in the following cocartesian diagram of topological spaces:

\[
\begin{array}{ccc}
U & \xrightarrow{j} & X \\
\downarrow j & & \downarrow j_1 \\
X & \xrightarrow{j_2} & X'
\end{array}
\]

and let \( \pi : X' \to X \) be the unique continuous map with \( \pi \circ j_i = 1_X \) for \( i = 1, 2 \). We notice:

**Proposition 10.4.7.** In the situation of (10.4.6), let also \( \mathcal{F} \) be any sheaf on \( X \). Then we have:

(i) If \( \mathcal{F} \) is flabby, the same holds for \( \pi^* \mathcal{F} \).

(ii) If moreover \( \mathcal{F} \) is an \( \mathcal{A} \)-module, the following holds:
(a) We have a natural isomorphism in $D^+(\mathcal{A}(X)-\text{Mod})$
\[
R\Gamma\mathcal{F}\oplus R\Gamma_Z\mathcal{F} \xrightarrow{\sim} R\Gamma(\pi^*\mathcal{F}).
\]

(b) If $X$ is coherent and $Z$ is constructible in $X$, then $R^i\Gamma_Z\mathcal{F} = 0$ for every $i > \dim X$.

(c) If $X$ is spectral and $Z$ is constructible in $X$, define $d_Z$ as in theorem \[10.1.35\](ii). Then
\[
R^i\Gamma_Z\mathcal{F} = 0 \quad \text{for every } i > d_Z.
\]

**Proof.** (i): Set $V_i := j'_i(X)$ for $i = 1, 2$; then $X'$ admits the open covering $X' = V_1 \cup V_2$, and the restriction of $\pi^*\mathcal{F}$ is flabby on $V_1$ and $V_2$. Then the assertion follows from lemma \[10.1.2\].

(ii.a): For $i = 1, 2$ and every $\mathcal{A}$-module $\mathcal{G}$, we have a natural isomorphism of $\mathcal{A}(X)$-modules
\[
\psi_{\mathcal{G},i} : \Gamma(X, \mathcal{F}) \xrightarrow{\sim} \Gamma(V_i, \mathcal{G}).
\]
Moreover, for every $(\sigma, \tau) \in \Gamma\mathcal{G} \oplus \Gamma_Z\mathcal{G}$ there exists a unique section $\varphi_{\mathcal{G}}(\sigma, \tau) \in \Gamma(\pi^*\mathcal{G})$ whose restriction to $V_1$ agrees with $\psi_{\mathcal{G},1}(\sigma)$ and whose restriction to $V_2$ agrees with $\psi_{\mathcal{G},2}(\sigma + \tau)$ (details left to the reader). The rule $(\sigma, \tau) \mapsto \varphi_{\mathcal{G}}(\sigma, \tau)$ yields a natural isomorphism
\[
\varphi_{\mathcal{G}} : \Gamma\mathcal{G} \oplus \Gamma_Z\mathcal{G} \xrightarrow{\sim} \Gamma(\pi^*\mathcal{G}).
\]

Now, let $\mathcal{F} \to \mathcal{G}^*$ be a resolution of $\mathcal{F}$ by a complex of injective $\mathcal{A}$-modules; by lemma \[10.1.5\](v), the complex $\pi^*\mathcal{G}^*$ is a resolution of $\pi^*\mathcal{F}$ by flabby $\pi^*\mathcal{A}$-modules. Combining with lemma \[10.4.4\](i) and remark \[7.3.29\](iv), we deduce that $\varphi_{\mathcal{G}^*} : \Gamma\mathcal{G}^* \oplus \Gamma_Z\mathcal{G}^* \xrightarrow{\sim} \Gamma(\pi^*\mathcal{G}^*)$ is the sought natural isomorphism.

Lastly, if $X$ is coherent (resp. spectral) and $Z$ is constructible, the open subsets $V_1$ and $V_2$ are coherent (resp. spectral) and retro-compact in $X'$; by lemma \[8.1.21\](iv), in this case $X'$ is coherent (resp. $X'$ is spectral, and it is easily seen that $d_{\pi^*\mathcal{F}} = d_Z$). Then (ii.b) and (ii.c) follow directly from (ii.a) and theorem \[10.1.35\].

10.4.8. In the situation of \[10.1.8\], suppose that the maps $g$ and $g_\lambda$, for every $\lambda \in \text{Ob}(\Lambda)$ are open immersions, and set
\[
Z := X \setminus Y \quad Z_\lambda := X_\lambda \setminus Y_\lambda \quad \text{for every } \lambda \in \text{Ob}(\Lambda).
\]
Consider also a compatible system $(\mathcal{G}_\lambda \mid \lambda \in \text{Ob}(\Lambda))$ of sheaves on $X_\bullet$, where $\mathcal{G}_\lambda$ is a $\mathcal{A}_{X_\lambda}$-module for every $\lambda \in \Lambda$, with transition maps
\[
\varphi_u^{-1}\mathcal{G}_\lambda \to \mathcal{G}_\mu \quad \text{for every morphism } u : \mu \to \lambda \in \Lambda
\]
and set
\[
\mathcal{G} := \varprojlim_{\lambda \in \text{Ob}(\Lambda)} \varphi_\lambda^*\mathcal{G}_\lambda.
\]
Notice that for every $\lambda \in \text{Ob}(\Lambda)$ and every morphism $u : \mu \to \lambda \in \Lambda$ we have
\[
\varphi_u^{-1}Z_\lambda \subset Z_\mu \quad \text{and} \quad \varphi_\lambda^{-1}Z_\lambda \subset Z.
\]
There follows a system of natural morphisms
\[
\tau_u : \varphi_u^*\Gamma_{Z_\lambda}\mathcal{G}_\lambda \to \Gamma_{Z_\mu}\mathcal{G}_\mu \quad \text{and} \quad \tau_\lambda : \varphi_\lambda^*\Gamma_{Z_\lambda}\mathcal{G}_\lambda \to \Gamma_Z\mathcal{G}
\]
amounting to a co-cone $\tau_\bullet$ with vertex $\Gamma_Z\mathcal{G}$.

**Proposition 10.4.9.** In the situation of \[10.4.8\], the co-cone $\tau_\bullet$ induces a natural isomorphism
\[
\varprojlim_{\lambda \in \text{Ob}(\Lambda)} \varphi_\lambda^* R^i\Gamma_{Z_\lambda}\mathcal{G}_\lambda \xrightarrow{\sim} R^i\Gamma_Z\mathcal{G} \quad \text{for every } i \in \mathbb{N}.
\]
Proof. From proposition [10.1.10(ii)] we deduce a natural isomorphism
\[ \text{colim}_{\lambda \in \text{Ob}(A)} \varphi_{\lambda}^* \Gamma_{Z_X} \mathcal{F}_\lambda = \text{colim}_{\lambda \in \text{Ob}(A)} \varphi_{\lambda}^* \text{Ker} (\mathcal{G}_\lambda \to g_{\lambda*}g_{\lambda}^* \mathcal{G}_\lambda) \]
\[ \cong \text{Ker} (\mathcal{G} \to g_*g^* \mathcal{G}) = \Gamma_Z \mathcal{G}. \]

Now, let us choose a compatible system of injective resolutions \( \mathcal{G}_\lambda \to \mathcal{I}_\lambda \), so that the transition maps for the system \( (\mathcal{G}_\lambda | \lambda \in \text{Ob}(A)) \) extend to a system of transition morphisms of complexes \( (\mathcal{I}_\lambda | \lambda \in \text{Ob}(A)) \). On the one hand, claim [10.1.11] says that
\[ \mathcal{I}^\bullet := \text{colim}_{\lambda \in \text{Ob}(A)} \varphi_{\lambda}^* \mathcal{I}_\lambda \]
is a qc-flabby resolution of \( \mathcal{G} \). On the other hand, the foregoing yields a natural isomorphism
\[ \text{colim}_{\lambda \in \text{Ob}(A)} \varphi_{\lambda}^* R\Gamma_{Z_X} \mathcal{G}_\lambda \cong H^1 \Gamma_Z \mathcal{I}^\bullet. \]

Then the assertion follows from lemma [10.4.4(iii.a)].

Corollary 10.4.10. Let \( (X, \mathcal{A}) \) be a ringed topological space with \( X \) locally spectral, \( Z \subset X \) a constructible closed subset, \( x \in Z \) any point, and denote by \( j_x : X(x) \to X \) the inclusion map (notation of definition [8.1.42(iii)]). We have a natural isomorphism of functors
\[ j_x^* R\Gamma_Z \mathcal{F} \cong R\Gamma_{Z(x)}^{\mathcal{F}} \quad \text{in } D^+(j_x^* \mathcal{A}-\text{Mod}). \]

Proof. We may assume that \( X \) is spectral, in which case \( X(x) \) is the limit of the cofiltered system of all quasi-compact open neighborhoods of \( x \) in \( X \), and if \( U \) is any such neighborhood, the inclusion map \( U \to X \) is quasi-compact and quasi-separated. The sought isomorphism \( \varphi^* \) is then deduced from a co-cone constructed as in [10.4.8], and it suffices to check that \( H^1 \varphi^* \) is an isomorphism on the underlying \( \mathbb{Z}_{X(x)} \)-modules for every \( i \in \mathbb{Z} \), so the assertion is reduced to proposition [10.4.9].

10.4.11. In the situation of (10.4.1), notice the natural isomorphism of \( \mathcal{A} \)-modules:
\[ \mathcal{H}\text{om}_{\mathbb{Z}}(i_* \mathbb{Z}_Z, \mathcal{F}) \cong \Gamma_Z \mathcal{F} \quad \text{for every } \mathcal{A} \text{-module } \mathcal{F}, \]
whence a natural isomorphism of \( \mathcal{A}(X) \)-modules:
\[ \text{Hom}_{\mathbb{Z}}(i_* \mathbb{Z}_Z, \mathcal{F}) \cong \Gamma_Z \mathcal{F} \quad \text{for every } \mathcal{A}(X) \text{-module } \mathcal{F}. \]

Now, let \( \mathcal{U} := (U_i | i \in I) \) be any open covering of \( U \), indexed by a set \( I \), and fix any total ordering on \( I \). By proposition [10.2.6(iv)], we get natural isomorphisms in \( D^+(\mathcal{A}-\text{Mod}) \) and \( D^+(\mathcal{A}(X)-\text{Mod}) \)
\[ R\mathcal{H}\text{om}^\bullet(R_\mathcal{U}^\text{alt}(\mathcal{I}[1], K)^* \cong R\Gamma_Z K^* \quad R\text{Hom}_{\mathbb{Z}}^\bullet(R_\mathcal{U}^\text{alt}(\mathcal{I}[1], K)^* \cong R\Gamma_Z K^* \]
for every bounded below complex \( K^* \) of \( \mathcal{A} \)-modules. These isomorphisms allow us to compute \( R\Gamma_Z K^* \) as a Čech cohomology functor, as follows. Clearly, the rule : \( \mathcal{F} \mapsto C^\text{alt}_\mathcal{U}(\mathcal{I}, \mathcal{F}) \) defines a functor \( \mathcal{A}-\text{Mod} \to C(\mathcal{A}(X)-\text{Mod}) \) (notation of definition [10.2.2(ii)]). Now, pick any resolution \( K^* \cong \mathcal{I}^\bullet \) by a bounded below complex of injective \( \mathcal{A} \)-modules; the foregoing yields a natural isomorphism:
\[ R\Gamma_Z K^* \cong \text{Tot } C^\text{alt}_\mathcal{U}(\mathcal{I}, \mathcal{I}^\bullet)[-1] \quad \text{in } D^+(\mathcal{A}(X)-\text{Mod}). \]
10.4.12. We define a bifunctor

\[ \mathcal{H}om_\mathcal{Z} := \Gamma_Z \circ \mathcal{H}om_\mathcal{fd} : \mathcal{C}(\mathcal{A}\text{-Mod}) \times \mathcal{C}(\mathcal{A}\text{-Mod})^\circ \to \mathcal{C}(\mathcal{A}\text{-Mod}). \]

The bifunctor \( \mathcal{H}om_\mathcal{Z} \) admits a right derived functor:

\[ R\mathcal{H}om_\mathcal{Z}^+ : \mathcal{D}^+(\mathcal{A}\text{-Mod}) \times \mathcal{D}(\mathcal{A}\text{-Mod})^\circ \to \mathcal{D}(\mathcal{A}\text{-Mod}). \]

The construction can be outlined as follows. First, for a fixed complex \( K_\bullet \) of \( \mathcal{A} \)-modules, one can consider the right derived functor of the functor \( \mathcal{G} \mapsto \mathcal{H}om_\mathcal{Z}(K_\bullet, \mathcal{G}) \), which is denoted \( R\mathcal{H}om_\mathcal{Z}(K_\bullet, -) \). Next, one verifies that every quasi-isomorphism \( K_\bullet \to K'_\bullet \) induces an isomorphism of functors \( R\mathcal{H}om_\mathcal{Z}(K_\bullet, -) \cong R\mathcal{H}om_\mathcal{Z}(K'_\bullet, -) \), hence the natural transformation \( K_\bullet \to R\mathcal{H}om_\mathcal{Z}(K_\bullet, -) \) factors through \( \mathcal{D}(\mathcal{A}\text{-Mod}) \), and this is the sought bifunctor \( R\mathcal{H}om_\mathcal{Z}^+ \). In case \( Z = X \), one recovers the functor \( R\mathcal{H}om_\mathcal{Z}^+ \) of (10.1.13).

**Lemma 10.4.13.** In the situation of [10.4.1], the following holds:

(i) The functor \( \Gamma_Z \) is right adjoint to \( i_*i^* \). More precisely, for any two \( \mathcal{A} \)-modules \( \mathcal{F} \) and \( \mathcal{G} \) we have natural isomorphisms:

(a) \( \mathcal{H}om_\mathcal{fd}((\mathcal{F}, \Gamma_Z(\mathcal{G})), \mathcal{H}om_\mathcal{fd}(i_*i^*(\mathcal{F}), \mathcal{G})) \)

(b) \( R\mathcal{H}om_\mathcal{Z}^+(\mathcal{F}, \mathcal{R}\Gamma_Z(\mathcal{G})) \cong R\mathcal{H}om_\mathcal{Z}(i_*i^*(\mathcal{F}), \mathcal{G}) \).

(ii) If \( \mathcal{F} \) is an injective (resp. flabby) \( \mathcal{A} \)-module on \( X \), then the same holds for \( \Gamma_Z(\mathcal{F}) \).

(iii) There are natural isomorphisms of bifunctors:

\[ R\mathcal{H}om_\mathcal{Z}^+ \cong \mathcal{R}\Gamma_Z \circ R\mathcal{H}om_\mathcal{Z}^+ \cong R\mathcal{H}om_\mathcal{Z}^+(-, \mathcal{R}\Gamma_Z(-)) \]

(iv) If \( W \subset X \) is any other closed subset, there is a natural isomorphism of functors:

\[ \mathcal{R}\Gamma_{W \cap Z} \cong \mathcal{R}\Gamma_W \circ \mathcal{R}\Gamma_Z \]

(v) If \( f : (Y, \mathcal{B}) \to (X, \mathcal{A}) \) is any morphism of ringed spaces, there is a natural isomorphism of functors:

\[ Rf_* \circ \mathcal{R}\Gamma_{f^{-1}Z} \cong \mathcal{R}\Gamma_Z \circ Rf_* : \mathcal{D}^+(\mathcal{B}\text{-Mod}) \to \mathcal{D}^+(\mathcal{A}\text{-Mod}). \]

(vi) There is a natural isomorphism of bifunctors on \( \mathcal{D}^+(\mathcal{A}\text{-Mod})^\circ \times \mathcal{D}^+(\mathcal{A}\text{-Mod})^\circ : \)

\[ R\mathcal{H}om_\mathcal{Z}^+(\mathcal{R}\Gamma_{Z(-)}, -) \cong R\mathcal{H}om_\mathcal{Z}(\mathcal{R}\Gamma_{Z(-)}, -) \]

**Proof.**

(i): To establish the isomorphism (a), one uses the short exact sequence

\[ 0 \to j^*j^* \mathcal{F} \to \mathcal{F} \to i_*i^* \mathcal{F} \to 0 \]

to show that any map \( \mathcal{F} \to \Gamma_Z(\mathcal{G}) \) factors through \( \mathcal{H} := i_*i^* \mathcal{F} \). Conversely, since \( j_*j^* \mathcal{H} = 0 \), it is clear that every map \( \mathcal{H} \to \mathcal{G} \) must factor through \( \Gamma_Z(\mathcal{G}) \). The isomorphism (b) is derived easily from (a) and (ii).

(iii): According to [125] Th.10.8.2, the first isomorphism in (iii) is deduced from lemmata [10.4.4] (i) and [10.1.4] (ii). The second isomorphism in (iii) follows from [125] Th.10.8.2, and assertion (ii) concerning injective sheaves.

(ii): Suppose first that \( \mathcal{F} \) is injective; let \( \mathcal{G}_1 \to \mathcal{G}_2 \) a monomorphism of \( \mathcal{A} \)-modules and \( \varphi : \mathcal{G}_1 \to \Gamma_Z(\mathcal{F}) \) any \( \mathcal{A} \)-linear map. By (i) we deduce a map \( i_*i^* \mathcal{G}_1 \to \mathcal{F} \), which extends to a map \( i_*i^* \mathcal{G}_2 \to \mathcal{F} \), by injectivity of \( \mathcal{F} \). Finally, (i) again yields a map \( \mathcal{G}_2 \to \Gamma_Z(\mathcal{F}) \) extending \( \varphi \).

Next, if \( \mathcal{F} \) is flabby, let \( V \subset X \) be any open subset, and \( s \in \mathcal{F}(V) \); since \( s|_{V \setminus Z} = 0 \), we can extend \( s \) to a section \( s' \in \Gamma_Z(\mathcal{F}(V \cup (X \setminus Z))) \). Since \( \mathcal{F} \) is flabby, \( s' \) extends to a section \( s'' \in \mathcal{F}(X) \); however, by construction \( s'' \) vanishes on the complement of \( Z \).

(iv): Clearly \( \Gamma_W(\mathcal{F}) \cong \mathcal{R}\Gamma_W(\mathcal{F}) \), so the claim follows easily from (ii) and [125] Th.10.8.2.

(v): Since flabby \( \mathcal{B} \)-modules are acyclic for \( f_* \) and \( \mathcal{R}\Gamma_{f^{-1}Z} \) (lemmata [10.1.4] (ii) and [10.4.4] (i)), one can apply (ii) and [125] Th.10.8.2 to identify both functors with \( R(\Gamma_Z \circ f_*) \).
(vi): Let $I^\bullet$ and $J^\bullet$ be two bounded below complexes of injective $\mathcal{A}$-modules. Clearly any morphism $\bigcup_Z I^\bullet \to J^\bullet$ vanishes on $U$, whence the assertion. □

**Definition 10.4.14.** Let $X$ be a topological space, and $K^\bullet \in D^+(\mathcal{O}_X-\text{Mod})$.

(i) The depth of $K^\bullet$ along $Z$ is

$$\text{depth}_Z K^\bullet := \sup \{ n \in \mathbb{Z} | R^i \Gamma_Z K^\bullet = 0 \text{ for all } i < n \} \in \mathbb{Z} \cup \{ +\infty \}.$$  

From lemma [10.4.13 (ii,iv)] and the Grothendieck spectral sequence ([100, Th.5.8.3]), we see that

(10.4.15) \[ \text{depth}_W K^\bullet \geq \text{depth}_Z K^\bullet \quad \text{whenever } W \subset Z. \]

(ii) Let $\Phi := (Z_\lambda | \lambda \in \Lambda)$ be a family of closed subsets of $X$, and suppose that $\Phi$ is cofiltered by inclusion. Due to (10.4.15), it is reasonable to define the depth of $K^\bullet$ along $\Phi$ as

$$\text{depth}_\Phi K^\bullet := \sup \{ \text{depth}_{Z_\lambda} K^\bullet | \lambda \in \Lambda \} \in \mathbb{Z} \cup \{ +\infty \}.$$  

10.4.16. Let now $X$ be a scheme and $i : Z \to X$ a closed immersion of schemes, such that $Z$ is constructible in $X$. Then the open immersion $j : X \setminus Z \to X$ is quasi-compact and separated, hence the functors $R^i j_*$, preserve the subcategories of quasi-coherent modules, for every $q \in \mathbb{N}$ ([46 Ch.III, Prop.1.4.10]). In light of (10.4.15) we deduce that $R^q \Gamma_Z$ restricts to a functor:

$$R^q \Gamma_Z : \mathcal{O}_X-\text{Mod}_{\text{qcoh}} \to \mathcal{O}_X-\text{Mod}_{\text{qcoh}} \quad \text{for every } q \in \mathbb{N}.$$  

**Lemma 10.4.17.** In the situation of (10.4.16), the following holds :

(i) The functor $R\Gamma_Z$ restricts to a triangulated functor:

$$R\Gamma_Z : D^+(\mathcal{O}_X-\text{Mod})_{\text{qcoh}} \to D^+(\mathcal{O}_X-\text{Mod})_{\text{qcoh}}$$  

(note of (10.3.11)).

(ii) Let $f : Y \to X$ be an affine morphism of schemes, $K^\bullet$ any object of $D^+(\mathcal{O}_Y-\text{Mod})_{\text{qcoh}}$. Then we have the identity:

$$\text{depth}_{f^{-1}Z} K^\bullet = \text{depth}_Z Rf_* K^\bullet.$$  

(iii) Let $f : Y \to X$ be a flat morphism of schemes, $K^\bullet$ any object of $D^+(\mathcal{O}_X-\text{Mod})_{\text{qcoh}}$. Then the natural map

$$f^* R\Gamma_Z K^\bullet \to R\Gamma_{f^{-1}Z} f^* K^\bullet$$

is an isomorphism in $D^+(\mathcal{O}_Y-\text{Mod})_{\text{qcoh}}$. Especially, we have

$$\text{depth}_{f^{-1}Z} f^* K^\bullet \geq \text{depth}_Z K^\bullet$$

and if $f$ is faithfully flat, the inequality is actually an equality.

(iv) Let $K^\bullet$ be any object of $D^+(\mathcal{O}_X-\text{Mod})$, and $\mathcal{F}$ a flat quasi-coherent $\mathcal{O}_X$-module. Then the natural map

$$\mathcal{F} \otimes_{\mathcal{O}_X} R\Gamma_Z K^\bullet \to R\Gamma_Z (\mathcal{F} \otimes_{\mathcal{O}_X} K^\bullet)$$

is an isomorphism in $D(\mathcal{O}_X-\text{Mod})$.

**Proof.** (i): Indeed, if $K^\bullet$ is an object of $D^+(\mathcal{O}_X-\text{Mod})_{\text{qcoh}}$, we have a spectral sequence:

$$E^{pq}_{2} := R^p \Gamma_Z H^q K^\bullet \Rightarrow R^{p+q} \Gamma_Z K^\bullet.$$  

(This spectral sequence is obtained from a Cartan-Eilenberg resolution of $K^\bullet$; see e.g. [125 §5.7].) Hence $R^p \Gamma_Z K^\bullet$ admits a finite filtration whose quotients are quasi-coherent; then the lemma follows from [46 Ch.III, Prop.1.4.17].

(ii): To start with, a spectral sequence argument as in the foregoing shows that $Rf_*$ restricts to a functor $D^+(\mathcal{O}_Y-\text{Mod})_{\text{qcoh}} \to D^+(\mathcal{O}_X-\text{Mod})_{\text{qcoh}}$, and moreover we have natural identifications:

$$R^i f_* K^\bullet \simeq f_* H^i K^\bullet$$

for every $i \in \mathbb{Z}$ and every object $K^\bullet$ of $D^+(\mathcal{O}_X-\text{Mod})_{\text{qcoh}}$. In
view of lemma \ref{10.4.13}(v), we derive natural isomorphisms: \( R^i \Gamma_Z Rf_! K^\bullet \simto Rf_! R^i \Gamma_{f^{-1}Z} K^\bullet \) for every object \( K^\bullet \) of \( D^+(\mathcal{O}_Y\text{-Mod})_{qcoh} \). The assertion follows easily.

(iii): A spectral sequence argument as in the proof of (i) allows us to assume that \( K^\bullet = \mathcal{F}[0] \) for some quasi-coherent \( \mathcal{O}_X \)-module \( \mathcal{F} \). In this case, let \( j_X : X \setminus Z \rightarrow X \) and \( j_Y : Y \setminus f^{-1}Z \rightarrow Y \) be the open immersions; considering the exact sequences \( f^* (\ref{10.4.2}) \) and \( f^* (\ref{10.4.3}) \), we reduce to showing that the natural map \( f^* Rj_{X*} j_X^! \mathcal{F} \rightarrow Rj_{Y*} j_Y^! f^* \mathcal{F} \) is an isomorphism in \( D^+(\mathcal{O}_Y\text{-Mod})_{qcoh} \). The latter assertion follows from corollary \ref{10.3.8}.

(iv): The map in question is obtained as follows. We may assume that \( K^\bullet \) is a complex of injective \( \mathcal{O}_X \)-modules, and let \( i : \bigoplus K^\bullet \rightarrow K^\bullet \) be the inclusion map; clearly \( \mathcal{F} \otimes_{\mathcal{O}_X} i \) factors through the inclusion map \( \bigoplus \mathcal{F} \otimes_{\mathcal{O}_X} K^\bullet \rightarrow \mathcal{F} \otimes_{\mathcal{O}_X} K^\bullet \), whence the sought map \( \omega_\mathcal{F} : \mathcal{F} \otimes_{\mathcal{O}_X} \bigoplus K^\bullet \rightarrow \bigoplus (\mathcal{F} \otimes_{\mathcal{O}_X} K^\bullet) \). Now, the assertion is local on \( X \), hence we may assume that \( X = \text{Spec } A \) for some ring \( A \), and \( \mathcal{F} = F^\sim \) for some flat \( A \)-module \( F \). Then \( F \) is the colimit of a filtered system \( (L_\lambda | \lambda \in \Lambda) \) of free \( A \)-modules of finite rank (\cite[Ch.I, Th.1.2]{95}), and by virtue of lemma \ref{10.4.4}(iii), the map \( \omega_\mathcal{F} = \text{colim } \omega_{L_\lambda} \). Thus, we are reduced to the case where \( F \) is a free \( A \)-module of finite rank, in which case the assertion is clear.

\begin{proposition}
\label{10.4.18}
Let \( X \) be an affine scheme, \( Z \subset X \) any closed subset, \( \mathcal{F}^\bullet \) a bounded below complex of quasi-coherent \( \mathcal{O}_X \)-modules, and \( \mathcal{U} := \{ U_t | t \in T \} \) a family of affine open subsets of \( X \) such that \( \bigcup_{t \in T} U_t = X \setminus Z \). There exists a natural isomorphism
\[ R\Gamma_Z \mathcal{F}^\bullet \simto \text{Tot } C^\bullet_{alt}(\mathcal{U}, \mathcal{F}^\bullet)[-1] \quad \text{in } D^+(\mathcal{O}_X(X)\text{-Mod}) \]
where \( C^\bullet_{alt} \) denotes the augmented alternating Čech complex).
\end{proposition}

\begin{proof}
Pick any resolution \( \mathcal{F}^\bullet \simto \mathcal{F}^\bullet \) by a bounded below complex of injective \( \mathcal{O}_X \)-modules; by virtue of \ref{10.4.11} it suffices to show that the natural map of double complexes
\[ C^\bullet_{alt}(\mathcal{U}, \mathcal{F}^\bullet) \rightarrow C^\bullet_{alt}(\mathcal{U}, \mathcal{F}^\bullet) \]
induces a quasi-isomorphism on total complexes. To this aim, we can argue as in the proof of theorem \ref{10.2.28}(ii): the details shall be left to the reader (the condition that \( X \) is affine, is needed here, since we are dealing with the augmented Čech complex, whereas in the proof of theorem \ref{10.2.28}(ii) only the ordinary version intervenes, so for the proof of the latter it is only required that the intersection of any closed system of members of \( \mathcal{U} \) is affine).
\end{proof}

\begin{lemma}
\label{10.4.20}
Let \( X \) be a scheme; for every \( x \in X \), we consider the cofiltered family \( \Phi(x) \) of all non-empty constructible closed subsets of \( X(x) := \text{Spec } \mathcal{O}_{x,x} \); clearly \( \bigcap_{Z \in \Phi(x)} Z = \{ x \} \). Let \( K^\bullet \) be any object of \( D^+(\mathcal{Z}_X\text{-Mod}) \); we are interested in the quantities:
\[ \delta(x, K^\bullet) := \text{depth}_{x} K^\bullet(x) \quad \text{and} \quad \delta'(x, K^\bullet) := \text{depth}_{\Phi(x)} K^\bullet(x) \]
\[ (\text{notation of definition } \ref{4.9.17}(iii)) \]
Especially, we wish to compute the depth of a complex \( K^\bullet \) along a closed subset \( Z \subset X \), in terms of the local invariants \( \delta(x, K^\bullet) \) or \( \delta'(x, K^\bullet) \), evaluated at the points \( x \in Z \). This shall be achieved by theorem \ref{10.4.21}. To begin with, we remark:

\begin{enumerate}
\item \label{10.4.20-1} \( \delta(x, K^\bullet) \geq \delta'(x, K^\bullet) \) for every \( x \in X \) and every \( K^\bullet \in \text{Ob}(D^+(\mathcal{Z}_X\text{-Mod})) \).
\item \label{10.4.20-2} If the topological space \( |X| \) underlying \( X \) is locally noetherian, the inequality of \ref{10.4.20-1} is actually an equality.
\item \label{10.4.20-3} If \( \mathcal{F} \) is a flat quasi-coherent \( \mathcal{O}_X \)-module, then \( \delta'(x, \mathcal{F}) \geq \delta'(x, \mathcal{O}_X) \).
\end{enumerate}
\end{lemma}

\begin{proof}
\ref{10.4.20-1} follows easily from \ref{10.4.15}. Likewise, \ref{10.4.20-2} follows likewise from \ref{10.4.15} and the fact that if \( |X| \) is locally noetherian, \( \{ x \} \) is the smallest element of the family \( \Phi(x) \).
\end{proof}
(iii): According to [95, Ch.I, Th.1.2], the $\mathcal{O}_X$-module $\mathcal{F}(x)$ is the colimit of a filtered system $(\mathcal{L}_\lambda \mid \lambda \in \Lambda)$ of free $\mathcal{O}_X$-modules of finite rank. In view of lemma [10.4.4(iii), it is easily seen that

$$\text{depth}_Z \mathcal{F} \geq \inf_{\lambda \in \Lambda} \text{depth}_Z \mathcal{L}_\lambda = \text{depth}_Z \mathcal{O}_X$$

for every closed constructible subset $Z \subset X$. The assertion follows. \qed

**Theorem 10.4.21.** With the notation of (10.4.19), let $Z \subset X$ be any closed constructible subset, $K^\bullet$ any object of $D^+(\mathbb{Z}_X\text{-Mod})$. Then

$$\text{depth}_Z K^\bullet = \inf \{ \delta(x, K^\bullet) \mid x \in Z \} = \inf \{ \delta'(x, K^\bullet) \mid x \in Z \}.$$  

**Proof.** Let $d := \text{depth}_Z K^\bullet$; in light of corollary 10.4.10 it is clear that $\delta(x, K^\bullet) \geq d$ for all $x \in Z$, hence, in order to prove the first identity it suffices to show:

**Claim 10.4.22.** Suppose $d < +\infty$. Then there exists $x \in Z$ such that $R^d \Gamma(x) K^\bullet(x) \neq 0$.

**Proof of the claim.** By definition of $d$, we can find an open subset $V \subset X$ and a non-zero section $s \in \Gamma(V, R^d \Gamma_Z K^\bullet)$. The support of $s$ is a closed subset $S \subset Z$. Let $x$ be a maximal point of $S$. From lemma [10.4.13(iv)] we deduce a spectral sequence

$$E_2^{pq} := R^p \Gamma_X R^q \Gamma_Z K^\bullet(x) \Rightarrow R^{p+q} \Gamma(x) K^\bullet(x)$$

and corollary [10.4.10] implies that $E_2^{pq} = 0$ whenever $q < d$, therefore:

$$R^d \Gamma(x) K^\bullet(x) \simeq R^0 \Gamma(x) R^d \Gamma_Z K^\bullet(x).$$

However, the image of $s$ in $R^d \Gamma_Z K^\bullet(x)$ is supported precisely at $x$, as required. \qed

**Corollary 10.4.23.** Let $Z \subset X$ be a closed and constructible subset, $\mathcal{F}$ a $\mathbb{Z}_X$-module, and $j : X \setminus Z \to X$ the induced open immersion. Then the natural map $\mathcal{F} \to j_* j^* \mathcal{F}$ is an isomorphism if and only if $\delta(x, \mathcal{F}) \geq 2$, if and only if $\delta'(x, \mathcal{F}) \geq 2$ for every $x \in Z$. \qed

10.4.24. Let now $X$ be an affine scheme, say $X := \text{Spec} A$ for some ring $A$, and $Z \subset X$ a constructible closed subset. In this case, we wish to show that the depth of a complex of quasi-coherent $\mathcal{O}_X$-modules along $Z$ can be computed in terms of Ext functors on the category of $A$-modules. This is the content of the following:

**Proposition 10.4.25.** In the situation of (10.4.24), let $N$ be any finitely presented $A$-module such that $\text{Supp} N = Z$, and $M^\bullet$ any bounded below complex of $A$-modules. Then:

$$\text{depth}_Z M^{\bullet\sim} = \sup \{ n \in \mathbb{Z} \mid \text{Ext}_A^j(N, M^\bullet) = 0 \text{ for all } j < n \}.$$  

**Proof.** ($M^{\bullet\sim}$ is the complex of quasi-coherent $\mathcal{O}_X$-modules determined by $M^\bullet$, as in (10.3)).

**Claim 10.4.26.** There is a natural isomorphism in $D^+(A\text{-Mod})$:

$$R\text{Hom}^*_A(N, M^\bullet) \xrightarrow{\sim} R\text{Hom}^*_{\mathcal{O}_X}(N^{\sim}, R^\Gamma_Z M^{\bullet\sim}).$$

**Proof of the claim.** Let $i : Z \to X$ be the closed immersion. The assumption on $N$ implies that $N^{\sim} = i_* i^* N^{\sim}$; hence lemma [10.4.13(i,b)] yields a natural isomorphism

$$R\text{Hom}^*_{\mathcal{O}_X}(N^{\sim}, M^{\bullet\sim}) \xrightarrow{\sim} R\text{Hom}^*_{\mathcal{O}_X}(N^{\sim}, R^\Gamma_Z M^{\bullet\sim}).$$

The claim follows by combining corollary [10.3.2(i)] and (10.4.27). \qed

From claim 10.4.26 we see already that $\text{Ext}_A^j(N, M^\bullet) = 0$ whenever $j < \text{depth}_Z M^{\bullet\sim}$. Suppose that $\text{depth}_Z M^{\bullet\sim} = p < +\infty$; in this case, claim 10.4.26 gives an isomorphism:

$$\text{Ext}_A^j(N, M^\bullet) \simeq \text{Hom}_{\mathcal{O}_X}(N^{\sim}, R^p \Gamma_Z M^{\bullet\sim}) \simeq \text{Hom}_A(N, R^p \Gamma_Z M^{\bullet\sim})$$
where the last isomorphism holds by lemma [10.4.17]. To conclude the proof, we have to exhibit a non-zero map from $N$ to $Q := R\pi Z M^{\sim}$. Let $F_0(N) \subset A$ denote the Fitting ideal of $N$; this is a finitely generated ideal, whose zero locus coincides with the support of $N$. More precisely, $\text{Ann}_A(N)^r \subset F_0(N) \subset \text{Ann}_A(N)$ for all sufficiently large integers $r > 0$. Let now $x \in Q$ be any non-zero element, and $f_1, \ldots, f_k$ a finite system of generators for $F_0(N)$; since $x$ vanishes on $X \setminus Z$, the image of $x$ in $Q_{f_i}$ is zero for every $i \leq k$, i.e. there exists $n_i \geq 0$ such that $f_i^{n_i}x = 0$ in $Q$. It follows easily that $F_0(N)^n \subset \text{Ann}_A(x)$ for a sufficiently large integer $n$, and therefore $x$ defines a map $\varphi : A/F_0(N)^n \to \hat{Q}$ by the rule : $a \mapsto ax$. According to [59] Lemma 3.2.21, we can find a finite filtration $0 = J_m \subset \cdots \subset J_1 \subset J_0 := A/F_0(N)^n$ such that each $J_i/J_{i+1}$ is quotient of a direct sum of copies of $N$. Let $s \leq m$ be the smallest integer such that $J_s \subset \text{Ker} \varphi$. By restriction, $\varphi$ induces a non-zero map $J_{s-1}/J_s \to \hat{Q}$, whence a non-zero map $N^{(s)} \to \hat{Q}$, for some set $S$, and finally a non-zero map $N \to \hat{Q}$, as required. \hfill $\square$

**Remark 10.4.28.** Notice that the existence of a finitely presented $A$-module $N$ with $\text{Supp} \ N = Z$ is equivalent to the constructibility of $Z$.

10.4.29. In the situation of (10.4.24), let $I \subset A$ be a finitely generated ideal such that $V(I) = Z$, and $M^*$ a bounded below complex of $A$-modules. Then it is customary to set :

$$\text{depth}_IM^{\sim} := \text{depth}_ZM^{\sim}$$

and the depth along $Z$ of $M^{\sim}$ is also called the $I$-depth of $M^*$. Moreover, if $A$ is a local ring with maximal ideal $m_A$, we shall often use the standard notation :

$$\text{depth}_AM^* := \text{depth}_{(m_A)}M^{\sim}$$

and this invariant is often called briefly the depth of $M^*$. With this notation, theorem [10.4.21] can be rephrased as the identity :

$$\text{(10.4.30) \quad \text{depth}_IM^* = \inf_{p \in V(I)} \text{depth}_{A_p}M^*_p.}$$

10.4.31. **Depth sensitivity of the Koszul complex.** Let now $f := (f_1, \ldots, f_r)$ be a finite system of generators of the ideal $I \subset A$, and $Z := \text{Spec} A/I$. In this generality, the Koszul complex $K^*(f)$ of remark [7.8.1 (ii)] is not a resolution of the $A$-module $A/I$, and thus $H^*(f, M)$ (for an $A$-module $M$) does not necessarily agree with $\text{Ext}_A^*(A/I, M)$. Nevertheless, we have :

**Proposition 10.4.32.** (i) In the situation of (10.4.31), let $M^* \in \text{Ob}(D^+(A\text{-Mod}))$; then :

$$\text{depth}_IM^* = d := \sup \{ i \in \mathbb{Z} \mid H^j(f, M^*) = 0 \text{ for all } j < i \}.$$ 

(ii) If $d < +\infty$, there are natural $A$-linear isomorphisms :

$$H^d(f, M^*) \sim \text{Hom}_A(A/I, R^d\pi Z M^{\sim}) \sim \text{Ext}_A^d(A/I, M^*).$$

(iii) Moreover we have a natural isomorphism in $D(A\text{-Mod})$ :

$$\text{colim}_{m \in \mathbb{N}} K^*(f^m, M^*) \sim R\pi Z M^{\sim}$$

where the transition maps in the colimit are the maps $\varphi_m^*$ of (7.8.20).

**Proof.** (i): Let $B := \mathbb{Z}[t_1, \ldots, t_r] \to A$ be the ring homomorphism defined by the rule : $t_i \mapsto f_i$, for $i = 1, \ldots, r$; we denote $\psi : X \to Y := \text{Spec} B$ the induced morphism, $J \subset B$ the ideal generated by the system $t := (t_i \mid i = 1, \ldots, r)$, and set $W := V(J) \subset Y$. From lemma [10.4.13 (v)] we deduce a natural isomorphism in $D(\mathcal{O}_Y\text{-Mod})$ :

$$\text{(10.4.33) \quad \psi^* R\pi Z M^{\sim} \sim R\pi W M^{\sim} \sim.}$$

Hence we are reduced to showing :

**Claim 10.4.34.** $d = \text{depth}_J \psi^* M^*$. 

Proof of the claim. Notice that \( t \) is a regular sequence in \( B \), hence \( \text{Ext}^*_B(B/J, \psi_*M^*) \cong H^*(t, \psi_*M^*) \); by proposition 10.4.25 there follows the identity:

\[
\text{depth}_J \psi_*M^* = \sup \{ n \in \mathbb{N} \mid H^i(t, \psi_*M^*) = 0 \text{ for all } i < n \}.
\]

Then the assertion follows from lemma \([7.8.2]\) iv).

(ii): From lemma \([10.4.13]\) i.b and corollary \([10.3.2]\) i) we derive a natural isomorphism:

\[
R^\text{Hom}^*_B((B/J)^\sim, \Gamma^*_W \psi_*M^\sim) \cong \text{RHom}^*_B(B/J, (B/J)^\sim, \Gamma^*_W \psi_*M^\sim).
\]

However, due to \([10.4.33]\) and claim \([10.4.34]\) we may compute:

\[
R^d\text{Hom}^*_B((B/J)^\sim, \Gamma^*_W \psi_*M^\sim) \cong \text{Hom}_B(B/J, R^d\Gamma^*_W \psi_*M^\sim) \cong \text{Hom}_A(A/I, R^d\Gamma^*_Z M^\sim).
\]

The first claimed isomorphism easily follows. Similarly, one applies lemma \([10.4.13]\) i.b and corollary \([10.3.2]\) i to compute \( \text{Ext}^*_A(A/I, M^*) \), and deduces the second isomorphism of (ii) using (i). Assertion (iii) follows immediately from \([10.2.27]\) and proposition \([10.4.18]\).

Corollary 10.4.35. Let \( A \) be a noetherian ring, \( I \subset A \) an ideal, \( M^* \) an object of \( D^+(A\text{-Mod}) \), and set \( Z := \text{Spec} A/I \). We have a natural isomorphism

\[
\text{colim}_{n \in \mathbb{N}} R^i\text{Hom}^*_A(A/I^n, M^*) \cong R^i\Gamma^*_Z M^\sim \quad \text{for every } i \in \mathbb{Z}.
\]

Proof. This is obtained by combining proposition \([10.4.32]\) iii) and remark \([7.8.45]\).

Corollary 10.4.36. Let \( A \) be a noetherian ring, \( M \) an \( A \)-module, and \( f := (f_1, \ldots, f_r) \) a finite sequence of elements of \( A \) that generates an ideal \( I \subset A \). Suppose that:

\begin{itemize}
  \item [(a)] \( \text{depth}_{A_p}(M_p) \geq \text{dim} A_p \) for every \( p \in Z := \text{Spec} A/I \).
  \item [(b)] \( Z \) has pure codimension \( r \) in \( \text{Spec} A \).
\end{itemize}

Then \( H^i(f, M) = 0 \) for every \( i < r \), and for every \( p \in Z \) we have:

\[
\text{depth}_{A_p}(M_p/I_p M_p) = \text{depth}_{A_p}(M_p) - r \quad \text{and} \quad \text{dim} A_p/I_p = \text{dim}(A_p) - r.
\]

Proof. Assumption (b) says that \( \text{dim} A_p \geq r \) for every \( p \in Z \), so that \( \text{depth}_{A_p} M_p \geq r \) for every such \( r \), due to (a); then the first assertion follows immediately from \([10.4.30]\) and proposition \([10.4.32]\) i). Next, we have \( \text{dim} A_p/I_p \geq \text{dim}(A_p) - r \) for every \( p \in Z \), by \([100\text{ Th.13.6}(i)]\), and the opposite inequality follows easily from (b).

Set now \( \overline{M} := M/I M \), and notice that for every \( p \in Z \), we have either \( \text{depth}_{A_p} M_p = \text{dim} A_p \), or else \( \text{depth}_{A_p} M_p = +\infty \), by assumption (a) and proposition \([10.4.47]\) ii.b). In the latter case, we have \( 0 = H^*(f, M_p) = H_0(f, M_p) = \overline{M}_p \), by proposition \([10.4.32]\) (i), lemma \([7.8.2]\) v) and remark \([7.8.1]\) iii), so \( \text{depth}_{A_p}(\overline{M}_p) = +\infty \), as required. Suppose then that \( \text{depth}_{A_p} M_p = \text{dim} A_p \), for a given \( p \in Z \). Pick a sequence \( f' := (f_{r+1}, \ldots, f_n) \) whose image in \( A_p/I_p \) is a system of parameters for the latter local ring (see \([100\text{ §14}]\)); then the sequence \( f'' := (f_1, \ldots, f_n) \) generates a \( pA_p \)-primary ideal \( J \subset A_p \), and notice that, by the foregoing, we have \( n - r = \text{dim} A_p/I_p = \text{dim}(A_p) - r \), i.e. \( n = \text{dim} A_p \), so \( f'' \) is a system of parameters for \( A_p \). By proposition \([10.4.32]\) i and our assumptions on \( p \), it follows that \( f'' \) is completely secant on \( M_p \), and \( H^n(f'', M_p) = M_p/J M_p \neq 0 \). Therefore, \( f'' \) is \( M_p \)-regular (proposition \([7.8.15]\)). Then \( f' \) is \( \overline{M}_p \)-regular, and \( \overline{M}_p/J \overline{M}_p \neq 0 \); therefore \( f' \) is also completely secant on \( M_p \), again by proposition \([7.8.15]\) and moreover \( H^n-r(f', \overline{M}_p) \neq 0 \). Invoking again proposition \([10.4.32]\) i), we conclude that \( \text{depth}_{A_p}(\overline{M}_p) = n - r \), as required.

Corollary 10.4.37. In the situation of \([10.4.29]\), let \( B \) be a faithfully flat \( A \)-algebra. Then:

\[
\text{depth}_{IB} B \otimes_A M^* = \text{depth}_I M^*.
\]
\textbf{Proof.} It is a special case of lemma \[10.4.17\] (iii). Alternatively, one remarks that

\[ K^\bullet(g, M^\bullet \otimes_A B) \simeq K^\bullet(g, M^\bullet) \otimes_A B \]

for every finite sequence of elements \( g \) in \( A \) which allows us to apply proposition \[10.4.32\] (iii).

\[ \square \]

\textbf{Theorem 10.4.38.} Let \( A \to B \) be a local homomorphism of local rings, and suppose that the maximal ideals \( m_A \) and \( m_B \) of \( A \) and \( B \) are finitely generated. Let also \( M \) be an \( A \)-module and \( N \) a \( B \)-module which is flat over \( A \). Then we have:

\[ \text{depth}_B(M \otimes_A N) = \text{depth}_A M + \text{depth}_{B/m_A B}(N/m_A N). \]

\textbf{Proof.} Let \( f := (f_1, \ldots, f_r) \) and \( g := (g_1, \ldots, g_s) \) be finite systems of generators for \( m_A \) and respectively \( \overline{m}_B \), the maximal ideal of \( B/m_A B \). We choose an arbitrary lifting of \( g \) to a finite system \( \mathfrak{g} \) of elements of \( m_B \); then \( (f, \mathfrak{g}) \) is a system of generators for \( m_B \). We have a natural identification of complexes of \( B \)-modules:

\[ K_\bullet(f, g) \cong \text{Tot}_\bullet(K_\bullet(f) \otimes_A K_\bullet(g)) \]

whence natural isomorphisms:

\[ K^\bullet((f, g), M \otimes_A N) \cong \text{Tot}^\bullet(K^\bullet(f, M) \otimes_A K^\bullet(g, N)). \]

A standard spectral sequence, associated with the filtration by rows, converges to the cohomology of this total complex, and since \( N \) is a flat \( A \)-module, \( K^\bullet(g, N) \) is a complex of flat \( A \)-modules, so that the \( E_1 \) term of this spectral sequence is found to be:

\[ E_1^{pq} \simeq H^q(f, M) \otimes_A K^p(g, N) \]

and the differentials \( d_1^{pq} : E_1^{pq} \to E_1^{p+1,q} \) are induced by the differentials of the complex \( K^\bullet(g, N) \). Set \( \kappa_A := A/m_A \); notice that \( H^q(f, M) \) is a \( \kappa_A \)-vector space, hence

\[ H^q(f, M) \otimes_A H^\bullet(g, N) \simeq H^\bullet(H^q(f, M) \otimes_{\kappa_A} K^\bullet(g, N/m_A N)) \]

and consequently:

\[ E_2^{pq} \simeq H^q(f, M) \otimes_{\kappa_A} H^p(g, N/m_A N). \]

Especially:

\[ (10.4.39) \quad E_2^{pq} = 0 \text{ if either } p < d := \text{depth}_A M \text{ or } q < d' := \text{depth}_{B/m_A B}(N/m_A N). \]

Hence \( H^i((f, g), M \otimes_A N) = 0 \) for all \( i < d + d' \) and moreover, if \( d \) and \( d' \) are finite, \( H^{d+d'}((f, g), M \otimes_A N) \simeq E_2^{d+d'} \neq 0 \). Now the sought identity follows readily from proposition \[10.4.32\] (i).

\[ \square \]

\textbf{Remark 10.4.40.} Let \( d \) and \( d' \) be as in \[10.4.39\], and suppose that \( d \) and \( d' \) are finite. By inspection of the proof, we see that – under the assumptions of theorem \[10.4.38\] – a natural isomorphism has been exhibited:

\[ \text{Ext}^{d+d'}_A(B/m_B, M \otimes_A N) \simeq \text{Ext}_A^d(A/m_A, M) \otimes_A \text{Ext}^d_{B/m_A B}(B/m_B, N/m_A N). \]

\textbf{Definition 10.4.41.} Let \( (A, m) \) be a local ring, and \( M_\bullet \in \text{Ob}(D^b(A-\text{Mod})) \). The \textit{residual Tor dimension} \( \text{rTor.dim}_A(M_\bullet) \) of \( M_\bullet \) is sup \( \{ i \in \mathbb{Z} | H_i(M_\bullet \otimes_A A/m) \neq 0 \} \) \( \in \mathbb{Z} \cup \{ \pm \infty \} \).

\textbf{Remark 10.4.42.} If \( A \) is a noetherian local ring, and \( M \) is any \( A \)-module of finite type, then \( \text{rTor.dim}_A(M) \) equals the projective dimension of \( M \) : see \[100\] §19, Lemma 1.

\textbf{Theorem 10.4.43.} Let \( A \) be a local noetherian ring, and \( M_\bullet \in \text{Ob}(D^b(A-\text{Mod})) \). Then:

(i) depth\( A(M_\bullet) = +\infty \) if and only if \( \text{rTor.dim}_A(M_\bullet) = -\infty \).

(ii) If \( \text{rTor.dim}_A(M_\bullet) \in \mathbb{Z} \), we have the Auslander-Buchsbaum identity:

\[ \text{depth}_A(M_\bullet) + \text{rTor.dim}_A(M_\bullet) = \text{depth}_A A. \]
10.4.46. Let $f : X \to S$ be any morphism of schemes. Recall that an $\mathcal{O}_X$-module $\mathcal{F}$ is said to be $f$-flat at a point $x \in X$ if $\mathcal{F}_x$ is a flat $\mathcal{O}_{S,f(x)}$-module. We say that $\mathcal{F}$ is $f$-flat over a point $s \in S$ if $\mathcal{F}$ is $f$-flat at all points of $f^{-1}(s)$. Finally, we say that $\mathcal{F}$ is $f$-flat if $\mathcal{F}$ is $f$-flat at all the points of $X$ ([144 Ch.0, §6.7.1]).
Corollary 10.4.47. Let \( f : X \to S \) be a finitely presented morphism of schemes, \( \mathcal{F} \) a \( f \)-flat quasi-coherent \( \mathcal{O}_X \)-module of finite presentation, \( \mathcal{G} \) any quasi-coherent \( \mathcal{O}_S \)-module, \( x \in X \) any point, \( i : f^{-1}(x) \to X \) the natural morphism. Then:

\[
\delta'(x, \mathcal{F} \otimes_{\mathcal{O}_X} f^* \mathcal{G}) = \delta'(x, i^* \mathcal{F}) + \delta'(f(x), \mathcal{G}).
\]

Proof. Set \( s := f(x) \), and denote by

\[
j_s : S(s) := \text{Spec} \mathcal{O}_{S,s} \to S \quad \text{and} \quad f_s : X(s) := X \times_S S(s) \to S(s)
\]

the induced morphisms. By inspecting the definitions, one checks easily that

\[
\delta'(x, \mathcal{F} \otimes_{\mathcal{O}_X} f^* \mathcal{G}) = \delta'(x, \mathcal{F}|_{X(s)} \otimes_{\mathcal{O}_{X(s)}} f_s^* \mathcal{G}(s)) \quad \text{and} \quad \delta'(s, \mathcal{G}) = \delta'(s, \mathcal{G}(s))
\]

(notation of definition 4.9.17(iii)). Thus, we may replace \( S \) by \( S(s) \) and \( X \) by \( X(s) \), and assume from start that \( S \) is a local scheme and \( s \) its closed point. Clearly we may also assume that \( X \) is affine and finitely presented over \( S \). Then we can write \( S \) as the limit of a cofiltered family \((S_\lambda \mid \lambda \in \Lambda)\) of local noetherian schemes, with local transition maps, and we may assume that \( f : X \to S \) is a limit of a cofiltered family \((f_\lambda : X_\lambda \to S_\lambda \mid \lambda \in \Lambda)\) of morphisms of finite type, such that \( X_\mu = X_\lambda \times_{S_\lambda} S_\mu \) whenever \( \mu \geq \lambda \). Likewise, we may descend \( \mathcal{F} \) to a family \((\mathcal{F}_\lambda \mid \lambda \in \Lambda)\) of finitely presented quasi-coherent \( \mathcal{O}_{X_\lambda} \)-modules, such that \( \mathcal{F}_\mu = \varphi_{\mu\lambda}^* \mathcal{F}_\lambda \) for every \( \mu \geq \lambda \) (where \( \varphi_{\mu\lambda} : X_\mu \to X_\lambda \) is the natural morphism). Furthermore, up to replacing \( \Lambda \) by some cofinal subset, we may assume that \( \mathcal{F}_\lambda \) is \( f_\lambda \)-flat for every \( \lambda \in \Lambda \) ([50, Ch.IV, Cor.11.2.6.1(ii)]). For every \( \lambda \in \Lambda \), denote by \( \psi_\lambda : S \to S_\lambda \) the natural morphism, so that \( s_\lambda := \psi_\lambda(s) \) is the closed point of \( S_\lambda \); for every constructible closed subset \( Z_\lambda \subset S_\lambda \), the set \( Z := \psi_\lambda^{-1} Z_\lambda \) is constructible and closed in \( S \), and according to lemma 10.4.17(ii) we have

\[
\text{depth}_Z \mathcal{G} = \text{depth}_{Z_\lambda} \psi_\lambda^{-1} \mathcal{G}.
\]

On the other hand, every closed constructible subset \( Z \subset S \) is of the form \( \psi_\lambda^{-1} Z_\lambda \) for some \( \lambda \in \Lambda \) and some \( Z_\lambda \) closed constructible in \( S_\lambda \) ([50, Ch.IV, Cor.8.3.11]), so that:

\[
\delta'(s, \mathcal{G}) = \sup \{ \delta'(s_\lambda, \mathcal{F}_\lambda) \mid \lambda \in \Lambda \}.
\]

Similarly, for every \( \lambda \in \Lambda \) let \( x_\lambda \) be the image of \( x \) in \( X_\lambda \) and denote by \( i_\lambda : f_\lambda^{-1}(s_\lambda) \to X_\lambda \) the natural morphism. Notice that \( f_\lambda^{-1}(s_\lambda) \) is a scheme of finite type over \( \text{Spec} \mathcal{O}_K(s_\lambda) \), especially it is noetherian, hence

\[
\delta'(x_\lambda, i_\lambda^* \mathcal{F}_\lambda) = \delta'(x, i^* \mathcal{F}) = \delta'(x_\lambda, i_\lambda^* \mathcal{F}_\lambda),
\]

by lemma 10.4.20(ii); by the same token we have as well the identity:

\[
\delta'(x, i^* \mathcal{F}) = \delta'(x_\lambda, i_\lambda^* \mathcal{F}_\lambda).
\]

Denote by \( g_\lambda : f^{-1}(s) \to f_\lambda^{-1}(s_\lambda) \) and \( g_{\lambda,x} : \text{Spec} \mathcal{O}_{f^{-1}(s),x} \to \text{Spec} \mathcal{O}_{f_\lambda^{-1}(s_\lambda),x_\lambda} \) the induced morphisms.

Claim 10.4.49. There exists \( \lambda \in \Lambda \) such that \( g_{\mu,1}^{-1}(x_\mu) = \{ x \} \) for every \( \mu \geq \lambda \).

Proof of the claim. Let \( Z \) be the topological closure of \( \{ x \} \) in \( f^{-1}(s) \); we may find \( \lambda \in \Lambda \) and a closed subset \( Z_\lambda \subset f_\lambda^{-1}(s_\lambda) \) such that \( Z = g_\lambda^{-1} Z_\lambda \) ([50, Ch.IV, Cor.8.3.11]). Since \( Z \) is irreducible and \( g_\lambda \) is surjective, it is easily seen that \( Z_\lambda \) is irreducible. Moreover, the topological closure \( Z_\lambda' \) of \( \{ x_\lambda \} \) in \( f_\lambda^{-1}(s_\lambda) \) lies in \( Z_\lambda \), and \( g_\lambda^{-1} Z_\lambda' \) contains \( x \); thus, \( Z_\lambda = Z_\lambda' \). It follows that \( g_{\lambda,x}^{-1}(x_\lambda) = \{ x \} \), whence the assertion.

Since \( g_{\lambda,x} \) is faithfully flat, from claim 10.4.49 and corollary 10.4.37 we see that, after replacing \( \Lambda \) by a cofinal subset, we may assume:

\[
\delta'(x_\lambda, i_\lambda^* \mathcal{F}_\lambda) = \delta'(x, i^* \mathcal{F}) \quad \text{for every} \ \lambda \in \Lambda.
\]

Claim 10.4.51. Let \( K \) be a field, \( X \) and \( Y \) two \( K \)-schemes, and set \( Z := X \times_{\text{Spec} K} Y \). Let also \( p : Z \to X \) and \( q : Z \to Y \) be the projections, \( \mathcal{M} \) any \( \mathcal{O}_X \)-module, and \( \mathcal{N} \) any \( \mathcal{O}_Y \)-module. Then we have:

\[
\text{Supp} (p^* \mathcal{M} \otimes_{\mathcal{O}_X} q^* \mathcal{N}) = p^{-1}(\text{Supp} \mathcal{M}) \cap q^{-1}(\text{Supp} \mathcal{N}).
\]
Proof of the claim. To ease notation, set $\mathcal{P} := p^* \mathcal{M} \otimes_{\mathcal{O}_x} q^* \mathcal{N}$. Let $z \in Z$ be any point with $x := p(z) \in \text{Supp} \mathcal{M}$ and $y := q(z) \in \text{Supp} \mathcal{N}$; it suffices to show that $\mathcal{P}_z \neq 0$. Now, $\mathcal{O}_{Z,z}$ is a localization of $\mathcal{O}_{X,x} \otimes K \mathcal{O}_{Y,y}$, at a prime ideal $p$, and $\mathcal{P}_z = (\mathcal{M} \otimes_{\mathcal{O}_x} \mathcal{N}_y)_p$. We come down to the following situation. Let $A$ and $B$ be two local $K$-algebras, $m_A \subset A$, $m_B \subset B$ the respective maximal ideals, $M \neq 0$ an $A$-module, $N \neq 0$ a $B$-module, and $p \in A \otimes_{\mathcal{O}} B$ a prime ideal such that

$$\text{(10.4.52)} \quad m_A \otimes_{\mathcal{O}} B + A \otimes_{\mathcal{O}} m_B \subset p.$$  

We have to check that $(M \otimes_{\mathcal{O}} N)_p \neq 0$. To this aim, we may reduce easily to the case where $M$ and $N$ are cyclic modules, in which case there exist a surjective $A$-linear map $M \to \kappa(A) := A/m_A$ and a surjective $B$-linear map $N \to \kappa(B) := B/m_B$; we are then further reduced to showing that $(\kappa(A) \otimes_{\mathcal{O}} \kappa(B))_p \neq 0$, which is ensured by (10.4.52). \quad \Box

Next, notice that the local scheme $X(x)$ is the limit of the cofiltered system of local schemes $(X_{\lambda}(x) \mid \lambda \in \Lambda)$. Let $Z_{\lambda} \subset X_{\lambda}(x_{\lambda})$ be a closed constructible subset and set $Z := \varphi_{\lambda}^{-1} Z_{\lambda}$, where $\varphi_{\lambda} : X(x) \to X_{\lambda}(x_{\lambda})$ is the natural morphism. Let $Y_{\lambda}$ be the fibre product in the cartesian diagram of schemes:

$$
Y_{\lambda} \xrightarrow{q_{\lambda}} X_{\lambda}(x_{\lambda}) \xrightarrow{p_{\lambda}} S_{\lambda},
$$

The morphism $\varphi_{\lambda}$ factors through a unique morphism of $S$-schemes $\varphi_{\lambda} : X(x) \to Y_{\lambda}$, and if $y_{\lambda} \in Y_{\lambda}$ is the image of the closed point $x \in X(x)$, then $\varphi_{\lambda}$ induces a natural identification $X(x) \xrightarrow{\sim} Y_{\lambda}(y_{\lambda})$. To ease notation, let us set :

$$
\mathcal{H} := \mathcal{F} \otimes_{\mathcal{O}_x} f^* \mathcal{G} \quad \text{and} \quad \mathcal{H}_{\lambda} := \mathcal{F}_{\lambda} \otimes_{\mathcal{O}_{x_{\lambda}}} f_{\lambda}^* \psi_{\lambda} \mathcal{G}.
$$

In view of corollary [10.4.10] there follows a natural isomorphism :

$$
\text{(10.4.53)} \quad R^1 \mathcal{G}_{\lambda}(x) \xrightarrow{\sim} \varphi_{\lambda}^* R^1 \mathcal{G}_{x_{\lambda}}(\varphi_{\lambda}(x_{\lambda})) \otimes_{\mathcal{O}_{x_{\lambda}}} p_{\lambda}^* \mathcal{G}.
$$

On the other hand, applying the projection formula (see remark [10.3.7]) we get :

$$
\text{(10.4.54)} \quad q_{\lambda*}(q_{\lambda}^* \mathcal{F}_{\lambda}(x_{\lambda}) \otimes_{\mathcal{O}_{x_{\lambda}}} p_{\lambda}^* \mathcal{G}) \simeq \mathcal{H}_{\lambda}(x_{\lambda}).
$$

Combining (10.4.53), (10.4.54) and lemma [10.4.13] we deduce :

$$
R^1 \mathcal{H}_{\lambda}(x) \simeq \varphi_{\lambda}^* R^1 \mathcal{G}_{\lambda}(x_{\lambda}).
$$

Notice that the foregoing argument applies also in case $S$ is replaced by some $S_{\mu}$ for some $\mu \geq \lambda$ (and consequently $X$ is replaced by $X_{\mu}$); we arrive therefore at the inequality :

$$
\text{(10.4.55)} \quad \delta'(x_{\lambda}, \mathcal{H}_{\lambda}) \leq \delta'(x_{\mu}, \mathcal{H}_{\mu}) \leq \delta'(x, \mathcal{H}) \quad \text{whenever} \ \mu \geq \lambda.
$$

Claim 10.4.56. $\delta'(x, \mathcal{H}) = \sup \{ \delta'(x_{\lambda}, \mathcal{H}_{\lambda}) \mid \lambda \in \Lambda \}$.

Proof of the claim. Due to (10.4.55) we may assume – again after replacing $\Lambda$ by a cofinal subset – that $\delta'(x_{\lambda}, \mathcal{H}_{\lambda})$ is a constant $d \in \mathbb{N}$ independent of $\lambda$. Especially, $R^1 \mathcal{G}_{\lambda}(x_{\lambda}) \neq 0$ for every $\lambda \in \Lambda$ and every closed constructible subset $Z_{\lambda} \subset X_{\lambda}(x_{\lambda})$. We have to show that $R^1 \mathcal{G}_{\lambda}(x_{\lambda}) \neq 0$ for arbitrarily small constructible closed subsets $Z \subset X(x)$. However, given such $Z$, there exist $\lambda \in \Lambda$ and $Z_{\lambda}$ closed constructible in $X_{\lambda}(x_{\lambda})$ such that $Z = \varphi_{\lambda}^{-1}(Z_{\lambda})$ ([50] Ch.IV, Cor.8.3.11)). Say that :

$$
S = \text{Spec} A \quad S_{\lambda} = \text{Spec} A_{\lambda} \quad X_{\lambda}(x_{\lambda}) = \text{Spec} B_{\lambda}.
$$

Hence $Y_{\lambda} \simeq \text{Spec} A \otimes_{A_{\lambda}} B_{\lambda}$. Let also $F_{\lambda}$ (resp. $G_{\lambda}$) be a $B_{\lambda}$-module (resp. $A$-module) such that $F_{\lambda} \simeq \mathcal{F}_{\lambda}$ (resp. $G_{\lambda} \simeq \mathcal{G}$). Then $\mathcal{H}_{\lambda} \simeq (F_{\lambda} \otimes_{A_{\lambda}} G_{\lambda})$. Let $m_{\lambda} \subset B_{\lambda}$ and $n_{\lambda} \subset A_{\lambda}$ be the
10.4.57. Consider now a finitely presented morphism of schemes and then the corollary follows from (10.4.48), (10.4.50) and claim 10.4.56.

Then the following holds:

In the situation of Proposition 10.4.61.

(i) Let $Y' 	o Y$ be any morphism of schemes, set $X' := X \times_Y Y'$, and let $g : X' \to X$, $f' : X' \to Y'$ be the induced morphisms. Then:

$$
L_{g^* f'}(d) := g^{-1} L_{f'}(d)
$$

for every $d \in \mathbb{N}$.

Proof. (ii): The identity can be checked on the fibres, hence we may assume that $Y = \text{Spec } k$ and $Y' = \text{Spec } k'$ for some fields $k \subset k'$. Let $x' \in X'$ be any point and $x \in X$ its image; since the map $\mathcal{O}_{X,x} \to \mathcal{O}_{X',x'}$ is faithfully flat, corollary 10.4.37 implies:

$$
\text{depth}_{g^* f'}(x') = \text{depth}_{f'}(x)
$$

whence (ii).

(i): We may assume that $Y = \text{Spec } A$, $X = \text{Spec } B$, $\mathcal{I} = I^*$, where $A$ is a ring, $B$ is a finitely presented $A$-algebra, and $I \subset B$ is a finitely generated ideal, for which we choose a
Taking into account (10.4.30) and (10.4.60), we deduce:

\[ N_{\mathcal{F}}(i) = \bigcup_{y \in Y} \text{Supp} H^i(\mathbb{K}^*(f, B) \otimes_A \kappa(y)). \]

Taking into account (10.4.30) and (10.4.60), we deduce:

\[ L_{\mathcal{F}}(d) = \bigcap_{i=0}^{d-1} (X \setminus N_{\mathcal{F}}(i)). \]

It suffices therefore to show that each subset \( N_{\mathcal{F}}(i) \) is constructible. For every \( j \in \mathbb{N} \) we set:

\[ Z^j := \ker(d^j : \mathbb{K}^j(f, B) \to \mathbb{K}^{j+1}(f, B)) \quad \text{and} \quad B^j := \text{Im}(d^{j-1} : \mathbb{K}^{j-1}(f, B) \to \mathbb{K}^j(f, B)). \]

Using [50, Ch.IV, Cor. 8.9.5], one deduces easily that there exists an affine open subscheme \( U \subset Y \), say \( U = \text{Spec} \, A' \) for some flat \( A \)-algebra \( A' \), such that \( A' \otimes_A \mathbb{Z}^* \), \( A' \otimes_A \mathbb{B}^* \) and \( A' \otimes_A H^*(\mathbb{K}^*(f, B)) \) are flat \( A' \)-modules. By noetherian induction, we can then replace \( Y \) by \( U \) and \( X \) by \( X \times_Y U \), and assume from start that \( Z^*, B^* \) and \( H^*(\mathbb{K}^*(f, B)) \) are flat \( A \)-modules. In such manner the complex \( \mathbb{K}^*(f, B) \) commutes with any base change; therefore:

\[ N_{\mathcal{F}}(i) = \bigcup_{y \in Y} \text{Supp} H^i(f, B) \otimes_A \kappa(y) = \text{Supp} H^i(f, B) \]

whence the claim, since the support of a \( B \)-module of finite type is closed in \( X \).

Finally, for a general ring \( A \), we can find a noetherian subalgebra \( A' \subset A \), an \( A' \)-algebra \( B' \) of finite type and a finitely generated ideal \( I' \subset B' \) such that \( B = A \otimes_{A'} B \) and \( I = I'B \). Let \( \mathcal{F}' \) be the sheaf of ideals on \( X' := \text{Spec} B' \) determined by \( I' \); by the foregoing, \( L_{\mathcal{F}'}(d) \) is a constructible subset of \( X' \). Thus, the assertion follows from (ii), and the fact that a morphism of schemes is continuous for the constructible topology (48 Ch.IV, Prop.1.8.2)).

\[ \square \]

10.5. Depth and associated primes.

**Definition 10.5.1.** Let \( X \) be a scheme, \( \mathcal{F} \) a quasi-coherent \( \mathcal{O}_X \)-module.

(i) Let \( x \in X \) be any point; we say that \( x \) is **associated with** \( \mathcal{F} \) if there exists \( f \in \mathcal{F}_x \) such that the radical of the annihilator of \( f \) in \( \mathcal{O}_{X,x} \) is the maximal ideal of \( \mathcal{O}_{X,x} \). If \( x \) is a point associated with \( \mathcal{F} \) and \( x \) is not a maximal point of \( \text{Supp} \, \mathcal{F} \), we say that \( x \) is an **imbedded point** for \( \mathcal{F} \). We shall denote:

\[ \text{Ass} \, \mathcal{F} := \{ x \in X \mid x \text{ is associated with } \mathcal{F} \}. \]

(ii) We say that the \( \mathcal{O}_X \)-module \( \mathcal{F} \) **satisfies condition** \( S_1 \) if every associated point of \( \mathcal{F} \) is a maximal point of \( X \).

(iii) Likewise, if \( X \) is affine, say \( X = \text{Spec} \, A \), and \( M \) is any \( A \)-module, we denote by \( \text{Ass}_A \) \( M \subset X \) (or just \( \text{Ass} \) \( M \), if the notation is not ambiguous) the set of prime ideals associated with the \( \mathcal{O}_X \)-module \( M^\sim \) arising from \( M \). An associated (resp. imbedded) point of \( M^\sim \) is also called an **associated** (resp. imbedded) **prime ideal** of \( M \).

We say that \( M \) satisfies condition \( S_1 \) if the same holds for the \( \mathcal{O}_X \)-module \( M^\sim \).

(iv) Let \( x \in X \) be a point, \( \mathcal{G} \) a quasi-coherent \( \mathcal{O}_X \)-submodule of \( \mathcal{F} \). We say that \( \mathcal{G} \) is a **\( x \)-primary submodule** of \( \mathcal{F} \) if \( \text{Ass} \, \mathcal{F}/\mathcal{G} = \{ x \} \). We say that \( \mathcal{G} \) is a primary submodule of \( \mathcal{F} \) if there exists a point \( x \in X \) such that \( \mathcal{G} \) is \( x \)-primary.

(v) We say that a submodule \( \mathcal{G} \) of the \( \mathcal{O}_X \)-module \( \mathcal{F} \) admits a **primary decomposition** if there exist primary submodules \( \mathcal{G}_1, \ldots, \mathcal{G}_n \subset \mathcal{F} \) such that \( \mathcal{G} = \mathcal{G}_1 \cap \cdots \cap \mathcal{G}_n \).
Remark 10.5.2. (i) Our definition of associated point is borrowed from [69, Partie I, Déf.3.2.1], and it corresponds to Bourbaki’s notion of weakly associated prime ([28, Ch.IV, §1, Exerc.17]), also called weak Bourbaki prime in other works. Bourbaki’s definition of associated prime, in [28, Ch.IV, §1, no.1] (which is the same as in [68, Exp.III, Déf.1.1]), agrees with ours for modules over noetherian rings (see lemma [10.5.3] (ii)), but in general the two notions diverge.

(ii) For a noetherian ring \( A \) and a finitely generated \( A \)-module \( M \), our condition \( S_1 \) is the same as in [72]. It also agrees with that of [49, Ch.V, Déf.5.7.2], in case \( \text{Supp} M = \text{Spec} A \).

Lemma 10.5.3. Let \( A \) be a ring, and \( M \) any \( A \)-module. The following holds:

(i) \( \text{Ass} M = \{ \mathfrak{p} \in \text{Spec} A \mid \text{Ass} M \} \)

(ii) \( \text{Ass} M \) is a set of all \( \mathfrak{p} \in \text{Spec} A \) with the following property. There exists \( m \in M \), such that \( \mathfrak{p} \) is a maximal point of the closed subset \( \text{Supp}(m) \) (i.e. \( \mathfrak{p} \) is the preimage of a minimal prime ideal of the ring \( A/\text{Ann}_A(m) \)).

(iii) \( \mathfrak{p} \in \text{Ass} M \) and \( \mathfrak{p} \) is finitely generated, there exists \( m \in M \) with \( \mathfrak{p} = \text{Ann}_A(m) \).

(iv) The natural map \( M \to \prod_{\mathfrak{p} \in \text{Ass} M} M_{\mathfrak{p}} \) is injective.

Proof. (i): Indeed, suppose that \( m \in M \setminus \{0\} \) is any element, and \( \mathfrak{p} \) is a maximal point of \( V(\text{Ann}_A(m)) \); denote by \( m_\mathfrak{p} \in M_{\mathfrak{p}} := M \otimes_A \mathfrak{p} \) the image of \( m \). Then:

\[
\text{Ann}_A(m_\mathfrak{p}) = \text{Ann}_A(m) \otimes_A \mathfrak{p}.
\]

Hence \( A_{\mathfrak{p}}/\text{Ann}_A(m_\mathfrak{p}) = (A/\text{Ann}_A(m)) \otimes_A \mathfrak{p} \), and the latter is by assumption a local ring of Krull dimension zero; it follows easily that the radical of \( \text{Ann}_A(m_\mathfrak{p}) \) is \( \mathfrak{p} A_{\mathfrak{p}} \), i.e. \( \mathfrak{p} \in \text{Ass} A M \).

Conversely, suppose that \( \mathfrak{p} \in \text{Ass} A M \); then there exists \( m_\mathfrak{p} \in M_{\mathfrak{p}} \) such that the radical of \( \text{Ann}_A(m_\mathfrak{p}) \) equals \( \mathfrak{p} A_{\mathfrak{p}} \). We may assume that \( m_\mathfrak{p} \) is the image of some \( m \in M \); then (10.5.4) implies that \( V(\text{Ann}_A(m)) \cap \text{Spec} A = \text{V}(\text{Ann}_A(m_\mathfrak{p})) = \{ \mathfrak{p} \} \), so \( \mathfrak{p} \) is a maximal point of \( V(\text{Ann}_A(m)) \).

(ii) Suppose \( \mathfrak{p} \in \text{Ass} M \) is finitely generated; by definition, there exists \( y \in M_{\mathfrak{p}} \) such that the radical of \( I := \text{Ann}_A(y) \) equals \( \mathfrak{p} A_{\mathfrak{p}} \). Since \( \mathfrak{p} \) is finitely generated, some power of \( \mathfrak{p} A_{\mathfrak{p}} \) is contained in \( I \). Let \( t \in \mathbb{N} \) be the smallest integer such that \( \mathfrak{p}^t A_{\mathfrak{p}} \subseteq I \), and pick any non-zero element \( x \in \mathfrak{p}^{t-1} A_{\mathfrak{p}} y \); then \( \text{Ann}_A(x) = \mathfrak{p} A_{\mathfrak{p}} \). After clearing some denominators, we may assume that \( x \in M \).

(iii) The assertion means that for every \( m \in M \setminus \{0\} \) there exists \( \mathfrak{p} \in \text{Ass} M \) such that \( m \) does not vanish in \( M_{\mathfrak{p}} \). But according to (i), \( \text{Ass} M \) contains every maximal point \( \mathfrak{p} \) of \( \text{Supp}(m) \).

Lemma 10.5.5. Let \( X \) be a scheme, \( \mathcal{F} \) a quasi-coherent \( \mathcal{O}_X \)-module. Then:

(i) \( \text{Ass} \mathcal{F} \subset \text{Supp} \mathcal{F} \).

(ii) \( \text{Ass} \mathcal{F}_U = U \cap \text{Ass} \mathcal{F} \) for every open subset \( U \subset X \).

(iii) \( \mathcal{F} = 0 \) if and only if \( \text{Ass} \mathcal{F} = \emptyset \).

Proof. (i) and (ii) are obvious. To show (iii), we may assume that \( X \) is affine, according to (ii). Then the assertion follows immediately from lemma [10.5.5] (iii).

Proposition 10.5.6. Let \( X \) be a scheme, \( \mathcal{F} \) a quasi-coherent \( \mathcal{O}_X \)-module. We have:

(i) \( \text{Ass} \mathcal{F} = \{ x \in X \mid \delta(x, \mathcal{F}) = 0 \} \).

(ii) If \( 0 \to \mathcal{F}' \to \mathcal{F} \to \mathcal{F}'' \) is an exact sequence of quasi-coherent \( \mathcal{O}_X \)-modules, then:

\[
\text{Ass} \mathcal{F}' \subset \text{Ass} \mathcal{F} \subset \text{Ass} \mathcal{F}' \cup \text{Ass} \mathcal{F}''.
\]

(iii) If \( x \in X \) is any point, and \( \mathcal{G}_1, \ldots, \mathcal{G}_n \) (for some \( n > 0 \)) are \( x \)-primary submodules of \( \mathcal{F} \), then \( \mathcal{G}_1 \cap \cdots \cap \mathcal{G}_n \) is also \( x \)-primary.

(iv) Let \( f : X \to Y \) be a finite morphism of schemes. Then
(a) The natural map:

$$
\bigoplus_{x \in f^{-1}(y)} \Gamma_{\{x\}} \mathcal{F}|X(x) \to \Gamma_{\{y\}} f_* \mathcal{F}|Y(y)
$$

is a bijection for all $y \in Y$.

(b) $\text{Ass} f_* \mathcal{F} = f(\text{Ass} \mathcal{F})$.

(v) Suppose that $\mathcal{F}$ is the union of a filtered family $(\mathcal{F}_\lambda \mid \lambda \in \Lambda)$ of quasi-coherent $\mathcal{O}_X$-submodules. Then:

$$
\bigcup_{\lambda \in \Lambda} \text{Ass} \mathcal{F}_\lambda = \text{Ass} \mathcal{F}.
$$

(vi) Let $f : Y \to X$ be a flat morphism of schemes, and suppose that the topological space $|X|$ underlying $X$ is locally noetherian. Then $\text{Ass} f^* \mathcal{F} \subset f^{-1} \text{Ass} \mathcal{F}$.

**Proof.** (i) and (v) follow directly from the definitions.

(ii): Consider, for every point $x \in X$ the induced exact sequence of $\mathcal{O}_{X(x)}$-modules:

$$
0 \to \Gamma_{\{x\}} \mathcal{F}'_x \to \Gamma_{\{x\}} \mathcal{F}_x \to \Gamma_{\{x\}} \mathcal{F}''_x.
$$

Then:

$$
\text{Supp} \Gamma_{\{x\}} \mathcal{F}'_x \subset \text{Supp} \Gamma_{\{x\}} \mathcal{F}_x \subset \text{Supp} \Gamma_{\{x\}} \mathcal{F}'_x \cup \text{Supp} \Gamma_{\{x\}} \mathcal{F}''_x
$$

which, in light of (i), is equivalent to the contention.

(iii): One applies (ii) to the natural injection: $\mathcal{F} / (\mathcal{G}_1 \cap \cdots \cap \mathcal{G}_n) \to \bigoplus_{i=1}^n \mathcal{F} / \mathcal{G}_i$.

(iv): We may assume that $Y$ is a local scheme with closed point $y \in Y$. Let $x_1, \ldots, x_n \in X$ be the finitely many points lying over $y$; for every $i, j \leq n$, we let

$$
\pi_j : X(x_j) \to Y \quad \text{and} \quad \pi_{ij} : X(x_i) \times_X X(x_j) \to Y
$$

be the natural morphisms. To ease notation, denote also by $\mathcal{F}_i$ (resp. $\mathcal{F}_{ij}$) the pull back of of $\mathcal{F}$ to $X(x_j)$ (resp. to $X(x_i) \times_X X(x_j)$). The induced morphism $U := X(x_1) \amalg \cdots \amalg X(x_n) \to X$ is faithfully flat, so descent theory yields an exact sequence of $\mathcal{O}_Y$-modules:

$$(10.5.7) \quad 0 \longrightarrow f_* \mathcal{F} \longrightarrow \prod_{i=1}^n \pi_{ij*} \mathcal{F}_{ij} \overset{p_1^*}{\longrightarrow} \prod_{i,j=1}^n \pi_{ij*} \mathcal{F}_{ij}.$$ 

where $p_1, p_2 : U \times_X U \to U$ are the natural morphisms.

**Claim 10.5.8.** The induced maps:

$$
\Gamma_{\{y\}} p_1^* \Gamma_{\{y\}} p_2^* : \prod_{j=1}^n \Gamma_{\{y\}} \pi_{ij*} \mathcal{F}_{ij} \to \prod_{i,j=1}^n \Gamma_{\{y\}} \pi_{ij*} \mathcal{F}_{ij}
$$

coincide.

**Proof of the claim.** Indeed, it suffices to verify that they coincide after projecting onto each factor $\mathcal{G}_{ij} := \Gamma_{\{y\}} \pi_{ij*} \mathcal{F}_{ij}$. But this is clear from definitions if $i = j$. On the other hand, if $i \neq j$, the image of $\pi_{ij}$ in $Y$ does not contain $y$, so the corresponding factor $\mathcal{G}_{ij}$ vanishes. $\diamond$

From $$(10.5.7)$$ and claim 10.5.8 we deduce that the natural map

$$
\Gamma_{\{y\}} f_* \mathcal{F} \to \prod_{j=1}^n \Gamma_{\{y\}} \pi_{j*} \mathcal{F}_j
$$

is a bijection. Clearly $\Gamma_{\{y\}} \pi_{j*} \mathcal{F}_j = \Gamma_{\{x\}} \mathcal{F}_j$, so both assertions follow easily.

(vi): Let $x \in X$ be any point; since $|X|$ is locally noetherian, the subset $\{x\}$ is closed and constructible in $X(x)$, and then $f^{-1}(x)$ is closed and constructible in $Y \times_X X(x)$. Hence $\delta(y, f^* \mathcal{F}) \geq \delta(x, \mathcal{F})$ for every $y \in f^{-1}(x)$ (lemma 10.4.17(iii) and theorem 10.4.21). Then the assertion follows from (i). $\square$
Corollary 10.5.9. In the situation of corollary 10.4.47, suppose furthermore that $|S|$ is a locally noetherian topological space. Then we have:

$$\text{Ass } \mathcal{F} \otimes_{O_X} f^*\mathcal{G} = \bigcup_{s \in \text{Ass } \mathcal{F}} \text{Ass } \mathcal{F} \otimes_{O_{S,s}} \kappa(s).$$

Proof. Under the stated assumptions, it is easily seen that, for every $x \in X$ (resp. $s \in S$), the subset $\{x\}$ (resp. $\{s\}$) is constructible in $X(x)$ (resp. in $S(s)$). Then the assertion follows immediately from proposition 10.5.6(i) and theorem 10.4.21.

Remark 10.5.10. (i) Actually, it can be shown that the extra assumption on $|S|$ in corollary 10.5.9 is superfluous: see [69] Part I, Prop.3.4.3.

(ii) In the situation of proposition 10.5.6 one could also consider the set of points $x \in X$ such that $\delta'(x, \mathcal{F}) = 0$. This set contains $\text{Ass } \mathcal{F}$, by proposition 10.5.6(i) and lemma 10.4.20(i). Such points are called attached primes or strong Krull primes of $\mathcal{F}$ in some literature: see e.g. [53], [52] (though the terminology “attached prime” is used also for a different, unrelated notion: see the footnote on page 404 of [52]).

Corollary 10.5.11. Let $X$ be a quasi-compact and quasi-separated scheme, $\mathcal{F}$ a quasi-coherent $O_X$-module and $\mathcal{G} \subseteq \mathcal{F}$ a quasi-coherent submodule. Then:

(i) For every quasi-compact open subset $U \subseteq X$ and every quasi-coherent primary $O_U$-submodule $\mathcal{N} \subseteq \mathcal{F}|_U$, with $\mathcal{G}|_U \subseteq \mathcal{N}$, there exists a quasi-coherent primary $O_X$-submodule $\mathcal{M} \subseteq \mathcal{F}$ such that $\mathcal{M}|_U = \mathcal{N}$ and $\mathcal{G} \subseteq \mathcal{M}$.

(ii) If $\mathcal{G}$ admits a primary decomposition if and only if there exists a finite open covering $X = U_1 \cup \cdots \cup U_n$ consisting of quasi-compact open subsets, such that the submodules $\mathcal{G}|_{U_i} \subseteq \mathcal{F}|_{U_i}$ admit primary decompositions for every $i = 1, \ldots, n$.

Proof. Say that $\mathcal{N}$ is $x$-primary for some point $x \in U$, and set $Z := X \setminus U$. According to [44], Ch.I, Prop.9.4.2], we can extend $\mathcal{N}$ to a quasi-coherent $O_X$-submodule $\mathcal{M}_1 \subseteq \mathcal{F}$; up to replacing $\mathcal{M}_1$ by $\mathcal{M}_1 + \mathcal{G}$, we may assume that $\mathcal{G} \subseteq \mathcal{M}_1$. Since $(\mathcal{F}/\mathcal{M}_1)|_U = \mathcal{F}|_U/\mathcal{N}$, it follows from lemma 10.5.5(ii) that $\text{Ass } \mathcal{F}/\mathcal{M}_1 \subseteq \{x\} \cup Z$. Let $\overline{\mathcal{M}} := \bigcap Z(\mathcal{F}/\mathcal{M}_1)$, and denote by $\overline{\mathcal{M}}$ the preimage of $\mathcal{M}$ in $\mathcal{F}$. There follows a short exact sequence:

$$0 \to \overline{\mathcal{M}} \to \mathcal{F}/\mathcal{M}_1 \to \mathcal{F}/\mathcal{M} \to 0.$$

Clearly $R^1\Gamma_Z(\overline{\mathcal{M}}) = 0$, whence a short exact sequence

$$0 \to \Gamma_Z(\overline{\mathcal{M}}) \to \Gamma_Z(\mathcal{F}/\mathcal{M}_1) \to \Gamma_Z(\mathcal{F}/\mathcal{M}) \to 0.$$

We deduce that $	ext{depth}_Z(\mathcal{F}/\mathcal{M}) > 0$; then theorem 10.4.21 and proposition 10.5.6(i) show that $Z \cap \text{Ass } (\mathcal{F}/\mathcal{M}) = \emptyset$, so that $\mathcal{M}$ is $x$-primary, as required.

(ii) We may assume that a covering $X = U_1 \cup \cdots \cup U_n$ is given with the stated property. For every $i \leq n$, let $\mathcal{G}|_{U_i} = \mathcal{N}_{i1} \cap \cdots \cap \mathcal{N}_{ik_i}$ be a primary decomposition; by (i) we may extend every $\mathcal{N}_{ij}$ to a primary submodule $\mathcal{M}_{ij} \subseteq \mathcal{F}$ containing $\mathcal{G}$. Then $\mathcal{G} = \bigcap_{i=1}^n \bigcap_{j=1}^{k_i} \mathcal{M}_{ij}$ is a primary decomposition of $\mathcal{G}$.

10.5.12. Let $A$, $B$ be two local rings, with $A$ a domain, $f : A \to B$ a local ring homomorphism, $M$ an $f$-flat $B$-module of finite presentation. Denote by $K$ (resp. $\kappa$) the field of fractions (resp. the residue field) of $A$, and set

$$B_0 := B \otimes_A \kappa \quad B_K := B \otimes_A K \quad M_0 := M \otimes_A \kappa \quad M_K := M \otimes_A K.$$

Proposition 10.5.13. In the situation of 10.5.12, suppose that:

(a) either, $A$ and $B$ are both noetherian rings
(b) or else, $f$ is essentially of finite presentation.
Let \( p \in \text{Ass}_{B_K} M_K \) be any point, and denote by \( V(p) \) the topological closure of \( \{p\} \) in \( \text{Spec} B \). Then all the maximal points of \( V(p) \cap \text{Spec} B_0 \) lie in \( \text{Ass}_{B_0} M_0 \).

**Proof.** We consider first case (a). Via the inclusion map \( \text{Spec} B_K \to \text{Spec} B \) we may regard \( p \) as a prime ideal of \( B \), and \( \text{Ass}_{B_K} M_K \) as a subset of \( \text{Ass}_B M \); by lemma 10.5.3(ii), there exists a cyclic \( B \)-submodule \( N \) of \( M \) such that \( \text{Ann}_{B_K} N = p \). Denote by \( m_A \) the maximal ideal of \( A \), endow \( M \) with its \( m_A \)-adic filtration \( \text{Fil}_i^* M \), and \( N \) with the filtration \( \text{Fil}_i^* N \) induced by \( \text{Fil}_i^* M \). Let also \( \text{gr}^i M \) and \( \text{gr}^i N \) be the graded \( B_q \)-modules associated with these filtrations on \( M \) and \( N \). Since \( M \) is \( f \)-flat, we have a \( B_0 \)-linear isomorphism

\[
\text{gr}^i M \cong (m_i^i/m_{i+1}^i)^{\otimes N} \quad \text{for every } i \in \mathbb{N}
\]

which implies that \( \text{Ass}_B (\text{gr}^i M) = \text{Ass}_B M_0 \) for every \( i \in \mathbb{N} \). From this, proposition 10.5.6(ii) and an easy induction on \( i \in \mathbb{N} \), we deduce that

\[
\text{Ass}_B (N/\text{Fil}_i^* N) \subset \text{Ass}_B (M/\text{Fil}_i^* M) \subset \text{Ass}_B M_0 \quad \text{for every } i \in \mathbb{N}
\]

On the other hand, by the Artin-Rees lemma ([100, Th.8.5]), there exist \( i, j \in \mathbb{N} \) such that

\[
m_j^i \in N/\text{Fil}_i^* N \subset m_A N
\]

so that \( \text{Supp} N/m_A N = \text{Supp} N/\text{Fil}_i^* N \). However, lemma 10.5.3(i) implies that all the maximal points of \( \text{Supp} N/\text{Fil}_i^* N \) lie in \( \text{Ass}_B (N/\text{Fil}_i^* N) \). To conclude, it suffices to remark that the support of \( N/m_A N \) equals \( V(p) \cap \text{Spec} B_0 \).

Next, suppose that (b) holds, and say that \( B = C_q \) for some finitely presented \( A \)-algebra \( C \) and some prime ideal \( q \subset C \) whose preimage in \( A \) is the maximal ideal. We write \( A \) as the colimit of a filtered system \( (A_\lambda | \lambda \in \Lambda) \) of noetherian local subrings, such that the transition maps \( A_\mu \to A_\lambda \) are local ring homomorphisms for every \( \lambda, \mu \in \Lambda \) with \( \lambda \geq \mu \); then there exist \( \mu \in \Lambda \) and an \( A_\mu \)-algebra \( C_\mu \) of finite type with an isomorphism of \( C_\mu \otimes_{A_\mu} A \to C \) of \( A \)-algebras. For every \( \lambda \geq \mu \), let \( C_\lambda := C_\mu \otimes_{A_\mu} A_\lambda \), denote by \( q_\lambda \subset C_\lambda \) the preimage of \( q \) under the induced map \( C_\lambda \to C \), and set \( B_\lambda := (C_\lambda)_{q_\lambda} \). Clearly \( B \) is the colimit of the resulting filtered system of rings \( (B_\lambda | \lambda \in \Lambda, \lambda \geq \mu) \), and the induced maps \( A_\lambda \to B_\lambda \) are local ring homomorphisms, for every \( \lambda \geq \mu \); therefore we may assume that there exists a finitely generated \( B_\mu \)-module \( M_\mu \), with a \( B \)-linear isomorphism \( M_\mu \otimes_{B_\mu} B \cong M \), and we may likewise define \( M_\lambda := M_\mu \otimes_{B_\mu} B_\lambda \) for every \( \lambda \geq \mu \). In view of ([50, Ch.IV, Cor.11.2.6.1(i)]), we may further assume that \( M_\lambda \) is a flat \( A_\lambda \)-module, for every \( \lambda \geq \mu \), and after replacing \( \Lambda \) by a cofinal subset, we may assume that \( \mu \) is the initial element of the partially ordered set \( \Lambda \). Then, to ease notation, denote by \( K_\lambda \) (resp. \( \kappa_\lambda \)) the field of fractions (resp. the residue field) of \( A_\lambda \), and set

\[
B_{K,\lambda} := B_\lambda \otimes_{A_\lambda} K_\lambda \quad M_{K,\lambda} := M_\lambda \otimes_{A_\lambda} K_\lambda \quad C_{K,\lambda} := C_\lambda \otimes_{A_\lambda} K_\lambda
\]

\[
B_{0,\lambda} := B_\lambda \otimes_{A_\lambda} \kappa_\lambda \quad M_{0,\lambda} := M_\lambda \otimes_{A_\lambda} \kappa_\lambda
\]

Notice that the resulting map \( f_\lambda : C_{K,\lambda} \to C_K := C \otimes_A K \) induces an isomorphism

\[
C_{K,\lambda} \otimes_{K_\lambda} K \cong C_K.
\]

So, \( f_\lambda \) is a flat ring homomorphism, hence the natural morphism \( \varphi_{K,\lambda} : \text{Spec} B_K \to \text{Spec} B_{K,\lambda} \) is also flat, and proposition 10.5.6(vi) yields

\[
(10.5.14) \quad \text{Ass}_{B_K} M_K \subset \varphi_{K,\lambda}^{-1} \text{Ass}_{B_{K,\lambda}} (M_{K,\lambda}) \quad \text{for every } \lambda \in \Lambda.
\]

Now, say that \( p \in \text{Ass}_{B_K} M_K \), and let \( p_\lambda \subset B_{K,\lambda} \) be the preimage of \( p \), for every \( \lambda \in \Lambda \); we have \( p_\lambda \in \text{Ass}_{B_{K,\lambda}} (M_{K,\lambda}) \) by virtue of (10.5.14), so in this situation the case (a) of the proposition applies and shows that

\[
Z_\lambda := \text{Max}(\text{Spec} B_{0,\lambda}/p_\lambda B_{0,\lambda}) \subset Z'_\lambda := \text{Ass}_{B_\lambda} (M_{0,\lambda}) \quad \text{for every } \lambda \in \Lambda
\]
(where, for a scheme $Z$, we have denoted $\text{Max}(Z)$ the set of maximal points of $Z$). Notice moreover, that the natural morphism $\varphi_{0,\lambda} : \text{Spec } B_0 \to \text{Spec } B_{0,\lambda}$ is also flat, so we have

$$\text{Max}(\text{Spec } B_0/p_\lambda B_0) = \bigcup_{z \in Z_\lambda} \text{Max}(\varphi_{0,\lambda}^{-1}(z))$$

for every $\lambda \in \Lambda$. Summing up, we are reduced to checking that there exists $\lambda \in \Lambda$ such that the surjection $B_0/p_\lambda B_0 \to B_0/pB_0$ is an isomorphism, i.e. such that $p_\lambda B_0 = pB_0$. However, clearly $pB_0$ is the filtered union of the system of subideals $(p_\lambda B_0 | \lambda \in \Lambda)$; but $B_0$ is a noetherian ring, so the claim is obvious. □

**Lemma 10.5.15.** Let $X$ be a quasi-separated and quasi-compact scheme, $\mathcal{F}$ a quasi-coherent $\mathcal{O}_X$-module of finite type. Then the submodule $0 \subset \mathcal{F}$ admits a primary decomposition if and only if the following conditions hold:

(a) $\text{Ass } \mathcal{F}$ is a finite set.

(b) For every $x \in \text{Ass } \mathcal{F}$ there is a $x$-primary ideal $I \subset \mathcal{O}_{X,x}$ such that the natural map

$$\Gamma_{(x)} \mathcal{F}_x \to \mathcal{F}_x/I \mathcal{F}_x$$

is injective.

**Proof.** In view of corollary [10.5.11](i) we are reduced to the case where $X$ is an affine scheme, say $X = \text{Spec } A$, and $\mathcal{F} = M^-$ for an $A$-module $M$ of finite type. Suppose first that $0$ admits a primary decomposition:

$$0 = \bigcap_{i=1}^k N_i, \tag{10.5.16}$$

Then the natural map $M \to \bigoplus_{i=1}^k M/N_i$ is injective, hence

$$\text{Ass } M \subset \bigcup_{i=1}^k M/N_i \subset \bigcup_{i=1}^k \text{Ass } M/N_i \tag{10.5.17}$$

by proposition [10.5.6](ii), and this shows that (a) holds. Next, if $N_i$ and $N_j$ are $p$-primary for the same prime ideal $p \subset A$, we may replace both of them by their intersection (proposition [10.5.6](iii)). Proceeding in this way, we achieve that the $N_i$ appearing in (10.5.16) are primary submodules for pairwise distinct prime ideals $p_1, \ldots, p_k \subset A$. By (10.5.17) we have $\text{Ass } M \subset \{p_1, \ldots, p_k\}$. Suppose that $p_i \not\in \text{Ass } M$, and set $Q := \ker (M \to \bigoplus_{i=2}^k M/N_i)$. For every $j > 1$ we have $\Gamma_{(p_j)}(M/N_i) \sim = 0$, therefore:

$$\Gamma_{(p_j)} Q_{p_j} \sim = \ker (\Gamma_{(p_j)} M_{p_j} \to \bigoplus_{i=1}^k (M/N_i)_{p_j}) = 0.$$ 

Hence $\text{Ass } Q = \emptyset$, by proposition [10.5.6](ii), and then $Q = 0$ by lemma [10.5.3]. In other words, we can omit $N_1$ from (10.5.16), and still obtain a primary decomposition of $0$; iterating this argument, we may achieve that $\text{Ass } M = \{p_1, \ldots, p_k\}$. After these reductions, we see that

$$\Gamma_{(p_j)}(M/N_i)_{p_j} \sim = 0 \quad \text{whenever } i \neq j$$

and consequently:

$$\ker (\varphi_j : \Gamma_{(p_j)} M_{p_j} \to (M/N_j)_{p_j}) = 0 \quad \text{for every } j = 1, \ldots, k.$$
Now, for given \( j \leq k \), let \( f_1, \ldots, f_n \) be a system of non-zero generators for \( M/N_j \); by assumption \( I_j := \Ann_A(f_i) \) is a \( p_j \)-primary ideal for every \( i \leq n \). Hence \( q_j := \Ann_A(M/N_j) = \bigcap_{i=1}^n I_i \) is \( p_j \)-primary as well; since \( \varphi_j \) factors through \( (M/q_j M)_{p_j} \), we see that (b) holds.

Conversely, suppose that (a) and (b) hold. Say that \( \Ass M = \{ p_1, \ldots, p_k \} \); for every \( j \leq k \) we choose a \( p_j \)-primary ideal \( \alpha_j \) such that the map \( \Gamma_{(p_j)} M_{p_j}^\infty \to M_{p_j}/q_j M_{p_j} \) is injective. Clearly \( N_j := \Ker (M \to M_{p_j}/q_j M_{p_j}) \) is a \( p_j \)-primary submodule of \( M \); moreover, the induced map \( \varphi : M \to \bigoplus_{j=1}^k M/N_j \) is injective, since \( \Ass \Ker \varphi = \emptyset \) (proposition 10.5.6(ii) and lemma 10.5.5(iii)). In other words, \( 0 = \bigcap_{j=1}^k N_j \) is a primary decomposition of 0.

**Proposition 10.5.18.** Let \( X \) be a quasi-compact and quasi-separated scheme, and \( 0 \to \mathcal{F}' \to \mathcal{F} \to \mathcal{F}'' \to 0 \) a short exact sequence of quasi-coherent \( \mathcal{O}_X \)-modules of finite type such that

(a) \( \Ass \mathcal{F}' \cap \Supp \mathcal{F}'' = \emptyset \).

(b) The submodules \( 0 \subset \mathcal{F}' \) and \( 0 \subset \mathcal{F}'' \) admit primary decompositions.

Then the submodule \( 0 \subset \mathcal{F} \) admits a primary decomposition.

**Proof.** The assumptions imply that \( \Ass \mathcal{F}' \) and \( \Ass \mathcal{F}'' \) are finite sets, (lemma 10.5.15), hence the same holds for \( \Ass \mathcal{F} \) (proposition 10.5.6(ii)). Given any point \( x \in X \) and any \( x \)-primary ideal \( I \subset \mathcal{O}_{X,x} \), we may choose the commutative diagram with exact rows:

\[
\begin{array}{ccccccc}
0 & \to & \Gamma_{(x)} \mathcal{F}' & \to & \Gamma_{(x)} \mathcal{F}_x & \to & \Gamma_{(x)} \mathcal{F}_x'' \\
& & \downarrow \alpha & & \downarrow \beta & & \downarrow \gamma \\
& & \Tor_{1}^{\mathcal{O}_{X,x}}(I, \mathcal{F}_x') & \to & \mathcal{F}_x'/I \mathcal{F}_x & \to & \mathcal{F}_x'/I \mathcal{F}_x'' \\
\end{array}
\]

Now, if \( x \in \Ass \mathcal{F}' \), assumption (a) implies that \( \Gamma_{(x)} \mathcal{F}_x'' = 0 = \Tor_{1}^{\mathcal{O}_{X,x}}(I, \mathcal{F}_x') \), and by (b) and lemma 10.5.15 we can choose \( I \) such that \( \alpha \) is injective; a little diagram chase then shows that \( \beta \) is injective as well. Similarly, if \( x \in \Ass \mathcal{F}'' \), we have \( \Gamma_{(x)} \mathcal{F}_x' = 0 \) and we may choose \( I \) such that \( \gamma \) is injective, which implies again that \( \beta \) is injective. To conclude the proof it suffices to apply again lemma 10.5.15.

**Proposition 10.5.19.** Let \( Y \) be a quasi-compact and quasi-separated scheme, \( f : X \to Y \) a finite morphism and \( \mathcal{F} \) a quasi-coherent \( \mathcal{O}_X \)-module of finite type. Then the \( \mathcal{O}_X \)-submodule \( 0 \subset \mathcal{F} \) admits a primary decomposition if and only if the same holds for the \( \mathcal{O}_Y \)-submodule \( 0 \subset f_* \mathcal{F} \).

**Proof.** Under the stated assumptions, we can apply the criterion of lemma 10.5.15. To start out, it is clear from proposition 10.5.6(iv.b) that \( \Ass \mathcal{F} \) is finite if and only if \( \Ass f_* \mathcal{F} \) is finite. Next, suppose that \( 0 \subset \mathcal{F} \) admits a primary decomposition, let \( y \in \Ass f_* \mathcal{F} \) be any point and set \( f^{-1}(y) := \{ x_1, \ldots, x_n \} \); for every \( j \leq n \) we can find an \( x_j \)-primary ideal \( I_j \subset \mathcal{O}_X \) such that the map \( \Gamma_{(x_j)} \mathcal{F}_x \to \mathcal{F}_x/I \mathcal{F}_x \) is injective. Let \( I \) be the kernel of the natural map \( \mathcal{O}_Y \to f_* (\mathcal{O}_X/(I_1 \cap \cdots \cap I_n)) \). Then \( I \) is a quasi-coherent \( y \)-primary ideal of \( \mathcal{O}_Y \) and we deduce a commutative diagram:

\[
\begin{array}{ccc}
\bigoplus_{j=1}^n \Gamma_{(x_j)}(\mathcal{F}_x) & \to & \Gamma_{(y)}(f_* \mathcal{F}_y) \\
\alpha \downarrow & & \beta \downarrow \\
\bigoplus_{j=1}^n \mathcal{F}_x/I \mathcal{F}_x & \to & f_* \mathcal{F}_y/I f_* \mathcal{F}_y
\end{array}
\]

whose horizontal arrows are isomorphisms, in view of proposition 10.5.6(iv.a), and where \( \alpha \) is injective by construction. It follows that \( \beta \) is injective, so condition (b) of lemma 10.5.15 holds for the stalk \( f_* \mathcal{F}_y \), and since \( y \in \Ass f_* \mathcal{F} \) is arbitrary, we see that \( 0 \subset f_* \mathcal{F} \) admits a primary decomposition. Conversely, suppose that \( 0 \subset f_* \mathcal{F} \) admits a primary decomposition;
then for every $y \in Y$ we can find a quasi-coherent $y$-primary ideal $I \subset \mathcal{O}_Y$ such that the map $\beta$ of \ref{equation:correspondence} is injective; hence $\alpha$ is injective as well, and again we deduce easily that $0 \subset \mathcal{F}$ admits a primary decomposition. \qed

**Proposition 10.5.21.** Let $X$ and $\mathcal{F}$ be as in lemma \ref{lemma:primary} $i : Z \to X$ a closed constructible immersion, and $U := X \setminus Z$. Suppose that:

(a) The $\mathcal{O}_U$-submodule $0 \subset \mathcal{F}|_U$ and the $\mathcal{O}_Z$-submodule $0 \subset i^* \mathcal{F}$ admit primary decompositions.

(b) The natural map $\Gamma_Z \mathcal{F} \to i_* i^* \mathcal{F}$ is injective.

Then the $\mathcal{O}_X$-submodule $0 \subset \mathcal{F}$ admits a primary decomposition.

**Proof.** We shall verify that conditions (a) and (b) of lemma \ref{lemma:primary} hold for $\mathcal{F}$. To check condition (a), it suffices to remark that $U \cap \text{Ass} \mathcal{F} = \text{Ass} \mathcal{F}|_U$ (which is obvious) and that $Z \cap \text{Ass} \mathcal{F} \subset \text{Ass} i^* \mathcal{F}$, which follows easily from our current assumption (b).

Next we check that condition (b) of loc.cit. holds. This is no problem for the points $x \in U \cap \text{Ass} \mathcal{F}$, so suppose that $x \in Z \cap \text{Ass} \mathcal{F}$. Moreover, we may also assume that $X$ is affine, say $X = \text{Spec} A$, so that $Z = V(J)$ for some ideal $J \subset A$. Due to proposition \ref{proposition:primary} we know that $0 \subset \mathcal{F} := i_* i^* \mathcal{F}$ admits a primary decomposition, hence we can find an $x$-primary ideal $I \subset A$ such that the natural map $\Gamma_{(x)} \mathcal{F} \to \mathcal{G}_x/1\mathcal{G}_x \cong \mathcal{F}_x/(I + J)\mathcal{F}_x$ is injective. Clearly $I + J$ is again an $x$-primary ideal; since $Z$ is closed and constructible, corollary \ref{corollary:primary} and our assumption (b) imply that the natural map $\Gamma_{(x)} \mathcal{F} \to \Gamma_{(x)} \mathcal{G}$ is injective, hence the same holds for the map $\Gamma_{(x)} \mathcal{F} \to \mathcal{F}_x/(I + J)\mathcal{F}_x$, as required. \qed

10.5.22. Let now $A$ be a ring, $p \subset A$ any prime ideal, and $n \geq 1$ any integer; if $A/p^n$ does not admit imbedded primes, then the ideal $p^n$ is $p$-primary. In the presence of imbedded primes, this fails. For instance, we have the following:

**Example 10.5.23.** Let $k$ be a field, $k[x, y]$ the free polynomial algebra in indeterminates $x$ and $y$; consider the ideal $I := (xy, y^2)$, and set $A := k[x, y]/I$. Let $\mathfrak{p}$ and $\mathfrak{q}$ be the images of $x$ and $y$ in $A$; then $p := (\mathfrak{q}) \subset A$ is a prime ideal, and $p^2 = 0$. However, $m := \text{Ann}_A(\mathfrak{q})$ is the maximal ideal generated by $\mathfrak{p}$ and $\mathfrak{q}$, so the ideal $0 \subset A$ is not $p$-primary.

There is however a natural sequence of $p$-primary ideals naturally attached to $p$. To explain this, let us remark, more generally, the following:

**Lemma 10.5.24.** Let $A$ be a ring, $p \subset A$ a prime ideal. Denote by $\varphi_p : A \to A_p$ the localization map. The rule:

$$I \mapsto \varphi_p^{-1} I$$

induces a bijection from the set of $pA_p$-primary ideals of $A_p$, to the set of $p$-primary ideals of $A$.

**Proof.** Suppose that $I \subset A_p$ is $pA_p$-primary; since the natural map $A/\varphi^{-1} I \to A_p/I$ is injective, it is clear that $\varphi_p^{-1} I$ is $p$-primary. Conversely, suppose that $I \subset A$ is $p$-primary; we claim that $I = \varphi_p^{-1}(J_p)$. Indeed, by assumption (and by lemma \ref{lemma:primary}(iii)) we have $(A/J)_q = 0$ whenever $q \neq p$; it follows easily that the localization map $A/J \to A_p/J_p$ is an isomorphism, whence the contention. \qed

**Definition 10.5.25.** Keep the notation of lemma \ref{lemma:primary} for every $n \geq 0$ one defines the $n$-th symbolic power of $p$, as the ideal:

$$p^{(n)} := \varphi_p^{-1}(p^n A_p).$$

By lemma \ref{lemma:primary}, the ideal $p^{(n)}$ is $p$-primary for every $n \geq 1$. More generally, for every $A$-module $M$, let $\varphi_{M, p} : M \to M_p$ be the localization map; then one defines the $p$-symbolic filtration on $M$, by the rule:

$$\text{Fil}_p^{(n)} M := \varphi_{M_p}^{-1}(p^n M_p) \quad \text{for every } n \geq 0.$$
The filtration $\text{Fil}_p^{(n)} M$ induces a (linear) topology on $M$, called the $p$-symbolic topology.

More generally, if $\Sigma \subset \text{Spec} A$ is any subset, we define the $\Sigma$-symbolic topology on $M$, as the coarsest linear topology $\mathcal{T}_\Sigma$ on $M$ such that $\text{Fil}_p^{(n)} M$ is an open subset of $\mathcal{T}_\Sigma$, for every $p \in \Sigma$ and every $n \geq 0$. If $\Sigma$ is finite, it is induced by the $\Sigma$-symbolic filtration, defined by the submodules:

$$\text{Fil}_\Sigma^{(n)} M := \bigcap_{p \in \Sigma} \text{Fil}_p^{(n)} M \quad \text{for every } n \geq 0.$$
