that the image of $X^\wedge$ in $Y$ contains $V'$, and then the image of $X^\wedge$ in $X^\wedge+$ contains $V''$, so $j''_X$ spreads over $V$.

(ii): Set $B := A_X[f_0^{-1}], B' := A_X^+[f_1/f_0, \ldots , f_n/f_0] \subset B$, say that $Y = (Y, \mathcal{R}_Y, B')$, and let $Y^+ := \text{Spec } B^+$. There follows a commutative diagram of schemes

$$
\begin{array}{ccc}
Y & \xrightarrow{\iota} & \text{Spec } B \\
\downarrow & & \downarrow ^\rho \\
X & \xrightarrow{h} & \text{Spec } A_X \\
\end{array}
$$

whose left square subdiagram is cartesian. Denote by $V' \subset \text{Spec } B'$ and $V'' \subset Y^+$ the preimages of $V$, and let $g \in A^+_X$ be any element such that $\text{Spec } A^+_X[g^{-1}] \subset V$; according to lemma [15.6.3](ii), the induced map $A^+_X[g^{-1}] \to A_X[g^{-1}]$ is an isomorphism. Especially, we may regard $f_0, \ldots, f_n$ as elements of $C := A^+_X[g^{-1}]$, and by assumption $\sum^n_{i=0} f_iC = C$. It follows easily that $f_0$ is invertible in the subring $B'[g^{-1}] = C[f_1/f_0, \ldots, f_n/f_0]$ of $B[g^{-1}]$, i.e. $B'[g^{-1}] = B[g^{-1}]$, and since $g$ is arbitrary, it follows that $\rho$ restricts to an isomorphism $\rho^{-1}V'' \xrightarrow{\sim} V''$. Recalling now that $B^+$ is the integral closure of $B'$ in $\mathcal{O}_Y(Y) = B$, we deduce that $\gamma_Y$ restricts as well to an isomorphism $\gamma_Y^{-1}V'' \xrightarrow{\sim} V''$. Lastly, since $\beta_X(X)$ contains $V$, clearly the image of $\beta_Y$ contains $V''$. The assertion follows easily (details left to the reader).

(iii): Say that $Y = (Y, \mathcal{R}_Y, A^+_Y)$, $Y' = (Y', \mathcal{R}_{Y'}, A^+_Y)$, and set $Y^+ := \text{Spec } A^+_Y$, $Y'^+ := \text{Spec } A^+_Y$. Set also $Z := \mathcal{O}_Y \times_X Y'$ and $(A_Z, A^+_Z, Z) := \Gamma(Z)$, so that $Z = Y \times_X Y'$. Denote $\varphi : Z \to Z' := Y^+ \times_X Y'^+$ and $\pi : Z' \to X^+$ the induced morphisms. With this notation, $\varphi_*, \mathcal{O}_Z$ is a sheaf of quasi-coherent $\mathcal{O}_{Z'}$-algebras, and $A^+_Z = \mathcal{O}(Z')$, where $\mathcal{O}$ is the integral closure of the image of $\mathcal{O}_{Z'}$ in $\mathcal{O}_Z$. Set $V' := \pi^{-1}V$; under the current assumptions it is clear that the associated morphism $\varphi^* : \mathcal{O}_{Z'} \to \mathcal{O}_Z$ restricts to an isomorphism $\mathcal{O}_{Z|V'} \xrightarrow{\sim} (\mathcal{O}_Z|V')$, whence $\mathcal{O}_V = (\mathcal{O}_Z|V')$, which means that the natural morphism $\nu : Z^+ := \text{Spec } A^+_Z \to Z'$ restricts to an isomorphism $\nu^{-1}V' \xrightarrow{\sim} V'$; lastly, since the image of $\varphi$ contains $V'$, it is clear that the image of $\beta_Z$ contains $\nu^{-1}V'$, whence the assertion.

(iv): Set $U := U \times_X X$, and let $h : U \to X^+$ be the composition of the open immersion $U \to \beta_X^{-1}V$ and the restriction $\beta_X^{-1}V \to X^+$ of $\beta_X$. Then $h = \varphi^+ \circ \beta_U^+$, and clearly $\beta_U^+$ has schematically dense image; by claim [15.6.3] we deduce that $\beta_U^+$ is an open immersion, whence the contention.

15.6.7. Let $X$ and $V$ be as in definition [15.6.1] and suppose that $X$ is topologically local and spreads over $V$. We denote by

$$
\mathcal{R}_V(X)
$$

the site whose underlying category is the full subcategory of $\mathcal{R}(X)$ whose objects are the rational subsets $R$ such that the sub-presheaf $h_R \subset h_{\text{Spa}_X}$ is represented by a morphism $Y \to X$ of quasi-affinoid schemes that spreads over $V$. Notice that, in view of proposition [15.6.6](iii), if $R, R' \in \text{Ob}(\mathcal{R}_V(X))$, then also $R \cap R' \in \text{Ob}(\mathcal{R}_V(X))$. As usual, a family $(R_i \to R \mid i \in I)$ of morphisms of $\mathcal{R}_V(X)$ generates a covering sieve of $\mathcal{R}_V(X)/R$ if and only if $\bigcup_{i \in I} R_i = R$.

In light of proposition [15.6.6](iii), we see that all fibre products are representable in $\mathcal{R}_V(X)$, and the inclusion functor $\iota : \mathcal{R}_V(X) \to \mathcal{R}(X)$ commutes with fibre products. By lemma 4.2.4 it follows that $\iota$ is continuous, i.e the induced functor on presheaves $\iota^\wedge : \mathcal{R}(X)^\wedge \to \mathcal{R}_V(X)^\wedge$ restricts to a functor on the respective subcategories of sheaves

$$
\iota_* : \mathcal{R}(X)^\wedge \to \mathcal{R}_V(X)^\wedge.
$$

We will denote as well by $\iota_*$ the corresponding functor on abelian sheaves. For every presheaf $\mathcal{F}$ on $\mathcal{R}(X)$ or $\mathcal{R}_V(X)$, let us denote as usual by $\mathcal{F}^a$ the sheaf associated to $\mathcal{F}$.
Proposition 15.6.8. In the situation of (15.6.7), let $\mathcal{G}$ be a presheaf, $\mathcal{A}$ an abelian presheaf, and $\mathcal{F}$ an abelian sheaf on $\mathcal{R}(X)$. The following holds:

(i) The natural morphism $(\iota^\mathcal{G})^a \to \iota^\mathcal{A}(\mathcal{G}^a)$ is an isomorphism.

(ii) The natural morphism $\iota_*\mathcal{F} \to R_i\iota_*\mathcal{F}$ is an isomorphism in $\text{D}(\mathbb{Z}_{\mathcal{R}(X)}\text{-Mod})$.

(iii) The natural map $H^i(\mathcal{R}_X, \iota^\mathcal{A}) \to H^i(\mathcal{R}(X), \mathcal{A})$ is bijective for every $i \in \mathbb{N}$.

Proof. (i): Define $\mathcal{F}^+$ as in the proof of theorem 4.1.13; in view of claim 4.1.16 it suffices to check that the natural morphism $(\iota^\mathcal{G})^+ \to \iota^\mathcal{A}(\mathcal{G}^+)$ is an isomorphism. For the injectivity, let $U \in \text{Ob}(\mathcal{R}_X)$ be any rational subset, and $s,t \in (\iota^\mathcal{G})^+(U)$ any two sections whose images agree in $\mathcal{F}^+(U)$. Then we may find a covering family $(U_\lambda \to U \mid \lambda \in \Lambda)$ of $\mathcal{R}_X/U$ such that the images of $s$ and $t$ are the classes of compatible systems $(s_\lambda \mid \lambda \in \Lambda), (t_\lambda \mid \lambda \in \Lambda)$ with $s_\lambda,t_\lambda \in \mathcal{G}(U_\lambda)$ for every $\lambda \in \Lambda$, and the assumption means that for every $\lambda \in \Lambda$ there exists a covering family $(U_{\lambda,i} \to U_\lambda \mid i \in I_\lambda)$ of $\mathcal{R}(X)/U_\lambda$ such that $s_\lambda|U_{\lambda,i} = t_\lambda|U_{\lambda,i}$ for every $\lambda \in \Lambda$ and every $i \in I_\lambda$. By proposition 15.6.6(ii) and lemma 15.5.21, the covering $U_\lambda$ can be refined by a covering $(U_{\lambda,i} \to U_\lambda \mid i \in I_\lambda)$ of $\mathcal{R}_X/U_\lambda$, for every $\lambda \in \Lambda$. Then $s_\lambda,t_\lambda \in \mathcal{F}(U_\lambda)$, for every $\lambda \in \Lambda$ and every $i' \in I_{\lambda'}$, so that $s = t$. Lastly, let $s \in \mathcal{G}^+(U)$ be any section; by definition we may find a covering family $(U_\lambda \to U \mid \lambda \in \Lambda)$ of $\mathcal{R}(X)/U$ such that $s$ is represented by a compatible system $(s_\lambda \mid \lambda \in \Lambda)$ with $s_\lambda \in \mathcal{G}(U_\lambda)$ for every $\lambda \in \Lambda$. But again, the covering $U_\lambda$ can be refined by a covering of $\mathcal{R}_X(X)$, and we deduce that $s$ is the image of a section of $(\iota^\mathcal{G})^+(U)$.

(ii): The assertion means that $R^i\iota_*\mathcal{F} = 0$ for every $i > 0$. However, recall that $R^i\iota_*\mathcal{F}$ is the sheaf associated to the presheaf that assigns to every $U \in \text{Ob}(\mathcal{R}_X)$ the abelian group $H^i(\mathcal{R}(X)/U, \mathcal{F}|_U)$. Hence, let us fix such a rational subset $U$, and let $s \in H^i(\mathcal{R}(X)/U, \mathcal{F}|_U)$ be any element; it suffices to exhibit a covering $U \to U \mid \lambda \in \Lambda$ of $\mathcal{R}(X)/U$ such that $s_\lambda|U \to U \mid \lambda \in \Lambda$ vanishes for every $\lambda \in \Lambda$. However, notice that there exists a covering $(U_{\lambda,i} \to U \mid \lambda \in \Lambda')$ of $\mathcal{R}(X)/U$ such that the image of $s$ in $H^i(\mathcal{R}(X)/U, \mathcal{F}|_{U_{\lambda,i}})$ vanishes for every $\lambda \in \Lambda'$. This is clear, since these cohomology groups are computed by an injective resolution of $\mathcal{F}$, which is exact in degrees $> 0$. But by proposition 15.6.6(ii) and lemma 15.5.21, the covering $U_{\lambda,i}$ can be refined by a covering $U_{\lambda,i}$ consisting of objects of $\mathcal{R}_X(X)$, and clearly such $U_{\lambda,i}$ will do.

(iii): This is an immediate consequence of the fact – already remarked in the foregoing – that every covering family of $\mathcal{R}(X)$ can be refined by a covering family of $\mathcal{R}_X(X)$: the details shall be left to the reader. \qed

15.6.9. Consider a quasi-affinoid ring $A := (A,A^+,U)$ such that $A$ is an adic (and f-adic) topological ring; let $A_U := \Theta(U)$ and $U^+ := (U, U^+, A_U) := \text{Spec } A_U$, and set

$$X_A := \text{Spec } A \quad X_A^+ := \text{Spec } A_U^+ \quad X_A^0 := \text{Spec } A_U^0.$$

The induced map $A \to A_U$ is f-adic, so its image lies in $A_U^0$ (lemma 8.3.24(iii)), and we get a commutative diagram of schemes:

$$
\begin{array}{ccc}
U & \xrightarrow{i} & X_A \\
\downarrow{j} & & \downarrow{j'} \\
\text{Spec } A_U & \xrightarrow{j'} & X_A^0 \\
\end{array}
$$

Let also $Z \subset X_A^0$ be the support of the $A_U^0$-module $A_U^0/A_U^+$, and $Z' := X_A^0 \setminus j' \circ j(U)$.

Lemma 15.6.10. With the notation of (15.6.9), the following holds:

(i) $i$, $j$, and $j' \circ j$ are open immersions.

(ii) The images of $j$ and $j'$ are schematically dense.
(iii) The open subset $j' \circ j(U)$ contains the analytic locus of $X^0_A$.
(iv) $X^+_A \setminus \Omega_U$ is the topological closure of $Z \cup t(Z')$.

**Proof.** (ii): The assertion for $j'$ is clear. Next, let $\mathcal{F}$ be the kernel of the induced morphism $j^\#: O_{\mathrm{Spec} A_U} \to j_\# O_U$; since $U$ is quasi-compact, $j_\# O_U$ is a quasi-coherent $O_{\mathrm{Spec} A_U}$-module, so the same holds for $\mathcal{F}$, and we are reduced to checking that $\Gamma(\mathrm{Spec} A_U, \mathcal{F}) = 0$, which is clear, since $j^\#$ induces an isomorphism on global sections.

(i): For $i$ there is nothing to prove, and the assertion for $j$ follows from [45, Ch.II, Prop.5.1.2]. The assertion for $j' \circ j$ follows from claim [15.6.5](i).

(iii): Notice that $j'$ maps the analytic locus of $\mathrm{Spec} A_U$ isomorphically onto that of $X^0_A$ (lemma [8.3.29](iii)); likewise, it is easily seen that $j'' \circ j'$ restricts to an isomorphism from the analytic locus of $\mathrm{Spec} A_U$ onto that of $X_A$. Summing up, we conclude that $j''$ restricts to an isomorphism from the analytic locus of $X^0_A$ onto that of $X_A$, whence the assertion.

(iv): Consider the commutative diagram of schemes

$$
\beta^{-1}_U \Omega_U \xrightarrow{f} t^{-1} \Omega_U \\
\downarrow h \quad \quad \downarrow g \\
\Omega_U
$$

where $f$ is the restriction of $j' \circ j$, and $g$ is the restriction of $t$. Thus, $h$ is the restriction of $\beta_U$, and it is an isomorphism, by definition of $\Omega_U$; moreover, clearly $f$ has schematically dense image. By claim [15.6.5] it follows that $f$ is a surjective open immersion, i.e. it is an isomorphism, and then the same holds for $g$ as well. Now, if $x \notin \Omega_U$ is any point, it follows immediately that $x \notin Z$; moreover $g^{-1}(x)$ is the unique point of $t^{-1}(x)$, and this point lies in $j' \circ j(U)$.

This shows that $Z \cup t(Z') \subset X^+_A \setminus \Omega_U$. Conversely, suppose that $x \in X^+_A$ lies neither in $\Omega_U$ nor the topological closure of $Z$; then there exists an open neighborhood $V$ of $x$ in $X^+_A$ with $V \cap Z = \emptyset$, and it follows that $t$ restricts to an isomorphism $t^{-1}V \xrightarrow{\sim} V$. In view of (i), the restriction $\beta^{-1}_U V \to t^{-1} V$ of $j' \circ j$ is still an open immersion, so the same holds for the restriction $\beta^{-1}_U V \to V$ of $\beta_U$, and consequently $\beta_U(U) \cap V = \beta_U(\beta^{-1}_U V) \subset \Omega_U$, according to lemma [15.6.3](ii). We conclude that $x \notin \beta_U(U)$, and since $x \in t(V)$, we finally get $x \in t(Z')$, whence (iv).

15.7. **Etale coverings of quasi-affinoid schemes.** Let $\mathbf{Sch}$ be the category of schemes (in the universe $U$). For every scheme $X$, let also $X_{\text{ét}}$ be the full subcategory of the category $\mathbf{Sch}/X$, whose objects are the étale morphisms $Y \to X$ with $Y$ quasi-compact and quasi-separated; notice that every morphism in $X_{\text{ét}}$ is étale. We endow $X_{\text{ét}}$ with its standard étale topology $J_{X,\text{ét}}$, whose covering families are all the systems $(f_i : Y_i \to Y \mid i \in I)$ of families of morphisms of $X$-schemes such that $\bigcup_{i \in I} f_i(Y_i) = Y$. The site $(X_{\text{ét}}, J_{X,\text{ét}})$ is called the étale site of $X$, and is also often denoted simply by $X_{\text{ét}}$, when no ambiguities are likely to arise. It is easily seen that $X_{\text{ét}}$ is a lex-site if and only if $X$ is a quasi-compact and quasi-separated scheme (the details are left to the reader). Recall that we have a fibration $\mathbf{Cov} \to \mathbf{Sch}$ whose fibre category over every $Y \in \mathrm{Ob}(\mathbf{Sch})$ is the category of finite étale $Y$-schemes (see [13.1]). From the natural functor

$$X_{\text{ét}} \to \mathbf{Sch} \quad (Y \to X) \mapsto Y$$

we deduce a fibration

$$\mathbf{Cov}_{X_{\text{ét}}} := X_{\text{ét}} \times_{\mathbf{Sch}} \mathbf{Cov} \to X_{\text{ét}}.$$ 

By faithfully flat descent, it is easily seen that $\mathbf{Cov}_{X_{\text{ét}}}$ is an ind-finite stack over the site $X_{\text{ét}}$.

For every $k \in \mathbb{N}$ let $[k] := \{0, \ldots, n\}$, and set as well $[-1] := \emptyset$; we denote by $\mathbb{N}$ the full subcategory of the category $\mathbf{Set}$ with $\mathrm{Ob}(\mathbb{N}) := \{[k] \mid k \geq -1\}$. Then, let $N_{X_{\text{ét}}}$ be the constant
presheaf of categories on $X_{\text{ét}}$ with value $N$, i.e. the presheaf such that $\mathbb{N}_{X_{\text{ét}}}(Y) := N$ for every $Y \in \text{Ob}(X_{\text{ét}})$, and $N_X(f) := 1_N$ for every morphism $f$ of $X_{\text{ét}}$. We get an $X_{\text{ét}}$-cartesian functor

$$\omega_X : \mathcal{F}ib(N_{X_{\text{ét}}}) \to \text{Cov}_{X_{\text{ét}}}, (Y, [k]) \mapsto ([k] \times Y \to Y).$$

**Lemma 15.7.1.** The functor $\omega_X$ is $i$-covering for $i = 0, 1, 2$.

**Proof.** Let $f : Y \to X$ be a finite étale covering, and $x \in X$; in order to check the assertion for $i = 0$, we need to exhibit an étale morphism $g : X' \to X$ and $k \in \mathbb{N}$ from an affine scheme $X'$ such that $x \in g(X')$, with an isomorphism of $X'$-schemes $X' \times_X Y \to [k] \times X'$. To this aim, let $\xi : \text{Spec } \kappa \to X$ be a geometric point localized at $x$. Notice that the diagonal morphism $\Delta_{Y/X} : Y \to Y \times_X Y$ is a finite étale morphism, hence its image is open and closed in $Y \times_X Y$. Thus, the $Y$-scheme $Y \times_X Y$ is isomorphic to the disjoint union of $Y$ and a finite étale covering $h : Z \to Y$. The geometric point $\xi$ lifts to a geometric point $\xi_Y : \text{Spec } \kappa \to Y$, and it is then easily seen that $h^{-1}(\xi_Y) = c - 1$. By inductive assumption, we find an étale morphism $g_Y : Y' \to Y$ from an affine scheme $Y'$, such that $g_Y(\xi_Y)$ contains the support of $\xi_Y$, and such that the $Y'$-scheme $Y' \times_Y Z$ is isomorphic to $[c - 2] \times Y'$. We may then take $X' := Y'$ and $g := f \circ g_Y$.

Next, to check the assertion for $i = 1$, let $k, k' \geq -1$ be two integers, $g : [k] \times X \to [k'] \times X$ a morphism of $X$-schemes, and $x \in X$; it suffices to find an affine open neighborhood $U$ of $x$ in $X$, and a map of sets $\varphi : [k] \to [k']$ such that the restriction $g_U : [k] \times U \to [k'] \times U$ of $g$ agrees with $\varphi \times U$. To this aim, it suffices to invoke [51] Ch.IV, Cor.17.4.7 : the details are left to the reader. Lastly, it is clear from the definitions that $\omega_X$ is a 2-covering functor. \hfill \blackqed

15.7.2. Denote by $\text{Sch}_{\text{qcqs}}$ the full subcategory of $\text{Sch}$ whose objects are the quasi-compact and quasi-separated schemes, and by $\text{Sch}_{\text{ét}}^{\text{qcqs}}$ the full subcategory of $\text{Morph}(\text{Sch}_{\text{qcqs}})$ whose objects are the étale morphisms of schemes. The restriction

$$t : \text{Sch}_{\text{ét}}^{\text{qcqs}} \to \text{Sch}_{\text{qcqs}}$$

of the target functor $t : \text{Morph}(\text{Sch}_{\text{qcqs}}) \to \text{Sch}_{\text{qcqs}}$ is a fibration, and for every $X \in \text{Ob}(\text{Sch}_{\text{qcqs}})$, the fibre category $t^{-1}(X)$ is the previously defined category $X_{\text{ét}}$, which we endow with its étale topology $J_{X_{\text{ét}}}$; we get therefore a well defined fibred site:

$$(\text{Sch}_{\text{ét}}^{\text{qcqs}}, t, J_{\text{ét}}).$$

For every category $I$ and every functor $F : I \to \text{Sch}_{\text{qcqs}}$ we let

$$F_{\text{ét}} := I \times_{(\text{Sch}_{\text{qcqs}}, F)} (\text{Sch}_{\text{ét}}^{\text{qcqs}}, t, J_{\text{ét}})$$

(notation of [4.5.11]). Thus, $F_{\text{ét}}$ is a fibred lex-site over $I$, whose fibre category over every $i \in \text{Ob}(I)$ is naturally identified with the lex-site $(F_i)_{\text{ét}}$. Moreover, we have a natural functor:

$$F_{\text{ét}} \to \text{Sch}, (i, Y \to F_i) \mapsto Y$$

from which we deduce a fibration over $F_{\text{ét}}$ :

$$\text{Cov}_{F_{\text{ét}}} := F_{\text{ét}} \times_{\text{Sch}} \text{Cov} \to F_{\text{ét}}$$

whose restriction to the fibre category $(F_i)_{\text{ét}}$ is naturally identified with the fibration $\text{Cov}((F_i)_{\text{ét}})$, for every $i \in \text{Ob}(I)$. Explicitly, the objects of $\text{Cov}_{F_{\text{ét}}}$ are the data $(i, f : Y \to F_i, g : Z \to Y)$ where $f$ is an étale morphism, $g$ is a finite étale morphism, and $i \in \text{Ob}(I)$. Let $N_{F_{\text{ét}}}$ be the
constant presheaf of categories on \( F_{\text{ét}} \) with value \( N \); as in (15.7), we then have a cartesian functor of \( F_{\text{ét}} \)-fibrations:

\[
\mathcal{F}ib(N_{F_{\text{ét}}}) \to \text{Cov}_{F_{\text{ét}}}
\]

\((i, f : Y \to F \times [k]) \to (i, f : Y \to F, [k] \times Y \to Y)\).

Clearly the restriction of (15.7.3) to each fibre category \((Fi)_{\text{ét}}\) is naturally identified with the functor \( \omega_{Fi} \) of (15.7); in view of lemma 15.7.1 and proposition 5.7.1(i) we deduce that also (15.7.3) is \( i \)-covering for \( i = 0, 1, 2 \).

15.7.4. Let \( X := (X, \mathcal{R}_X, A_X) \) be a topologically henselian quasi-affinoid scheme; we attach to \( X \) a site \((\mathcal{D}(X), J_\mathcal{D})\) of quasi-affinoid open subsets, as in (15.5.11). We now define as follows a fibred lex-site over the category \( \mathcal{D}(X) \). For every \( U \in \text{Ob}(\mathcal{D}(X)) \) choose a topologically henselian quasi-affinoid scheme \( X_U^h := (X_U^h, \mathcal{R}_U^h, A_U^{ht}) \) representing the sub-presheaf \( h_U^h \) of \( h_X^h \) (notation of remark 15.5.9(i)). Every inclusion \( U \subset U' \) of quasi-affinoid subsets of \( \text{Spa} \ X \) induces a morphism

\[
i_{UU'} : X_U^h \to X_{U'}^h,
\]

of quasi-affinoid schemes (cp. (15.5.11)), and for every further inclusion \( U' \subset U'' \) of quasi-affinoid open subsets of \( \text{Spa} \ X \) we have \( i_{UU''} \circ i_{UU'} = i_{UU''} \), so we get a well defined functor

\[
X^h : \mathcal{D}(X) \to \text{Sch}^{qcqs}
\]

whence an associated fibred site as in (15.7.2)

\[
\pi_X : X^h_{*, \text{ét}} := \mathcal{D}(X) \times_{\text{Sch}^{qcqs}} (\text{Sch}^{qcqs}, t, J_{*, \text{ét}}) \to \mathcal{D}(X).
\]

Notice that \( X^h_{*, \text{ét}} \) is a fibred lex-site, since \( X_U^{h, \text{ét}} \) is quasi-compact and quasi-separated for every \( U \in \text{Ob}(\mathcal{D}(X)) \). We let \((X^h_{*, \text{ét}}, J)\) be the associated total site.

- The identity functor \( 1_{\mathcal{D}(X)} : \mathcal{D}(X) \to \mathcal{D}(X) \) is naturally identified with the fibration \( \mathcal{F}ib(F_1) \to \mathcal{D}(X) \), where \( F_1 : \mathcal{D}(X)^o \to \text{Cat} \) is the constant pseudo-functor with value \( 1 \). The category \( 1 \) admits a unique topology \( \mathcal{T}_I \), and the resulting pair \((1, \mathcal{T}_I)\) is obviously a lex-site, so we have the fibred lex-site

\[
(\mathcal{D}(X), 1_{\mathcal{D}(X)}, J^*_{\mathcal{T}_I})
\]

where \( J_{\mathcal{T}_I} \) is the unique topology on the fibre \( 1_{\mathcal{D}(X)}(U) \sim 1 \), for every \( U \in \text{Ob}(\mathcal{D}(X)) \), and we let \((\mathcal{D}(X), J^*_\mathcal{D})\) be the resulting total site.

- Denote by

\[
e : \mathcal{D}(X) \to X^h_{*, \text{ét}}.
\]

the functor that assigns to every \( U \in \text{Ob}(\mathcal{D}(X)) \) the final object \( X_U^h \) of the fibre category \( X_{U, \text{ét}}^{h, \text{ét}} \), and to every inclusion \( U \subset U' \) the morphism \( i_{UU'} \). It is easily seen that \( e \) is a \( \mathcal{D}(X) \)-cartesian functor. Moreover, \( e \) restricts to a morphism of sites \( X_U^{h, \text{ét}} \to (1, \mathcal{T}_I) \) for every \( U \in \text{Ob}(\mathcal{D}(X)) \), so \( e \) is a morphism of fibred lex-sites, and also a morphism of total sites

\[
e : (X^h_{*, \text{ét}}, J) \to (\mathcal{D}(X), J^*_\mathcal{D}).
\]

- Lastly, for every \( U \in \text{Ob}(\mathcal{D}(X)) \) we have an inclusion functor \( i_U : X_U^{h, \text{ét}} \to X^h_{*, \text{ét}} \) which identifies \( X_U^{h, \text{ét}} \) with the fibre category over \( U \). This is a weak morphism of sites

\[
i_U : (X^h_{*, \text{ét}}, J) \to X^h_{U, \text{ét}}
\]

and for \( U = \text{Spa} \ X \) it is even a morphism of sites (example 4.5.8). Let now \( E \) be a stack on the étale site \( X_{\text{ét}} \); we consider the fibration:

\[
E_{/\mathcal{D}} := \text{St}(e)_* \circ \text{St}(i_{\text{Spa} X})^* E.
\]
Remark 15.7.5. (i) The fibres of the fibration \( E/\mathcal{G} \) can be described as follows. Let \( c_X : \mathcal{D}(X) \to \text{Sch}^{\text{qcqs}} \) be the constant functor with value \( X \); we consider as well the fibred lex-site
\[
\mathcal{D}(X) \times X_{\text{ét}} = \mathcal{D}(X) \times (\text{Sch}^{\text{qcqs}}, c_X) (\text{Sch}^{\text{qcqs}}_{\text{ét}}, \iota, J_{\text{ét}}) \to \mathcal{D}(X)
\]
(see (4.5.11)) whose fibre categories are all naturally identified with \( X_{\text{ét}} \). Then the rule \( U \mapsto (i_U, \text{Spa}_X : X^h_U \to X) \) defines a natural transformation \( X^h_{\text{ét}} \Rightarrow c_X \) which induces, after choosing a cleavage for the fibration \( \text{Sch}^{\text{qcqs}}_{\text{ét}} \), a morphism of fibred lex-sites over \( \mathcal{D}(X) \):
\[
j_X : X^h_{\text{ét}} \to \mathcal{D}(X) \times X_{\text{ét}}
\]
(see (4.5.12)) which is also a morphism on the respective total sites
\[
j_X : (X^h_{\text{ét}}, J) \to (\mathcal{D}(X) \times X_{\text{ét}}, J').
\]
Moreover, let \( l_X : X_{\text{ét}} \to \mathcal{D}(X) \times X_{\text{ét}} \) be the inclusion functor that identifies \( X_{\text{ét}} \) with the fibre category over the final object of \( \mathcal{D}(X) \). By example 4.5.8, this functor is a morphism of sites
\[
l_X : (\mathcal{D}(X) \times X_{\text{ét}}, J') \to X_{\text{ét}}
\]
and notice that \( i_{\text{Spa}_X} = j_X \circ l_X \). Furthermore, the projection \( p_X : \mathcal{D}(X) \times X_{\text{ét}} \to X_{\text{ét}} \) is left adjoint to \( l_X \), and from corollary 5.7.2 (ii) it follows easily that \( p_X \) is a weak morphism of sites for the topology \( J' \). Combining with proposition 5.4.29 (ii, iii), we deduce a pseudo-natural equivalence of pseudo-functors:
\[
\text{St}(l_X)^* \sim \text{St}(p_X)^*.
\]
Especially, we get an equivalence of stacks:
\[
\text{St}(i_{\text{Spa}_X})^* E \sim \text{St}(j_X)^* \text{St}(p_X)^*(E) = \text{St}(j_X)^*(\mathcal{D}(X) \times E).
\]
In light of proposition 5.7.3, we deduce a natural equivalence of stacks on \( X^h_U, \text{ét} \):
\[
\text{St}(i_U)^* \circ \text{St}(i_{\text{Spa}_X})^* E \sim E_U := \text{St}((i_U, \text{Spa}_X)_{\text{ét}})^* E \quad \text{for every } U \in \text{Ob}(\mathcal{D}(X)).
\]
Summing up, we conclude that the fibre category over \( U \) of the fibration \( E/\mathcal{G} \) is naturally equivalent to the fibre category \( (E_U)_{X^h_U} \) of the fibration \( E_U \), over the final object \( X^h_U \) of the site \( X^h_{J, \text{ét}} \).

(ii) By construction, \( E/\mathcal{G} \) is a stack on the site \( (\mathcal{D}(X), J_\mathcal{G}) \); but in fact we have:

**Theorem 15.7.6.** If \( E \) is ind-finite, the fibration \( E/\mathcal{G} \) is a stack on the site \( (\mathcal{D}(X), J_\mathcal{G}) \).

**Proof.** It suffices to check that the natural functor
\[
E/\mathcal{G}(U) \to \text{2-colim}_{\mathcal{J} \in J_\mathcal{G}(U)} \text{Cart}_{\mathcal{J}^\mathcal{G}}(\mathcal{J}, E/\mathcal{G}) \quad \text{for every } U \in \text{Ob}(\mathcal{D}(X))
\]
is an equivalence. Since \( J_\mathcal{G}(U) \) is cofiltered for the order given by inclusion of sieves, this 2-colimit is represented by the colimit of the same system of categories (example 3.2.13 (iv)); then arguing as in the proof of theorem 15.5.26 we may assume that \( U = \text{Spa}_X \), and replace \( J_\mathcal{G}(\text{Spa}_X) \) by its cofinal subset consisting of the sieves generated by the standard coverings. Thus, let \( f_\bullet := (f_0, \ldots, f_n) \) and \( R_\bullet \) be as in remark 15.5.25 (i); for every \( k \in \mathbb{N} \), let \( [k] := \{0, \ldots, k\} \), and set as well \( [-1] := \emptyset \). We consider the category \( \Sigma^+_2, n \) whose objects are all the maps \( [j] \to [n] \) for \( j = -1, 0, 1, 2 \); for two such objects \( [j] \xrightarrow{\varphi} [n] \xrightarrow{\varphi'} [k] \), the morphisms \( \mu : \varphi \to \varphi' \) are the injective non-decreasing maps \( \mu : [j] \to [k] \) such that \( \varphi' \circ \mu = \varphi \). The unique map \( \varphi_0 : [-1] \to [n] \) is clearly the initial object of \( \Sigma^+_2, n \). Let also \( \Sigma^+_2, n \subset \Sigma^+_2 \) be the full subcategory whose objects are the morphisms \( [j] \to [n] \) with \( j \geq 0 \). Consider the functor
\[
\Phi^+ : \Sigma^+_2, n \to \mathcal{D}(X) : ([j] \xrightarrow{\varphi} [n]) \mapsto R_{\varphi}(j)
\]
(here $R_{\Lambda} \subset \text{Spa} X$ is defined as in remark 15.5.25(i), for every subset $\Lambda \subset [n]$, and let $\Phi : \Sigma^{o}_{2,n} \to \mathcal{D}(\underline{X})$ be the restriction of $\Phi^+$. Taking into account the discussion of (3.4.18), we come down to checking that the natural functor

$$\mathcal{E}_{/\mathcal{D}}(\text{Spa} X) \to 2\lim_{\Sigma^{o}_{2,n}} \mathcal{E}_{/\mathcal{D}}(-) \circ \Phi^o$$

is an equivalence (notation of (3.1.41)). Following (4.5.11), we deduce two other fibred lex-sites

$$\Upsilon_{\Psi}^h := \Sigma^{+o}_{2,n} \times \mathcal{D}(\underline{X}) (\underline{\Sigma}_{\Psi, et}, J) \to \Sigma^{+o}_{2,n}, \quad \Sigma^{+o}_{2,n} := \Sigma^{+o}_{2,n} \times \mathcal{D}(\underline{X}) (\mathcal{D}(\underline{X}), 1_{\mathcal{D}(\underline{X})}, J^*)$$

and according to (4.5.11) and (5.7) and proposition 5.4.29(ii), the projections $\Phi^+$ and $\pi_{\Psi} : \Upsilon_{\Psi}^h \to \Sigma^{+o}_{2,n}$

are cocontinuous weak morphisms of sites for the topologies of the respective total sites. Furthermore, the functor $e \circ \Phi^+ : \Sigma^{+o}_{2,n} \to X^h_{*, et}$ factors uniquely through a $\Sigma^{+o}_{2,n}$-cartesian functor

$$e_{\Psi} : \Sigma^{+o}_{2,n} \to \Upsilon_{\Psi}^h$$

and the projection $\pi_{\Psi}$. Just like for $e$, the functor $e_{\Psi}$ is a morphism of the respective total sites. Set $\mathcal{F} := \text{St}(\pi_{\Psi})_* \circ \text{St}(i_{\text{Spa} X})^* \mathcal{E}$; a direct inspection yields an equivalence of stacks

$$\mathcal{G} := \text{St}(e_{\Psi})_* \circ \text{St}(\Phi^+)_* (\mathcal{E}_{/\mathcal{D}})$$

over the total site of $\Sigma^{+o}_{2,n}$, and we are reduced to checking that the natural functor

$$(15.7.7) \quad \mathcal{G}(\varphi_{\mathcal{D}}) \to 2\lim_{\Sigma^{o}_{2,n}} \mathcal{G}(-)$$

is an equivalence. To this aim, we proceed as in remark 15.7.5(iv): from the constant functor $c_X : \Sigma^{+o}_{2,n} \to \text{Sch}^{qcqs}$ we deduce the fibred site

$$\Sigma^{+o}_{2,n} \times X_{et} = \Sigma^{+o}_{2,n} \times_{(\text{Sch}^{qcqs}, c_X)} (\text{Sch}^{qcqs}, t, J_{*, et}) \to \Sigma^{+o}_{2,n}$$

whose fibre categories are naturally identified with $X_{et}$, endowed with its étale topology. Let $j_X : X^h_{*, et} \to \mathcal{D}(\underline{X}) \times X_{et}$ be as in remark 15.7.5(i); we deduce a morphism of fibred lex-sites

$$j_{\Sigma} := \Sigma^{+o}_{2,n} \times \mathcal{D}(\underline{X}) j_X : \Upsilon_{\Psi}^h \to \Sigma^{+o}_{2,n} \times X_{et}$$

which as usual induces a morphism on total sites, and by the same token, the projection

$$\Sigma^{+o}_{2,n} \times \mathcal{D}(\underline{X}) p_X : \Sigma^{+o}_{2,n} \times X_{et} \to X_{et}$$

is a weak morphism of sites, for the topology of the total site, and is left adjoint to the inclusion functor

$$l_{\Sigma} := \Sigma^{+o}_{2,n} \times \mathcal{D}(\underline{X}) l_X : X_{et} \to \Sigma^{+o}_{2,n} \times X_{et}.$$  

By proposition 5.7.3 we have then an equivalence of stacks over the total site of $\Upsilon_{\Psi}^h$:

$$\mathcal{F} \simeq \text{St}(j_{\Sigma})^* (\Sigma^{+o}_{2,n} \times \mathcal{E}).$$

Next, let $A_0 \subset A := \mathcal{O}^h_{\text{Spa} X}(\text{Spa} X)$ be a subring of definition, and $I_0 \subset A_0$ an ideal of adic definition; set $S := \text{Spec} A_0$ and $S' := \text{Spec} A_0/I_0$. As in remark 15.5.25(iv,v), the sequence $f_*$ induces a morphism of schemes $X \to \mathbb{P}^n_S$, whose schematic image we denote by $V$, and we let $\psi : X \to V$ be the resulting morphism of $S$-schemes; moreover, for every non-empty subset $\Lambda \subset [n]$ we have an open subset $V_{\Lambda} \subset V$ which is naturally identified with $\text{Spec} A_0[j_k/f_i | (k, i) \in [n] \times \Lambda]$, and we set as well $V_{\varnothing} := V$. Then, for every $\Lambda \subset [n]$ let $V_{\Lambda}^h$ be the henselization of $V_{\Lambda}$ along its closed subscheme $V_{\Lambda}' := S' \times_S V_{\Lambda}$; we have natural identifications

$$X^h_{\Lambda} \simeq X \times_X V^h_{\Lambda} \quad \text{for every } \Lambda \subset [n],$$

for every $\Lambda \subset [n]$.
and we denote by $\psi_h^\Lambda : X_h^\Lambda \to V_h^\Lambda$ the induced projection, and by $q_\Lambda : V_h^\Lambda \to V$ the composition of the henselization map $V_h^\Lambda \to V_\Lambda$ with the open immersion $V_\Lambda \to V$. We consider the functors

$$G : \Sigma_2^+_{2,n} \to \text{Sch}^{\text{qcqs}} : ([j] \xrightarrow{\varphi} [n]) \mapsto V_h^\varphi([j])$$

$$G' : \Sigma_2^+_{2,n} \to \text{Sch}^{\text{qcqs}} : ([j] \xrightarrow{\varphi} [n]) \mapsto V_h^\varphi([j])$$

which to every morphism $\mu : \varphi \to \varphi'$ as in the foregoing assign the natural morphisms

(15.7.8) \[ V_h^\varphi([k]) \to V_h^\varphi([j]) \quad \text{and respectively} \quad V_h^{\varphi'}([k]) \to V_h^{\varphi'}([j]). \]

As in (15.7.2) we deduce fibred lex-sites

$$\mathcal{Y}_h^J : \begin{array}{c} \psi_h \downarrow \mathcal{Y}_f^h \quad \tau_r \downarrow \mathcal{Y}_f^r \quad \mathcal{Y}_f^r \quad \mathcal{Y}_f' \quad \psi_h \end{array} : \begin{array}{c} \Sigma_2^+_{2,n} \times (\text{Sch}^{\text{qcqs}}_\text{et}, t, J_{\text{et}}) \to \Sigma_2^+_{2,n} \end{array}$$

The morphisms $(\psi_h^{\Lambda} | \Lambda \subset [n]), (q_\Lambda | \Lambda \subset [n])$, the closed immersions $(V_h^\Lambda \to V_h^\Lambda | \Lambda \subset [n])$ and $V' \to V$, and the open immersions $(V_h^\Lambda \to V' | \Lambda \subset [n])$ define natural transformations $\Sigma_2^+_{2,n} \circ \Phi^+ \Rightarrow G, G \Rightarrow c_V, G' \Rightarrow G, c_V^+ \Rightarrow c_V$ and respectively $G' \Rightarrow c_V^+$, where $c_V : \Sigma_2^+_{2,n} \to \text{Sch}$ is the constant functor with value $V$, and likewise for $c_V^+$. After fixing cleavages, these natural transformations induce morphisms of fibred lex-sites

(see (4.5.12), which are also morphisms of sites for the topologies of the respective total sites (proposition 4.5.9)). Define functors $e_{\varphi} : \Sigma_2^+_{2,n} \to \mathcal{Y}_f^h$ and $e_{\varphi'} : \Sigma_2^+_{2,n} \to \mathcal{Y}_f^r$ by the rules:

$$\varphi \mapsto (\varphi, V_h^\varphi([j])) \quad \text{and respectively} \quad \varphi \mapsto (\varphi, V_h^{\varphi'}([j])) \quad \text{for every} \quad \varphi : [j] \to [n]$$

and which assign to every morphism $\mu : \varphi \to \psi$ as in the foregoing, the morphisms (15.7.8). Just as for $e$ and $e_{\varphi}$, both $e_{\varphi}$ and $e_{\varphi'}$ are morphisms of the respective total sites, and we get a commutative diagram of morphisms of sites:

(15.7.9) \[ \begin{array}{ccc}
V_h^\Lambda & \xrightarrow{\tau_r} & V_h^\varphi \leftarrow \psi_h \\
\downarrow i_{\varphi'} & & \downarrow i_V \\
\Sigma_2^+_{2,n} \times V_h^\varphi & \xrightarrow{\tau_r} & \Sigma_2^+_{2,n} \times V_h^\varphi \leftarrow \psi_h \\
\downarrow q & & \downarrow q \\
\mathcal{Y}_f^r & \xrightarrow{\tau_r} & \mathcal{Y}_f^h \leftarrow \psi_h \\
\downarrow e_{\varphi'} & & \downarrow e_{\varphi} \\
\Sigma_2^+_{2,n} & \xrightarrow{\psi_h} & \Sigma_2^+_{2,n} \leftarrow \Sigma_2^+_{2,n}.
\end{array} \]

where $\psi_\Sigma$ is likewise deduced from $\psi$. Set $\mathcal{F}' := \text{St}(e_{\varphi})_{\ast} \mathcal{F}$. There follows an equivalence:

$$\mathcal{G} \xrightarrow{\sim} \text{St}(e_{\varphi})_{\ast} \mathcal{F}'.$$

We regard the left square of the bottom row and the right square of the central row in (15.7.9) as oriented squares of sites, with orientations given by $1_{e_{\varphi}}$, respectively $1_{q_0 \psi_{\varphi}}$. We remark:

**Claim** 15.7.10. For every ind-finite stack $\mathcal{A}$ on $\mathcal{Y}_f^h$, the base change transformation

$$\Upsilon(\text{St}(1_{e_{\varphi}})_{\ast} \mathcal{A}) : \text{St}(e_{\varphi})_{\ast} (\mathcal{A}) \to \text{St}(e_{\varphi'}), \text{St}(\tau_r)^{\ast} (\mathcal{A})$$

is a natural equivalence (notation of (2.3.8) and (5.5.23)).
Proof of the claim. This follows by combining corollary \[5.7.26\] and \[58\] Th.1’ and Cor.1]. Notice that the proof of loc.cit. relies on proposition 1 of the same article; for the latter, a complete proof is available in \[84\] Exp.XX, Prop.6.3.2]. More precisely, in the latter reference, the required results are stated only for stacks in groupoids; however, a direct inspection shows that the proofs work verbatim for arbitrary ind-finite stacks.

Notice as well the pseudo-natural equivalences of pseudo-functors:

\[(15.7.11)\quad \text{St}(e_{\bar{\nu}}) \simeq \text{St}(e_{\bar{\nu}}) \circ \text{St}(\psi_{\bar{\nu}}) \circ \text{St}(\tau_{\bar{\nu}}) \circ \text{St}(q)^* \simeq \text{St}(q')^* \circ \text{St}(\tau_{\Sigma})^*.
\]

**Claim 15.7.12.** The base change transformation

\[\Upsilon(\text{St}(1_{q\psi_{\bar{\nu}}})) : \text{St}(q)^* \circ \text{St}(\psi_{\bar{\nu}}) \circ \text{St}(\tau_{\Sigma})^* \to \text{St}(\psi_{\bar{\nu}}) \circ \text{St}(j_{\Sigma})^*\]

is a pseudo-natural equivalence.

**Proof of the claim.** For every subset \(\Lambda \subset [n]\) we consider the oriented square of lex-sites:

\[
\begin{array}{c}
X_{\Lambda,\text{ét}} \xrightarrow{\psi_{\Lambda}} V_{\Lambda,\text{ét}} \\
\downarrow \psi_A \quad \downarrow q_{\Lambda} \\
\psi \quad \psi_A
\end{array}
\]

According to corollary \[5.7.26\], it suffices to check that the base change transformation

\[\Upsilon(\text{St}(1_{\psi_{\bar{\nu}}})) : \text{St}(q_A)^* \circ \text{St}(\psi_A) \to \text{St}(\psi_{\bar{\nu}}) \circ \text{St}(j_{\Lambda})^*\]

is a pseudo-natural equivalence for every such \(\Lambda\). However, \(V_{\Lambda}^h\) is the limit of a cofiltered system of quasi-compact and quasi-separated \(V\)-schemes \((V_{\Lambda,i} \mid i \in I)\) with affine transition morphisms, and \(X_{\Lambda,i}^h\) is the limit of the induced cofiltered system \((X_{\Lambda,i} := X \times V V_{\Lambda,i} \mid i \in I)\); hence \(V_{\Lambda,\text{ét}}^h\) and \(X_{\Lambda,\text{ét}}^h\) represent the 2-limits of the induced systems of lex-sites \(V_{\bullet,\text{ét}}^h := (V_{i,\text{ét}} \mid i \in I)\) and \(X_{\bullet,\text{ét}}^h := (X_{i,\text{ét}} \mid i \in I)\). We regard \(I\) as a category (see example \[1.16\] ii)), and we may assume that \(I\) admits a final object \(i_0\) such that \(V_{\Lambda,i_0} = V\); then \(V_{\Lambda,\bullet,\text{ét}}^h\) and \(X_{\Lambda,\bullet,\text{ét}}^h\) yield fibred lex-sites \(V_{\Lambda,\bullet,\text{ét}}^h\) and \(X_{\Lambda,\bullet,\text{ét}}^h\) over \(I\), and the system of projections \((X_{\Lambda,i} \to V_{\Lambda,i} \mid i \in I)\) induces a morphism of fibred lex-sites \(X_{\Lambda,\bullet,\text{ét}}^h \to V_{\Lambda,\bullet,\text{ét}}^h\). Then the assertion follows from corollary \[5.7.30\].

Now, from proposition \[5.6.34\] we see that \(\Sigma_{2,n}^h \times \mathcal{E}^h\) is an ind-finite stack, and then the same holds for \(\mathcal{F}\) (theorem \[5.6.33\]), and also for \(\mathcal{F}'\), again by proposition \[5.6.34\]. Set

\[\mathcal{E}' := \text{St}(\tau_{\text{ét}})^* \circ \text{St}(\psi_{\text{ét}})^* (\mathcal{E}).\]

From (15.7.11) and claims \[15.7.10\] and \[15.7.12\] we deduce an equivalence of stacks:

\[\mathcal{F} \simeq \text{St}(e_{\bar{\nu}}) \circ \text{St}(q')^* \circ \text{St}(\tau_{\Sigma})^* \circ \text{St}(\psi_{\bar{\nu}}) (\Sigma_{2,n}^h \times \mathcal{E}')\]

\[\simeq \text{St}(e_{\bar{\nu}}) \circ \text{St}(q')^* \circ \text{St}(l_{V'})^* (\mathcal{E}')^*\]

Once again, by corollary \[5.7.2\] ii) the projection \(\Sigma_{2,n}^h \times V_{\text{ét}}' \to V_{\text{ét}}'\) is a weak morphism of sites, for the topology of the total site, and is left adjoint to \(l_V\), so we get an equivalence

\[\text{St}(l_{V'})^* (\mathcal{E}')^* \simeq \Sigma_{2,n}^h \times \mathcal{E}'\]

(proposition \[5.4.29\] ii,iii)). Similarly, the functor \(q'\) admits a left adjoint

\[s : \mathcal{F}' \to \Sigma_{2,n}^h \times V_{\text{ét}}' \quad ([j] \xrightarrow{\varphi} [n], U \xrightarrow{f} V_{\varphi([j])}) \to (\varphi, U \xrightarrow{f} V_{\varphi([j])} \to V')\]

and as explained in remark \[5.7.34\] the functor \(s\) is cocontinuous and is a weak morphism of sites, for the topologies of the total sites, whence a pseudo-natural equivalence:

\[\text{St}(q')^* \simeq \text{St}(s)^*\]
Summing up, we obtain an equivalence of stacks:

\[(15.7.13) \quad \mathcal{G} \sim \text{St}(e_{Y'}) \circ \text{St}(s)_* (\Sigma^{+}_{2,n} \times \mathcal{E}') .\]

Lastly, consider the functor

\[\Psi : \Sigma^{+}_{2,n} \to V'_{\text{et}} \quad ([j] \xrightarrow{\varphi} [n]) \mapsto V'_\varphi([j])\]

and let \(\Psi : \Sigma^0_{2,n} \to V'_\varphi\) be the restriction of \(\Psi\). By inspecting the definitions, we find that the equivalence \((15.7.13)\) identifies the functor \((15.7.7)\) with the similar natural functor

\[\mathcal{E}'(V') \to 2\text{-lim}_{\Sigma^0_{2,n}} \mathcal{E}'(-) \circ \Psi^0 .\]

The latter is an equivalence, since \(\mathcal{E}'\) is a stack on \(V'_{\text{et}}\), whence the theorem.

15.7.14. Let \(f : X' \to X\) be an adic morphism of topologically henselian quasi-affinoid schemes, and \((U_1, \ldots, U_n)\) a finite covering of \(\text{Spa} X\) consisting of quasi-affinoid open subsets; recall that \(U_i' := (\text{Spa} f)^{-1}U_i\) is a quasi-affinoid subset of \(\text{Spa} U_i\) for every \(i = 1, \ldots, n\) (remark 15.5.9 iv)). As in (15.7.4), define the corresponding functors

\[X^h : \mathcal{D}(X) \to \text{Sch}^{\text{qcqs}} \quad X^h_{\mathcal{U}} : \mathcal{D}(X') \to \text{Sch}^{\text{qcqs}} \quad \text{for every } \Lambda \subset \{1, \ldots, n\} , \]

and for every \(\Lambda \subset \{1, \ldots, n\}\), set \(U_\Lambda := \bigcap_{i \in \Lambda} U_i\) (with \(U_\emptyset := \text{Spa} X\)) and \(U'_\Lambda := (\text{Spa} f)^{-1}U_\Lambda\). To ease notation, let \(X_\Lambda\) (resp. \(X'_{\Lambda}\)) be the scheme underlying the quasi-affinoid scheme \(X^h_{U_\Lambda}\) (resp. \(X^h_{U'_\Lambda}\)). Recall that \(X^h_{U'_\Lambda}\) is the topological henselization of \(Z_\Lambda := X' \times_{X} X^h_{U_\Lambda}\); the composition of the henselization morphism \(X^h_{U'_\Lambda} \to Z_\Lambda\) and the projection \(Z_\Lambda \to X^h_{U_\Lambda}\) is then a morphism of quasi-affinoid schemes

\[f_\Lambda : X^h_{U'_\Lambda} \to X^h_{U_\Lambda}\]

so we have a commutative diagram of schemes:

\[
\begin{array}{ccc}
X' & \xrightarrow{f_\Lambda} & X \\
p'_\Lambda \downarrow & & \downarrow p_\Lambda \\
X'_\Lambda & \xrightarrow{f} & X
\end{array}
\]

where \(p_\Lambda\) and \(p'_\Lambda\) are the natural projections. Let also \(\mathcal{E}\) be an ind-finite stack on \(X_{\text{et}}\), and set

\[\mathcal{E}' := \text{St}(f_{\text{et}})_* \mathcal{E} \quad \mathcal{E}'_{\Lambda} := \text{St}(p_{\Lambda, \text{et}})_* \mathcal{E} \quad \mathcal{E}'_{\Lambda} := \text{St}(f_{\text{et}})_* \mathcal{E}_{\Lambda} \quad \text{for every } \Lambda \subset \{1, \ldots, n\} .\]

We consider the units of adjunction:

\[\eta : \mathcal{E} \to \text{St}(f_{\text{et}})_* \mathcal{E}' \quad \text{and} \quad \eta_\Lambda : \mathcal{E}'_{\Lambda} \to \text{St}(f_{\text{et}})_* \mathcal{E}'_{\Lambda} \quad \text{for every } \Lambda \subset \{1, \ldots, n\} .\]

**Lemma 15.7.15.** In the situation of (15.7.14), suppose that the functor

\[\eta_{\Lambda, X_\Lambda} : \mathcal{E}_{\Lambda, X_\Lambda} \to \mathcal{E}'_{\Lambda, X_\Lambda}\]

is an equivalence for every non-empty \(\Lambda \subset \{1, \ldots, n\}\). Then \(\eta_X : \mathcal{E}_X \to \mathcal{E}'_X\) is an equivalence.

**Proof.** Define the category \(\Sigma^{+}_{2,n}\), its full subcategory \(\Sigma^0_{2,n}\), the fibred site \(\Sigma^{+}_{2,n}\) and the site \((\mathcal{D}(X), J^+_\mathcal{D})\) as in the proof of theorem 15.7.6. We consider the functor

\[\Phi^+ : \Sigma^{+}_{2,n} \to \mathcal{D}(X) \quad ([j] \xrightarrow{\varphi} [n]) \mapsto U_{\varphi([j])}\]

and its restriction \(\Phi : \Sigma^0_{2,n} \to \mathcal{D}(X)\). We attach likewise to the covering \((U'_1, \ldots, U'_n)\) of \(\text{Spa} X'\) the corresponding functors \(\Phi'^+ : \Sigma^{+}_{2,n} \to \mathcal{D}(X')\) and its restriction \(\Phi'\) to \(\Sigma^0_{2,n}\). Then, from \(\Psi' := X^h_{\mathcal{U}} \circ \Phi^+\) and \(\Psi'^+ := X^h_{\mathcal{U'}} \circ \Phi'^+\) we get fibred sites:

\[\mathcal{U}' := \Sigma^{+}_{2,n} \times_{\text{Sch}, \Psi^+} (\text{Sch}^{\text{qcqs}}_{\text{et}}, t, J^+_{\mathcal{D}}), \quad \mathcal{U} := \Sigma^{+}_{2,n} \times_{\text{Sch}, \Psi'^+} (\text{Sch}^{\text{qcqs}}_{\text{et}}, t, J^+_{\mathcal{D}}).\]
Next, let \( e : \Sigma_{2,n}^+ \to \mathcal{U} \) be the functor that assigns to every \( ([j] \xrightarrow{\omega} [n]) \in \text{Ob}(\Sigma_{2,n}^+) \) the final object \( X_{\varphi([j])} \) of the site \( X_{\varphi([j])}, \epsilon \); let also \( i : X_{\varphi} \to \mathcal{U} \) be the inclusion functor which identifies \( X_{\varphi} \) with the fibre category of the fibration \( \mathcal{U} \to \Sigma_{2,n}^+ \), over the final object \([-1]\) in \( \text{Ob}(\Sigma_{2,n}^+) \). Likewise we define the functor \( e' : \Sigma_{2,n}^+ \to \mathcal{U}' \) and \( i' : X_{\varphi} \to \mathcal{U}' \).

With this notation, \( \Phi^+ \) is a weak morphism of sites \( (\mathcal{Q}(X), J_\mathcal{Q}) \to \Sigma_{2,n}^+ \) for the topology of the total site of \( \Sigma_{2,n}^+ \), and likewise for \( \Phi'^+ \). Also, both \( i \) and \( e \) are morphisms of sites for the topologies of the total sites, and likewise for \( i' \) and \( e' \). Furthermore, the rule \( ([j] \xrightarrow{\omega} [n]) \mapsto f_{\varphi([j])} \) for every \( \varphi \in \text{Ob}(\Sigma_{2,n}^+) \) defines a natural transformation
\[
\Phi^+ \circ \eta \Rightarrow \Phi'^+ \circ \eta
\]
which, after choosing a cleavage for the fibration \( \mathcal{Q}(\mathcal{O}_\Sigma) \to \mathcal{Q}(\mathcal{O}_\Sigma) \to \Sigma_{2,n}^+ \), determines a morphism of fibred sites \( \varphi : \mathcal{U}' \to \mathcal{U} \), which is again a morphism of sites for the topologies of the respective total sites. A direct inspection then yields a commutative diagram of morphisms of sites:
\[
\begin{array}{cccc}
\Sigma_{2,n}^+ & \xrightarrow{e'} & \mathcal{U}' & \xrightarrow{i'_{\mathcal{U}'}} X'_{\varphi} \\
\downarrow & & \downarrow & \downarrow f_{\varphi} \\
\Sigma_{2,n}^+ & \xrightarrow{e} & \mathcal{U} & \xrightarrow{i_\mathcal{U}} X_{\varphi}
\end{array}
\]

By theorem \[\text{15.7.6}\] we associate with \( \mathcal{E} \) a stack \( \mathcal{E}_{\mathcal{U}} \) on \( (\mathcal{Q}(X), J_\mathcal{Q}) \); likewise, since \( \mathcal{E}' \) is also ind-finite (theorem \[\text{5.6.33}\]), we get the stack \( \mathcal{E}'_{\mathcal{U}} \) on \( (\mathcal{Q}(X), J_\mathcal{Q}) \). Then, arguing as in the proof of theorem \[\text{15.7.6}\] we get equivalences of fibrations over \( \Sigma_{2,n}^+ \):
\[
\text{St}(\Phi^+)_* (\mathcal{E}_{\mathcal{U}}) \simeq \text{St}(\mathcal{E}^+)_* (\mathcal{E}'_{\mathcal{U}}) \quad \text{St}(\Phi'^+)_* (\mathcal{E}'_{\mathcal{U}}) \simeq \text{St}(\mathcal{E}'^+)_* (\mathcal{E}'_{\mathcal{U}})
\]
On the other hand, from diagram \[\text{15.7.14}\] we deduce an equivalence of stacks
\[
\text{St}(g)^* \circ \text{St}(i_X)^* (\mathcal{E}) \simeq \text{St}(i_X)^* (\mathcal{E}')
\]
whence, by adjunction, a morphism of stacks:
\[
\text{St}(i_X)^* (\mathcal{E}) \to \text{St}(g) \circ \text{St}(i_X)^* (\mathcal{E}')
\]
and after composing with \( \text{St}(e)_* \), we arrive at a morphism of fibrations over \( \Sigma_{2,n}^+ \):
\[
\omega : \mathcal{E}_{\mathcal{U}} \to \mathcal{E}'_{\mathcal{U}}.
\]
Now, pick cleavages for \( \mathcal{E}_{\mathcal{U}} \) and \( \mathcal{E}'_{\mathcal{U}} \), and let \( c \) and \( c' \) be the associated pseudo-functors; then \( \omega \) corresponds to a pseudo-natural transformation \( \omega_* : c \Rightarrow c' \). Arguing as in remark \[\text{15.7.5}\]i), we see that \( c_\varphi \) is equivalent to \( c_{\varphi([j])} \) for every \( ([j] \xrightarrow{\omega} [n]) \in \text{Ob}(\Sigma_{2,n}^+) \), and likewise for \( c'_{\varphi} \), so we have for every such \( \varphi \) an essentially commutative diagram of categories:
\[
\begin{array}{ccc}
\mathcal{E}_{\varphi([j])} & \xrightarrow{\omega_\varphi} & \mathcal{E}'_{\varphi([j])} \\
\downarrow & & \downarrow \\
\mathcal{E}_{\varphi([j])} & \xrightarrow{\omega^2_{\varphi}} & \mathcal{E}'_{\varphi([j])}
\end{array}
\]
whose vertical arrows are equivalences. Lastly, since \( \mathcal{E}_{\mathcal{U}} \) and \( \mathcal{E}'_{\mathcal{U}} \) are stacks for the topologies \( J_\mathcal{Q} \) and respectively \( J_\mathcal{Q}' \), we know that the natural functors
\[
\mathcal{E}_X \to \lim_{\Sigma_{2,n}} c \quad \mathcal{E}'_X \to \lim_{\Sigma_{2,n}} c'
\]
are equivalences, hence \( \omega^\varphi : \mathcal{E}_X \to \mathcal{E}'_X \), is identified, up to equivalences of categories and isomorphisms of functors, with the induced functor

\[
\lim_{\Sigma_{2,n}} \omega \cdot : \lim_{\Sigma_{2,n}} c \to \lim_{\Sigma_{2,n}} c'.
\]

To conclude the proof, it then suffices to check that for every \( \varphi : [j] \to [n] \), the functor \( \omega^\varphi \) is isomorphic to the functor \( \eta_{A_\Lambda X_A} \), with \( \Lambda := \varphi([j]) \). To this aim, we notice that the right square subdiagram of \((15.7.14)\) can be regarded as an oriented square of links, after choosing adjoints and fixing adjunctions for its four arrows; its orientation (from the bottom left corner to the upper right corner) is given by the identity \( \text{1}_{i_X^\text{log}} : i_X \circ g \Rightarrow f_{\text{et}} \circ i_X' \). Then, proposition \( 5.7.3 \) says that the base change transformation

\[
\Upsilon(\text{St}(1^X_X^\text{log})) : \text{St}(f_{\text{et}})^* \circ \text{St}(i_X^\Lambda)^* \to \text{St}(i_X')^* \circ \text{St}(g)^*
\]

is a pseudo-natural equivalence. The assertion then follows, after combining with proposition \( 2.3.14 \): the details shall be left to the reader. □

15.7.16. Resume the situation of \((15.7.14)\), and let also \( X^\Lambda := (X^\wedge, \mathcal{T}_X^\wedge, A_X^\wedge) \) be the completion of \( X \), and denote by \( \pi_X : X^\wedge \to X \) the completion morphism of quasi-affinoid schemes (given by the counit of the adjunction of proposition \( 15.4.12 \)). The morphism \( \pi_X \) induces a morphism of étale sites \( \pi_X, \text{et} : X^\wedge_{\text{et}} \to X_{\text{et}}, \) and for every stack \( \mathcal{E} \) on \( X_{\text{et}} \) we let

\[
\mathcal{E}^\wedge := \text{St}(\pi_X, \text{et})^*(\mathcal{E}).
\]

**Theorem 15.7.17.** With the notation of \((15.7.16)\), if \( \mathcal{E} \) is ind-finite, the unit of adjunction

\[
\mathcal{E}_X \to \mathcal{E}_X^\wedge = \text{St}(\pi_X, \text{et})_*(\mathcal{E}^\wedge)_X
\]

is an equivalence of categories.

**Proof.** To begin with, let \( f : Y \to X \) be any \( f \)-adic morphism of quasi-affinoid schemes; since \( \pi_X : X^\wedge \to X \) is also \( f \)-adic, the fibre product \( Y' := X^\wedge \times_X Y \) is well defined (example \( 15.4.8 \)), and we let \( X^\Lambda \overset{\mathcal{E}}{\rightarrow} Y' \overset{\mathcal{P}_2}{\rightarrow} Y \) be the natural projections. The morphism \( f^\wedge : Y^\wedge \to X^\wedge \) induced by \( f \), and the completion morphism \( \pi_Y : Y^\wedge \to Y \) determine a unique morphism of quasi-affinoid schemes

\[
g : Y^\wedge \to Y'
\]

such that \( p_1 \circ g = f^\wedge \) and \( p_2 \circ g = \pi_Y \).

Moreover, since \( Y^\wedge \) is complete, by adjunction \( g \) factors uniquely through a morphism of quasi-affinoid schemes \( h : Y^\wedge \to Y'^\wedge \) and the completion morphism \( \pi_{Y'} : Y'^\wedge \to Y' \).

**Claim 15.7.18.** In the foregoing situation, \( h \) is an isomorphism of quasi-affinoid schemes.

**Proof of the claim.** It suffices to show that the morphisms \( p_2 \circ \pi_{Y'} \) and \( \pi_Y \) satisfy the same universal property. Thus, let \( Z \) be a complete quasi-affinoid schemes, and \( k : Z \to Y \) any morphism of quasi-affinoid schemes; the composition \( f \circ k : Z \to X \) factors uniquely through a morphism \( l : Z \to X^\wedge \) and \( \pi_X \), and there exists a unique morphism \( l' : Z \to Y' \) such that \( p_1 \circ l' = l \) and \( p_2 \circ l' = k \). Again, \( l' \) factors uniquely through a morphism \( l'^\wedge : Z \to Y'^\wedge \) and \( \pi_{Y'} \). It follows easily that \( l'^\wedge \) is the unique morphism such that \( p_2 \circ \pi_{Y'} \circ l'^\wedge = k \), whence the contention. \( \diamond \)

**Claim 15.7.19.** In order to prove the theorem, we may assume that \( X \) is an affinoid scheme.

**Proof of the claim.** Let \( U_* := (U_1, \ldots, U_n) \) be an open covering of Spa \( X \) consisting of finitely many affinoid open subsets. (To find such \( U_* \), let \( A_X := \mathcal{O}_X(X) \), and \( J \subset A_X \) a finitely generated ideal such that \( \text{Spec} A_X/J = \text{Spec} A_X \setminus X \); then we may take a finite set of generators \( f_* := (f_1, \ldots, f_n) \) of \( J \), and let \( U_* \) be the standard covering associated with \( f_* \), as in \((15.5.20)\).)
For every $\Lambda \subset \{1, \ldots, n\}$, define the affinoid open subset $U_\Lambda \subset \Spa X$ as in (15.7.14), and notice that $U_\Lambda^h := (\Spa X)^\Lambda U_\Lambda$ is an affinoid open subset of $\Spa X$. To ease notation, let also $X_\Lambda := X^h_{U_\Lambda}$ and $X'_\Lambda := X'^h_{U_\Lambda}$, for every such $\Lambda$. Let $p_\Lambda : X_\Lambda \to X$ be the natural projection, and set $q_\Lambda := \St(p_{\Lambda, \et})^* \epsilon_\Lambda$ and $\epsilon'_\Lambda := \St(p_{\Lambda, \et})^* \epsilon'_\Lambda$, for every $\Lambda \subset \{1, \ldots, n\}$. By lemma 15.7.15 in order to prove the theorem it suffices to show that the unit of adjunction

$$\eta_\Lambda : \epsilon_{\Lambda,X_\Lambda} \to \epsilon'_{\Lambda,X_\Lambda}$$

is an equivalence for every non-empty $\Lambda \subset \{1, \ldots, n\}$. To aim this, let $q_\Lambda : (X_\Lambda)^\Lambda \to X_\Lambda$ and $q'_\Lambda : (X'_\Lambda)^\Lambda \to X'_\Lambda$ be the completion morphisms, and denote by $(X_\Lambda)^\Lambda$ (resp. $(X'_\Lambda)^\Lambda$) the scheme underlying $(X_\Lambda)^\Lambda$ (resp. $(X'_\Lambda)^\Lambda$); since $(X'_\Lambda)^\Lambda$ is also the completion of $X_\Lambda^\Lambda X$, $X_\Lambda$ (remark 15.4.10(vi) and corollary 8.4.14(i)), claim 15.7.18 yields an isomorphism of affinoid schemes

$$h : (X_\Lambda)^\Lambda \xrightarrow{\sim} (X'_\Lambda)^\Lambda \quad \text{such that} \quad \pi_\Lambda \circ q'_\Lambda \circ h = q_\Lambda.$$

Set $\epsilon_{\Lambda}^\Lambda := \St(q_{\Lambda, \et})^* \epsilon_\Lambda$ and $\epsilon'_{\Lambda}^\Lambda := \St(q'_{\Lambda, \et})^* \epsilon'_\Lambda$, and denote

$$\eta_{\Lambda}^\Lambda : \epsilon_{\Lambda,X_\Lambda} \to \epsilon'_{\Lambda,X_\Lambda} \quad \text{and} \quad \eta_{\Lambda}^\Lambda : \epsilon_{\Lambda,X_\Lambda} \to \epsilon'_{\Lambda,(X'_\Lambda)^\Lambda}$$

the units of adjunction. Now, up to equivalences of categories and isomorphisms of functors, the composition $\eta_{\Lambda} \circ \eta_{\Lambda}$ is naturally identified with the counit

$$\epsilon_{\Lambda,X_\Lambda} \to \St((\pi_\Lambda \circ q_{\Lambda, \et})^* \epsilon_\Lambda)_{(X'_\Lambda)^\Lambda}$$

and the latter is an equivalence if and only if the same holds for $\eta_{\Lambda}^\Lambda$, due to (15.7.20). Thus, if both $\eta_{\Lambda}^\Lambda$ and $\eta_{\Lambda}^\Lambda$ are equivalences, the same will follow for $\eta_{\Lambda}$. Summing up, the theorem will follow for the quasi-affinoid scheme $X$, once we have shown that the theorem holds for the affinoid schemes $X_\Lambda$ and $X'_\Lambda$, for every non-empty $\Lambda \subset \{1, \ldots, n\}$, whence the claim.

For every scheme $Y$ and every finite group $G$, let $G_Y$ be the group scheme $G \times Y$ over $Y$; recall that a (right) $G$-torsor on $Y_{\et}$ is the datum of a surjective étale morphism of schemes $Z \to Y$, together with a morphism $\rho : Z \times Y G_Y \to Z$ that induces an action of the group $G_Y(T)$ of $T$-sections of $G_Y$ on the set $Z(T)$ of $T$-sections of $Z$, for every $Y$-scheme $T$, and such that $\rho$ and the projection $Z \times Y G_Y \to Z$ induce an isomorphism

$$Z \times Y G_Y \xrightarrow{\sim} Z \times Y Z.$$

A morphism of $G_Y$-torsors $(Z, \rho) \to (Z', \rho')$ is a morphism of schemes $Z \to Z'$ compatible in the obvious way with the morphisms $\rho$ and $\rho'$. Clearly the $G$-torsors over $Y_{\et}$ form a category:

$$\text{Tors}(Y_{\et}, G).$$

According to [84, Exp.XX, Prop.6.3.2], in order to prove the theorem, it suffices to check that:

(i) for every sheaf $\mathcal{F}$ on $X_{\et}$, the natural map $H^0(X_{\et}, \mathcal{F}) \to H^0(X^h_{\et}, \mathcal{F}_{X_{\et}})$ is bijective

(ii) for every finite group $G$, and every finite morphism of schemes $Y \to X$, the natural functor $\text{Tors}(Y_{\et}, G) \to \text{Tors}((X^h \times_X Y)_{\et}, G)$ is an equivalence of categories.

Moreover, according to [9, Exp.XII, Prop.6.5(i)], condition (i) is equivalent to:

(iii) for every finite morphism of schemes $Y \to X$, the natural map $H^0(Y_{\et}, \Z/2\Z) \to H^0((X^h \times_X Y)_{\et}, \Z/2\Z)$ is bijective.

However, for every scheme $Z$, the group $H^0(Z_{\et}, \Z/2\Z)$ is naturally identified with the automorphism group of the trivial $\Z/2\Z$-torsor on $Z_{\et}$, so (iii) follows from (ii), for $G := \Z/2\Z$.

Now, for every finite morphism of schemes $f : Y \to X$, let $Y' := Y \times_X X$, and recall that the morphism of quasi-affinoid schemes $f : Y \to X$ is $f$-adic (see example 15.4.9(v)), hence $Y'^h := X^h \times_X Y$ is well defined, and according to claim 15.7.18 we have an isomorphism
Let $G$ be any finite group; we deduce an essentially commutative diagram:

\[
\begin{array}{ccc}
\text{Tors}(Y_{\text{ét}}, G) & \longrightarrow & \text{Tors}(Y'_{\text{ét}}, G) \\
\downarrow & & \downarrow \\
\text{Tors}(Y^\wedge_{\text{ét}}, G) & \longrightarrow & \text{Tors}(Y'^\wedge_{\text{ét}}, G)
\end{array}
\]

where $Y'$, $Y^\wedge$, $Y'^\wedge$ are the schemes underlying respectively $Y'$, $Y^\wedge$, $Y'^\wedge$. The vertical arrows are induced by $\pi_Y : Y^\wedge \to Y$ and $\pi_{Y'} : Y'^\wedge \to Y'$, and the bottom horizontal arrow is induced by $h$, so it is an equivalence. Hence, condition (ii) will follow for $f : Y \to X$, if we show that the vertical arrows of the diagram are equivalences. Moreover, by comparing the respective universal properties, we easily obtain a natural isomorphism of affinoid schemes $Y' \iso (X^\wedge \times X Y) \times_{X^\wedge} X^\wedge$; since $X^\wedge$ is topologically henselian, example 15.4.9(vi) implies that the same holds for $Y'$. With claim 15.7.19, we are then reduced to checking that for every topologically henselian affinoid scheme $(X, \mathcal{T}_X, A^+_X)$ and every finite group $G$, the completion morphism induces an equivalence $\text{Tors}(X_{\text{ét}}, G) \to \text{Tors}(X^\wedge_{\text{ét}}, G)$.

Let $A_0 \subset A := \mathcal{O}_X(X)$ be a subring of definition; let also $(A_i \mid i \in I)$ be the filtered system of finite type $A_0$-subalgebras of $A$. For every $i \in I$, endow $A_i$ and $A_i^+ := A_i \cap A^+_X$ with the topologies $\mathcal{T}_i$ and $\mathcal{T}_i^+$ induced by the inclusions into $A$. Let $A_0^\wedge_i$ be the completion of $A_0$; then the completions of $A_i$ and $A_i^+$ are respectively $A_i^\wedge := A_0^\wedge \otimes_{A_0} A_i$ and $A_i^\wedge^+ := A_0^\wedge \otimes_{A_0} A_i^+$ for every $i \in I$, and the completion of $A$ is $A^\wedge := A_0^\wedge \otimes_{A_0} A$, so $A^\wedge$ is the colimit of the induced filtered system of $A_0^\wedge$-algebras $(A_i^\wedge \mid i \in I)$. Set as well $X_i := \text{Spec} A_i$ and $X_i^\wedge := \text{Spec} A_i^\wedge$, and let $\mathcal{T}_i^\wedge$ be the topology of $A_i^\wedge$, for every $i \in I$; then $X_i^\wedge$ is topologically henselian affinoid scheme (proposition 8.4.2(iii)), and its completion $X^\wedge_i$ is $(X_i^\wedge, \mathcal{T}_i^\wedge, A_i^\wedge)$.

From [50] Ch.IV, Th.8.8.2, Th.8.10.5, Th.11.2.6 it follows easily that the natural functors

\[
\begin{align*}
\text{2-colim}_{i \in I} \text{Tors}(X_i_{\text{ét}}, G) & \to \text{Tors}(X_{\text{ét}}, G) \\
\text{2-colim}_{i \in I} \text{Tors}(X_i^\wedge_{\text{ét}}, G) & \to \text{Tors}(X^\wedge_{\text{ét}}, G)
\end{align*}
\]

are equivalences of categories. Hence it suffices to check that for every $i \in I$ the functor

\[
\text{Tors}(X_i_{\text{ét}}, G) \to \text{Tors}(X_i^\wedge_{\text{ét}}, G)
\]

is an equivalence. We may therefore assume from start that $A$ is an $A_0$-algebra of finite type, say $A = A_0[t_1, \ldots, t_n]$ for a finite sequence $t_\bullet := (t_1, \ldots, t_n)$ of elements of $A$. For every $k = 0, \ldots, n$, we shall say that the sequence $t_\bullet$ is adequate up to $k$ if for every $i = 1, \ldots, k$, either one of the following conditions holds:

(a) $t_i \in A^+_k$

(b) $t_i \in A^+_k$ and $1/t_i \in A^+$.

Claim 15.7.21. In order to prove the theorem, we may assume that $t_\bullet$ is adequate up to $n$. 

Proof of the claim. Suppose that the theorem is known for every $f$-adic ring $A$ generated over some topologically henselian subring of definition $A_0$ by a sequence of elements $(t_1, \ldots, t_n)$ adequate up to $n$. We argue by descending induction on $k \leq n$, that the theorem then also holds for every $f$-adic ring generated over any such subring $A_0$ by a sequence $(t_1, \ldots, t_n)$ that is only adequate up to $k$. If $k = n$, there is nothing to show; let then $k \leq n$ and $t_k$ a sequence adequate up to $k - 1$, and suppose that we have already proved our assertion for all sequences adequate up to $k$. Let $A$ be the affinoid ring $(A, A^+_k)$; we consider the affinoid rings

\[
B := A \left( \frac{1, t_k}{1} \right) \quad C := A \left( \frac{1, t_k}{t_k} \right) \quad D := B \otimes_A C
\]

(notation of 15.5.1 and example 15.4.5(i)). Explicitly, we have $B = (B, B^+_k)$ and $C = (C, C^+_k)$, where the ring underlying the topological ring $B$ (resp. $C$) is $A$ (resp. $A[1/t_k]$) and
\( B^+ \) (resp. \( C^+ \)) is the integral closure in \( B \) (resp. \( C \)) of \( A^+[1/t_k] \) (resp. \( A^+[1/t_k] \)); moreover, \( B \) (resp. \( C \)) admits the ring of definition \( B_0 := A_0[t_k] \) (resp. \( C_0 := A_0[1/t_k] \)). Recall that the topological henselization \( B^h \) of \( B \) is \( B_0^h \otimes_{B_0} B \), with \( B_0^h \) the topological henselization of \( B_0 \). Hence the image in \( B^h \) of the sequence \( t_\bullet \) generates the \( t \)-adic \( B_0^h \)-algebra \( B^h \), and is adequate up to \( k \). Likewise we see that the image of \( t_\bullet \) generates the \( C^h \)-algebra \( C^h \), and then the same follows for the image of \( t_\bullet \) in the topological ring underlying \( D^h \) : the details are left to the reader. By inductive assumption, the theorem then holds for the affinoid schemes \( \Spec B^h \), \( \Spec C^h \) and \( \Spec D^h \). But notice that \( B^h \) and \( C^h \) represent two affinoid open subsets \( U' \) and \( U'' \) of \( \Spa X, \) and \( D^h \) represents \( U' \cap U'' \) ; more precisely, \( (U', U'') \) is the standard covering of \( \Spa A \) associated with the sequence \((1, t_k)\) (see \( (15.5.20) \)); arguing as in the proof of claim \( 15.7.19 \) we deduce that the theorem holds for \( \Spec A \), as required.

Henceforth, we assume that \( t_\bullet \) is an adequate sequence up to \( n \); let \( S := \{i \leq n \mid t_i \in A^+\} \) and \( T := \{1, \ldots, n\} \setminus S \), and set \( t'_i := t_i \) for every \( i \in S \) and \( t'_i := 1/t_i \) for every \( i \in T \). Moreover, set \( t = \prod_{i \in S} t'_i \). The subring \( A'_0 := A_0[t'_1, \ldots, t'_n] \) is open and bounded in \( A \), hence it is a subring of definition of \( A \), and after replacing \( A_0 \) by \( A'_0 \) we may assume that \( A = A_0[t^{-1}] \) for an element \( t \in A_0 \cap A^\times \). Let \( I_0 \subset A_0 \) be a finite type ideal of adic definition, and denote by \( B \) the topological ring whose underlying ring is the same as \( A \), and whose topology is the \((t, I_0)\)-adic topology as defined in \( 59 \) Def.5.4.10(ii) (invoking remark \( 8.3.2(i) \)), it is easily seen that the \((t, I_0)\)-adic topology is a ring topology on \( A \).

Since \( t \in A^\times \), the ideal \( t^n I_0 \) is open in \( A \) for every \( n \in \mathbb{N} \), therefore the identity is a continuous map \( A \to B \), and its completion is a morphism of topological rings:

\[
\phi : A^\wedge \to B^\wedge.
\]

Let also \( g : A \to A^\wedge \) and \( h : B \to B^\wedge \) be the completion maps, \( I_0^\wedge \) the topological closure of the image of \( I_0 \) in \( A^\wedge \), and \( \mathcal{T} \) the \((t, I_0^\wedge)\)-adic topology on \( A^\wedge \). We notice:

**Claim 15.7.22.** The map \( f \) is also a morphism \((A^\wedge, \mathcal{T}) \to B^\wedge \) of topological rings, and induces an isomorphism of topological rings:

\[
\phi^\wedge : (A^\wedge, \mathcal{T})^\wedge \xrightarrow{\sim} B^\wedge.
\]

**Proof of the claim.** Let \( J_0^\wedge \) be the topological closure of the image of \( I_0 \) in \( B^\wedge \) ; it is clear that \( f \) is a continuous map \((A^\wedge, \mathcal{T}) \to B^\wedge \), since \( f(t^n I_0^\wedge) \subset t^n J_0 \) for every \( n \in \mathbb{N} \). In order to show that \( f^\wedge \) is an isomorphism, we apply the criterion of theorem \( 8.2.8(iii) \) : first, obviously the image of \( f \) is dense in \( B^\wedge \), since the image of \( A \) in \( B^\wedge \) is already dense. It remains to check that \( \mathcal{T} \) agrees with the topology induced from \( B^\wedge \) via \( f^\wedge \); we show more precisely:

\[
t^n I_0^\wedge = f^{-1}(t^n J_0^\wedge) \quad \text{for every } n \in \mathbb{N}.
\]

Indeed, since both \( t^n I_0^\wedge \) and \( f^{-1}(t^n J_0^\wedge) \) are open subgroups of \((A^\wedge, \mathcal{T})\), it suffices to check that \( g^{-1}(t^n I_0^\wedge) = g^{-1}(f^{-1}(t^n J_0^\wedge)) \); but \( g^{-1}(t^n I_0^\wedge) = t^n g^{-1}(I_0^\wedge) = t^n I_0 \), and \( g^{-1}(f^{-1}(t^n J_0^\wedge)) = h^{-1}(t^n J_0^\wedge) = t^n h^{-1}(J_0^\wedge) = t^n I_0 \).

Since \( h = f \circ g \), it suffices to check that \( f \) and \( h \) induce equivalences of categories:

\[
\Tors((\Spec A^\wedge)_{\et}, G) \xrightarrow{\sim} \Tors((\Spec B^\wedge)_{\et}, G) \xleftarrow{\sim} \Tors((\Spec A)_{\et}, G).
\]

Now, the pair \((A_0, I_0)\) is henselian by assumption, and since \( A_0^\wedge \) is complete for the \( I_0^\wedge \)-adic topology, also the pair \((A_0^\wedge, I_0^\wedge)\) is henselian; it then follows that the pairs \((A_0, tI_0)\) and \((A_0^\wedge, tI_0^\wedge)\) are henselian \( 59 \) Rem.5.1.10(iv)). By \( 59 \) Prop.5.4.53 and claim \( 15.7.22 \) we deduce that \( f \) and \( h \) induce equivalences of categories of finite étale morphisms

\[
(15.7.23) \quad \text{Cov}(\Spec A^\wedge) \xrightarrow{\sim} \text{Cov}(\Spec B^\wedge) \xleftarrow{\sim} \text{Cov}(\Spec A)
\]

(notation of \( (13.1) \)). Now, for any scheme \( Y \), the \( G \)-torsors over \( Y_{\et} \) are the objects \( \phi : Z \to Y \) of \( \text{Cov}(\Spec A^\wedge) \) endowed with a (right) \( G \)-action and such that \( \phi \) is a surjective morphism.
Such a morphism has an open and closed image in \( Y \), hence it is surjective if and only if it is an epimorphism (in the category \( \mathbf{Cov}(Y) \)). The equivalences \((15.7.23)\) induce formally equivalences for the corresponding categories of objects endowed with \( G \)-action (details left to the reader), and obviously respect epimorphisms, whence the contention. \( \square \)

**Remark 15.7.24.** For every finite group \( G \), let \( \mathcal{C}_G \) be the category with \( \text{Ob}(\mathcal{C}_G) = \{o\} \) and such that the monoid \( \text{Hom}_{\mathcal{C}_G}(o, o) \) is isomorphic to \( G \). For every scheme \( X \), let also \( \mathcal{C}_{G, X_{et}} \) be the constant presheaf on \( X_{et} \) with value \( \mathcal{C}_G \). By arguing as in the proof of lemma \((15.7.1)\) it is easily seen that the associated stack \( \mathcal{C}_{G, X_{et}}^o \) is naturally equivalent to the stack of \( G \)-torsors on \( X_{et} \) : the details shall be left to the reader.

15.7.25. For every \( U \in \text{Ob}(\mathcal{Q}(X)) \), choose a complete and separated quasi-affinoid scheme \( \mathcal{X}^\wedge_U := (X^\wedge_U, \mathcal{T}^\wedge_U, A_U^+) \) representing the sub-presheaf \( h^o_U \subset h^o_{X_{et}} \) (notation of remark \((15.5.9)\)). Any inclusion \( U \subset U' \) of quasi-affinoid subsets of \( \text{Spa} X \) induces a morphism \( j_{U'U} : \mathcal{X}^\wedge_U \to \mathcal{X}^\wedge_U \) of quasi-affinoid schemes (cp. \((15.5.11)\)), and for any further inclusion \( U' \subset U'' \) we have

\[
j_{U''U'} \circ j_{U'U} = j_{U''U}
\]

whence a well defined functor

\[
\mathcal{X}^\wedge_U : \mathcal{Q}(X) \to \text{Sch} \quad U \mapsto \mathcal{X}^\wedge_U
\]

and we consider the fibration over \( \mathcal{Q}(X) \)

\[
\text{Cov}^\wedge_X := \text{Fib}(\mathcal{X}^\wedge_U)^*(\text{Cov})
\]

where the fibration \( \text{Cov} \to \text{Sch} \) is defined as in \((15.7)\). With this notation, we can now state :

**Corollary 15.7.26.** The fibration \( \text{Cov}^\wedge_X \) is a stack on the site \( (\mathcal{Q}(X), J_\mathcal{Q}) \).

**Proof.** We have already remarked that the stack \( \text{Cov}_{X_{et}} \) is ind-finite on \( X_{et} \), hence the fibration \( \text{Cov}_{X_{et}}/\mathcal{Q} \) is a stack on \( (\mathcal{Q}(X), J_\mathcal{Q}) \), by theorem \((15.7.6)\). But from theorem \((15.7.17)\) we easily deduce an equivalence of fibrations \( \text{Cov}_{X_{et}}/\mathcal{Q} \sim \text{Cov}^\wedge_X \), whence the assertion. \( \square \)

**Remark 15.7.27.** A variant of corollary \((15.7.26)\) appears in \([90\text{, Th.2.6.9}].\)

15.7.28. We wish to give an explicit description, up to natural equivalence of categories, of the stalks of the fibration \( \text{Cov}^\wedge_X \). Hence, let \( x \in \text{Spa} X \) be any point; recall that the stalk of \( \text{Cov}^\wedge_X \) over \( x \) is the category

\[
\text{Cov}^\wedge_X(x) := \text{2-colim}_{U \in \mathcal{Q}(X,x)^o} \text{Cov}(X^\wedge_U)
\]

where \( \mathcal{Q}(X, x) \) denotes the set of all quasi-affinoid open neighborhoods of \( x \) in \( \text{Spa} X \), which is cofiltered by inclusion. Pick a finitely generated ideal \( J \subset A_X := \mathcal{O}_X(X) \) such that \( X = \text{Spec} A_X \setminus \text{Spec} A_X/J \), and let \( f_0, \ldots, f_n \) be a finite system of generators of \( J \). Set \( U_i := R_{A_X} \left( \frac{f_0, \ldots, f_i}{f_{i+1}, \ldots, f_n} \right) \cap \text{Spa} X \) for \( i = 0, \ldots, n \). Then we have

\[
U_0 \cup \cdots \cup U_n = \text{Spa} X
\]

and we may assume that \( x \in U_0 \). Notice that \( h^o_{U_0} \) is represented by a quasi-affinoid scheme \( X^\wedge_{U_0} := (X^\wedge_{U_0}, \mathcal{T}^\wedge_{U_0}, A^+_{U_0}) \) with \( X^\wedge_{U_0} = \text{Spec} \mathcal{O}^\wedge_{\text{Spa} X}(U_0) \). Then, since \( X^\wedge_{U_0} \) is affine, every rational subset of \( \text{Spa} X^\wedge_{U_0} \) containing \( x \) is likewise represented by a quasi-affinoid scheme whose underlying scheme is affine, and the system of such rational subsets is naturally identified with a cofinal subset of \( \mathcal{Q}(X, x) \). Taking into account lemma \((13.1.6)\) we deduce a natural equivalence

\[
\text{Cov}^\wedge_X(x) \sim \text{Cov}(\text{Spec} \mathcal{O}^\wedge_{\text{Spa} X,x}).
\]
• Next, if \( x \) is analytic, combining with lemma [5.5.14(i,v.c), proposition 9.1.16(iii) and [51 Ch.IV, Prop.18.5.15] we arrive at a natural equivalence

\[
\text{Cov}_x^\wedge(x) \xrightarrow{\sim} \text{Cov}(\text{Spec } \kappa(x^\wedge)) \xrightarrow{\sim} \text{Cov}(\text{Spec } \kappa(x)^\wedge)
\]

where \( \kappa(x^\wedge) \) is the residue field of the natural valuation \( | \cdot |_x^\wedge \) on \( \mathcal{O}_{\text{Spa} X,x}^{\wedge} \), and \( \kappa(x)^\wedge \) is the completion of \( \kappa(x^\wedge) \) for its valuation topology (see (15.5.12)).

• Lastly, if \( x \) is non-analytic, lemma [5.5.14 vi.b] and [59 Th.5.5.7(iii)] yield the natural equivalence

\[
\text{Cov}_x^\wedge(x) \xrightarrow{\sim} \text{Cov}(\text{Spec } \mathcal{O}_{\text{Spa} X,x}^{\wedge}/\mathcal{O}_{\text{Spa} X,x}^{\wedge}).
\]

In this chapter we develop a generalization of Scholze’s theory of perfectoid rings and perfectoid spaces.

16.1. Distinguished elements and transversal pairs. Let \( p \) be a prime number, \((A, \mathcal{T})\) a complete and separated topological ring whose topology \( \mathcal{T} \) is linear and coarser than the \( p \)-adic topology. Remark [9.4.12(ii)] endows the topological monoid \( E(A) \) with a natural structure of perfect topological \( \mathbb{F}_p \)-algebra, such that :

• For every topologically nilpotent ideal \( I \subset A \) containing \( pA \), and which is either closed for the topology \( \mathcal{T} \), or else finitely generated and closed for the \( p \)-adic topology of \( A \), the projection \( \pi_I : A \to A/I \) induces an isomorphism of topological rings

\[
E(\pi_I) : E(A) \xrightarrow{\sim} E(A/I)
\]

where \( A/I \) is endowed with the quotient topology induced by \( \mathcal{T} \) via \( \pi_I \).

• Moreover, if \((A', \mathcal{T}')\) is any other topological ring fulfilling the above conditions, and \( f : A \to A' \) is any continuous ring homomorphism, the map \( E(f) : E(A) \to E(A') \) is a morphism of topological rings.

In light of this canonical identification of \( E(A) \) with \( E(A/I) \), we shall henceforth write slightly abusively

\[
\overline{\pi}_{A/I} : E(A) \to A/I
\]

for the map that would be denoted \( \overline{\pi}_{A/I} \circ E(\pi_I) \), or equivalently, \( \pi_I \circ \overline{\pi}_A \), with the notation of section 9.4. Another basic construction of this chapter shall be the topological ring :

\[
A(A, \mathcal{T}) := W(E(A))
\]

where \( W(-) \) denotes the ring of Witt vectors as in (9.3.11). From remark [9.4.9(i) and lemma 9.3.33(ii,iii)] we also know that the topologies of \( E(A) \) and \( A(A, \mathcal{T}) \) are linear, complete and separated. Unless we have to deal with several different topologies on \( A \), we shall usually omit mentioning explicitly \( \mathcal{T} \), and write simply \( A(A) \). According to proposition [9.3.45(ii)], the ring \( A(A) \) is also complete and separated for its \( p \)-adic topology, and the same holds for \( A \), by lemma [8.3.12]. Moreover we see from (9.3.42) that \( p \) is a regular element of \( A(A) \), and by remark [9.3.28(i)] the ghost component \( \omega_0 \) descends to an isomorphism of topological rings

\[
A(A) \otimes_{\mathbb{Z}} \mathbb{F}_p \xrightarrow{\sim} E(A)
\]

provided we endow \( A(A) \otimes_{\mathbb{Z}} \mathbb{F}_p \) with the quotient topology induced from \( A(A) \) via the projection \( A(A) \to A(A) \otimes_{\mathbb{Z}} \mathbb{F}_p \). The map \( \omega_0 \) also admits a continuous set-theoretic multiplicative splitting, the Teichmüller mapping of (9.3.35), which will be here denoted :

\[
\tau_A : E(A) \to A(A).
\]

Lemma 16.1.1. With the notation of (16.1), the following holds :
(i) There exists a unique ring homomorphism $u_A : A(A) \to A$ that makes commute the diagram:

$$\begin{array}{ccc}
A(A) & \xrightarrow{\mu_A} & A \\
\omega_0 & \downarrow & \pi_{pA} \\
E(A) & \xrightarrow{\pi_{A/pA}} & A/pA.
\end{array}$$

(ii) The map $u_A$ is continuous for the topology $\mathcal{T}$ and the topology of $A(A, \mathcal{T}_A)$.

(iii) $A(A)^\times = u_A^{-1}(A^\times)$.

(iv) $u_A \circ \tau_A = \overline{\nu_A}$.

**Proof.** We have already remarked that $A$ is complete and separated for its $p$-adic topology, and the filtration $(J_n := p^nA \mid n \in \mathbb{N})$ of $A$ trivially fulfills the condition of lemma 9.3.4; therefore (i) follows immediately from proposition 9.3.53(iii). More precisely, (9.3.54) translates as the following explicit expression for $u_A$:

$$u(a) = \sum_{n \in \mathbb{N}} p^n \cdot \overline{\nu_A}(a_n)$$

for every $a := (a_n \mid n \in \mathbb{N}) \in A(A)$ from which (ii) follows easily: details left to the reader.

(iii): The inclusion $A(A)^\times \subset u_A^{-1}(A^\times)$ is obvious. For the converse, let $\alpha \in A(A)$ be any element such that $u_A(\alpha) \in A^\times$; then $\omega_0(\alpha) \in \overline{\nu_A}^{-1}(A^\times)$. By remark 9.4.5(iii) we deduce that $\omega_\alpha(\alpha) \in A(E(A)^\times)$, so it remains only to notice that $\omega_\alpha^{-1}(E(A)^\times) = A(A)^\times$, due to proposition 9.3.45(iii).

(iv) is clear from the foregoing explicit formula for $u_A$. \qed

Furthermore, $A(A)$ is endowed with an automorphism $\sigma_A : A(A) \to A(A)$ that lifts the Frobenius map of $E(A)$, i.e. such that the horizontal arrows of the diagram:

$$\begin{array}{ccc}
A(A) & \xrightarrow{\sigma_A} & A(A) \\
\omega_0 & \downarrow & \omega_0 \\
E(A) & \xrightarrow{\Phi_{E(A)}} & E(A)
\end{array}$$

commute with the downward arrows (proposition 9.3.22(iii)). The horizontal arrows commute also with the upward ones, due to (9.3.44).

16.1.3. **Keep the notation of (16.1), and recall that $\tau_A$ induces a continuous map Spec $\tau_A : \text{Spec } A(A) \to \text{Spec } E(A)$ as in proposition 9.3.67(ii); in light of lemma 16.1(iv) and remark 8.1.20(ii) we deduce a continuous and spectral map $\text{Spec } \overline{\nu_A} := (\text{Spec } \tau_A) \circ (\text{Spec } u_A) : \text{Spec } A \to \text{Spec } E(A) \quad p \mapsto \overline{\nu_A}^{-1}p$.

Moreover, due to proposition 9.3.67(iv), every morphism $\varphi : A \to A'$ of topological algebras that fulfill the conditions of (16.1) induces a commutative diagram of topological spaces:

$$\begin{array}{ccc}
\text{Spec } A' & \xrightarrow{\text{Spec } \pi_A'} & \text{Spec } E(A') \\
\text{Spec } \varphi & \downarrow & \downarrow \\
\text{Spec } A & \xrightarrow{\text{Spec } \pi_A} & \text{Spec } E(A).
\end{array}$$

**Lemma 16.1.5.** In the situation of (16.1.3), let $p \in \text{Spec } A$ be any prime ideal, set $q := \text{Spec } \overline{\nu_A}(p) \in \text{Spec } E(A)$, and let $\pi_p : A \to \kappa(p)$, $\pi_q : E(A) \to \kappa(q)$ be the projections. If $p$ is a closed subset in the $p$-adic topology of $A$, then $\overline{\nu_A}$ induces a morphism of multiplicative monoids $\overline{\nu_p} : \kappa(q) \to \kappa(p)$ such that $\overline{\nu_p} \circ \overline{\nu_q} = \overline{\nu_p} \circ \overline{\nu_A}$. 
Proof. Since \( u_A \) is continuous for the \( p \)-adic topologies, \( u_A^{-1}p \) is a closed subset for the \( p \)-adic topology of \( A(A) \), so the assertion follows immediately from proposition 9.3.67(iii). \( \square \)

With the following definition, we single out certain elements of \( A(A) \) that shall play a special role in the study of perfectoid rings.

**Definition 16.1.6.** Let \( (E, \mathcal{T}) \) be any topological \( \mathbb{F}_p \)-algebra.

(i) An element \( (a_n \mid n \in \mathbb{N}) \in W(E) \) is called distinguished if \( a_0 \) is topologically nilpotent in \( E \), and \( a_1 \in E^\infty \).

(ii) An ideal of \( W(E) \) is called distinguished if it is generated by a distinguished element.

**Remark 16.1.7.** Let \( E \) be any topological \( \mathbb{F}_p \)-algebra, \( a := (a_n \mid n \in \mathbb{N}) \) and \( b := (b_n \mid n \in \mathbb{N}) \) two elements of \( W(E) \), such that \( a \) is distinguished and set \( c := a \cdot b \).

(i) Suppose that the topology of \( E \) is linear, complete and separated. Then \( c \) is distinguished if and only if \( b \) is invertible in \( W(E) \). Indeed, say that \( c = (c_n \mid n \in \mathbb{N}) \). Then remark 9.3.8 says that \( c_0 = a_0b_0 \), especially \( c_0 \) is topologically nilpotent. Also, \( c_1 = a_0^ib_0 + a_1b_0^p \), and notice that \( b_0 \in E^\infty \), if and only if \( b \in W(E) \) (proposition 9.3.45(iii)); on the other hand, since the topology of \( E \) is linear, \( a_0^ib_0 \) is topologically nilpotent (remark 8.3.9)). Since the topology of \( E \) is linear, complete and separated, it follows that \( c_1 \) is invertible if and only if the same holds for \( b_0 \) (details left to the reader), whence the assertion.

(ii) If \( E \) is reduced, then every distinguished ideal of \( W(E) \) is a closed subset for the \( p \)-adic topology of \( W(E) \) and a free \( W(E) \)-module of rank one (proposition 9.3.48(i,v)).

(iii) Let \( E \) be as in (i), and \( I, J \subset W(E) \) any two distinguished ideals such that \( I \subset J \); then (i) implies that \( I = J \). By the same token, we see that every generator of \( I \) is distinguished. Indeed, let \( a_1 \) and \( a_2 \) be any two generators of \( I \); then there exists \( u := (u_n \mid n \in \mathbb{N}) \in W(E) \) such that \( a_2 = u \cdot a_1 \). Let \( N \subset E \) be the nilpotent ideal, and endow \( E_{\text{red}} := E/N \) with the quotient topology induced from \( E \); it follows from (ii) that the image of \( u \) is invertible in \( W(E_{\text{red}}) \), therefore the image of \( u_0 \) is invertible in \( E_{\text{red}} \), so \( u_0 \) is invertible in \( E \), and finally \( u \) is invertible in \( W(E) \) (proposition 9.3.48(iii))

**Example 16.1.8.** With the notation of example 9.3.79, notice that the only distinguished elements of \( W(A, \mathcal{T}) = \mathbb{Z}_p \{ T^{1/p^n} \} \) are of the form \( pu \), where \( u \in W(A, \mathcal{T}) \) is an arbitrary element; especially, the only distinguished ideal of \( \mathbb{Z}_p \{ T^{1/p^n} \} \) is the principal ideal generated by \( p \). On the other hand, the distinguished elements of \( W(A^\lambda, \mathcal{T}) \) are all those of the form \( pu + aT^\lambda \), where \( a \) (resp. \( u \)) is an arbitrary element (resp. invertible element) of \( W(A^\lambda, \mathcal{T}) \), and \( \lambda \in \mathbb{N}[1/p] \) is any strictly positive number.

The following result shall be applied to produce useful distinguished elements in various situations.

**Lemma 16.1.9.** Let \( E \) be an \( \mathbb{F}_p \)-algebra, \( \mathcal{I} \subset W(E) \) an ideal, \( a := (a_n \mid n \in \mathbb{N}) \in \mathcal{I} \) any element, \( \beta^* := (\beta_1, \ldots, \beta_k) \) a finite system of elements of \( E \). Denote by \( J \) the ideal generated by \( \beta^* \), and by \( u : W(E) \to A := W(E)/\mathcal{I} \) the natural projection. Suppose furthermore that :

(a) \( \alpha_0 \) lies in the Jacobson radical of \( E \) and \( \alpha_1 \in E^\infty \).

(b) The Frobenius endomorphism \( \Phi_E \) of \( E \) is surjective.

(i) Then the following conditions are equivalent :

(c) \( pA \) is contained in the ideal of \( A \) generated by \( u \circ \tau_E(\beta_1), \ldots, u \circ \tau_E(\beta_k) \).

(d) There exists an element \( \alpha' := (\alpha'_n \mid n \in \mathbb{N}) \in \mathcal{I} \) such that \( \alpha'_0 \in J \) and the image of \( \alpha'_1 \) is invertible in \( E/J \).

(e) There exists an element \( \alpha' := (\alpha'_n \mid n \in \mathbb{N}) \in \mathcal{I} \) such that \( \alpha'_0 \in J \) and \( \alpha'_1 \in E^\infty \).

(ii) Suppose furthermore that \( \mathcal{I} = \alpha_0 W(E) \). Then (c),(d) and (e) are also equivalent to :

(f) \( \alpha_0 \in J \).
Proof. (c)⇒(d): Assumption (c) implies that there exist \( \gamma_1, \ldots, \gamma_k \in W(E) \) such that
\[
\alpha^\prime := p + \sum_{i=1}^k \gamma_i \cdot \tau_E(\beta_i) \in \mathcal{I}
\]
and we claim that (d) holds for this \( \alpha^\prime \). Indeed, \( \alpha_0^\prime = \sum_{i=1}^k \omega_0(\gamma_i) \cdot \beta_i \in J \), and clearly the image of \( \alpha^\prime \) in \( W(E/J) \) equals \( p \), i.e. \( \alpha_1^\prime \equiv 1 \pmod{J} \).

(d)⇒(c): Let \( \alpha^\prime \) be as in (d); then there exists \( \lambda \in E \) such that \( \lambda \cdot \alpha_1 \equiv 1 + J \), and assumption (b) implies that \( \lambda = \gamma^p \) for some \( \gamma \in E \). Recall that \( \alpha^{\prime\prime} := \tau_E(\gamma) \cdot \alpha^\prime = (\gamma^p \cdot \alpha_n^\prime) \mid n \in \mathbb{N} \) (proposition 9.3.37(i)); we may then replace \( \alpha^\prime \) by \( \alpha^{\prime\prime} \), after which we may assume that \( \alpha_1^\prime \equiv 1 \pmod{J} \). Say that \( \alpha_0^\prime = \sum_{i=1}^k c_i \beta_i \) for some \( c_1, \ldots, c_k \in E \), and set
\[
\delta := \alpha^\prime - \sum_{i=1}^k \tau_E(c_i) \cdot \tau_E(\beta_i).
\]
Notice that \( \delta_0 = 0 \), and the images of \( \alpha^\prime \) and \( \delta \) agree in \( W(E/J) \). Invoking (b) again, we may find \( \gamma \in E \) such that \( \gamma^p = \delta_1 \), and after replacing \( \alpha^\prime \) by \( \tau_A(\gamma^{p-1}) \cdot \alpha^\prime \), and \( c_i \) by \( \gamma^{p-1} \cdot c_i \) for \( i = 1, \ldots, k \), we may further assume that \( \delta_1 \equiv 1 \pmod{\Phi_E(J)} \). In this case, say that \( \delta_1 = 1 + \sum_{i=1}^k d_i \beta_i^\prime \) for some \( d_1, \ldots, d_k \in E \); taking into account remark 9.3.8(ii) and (9.3.42) we see that
\[
\delta \equiv p + p \cdot \sum_{i=1}^k \tau_E(d_i) \cdot \tau_E(\beta_i) \pmod{p^2 W(E)}.
\]
Summing up, we conclude that there exists \( x \in W(E) \) such that \( p + p^2 x - \alpha^\prime \) lies in the ideal generated by \( (\tau_E(\beta_1), \ldots, \tau_E(\beta_k)) \). Hence, \( p \cdot (1 + p \cdot u(x)) \) lies in the ideal generated by \( (u \circ \tau_E(\beta_1), \ldots, u \circ \tau_E(\beta_k)) \). Lastly, we have \( 1 + p \cdot x \in W(E)^\times \), since \( p \) is topologically nilpotent in \( W(E) \), whence (c).

Obviously, (e)⇒(d), so we suppose that (d) holds, and we show (e). Arguing as in the foregoing, we may assume that \( \alpha_1^\prime \equiv 1 \pmod{J} \). Next, using (b) we find \( \gamma \in E \) such that \( \gamma^p = \alpha_1^\prime \), and after replacing \( \alpha^\prime \) by \( \tau_E(\gamma^{p-1}) \cdot \alpha^\prime \), we may even assume that \( \alpha_1^\prime \equiv 1 \pmod{\Phi_E(J)} \).

Likewise, we may find \( \delta \in E \) such that \( \delta^p = \alpha_1^\prime \), and after replacing \( \alpha \) by \( \tau_E(\delta) \cdot \alpha \) we may assume that \( \alpha_1 = 1 \). Now, write \( \alpha_1 = 1 - x^p \) for some \( x \in J \), and set
\[
\alpha^{\prime\prime} := \alpha^\prime + \tau_E(x) \cdot \alpha.
\]
In light of remark 9.3.8(ii), we easily see that \( \alpha_0^\prime \in J \) and \( \alpha_1^\prime = 1 - \alpha_0^\prime \in \alpha_0^\prime E \). Since \( \alpha_0 \) lies in the Jacobson radical of \( E \), it follows that \( \alpha_1^\prime = \alpha_1 \in E^\times \), whence (e).

Lastly, suppose that \( \mathcal{I} = \alpha W(E) \). In this case, we already know that (f)⇒(e). Conversely, if (e) holds, remark 9.3.8(ii) shows that there exists \( \beta := (\beta_n \mid n \in \mathbb{N}) \in W(A) \) with
\[
\alpha_0^\prime \beta_0 \in J \quad \text{and} \quad \alpha_0^\prime \beta_1 + \alpha_1 \beta_0^\prime \in E^\times.
\]
Then, since \( \alpha_0 \) is in the Jacobson radical of \( E \), we deduce that \( \alpha_1 \beta_0^\prime \in E^\times \), so also \( \beta_0 \in E^\times \), and (f) follows.

---

16.1.10. Additionally, often we will be dealing with pairs \( (\alpha, \mathcal{X}) \) consisting of an ideal \( \mathcal{X} \) in a given \( \mathbb{F}_p \)-algebra \( E \), and an element \( \alpha \in W(E) \) (usually \( \alpha \) shall be a distinguished element); then we shall say that \( (\alpha, \mathcal{X}) \) is a transversal pair if we have
\[
W(\mathcal{X}) \cap \alpha W(E) = \alpha W(\mathcal{X}).
\]
This property plays a crucial role in several questions about perfectoid rings, and the following proposition collects a few example of such pairs. One more case is given by theorem 16.3.36(iv).
Proposition 16.1.11. Let $E$ be any perfect $\mathbb{F}_p$-algebra, and $a := (a_n \mid n \in \mathbb{N}) \in W(E)$ any element. The following holds:

(i) Suppose that $a_1 \in E^\times$, and let $J_1, J_2 \subset E$ be any two ideals such that

(a) $J_1^{(1)} E = J_2$ and $J_2^{(1)} E = J_2$ (notation of (9.3.69))
(b) there exist $n, m \in \mathbb{N}$ such that $a_0^n J_1 \subset J_2$ and $a_0^m J_2 \subset J_1$.

Then the pair $(a, J_1)$ is transversal if and only if the same holds for the pair $(a, J_2)$.

(ii) Suppose that $E = \sum_{n \in \mathbb{N}} a_n E$. Then the pair $(a, I^{(r)} E)$ is transversal, for every ideal $I \subset E$ and every $r \in \mathbb{N}^+$ (notation of remark (9.3.71(i))

(iii) Let $J \subset E$ be any ideal such that $J^{(1)} E = J$. Then the pair $(p, J)$ is transversal.

Proof. (iii) is immediate from (9.3.46) and remark (9.3.71(iv).

(i) First, we show that the assertion holds in the special case where $n = 0$ and $m = 1$. To begin with, from lemma (9.3.27(i) and our assumption on $a_1$ we obtain

$$a = \tau_E(a_0) + pu$$

for some $u \in W(E)^\times$.

Notice as well that $a$ is a regular element of $W(E)$, by virtue of proposition (9.3.48(i). Now, suppose first that the pair $(a, J_1)$ is transversal, and let $x \in W(E)$ be any element such that $a \cdot x \in W(J_2)$; then $\tau_E(a_0) \cdot a \cdot x \in W(J_1)$ (proposition (9.3.37(i)), so $\tau_A(a_0) \cdot x \in W(J_1)$ by assumption. Hence $pu \cdot x = (a - \tau_E(a_0)) \cdot x \in W(J_2)$, so $px \in W(J_2) \cap pW(E) = pW(J_2)$, where the last equality follows from (i.a) and (iii); therefore $x \in W(J_2)$, as $p$ is regular in $W(E)$.

Likewise, suppose that $(a, J_2)$ is a transversal pair, and let $x \in W(E)$ be any element such that $a \cdot x \in W(J_1)$; then $\tau_E(a_0) \cdot a \cdot x \in W(J_2)$, and $\tau_E(a_0) \cdot x \in W(J_2)$ (again, by proposition (9.3.37(i)). It follows that $pu \cdot x = (a - \tau_E(a_0)) \cdot x \in W(J_2)$, whence $px \in W(J_2) \cap pW(E) = pW(J_2)$, as required.

Next, let $(J_1, J_2)$ be any pair of ideals fulfilling conditions (i.a) and (i.b). Notice that we have $(a_0 J_1)^{(1)} E = a_0 J_1$ for every $i \in \mathbb{N}$ (lemma (9.3.70(iii)), and the foregoing case implies that assertion (i) holds for the pair $(a_0^n J_1, a_0^{i+1} J_1)$, for every $i \in \mathbb{N}$. It follows that assertion (i) also holds for the pair $(J_1, a_0^n J_1)$; consequently we are reduced to showing assertion (i) for the pair $(J_2, a_0^n J_1)$, and notice that $a_0^{m+n} J_2 \subset a_0^m J_1$. Thus, we may replace $J_1$ by $a_0^n J_1$, $m$ by $n + m$, and assume from start that $J_1 \subset J_2$ and $a_0^m J_2 \subset J_1$. Now, we have

$$a_0 \cdot (J_1 + a_0^{i+1} J_2)^{(1)} E = (a_0 J_1 + a_0^{i+1} J_2)^{(1)} E \subset (J_1 + a_0^{i+1} J_2)^{(1)} E$$

for every $i \in \mathbb{N}$ so that – again by the foregoing case – we know that assertion (i) holds for the pair

$$(J_1 + a_0^{i+1} J_2)^{(1)} E, (J_1 + a_0^{i+1} J_2)^{(1)} E)$$

and then also holds for the pair $(J_1 + a_0^{m+n} J_2)^{(1)} E, (J_1 + a_0^m J_2)^{(1)} E)$; but $(J_1 + a_0^m J_2)^{(1)} E = J_1$ and $(J_1 + a_0^m J_2)^{(1)} E = J_2$, whence the contention.

(ii): Indeed, let $b \in W(A)$ be any element, and suppose that $a \cdot b \in W(I^{(r)} E)$. Define $R_E$ as in lemma (9.3.85) by lemma (9.3.85)(iv) and proposition (9.3.82(iii)), we deduce that

$$|a|_1 \cdot |b|_1 = |a \cdot b|_1 \leq |I|_r$$

for every $| \cdot |$ in $R_E$.

But since the system $\{a_n \mid n \in \mathbb{N}\}$ generates $E$, it is easily seen that $|a|_1 = 1$ for every $| \cdot |$ in $R_E$. We conclude that $|b|_1 \leq |I|_r$ for every such $| \cdot |$, and then the assertion follows, again by invoking lemma (9.3.85)(iv).

Corollary 16.1.12. Let $E$ be a perfect $\mathbb{F}_p$-algebra, $b := (b_1, \ldots, b_n)$ a finite system of elements of $E$, and $\mathcal{I} \subset W(E)$ the ideal generated by $(\tau_E(b_1), \ldots, \tau_E(b_n))$. Let also $a := (a_n \mid n \in \mathbb{N}) \in W(E)$ be any element, and suppose that:

(a) $E = \sum_{n \in \mathbb{N}} a_n E$.
(b) $W(E)$ is complete and separated for its $\mathcal{I}$-adic topology.

Then $a\mathcal{I}$ is a closed ideal for the $\mathcal{I}$-adic topology of $W(E)$. 

\[\square\]
Proof. Let \( I \subseteq E \) be the ideal generated by \( b_\bullet \). Taking into account proposition \[9.3.78\](i) and lemma \[9.3.70\](iv), we easily see that the \( \mathcal{I} \)-adic topology on \( W(E) \) agrees with the linear topology defined by the cofiltered system of ideals \( (W(I^{[q]}) \mid q \in Q_+) \). Then, propositions \[16.1.11\](ii) \[9.3.48\](ii) imply that scalar multiplication by \( a \) is a \( W(E) \)-linear isomorphism

\[
W(E) \rightarrow aW(E)
\]

that identifies the \( \mathcal{I} \)-adic topology of \( aW(E) \) with the one induced by the \( \mathcal{I} \)-adic topology of \( W(E) \). Since \( W(E) \) is complete and separated for its \( \mathcal{I} \)-adic topology, it follows that \( aW(E) \) is complete and separated for the subspace topology induced from the \( \mathcal{I} \)-adic topology of \( W(E) \), and the contention follows. \( \square \)

16.2. \textbf{P-rings}. In this section we make a preliminary study of an auxiliary class of topological rings containing the perfectoid rings that shall be introduced in section \[16.3\].

\textbf{Definition 16.2.1.} A complete and separated topological ring \((A, \mathcal{I})\) is called a \textit{P-ring} if there exist a prime integer \( p \) and an ideal \( I \subset A \) such that the following conditions hold:

\begin{itemize}
  \item[(a)] \( I \) is finitely generated and \( \mathcal{I} \) agrees with the \( I \)-adic topology.
  \item[(b)] \( pA \subset I^2 \) and the Frobenius endomorphism of \( A/I^2 \) is a surjection
  \[
  \Phi_{A/I^2} : A/I^2 \rightarrow A/I^2 \quad a \mapsto a^p.
  \]
\end{itemize}

Any ideal \( I \) of \( A \) fulfilling conditions (a) and (b) is called an \textit{ideal of definition} of \( A \). Moreover, we say that \( I \) is \textit{special}, if the following holds:

\begin{itemize}
  \item[(c)] There exists a finite set of generators \( a_1, \ldots, a_n \) of \( I \) such that \( pA \subset I^{(p)} := \sum_{i=1}^n Aa_i^p \).
\end{itemize}

It turns out that if \( I \) is a special ideal of definition of the P-ring \( A \), the ideal \( I^{(p)} \) depends only on \( I \) (and not on the choice of a system of generators for \( I \)), so this notation is not abusive. Indeed, we have more generally:

\textbf{Lemma 16.2.2.} Let \( A \) be any ring, \( p \) a prime integer, and \((a_1, \ldots, a_n), (b_1, \ldots, b_m)\) two sequences of elements of \( A \). Suppose that

\[
I := \sum_{i=1}^n Aa_i \subset J := \sum_{i=1}^m Ab_i \quad \text{and} \quad p \in I^{(p)} := \sum_{i=1}^n Aa_i^p.
\]

Then:

\begin{itemize}
  \item[(i)] \( I^{(p)} \subset J^{(p)} := \sum_{i=1}^m Ab_i^p \).
  \item[(ii)] Especially, if \( I = J \), we have \( I^{(p)} = J^{(p)} \).
\end{itemize}

\textbf{Proof.} It is easily seen that (i)\(\Rightarrow\)(ii), so we need only check (i). To this aim, it suffices to show that \( I^{(p)} \subset J^{(p)} \) for every maximal ideal \( \mathfrak{m} \subset A \), so we may replace \( A \) by \( A_{\mathfrak{m}} \) and assume from start that \( A \) is local. Now, suppose first that \( J = A \); then it is easily seen that \( J^{(p)} = A \) as well, so the assertion is clear in this case. Hence, we may also assume that \( J \) is contained in the maximal ideal of \( A \). By assumption, for every \( i = 1, \ldots, n \) we may write \( a_i = \sum_{j=1}^m x_{ij}b_j \) for certain \( x_{i1}, \ldots, x_{in} \in A \); it follows easily that \( a_i^{(p)} = \sum_{j=1}^m a_j^{(p)}b_j^{(p)} \in pJ^p \) (details left to the reader). Summing up, we see that \( I^{(p)} \subset J^{(p)} + pJ^p \subset J^{(p)} + I^{(p)}J^{(p)} \), and the assertion follows by Nakayama’s lemma. \( \square \)

\textbf{Lemma 16.2.3.} Let \( A \) be any P-ring, and \( I \) any ideal of definition of \( A \). We have:

\begin{itemize}
  \item[(i)] If \( A \neq 0 \), there exists a unique prime integer \( p \), independent of \( I \), such that condition (b) of definition \[16.2.1\] is fulfilled.
  \item[(ii)] \( I \) is contained in the Jacobson radical of \( A \).
  \item[(iii)] There exists a special ideal of definition \( J \) such that \( J^{(p)} = I \).
\end{itemize}
(iv) For $p$ as in (i), the Frobenius endomorphism $\Phi_{A/pA} : A/pA \to A/pA$ is a surjective ring homomorphism, and there exist $\pi \in A$ and $u \in A^\times$ such that $p = u\pi^p$.

(v) For $p$ as in (i), the ring $A$ is $p$-adically complete and separated.

Proof. (ii) is standard: if $a \in I$, then $1 - ab$ is invertible in $A$ for every $b \in A$, since $A$ is $I$-adically complete and separated (the inverse is given by the convergent series $\sum_{k \in \mathbb{N}} (ab)^n$); the claim follows.

(i): Let $J$ be another ideal of definition of $A$, and $p, q \in \mathbb{Z}$ two prime integers with $p \in I^2$ and $q \in J^2$. By (ii), both $p$ and $q$ lie in the Jacobson radical of $A$; as $A \neq 0$, we get $p = q$.

(ii): Let $(f_\lambda | \lambda \in \Lambda)$ be a finite system of generators (indexed by the finite set $\Lambda$) for $I$; by assumption, we may find $g_\lambda \in A$ such that $f_\lambda - g_\lambda^p \in I^2$ for every $\lambda \in \Lambda$. From (ii) and Nakayama’s lemma, we deduce that the system $(g_\lambda^p | \lambda \in \Lambda)$ generates $I$, so we can take for $J$ the ideal generated by the system $(g_\lambda | \lambda \in \Lambda)$.

Remark 16.2.4. Suppose that $\phi$ is a special case of lemma 8.3.12.

Proof. (iv) is standard: if $a \in I$, then $1 - ab$ is invertible in $A$ for every $b \in A$, since $A$ is $I$-adically complete and separated (the inverse is given by the convergent series $\sum_{k \in \mathbb{N}} (ab)^n$); the claim follows.

(i): Let $J$ be another ideal of definition of $A$, and $p, q \in \mathbb{Z}$ two prime integers with $p \in I^2$ and $q \in J^2$. By (ii), both $p$ and $q$ lie in the Jacobson radical of $A$; as $A \neq 0$, we get $p = q$.

(ii): Let $(f_\lambda | \lambda \in \Lambda)$ be a finite system of generators (indexed by the finite set $\Lambda$) for $I$; by assumption, we may find $g_\lambda \in A$ such that $f_\lambda - g_\lambda^p \in I^2$ for every $\lambda \in \Lambda$. From (ii) and Nakayama’s lemma, we deduce that the system $(g_\lambda^p | \lambda \in \Lambda)$ generates $I$, so we can take for $J$ the ideal generated by the system $(g_\lambda | \lambda \in \Lambda)$.

Remark 16.2.4. Suppose that $A$ is a complete and separated topological $\mathbb{F}_p$-algebra. Then it follows easily from lemma 16.2.3(iv) that $A$ is a $P$-ring if and only if its Frobenius endomorphism $\Phi_A$ is surjective, and there exists a finitely generated ideal $I \subset A$ such that the topology of $A$ agrees with the $I$-adic topology.

Proposition 16.2.5. Let $A$ be a ring, $p$ a prime integer, $I \subset A$ a finitely generated ideal such that $pA \subset I$, and denote by $\mathcal{T}_I$ (resp. $\mathcal{T}_p$) the $I$-adic (resp. $p$-adic) topology on $A$. We have:

(i) $\mathcal{T}_I$ is a $P$-ring, the same holds for $(A, \mathcal{T}_p)$.

(ii) $\mathcal{T}_I$ is a $P$-ring, the same holds for the completion $(A_I^\wedge, \mathcal{T}_I^\wedge)$ of $(A, \mathcal{T}_I)$.
Proof. (i) follows immediately from lemma [16.2.3 iv,v).

(ii): Let \( f_1, \ldots, f_k \) be a finite system of generators of \( I \); by lemma [16.2.3 iv] there exists \( \pi \in A \) such that \( pA = \pi pA \), and the Frobenius endomorphism \( \Phi_{A/pA} \) of \( A/pA \) is surjective, so for every \( i = 1, \ldots, k \) we may find \( g_i \in A \) such that \( f_i - g_i \in pA \), and we let \( J \subset A \) be the ideal generated by the finite system \( \{g_1, \ldots, g_k, \pi\} \). Set \( N := (p - 1)(k + 1) + 1 \), and notice that \( J^N \subset I \subset J^p \). Especially, \( \mathfrak{T}_I \) agrees with the \( -adic topology on A, and moreover \( p \in J^2 \). Furthermore, \( \mathfrak{T}_I \) agrees with the \( J^\wedge \)-adic topology on \( A \) (remark [8.3.32 iv]), and the natural map \( A/J^2 \to A^\wedge_1/J^2A^\wedge_1 \) is an isomorphism (remark [8.3.3 ii,iv]); since \( \Phi_{A/pA} \) is surjective by assumption, the same holds for \( \Phi_{A/pA} \), and the assertion follows. \( \square \)

16.2.6. Henceforth we fix a prime integer \( p \), and we shall assume that the topology of every \( P \)-ring that appears throughout the rest of this chapter is coarser than the \(-adic topology. Let \( (A, \mathfrak{T}) \) be any \( P \)-ring and \( I \subset A \) an ideal of definition. Notice that if \( I \) is special (definition [16.2.1]), the Frobenius endomorphism \( \Phi_{A/I} \) of \( A/I \) factors uniquely as the composition of a morphism of topological rings

\[
\Phi_{A/I} : A/I \to A/I^{(p)}
\]

and the natural projection \( A/I^{(p)} \to A/I \).

Lemma 16.2.7. In the situation of \( [16.2.6] \), we have:

(i) The maps \( u_A : A(A) \to A \) and \( \pi_{A/pA} : E(A) \to A/pA \) are open and surjective.

(ii) \( \ker u_A \) contains a distinguished element of \( A(A) \) (see definition [16.1.6]).

(iii) If \( \alpha := (\alpha_n | n \in \mathbb{N}) \) is any distinguished element in \( \ker u_A \), we have

\[
\pi_A(\alpha_0) = pu \quad \text{for some } u \in A^x.
\]

Proof. (i): Let \( I \subset A \) be any ideal of definition of \( A \), so that the topology of \( A/pA \) agrees with the \( I/pA \)-adic topology; by lemma [16.2.3 iv] we know already that \( \Phi_{A/pA} \) is surjective, and then it is easily seen that there exists \( n \in \mathbb{N} \) such that \( (I/pA)^n \subset \Phi_{A/pA}(I) \). Especially, \( \Phi_{A/pA} \) is an open map; then, the assertion for \( \pi_{A/pA} \) follows from remark [9.4.9 ii). By virtue of [100, Th.8.4], we deduce the surjectivity of \( u_A \). Next, let \( (a_1, \ldots, a_r) \) be a finite system of generators for \( I \), and denote by \( \overline{a_i} \) the image of \( a_i \) in \( A/pA \), for every \( i = 1, \ldots, k \). Since \( 
\pi_{A/pA} \) is surjective, we may find \( \overline{a_1}, \ldots, \overline{a_k} \in E(A) \) such that \( \pi_{A/pA}(\overline{a_i}) = \overline{a_i} \) for \( i = 1, \ldots, k \), and we set \( \alpha_i := \tau_A(\overline{a_i}) \) for \( i = 1, \ldots, k \) (notation of [16.1]). Since \( I \) is topologically nilpotent in \( A \), it is easily seen that \( \overline{a_i} \) is topologically nilpotent in \( E(A) \), and since \( \tau_A \) is continuous, we deduce that \( \alpha_i \) is topologically nilpotent in \( A(A) \), for every \( i = 1, \ldots, k \). Let \( \mathfrak{I} \subset A(A) \) be the ideal generated by the system \( (\alpha_1, \ldots, \alpha_k) \); it follows easily that \( \mathfrak{I} \) is topologically nilpotent as well. On the other hand, by construction we have \( a_i - u_A(\alpha_i) \in pA \subset I^2 \) for every \( i = 1, \ldots, k \), so that \( u_A(\mathfrak{I}) = I \), by Nakayama’s lemma. Lastly, let \( \mathfrak{I} \subset A(A) \) be any open ideal; then \( \mathfrak{I}^n \subset \mathfrak{I} \) for every sufficiently large \( n \in \mathbb{N} \), so \( \mathfrak{I}^n \subset u_A(\mathfrak{I}) \), and the assertion follows.

(ii): We notice the following:

Claim 16.2.8. There exist \( w \in A^x \) and \( t \in E(A) \) such that \( p = w \cdot \pi_A(t) \) in \( A \).

Proof of the claim. By lemma [16.2.3 iv], we may write \( p = v \cdot \pi_A(s) \) for some \( v \in A^x \) and \( x \in A \). Since \( \pi_{A/pA} \) is surjective, we may find \( s \in E(A) \) such that \( x = \pi_A(s) \) (mod \( pA \)). In view of lemma [9.3.4 i) we deduce that \( p = \pi_A(s)^p \) (mod \( p^2A \)), i.e. \( p = v \cdot \pi_A(t) + p^2b \) for \( t := s^p \) and some \( b \in A \); thus \( p \cdot (1 - pb) = v \cdot \pi_A(t) \). But since \( A \) is \( p \)-adically complete and separated (lemma [16.2.3 v]), \( 1 - pb \in A^x \) (remark [8.3.10 v]), so we get the sought identity with \( w := v \cdot (1 - pb)^{-1} \). \( \Diamond \)

Now, take \( w \) and \( t \) as in claim [16.2.8]. Since \( u_A \) is surjective, we may find \( \beta := (b_n | n \in \mathbb{N}) \in A(A) \) with \( u_A(\beta) = w \). By proposition [9.3.37 i) we have \( \beta \cdot \tau_A(t) = (p^\alpha b_n | n \in \mathbb{N}) \),
and (9.3.43) and remark 9.3.8(ii) show that
\[ \gamma := \beta \cdot \tau_A(t) - p = (tb_0, t^p b_1, \ldots) - (0, 1, \ldots) = (tb_0, t^p b_1 - 1, \ldots). \]
But notice that \( t \) is topologically nilpotent in \( E(A) \); since the topology of \( E(A) \) is linear, it follows that \( tb_0 \) and \( t^p b_1 \) are topologically nilpotent in \( E(A) \), and since \( E(A) \) is complete and separated, \( 1 - t^p b_1 \in E(A)^\times \), so \( \gamma \) is distinguished, and it lies in the kernel of \( u_A \), due to lemma 16.1.1(iv).

(iii): Indeed, from (9.3.42) and lemma 9.3.27(i) we get \( \alpha = \tau_A(\alpha_0) + p \cdot \beta \), where \( \beta := (\alpha_{n+1}^\prime | n \in \mathbb{N}) \), and since \( \alpha_1 \in E(A)^\times \), we have \( \beta \in A(A)^\times \) (proposition 9.3.45(iii)); now, \( \pi_A(\alpha_0) = -p \cdot u_A(\beta) \), whence the assertion, in light of lemma 16.1.1(iv). □

**Proposition 16.2.9.** In the situation of (16.2.6), the following conditions are equivalent :

(a) \( E(A) \) is a \( P \)-ring.
(b) There exists an ideal of definition \( I \) of \( A \) such that \( \text{Ker} \Phi_{A/I} \) is a finitely generated ideal of \( A/I \).
(c) There exists a special ideal of definition \( J \) of \( A \) such that \( \Phi_{A/J} \) is an isomorphism.

**Proof.** For any ideal of definition \( I \) of \( A \), recall that \( E(A/I) \) is the limit of the inverse system \((A_n \mid n \in \mathbb{N})\) with \( A_n := A/I \) for every \( n \in \mathbb{N} \), and with transition maps \( \varphi_n : A_{n+1} \to A_n \) given by the Frobenius endomorphism \( \Phi_{A/I} \) of \( A/I \). For every \( n \in \mathbb{N} \) we shall denote by
\[ \overline{\pi}_n : E(A) \to A_n \]
the composition of the canonical identification \( E(A) \overset{\sim}{\to} E(A/I) \) as in (16.1), with the natural projection \( E(A/I) \to A_n \). Especially \( \overline{\pi}_0 = \overline{\pi}_I \); also, each \( \overline{\pi}_n \) is surjective, since the same holds for \( \Phi_{A/J} \). Set \( J_0 := \text{Ker} \overline{\pi}_A/I \), and let \( \Phi_{E(A)} \) be the Frobenius endomorphism of \( E(A) \); then the family of ideals
\[ J_n := \Phi^n_{E(A)}(J_0) = \text{Ker} \overline{\pi}_n \quad \text{for every } n \in \mathbb{N} \]
is a fundamental system of open neighborhoods of \( 0 \) for the topology \( T_{E(A)} \) of \( E(A) \). Especially, every element of \( J_0 \) is topologically nilpotent, and since \( E(A) \) is complete and separated (remark 9.4.9(ii)), we easily deduce that \( J_0 \) is contained in the Jacobson radical of \( E(A) \) (cp. the proof of lemma 16.2.3(ii)).

(c)⇒(a): Let \( J \) be as in (c), and take \( I := J \) in the foregoing. Pick a finite system \((a_1, \ldots, a_r)\) of generators of \( J \), and let \( \pi : A \to A/J^{(p)} \) be the projection. A simple inspection of the definition yields the identity :
\[ \overline{\pi}_{A/J^{(p)}} = \overline{\Phi}_{A/J} \circ \overline{\pi}_1. \]
Since \( \overline{\Phi}_{A/J} \) is an isomorphism, we deduce that \( \overline{\pi}_{A/J^{(p)}} \) is a surjection and we may find
\[ a_1, \ldots, a_r \in E(A) \quad \text{with} \quad \overline{\pi}_{A/J^{(p)}}(a_i) = \pi(a_i) \quad \text{for every } i = 1, \ldots, r. \]
Let \( J_0' \subset E(A) \) be the ideal generated by the system \((a_1, \ldots, a_r)\), and set
\[ J_n' := \Phi^n_{E(A)}(J_0') \quad \text{for every } n \in \mathbb{N}. \]
**Claim 16.2.10.** \( J_0' = J_0 \), and the \( J_0 \)-adic topology on \( E(A) \) agrees with \( T_{E(A)} \).

**Proof of the claim.** A simple inspection shows that \( J_0' \subset J_0 \), and consequently \( J_n' \subset J_n \) for every \( n \in \mathbb{N} \). Moreover, \( \overline{\pi}_{A/J^{(p)}}(J_0') = J/J^{(p)} \), and therefore
\[ \overline{\pi}_1(J_0') = \overline{\Phi}_{A/J}^{-1} \circ \overline{\pi}_{A/J^{(p)}}(J_0') = \overline{\Phi}_{A/J}^{-1}(J/J^{(p)}) = \text{Ker} \varphi_0 = J_0/J_1. \]
Especially, the natural map \( J_n' / J_1' \to J_0 / J_1 \) is surjective, and since \( \Phi_{E(A)} \) is an automorphism, we deduce that the induced map \( J_n' / J_{n+1}' \to J_n / J_{n+1} \) is surjective for every \( n \in \mathbb{N} \). The filtration \((J_n \mid n \in \mathbb{N})\) is separated on \( E(A) \), so the identity \( J_0 = J_0' \) will follow from
after we show that $\mathbb{E}(A)$ is complete for the topology $\mathcal{T}$ defined by the filtration $(\mathcal{J}_n^k \mid n \in \mathbb{N})$. However, since $\mathcal{J}_n^k$ is finitely generated, for every $n \in \mathbb{N}$ there exists $k(n) \in \mathbb{N}$ such that $\mathcal{J}_n^k \subset \mathcal{J}_n^{k(n)} \subset \mathcal{J}_n^0$, so the topology $\mathcal{T}$ agrees with the $\mathcal{J}_0^0$-adic topology, and $\mathcal{J}_n^k$ is topologically nilpotent for the topology $\mathcal{E}(A)$, since it is contained in $\mathcal{J}_0$. Then, the assertion follows from lemma 8.3.12. By the same token, we see that the $\mathcal{J}_0^0$-adic topology agrees with $\mathcal{E}(A)$. \hfill \Box

The assertion follows immediately from claim [16.2.10] and remark [16.2.4]

(a)$\Rightarrow$(b): Let $I \subset A$ and $\mathcal{I} \subset \mathbb{E}(A)$ be two ideals of definition; then there exists $n \in \mathbb{N}$ such that $\mathcal{J}_n \subset \mathcal{I}$. Clearly $\mathcal{J}_n = \mathcal{J}_n^0$, so $\mathcal{J}_n \subset \mathcal{I}$, and since $\mathcal{J}_n^0 \subset \mathcal{I}$, we may therefore assume that $\mathcal{J}_0 \subset \mathcal{I}$. Write $\pi_{A/I}(\mathcal{I}) = I/I$ for an ideal $I \subset A$; we have:

**Claim 16.2.11.** $\mathcal{I} = \text{Ker} \pi_{A/I}$ and $I'$ is an ideal of definition of $A$.

**Proof of the claim.** We have just remarked that $\text{Ker} \pi_{A/I} \subset \mathcal{I}$, and the stated identity is an easy consequence. Next, since both $\mathcal{I}$ and $I$ are finitely generated, the same holds for $I'$, and obviously $pA \subset I'$. Also $\mathcal{I}$ is topologically nilpotent in $\mathbb{E}(A)$, and the topology of $A/I$ is discrete, hence $I'/I$ is a nilpotent ideal of $A/I$, and it follows easily that the $I'$-adic topology on $A$ agrees with the $I'$-adic topology.

Due to claim [16.2.11], we may replace $I$ by $I'$, and assume from start that $\mathcal{I} = \mathcal{J}_0$. We may write $\pi_1(\mathcal{J}_0) = J_1/I$ for an ideal $J_1 \subset A$ containing $I$, and since $\mathcal{J}_0$ and $I$ are finitely generated, the same holds for $J_1$. It suffices now to notice that

$$J_1/I = \pi_{A/I} \varphi_0.$$  

(b)$\Rightarrow$(c): By assumption, there exists a finitely generated ideal $J_1 \subset A$ containing $I$ and such that [16.2.12] holds. Furthermore, by lemma [16.2.3](iii) we may write $I = J^{(p)}$ for some ideal of definition $J' \subset A$. Set $J := J' + J_1$. From [16.2.12] we get $J_1^{(p)} \subset I$, therefore $J^{(p)} = J^{(p)} + J_1^{(p)} = I$. We conclude that $\pi_{A/I}$ induces an isomorphism $A/J_1 \cong A/I = A/J^{(p)}$; but the latter factors through $\overline{\pi}_{A/J}$ and the projection $A/J_1 \to A/J$, so $\overline{\pi}_{A/J}$ is an isomorphism as well (and $J = J_1$). Lastly, since $\mathcal{J}_0$ is topologically nilpotent, $J_1/I$ is a nilpotent ideal, so the same holds for $J/J'$, and consequently the $J$-adic topology agrees with the $J'$-adic topology; so $J$ is an ideal of definition, whence (b).

Let $A$ be any P-ring; by lemma [16.2.7](ii), the kernel of $u_A$ contains a distinguished element $a$, and we shall see later that the case where actually $a$ generates the ideal $\text{Ker} u_A$ is the most interesting for our purposes. For the moment, let us just notice that, if the latter condition holds, the datum $(E := \mathbb{E}(A), a)$ suffices to recover $A$; indeed, lemma [16.2.7](i) says that in that case $u_A$ induces an isomorphism of topological rings $W(E)/aW(E) \cong A$ (where $W(E)/aW(E)$ is endowed with the quotient topology induced from $W(E)$ via the natural projection). It is then convenient to insert hereafter a preliminary study of pairs $(E, a)$ of this type.

16.2.13. Let $(E, \mathcal{T}_E)$ be a perfect topological $\mathbb{F}_p$-algebra, $a := (a_n \mid n \in \mathbb{N}) \in W(E)$ any element, and suppose that $\mathcal{T}_E$ agrees with the $a_0$-adic topology. Denote by $E^\wedge$ the separated completion of $E$, and let also $E_d$ (resp. $E_d^\wedge$) be the ring $E$ (resp. $E^\wedge$) endowed with its discrete topology. To ease notation, set

$$A(E) := W(E)/aW(E)$$

which we view as a topological ring, with the quotient topology induced from $W(E)$. Define likewise the topological rings $A(E_d), A(E^\wedge)$ and $A(E_d^\wedge)$. The natural diagram of continuous
ring homomorphisms

\[
\begin{array}{ccc}
E_d & \longrightarrow & E_d^\wedge \\
\downarrow & & \downarrow \\
E & \longrightarrow & E^\wedge
\end{array}
\]

induces a commutative diagram of topological rings

\[
\begin{array}{ccc}
A(E_d) & \longrightarrow & A(E_d^\wedge) \\
\downarrow & & \downarrow \\
A(E) & \longrightarrow & A(E^\wedge).
\end{array}
\] (16.2.14)

Moreover, notice that there are natural isomorphisms of topological rings

\[
(16.2.15) \quad A(E) \otimes_\mathbb{Z} \mathbb{F}_p \xrightarrow{\sim} E/a_0E \quad A(E^\wedge) \otimes_\mathbb{Z} \mathbb{F}_p \xrightarrow{\sim} E^\wedge/a_0E^\wedge
\]

(where, again the sources and the targets are endowed with the quotient topologies induced from \(A(E)\), \(E\), \(A(E^\wedge)\), and respectively \(E^\wedge\)). The composition of the first of these maps with the projection \(A(E) \rightarrow A(E) \otimes_\mathbb{Z} \mathbb{F}_p\) is the continuous ring homomorphism

\[
\pi_A : A(E) \rightarrow E/a_0E \quad ((b_n \mid n \in \mathbb{N}) \mod aW(E)) \mapsto (b_0 \mod a_0E)
\]

and likewise we can describe the corresponding map \(\pi_A^\wedge : A(E^\wedge) \rightarrow E^\wedge/a_0E^\wedge\). Lastly, denote

\[
\beta : \mathbf{E}(A(E)) \rightarrow E^\wedge
\]

the morphism of topological monoids obtained by composing \(\mathbf{E}(\pi_A)\) with the isomorphism of topological rings \(\mathbf{E}(E/a_0E) \xrightarrow{\sim} E^\wedge\) provided by corollary 9.4.14.

**Proposition 16.2.16.** In the situation of (16.2.13), suppose that \(a_0E + a_1E = E\). Then the following holds:

(i) The image of \(a\) is a distinguished element of \(W(E^\wedge)\).

(ii) All the arrows of (16.2.14) are isomorphisms of topological rings.

(iii) \(A(E)\) is a \(P\)-ring, and its topology agrees with the \(p\)-adic topology.

(iv) \(\beta\) is an isomorphism of topological rings (for the topological ring structure on \(A(E)\) provided by (16.1)), and we have a commutative diagram of topological rings

\[
\begin{array}{ccc}
A(A(E)) & \xrightarrow{W(\beta)} & W(E^\wedge) \\
\downarrow_{u_{\mathbf{E}(E)}} & & \downarrow_{\pi_W^\wedge} \\
A(E) & \xrightarrow{j_A} & A(E^\wedge)
\end{array}
\]

where \(\pi_W^\wedge\) is the natural projection.

**Proof.** (i): By remark 8.3.10(v), the image of \(a_0\) lies in the Jacobson radical of \(E^\wedge\), and since \(a_0E + a_1E = E\), it follows easily that \(a_1 \in E^\times\) (details left to the reader), whence the assertion.

(ii): Let \(\mathcal{I} \subset W(E)\) (resp. \(\mathcal{I}^\wedge \subset W(E^\wedge)\)) be the ideal generated by the system \((p, \tau_{E^\wedge}(a_0))\) (resp. \((p, \tau_{E^\wedge}(a_0))\)); proposition 9.3.78(ii) says that the topology of \(W(E)\) (resp. of \(W(E^\wedge)\)) agrees with the \(\mathcal{I}\)-adic (resp. \(\mathcal{I}^\wedge\)-adic) topology, whereas the topologies of both \(W(E_d)\) and \(W(E_d^\wedge)\) are \(p\)-adic. Let \(\overline{\mathcal{I}}\) (resp. \(\overline{\mathcal{I}}^\wedge\)) be the image of \(\mathcal{I}\) in \(A(E)\) (resp. in \(A(E^\wedge)\)); it follows easily that the topology of \(A(E)\) (resp. of \(A(E^\wedge)\)) agrees with the \(\overline{\mathcal{I}}\)-adic (resp. \(\overline{\mathcal{I}}^\wedge\)-adic) topology, whereas the topologies of both \(A(E_d)\) and \(A(E_d^\wedge)\) are still \(p\)-adic. However, set \(\overline{b} := (a_1^{1/p}, a_2^{1/p}, \ldots)\), and notice that

\[
(16.2.17) \quad a = \tau_{E^\wedge}(a_0) + p \cdot \overline{b} \quad \text{in } W(E)
\]
is invertible in the natural map is a fundamental system of open neighborhoods of $0$ with the $p$-adic topology. Hence also for the $\mathcal{I}$-adic topology. Recall as well that the family of ideals $\Ker (W(E) \to W_n(E/a^k_0E))$ for every $k, n \in \mathbb{N}$

is a fundamental system of open neighborhoods of $0 \in W(E)$ for the $\mathcal{I}$-adic topology, therefore the natural map $A(E) \to \lim_{k, n \in \mathbb{N}} W_n(E/a^k_0E)\mod W_n(E/a^k_0E)$ is an isomorphism of topological rings. By the same token, the same description applies to $A(E^{\wedge})$, so we conclude that also the horizontal arrows of (16.2.14) are isomorphisms.

(iii): We know already that the topology of $A(E)$ is complete and separated, and agrees with the $p$-adic topology. On the other hand, notice that $b$ is invertible in $W(E^{\wedge})$, by (i) and proposition 9.3.45(iii); since the images of $\tau_{E^{\wedge}}(a_0)$ and $-p \cdot b$ agree in $A(E^{\wedge})$, we deduce that the $p$-adic filtration agrees with the $\tau_{E^{\wedge}}(a_0)$-adic filtration on $A(E^{\wedge})$, and therefore also on $A(E)$, since we already know that $j_A$ is an isomorphism. Set $J := \tau_{E^{\wedge}}(a_0^{1/p}) \cdot A(E)$; it follows that the topology of $A(E)$ agrees with the $J$-adic topology, and moreover $p \in J^p \subset J^2$. Lastly, the Frobenius endomorphism is surjective on $A(E)/J^2$, due to the isomorphism (16.2.15), whence the assertion.

(iv): From (iii) and the discussion of (16.1) we see that $\beta$ is an isomorphism of topological rings; also, under the identifications (16.2.15), the morphism $j_{A} \otimes_{\mathbb{Z}} \mathbb{F}_p$ corresponds to the natural map $\iota : E/a_0E \sim \overset{\wedge}{\longrightarrow} E^{\wedge}/a_0E^{\wedge}$. Therefore we have

$$\pi_{A}^{\wedge} \circ j_{A} \circ u_{A(E)} = \iota \circ \pi_{A} \circ u_{A(E)} = \iota \circ \pi_{A} \circ \overline{u}_{A(E)} \circ \omega_0$$

where $\omega_0 : A(A(E)) \to E(A(E))$ is the 0-th ghost component map. Then, since $A(E^{\wedge})$ is complete and separated for the $p$-adic topology, proposition 9.3.53(iii) reduces to checking

**Claim 16.2.18.** $\pi_{A}^{\wedge} \circ \pi_{W}^{\wedge} \circ W(\beta) = \iota \circ \pi_{A} \circ \overline{u}_{A(E)} \circ \omega_0$.

**Proof of the claim.** Notice the identities:

$$\beta \circ \omega_0 = \omega_0^\wedge \circ W(\beta) \quad \pi_{A}^{\wedge} \circ \pi_{W}^{\wedge} = \pi_{E^{\wedge}} \circ \omega_0^\wedge$$

(where $\omega_0^\wedge : W(E^{\wedge}) \to E^{\wedge}$ is the 0-th ghost component map, and $\pi_{E^{\wedge}} : E^{\wedge} \to E^{\wedge}/a_0E^{\wedge}$ is the projection) in light of which, it suffices to show that

$$\pi_{E^{\wedge}} \circ \beta = \iota \circ \pi_{A} \circ \overline{u}_{A(E)}.$$

The latter follows by a simple inspection of the definition of $\beta$: details left to the reader. □

16.2.19. For any prime $p$, consider the following categories:

- The category $\mathcal{E}$ whose objects are all the pairs $(E, \mathcal{I})$ where $E$ is a perfect topological $\mathbb{F}_p$-algebra and a $p$-ring, and $\mathcal{I} \subset W(E)$ is a distinguished ideal. The morphisms $(E, \mathcal{I}) \to (E', \mathcal{I}')$ are the continuous ring homomorphisms $f : E \to E'$ such that $W(f)(\mathcal{I}) \subset \mathcal{I}'$.
- The category $\mathcal{A}$ of all $p$-rings $A$ such that $\Ker u_A$ is a distinguished ideal of $W(A)$. The morphisms in $\mathcal{A}$ are all the continuous ring homomorphisms.
- The full subcategory $\mathcal{E}_p$ of $\mathcal{E}$ whose objects are all the pairs $(E, \mathcal{I})$ such that the topology of $E$ agrees with the $\omega_0(\mathcal{I})$-adic topology, and the full subcategory $\mathcal{A}_p$ of $\mathcal{A}$ consisting of those objects $A$ whose topology agrees with the $p$-adic topology.
Then proposition \ref{16.2.16}(iii,iv) yields an equivalence of categories
\begin{equation}
\mathcal{E}_p \xrightarrow{\sim} \mathcal{A}_p : (E, \mathcal{I}) \mapsto A(E, \mathcal{I}) := W(E)/\mathcal{I}
\end{equation}
with quasi-inverse given by the rule : \( A \mapsto (E(A), \text{Ker } u_A) \). In the following, we aim to extend this equivalence to the whole of \( \mathcal{E} \). The first step is :

**Proposition 16.2.21.** With the notation of \ref{16.2.19}, let \((E, \mathcal{I})\) be any object \( \mathcal{E} \). Then :

(i) \( A(E, \mathcal{I}) \) is a \( P \)-ring.

(ii) Especially, \( \mathcal{I} \) is closed in the topology \( \mathcal{I}_{W(E)} \).

**Proof.** Clearly, it suffices to check (i). To this aim, let \( (a_n \mid n \in \mathbb{N}) \in \mathcal{I} \) be any distinguished element, \( I \subset E \) be any ideal of definition, \((x_0, \ldots, x_r)\) a finite system of generators for \( I \), denote by \( \mathcal{I} \subset W(E) \) the ideal generated by the system \((\tau_E(x_0), \ldots, \tau_E(x_r))\), and set \( \mathcal{I}^p := \mathcal{I} + pW(E) \). By proposition \ref{9.3.78}(ii), we know that the topology of \( A(E) \) agrees with the \( \mathcal{I}^p \)-adic topology. Now, by assumption \( a_0 \) is topologically nilpotent, hence \( a_0^k \in I \) for every sufficiently large \( k \in \mathbb{N} \); since the Frobenius endomorphism \( \Phi_E \) is an automorphism of the topological ring \( E \), we may then replace \( I \) by \( \Phi_E^{-t} I \) for some suitably large \( t \in \mathbb{N} \), after which we may assume that \( a_0 \in I^{(p)} \), and recall that \( I^{(p)} \) is generated by \((x_0^p, \ldots, x_r^p)\). Then, lemma \ref{16.1.9}(ii) implies that
\begin{equation}
p \in \mathcal{I}^2 A(E).
\end{equation}
and therefore \( \mathcal{I}^2 A(E) = \mathcal{I} A(E) \); especially, the topology of \( A(E) \) agrees with the \( \mathcal{I}^p \)-adic topology. We remark :

**Claim 16.2.23.** \( \mathcal{I} \) is a closed subset for the \( \mathcal{I}^p \)-adic topology on \( W(E) \).

**Proof of the claim.** By lemma \ref{9.3.33}(ii) and \ref{8.3.12} the ring \( W(E) \) is complete and separated for its \( \mathcal{I}^p \)-adic topology, so the assertion follows from corollary \ref{16.1.12}.

Claim \ref{16.2.23} implies that \( A(E) \) is complete and separated for its \( \mathcal{I}^p \)-adic topology. Moreover, the Frobenius endomorphism of \( A(E)/\mathcal{I} A(E) \) is surjective, by virtue of \ref{16.2.15}; taking into account \ref{16.2.22}, the proposition follows.

To define a quasi-inverse for our extension of \ref{16.2.20}, we shall also need the following:

**Proposition 16.2.24.** Let \( A \) be any \( P \)-ring. We have :

(i) If \( \text{Ker } u_A \) is the topological closure of a finitely generated ideal, \( E(A) \) is a \( P \)-ring.

(ii) The following conditions are equivalent :

(a) \( \text{Ker } u_A \) is generated by any distinguished element contained in it.

(b) \( \text{Ker } u_A \) is a principal ideal.

(c) \( \text{Ker } u_A \) is the topological closure of a principal ideal.

**Proof.** (i): For any topological space \( X \), and any subset \( S \subset X \), denote by \( S^c \) the topological closure of \( S \) in \( X \). By assumption, there exists a finitely generated ideal \( \mathcal{I} \subset A(A) \) such that \( \mathcal{I}^c = \text{Ker } u_A \). Let now \( \omega_0 : A(A) \to E(A) \) be the 0-th ghost component; we notice :

**Claim 16.2.25.** (i) \( \omega_0(\text{Ker } u_A) = \ker (\overline{\pi}_{A/pA} : E(A) \to A/pA) \).

(ii) \( (\ker \overline{\pi}_{A/pA})^c = \ker \overline{\pi}_{A/(pA)^c} \).

**Proof of the claim.** (i): Say that \( x \in \ker \overline{\pi}_{A/pA} \), and pick any \( y \in A(A) \) such that \( \omega_0(y) = x \); then \( u_A(y) = pa \) for some \( a \in A \). We pick \( z \in A(A) \) such that \( u_A(z) = a \); then \( y - pz \in \ker u_A \) and \( \omega_0(y - pz) = x \), whence the contention.

(ii): The ideal \( K := (\ker \overline{\pi}_{A/pA})^c \) contains \( \ker \overline{\pi}_{A/pA}(K) \), therefore
\begin{equation}
K = \overline{\pi}_{A/pA}^{-1}(\overline{\pi}_{A/pA}(K)).
\end{equation}
so \( \pi_{A/pA}(K) \) is a closed ideal of \( A/pA \), by lemma [16.2.7(i)], hence \((pA)^c/pA \subset \pi_{A/pA}(K)\) and consequently \( K = \pi_{A/pA}^{-1}((pA)^c/pA) \). On the other hand, \( \pi_{A/(pA)^c} \) is the composition of \( \pi_{A/pA} \) with the projection \( A/pA \to A/(pA)^c \), whence the claim. \( \square \)

Claims [8.3.25] and [16.2.25(ii)] imply that \( \omega_0(\mathcal{J})^c = (\text{Ker} \ \pi_{A/pA})^c \). From claim [16.2.25(ii)] we deduce that \( \text{Ker} \ \pi_{A/(pA)^c} \) is the topological closure in \( E(A) \) of a finitely generated ideal. Next, let \( I \subset A \) be any ideal of definition, and \( \mathcal{J} \subset E(A) \) any finitely generated ideal such that \( \pi_{A/(pA)^c}(\mathcal{J}) = I/(pA)^c \); it follows easily that \( \mathcal{J} + \text{Ker} \ \pi_{A/(pA)^c} = \text{Ker} \ \pi_{A/I} \) (details left to the reader), and then also \( \text{Ker} \ \pi_{A/I} \) is the topological closure of a finitely generated ideal of \( E(A) \). Lastly, we have a commutative diagram of continuous and surjective ring homomorphisms

\[
\begin{array}{ccc}
E(A) & \xrightarrow{\pi_{A/I}} & A/I \\
v \downarrow & & \downarrow \Phi_{A/I} \text{ (details left to the reader)} \\
A/I & \xrightarrow{\Phi_{A/I}} & A/I \\
\end{array}
\]

whence \( v(\text{Ker} \ \pi_{A/I}) = \text{Ker} \ \Phi_{A/I} \). Since the topology of \( A/I \) is discrete, claim [8.3.25] implies that \( \text{Ker} \ \Phi_{A/I} \) is a finitely generated ideal, so the assertion follows from proposition [16.2.9(ii)].

(ii): Clearly \( (a) \Rightarrow (b) \), and since \( \text{Ker} \ u_A \) is a closed subset of \( W(A) \), we have as well \( (b) \Rightarrow (c) \). Thus, it remains only to check that \( (c) \Rightarrow (a) \). To this aim, let again \( I \subset A \) be any ideal of definition, denote by \( J \subset A \) the radical of \( I \), and fix any element \( \bar{b} := (b_n \mid n \in \mathbb{N}) \in A(A) \) such that \( \text{Ker} \ u_A \) is the topological closure of \( bA(A) \) in \( A(A) \). We notice that \( A/J \) is a perfect \( \mathbb{F}_p \)-algebra, and its quotient topology induced by the projection \( \pi : A \to A/J \) is discrete. We have a commutative diagram of continuous and surjective ring homomorphisms

\[
\begin{array}{ccc}
A(A) & \xrightarrow{u_A} & A \\
\downarrow f & & \downarrow \pi \\
W(A/J) & \xrightarrow{\varphi_0} & A/J \\
\end{array}
\]

whose bottom horizontal arrow is the 0-th ghost map (see (9.3.2)), and with \( f := W(\varphi) \), where \( \varphi : E(A) \to A/J \) is the composition of \( \pi_{A/pA} : E(A) \to A/pA \) with the natural projection \( A/pA \to A/J \) (details left to the reader).

Claim 16.2.26. \( f(\text{Ker} \ u_A) = pW(A/J) \).

Proof of the claim. It is clear that \( f(\text{Ker} \ u_A) \subset pW(A/J) \), so we need only show the converse inclusion. Now, according to lemma [16.2.7(ii)], we may find a distinguished element \( a := (a_n \mid n \in \mathbb{N}) \in \text{Ker} \ u_A \). Since \( a_0 \) is topologically nilpotent in \( E(A) \), the element \( \pi_{A/pA}(a_0) \) is topologically nilpotent in \( A/pA \), and therefore its image vanishes in \( A/J \); in other words, \( a_0 \in \text{Ker} \ \varphi \). However, \( a = \tau_A(a_0) + p \cdot u \), for some \( u \in A(A)^\times \), so that

\[
f(a) = f \circ \tau_A(a_0) + p \cdot f(u) = \tau_{A/J} \circ \varphi(a_0) + p \cdot f(u) = p \cdot f(u)
\]

(see (9.3.36)) whence the claim. \( \square \)

In light of claims [8.3.25] and [16.2.26] and example [9.3.49(i)] we deduce that \( f(\bar{b}) \cdot W(A/J) \) is a dense subset of \( pW(A/J) \), for the \( p \)-adic topology on \( W(A/J) \); especially, we have

\[
pW(A/J) = p^2 W(A/J) + f(\bar{b}) \cdot W(A/J).
\]

Then, since \( p \) lies in the Jacobson radical of \( W(A/J) \), Nakayama’s lemma shows that \( f(\bar{b}) \cdot W(A/J) = pW(A/J) \), which in turn implies that \( \varphi(b_0) = 0 \) and \( \varphi(b_1) \) is invertible in \( A/J \).

Claim 16.2.27. \( \bar{b} \) is a distinguished element of \( A(A) \).
Proof of the claim. First, since \( J \) is contained in the Jacobson radical of \( A \) (remark 8.3.10(v)) and \( \varphi(b_i) \in (A/J)\times \), we deduce that \( \pi_A(b_i) \in A\times \), and therefore \( b_i \in E(A)\times \), by remark 9.4.5(iii). Likewise, we have \( \pi_A(b_0) \in JA \), which easily implies that \( b_0 \) is topologically nilpotent in \( E(A) \) (details left to the reader).

Now, from (i) and assumption (ii.c) we see that \( E(A) \) is a P-ring; from claim 16.2.27 and proposition 16.2.21(ii) it then follows that \( bA(A) \) is a closed ideal of \( A(A) \), and therefore it must coincide with \( \text{Ker } u_A \). Lastly, let \( a \) be any other distinguished element of \( A(A) \) contained in \( \text{Ker } u_A \); taking into account remark 16.1.7(i) and again claim 16.2.27 we conclude that \( aA(A) = bA(A) \), whence (ii.a).

16.3. Perfectoid rings. We are now ready to introduce our generalizations of Scholze’s perfectoid rings that will intervene in the proof of the log regular version of almost purity.

Definition 16.3.1. Let \( A \) be any P-ring. We say that \( A \) is perfectoid if and only if it fulfills any of the three equivalent conditions of proposition 16.2.24(ii).

Example 16.3.2. (i) Let \((A, \mathcal{T})\) be any topological \( \mathbb{F}_p \)-algebra. Then \( A \) is perfectoid if and only if it is perfect, \( \mathcal{T} \) is complete and separated, and there exists a finitely generated ideal \( I \subset A \) such that \( \mathcal{T} \) agrees with the \( I \)-adic topology. Indeed, under these assumptions, \( A \) is a P-ring (remark 16.2.4), and the map \( \pi_A : E(A) \rightarrow A \) is an isomorphism of topological rings that identifies \( u_A \) with the 0-th ghost map \( \omega_0 : W(A) \rightarrow A \), whose kernel is the principal ideal \( pW(A) \), by (9.3.46), so \( A \) is perfectoid. Conversely, clearly \( p \in \text{Ker } u_A \), and \( p \) is obviously a distinguished element of \( A(A) \), so if \( A \) is a perfectoid \( \mathbb{F}_p \)-algebra we must have \( \text{Ker } u_A = pW(A) \); moreover, \( u_A \) is an open ring homomorphism (lemma 16.2.7(i)), so it induces an isomorphism \( E(A) \xrightarrow{\sim} A \) of topological rings, especially \((A, \mathcal{T})\) is a perfect topological \( \mathbb{F}_p \)-algebra, as claimed.

(ii) Let \( E \) be any perfectoid \( \mathbb{F}_p \)-algebra, and \( a := (a_n \mid n \in \mathbb{N}) \) any distinguished element of \( W(E) \). Then \( A(E) := W(E)/gW(E) \) is perfectoid for the quotient topology induced by \( W(E) \). Indeed, \( A(E) \) is a P-ring, by proposition 16.2.21(i); next, lemma 8.3.12 implies that \( E \) is complete and separated for the \( a_0 \)-adic topology, and therefore proposition 16.2.16(ii,iv) applies, and shows that \( \text{Ker } u_{A(E)} \) is a principal ideal, whence the contention. Moreover, in this case the perfectoid ring \( E \) can be recovered from \( A(E) \); indeed, we have a natural isomorphism of topological rings

\[
E(A(E)) \xrightarrow{\sim} E
\]

obtained as follows. First, since the 0-th ghost component \( W(E) \rightarrow E \) is an open and surjective map, the same holds for the projection \( \alpha : A(E) \rightarrow A(E)/pA(E) \xrightarrow{\sim} E/a_0E \), where \( E/a_0E \) is endowed with the quotient topology induced by \( E \). Then, \( \alpha \) induces an isomorphism \( E(\alpha) : E(A(E)) \xrightarrow{\sim} E(A(E)/a_0E) \) of topological rings, by (16.1). But since \( a_0 \) is topologically nilpotent, the projection \( \beta : E(E) \rightarrow E(E/a_0E) \) is an isomorphism of topological rings as well (theorem 9.4.10), and the same holds for the map \( \pi_E : E(E) \rightarrow E \), since \( E \) is perfect. Thus, the sought isomorphism is the composition \( \pi_E \circ \beta^{-1} \circ E(\alpha) \).

Let us also point out the following complement to proposition 16.2.9:

Corollary 16.3.3. Let \( A \) be any perfectoid ring. Then \( \mathbb{F}_{A/J} \) is an isomorphism for every special ideal of \( A \).

Proof. Set \( E := E(A) \); we may assume that there exists a distinguished element \( a := (a_n \mid n \in \mathbb{N}) \in W(E) \) such that \( A \) is the ring \( A(E) \) as defined in (16.2.13), and \( u_A : W(E) \rightarrow A(E) \) is the projection. Moreover, we may find a finite system \( x_\bullet := (x_0, \ldots, x_r) \) of elements of \( W(E) \), such that \( J \) is the image in \( A(E) \) of the ideal generated by \( x_\bullet \). We may write

\[
(16.3.4) \quad x_i = \tau_E(t_i) + p \cdot y_i \quad \text{where } t_i \in E \text{ and } y_i \in W(E) \text{ for every } i = 0, \ldots, r.
\]
In view of lemma [9.3.4](i), we deduce that
(16.3.5) \[ J_i^p \equiv \tau_E(t_i)^p \pmod{p^2W(E)} \quad \text{for } i = 0, \ldots, r. \]
Let \( \mathcal{J} \subset W(E) \) be the ideal generated by \( \tau_E(t_0), \ldots, \tau_E(t_r) \); we notice:

**Claim 16.3.6.** \( p \in \mathcal{J}(E) A(E) \) and \( \mathcal{J} A(E) = J \).

**Proof of the claim.** It follows easily from (16.3.5) that there exists \( z \in W(E) \) with
\[ p \cdot u_A(1 + p \cdot z) \in \mathcal{J}(p) A(E) \]
(recall that \( \mathcal{J}(p) \) is the ideal generated by \( \tau_E(t_0)^p, \ldots, \tau_E(t_r)^p \); see definition [16.2.1]). However, \( p \) is topologically nilpotent in \( W(E) \), therefore \( 1 + p \cdot z \in W(E)^\times \), so \( p \in \mathcal{J}(p) A(E) \). The other assertion follows directly from the first one and (16.3.4); details left to the reader. ◊

Let \( I \subset E \) be the ideal generated by \( t_0, \ldots, t_r \), and set \( E_0 := E/\alpha_0 E \); taking into account lemma [16.1.9](ii) and claim [16.3.6], we deduce that \( \alpha_0 \in I(p) \). Also, it is clear that the natural isomorphism (16.2.15) maps the image of \( J \) (resp. of \( J(p) \)) onto \( IE_0 \) (resp. \( I(p) E_0 \)). But it also follows that \( E_0/IE_0 = E/I \) and \( E_0/I(p) E_0 = E/I(p) \); lastly, since \( E \) is perfect, the Frobenius endomorphism \( \Phi_E \) maps \( I \) onto \( I(p) \), whence the contention. □

**Remark 16.3.7.** (i) We may now say that the category \( \mathcal{A} \) of (16.2.19) is the category of perfectoid rings, and we shall denote it henceforth by \( \text{Perf} \).

More generally, if \( A \) is any perfectoid ring, we shall write
\[ A\text{-Perf} \]
for the category \( A/\text{Perf} \) of perfectoid \( A \)-algebras, whose objects are the continuous ring homomorphisms \( A \to B \) with \( B \) perfectoid. The objects of the category \( \mathcal{E} \) of (16.2.19) are the pairs \( (E, \mathcal{J}) \) consisting of a perfectoid \( \mathbb{F}_p \)-algebra and a distinguished ideal of \( W(E) \). Taking into account example [16.3.2], we see that (16.2.19) generalizes verbatim to an equivalence
\[ \mathcal{E} \xrightarrow{\sim} \text{Perf} : (E, \mathcal{J}) \mapsto A(E, \mathcal{J}) := W(E)/\mathcal{J} \]
with a natural quasi-inverse given by the functor \( E \), which restricts to equivalences
\[ E : A\text{-Perf} \xrightarrow{\sim} E(A)\text{-Perf} \quad \text{for every perfectoid ring } A. \]

Hereafter, we shall study the stability of the class of perfectoid rings under some standard operations. The following observations (iii) and (iv) show stability under completion with respect to the \( J \)-adic topology corresponding to an ideal \( J \subset A \) of finite type with \( pA \subset J \).

(ii) Let \( A \) be any perfectoid ring, set \( E := E(A) \), and let \( \alpha_\bullet := (\alpha_n \mid n \in \mathbb{N}) \) be any distinguished element in \( \text{Ker } u_A \). Notice that \( \pi_A/pA \) : \( E \to A/pA \) induces an isomorphism of topological rings:
\[ \omega : E/\alpha_0 E \xrightarrow{\sim} A/pA \]
for the quotient topologies induced by the projections \( A \to A/pA \) and \( E \to E/\alpha_0 \). Indeed, \( \pi_A/pA \) is open and surjective (lemma [16.2.7](i)), and \( \alpha_\bullet \) generates \( \text{Ker } u_A \), so \( \alpha_0 \) generates the kernel of \( u_{A/pA} \), by virtue of lemma [16.1.1](ii), whence the contention.

(iii) The isomorphism \( \omega \) of (ii) induces a natural bijection:
\[ \{ \text{ideals } \mathcal{J} \subset E \mid \alpha_0 E \subset \mathcal{J} \} \leftrightarrow \{ \text{ideals } J \subset A \mid pA \subset J \}. \]
Namely, \( \mathcal{J} \subset E \) and \( J \subset A \) correspond under this bijection, if and only if \( \omega(\mathcal{J}/\alpha_0 E) = J/pA \). Then, clearly \( J \) is finitely generated if and only if the same holds for \( \mathcal{J} \). Let \( \mathcal{T}_J \) (resp. \( \mathcal{T}_F \)) denote the \( J \)-adic (resp. \( J \)-adic) topology on \( A \) (resp. on \( E \)); taking into account remark [9.4.9](ii), we deduce that if \( J \) is finitely generated, then the topology of \( E(A, \mathcal{T}_F) \) agrees
with \( \mathcal{T}_f \). Combining with example \([16.3.2]\) (i), lemma \([8.3.32]\) (iv), example \([9.3.49]\) (ii) and remark \([9.4.9]\) (v), we conclude that the completion \( E(A, \mathcal{T}_j)^\wedge \) of \( E(A, \mathcal{T}_j) \) is perfectoid.

(iv) In the situation of (iii), suppose that \( J \) and \( \mathcal{I} \) are finitely generated; notice that, since \( a_0 \in \mathcal{I} \), the image of \( a_\bullet \) is distinguished in \( W(E(A, \mathcal{T}_j)^\wedge) \), and let \( \mathcal{I} := a_\bullet W(E(A, \mathcal{T}_j)^\wedge) \).

We claim that there is a natural isomorphism of topological rings

\[
W(E(A, \mathcal{T}_j)^\wedge)/\mathcal{I} \cong (A_J, \mathcal{T}_j)^\wedge
\]

for the quotient topology on \( W(E(A, \mathcal{T}_j)^\wedge)/\mathcal{I} \) induced by \( W(E(A, \mathcal{T}_j)^\wedge) \). Especially, this shows that \( (A_J, \mathcal{T}_j)^\wedge \) is perfectoid. For the proof, fix a finite system \( (\beta_1, \ldots, \beta_k) \) of generators of \( \mathcal{I} \), and let \( \mathcal{I}_W \subset W(E) \) be the ideal generated by the system \( (p, \tau_E(\beta_1), \ldots, \tau_E(\beta_k)) \); by proposition \([9.3.78]\) (ii), the topology \( \mathcal{I}_W \) of \( W(E, \mathcal{T}_j) \) agrees with the \( \mathcal{I}_W \)-adic topology. By construction we have \( u_A(\mathcal{I}_W)/pA = J/pA \), and consequently \( u_A(\mathcal{I}_W) = J \), so the quotient topology induced by \( \mathcal{I}_W \) on \( A \) via \( u_A \) agrees with \( \mathcal{I}_j \). Lastly, in view of (iii) and proposition \([16.2.21]\) (ii) we know that \( \mathcal{I} \) is a closed ideal of \( W(E(A, \mathcal{T}_j)^\wedge) \). Taking into account proposition \([8.2.13]\) (v) and lemma \([9.3.33]\) (iv), the assertion follows.

We can summarize these observations in the following:

**Proposition 16.3.8.** Let \( A \) be a ring, \( p \) a prime integer, \( I \subset A \) a finitely generated ideal such that \( pA \subset I \), and denote by \( \mathcal{T}_I \) (resp. \( \mathcal{T}_p \)) the \( I \)-adic (resp. \( p \)-adic) topology on \( A \). We have:

(i) If \( (A, \mathcal{T}_I) \) is perfectoid, the same holds for \( (A, \mathcal{T}_p) \).

(ii) If \( (A, \mathcal{T}_p) \) is perfectoid, the same holds for the completion \( (A_I, \mathcal{T}_I)^\wedge \) of \( (A, \mathcal{T}_I) \).

**Proof.** (i) follows immediately from proposition \([16.2.5]\) (i).

(ii) It suffices to apply remark \([16.3.7]\) (iv) to the ideal \( I \subset A \) and the corresponding ideal \( \mathcal{I} := \tau_{A/pA}^{-1}(I/pA) \) of \( E(A) \).

The next observation establishes the stability of \( \text{Perf} \) under completed tensor products:

**Proposition 16.3.9.** Let \( A_0 \) be a perfectoid ring and \( A_1, A_2 \) two perfectoid \( A_0 \)-algebras. Then:

(i) The topological ring \( A_3 := A_1 \widehat{\otimes}_{A_0} A_2 \) is perfectoid.

(ii) There exists a natural isomorphism \( E(A_3)^\wedge \cong E(A_1)^\wedge \widehat{\otimes}_{E(A_0)} E(A_2)^\wedge \) in \( \text{Perf} \).

(iii) Especially, all finite coproducts are representable in the category \( \text{Perf} \).

**Proof.** (i): Set \( E_i := E(A_i) \) for \( i = 0, 1, 2 \), and pick a distinguished element \( \alpha \in W(E_0) \) that generates the kernel of \( u_{A_0} \); then the image of \( \alpha \) in \( W(E_i) \) is still distinguished, and we know that \( \alpha W(E_i) \) is the kernel of \( u_{A_i} \) also for \( i = 1, 2 \). Moreover, it is clear from remark \([9.3.57]\) (iii) that the \( \mathbb{F}_p \)-algebra \( E_3 := E_1 \widehat{\otimes}_{E_0} E_2 \) is perfectoid, and then the same holds for the topological ring \( A(E_3) := W(E_3)/\alpha W(E_3) \), by virtue of example \([16.3.2]\) (ii). Lastly, the isomorphism \([9.3.59]\) induces an isomorphism of topological rings

\[
A(E_3)^\wedge \cong A_1 \widehat{\otimes}_{A_0} A_2
\]

whence the assertion.

(ii): Example \([16.3.2]\) (ii) also identifies naturally \( E_3 \) with \( E(A(E_3)) \), whence the contention.

(iii) is clear, since complete tensor products represent these coproducts, by \([8.3.7]\).  

16.3.10. For any ring \( A \) and any ideal \( I \subset A \), let \( \mathcal{T}_I \) be the \( I \)-adic topology on \( A \), and denote \( (A_I^\wedge, \mathcal{T}_I^\wedge) \) the separated completion of \( (A, \mathcal{T}_I) \). Notice that if \( I' \subset A \) is another ideal with \( I' \subset I \), the identity map of \( A \) yields a continuous map \( (A, \mathcal{T}_I) \rightarrow (A, \mathcal{T}_{I'}) \), whose completion is a natural continuous ring homomorphism

\[
(16.3.11) \quad (A_I^\wedge, \mathcal{T}_I^\wedge) \rightarrow (A_{I'}^\wedge, \mathcal{T}_{I'}^\wedge).
\]
Now, suppose that $I, J \subset A$ are any two ideals; we deduce a commutative diagram

\[
\begin{array}{ccc}
(A_{I \cap J}^\wedge, T_{I \cap J}^\wedge) & \xrightarrow{\varphi_I} & (A_I^\wedge, T_I^\wedge) \\
\varphi_J & & \beta_I \\
(A_J^\wedge, T_J^\wedge) & \xrightarrow{\beta_J} & (A_{I+J}^\wedge, T_{I+J}^\wedge)
\end{array}
\]

whose arrows are the continuous ring homomorphisms \((16.3.11)\). Moreover, for every $k \in \mathbb{N}$ let $A_{I,k}^\wedge := A_I^\wedge / J^k A_I^\wedge$, and endow $A_{I,k}^\wedge$ with the quotient topology $T_{I,k}$ induced by $T^\wedge$ via the natural projection $A_I^\wedge \to A_{I,k}^\wedge$. We set

\[
(A_{I,k}^\wedge, T_{I,k}^\wedge) := \lim_{k \in \mathbb{N}} (A_{I,k}^\wedge, T_{I,k}^\wedge).
\]

For every $k \in \mathbb{N}$, let $T_{d,k}$ be the discrete topology on $A/(I + J)^k$; the system of continuous projections \((A_{I,k}^\wedge, T_{I,k}^\wedge) \to (A/(I + J)^k, T_d) \mid k \in \mathbb{N}\) factors uniquely through a system of continuous ring homomorphisms \((A_{I,k}^\wedge, T_{I,k}^\wedge) \to (A/(I + J)^k, T_d) \mid k \in \mathbb{N}\), whose limit is a natural continuous ring homomorphism

\[
(A_{I,k}^\wedge, T_{I,k}^\wedge) \to (A_{I+J}^\wedge, T_{I+J}^\wedge).
\]

**Lemma 16.3.15.** In the situation of \((16.3.10)\), we have:

(i) \((16.3.14)\) is an open and surjective map.

(ii) Suppose that $A$ is either a noetherian ring or a perfect $F_p$-algebra, and that both $I$ and $J$ are finitely generated. Then:

(a) \((16.3.12)\) is a cartesian diagram of topological rings and a cocartesian diagram of topological $A$-modules.

(b) \((16.3.14)\) is an isomorphism of topological rings.

**Proof.** For every $n \in \mathbb{N}$, we have a natural diagram of rings

\[
\begin{array}{ccc}
A/(I^n \cap J^n) & \xrightarrow{} & A/I^n \\
\downarrow & & \downarrow \\
A/J^n & \xrightarrow{} & A/(I^n + J^n)
\end{array}
\]

whence a complex of $A$-modules

\[
\Sigma_n : 0 \to A/(I^n \cap J^n) \to A/I^n \oplus A/J^n \to A/(I^n + J^n) \to 0
\]

and it is easily seen that $\Sigma_n$ is exact for every $n \in \mathbb{N}$. Therefore, \((16.3.16)\) is a cartesian diagram of discrete topological rings (details left to the reader); let $T_{d,n}$ be the discrete topology on $A/(I^n \cap J^n)$ for every $n \in \mathbb{N}$, and set

\[
(A', T') := \lim_{n \in \mathbb{N}} (A/(I^n \cap J^n), T_{d,n}).
\]

Notice as well that $(I + J)^{2n-1} \subset I^n + J^n \subset (I + J)^n$ for every $n \in \mathbb{N}$, so the $(I + J)$-adic topology on $A$ agrees with the linear topology defined by the descending system of ideals $(I^n + J^n \mid n \in \mathbb{N})$. In light of example \([5.14] (ii)\), we deduce that the limit of the system of these diagrams is a cartesian diagram of topological rings

\[
\begin{array}{ccc}
(A', T') & \xrightarrow{\varphi_I} & (A_I^\wedge, T_I^\wedge) \\
\varphi_J & & \beta_I \\
(A_J^\wedge, T_J^\wedge) & \xrightarrow{\beta_J} & (A_{I+J}^\wedge, T_{I+J}^\wedge)
\end{array}
\]
Moreover, since the inverse system $(A/(I^n \cap J^n) \mid n \in \mathbb{N})$ has surjective transition maps, the limit of the system of exact sequences $(\Sigma_n \mid n \in \mathbb{N})$ is still exact (see [125, Lemma 3.5.3]), and therefore (16.3.17) is also a cocartesian diagram of $A$-modules. Furthermore, by proposition 8.2.13(i,v) we have an induced morphism of exact complexes

$$\beta^\prime_{K,\Sigma} \subset A$$

especially, $\beta^\prime(n)$ is defined by the cofiltered system of ideals

$$\text{continuous ring homomorphism} \quad \text{topology} \quad \gamma$$

and a simple inspection shows that

$$\text{limit of the system of exact sequences} \quad (\Sigma_{\text{Coker}} \lim_{\rightarrow}^\Sigma_{\text{Coker}})$$

However, if

$$\text{Topology defined by the cofiltered system of ideals} \quad IJ$$

Thus, suppose $IJ$ is noetherian, the Artin-Rees lemma ([100, Th.8.5]) implies that for every

$$\nu : (A_{I^n \cap J^n}, \mathcal{T}_{I^n \cap J^n}) \to (A', \mathcal{T}')$$

and a simple inspection shows that $\varphi^I \circ \nu = \varphi_I$ and $\varphi^J \circ \nu = \varphi_J$. To conclude the proof of (iia), it then suffices to check:

**Claim 16.3.18.** Under the assumptions of (ii), the map $\nu$ is an isomorphism of topological rings.

**Proof of the claim.** Since $(IJ)^{2n} \subset (I \cap J)^{2n} \subset (IJ)^n$ for every $n \in \mathbb{N}$, the $(I \cap J)$-adic and $IJ$-adic topologies coincide on $A$. On the other hand, in case $A$ is noetherian, the Artin-Rees lemma ([100, Th.8.5]) implies that for every $n \in \mathbb{N}$ there exists $m \in \mathbb{N}$ such that $I^m \cap J^n \subset \Sigma(I^n \cap J^n) \subset (I^n \cap J^n)$, from which the claim follows easily.

Thus, suppose $A$ is perfect and both $I$ and $J$ are finitely generated, so the same holds for $IJ$, and therefore lemma 9.3.70(iv) says that the $IJ$-adic topology on $A$ agrees with the linear topology defined by the cofiltered system of ideals $((IJ)^n A \mid n \in \mathbb{N})$. Likewise, the linear topology on $A$ defined by the cofiltered system of ideals $((I^n \cap J^n) A \mid n \in \mathbb{N})$ agrees with the one defined by the cofiltered system of ideals $((I^{(n)} \cap J^{(n)}) A \mid n \in \mathbb{N})$. So, it suffices to prove that

$$I^{(m)} A \cap J^{(m)} A \subset (IJ)^{(n)} A$$

for every $n \in \mathbb{N}$.

However, if $x \in I^{(m)} A \cap J^{(m)} A$, we may write $x = x^{1/p} \cdot x^{(p-1)/p} \in I^{(n)} J^{((p-1)n/p)} A \subset (IJ)^{(n)} A$ whence the contention.

(ii.b): For every $h, k \in \mathbb{N}$, let $A_{h,k} := A/(I^h + J^k)$, and endow $A_{h,k}$ with the discrete topology $\mathcal{T}_{h,k}$; moreover, set

$$(C_k, \mathcal{T}_{C,k}) := \lim_{\rightarrow} (A_{h,k}, \mathcal{T}_{h,k}) \quad \text{for every} \quad k \in \mathbb{N}$$
By definition, for every \( \varepsilon \) choose a strictly positive \( B \). For the case where \( A \) is noetherian, this is clear, since in that case \( J \) is already closed in \( A \) (see example 1.5.14(ii)). On the other hand, the projection \( A \to A/J^k \) extends uniquely to a continuous map \( \varphi_k : (A_n^\lambda, \mathcal{T}_n^\lambda) \to (C_k, \mathcal{T}_C^k) \), and the latter factors uniquely through a continuous ring homomorphism

\[
\varphi_k : (A_n^\lambda, \mathcal{T}_n^\lambda) \to (C_k, \mathcal{T}_C^k) \quad \text{for every } n \in \mathbb{N}.
\]

With this notation, a simple inspection shows that (16.3.13) and (16.3.19) identify (16.3.14) with the limit of the system of maps \( (\varphi_k \mid k \in \mathbb{N}) \). However, proposition 8.2.13 i,v) says that \( \varphi_k \) is surjective and its kernel is the topological closure \( (J^k A^\lambda)^c \) of \( J^k A^\lambda \) in \( (A_n^\lambda, \mathcal{T}_n^\lambda) \), for every \( k \in \mathbb{N} \). Thus, in order to show the lemma, it suffices to check that the linear topology on \( A^\lambda \) defined by the system of ideals \( (J^k A^\lambda)^c \mid k \in \mathbb{N} \) agrees with the \( JA^\lambda \)-adic topology. In case \( A \) is noetherian, this is clear, since in that case \( J^k A^\lambda \) is already closed in \( A^\lambda \) (100 Th.8.11)).

For the case where \( A \) is perfect, we remark:

**Claim** 16.3.20. Let \( (B, \mathcal{T}_B) \) be a perfect, complete and separated topological \( \mathbb{F}_p \)-algebra, \( I, J \subset B \) two ideals of finite type, such that \( \mathcal{T}_B \) agrees with the \( I \)-adic topology. For every \( \lambda \in \mathbb{N}[1/p] \) let \( J^{(\lambda)} B^c \) be the topological closure of \( J^{(\lambda)} B \) in \( B \) (notation of 9.3.69)). Then

\[
J^{(\lambda)} B^c \subset \bigcap_{n \in \mathbb{N}} (J + I^n)^{(\lambda)} B \subset J^{(\lambda)} B \quad \text{for every } \lambda' < \lambda.
\]

**Proof of the claim.** We show first that \( J^{(\lambda)} B^c \subset J^{(\lambda)} B \). Indeed, pick a finite system of generators \( (b_1, \ldots, b_k) \) (resp. \( (b_{k+1}, \ldots, b_s) \)) for \( J \) (resp. for \( I \)), and let \( x \in J^{(\lambda)} B^c \) be any element; we can write

\[
x = \sum_{n \in \mathbb{N}} x_n \quad \text{with } x_n \in J^{(\lambda)} B \cap I^{(n)} B \quad \text{for every } n \in \mathbb{N}.
\]

Choose a strictly positive \( \varepsilon \in \mathbb{N}[1/p] \) such that \( \lambda'' := (1 - \varepsilon) \cdot \lambda > \lambda' \), and notice that

\[
x_n = x_n^{1-\varepsilon} \cdot x_n^\varepsilon \in J^{(\lambda'')} \cdot I^{(n\varepsilon)} B \quad \text{for every } n \in \mathbb{N}.
\]

By definition, for every \( n \in \mathbb{N} \) there exist:

- a finite set \( S_n \subset \mathbb{N}[1/p]^{\leq k} \) with \( \mu_1 + \cdots + \mu_k = \lambda'' \) for every \( \mu := (\mu_1, \ldots, \mu_k) \in S_n \)
- a system \( (a_\mu \mid \mu \in S_n) \) of elements of \( B \) such that

\[
x_n^{1-\varepsilon} = \sum_{\mu \in S_n} a_\mu b_\mu^{\mu} \quad \text{where } b_\mu := b_1^{\mu_1} \cdots b_k^{\mu_k} \text{ for every } \mu \in S_n.
\]

Now, choose \( N \in \mathbb{N} \) such that \( \lambda'' - \lambda' \geq kp^{-N} \) and define \( p \) and \( \mu^* \) as in the proof of proposition 9.3.78 so that \( p \in S := \{ \nu \in \mathbb{N}[1/p]^{\leq k} \mid \lambda'' \geq \nu_1 + \cdots + \nu_k > \lambda' \} \) for every \( n \in \mathbb{N} \) and every \( \mu \in S_n \). It follows that

\[
x = \sum_{\nu \in S} b_\nu c_\nu \quad \text{where } c_\nu := \sum_{n \in \mathbb{N}} x_n^\varepsilon \cdot \sum_{\mu \in S_n} a_\mu b_\mu^{\nu}.
\]

Clearly \( b_\nu \in J^{(\lambda')} B \), and by lemma 9.3.70 iv) the series \( c_\nu \) converges in the \( I \)-adic topology of \( B \) for every \( \nu \in S \); also it is easily seen that \( S \) is a finite set, whence the contention.

Next, for any \( n \in \mathbb{N} \), the ideal \( (J + I^n)^{(\lambda)} B \) is generated by all monomials of the form

\[
b_\mu := b_1^{\mu_1} \cdots b_s^{\mu_s} \quad \text{such that } \lambda_1 + n^{-1} \cdot \lambda_2 = \lambda \quad \text{where } \lambda_1 := \sum_{i=1}^k \mu_i \quad \lambda_2 := \sum_{i=k+1}^s \mu_i
\]
Theorem 16.3.21. In the situation of \(9.3.70\) (iv) (details left to the reader).

\[
\cap_{n \in \mathbb{N}} (J + I^n)(\lambda) B \subset \cap_{n \in \mathbb{N}} (J^{(\lambda'')}(\lambda) B + I^{(n-\lambda'')}(\lambda) B) = J^{(\lambda'')}(\lambda) B^c
\]

where the last identity follows from lemma \(9.3.70\) (iv). But we know already that \(J^{(\lambda'')}(\lambda) B^c \subset J^{(\lambda'')}(\lambda) B\), whence the claim.

To conclude, it suffices now to apply claim \(16.3.20\) with \(B := A^\wedge\) and invoke lemma \(9.3.70\) (iv) (details left to the reader).

**Theorem 16.3.21.** In the situation of \(16.3.10\), let \(\mathcal{T}_p\) be the \(p\)-adic topology of \(A\), and suppose:

(a) \((A, \mathcal{T}_p)\) is perfectoid.

(b) \(p^N \in I \cap J\) for every sufficiently large \(N \in \mathbb{N}\).

(c) \(I\) and \(J\) are finitely generated ideals of \(A\).

Then we have:

(i) \((16.3.12)\) is a cartesian diagram of rings and a cocartesian diagram of \(A\)-modules.

(ii) \((16.3.14)\) is an isomorphism of topological rings.

**Proof.** (i): Let \(\pi \in A\) be as in lemma \(16.2.3\) (iv); quite generally, if \(K \subset A\) is any finitely generated ideal containing \(p^N\) (for some \(N \in \mathbb{N}\)), then it is easily seen that the \(K\)-adic topology on \(A\) agrees with the \((K + pA)\)-adic topology. In view of our assumptions (b) and (c) we may therefore replace \(I\) and \(J\) by \(I + pA\) and respectively \(J + pA\), and assume from start that \(\pi \in I \cap J\). Fix a finite system \((\bar{b}_1, \ldots, \bar{b}_n)\) (resp. \((\bar{b}_{n+1}, \ldots, \bar{b}_m)\)) of generators of the ideal \(I/pA\) (resp. of \(J/pA\)) of \(A/pA\), and let also \(\alpha := (\alpha_n | n \in \mathbb{N})\) be a distinguished element of \(A := A(A, \mathcal{T}_p)\) that generates \(\text{Ker} A\). Pick elements \(\beta_1, \ldots, \beta_m \in \mathfrak{E} := \text{E}(A)\) such that \(\overline{\pi}_{A/pA}(\beta_i) = \bar{b}_i\) for \(i = 1, \ldots, m\), denote by \(\mathcal{E}_E\) (resp. \(\mathcal{E}_E\)) the ideal of \(E\) generated by the system \((\alpha_0, \beta_1, \ldots, \beta_n)\) (resp. \((\alpha_0, \beta_{n+1}, \ldots, \beta_m)\)), and let \((E^\wedge, \mathcal{T}_E)\) (resp. \((E^\wedge, \mathcal{T}_E)\), resp. \((E^\wedge_+, \mathcal{T}_E^+)\), resp. \((E^\wedge_+, \mathcal{T}_E^+)\), resp. \((E^\wedge_+, \mathcal{T}_E^+)\)) be the \(\mathcal{E}_E\)-adic (resp. \(\mathcal{E}_E\)-adic, resp. \((\mathcal{E} \cap \mathcal{F})\)-adic, resp. \((\mathcal{E} \cap \mathcal{F})\)-adic) completion of \(E\). By lemma \(16.3.15\) (ii), we get a cartesian diagram of topological rings

\[
\begin{array}{ccc}
(E^\wedge_{\mathcal{E} \cap \mathcal{F}}, \mathcal{T}^\wedge_{\mathcal{E} \cap \mathcal{F}}) & \longrightarrow & (E^\wedge, \mathcal{T}^\wedge) \\
\downarrow & & \downarrow \\
(E^\wedge_+, \mathcal{T}_E^+) & \longrightarrow & (E^\wedge_+, \mathcal{T}_E^+)
\end{array}
\]

which is also cocartesian as a diagram of topological abelian groups.

**Claim 16.3.22.** \(W(\mathcal{E})\) is still a cartesian diagram of topological rings, and a cocartesian diagram of \(A\)-modules.

**Proof of the claim.** The cartesian property follows from remark \(9.3.28\) (ii). To prove the cocartesian property, it suffices to show that the map of abelian groups deduced from \(W(\mathcal{E})\)

\[
\tau : W(E^\wedge) \oplus W(E^\wedge) \rightarrow W(E^\wedge_+)
\]

is surjective. Endow both target and source of \(\tau\) with their \(p\)-adic filtrations, so that \(\tau\) becomes a map of filtered abelian groups, and for every \(k \in \mathbb{N}\), denote by \(\text{gr}^k\tau\) the map induced by \(\tau\) on the respective \(k\)-graded subquotients. Since both target and source of \(\tau\) are \(p\)-adically complete and separated (proposition \(9.3.45\) (iii)), it then suffices to check that \(\text{gr}^k\tau\) is surjective for every \(k \in \mathbb{N}\) (\([23]\) Ch.III, §2, n.8, Cor.2)). Since multiplication by \(p\) is an injective endomorphism for both target and source of \(\tau\), we are then further reduced to the case where \(k = 0\), in which case
\( \varphi^0 \) is naturally identified with the map \( E_{y'} \oplus E^\wedge_{y'} \to E^\wedge_{y' + y} \) deduced from \( \mathcal{E} \). But the latter map is indeed surjective, since \( \mathcal{E} \) is cotorsion. \( \diamondsuit \)

Now, remark [16.3.7(iii)] says that the topology of \( E(A, \mathcal{T}_i) \) agrees with the \( \mathcal{I} \)-adic topology, so the completion \( E^\wedge_i \) of \( E(A, \mathcal{T}_i) \) is isomorphic to \( (E^\wedge_y, \mathcal{T}_y^\wedge) \). Likewise, the completion \( E^\wedge_j \) of \( E(A, \mathcal{T}_j) \) is isomorphic to \( (E^\wedge_y, \mathcal{T}_y^\wedge) \), and the completion \( E^\wedge_{i+j} \) of \( E(A, \mathcal{T}_{i+j}) \) is isomorphic to \( (E^\wedge_y, \mathcal{T}_y^\wedge) \).

Next, set \( \mathcal{K} := \mathcal{I} \amalg \mathcal{J} + \alpha_0 \mathcal{E} \subset \mathcal{E} \); since \( \mathcal{I} \) and \( \mathcal{J} \) are finitely generated and they both contain \( \alpha_0 \), it is easily seen that the \( (\mathcal{I} \cap \mathcal{J}) \)-adic topology on \( \mathcal{E} \) agrees with the \( \mathcal{K} \)-adic topology. Likewise, topology \( \mathcal{T}_{i+j} \) on \( A \) agrees with the \( (IJ) \)-adic topology. Moreover, \( \mathcal{K} \) is a finitely generated ideal, by construction \( p \in IJ, \) and \( \mathcal{I} / p \mathcal{A}(\mathcal{K}) = (IJ)/p^2 \mathcal{A}(\mathcal{K}) \), hence remark [16.3.7(iii)] also tells us that \( (E^\wedge_{i+j}, \mathcal{T}_y^\wedge) \) is isomorphic to the completion \( E^\wedge_{i+j} \) of \( E(A, \mathcal{T}_{i+j}) \).

Notice now that, since the image of \( A \) is dense in \( A^\wedge_{i+j} \), the map \( \varphi_d \) in [16.3.12] is the unique continuous homomorphism of topological \( A \)-algebras from \( A^\wedge_{i+j} \) to \( A^\wedge_{A, \mathcal{T}_{i+j}} \), and the other maps in [16.3.12] enjoy corresponding uniqueness properties. Combining with remark [16.3.7(iv)], we conclude that \( W(\mathcal{E}) \otimes_A A \) is naturally identified with [16.3.12], and the image of \( \alpha \) is still distinguished in each of the Witt rings appearing in \( W(\mathcal{E}) \). Due to of claim [16.3.22] we already see that [16.3.12] is a cocartesian diagram of \( A \)-modules; moreover, it will follow that it is a cartesian diagram of rings, once we know that

\[(16.3.23) \quad \text{Tor}^A_1(W(E^\wedge_{y', y} + y), A) = 0. \]

However \( A = A/\alpha^2 A \), and \( \alpha \) is a regular element of \( W(E^\wedge_{y', y} + y) \) (remark [16.1.7(ii)], so (16.3.23) holds by a standard calculation.

(ii): We know already that [16.3.14] is open and surjective (lemma [16.3.15(ii)]), so it suffices to show that this map is a ring isomorphism. However, in light of remark [16.3.7(iv)] we have a diagram of continuous maps

\[
\begin{array}{ccc}
(A^\wedge_i)_{y'} & \longrightarrow & A(E^\wedge_{y'}, \alpha_0 E^\wedge_{y'}) \\
\downarrow & & \downarrow \\
(A^\wedge_{i+j})_{y'} & \longrightarrow & A(E^\wedge_{y', y} + y, \alpha_0 E^\wedge_{y', y})
\end{array}
\]

whose left vertical arrow equals (16.3.14), and whose remaining arrows are ring isomorphisms. Thus, it suffices to check that \( \mathcal{D} \) commutes, i.e. that the two continuous ring homomorphisms \( f, g : (A^\wedge_i)_{y'} \to A(E^\wedge_{y', y} + y, \alpha_0 E^\wedge_{y', y}) \) deduced from \( \mathcal{D} \) coincide. However, let \( i : A \to (A^\wedge_i)_{y'} \) denote the completion map; a simple inspection shows that \( f \circ i = g \circ i \), and since the topology of \( A(E^\wedge_{y', y} + y, \alpha_0 E^\wedge_{y', y}) \) is separated and \( i \) has dense image, the assertion follows. \( \square \)

16.3.24. Let \( \overline{A}, \overline{B}, \overline{A} \) be three perfectoid rings, and set \( E := E(A), \overline{E} := E(\overline{B}) \). Suppose that \( \overline{A} \) is a discrete topological \( \mathbb{F}_p \)-algebra, so that \( E(\overline{A}) = \overline{A} \) (see also corollary [16.3.61(iii)]), let \( \varphi_A : \overline{D} \to \overline{A} \) and \( \pi_A : A \to \overline{A} \) be two continuous ring homomorphisms, and suppose as well that \( \pi_A \) is surjective. Define the topological rings \( D_A \) and \( D_E \) as the fibre products in the resulting cartesian diagrams of topological rings

\[
\begin{array}{ccc}
D_A & \xrightarrow{\varphi_A} & A \\
\downarrow & & \downarrow \\
\overline{D} & \xrightarrow{\varphi_A} & \overline{A}
\end{array}
\quad
\begin{array}{ccc}
D_E & \xrightarrow{\varphi_E} & E \\
\downarrow & & \downarrow \\
\overline{E} & \xrightarrow{\varphi_E} & \overline{A}
\end{array}
\]

where \( \pi_E := E(\pi_A) \) and \( \varphi_E := E(\varphi_A) \).
Proposition 16.3.25. In the situation of (16.3.24), the rings $D_A$ and $D_E$ are perfectoid, and there exists a natural isomorphism of topological rings

$$\omega : E(D_A) \sim E(D_E) \quad \text{such that} \quad \varphi_E \circ \omega = E(\varphi_A).$$

Proof. To begin with, we notice that $D_A$ (resp. $D_E$) is complete and separated, since $\overline{A}$ is separated and both $\overline{D}$ and $A$ (resp. $\overline{E}$ and $E$) are complete and separated. Let $(\alpha_n \mid n \in \mathbb{N})$ (resp. $(\alpha'_n \mid n \in \mathbb{N})$) be a distinguished element in $\ker u_A$ (resp. in $\ker u_{\overline{D}}$), and pick a finitely generated ideal of adic definition $J_E \subset \ker \pi_E$ (resp. $J_{\overline{E}} \subset \ker \pi_{\overline{D}}$) for $E$ (resp. for $\overline{E}$).

Claim 16.3.26. We may assume that $\alpha_0^{1/p^n} \in J_E$ and $\alpha_0^{1/p^n} \overline{E} \subset J_{\overline{E}}$.

Proof of the claim. For the first stated inclusion, notice that $\alpha_0^{1/p^n} \in \ker \pi_E$ for every $n \in \mathbb{N}$, so $J_E + \alpha_0^{1/p^n} \overline{E}$ is still an ideal of adic definition of $E$ contained in $\ker \pi_{\overline{E}}$, for every such $n$. The same argument applies to $J_{\overline{E}}$.

By virtue of claim 16.3.26 we may find a system of generators $\beta_* := (\beta_1, \ldots, \beta_k)$ for $J_E$ with $\beta_i = \alpha_0^{1/p^n}$, and we set $b_i := \pi_A(\beta_i)$ for $i = 1, \ldots, k$. It follows that $b_* := (b_1, \ldots, b_k)$ is a system of generators for an ideal $J_A$ of adic definition of $A$. Likewise, pick a system of generators $\beta'_* := (\beta'_1, \ldots, \beta'_h)$ for $J_{\overline{E}}$ with $\beta'_i = \alpha_0^{1/p^n}$, and set $b'_i := \pi_{\overline{D}}(\beta'_i)$ for $i = 1, \ldots, h$. Then $b'_* := (b'_1, \ldots, b'_h)$ is a system of generators for an ideal $J_{\overline{D}}$ of adic definition of $\overline{D}$. Notice that $J_A \times J_{\overline{D}} \subset D_A$ (resp. $J_E \times J_{\overline{D}} \subset D_E$), and the topology of $D_A$ (resp. of $D_E$) is the linear topology defined by the system of ideals $(J^n_A \times J^n_{\overline{D}} \mid n \in \mathbb{N})$ (resp. $(J^n_E \times J^n_{\overline{D}} \mid n \in \mathbb{N})$). Denote by $K_E \subset D_E$ the ideal generated by $(\beta_* \times \{0\}, \{0\} \times \beta'_*)$; it is easily seen that

$$J_{E}^{n+1} \times J_{\overline{E}}^{n+1} \subset K_E^n \subset J_{E}^n \times J_{\overline{E}}^n \quad \text{for every} \ n \in \mathbb{N}$$

so the topology of $D_E$ agrees with its $K_E$-adic topology, and therefore $D_E$ is a perfectoid $\mathbb{F}_p$-algebra. Likewise, let $K_{\overline{A}} \subset D_A$ be the ideal generated by $(b_* \times \{0\}, \{0\} \times b'_*)$; by the same token, we have

$$J_{A}^{n+1} \times J_{\overline{D}}^{n+1} \subset K_{\overline{A}}^n \subset J_{A}^n \times J_{\overline{D}}^n \quad \text{for every} \ n \in \mathbb{N}$$

so the topology of $D_A$ agrees with the $K_{\overline{A}}$-adic topology. Moreover, by construction we have $pA \subset J_{A}^p$ and $p\overline{D} \subset J_{\overline{D}}^p$ (lemma 16.2.7(iii)); since $p^2 - 1 \geq 2$, we deduce that $pD_A \subset K_{\overline{A}}^2$, and we see already that $D_A$ is a $\mathbb{P}$-ring. Next, by remark 9.3.28(ii), we deduce a short exact sequence of $W(D_A)$-modules

$$0 \to W(D_A) \to W(A) \oplus W(\overline{D}) \to W(\overline{A}) \to 0.$$

On the other hand, by lemma 16.2.7(ii) we may find a distinguished element $\alpha'' := (\alpha''_n \mid n \in \mathbb{N})$ in $\ker u_{D_A}$ and to ease notation we set $D'_A := W(D_A)/\alpha'' W(D_A)$; since the image of $\alpha''$ is still distinguished in $W(\overline{A})$, remark 16.1.7(ii) implies that $\text{Tor}_1^{W(D_A)}(D'_A, W(\overline{A})) = 0$, so the sequence

$$0 \to D'_A \to A \oplus \overline{D} \to \overline{A} \to 0$$

is still exact, and consequently $u_{D_A}$ induces a ring isomorphism $D'_A \to D_A$, i.e. $D_A$ is perfectoid. Lastly, notice that $u_A \otimes_{\mathbb{F}_p} \overline{E}$ and $u_{\overline{D}}$ induce isomorphisms of topological $\mathbb{F}_p$-algebras

$$D_A/pD_A \sim \overline{D}/p\overline{D} \times A/pA \sim \overline{D}/\alpha''_0 \overline{D} \times \overline{E}/\alpha''_0 \overline{E} \sim D_{\overline{E}}/\alpha''_0 D_{\overline{E}}.$$

Combining with theorem 9.4.10 we deduce an isomorphism

$$E(D_A) \sim E(D_A/pD_A) \sim E(D_{\overline{E}}/\alpha''_0 D_{\overline{E}}) \sim D_{\overline{E}}$$

which fulfills the stated condition, by a simple inspection. \qed

Definition 16.3.27. Let $A$ be a perfectoid ring and $\mathcal{J} \subset \mathcal{H} \subset \mathcal{E} := E(A)$ any two ideals. Let also $\alpha := (\alpha_n \mid n \in \mathbb{N}) \in \ker u_A$ be any distinguished element and $\beta \in \mathcal{E}$ any element.
(i) We say that the inclusion of $\mathcal{J}$ in $\mathcal{H}$ is $\beta$-taut if we have
\[ \beta \cdot \Phi_{E}^{-1}(\mathcal{H}^p) \subset \mathcal{J}. \]

(ii) We say that $\mathcal{J}$ is $\beta$-taut if the identity map of $\mathcal{J}$ is a $\beta$-taut inclusion.

(iii) We say that $\mathcal{J}$ is strictly $\beta$-taut if it is $\beta\lambda$-taut for some $\lambda \in \mathbb{Z}[1/p]$ with $0 \leq \lambda < 1$.

(iv) $\mathcal{J}$ is taut (resp. strictly taut) if it is $\alpha_0$-taut (resp. strictly $\alpha_0$-taut), and the inclusion $\mathcal{J} \subset \mathcal{H}$ is taut (resp. strictly taut), if it is $\alpha_0$-taut (resp. strictly $\alpha_0$-taut).

(v) We denote by $\{\mathcal{J}\} \subset A$ the topological closure of the ideal generated by the system $(\pi_A(x) \mid x \in \mathcal{J})$ (notation of (9.3.35)).

**Remark 16.3.28.** With the notation of definition [16.3.27] the following holds.

(i) It follows easily from remark [16.1.7]i) that the definition of taut and strictly taut ideals does not depend on the choice of $\lambda$.

(ii) By inspecting the definition of angular powers (see (9.3.69)), it is easily seen that $\mathcal{J}$ is 1-taut if and only if $\mathcal{J} = \mathcal{J}^{(1)}E$.

(iii) It follows from (ii) and lemma [9.3.70][ii.c] that for every ideal $\mathcal{J}$ of $E$ and every $\lambda \in \mathbb{N}[1/p]$, the ideal $\mathcal{J}^{(\lambda)}E$ is strictly taut. Moreover, say that $\alpha_0 \in \mathcal{J}^{(\epsilon)}E$ for some $\epsilon \in \mathbb{N}[1/p]$; then the inclusion $\mathcal{J}^{(\lambda+\epsilon)}E \subset \mathcal{J}^{(\lambda)}E$ is taut for every $\lambda \in \mathbb{N}[1/p]$, by lemma [9.3.70][ii.b].

(iv) If $\mathcal{J}_1, \mathcal{J}_2 \subset E$ are two $\beta$-taut (resp. strictly $\beta$-taut, resp. taut, resp. strictly taut) ideals, then the same holds for $\mathcal{J}_1 \cap \mathcal{J}_2$. Indeed, suppose that both ideals are $\beta$-taut; then we have:
\[
\beta \cdot \Phi_{E}^{-1}(\mathcal{J}_1 \cap \mathcal{J}_2^p) \subset \beta \cdot \Phi_{E}^{-1}(\mathcal{J}_1^p \cap \mathcal{J}_2^p) = \beta \cdot (\Phi_{E}^{-1}(\mathcal{J}_1^p) \cap \Phi_{E}^{-1}(\mathcal{J}_2^p)) \subset (\beta \cdot \Phi_{E}^{-1}(\mathcal{J}_1^p)) \cap (\beta \cdot \Phi_{E}^{-1}(\mathcal{J}_2^p)) \subset \mathcal{J}_1 \cap \mathcal{J}_2
\]
whence the claim. In the same vein, if $\mathcal{J}_1 \subset \mathcal{J}_2$ is a $\beta$-taut inclusion, and $\mathcal{H}$ is any $\beta$-taut ideal of $E$, then the inclusion $\mathcal{H} \cap \mathcal{J}_1 \subset \mathcal{H} \cap \mathcal{J}_2$ is $\beta$-taut as well (details left to the reader); the same holds if $\beta$-taut is replaced by strictly $\beta$-taut, taut or strictly taut.

(v) If $\mathcal{J}$ is $\beta$-taut, then the same holds for the topological closure $\mathcal{J}^c$ of $\mathcal{J}$ in $E$. Likewise, if $\mathcal{J} \subset \mathcal{H}$ is a $\beta$-taut inclusion, then the same holds for the inclusion $\mathcal{J}^c \subset \mathcal{H}^c$ of the respective topological closures; moreover, both $\mathcal{J}$ and $\mathcal{H}$ are $\beta$-taut. Then clearly the same assertions hold with $\beta$-taut replaced by strictly $\beta$-taut, taut, or strictly taut (details left to the reader). In the same vein, notice that
\[
\{\mathcal{J}^c\} = \{\mathcal{J}\} \quad \text{for every ideal } \mathcal{J} \subset E.
\]

(vi) Let $\mathcal{J}_1, \mathcal{J}_2, \mathcal{J}_3 \subset E$ be three ideals, $n, m \in \mathbb{N}$ any two integers, and suppose that
\[
\beta_1 \cdot \Phi_{E}^{-n}(\mathcal{J}_1^p) \subset \mathcal{J}_2 \quad \text{and} \quad \beta_2 \cdot \Phi_{E}^{-m}(\mathcal{J}_2^p) \subset \mathcal{J}_3
\]
for some $\beta_1, \beta_2 \in E$.

Then it is easily seen that $\beta_1 \beta_2 \cdot \Phi_{E}^{-n-m}(\mathcal{J}_1^{n+m}) \subset \mathcal{J}_3$. Especially, if $\mathcal{J}$ is $\beta$-taut, we have (16.3.29)
\[
\beta^n \cdot \Phi_{E}^{-n}(\mathcal{J}^p) \subset \mathcal{J} \quad \text{for every } n \in \mathbb{N}.
\]

(vii) For $i = 1, 2$, let $\beta_i \in E$ be any element, and $\mathcal{J}_i$ a $\beta_i$-taut ideal; then it is easily seen that $\mathcal{J}_1 \mathcal{J}_2$ is $\beta_1 \beta_2$-taut. More generally, if $\mathcal{J} \subset \mathcal{H}$ is a $\beta_1$-taut inclusion of ideals of $E$, and $\mathcal{J}' \subset E$ is any other $\beta_2$-taut ideal, then the inclusion $\mathcal{J} \mathcal{J}' \subset \mathcal{H} \mathcal{J}'$ is $\beta_1 \beta_2$-taut.

(viii) Suppose that $\mathcal{J}$ is an open ideal of $E$. Then the system $(\pi_A(x) \mid x \in \mathcal{J})$ generates an open ideal $J$ of $A$, and therefore $\{\mathcal{J}\} = J$ is open as well in $A$. Indeed, let $I \subset A$ be any ideal of definition, pick a finite system $(\bar{a}_1, \ldots, \bar{a}_k)$ of generators of $I/pA$, let $\alpha_1, \ldots, \alpha_k$ be elements of $E$ such that $\pi_{A/pA}(\alpha_i) = \bar{a}_i$ for $i = 1, \ldots, k$, and denote by $\mathcal{J} \subset E$ the ideal generated by the system $(\alpha_1, \ldots, \alpha_k)$. Arguing as in the proof of lemma [16.2.7][i), we see that the system
Let $\alpha := (\alpha_n \mid n \in \mathbb{N}) \in \text{Ker } u_A$ be any distinguished element.

(i): Let $x, y \in \mathcal{J}_0$ be any two elements, and set $\delta := \tau_A(x + y) - \tau_A(x) - \tau_A(y)$. In light of lemma \[16.1.1\]iv, we have to check that $u_A(\delta)$ lies in $\{\mathcal{J}_1\}$. However, proposition \[9.3.63\] expresses $\delta$ as a series of the form $\sum_{n \in \mathbb{N}} p^n b_n$, where each $b_n$ is in turn a finite sum of terms of the form $c_{n,\sigma} \tau_A(\beta_{n,\sigma})$ (for $\sigma$ ranging over a certain finite set $\Sigma_n$, and with $\beta_{n,\sigma} \in \Phi_{E}(J_2^{p^n})$ and $c_{n,\sigma} \in \mathbb{Z}_p$ for every $n \in \mathbb{N}$ and every $\sigma \in \Sigma_n$. Thus, we come down to checking that $p^n \cdot \pi_A(\beta_{n,\sigma}) \in \{\mathcal{J}_1\}$ for every $n \in \mathbb{N}$ and $\sigma \in \Sigma_n$. In light of lemma \[16.2.7\]ii, this holds if and only if $\pi_A(\alpha_{\beta_{n,\sigma}}) \in \{\mathcal{J}_1\}$, which in turns will follow, once we know that $\alpha_{\beta_{n,\sigma}} \in \mathcal{J}_1$. But the latter is clear from remark \[16.3.28\]vi (with $\beta := \alpha_0$; details left to the reader).

Lastly, for any $x \in \mathcal{J}_2$ and $\beta \in E$ we have $\tau_A(\beta x) = \tau_A(\beta) \cdot \tau_A(x)$, and the isomorphism $\omega$ of remark \[16.3.7\]ii maps the class of $\beta$ in $E/A$ to the class of $\pi_A(\beta)$ in $A/pA$; this shows that $\tau(\beta \cdot x) = \tilde{\alpha} \cdot \tau(x)$ for every $\tilde{\alpha} \in A/(pA)$ and every $x \in \mathcal{J}_2/\mathcal{J}_1$, whence (i).

Next, choose a strictly positive $\varepsilon \in \mathbb{N}[1/p]$ such that $\alpha_0 \in \mathcal{J}(\varepsilon)E$, and for every $r \in \mathbb{R}_+$ define the ideal $\mathcal{J}_{[r]}E$ as in remark \[9.3.7\]i; we point out the following special case of (ii):

Claim \[16.3.32\]. Let $\mathcal{J}$ be any ideal of definition of $E$, and $r, r' \in \mathbb{R}_+$ two real numbers such that $\varepsilon \geq r' - r \geq 0$. Then (ii) holds for the taut inclusion $\mathcal{J}_{[r]}E \subset \mathcal{J}_{[r']}E$.

Proof of the claim. Let us set $W[s] := W(\mathcal{J}^{[s]}E)$ for every $s \in \mathbb{N}[1/p]$ (notation of remark \[9.3.28\]iv); from \[9.3.74\] we see that $\tau_A$ induces a natural isomorphism $\mathcal{J}_{[r]}E/\mathcal{J}_{[r']}E \xrightarrow{\sim} W[r]/(pW[r] + W[r'])$ and we are reduced to showing that the restriction of $u_A$ to $W[r]$ induces an isomorphism

\begin{equation}
W[r]/(pW[r] + W[r']) \xrightarrow{\sim} \{\mathcal{J}_{[r]}E\}/\{\mathcal{J}_{[r']}E\}.
\end{equation}

However, remark \[16.3.28\]viii already implies that \[16.3.33\] is surjective, and its kernel is the image of $W[r] \cap \alpha W(E)$. In light of proposition \[16.1.1\]ii we then come down to showing:

$\alpha W[r] \subset pW[r] + W[r'].$

But due to our choice of $\varepsilon$ we get $\alpha_0 \mathcal{J}_{[r]}E \subset \mathcal{J}_{[r']}E$, so the latter inclusion follows again from \[9.3.74\].

Claim \[16.3.34\]. Let $B$ be any ring, $f : M \to M'$ and $g : M' \to M''$ two continuous maps of topological $B$-modules, and suppose that

(a) the topologies of $M$ and $M''$ are discrete and that of $M'$ is separated
(b) $f$ has dense image and $g \circ f$ is injective.

Then $f$ is an isomorphism of topological $B$-modules.
Proof of the claim. By assumption, the topological closure of \( f(M) \) in \( M' \) equals \( M' \); by claim 8.3.25 it follows that the topological closure of \( g \circ f(M) \) in \( M'' \) equals the topological closure of \( g(M') \). But since the topology of \( M'' \) is discrete, this just means that \( g \circ f(M) = g(M') \). We may therefore replace \( M'' \) by \( g(M') \), and assume from start that \( g \) is surjective and \( g \circ f \) is an isomorphism. Then we may even assume that \( M'' = M \) and \( g \circ f = 1_M \). Let us endow \( \text{Im} f \) and \( \text{Ker} g \) with the topologies induced from the inclusion into \( M' \); then the addition law of \( M' \) restricts to a continuous and bijective \( B \)-linear map

\[
h : \text{Im} f \oplus \text{Ker} g \to M'
\]

(where the direct sum is endowed with the product topology). However, the inverse of \( h \) is the map given by the rule : \( m' \mapsto (f \circ g(m'), m' - f \circ g(m')) \) for every \( m' \in M' \). Clearly, this map is also continuous, so \( h \) is an isomorphism of topological \( B \)-modules. Now, since \( M' \) is separated, the same must hold for \( \text{Ker} g \); especially, \( L := h(\text{Im} f \oplus 0) \) is a closed subset of \( M' \). On the other hand, \( \text{Im} f = L \); since \( f \) has dense image, we must then have \( L = M' \), i.e. \( \text{Ker} g = 0 \), whence the claim.

We may now complete the proof of (ii): fix an ideal of definition \( J \) of \( E \) with \( \alpha_0 \in J \), and for every ideal \( \mathcal{H} \subset E \) set

\[
\text{Fil}^n \mathcal{H} := \mathcal{H} \cap J^{[n]} E \quad \text{Fil}^n \{ \mathcal{H} \} := \{ \text{Fil}^n \mathcal{H} \} \quad \text{for every } n \in \mathbb{N}.
\]

If \( \mathcal{H}' \subset \mathcal{H} \) is any inclusion of ideals of \( E \), the image of \( \text{Fil}^* \mathcal{H} \) in \( \mathcal{H} / \mathcal{H}' \) defines a filtration \( \text{Fil}^* (\mathcal{H} / \mathcal{H}') \) of \( \mathcal{H} / \mathcal{H}' \), and likewise we get a filtration \( \text{Fil}^* (\{ \mathcal{H} \} / \{ \mathcal{H}' \}) \) on \( \{ \mathcal{H} \} / \{ \mathcal{H}' \} \). Notice that the inclusion \( \text{Fil}^{n+1} \mathcal{H} \subset \text{Fil}^n \mathcal{H} \) is taut for every \( n \in \mathbb{N} \) and every taut ideal \( \mathcal{H} \), and denote by \( \text{gr}^* \mathcal{H} \) (resp. \( \text{gr}^* \{ \mathcal{H} \} \)) the graded \( A/pA \)-module associated to the filtration \( \text{Fil}^* \mathcal{H} \) (resp. to \( \text{Fil}^* \{ \mathcal{H} \} \)). Likewise we define \( \text{gr}^* (\mathcal{H} / \mathcal{H}') \) and \( \text{gr}^* (\{ \mathcal{H} \} / \{ \mathcal{H}' \}) \) for an inclusion of ideals \( \mathcal{H}' \subset \mathcal{H} \). We remark :

Claim 16.3.35. If \( \mathcal{H} \) is taut, the map \( \tau \) of (i) induces an isomorphism

\[
\text{gr}^n \mathcal{H} \xrightarrow{\sim} \text{gr}^n \{ \mathcal{H} \} \quad \text{for every } n \in \mathbb{N}.
\]

Proof of the claim. Let us endow any ideal of \( E \) (resp. of \( A \)) with the topology induced from the inclusion into \( E \) (resp. into \( A \)), and for any inclusion \( J \subset J' \) (resp. \( I \subset I' \)) of ideals of \( E \) (resp. of \( A \)), let us endow \( J'/J \) (resp. \( I'/I \)) with the corresponding quotient topology. Notice that the inclusions \( \text{Fil}^{n+1} \mathcal{H} \subset \text{Fil}^n \mathcal{H} \) and \( \text{Fil}^{n+1} \{ \mathcal{H} \} \subset \text{Fil}^n \{ \mathcal{H} \} \) are both taut (remark 16.3.28 [iv]); from (i) we deduce a commutative diagram of \( A/pA \)-modules :

\[
\begin{array}{ccc}
\text{gr}^n \mathcal{H} & \longrightarrow & \text{gr}^n \{ \mathcal{H} \\
\downarrow & & \downarrow \\
\text{gr}^n E & \longrightarrow & \text{gr}^n A
\end{array}
\]

whose left vertical arrow is injective, and whose bottom horizontal arrow is already known to be an isomorphism, by claim 16.3.32. Moreover, all these maps are continuous, for the topologies that we have just defined on these modules, and furthermore, the top horizontal arrow has dense image. Also, since \( J \) is open, the same holds for \( J^{[r]} E \), and therefore the two modules on the bottom row have both the discrete topology. Likewise, \( \mathcal{H} \cap J^{[r]} E \) is open in \( \mathcal{H} \cap J^{[r]} E \), so also the source of the map on the top row is a discrete \( A/pA \)-module. Lastly, since \( \{ \mathcal{H} \cap J^{[r]} E \} \) is a closed ideal, the target of the same map is a separated \( A/pA \)-module. Thus, all the conditions of claim 16.3.34 are fulfilled, and it follows that the top horizontal arrow is an isomorphism.

\( \diamond \)
There follows, for every $n \in \mathbb{N}$ a commutative diagram with exact rows

$$
\begin{array}{ccc}
0 & \rightarrow & \text{gr}^n J_1 \\
\downarrow & & \downarrow \\
0 & \rightarrow & \text{gr}^n (J_2 / J_1) \\
\end{array}
$$

and claim 16.3.35 shows that the leftmost and central vertical arrows are both isomorphisms, so the same holds for the rightmost vertical arrow. Now, notice that the filtration Fil*(J_2 / J_1) defines a separated and complete topology on J_2 / J_1, since J_2 and J_1 are both closed ideals in E. The same holds for the topology on \{J_2\}/\{J_1\} determined by the filtration Fil*(\{J_2\}/\{J_1\}), since \{J_2\} and \{J_1\} are closed ideals in A. Then (ii) follows directly from [28, Ch.III, §2, n.8, Cor.3].

**Theorem 16.3.36.** Let A be any perfectoid ring, \( \mathcal{K} \) a taut ideal of \( E := E(A) \), and \( W(\mathcal{K}) \) the topological closure of \( W(\mathcal{K}) \) in \( A(A) \) (notation of remark 9.3.28(iv)). We have:

(i) \( \{ \mathcal{K} \} = u_A(W(\mathcal{K})^c) \).

(ii) \( \mathcal{K} \) is an open ideal if and only if the same holds for \( \{ \mathcal{K} \} \).

(iii) If \( \mathcal{K}' \subset \mathcal{K} \) is another taut ideal, and both \( \mathcal{K} \) and \( \mathcal{K}' \) are closed, then \( \mathcal{K} = \mathcal{K}' \) if and only if \( \{ \mathcal{K} \} = \{ \mathcal{K}' \} \).

(iv) Suppose that \( \mathcal{K} \) is 1-taut and closed, and let \( \alpha \) be any distinguished element of \( \text{Ker} u_A \). Then the pair \((\alpha, \mathcal{K})\) is transversal (see (16.1.10)).

**Proof.** Pick any distinguished element \( \alpha := (\alpha_n \mid n \in \mathbb{N}) \) of \( \text{Ker} u_A \).

(i): First we prove that \( u_A(W(\mathcal{K})^c) \subset \{ \mathcal{K} \} \). Indeed, let \( \mathfrak{a} := (a_n \mid n \in \mathbb{N}) \in W(\mathcal{K}) \) be any element; taking into account (9.3.47), we are easily reduced to showing that

\[
u_A\left(\mathfrak{a}^n \cdot \tau_A(\alpha_n)\right) \in \{ \mathcal{K} \}
\]

for every \( n \in \mathbb{N} \).

In light of lemmata 16.2.7(iii) and 16.1.1(iv), it then suffices to check that \( \pi_A(\alpha_0^na_0^{n-1}) \in \{ \mathcal{K} \} \), and the latter is clear from (16.3.29) (applied with \( \beta := \alpha_0 \)). Next, fix an ideal of definition \( \mathfrak{F} \) of \( E \) containing \( \alpha_0 \), and define the filtrations Fil* \( \mathcal{K} \) on \( \mathcal{K} \) and Fil* \( \{ \mathcal{K} \} \) on \( \{ \mathcal{K} \} \) as in the proof of theorem 16.3.31(ii); by (9.3.29) and remark 16.3.28(v) we may assume that \( \mathcal{K} \) is a closed ideal of \( E \), in which case theorem 16.3.31(ii) shows that the map \( \pi_A \) induces an isomorphism \( \text{gr}^k \mathcal{K} \rightarrow \text{gr}^k \{ \mathcal{K} \} \) on the respective associated graded \( A/pA \)-modules. Now, let \( \mathfrak{x} \in \{ \mathcal{K} \} \) be any element; it follows easily that we may write

\[
\mathfrak{x} = u_A\left(\sum_{n \in \mathbb{N}} \tau_A(\beta_n)\right)
\]

where \( \beta_n \in \text{Fil}^n \mathcal{K} \) for every \( n \in \mathbb{N} \) and the series converges in the topology of \( A(A) \). But clearly \( \tau_A(\beta_n) \in W(\mathcal{K}) \) for every \( n \in \mathbb{N} \), whence the sought converse inclusion.

(ii): In light or remark 16.3.28(viii) we may assume that \( \{ \mathcal{K} \} \) is open, and we need to show that the same holds for \( \mathcal{K} \); then, by lemma 8.3.21(ii,b), we may also assume that \( \mathcal{K} \) is a closed ideal. The inclusion of \( \mathfrak{F} \) into \( E \) is a map of filtered \( E \)-modules Fil* \( \mathcal{K} \rightarrow \text{Fil}^*E \), and likewise we get a map of filtered \( A \)-modules Fil* \{ \mathcal{K} \} → Fil* \( A \). The assumption on \{ \mathcal{K} \} implies that there exists \( n \in \mathbb{N} \) such that the map of associated graded modules \( \text{gr}^k \{ \mathcal{K} \} \rightarrow \text{gr}^k A \) is an isomorphism for every \( k \geq n \). Then theorem 16.3.31(ii) implies that the same holds for the corresponding map \( \text{gr}^k \mathcal{K} \rightarrow \text{gr}^k E \). However, both \( \mathcal{K} \) and \( E \) are complete and separated for their filtrations, so Fil* \( \mathcal{K} = \text{Fil}^*E = \mathfrak{F}^n \) (28, Ch.III, §2, n.8, Cor.3), i.e. \( \mathcal{K} \) is open.

(iii) is similar: we may assume that \( \{ \mathcal{K} \} = \{ \mathcal{K}' \} \), and we consider the induced map of filtered \( E \)-modules Fil* \( \mathcal{K}' \rightarrow \text{Fil}^* \mathcal{K} \). Arguing as in the proof of (ii), we see that the latter induces an isomorphism on the associated graded \( E \)-modules, so \( \mathcal{K} = \mathcal{K}' \), again by [28, Ch.III, §2, n.8, Cor.3].
(iv): Denote by \((\alpha_0, \mathcal{K})^c\) the topological closure of \(\alpha, \mathcal{K}\) in \(E\). We shall show first that

**Claim 16.3.37.** \(W(\mathcal{K}) \cap \text{Ker } u_A = W((\alpha_0, \mathcal{K})^c) \cap \text{Ker } u_A + \omega W(\mathcal{K})\).

**Proof of the claim.** Indeed, let \(\omega := (\omega_n | n \in \mathbb{N}) \in W(\mathcal{K}) \cap \text{Ker } u_A\) be any element; due to remarks 9.3.71(iv) and 16.3.28(ii), we may write

\[\omega = \tau_A(\omega_0) + p \cdot \omega'\]

for some \(\omega' \in W(\mathcal{K})\).

whence \(0 = u_A(\omega) = \pi_A(\omega) + p \cdot u_A(\omega')\), and especially, the image of \(\pi_A(\omega_0)\) vanishes in \((\alpha_0, \mathcal{K})^c\) (lemma 16.2.7(iii)). In view of theorem 16.3.31(ii), we deduce that \(\omega_0 \in (\alpha_0, \mathcal{K})^c\). Write also \(\alpha = \tau_A(\alpha_0) + pg\) for some \(g \in A(A)^{\times}\); we obtain

\[\omega = \tau_A(\omega_0) + (u^{-1} \alpha - \tau_A(\alpha_0)) \cdot \omega'\]

and it suffices to notice that \(u^{-1} \alpha \cdot \omega' \in A W(\mathcal{K}) \subset W(\mathcal{K}) \cap \text{Ker } u_A\), and consequently \(\tau_A(\omega_0) - \tau_A(\alpha_0) \cdot \omega' \in \text{Ker } W(\mathcal{K}) \cap \text{Ker } u_A\).

Notice next that if \(\mathcal{K}\) is 1-taut, then the same holds for \(\alpha, \mathcal{K}\), and then also for \((\alpha_0, \mathcal{K})^c\) (remark 16.3.28(v)). Thus, we may apply claim 16.3.37 to \((\alpha_0, \mathcal{K})^c\), and get

\[W((\alpha_0, \mathcal{K})^c) \cap \text{Ker } u_A = W((\alpha_0, \mathcal{K}^c)^{n+1}) \cap \text{Ker } u_A + \alpha W((\alpha_0, \mathcal{K})^c)\]

for every \(n \in \mathbb{N}\).

Now, let \(x_0 \in W(\mathcal{K}) \cap \alpha W(E)\) be any element; we may then find inductively identities

\[x_n = \alpha \cdot y_n + x_{n+1}\]

with \(x_{n+1} \in W((\alpha_0, \mathcal{K})^c) \cap \text{Ker } u_A\) and \(y_n \in W((\alpha_0, \mathcal{K})^c)\) for every \(n \in \mathbb{N}\). Therefore :

\[x_0 = \alpha \cdot (y_0 + y_1 + \cdots + y_n) + x_{n+1}\]

for every \(n \in \mathbb{N}\).

Lastly, since \(\mathcal{K}\) is 1-taut, the ideal \(W(\mathcal{K})\) is closed in the topology of \(W(E)\) (see remark 9.3.28(iv)), and since \(\alpha_0\) is topologically nilpotent, for every open ideal \(I\) of \(W(E)\) there exists \(n \in \mathbb{N}\) such that \(W((\alpha_0, \mathcal{K})^c)^{n+1} \subset I\). Consequently, the series \(\sum_{n \in \mathbb{N}} y_n\) converges to an element \(y \in W(\mathcal{K})\), and \(\lim_{n \to +\infty} x_n = 0\), so finally \(x = \alpha \cdot y\), which concludes the proof. 

**Corollary 16.3.38.** Let \(A\) be any perfectoid ring, \(\mathcal{K} \subset E := E(A)\) an ideal such that \(\Phi_E(\mathcal{K}) = \mathcal{K}\), and endow \(A/\{\mathcal{K}\}\) (resp. \(E/\mathcal{K}\)) with the quotient topology induced via the projection \(\pi_A : A \to A/\{\mathcal{K}\}\) (resp. \(\pi_E : E \to E/\mathcal{K}\)). Then \(A/\{\mathcal{K}\}\) is perfectoid, and there exists a natural isomorphism of topological rings

\[\omega : E(A/\{\mathcal{K}\}) \xrightarrow{\sim} E/\mathcal{K}\]

such that \(\omega \circ \pi_A = \pi_E\).

**Proof.** The topological \(F_p\)-algebra \(E/\mathcal{K}\) is complete and separated, and clearly \(\Phi_E(\mathcal{K}) = \mathcal{K}\), so \(E/\mathcal{K}\) is perfectoid, and we have

\[W(\mathcal{K}) = \text{Ker } W(E) = W(E/\mathcal{K})\).

It follows that the kernel of the induced projection \(\pi_A' : A \to A \otimes W(E)\) is naturally identified with \(u_A(W(\mathcal{K}))\). Moreover, since \(W(E/\mathcal{K})\) is separated (lemma 9.3.33(ii)), \(W(\mathcal{K})\) is a closed subset of \(W(E)\), and taking into account theorem 16.3.36(i) we deduce that \(\text{Ker } (\pi_A') = \{\mathcal{K}\}\), so we get a cocartesian diagram

\[
\begin{array}{ccc}
W(E) & \xrightarrow{W(\pi_E)} & W(E/\mathcal{K}) \\
\downarrow u_A & & \downarrow u' \\
A & \xrightarrow{\pi_A} & A/\{\mathcal{K}\}
\end{array}
\]
and notice that both \( u_A \) and \( \pi_A \) are open and surjective (lemma 16.2.7(i)), so the same holds for \( u' \), and therefore \( A/\{\mathcal{X}\} \) is perfectoid (proposition 16.2.21(i)). Let also \( \pi : A \to A/pA \) be the projection; taking into account remark 9.4.5(ii), there follows a commutative diagram

\[
\begin{array}{ccc}
E & \xrightarrow{\pi_E} & E/\mathcal{X} \\
\downarrow{E(\mathcal{D} \otimes \mathbb{Z} F_p)} & & \downarrow{E(\mathcal{D} \otimes \mathbb{Z} F_p)} \\
E(A/pA) & \xrightarrow{E(\pi_A \otimes \mathbb{Z} F_p)} & E(A/\{\mathcal{X}\} + pA)
\end{array}
\]

whose vertical arrows are both isomorphisms. The assertion follows easily. \( \square \)

**Remark 16.3.39.** (i) In the situation of corollary 16.3.38 let \( (\alpha_n \mid n \in \mathbb{N}) \) be any distinguished element of \( \text{Ker } u_A \), and suppose that \( \mathcal{X} \subset \text{Ann}_E(\alpha_0) \). Then the inclusion \( 0 \subset \mathcal{X}^c \) is taut, and therefore theorem 16.3.31(ii) yields a natural \( W(E) \)-linear identification

\[
\mathcal{X}^c \cong \{ \mathcal{X} \} \quad \beta \mapsto \pi_A(\beta).
\]

Especially, \( \{ \mathcal{X} \} \subset \text{Ann}_A(p) \).

(ii) Let \( \mathcal{I}, \mathcal{K} \subset E \) be two ideals such the topology of \( E \) agrees with the \( \mathcal{I} \)-adic topology, and suppose that

\[
\mathcal{I} \mathcal{J} = 0 \quad \text{and} \quad \Phi_E(\mathcal{K}) = \mathcal{K}.
\]

Notice that \( \mathcal{K} = \mathcal{K}(\lambda) \), and \( \alpha^0 \in \mathcal{I} \) for some \( n \in \mathbb{N} \), from which it follows easily that \( \mathcal{K} \subset \text{Ann}_E(\alpha_0) \). Moreover, \( \mathcal{K} \cap \mathcal{J} = 0 \); indeed, if \( x \in \mathcal{K} \cap \mathcal{J} \), then \( x^2 = 0 \), hence \( x = 0 \). Thus, \( \mathcal{K} + \mathcal{J} n = \mathcal{K} \oplus \mathcal{J} n \) for every \( n \in \mathbb{N} \), and therefore

\[
\bigcap_{n \in \mathbb{N}} (\mathcal{K} + \mathcal{J} n) = \mathcal{K} \oplus \bigcap_{n \in \mathbb{N}} \mathcal{J} n = \mathcal{K}
\]

i.e. \( \mathcal{K} \) is closed in the topology of \( E \), so corollary 16.3.38 says that \( E/\mathcal{K} \) and \( A/\{\mathcal{K}\} \) are perfectoid for their quotient topologies, and there exists an isomorphism of topological rings

\[
\omega : E(A/\{\mathcal{K}\}) \xrightarrow{\sim} E/\mathcal{K} \quad \text{such that} \quad \omega \circ E(\pi_A) = \pi_E
\]

where \( \pi_A : A \to A/\{\mathcal{K}\} \) and \( \pi_E : E \to E/\mathcal{K} \) are the projections.

**Corollary 16.3.40.** Let \( A \) be any perfectoid ring, and \( a_\bullet := (a_1, \ldots, a_k) \) a finite system of elements of \( E := E(A) \). Denote by \( J \subset E \) (resp. \( \mathcal{I} \subset W(E) \)) the ideal generated by \( a_\bullet \) (resp. by \( \tau_E(a_1), \ldots, \tau_E(a_k) \)), and define the ideal \( [a_\bullet]^{(\lambda)} \subset W(E) \) as in remark 9.3.71(iii), for every \( \lambda \in \mathbb{N}[1/p] \). We regard \( A \) as a \( W(E) \)-algebra, via the map \( u_A \). Then we have :

(i) \( [a_\bullet]^{(\lambda)} A \subset \{ J^{(\lambda)} E \} \subset [a_\bullet]^{(\lambda)} A \) for every \( \lambda' < \lambda \) in \( \mathbb{N}[1/p] \).

(ii) The following conditions are equivalent :

(a) \( J \) is open in \( E \)

(b) \( \mathcal{I} A \) is open in \( A \)

(c) \( [a_\bullet]^{(\lambda)} A \) is open in \( A \) for every \( \lambda \in \mathbb{N}[1/p] \)

(d) There exists a strictly positive \( \lambda \in \mathbb{N}[1/p] \) such that \( [a_\bullet]^{(\lambda)} A \) is open in \( A \)

and if these conditions hold, then \( [a_\bullet]^{(\lambda)} A = \{ J^{(\lambda)} E \} \) for every \( \lambda \in \mathbb{N}[1/p] \).

(iii) \( J^{(\lambda)} E \) is a topologically nilpotent open ideal of \( A \) for every \( \lambda > 0 \) in \( \mathbb{N}[1/p] \).

\[
\bigcap_{n \in \mathbb{N}} \{ J^{(\lambda)} E + I^{(\lambda_1)} E \} \subset \{ J^{(\lambda)} E \} \quad \text{for every} \ \lambda' < \lambda \in \mathbb{N}[1/p].
\]

**Proof.** (i): The first inclusion is clear. For the second, notice that \( \{ J^{(\lambda)} E \} = W(J^{(\lambda)})^c \cdot A \) by theorem 16.3.36(i) and remark 16.3.28(iii). On the other hand, pick any \( \lambda' \in \mathbb{N}[1/p] \) such that \( \lambda' < \lambda'' < \lambda \); we have \( W(J^{(\lambda')})^c = \prod_{n \in \mathbb{N}} (J^{(\lambda'')^n} E)^c \) (see remark 9.3.28(iv) and lemma 9.3.70(ii.a)), and moreover \( (J^{(\lambda')^n} E)^c \subset J^{(\lambda'')^n} E \) for every \( n \in \mathbb{N} \) (claim 16.3.20), hence \( W(J^{(\lambda)})^c \subset W(J^{(\lambda'')}) \subset [a_\bullet]^{(\lambda)} \).
where the last inclusion follows from proposition 9.3.78(i).

(ii): Taking into account conclusion 9.3.70(ii.a,iv), it is easily seen that (ii.b) ⇔ (ii.c) ⇔ (ii.d). Combining with (i), we conclude that (ii.b) holds if and only if \( \{ J^{(i)} E \} \) is open in \( A \). However, from theorem 16.3.36(ii) and remark 16.3.28(iii) we see as well that \( \{ J^{(i)} E \} \) is open in \( A \) if and only if \( J^{(i)} E \) is open in \( E \). Lastly, \( J^{(i)} E \) is open in \( E \) if and only if the same holds for \( J \), due to lemma 9.3.70(ii.a,iv). Thus (ii.a) ⇔ (ii.b). Next, we remark:

Claim 16.3.41. For every \( \lambda \in \mathbb{N}[1/p] \) and every \( n \in \mathbb{N} \), the ideal generated by the system \( (\pi_A(x) \mid x \in J^{(\lambda)} E) \) is contained in \( p^n A + [a_\bullet]^{(\lambda)} A \).

Proof of the claim. The claim follows easily from proposition 9.3.63 and lemma 16.1.1(iv) (details left to the reader).

Now, if \( f A \) is open in \( A \), the same holds for \( [a_\bullet]^{(\lambda)} A \), for every \( \lambda \in \mathbb{N}[1/p] \), in which case the latter contains \( p^n \) for some sufficiently large \( n \in \mathbb{N} \); taking into account claim 16.3.41 we get the second assertion of (ii).

(iii.a): It follows easily from (ii) that \( \{ I^{(\lambda)} \} \) is open, and combining lemma 9.3.70(ii.a,iv) with (i), it is easily seen that \( \{ I^{(\lambda)} E \} \) is topologically nilpotent; details left to the reader.

(iii.b): Fix \( N \in \mathbb{N} \) such that \( \lambda < (1 - p^{-N}) \lambda \), let \( x \in J^{(\lambda)} E \), \( y \in J^{(n)} \) be any two elements, and \( \alpha \in \mathbb{N}[1/p] \) any rational number \( \leq 1 \); notice that \( z_\alpha := \tau_A(x^{1-\alpha} \cdot y^n) \) lies in \( I^{(n/p^n)} E \) if \( \alpha \geq p^{-N} \), and lies in \( J^{(\lambda)} E \) otherwise. However, proposition 9.3.63 says that \( \tau_A(x + y) \) can be written as a \( p \)-adically convergent series whose terms are of the form \( u_\alpha \cdot z_\alpha \) for certain \( u_\alpha \in W(E) \); since (ii) implies that \( \{ I^{(n/p^n)} E \} \) is an open ideal in \( A \), we deduce

\[
\bigcap_{n \in \mathbb{N}} \{ J^{(\lambda)} E + I^{(n)} \} \subset \bigcap_{n \in \mathbb{N}} \left( \{ J^{(\lambda)} E \} + \{ I^{(n/p^n)} E \} \right) = \{ J^{(\lambda)} E \}
\]

where the last equality holds because \( \{ J^{(\lambda)} E \} \) is a closed ideal, taking into account (iii.a). □

Theorem 16.3.42. Let \( f : A \to A' \) be a continuous ring homomorphism of perfectoid rings; set \( C := \text{Im } f \) and \( D := \text{Im } E(f) \). The following holds:

(i) \( f \) is surjective (resp. bijective, resp. adic, resp. open, resp. open and injective) if and only if the same holds for \( E(f) \).

(ii) \( C \) is open in \( A' \) if and only if \( D \) is open in \( E(A') \).

(iii) Suppose that \( C \) is open in \( A' \), then we have:

(a) \( A'^{\text{op}} \subset C \).

(b) \( C \) is perfectoid both for the quotient topology induced by the projection \( A \to C \), and for the subspace topology induced by the inclusion map \( C \to A' \).

Proof. Set \( E := E(A) \) and \( E' := E(A') \). Also, denote by \( \mathcal{T}_D \) and \( \mathcal{T}_D' \) (resp. \( \mathcal{T}_C \) and \( \mathcal{T}_C' \)) the topologies on \( D \) (resp. on \( C \)) induced respectively by the projection \( E \to D \) and the open inclusion \( D \to E' \) (resp. induced by the projection \( A \to C \) and the open inclusion \( C \to A' \)).

Let \( \alpha_\bullet := (\alpha_n \mid n \in \mathbb{N}) \) be a distinguished element in the kernel of \( u_A : W(E) \to A \), and recall that the image of \( \alpha_\bullet \) in \( W(E') \) is a distinguished element in the kernel of \( u_{A'} \). We denote by \( \text{Fil}^{*} A \) and \( \text{Fil}^{*} A' \) the \( p \)-adic filtrations on \( A \) and respectively \( A' \); likewise, let \( \text{Fil}^{*} E \) and \( \text{Fil}^{*} E' \) be the \( \alpha_0 \)-adic filtrations on \( E \) and respectively \( E' \). Moreover, we let \( A^{*} \) be the complex concentrated in degrees 0 and 1, with \( A^{0} := A \), \( A^{1} := A' \), and \( d^{0} := f \). Likewise, we define the complex \( E^{*} := (E, E(f), E') \) in degrees 0 and 1. With the foregoing filtrations, \( A^{*} \) and \( E^{*} \) are filtered complexes of \( \mathbb{Z} \)-modules, and we wish to consider the associated spectral sequences, as described in (7.2.12). Explicitly, we have \( \text{Z}(A^{*})_{p}^{p} = 0 \) whenever \( p + q \neq 0, 1 \), and:

\[
\text{Z}(A^{*})_{p}^{p, -p} := \{ a \in \text{Fil}^{p} A \mid f(a) \in \text{Fil}^{p+r} A' \}
\]
\[
\text{Z}(A^{*})_{p}^{p, -p+1} := \text{Fil}^{p} A'
\]

for every \( p \in \mathbb{Z} \) and \( r \in \mathbb{N} \).
and correspondingly for $Z(E^*)_{r}^{pq}$. Since $\overline{\pi}_{A}(\text{Fil}^pE) \subset \text{Fil}^pA$ for every $p \in \mathbb{Z}$, and likewise for $\overline{\pi}_{A'}$, it is then clear that $\overline{\pi}_{A}$ and $\overline{\pi}_{A'}$ restrict to well defined maps

$$\pi_{r}^{pq} : Z(E^*)_{r}^{pq} \rightarrow Z(A^*)_{r}^{pq} \quad \text{for every } p, q \in \mathbb{Z} \text{ and } r \in \mathbb{N}.$$ 

Moreover, we have $B(A^*)_{r}^{pq} = 0$ whenever $p + q \neq 0, 1$, and:

$$B(A^*)_{r}^{p-r} := \text{Fil}^{p+1}A \cap Z(A^*)_{r}^{p-r}$$
$$B(A^*)_{r}^{p-r+1} := (\text{Fil}^{p+1}A' + f(\text{Fil}^{p-r+1}A)) \cap \text{Fil}^pA'$$ 

and correspondingly for $B(E^*)_{r}^{pq}$.

**Claim 16.3.43.** $\overline{\pi}_{r}^{a,b}(B(E^*)_{r}^{ab}) \subset B(A^*)_{r}^{a,b}$ for every $a, b \in \mathbb{Z}$ and $r \in \mathbb{N}$.

**Proof of the claim.** The assertion is trivial for $a + b \neq 0, 1$. If $b = -a$, the assertion follows directly from our explicit descriptions of $B(E^*)_{r}^{a,-a}$ and $B(A^*)_{r}^{a,-a}$. Next, notice that $B(E^*)_{0}^{a,-a+1} = \text{Fil}^{a+1}E'$, and likewise for $B(A^*)_{0}^{a,-a+1}$; the assertion follows then when $r = 0$ and $b = -a + 1$. For the case where $r > 0$ and $b = -a + 1$, lemma 7.2.13 shows that $B(E^*)_{r}^{a,-a+1} = \text{Fil}^{a+1}E' + f(Z(E^*)_{r-1}^{a-r+1,-a+r-1})$ and likewise for $B(A^*)_{r}^{a,-a+1}$. Hence, let $x \in \text{Fil}^{p+1}E'$ and $y \in Z(E^*)_{r-1}^{a-r+1,-a+r-1}$ and set $z := x + E(f)(y)$; we need to check that $\overline{\pi}_{A'}(z) = \overline{\pi}_{A'}(x) + \overline{\pi}_{A'} \circ E(f)(y) + w$, where $w$ is the limit of a $p$-adically convergent series whose terms are $\mathbb{Z}_p$-linear combinations of products of the form $p^n \cdot \overline{\pi}_{A'}(x^{\sigma_0}) \cdot E(f)(y)^{\sigma_1}$, with $n \in \mathbb{N} \setminus \{0\}$, $\sigma_0, \sigma_1 \in \mathbb{Q}_+$, and $\sigma_0 + \sigma_1 = 1$. Now:

$$\overline{\pi}_{A'} \circ E(f)(y) = f(\overline{\pi}_{A}(y)) \in f(Z(A^*)_{r-1}^{a-r+1,-a+r-1}) \quad \text{and} \quad \overline{\pi}_{A'}(x) \in \text{Fil}^{a+1}A'.$$

Moreover, since $f(\overline{\pi}_{A}(y)) \in \text{Fil}^{a}A'$, we see that $p^m$ divides $\overline{\pi}_{A'}(x^{\sigma_0}) \cdot E(f)(y)^{\sigma_1} = \overline{\pi}_{A'}(x)^{\sigma_0} \cdot f(\overline{\pi}_{A}(y))^{\sigma_1}$ in $A'$, for every integer $m \leq \sigma_0 \cdot (a + 1) + \sigma_1 \cdot a = \sigma_0 + \sigma_1$. Thus, $w \in \text{Fil}^{a+1}A'$, whence the contention.

Next, notice that $E(A^*)_{r}^{p-r} = \text{gr}^{p}A$ and $E(A^*)_{r}^{p-r+1} = \text{gr}^{p}A'$ for every $p \in \mathbb{Z}$, and likewise for $E(E^*)_{0}^{pq}$, whenever $p + q = 0, 1$. Especially, $E(A^*)_{r}^{a,b}$ is a $\mathbb{Z}/p\mathbb{Z}$-module for every $a, b \in \mathbb{Z}$ and $r \in \mathbb{N}$. Invoking proposition 9.3.63 again, we deduce that the composition

$$Z(E^*)_{r}^{pq} \xrightarrow{\overline{\pi}_{r}^{pq}} Z(A^*)_{r}^{pq} \rightarrow E(A^*)_{r}^{pq}$$

is an additive map, and combining with claim [16.3.43] it follows that the latter factors through a well defined group homomorphism

$$v_{r}^{pq} : E(E^*)_{r}^{pq} \rightarrow E(A^*)_{r}^{pq} \quad \text{for every } p, q \in \mathbb{Z} \text{ and } r \in \mathbb{N}.$$ 

Lastly, a simple inspection shows that the system of maps $v_{r}^{pq}$ yields a morphism of spectral sequences $E(E^*)_{r}^{pq} \rightarrow E(A^*)_{r}^{pq}$. Since $v_{0}^{pq}$ is an isomorphism for every $p, q \in \mathbb{Z}$, it follows that $v_{r}^{pq}$ is an isomorphism of spectral sequences.

Let us endow $\text{Coker } f$ with the filtration induced by $\text{Fil}^*A'$: namely

$$\text{Fil}^p(\text{Coker } f) := \text{Im}(\text{Fil}^pA' \rightarrow \text{Coker } f) \quad \text{for every } p \in \mathbb{Z}.$$ 

Likewise, we define a filtration $\text{Fil}^*\text{Coker } E(f)$ on $\text{Coker } E(f)$. Let moreover $\mathcal{T}_{A',p}$ be the $p$-adic topology on $A'$, and $\mathcal{T}_{E',0}$ the $\alpha_0$-adic topology on $E'$.

**Claim 16.3.44.** $C$ is open in $(A', \mathcal{T}_{A',p})$ (resp. $D$ is open in $(E', \mathcal{T}_{E',0})$) if and only if there exists $i \in \mathbb{N}$ such that $\text{gr}^i\text{Coker } f = 0$ (resp. such that $\text{gr}^i\text{Coker } E(f) = 0$).
Proof of the claim. Clearly, if \( C \) is open in \( (A', \mathcal{T}_{A',p}) \), then we find \( i \in \mathbb{N} \) with \( \text{gr}^i \text{Coker } f = 0 \). Conversely, if the latter condition holds, set \( M := \text{Fil}^i A' + C \subset A' \); we deduce that \( M = pM + C \), whence \( M = C \), by [100, Th.8.4] and lemma 16.2.3(v); i.e. \( \text{Fil}^i A' \subset C \), so \( C \) is open in \( (A', \mathcal{T}_{A',p}) \). Since \( E \) and \( E' \) are complete and separated for their \( \alpha_0 \)-adic topologies (see [16.2.19]), the same argument shows the assertion for \( D \).

According to (7.2.17), the spectral sequences \( E(A^*)_{\infty}^{p-a} \) and \( E(E^*)_{\infty}^{p-a} \) admit natural abutments, and by inspecting the constructions, we deduce natural isomorphisms:

\[
E(A^*)_{\infty}^{p-a} \cong \text{gr}^a \text{Coker } f \quad E(E^*)_{\infty}^{p-a} \cong \text{gr}^a \text{Coker } E(f) \quad \text{for every } a \in \mathbb{Z}.
\]

Moreover, by proposition 7.2.18 they converge in degree 1. Since these spectral sequences are isomorphic, combining with claim 16.3.44 we conclude that \( C \) is open in \( (A', \mathcal{T}_{A',p}) \) if and only if \( D \) is open in \( (E', \mathcal{T}_{E',\alpha_0}) \).

(ii): By the foregoing, we may assume that \( C \) is open in \( (A', \mathcal{T}_{A',p}) \) and \( D \) is open in \( (E', \mathcal{T}_{E',\alpha_0}) \). Hence, \( \alpha_0 E' \subset D \) for some \( n \in \mathbb{N} \), and since \( D \) and \( E' \) are perfect rings, it follows easily that \( \alpha_0 E' \subset D \), i.e. \( \text{gr}^1 \text{Coker } E(f) = 0 \). By the foregoing, we deduce that \( \text{gr}^1 \text{Coker } f = 0 \) as well, i.e. \( pA' \subset C \). Endow \( E'/\alpha_0 E' \) and \( A'/pA' \) with the quotient topologies \( \mathcal{T}_{E'/\alpha_0 E'} \) and \( \mathcal{T}_{A'/pA'} \) induced by \( E' \) and \( A' \), and recall that \( \pi_{A'/pA'} \) induces an isomorphism of topological rings

\[
\omega : (E'/\alpha_0 E', \mathcal{T}_{E'/\alpha_0 E'}) \cong (A'/pA', \mathcal{T}_{A'/pA'}),
\]

(remark 16.3.7(ii)); clearly \( \omega(C/pA') = D/\alpha_0 E' \), and especially \( C/pA' \) is open in \( A'/pA' \) if and only if \( D/\alpha_0 E' \) is open in \( E'/\alpha_0 E' \). The contention follows immediately.

(iii): In view of (ii), the subring \( D \) is open in \( E' \); since \( D \) is perfect, it follows easily that \( E'^{\infty} \subset D \). Endow \( D/\alpha_0 E' \) (resp. \( C/pA' \)) with the topology \( \mathcal{T}_{D/\alpha_0 E'} \) (resp. \( \mathcal{T}_{C/pA'} \)) induced by \( \mathcal{T}_D \) via the projection \( D \to D/\alpha_0 E' \) (resp. by \( \mathcal{T}_C \) via the projection \( C \to C/pA' \)). Then we have \( (D/\alpha_0 E', \mathcal{T}_{D/\alpha_0 E'}) = E'^{\infty} \), and notice that

\[
(D/\alpha_0 E', \mathcal{T}_{D/\alpha_0 E'})^{\infty} = (D, \mathcal{T}_D)^{\infty}/\alpha_0 E' \quad \text{and} \quad (C/pA', \mathcal{T}_{C/pA'})^{\infty} = (C, \mathcal{T}_C)^{\infty}/pA'.
\]

Moreover, according to lemma 8.2.3(i), the topology \( \mathcal{T}_{D/\alpha_0 E'}^{\infty} \) agrees with the topology induced by \( \mathcal{T}_{E'/\alpha_0 E'} \) via the inclusion map \( D/\alpha_0 E' \to E'/\alpha_0 E' \), and likewise for \( \mathcal{T}_{C/pA'}^{\infty} \); it follows that the foregoing isomorphism \( \omega \) restricts to an isomorphism of topological rings

\[
(C/pA', \mathcal{T}_{C/pA'}) \cong (D/\alpha_0 E', \mathcal{T}_{D/\alpha_0 E'}).
\]

Since \( (D/\alpha_0 E', \mathcal{T}_{D/\alpha_0 E'})^{\infty} = E'^{\infty}/\alpha_0 E' = (E'/\alpha_0, \mathcal{T}_{E'/\alpha_0})^{\infty} \), we get \( (C/pA', \mathcal{T}_{C/pA'})^{\infty} = (A'/pA', \mathcal{T}_{A'/pA'})^{\infty} = A'^{\infty}/pA' \), and finally \( A'^{\infty} = (C, \mathcal{T}_C)^{\infty} \).

(i): If \( f \) is bijective, then clearly the same holds for \( E(f) \); conversely, if \( E(f) \) is bijective, then the same holds for

\[
W(E)/\alpha_\bullet W(E) \otimes_{W(E)} W(E(f)) : W(E)/\alpha_\bullet W(E) \to W(E')/\alpha_\bullet W(E').
\]

But the image of \( \alpha_\bullet \) is still distinguished in \( W(E') \), and lies in \( \text{Ker } a_{A'} \), hence the latter map is naturally identified with \( f \); especially, \( f \) is bijective.

- If either \( f \) or \( E(f) \) is surjective, then \( pA' \subset C \) and \( \alpha_0 E' \subset D \) by the proof of (ii), and moreover the isomorphism \( E'/\alpha_0 E' \cong A'/pA' \) induced by \( \pi_{A'/pA'} \) restricts to an isomorphism \( D/\alpha_0 E' \cong C/pA' \). Then clearly \( C = A' \) if and only if \( D = E' \).

- Next, let \( \mathcal{J} \subset E \) be any ideal of definition, \( (\beta_1, \ldots, \beta_k) \) a finite system of generators for \( \mathcal{J} \), and \( J \subset A \) the ideal generated by \( (\pi_{A}(\beta_1), \ldots, \pi_{A}(\beta_k)) \). By corollary 16.3.40(ii), the ideal \( JA' \) is open in \( A' \) if and only if \( \mathcal{J} E' \) is open in \( E' \). Moreover, \( \mathcal{J} E' \) (resp. \( JA' \)) is topologically nilpotent in \( E' \) (resp. in \( A' \)), since the same holds for \( \mathcal{J} \) (resp. for \( J \)); thus, \( \mathcal{J} E' \) is an ideal of adic definition for \( E' \) if and only if \( JA' \) is an ideal of adic definition for \( A' \), i.e. \( f \) is adic if and only if \( E(f) \) is adic.
If either $f$ of $E(f)$ is open, we know already that $C$ is open in $A'$ and $D$ is open in $E'$, by (ii). Also, by the foregoing we know already that $f$ is adic if and only if the same holds for $E(f)$; combining with proposition\[8.3.18(v),\]we conclude that $f$ is open if and only if the same holds for $E(f)$.

Lastly, if either $f$ or $E(f)$ is open and injective, by the foregoing we know already that both $f$ and $E(f)$ are open, and then $A^{\infty} \subset C$ and $E^{\infty} \subset D$, by (iii.a). Endow $A' := A'/A^{\infty}, E' := E'/E^{\infty}, C := C/A^{\infty}$ and $D := D/E^{\infty}$ with their discrete topologies; then the foregoing isomorphism $\omega$ induces a ring isomorphism $E' \sim \sim A'$, restricting to a ring isomorphism $D \sim \sim C$. Moreover, we get natural isomorphisms of topological rings:

$$(C, \mathscr{T}_C) \sim \sim C \times_{\mathcal{A}} A' \quad \text{and} \quad (D, \mathscr{T}_D) \sim \sim D \times_{E'} E'.$$

Taking into account proposition\[16.3.25\] it follows that the projection $A \to (C, \mathcal{T}_C)$ is an isomorphism of topological rings if and only if the same holds for the projection $E \to (D, \mathcal{T}_D)$; i.e. $f$ is open and injective if and only if the same holds for $E(f)$.

(iii.b): The map $E(f)$ is a composition of continuous ring homomorphisms:

$$E \xrightarrow{g_1} (D, \mathcal{T}_D) \xrightarrow{g_2} (D, \mathcal{T}_D') \xrightarrow{g_3} E'$$

where $g_1$ is open and surjective, $g_2$ is bijective, and $g_3$ is an open injective map. Since $\ker g_1 = \ker E(f)$ is a closed ideal of $E$, we see that $(D, \mathcal{T}_D)$ is a perfect, separated and complete topological ring (proposition\[8.2.13(v)\]) whose topology is $I$-adic, for an ideal $I \subset D$ of finite type, i.e. $(D, \mathcal{T}_D)$ is perfectoid, and the same holds for $(D, \mathcal{T}_D')$ by virtue of corollaries\[8.3.20(i)\] and\[8.3.19(iii)\]. Since the category of perfectoid $A$-algebras is equivalent to that perfectoid $E$-algebras (remark\[16.3.7(i)\]) we deduce a corresponding factorization of $f$:

$$A \xrightarrow{f_1} C_1 \xrightarrow{f_2} C_2 \xrightarrow{f_3} A'$$

where $C_1$ and $C_2$ are perfectoid $A$-algebras with isomorphisms of perfectoid $E$-algebras

$$E(C_1) \sim \sim (D, \mathcal{T}_D) \quad \text{and} \quad E(C_2) \sim \sim (D, \mathcal{T}_D').$$

Moreover, $f_1$ is open and surjective, $f_2$ is bijective, and $f_3$ is open and injective, by (i). But then $C_1$ is isomorphic to $(C, \mathcal{T}_C)$ and $C_2$ is isomorphic to $(C, \mathcal{T}_C')$, whence the contention. 

In the situation of theorem\[16.3.36\] let $\mathcal{K}$ and $\mathcal{K}'$ be any two closed and taut ideals of $E$; we would like to show that $\mathcal{K} = \mathcal{K}'$ if and only if $\{\mathcal{K}\} = \{\mathcal{K}'\}$, and taking into account theorem\[16.3.36(iii)\] it would suffice to prove that $\{\mathcal{K} \cap \mathcal{K}'\} = \{\mathcal{K}\} \cap \{\mathcal{K}'\}$. We do not know whether the latter identity always holds, but we have at least the following:

**Theorem 16.3.45.** Let $A$ be any perfectoid ring, $\mathcal{K}$ and $\mathcal{K}'$ two taut and closed ideals of $E := E(A)$, and $(\alpha_n \mid n \in \mathbb{N})$ any distinguished element of $\ker \varphi_A$. Suppose that either one of the following conditions holds:

(a) $\alpha_0 \in \mathcal{K}'$

(b) $\mathcal{K}'$ is strictly taut and $\alpha_0^n \subset \mathcal{K}'$ for some sufficiently large $n \in \mathbb{N}$.

Then $\{\mathcal{K} \cap \mathcal{K}'\} = \{\mathcal{K}\} \cap \{\mathcal{K}'\}$.

**Proof.** Suppose that (a) holds; in this case, both inclusions $\mathcal{K}' \subset E$ and $\mathcal{K}' \cap \mathcal{K} \subset \mathcal{K}$ are taut, by remark\[16.3.28(iv)\]. There follows a commutative diagram of $A/pA$-modules

$$\begin{array}{ccc}
\mathcal{K}/(\mathcal{K}' \cap \mathcal{K}) & \longrightarrow & \{\mathcal{K}\}/\{\mathcal{K}' \cap \mathcal{K}\} \\
\downarrow & & \downarrow \\
E/\mathcal{K}' & \longrightarrow & A/\{\mathcal{K}'\}
\end{array}$$
both of whose horizontal arrows are isomorphisms, by theorem [16.3.31](ii), and whose left vertical arrow is clearly injective. Then the right vertical arrow is injective as well, whence the contention, in this case.

In case (b) holds, pick \( \varepsilon \in \mathbb{N}[1/p] \) with \( 0 < \varepsilon < 1 \) and such that \( \mathcal{K}' \) is \( \alpha_0^{1-\varepsilon} \)-taut. We set

\[
\mathcal{J}_n := \{ x \in E \mid \alpha_0^n x \in \mathcal{I} \} \quad \text{for every } n \in \mathbb{N} \text{ and every ideal } \mathcal{I} \subset E.
\]

**Claim 16.3.46.** With the foregoing notation we have:

(i) \( \mathcal{K}'_n \) is a closed ideal of \( E \), for every \( n \in \mathbb{N} \).

(ii) The inclusion \( \mathcal{K}'_n \subset \mathcal{K}'_{n+1} \) is taut for every \( n \in \mathbb{N} \).

(iii) \( \mathcal{K}'_n = \mathcal{K}' \) and \( \mathcal{K}'_r = E \) for every sufficiently large \( r \in \mathbb{N} \).

**Proof of the claim.** Since \( \mathcal{K}' \) is closed, it is easily seen that (i) holds. Say that \( \alpha_0^n \in \mathcal{K}' \); then clearly \( \mathcal{K}'_n = E \) for every integer \( k \geq \varepsilon^{-1}n \). Next, directly from the definition we see that, for any two ideals \( \mathcal{I}, \mathcal{J} \subset E \) and any \( n \in \mathbb{N} \) we have

\[
\mathcal{J} \cdot \mathcal{I}_n \subset (\mathcal{J} \mathcal{I})_n \quad \alpha_0^n \mathcal{J}_{n+1} \subset \mathcal{I}_n \quad (\mathcal{J}_n)^p \subset (\mathcal{I}^p)_n \quad (\Phi_E^{-1} \mathcal{J})_n = \Phi_E^{-1}(\mathcal{I}_n^p).
\]

Therefore:

\[
\alpha_0 \cdot \Phi_E^{-1}(\mathcal{K}'_{n+1})^p \subset \alpha_0 \cdot \Phi_E^{-1}(\mathcal{K}'_{(n+1)})^p
\]

\[
= \alpha_0 \cdot (\Phi_E^{-1} \mathcal{K}'_{n+1})^p
\]

\[
\subset \alpha_0^{1-\varepsilon} \cdot (\Phi_E^{-1} \mathcal{K}'_{n})^p
\]

\[
\subset (\alpha_0^{1-\varepsilon} \cdot \Phi_E^{-1} \mathcal{K}'_{n})^p
\]

\[
\subset \mathcal{K}'_{n+1}
\]

as required. \( \diamondsuit \)

By claim [16.3.46] we have \( \mathcal{K}'_r = E \) for some \( r \in \mathbb{N} \), and for every \( n \in \mathbb{N} \) we get a commutative diagram of \( A/pA \)-modules

\[
\begin{array}{ccc}
\{ \mathcal{K} \cap \mathcal{K}'_{n+1} \} / \{ \mathcal{K} \cap \mathcal{K}'_n \} & \longrightarrow & \{ \mathcal{K}'_{n+1} \} / \{ \mathcal{K}'_n \} \\
\downarrow & & \downarrow \\
(\mathcal{K} \cap \mathcal{K}'_{n+1}) / (\mathcal{K} \cap \mathcal{K}'_n) & \longrightarrow & \mathcal{K}'_{n+1} / \mathcal{K}'_n
\end{array}
\]

whose vertical arrows are isomorphisms, by theorem [16.3.31](ii), and whose bottom horizontal arrow is injective. Then the top horizontal arrow is injective as well, so that

\[
\{ \mathcal{K} \cap \mathcal{K}'_{n+1} \} \cap \{ \mathcal{K}'_n \} \subset \{ \mathcal{K} \cap \mathcal{K}'_n \} \quad \text{for every } n \in \mathbb{N}.
\]

We may now prove that \( \{ \mathcal{K} \} \cap \{ \mathcal{K}'_r \} = \{ \mathcal{K} \cap \mathcal{K}'_r \} \), by descending induction on \( n \). Indeed, the assertion is obvious in case \( n \geq r \). Suppose that the identity has already been shown for some \( n > 0 \); then we get

\[
\{ \mathcal{K} \} \cap \{ \mathcal{K}'_{n-1} \} = \{ \mathcal{K} \} \cap \{ \mathcal{K}'_n \} \cap \{ \mathcal{K}'_{n-1} \} = \{ \mathcal{K} \cap \mathcal{K}'_n \} \cap \{ \mathcal{K}'_{n-1} \} \subset \{ \mathcal{K} \cap \mathcal{K}'_{n-1} \}
\]

and the converse inclusion is obvious, so the sought identity holds for \( n - 1 \). Letting \( n = 0 \), we get the assertion. \( \square \)

In the same vein, let us also point out:

**Lemma 16.3.47.** In the situation of theorem [16.3.45] let \( \lambda_1, \lambda_2 \in \mathbb{N}[1/p] \) be two rationals such that \( \lambda_1 + \lambda_2 \leq 1 \), and \( \mathcal{I}_1, \mathcal{I}_2 \subset E \) two ideals such that \( \mathcal{I}_i \) is \( \alpha_0^{\lambda_i} \)-taut for \( i = 1, 2 \). Then

\[
(\{ \mathcal{I}_1 \} \{ \mathcal{I}_2 \})^c = \{ \mathcal{I}_1 \mathcal{I}_2 \}.
\]
Proof. The inclusion \( \{ \mathcal{J}_1 \} \{ \mathcal{J}_2 \} \subset \{ \mathcal{J}_1 \mathcal{J}_2 \} \) is obvious from the definitions, so it suffices to check that for every \( x \in \mathcal{J}_1 \mathcal{J}_2 \) we have \( \Pi_A(x) \in (\{ \mathcal{J}_1 \} \{ \mathcal{J}_2 \})^c \). However, every such \( x \) can be written as a finite sum \( \sum_{i=1}^n y_i z_i \), with \( y_1, \ldots, y_n \in \mathcal{J}_1 \) and \( z_1, \ldots, z_n \in \mathcal{J}_2 \); by proposition \( 9.3.63 \) we know that \( \Pi_A(x) \) is the limit of a \( p \)-adically convergent series of the form \( \sum_{j \in \mathbb{N}} w_j \), where in turn each \( w_j \) is a finite \( \mathbb{Z}_p \)-linear combination of terms of the form

\[
w^\mu_j := p^j \cdot \Pi_A((y_1 z_1)^{\mu_1} \cdots (y_n z_n)^{\mu_n}) \quad \text{for certain} \quad \mu_1, \ldots, \mu_n \in p^{-j} \mathbb{N} \quad \text{such that} \quad \sum_{i=1}^n \mu_i = 1.
\]

Thus, we are reduced to checking that any such term lies in \( \{ \mathcal{J}_1 \} \{ \mathcal{J}_2 \} \). Now, set \( y^\mu := y_1^{\mu_1} \cdots y_n^{\mu_n} \), and define likewise \( z^\mu \), for every \( \mu = (\mu_1, \ldots, \mu_n) \in p^{-\mathbb{N}} \); under our assumptions we have \( p = \Pi_A(\alpha_0^{\lambda_1+\lambda_2}) \cdot a \) for some \( a \in A \) (lemma \( 16.2.7 \)(iii)), hence

\[
w^\mu = a^j \cdot \Pi_A(\alpha_0^{\lambda_1} \cdot y^\mu) \cdot \Pi_A(\alpha_0^{\lambda_2} \cdot z^\mu)
\]

and notice that \( \alpha_0^{\lambda_1} \cdot y^\mu \in \alpha_0^{\lambda_1} \cdot \Phi^{-1}(\mathcal{J}^{(p)}) \subset \mathcal{J}_1 \) by \( 16.3.29 \). Likewise, \( \alpha_0^{\lambda_2} \cdot z^\mu \in \mathcal{J}_2 \), and the assertion follows. \( \square \)

**Corollary 16.3.48.** Let \( A \) be a perfectoid ring, \( \mathcal{K}, \mathcal{K}' \subset E(A) \) two taut and closed ideals, and suppose that either \( \mathcal{K} \) or \( \mathcal{K}' \) fulfills conditions (a) and (b) of theorem \( 16.3.45 \). Then we have \( \mathcal{K} \subset \mathcal{K}' \) if and only if \( \{ \mathcal{K} \} \subset \{ \mathcal{K}' \} \).

**Proof.** As already announced, this follows straightforwardly from remark \( 16.3.28 \)(iv) and theorems \( 16.3.45 \) and \( 16.3.36 \)(iii). \( \square \)

**Corollary 16.3.49.** In the situation of corollary \( 16.3.40 \) let \( a^*_\bullet := (a_1^*, \ldots, a_r^*) \) be another finite system of elements of \( E \), and \( J' \subset E \) the ideal generated by \( a^*_\bullet \). Define the ideal \( [a^*_\bullet]^{(\mu)} \subset W(E) \) as in remark \( 9.3.71 \)(iii), for every \( \beta \in \mathbb{N}[1/p] \). Moreover, let \( \lambda, \mu \in \mathbb{N}[1/p] \) be any two rational numbers. We have:

(i) The following conditions are equivalent:

(a) \( J^{(\lambda)} E \subset J'^{(\mu)} E \).

(b) \( [a^*_\bullet]^{(\lambda)} A \subset [a^*_\bullet]^{(\mu-\epsilon)} A \) for every \( \epsilon \in \mathbb{N}[1/p] \) with \( 0 < \epsilon \leq \mu \).

(ii) Suppose that either \( J \) or \( J' \) is open. Then the following conditions are equivalent:

(a) \( J^{(\lambda)} E \subset J'^{(\mu)} E \).

(b) \( [a^*_\bullet]^{(\lambda)} A \subset [a^*_\bullet]^{(\mu)} A \).

(iii) For every \( l, m \in \mathbb{N}[1/p] \) such that \( l\mu + m\lambda < \lambda \mu \) we have

\[
[a^*_\bullet]^{(\lambda)} A \cap [a^*_\bullet]^{(\mu)} A \subset [a^*_\bullet]^{(l)} \cdot [a^*_\bullet]^{(m)} A.
\]

**Proof.** (i): Suppose that (i.a) holds; we deduce:

\[
[a^*_\bullet]^{(\lambda)} A \subset [J^{(\lambda)} E] \subset [J'^{(\mu-\epsilon/p)} E] \subset [a^*_\bullet]^{(\mu-\epsilon)} A
\]

for every \( \epsilon \) as in (i.b), where the first and last inclusions follow from corollary \( 16.3.40 \)(i).

Conversely, suppose that (i.b) holds; fix a finite system \( b^*_\bullet := (b_1, \ldots, b_r) \) of generators for an ideal of definition \( I \) of the perfectoid ring \( E \), and for every \( n \in \mathbb{N} \), let \( b^*_n \) be the finite system consisting of the products of the form \( b_{j(1)} \cdots b_{j(n)} \), where \( j \) ranges over all the mappings \( \{1, \ldots, n\} \to \{1, \ldots, r\} \). For every \( n \in \mathbb{N} \), we may then form the system \( (a^*_\bullet, b^*_n) \) which is the union of the systems \( a^*_\bullet \) and \( b^*_n \), and for every \( \lambda \in \mathbb{N}[1/p] \) consider the ideal \( [a^*_\bullet, b^*_n]^{(\lambda)} \subset W(E) \) attached as in remark \( 9.3.71 \)(iii) to the system \( (a^*_\bullet, b^*_n) \). With this notation, corollary \( 16.3.40 \)(ii) yields:

\[
[a^*_\bullet]^{(\lambda)} A \subset [a^*_\bullet, b^*_n]^{(\mu-\epsilon/p)} A = \{ (J' + I^n)^{(\mu-\epsilon/p)} E \}
\]

for every \( n \in \mathbb{N} \) and \( \epsilon \) as in (i.a).
However, since the topology of $A$ is coarser than the $p$-adic topology, claim [16.3.41] implies that $[a_\bullet]^{(\lambda)} A$ is a dense subset of $\{J^{(\lambda)} E\}$; but $\{(J' + I^n)^{(\mu-\varepsilon/p)} E\}$ is a closed ideal, so 
\[(16.3.50) \quad \{J^{(\lambda)} E\} \subset \{(J' + I^n)^{(\mu-\varepsilon/p)} E\} \quad \text{for every } n \in \mathbb{N} \text{ and } \varepsilon \text{ as in (i.a)}.\]

Now, the topological closure $J^{(\lambda)} E^c$ of $J^{(\lambda)} E$ is (strictly) taut, and $\{J^{(\lambda)} E\} = \{J^{(\lambda)} E^c\}$ (remark 16.3.28 v); moreover, $(J' + I^n)^{(\mu-\varepsilon/p)} E$ is an open ideal of $W(E)$, hence, from corollary 16.3.48 and (16.3.50) we derive 
\[(J^{(\lambda)} E^c) \subset \{(J' + I^n)^{(\mu-\varepsilon/p)} E\} \quad \text{for every } n \in \mathbb{N} \text{ and } \varepsilon \text{ as in (i.a)}.
\]
and combining with claim [16.3.20] we conclude that $J^{(\lambda)} E \subset \{J^{(\mu)} E\}$ for every $\varepsilon$ as in (i.a).

(ii): From lemma 9.3.70 ii.a.iv it follows easily that $J'$ is open if and only if the same holds for $J^{(\lambda)} E$, and likewise, $J'$ is open if and only if the same holds for $J^{(\mu)} E$. Hence, suppose that $J$ is open; if condition (ii.a) holds, then it follows that $J'$ is open as well, and if (ii.b) holds, we use corollary 16.3.40(ii) to deduce first that $[a_\bullet]^{(\lambda)} A$ is open, so the same holds for $[a_\bullet]^{(\mu)} A$, and then also for $J'$, again by corollary 16.3.40(ii). In conclusion, for the proof of (ii) we may assume that $J'$ is open. Now, suppose that (ii.a) holds; then we get 
$$[a_\bullet]^{(\lambda)} A \subset \{J^{(\lambda)} E\} \subset \{J^{(\mu)} E\} = [a_\bullet]^{(\mu)} A$$
where the first inclusion follows from corollary 16.3.40(i), and the last identity follows from corollary 16.3.40(ii). Conversely, suppose that (ii.b) holds; since the topology of $A$ is coarser than the $p$-adic topology, claim 16.3.41 implies that $[a_\bullet]^{(\lambda)} A$ is a dense subset of $\{J^{(\lambda)} E\}$, and since $\{J^{(\mu)} E\}$ is a closed ideal, corollary 16.3.40(ii) yields $\{J^{(\lambda)} E\} \subset \{J^{(\mu)} E\}$. Then, arguing as in the proof of (i), we easily deduce that (ii.a) holds.

(iii): We may assume that $\lambda, \mu > 0$, since otherwise there is nothing to prove. Define $b_\bullet$ as in the foregoing, for every $n \in \mathbb{N}$; combining corollary 16.3.40(i) and theorem 16.3.45 we get 
$$[a_\bullet, b_\bullet]^{(\lambda)} A \cap [a_\bullet, b_\bullet]^{(\mu)} A = \{(J + I^n)^{\lambda} E\} \cap \{(J' + I^n)^{\mu} E\} = \{(J + I^n)^{\lambda} E \cap (J' + I^n)^{\mu} E\}$$
for every $n \in \mathbb{N}$. Now, pick $\alpha \in \mathbb{N}[1/p]$ such that $l/\lambda < 1 - \alpha$ and $m/\mu < \alpha$ and set $l' := (1 - \alpha)\lambda$, $m' := \alpha \mu$. If $x \in (J + I^n)^{\lambda} E \cap (J' + I^n)^{\mu} E$, we may write 
$$x = x^{(\alpha)} \cdot x^{1-\alpha} \in (J + I^n)^{(l')} \cdot (J' + I^n)^{(m')} E.$$ 
Next, to ease notation, for any finite sequence $\nu_\bullet := (\nu_1, \ldots, \nu_m)$ of elements of $\mathbb{N}[1/p]$ and any sequence $(x_1, \ldots, x_m)$ of elements of $E$, set 
$$x^{\nu_\bullet} := x_1^{\nu_1} \cdots x_m^{\nu_m} \quad \text{and} \quad |\nu_\bullet| := \nu_1 + \cdots + \nu_m.$$

We remark that the ideal $(J + I^n)^{(l')} \cdot (J' + I^n)^{(m')} E$ is generated by all products 
$$a^{\nu_\bullet}_\bullet \cdot a^{\nu_\bullet}_\bullet' \cdot b^{\nu_\bullet}_\bullet \cdot b^{\nu_\bullet}_\bullet' \quad \text{where} \quad |\nu_\bullet| + n^{-1} : |\beta_\bullet| = \lambda' \quad |\nu_\bullet'| + n^{-1} : |\beta_\bullet'| = \mu'.$$

Fix $l'', m'' \in \mathbb{N}[1/p]$ such that $l < l'' < l'$ and $m < m'' < m'$, and set $\varepsilon := (l' - l'') + (m' - m'')$; it is easily seen that each of the above products lies either in $J^{(l'')} \cdot J^{(m'')} E$ or else in $I^{(\varepsilon)} E$. Moreover, we can write $l'' = p^{-N} f$, $m'' := p^{-N} g$ for suitable $f, g, N \in \mathbb{N}$, and summing up, we conclude that, for every $\delta < p^{-N}$, the ideal $[a_\bullet]^{(\lambda)} A \cap [a_\bullet']^{(\mu)} A$ is contained in: 
$$\bigcap_{n \in \mathbb{N}} \{J^{(l'')} \cdot J^{(m'')} E + I^{(\varepsilon)} E\} = \bigcap_{n \in \mathbb{N}} \{(J^f J^{g(1/p^N)} + I^{(\varepsilon)} E) \subset \{(J^f J^{g(\delta)})\} E\}$$
where the first equality follows from lemma 9.3.70 ii.a.iii) the last inclusion follows from corollary 16.3.40(iii.b). Let us then choose $\delta, \delta' \in \mathbb{N}[1/p]$ with $p^{-N} > \delta > \delta'$ and $\delta'$ close enough to $p^{-N}$, so that $\delta' : f > l$ and $\delta' \cdot g > m$; using corollary 16.3.40(i) we get 
$$\{(J^f J^{g(\delta)})\} E \subset [a_\bullet]^{(\delta)} A \subset [a_\bullet]^{(l)} \cdot [a_\bullet']^{(m)} A$$
whence the contention. \qed
As an application, we can complement as follows theorem $16.3.21$ (i):

**Proposition 16.3.51.** In the situation of theorem $16.3.21$ we have:

- (i) $\mathbf{(16.3.12)}$ is a cartesian diagram of topological rings.
- (ii) All the topological rings appearing in $\mathbf{(16.3.12)}$ are perfectoid.

*Proof.* We know already that $\mathbf{(16.3.17)}$ is a cartesian diagram of topological rings. Moreover, it is easily seen that the $I$-adic topology on $A$ agrees with the $(I+pA)$-adic topology, and likewise for the $J$-adic and $(I+J)$-adic topologies, so all the topological rings appearing in $\mathbf{(16.3.17)}$ except possibly for $(A',\mathcal{T}')$ are perfectoid (proposition $16.3.8$(ii)). By the same token, the $IJ$-adic topology on $A$ agrees with the $(IJ+pA)$-adic topology, so the proposition will follow, once we have shown the following

**Claim 16.3.52.** The $IJ$-adic topology on $A$ agrees with the linear topology $\mathcal{T}$ defined by the cofiltered system of ideals $\langle I^n \cap J^n \mid n \in \mathbb{N} \rangle$.

*Proof of the claim.* Set $I' := I + pA$ and $J' := J + pA$, and notice that $I^{k+N} \subset I^{N+k} \subset I^{k+1}$ for every $k \in \mathbb{N}$, and likewise for $J$. Therefore, $\mathcal{T}$ agrees with the topology defined by the cofiltered system of ideals $\langle I^n \cap J^n \mid n \in \mathbb{N} \rangle$, and the $IJ$-adic topology on $A$ agrees with the $I'J'$-adic topology. Thus, we can replace $I, J$ by $I', J'$, and assume from start that $p \in I \cap J$. Now, let $(\alpha_n \mid n \in \mathbb{N})$ be any distinguished element in $\ker u_A$. Fix finite systems $\beta_\ast := (\beta_1, \ldots, \beta_k)$ and $\beta'_\ast := (\beta'_1, \ldots, \beta'_k)$ of elements of $E(A)$ such that $\overline{\alpha}_A(pA(\beta_\ast))$ (resp. $\overline{\alpha}_A(pA(\beta'_\ast))$) is a system of generators for $I/pA$ (resp. $J/pA$). In light of lemma $16.2.7$(iii), it follows that the sequence $(\overline{\alpha}_A(\alpha_0), \overline{\alpha}_A(\beta_1), \ldots, \overline{\alpha}_A(\beta_k))$ is a system of generators for $I$, and $(\overline{\alpha}_A(\beta_0), \overline{\alpha}_A(\beta'_1), \ldots, \overline{\alpha}_A(\beta'_k))$ is a system of generators for $J$. On the other hand, lemma $16.3.70$(iv) implies that the $I$-adic (resp. $J$-adic) topology on $A$ agrees with the linear topology defined by the cofiltered system of ideals $\langle (\alpha_0, \beta_\ast)^{k\times} A \mid \lambda \in \mathbb{N}[1/p] \rangle$ (resp. $\langle (\alpha_0, \beta'_\ast)^{k\times} A \mid \lambda \in \mathbb{N}[1/p] \rangle$). Then, the claim follows from corollary $16.3.49$(iii). \( \square \)

16.3.53. Let $A$ be a ring, and $a_\ast := (a_1, \ldots, a_k)$ a finite system of elements of $A$; denote by $I$ the ideal generated by $a_\ast$, and suppose that

\[(16.3.54) \quad p \in I^t \quad \text{where } t := k(p - 1) + 1.\]

Set $J := I^{(p)}$, the ideal generated by the system $(a_1^p, \ldots, a_k^p)$, and notice that

\[(16.3.55) \quad I^t \subset J\]

therefore $J$ is well defined independently of the choice of $a_\ast$ (lemma $16.2.2$). Denote by $gr_I A$ (resp. $gr_J A$) the graded ring associated with the $I$-adic (resp. $J$-adic) filtration on $A$. Notice that both these two rings are $F_p$-algebras.

**Remark 16.3.56.** Let $A$ be any $P$-ring, $I$ any ideal of definition of $A$, and $(a_1, \ldots, a_k)$ a system of generators of $I$. By virtue of lemma $16.2.3$(iii) and its proof, we may find a sequence of ideals $\langle I_n \mid n \in \mathbb{N} \rangle$ such that

- $I_{n+1} = I_n$ for every $n \in \mathbb{N}$
- $I_n$ admits a system of generators consisting of $k$ elements of $A$.

Then $I_n$ is still an ideal of definition of $A$ for every $n \in \mathbb{N}$, and $p \in I_n^t$ for every sufficiently large $n \in \mathbb{N}$, where $t$ is defined as in $16.3.53$. We may thus regard the following result as a refinement of corollary $16.3.3$.

**Proposition 16.3.57.** In the situation of $16.3.53$, the following holds:

- (i) The Frobenius endomorphism of $gr_I A$ factors through a graded ring homomorphism $\Phi_I : gr_I A \xrightarrow{\sim} gr_J A$ for every $n \in \mathbb{N}$ and $x \in I^n$. 

\[\Phi_I(x \mod I^{n+1}) := (x^p \mod J^{n+1}) \quad \text{for every } n \in \mathbb{N} \text{ and } x \in I^n.\]
(ii) Let \( \mathcal{T}_p \) be the \( p \)-adic topology on \( A \), and suppose that \( (A, \mathcal{T}_p) \) is perfectoid. Then \( \Phi_1 \) is an isomorphism.

**Proof.** (i): To begin with, we remark:

**Claim 16.3.58.** For every \( n \in \mathbb{N} \) and every \( x, y \in I^n \), we have \( (x + y)^p - x^p - y^p \in J^{n+1} \).

**Proof of the claim.** The difference in the claim is a sum of terms that lie in \( pI^{pn} \). Taking into account (16.3.54), we see that \( pI^{pn} \subset I^{1+pn} \), so it remains only to check that

\[
I^{1+pn} \subset J^{n+1}.
\]

We argue by induction on \( n \), and notice that the case where \( n = 0 \) is (16.3.55). Hence, suppose that \( r > 0 \), and that the sought inclusion has already been checked for \( n := r - 1 \). The ideal \( I^{1+pr} \) is generated by all elements of the form \( b := \prod_{j=1}^{1+pr} a_{\varphi(j)} \), where \( \varphi \) is any mapping \( \{1, \ldots, t + pr\} \rightarrow \{1, \ldots, k\} \). Since \( r \geq 0 \), it is easily seen that there exists at least one index \( i \in \{1, \ldots, k\} \) such that \( \varphi^{-1}(i) \) has cardinality \( \geq p \). For such index \( i \), we have \( b = a_i^p \cdot c \), where \( c \in I^{1+pn} \), and the inductive assumption says that \( c \in J^{n+1} \), whence \( b \in J^{r+1} \), as required. \( \diamond \)

Let us now check that if \( x \in I^n \), then \( x^p \in J^n \). Indeed, the assertion is clear if \( x \) is a monomial \( \prod_{i=1}^{n} a_{\varphi(j)} \) for some mapping \( \varphi : \{1, \ldots, n\} \rightarrow \{1, \ldots, k\} \). However, we may write \( x = x_1 + \cdots + x_r \) for some \( r \in \mathbb{N} \) and a sequence \( x_1, \ldots, x_r \) of such monomials. Lastly, claim 16.3.58 and an easy induction on \( r \) shows that \( x^p = \sum_{j=1}^{r+1} x_j^p \in J^{n+1} \), whence the contention. Thus, the map \( \Phi_1 \) is well defined, and claim 16.3.58 also shows that \( \Phi_1(x+y) = \Phi_1(x) + \Phi_1(y) \) for every \( x, y \in \mathfrak{g} I^p A \). For any such \( x \) and \( y \) it is also clear that \( \Phi_1(xy) = \Phi_1(x) \cdot \Phi_1(y) \), so \( \Phi_1 \) is a ring homomorphism.

(ii): Set \( E := E(A) \), and let \( \alpha := (a_n \mid n \in \mathbb{N}) \) be a distinguished element in \( \text{Ker} \, u_A \); arguing as in the proof of lemma (16.2.7)(i), we may assume that for every \( i = 1, \ldots, k \) we have \( a_i = \pi_A(\beta_i) \) for some \( \beta_i \in E \). Denote by \( J \subset E \) the ideal generated by \( (\beta_1, \ldots, \beta_k) \), and set \( \mathcal{J} := \mathcal{J}^{(p)} \), the ideal generated by \( (\beta_{1}^{p}, \ldots, \beta_{k}^{p}) \); from (16.3.54) and lemma 16.1.9(ii) we get (16.3.59)

\[
\alpha_0 \in \mathcal{J}^{1} \subset E.
\]

Let \( \mathfrak{g} \mathcal{J} \) and \( \mathfrak{g} \mathcal{J}^{p} \) be the graded rings associated with the \( \mathcal{J} \)-adic and \( \mathcal{J}^{p} \)-adic filtrations on \( E \).

**Claim 16.3.60.** (i) For every \( n \in \mathbb{N} \) we have:

(a) The inclusion \( \mathcal{J}^{n+1} \subset \mathcal{J}^{n} \) is \( \alpha_0^{1/p} \)-taut, and the inclusion \( \mathcal{J}^{n+1} \subset \mathcal{J}^{n} \) is taut.

(b) \( \{ \mathcal{J}^{n} \} = I^n \) and \( \{ \mathcal{J}^{n} \} = J^n \).

(ii) The map \( \pi_A : E(A) \rightarrow A \) induces graded ring isomorphisms

\[
\mathfrak{g} \mathcal{J}^{p} \cong \mathfrak{g} I^{p} \quad \mathfrak{g} \mathcal{J}^{p} \cong \mathfrak{g} \mathcal{J}^{p}.
\]

**Proof of the claim.** (i.a): Clearly \( \mathcal{J} = \Phi_E(\mathcal{J}) \), therefore it suffices to prove the assertion for \( \mathcal{J} \); however \( \alpha_0 \cdot \Phi_E^{1}(\mathcal{J}^{np}) = \alpha_0 I^{np} \subset \mathcal{J}^{t+np} \) by (16.3.59), and arguing as in the proof of claim 16.3.58 we see that \( \mathcal{J}^{t+np} \subset J^{n+1} \), whence the claim.

(i.b): We consider first the assertion for \( \mathcal{J}^{n} \). By construction, it is clear that \( a_i \in \{ \mathcal{J} \} \) for every \( i = 1, \ldots, k \), hence \( I^n \subset \{ \mathcal{J}^{n} \} \). On the other hand, since \( A \) is endowed with its \( p \)-adic topology, \( E \) carries the \( \alpha_0 \)-adic topology (see (16.2.19)), therefore \( \mathcal{J}^{n} \) is open in \( E \), and consequently \( \{ \mathcal{J}^{n} \} \) is the ideal generated by the system \( \{ \pi_A(x) \mid x \in \mathcal{J}^{n} \} \) (remark 16.3.28(viii)). Thus, we come down to checking that \( \pi_A(x) \in I^n \) for every \( x \in \mathcal{J}^{n} \). This is clear in case \( x \) is a monomial of the form \( \prod_{j=1}^{n} a_{\varphi(j)} \) for some mapping \( \varphi : \{1, \ldots, n\} \rightarrow \{1, \ldots, k\} \). In general, \( x \) shall be a finite sum \( x_1 + \cdots + x_s \), where \( x_1, \ldots, x_s \) are monomials of this type. According to proposition 9.3.63, \( \tau_A(x) \) can then be expressed as a \( p \)-adically convergent series \( \sum_{r \in \mathbb{N}} p^r \cdot y_r \), where each \( y_r \) is in turn a finite sum of terms of the form
$w \cdot \tau_A(z)$, for certain $w \in \mathbb{Z}_p$ and $z \in \Phi^-_E(A^n)^r$. In view of (i; A) and remark \[16.3.28\] vi, we have

$$\alpha_0^r/p \cdot \Phi^-_E(A^n)^r \subset A^n$$

for every $r, n \in \mathbb{N}$.

Pick $\pi \in A$ as in lemma \[16.2.3\] iv; recalling lemma \[16.2.7\] iii, we deduce that

$$\pi^r \cdot \pi_A(z) \in \pi^{(p-1)r} \cdot \{A^n + r\} \quad \text{for every } r \in \mathbb{N} \text{ and every } z \in \Phi^-_E(A^n)^r.$$

Since $\{A^n + r\}$ is closed in the $p$-adic topology of $A$ for every $n, r \in \mathbb{N}$, it follows that $\{A^n\} \subset I^n + \pi^{(p-1)r} \{A^n + r\}$ for every $r \in \mathbb{N}$. But clearly $\pi^{(p-1)r} \subset I^n$ for every large enough $r \in \mathbb{N}$, so $\{A^n\} \subset I^n$, as required.

To deal with $A^n$, we repeat the foregoing argument, to get $\{A^n\} \subset J^n + \{A^n + r\}$ for every $r \in \mathbb{N}$. However, clearly $\{A^n + r\} \subset \{A^n\}$; taking into account the previous case, we conclude that $\{A^n\} \subset J^n + I^s$ for every $s \in \mathbb{N}$. But we may find $s \in \mathbb{N}$ large enough, so that $I^s \subset J^n$, so at last $\{A^n\} \subset J^n$, whence the claim.

(ii) follows immediately from (i) and theorem \[16.3.3\] ii).

Claim \[16.3.6\] ii) yields a commutative diagram of graded rings

$$\begin{array}{ccc}
\text{gr}_\pi & \to & \text{gr}_\pi A \\
\downarrow & & \downarrow \Phi_I \\
\text{gr} & \to & \text{gr}_I A
\end{array}$$

whose horizontal arrows are isomorphisms, and whose left vertical arrow is induced by $\Phi_E$. Now, since $E$ is perfect, the left vertical arrow is an isomorphism, so the same holds for the right vertical arrow, as stated.

**Corollary 16.3.61.** Let $A$ be a perfectoid ring, and $\beta \in E(A)$ any element.

(i) $A$ is a reduced ring.

(ii) If $\beta \neq 0$, then $\pi_A(\beta) \neq 0$.

(iii) If the topology of $A$ is discrete, then $A$ is an $F_p$-algebra.

**Proof.** (i): Suppose that $A$ contains a nilpotent element $x \neq 0$, and let $n > 1$ be the smallest integer such that $x^n = 0$; set $y = x^{n-1}$, so that $y \neq 0$ and $y^n = 0$. By remark \[16.3.5\] we can find an ideal of definition $I$ of $A$ fulfilling condition (16.3.54); we set $J := I^{(p)}$ and let $\Phi_I : \text{gr}_\pi A \sim \text{gr}_I A$ be the isomorphism of proposition \[16.3.7\] ii). Let also $r \in \mathbb{N}$ be the largest integer such that $y \in I^r$, and denote by $\bar{y} \in \text{gr}_I A$ the class of $y$, so that $\bar{y} \neq 0$; but clearly $\Phi_I(\bar{y}) = 0$, a contradiction.

(ii) and (iii) are immediate consequences of (i).

**Theorem 16.3.62.** In the situation of (16.3.53), let $\mathcal{T}_I$ be the $I$-adic topology on $A$, and suppose that $(A, \mathcal{T}_I)$ is a $P$-ring. Define also the graded ring homomorphism $\Phi_I$ as in proposition \[16.3.7\] i). Then the following conditions are equivalent:

(a) $(A, \mathcal{T}_I)$ is perfectoid.

(b) The map $\Phi_I$ is an isomorphism.

**Proof.** Suppose that (a) holds, and let $\mathcal{T}_p$ be the $p$-adic topology on $A$; then $(A, \mathcal{T}_p)$ is perfectoid, by proposition \[16.3.8\] i), in which case proposition \[16.3.7\] ii) says that (b) holds.

Next, suppose that (b) holds; then proposition \[16.2.9\] and example \[16.3.2\] i) say that $E := E(A)$ is a perfectoid ring. Moreover, $\pi_{A/pA}$ is surjective (lemma \[16.2.7\] i)), so for every $i = 1, \ldots, k$ we may find $\beta_i \in E$ such that $\pi_{A/pA}(\beta_i)$ equals the image of $a_i$ in $A/pA$. Denote by $\mathcal{J} \subset E$ the ideal generated by the system $(\beta_1, \ldots, \beta_k)$; from claim \[16.2.10\] we see that $\mathcal{J}$ is an ideal of definition of $E$, and $\pi_{A/pA}$ induces a ring isomorphism

\[(16.3.63) \quad \frac{E}{\mathcal{J}} \sim A/I.\]
Denote by $\mathcal{J}_W \subset W(E)$ the ideal generated by $(\tau_E(\beta_1), \ldots, \tau_E(\beta_k))$; by construction we have $u_A(\tau_E(\beta_i)) - a_i \in pA$ for every $i = 1, \ldots, k$, and notice that $p \in I^1 \subset I^2$, so $\mathcal{J}_W A + I^2 = I$ and Nakayama’s lemma yields

\[(16.3.64)\quad \mathcal{J}_W A = I.\]

Furthermore, recall that $\mathcal{J} := \text{Ker } u_A$ contains a distinguished element $\alpha$ of $W(E)$ (lemma [16.2.7](ii)); on the other hand, (16.3.64) and (16.3.54) imply that $p \in \mathcal{J}_W A$, in which case we may apply lemma [16.1.9](i) to get an element $\alpha' := (\alpha_n) \in J$ such that $\alpha' \in \mathcal{J}$ and $\alpha' \in E^\times$. Especially, $\alpha$ is a distinguished element of $W(E)$, and so the ring

\[B := W(E)/\alpha W(E)\]

is perfectoid, for the quotient topology arising from the natural projection $W(E) \to B$ (example [16.3.2](ii)). By construction, $u_A$ factors through a surjective and continuous ring homomorphism

\[v : B \to A.\]

Moreover, set $I_B := \mathcal{J}_W B \subset B$, and notice that on the one hand, $u_B \circ \tau_E(\alpha') = pt$ for some $t \in B^\times$ (lemma [16.2.7](iii)), and on the other hand we have $u_B \circ \tau_E(\alpha') \in I_B$, so

\[(16.3.65)\quad p \in I_B.\]

Combining with proposition [9.3.78](ii), we deduce that $I_B$ is an ideal of definition of $B$, and taking into account (16.3.64), we also get

\[(16.3.66)\quad v(I_B) = I.\]

Set $J_B := I_B^{(p)}$; from (16.3.65), (16.3.66) and propositions [16.3.57](ii) and [16.3.8](i) we then get a commutative diagram of graded ring homomorphisms

\[
\begin{array}{ccc}
g_{J_B} B & \longrightarrow & g_{J_B} A \\
\downarrow & & \downarrow \\
g_{J_B} B & \longrightarrow & g_{J_B} A
\end{array}
\]

both of whose vertical arrows are isomorphisms, and whose horizontal arrows are induced by $v$. Since $B$ is complete and separated for its $I_B$-adic topology, and $A$ is complete and separated for its $I$-adic topology, the theorem will follow from:

**Claim** 16.3.68. The map $v$ induces a ring isomorphism $v_n : B/I_B^{(p^n)} \to A/I^{(p^n)}$ for every $n \in \mathbb{N}$.

**Proof of the claim.** We argue by induction on $n$. For $n = 0$, notice that the projection $W(E) \to B/I_B$ factors through $E$, and by construction, the kernel of the resulting surjection is $\mathcal{J}$. Then the assertion follows from (16.3.63). Next, suppose that $n \geq 0$, and that $v_n$ is an isomorphism. In this case, $v$ induces isomorphisms $g_{J_B} B \cong g_{J_B} A$ for every $r < p^n$. Due to (16.3.67), we then deduce that $v$ also induces isomorphisms $gr_{J_B}^r B \cong gr_{J_B}^r A$ for every $r < p^n$, from which it follows easily that $v$ induces an isomorphism $B/I_B^{(p^n)} \cong A/I^{(p^n)}$. However, clearly $J \subset I^n$ and $J_B \subset I_B^{(p)}$, hence $J_B^{(p^n)} \subset I_B^{(p^{n+1})}$ and $J B^{(p^n)} \subset I^{(p^{n+1})}$, so finally $v_{n+1}$ is an isomorphism.

As a corollary of theorem [16.3.62] we obtain the following criterion:

**Corollary** 16.3.69. Let $A$ be a ring, $n \in \mathbb{N}$ any integer, $\beta := (b_n \mid n \in \mathbb{N})$ an element of $E(A)$; suppose that $A$ is complete and separated for its $b_n$-adic topology $\mathcal{T}_0$, and $p = ab_0$ for some $a \in A$. Let also $J := \bigcup_{n \in \mathbb{N}} b_n A$. Consider the following conditions:

(a) $A/J$ is a perfect $\mathbb{F}_p$-algebra.

(b) The Frobenius endomorphism of $A/b_l^2 A$ induces a bijection $b_{l+1} A/b_{l+1}^2 A \cong b_l A/b_l^2 A$. 

(c) $\text{Ann}_A(b_0) = \text{Ann}_A(b_n)$ for every $n \in \mathbb{N}$.

(d) The Frobenius endomorphism $\Phi_{A/b_i}$ of $A/b_i A$ induces an isomorphism

$$\overline{\Phi}_{A/b_i A} : A/b_{i+1} A \sim A/b_i A \quad \text{for every } i \in \mathbb{N}.$$ 

(e) $(A, T_0)$ is a perfectoid ring.

Then (e) is equivalent to the conjunction of (a), (b), and (c), and also to the conjunction of (c) and (d). Moreover, if (e) holds, then $A/\text{Ann}_A(b_0)$ is perfectoid for the $b_0$-adic topology, and the map $\overline{\text{Ann}}_A : E(A) \to A$ induces an isomorphism of $E(A)$-modules:

\begin{equation}
\text{Ann}_{E(A)}(\beta) \sim \text{Ann}_A(b_0).
\end{equation}

Proof. Suppose first that (a), (b), (c) hold. For every $i, j > 0$, consider the commutative diagram

$$b_{i-1}^{-1} A/b_i A \xrightarrow{f_{i,j}} b_i^{-1} A/b_i^{-1} A \xrightarrow{\varphi_{i,j}} b_i^{-1} A/b_i^{-1} A \xrightarrow{\varphi_{i,j}} b_{i-1}^{-1} A/b_{i-1}^{-1} A$$

where $\varphi_{i,j}$ is induced by the Frobenius endomorphism of $A/p A$ for every $i, j \in \mathbb{N}$ with $i > 0$, and $f_{i,j}$ is induced by scalar multiplication by $b_i$ for every $i, j \in \mathbb{N}$ with $j > 0$. We notice:

Claim 16.3.71. (i) $f_{i,j}$ is an isomorphism for every $i, j \in \mathbb{N}$ with $j > 1$.

(ii) $\varphi_{i,1}$ is an isomorphism for every $i > t$.

Proof of the claim. (i): The surjectivity of $f_{i,j}$ is clear. For the injectivity, suppose that $x = b_{i-1}^{-1} y$ and $b_i x = b_i^{-1} z$ for some $y, z \in A$. It follows that $b_i y = b_i^{-1} z$, so $b_i (y - b_i z) = 0$, and therefore also $b_i (y - b_i z) = 0$, by (c). Since $j > 1$, we deduce that $x = b_i z$, whence the assertion.

(ii): We argue by induction on $i$. The case $i = t + 1$ is (b). Suppose then that $i > t$ and that the surjectivity of $\varphi_{i,1}$ is already known. This means that for every $x \in A$ there exist $y, z \in A$ such that $b_{i-1} x = b_{i-1} y + b_i^{-1} z$, i.e. that $b_{i-1} (x - y p - b_{i-1} z) = 0$. By assumption (c), we deduce that $b_i (x - y p - b_{i-1} z) = 0$. Set $z' := b_i^{-1} z$; then $b_i (x - y p - b_i z') = 0$, i.e. $b_i x = b_i y + b_i^{-1} z'$, whence the surjectivity of $\varphi_{i+1,1}$.

The injectivity of $\varphi_{i,1}$ means the following. For every $x \in A$ such that $b_{i-1} x p \in b_i^{-1} A$ we have $b_i x \in b_i^{-1} A$. Now, let $a \in A$, and suppose that $b_i a p \in b_i^{-1} A$; then $b_{i-1} (b_i^{-1} a p) = b_i^{2p-1} a p \in b_{i-1}^{-1} A$, so that $b_i^{2p-1} a = b_i b_{i-1}^{-1} a \in b_i^{-1} A$. Say that $b_i^{2p-1} a = b_i^{-1} b_i^p y$; then

$$b_i^{2p^2-1} (b_i a - b_i b_i^p y) = 0.$$ 

By assumption (c), it follows that $b_i^{2p^2-1} (b_i a - b_i b_i^p y) = 0$ as well, and therefore $b_i a \in b_i^{-1} A$, hence $\varphi_{i+1,1}$ is injective.

From claim [16.3.71] it follows immediately that $\varphi_{i,j}$ is an isomorphism for every $i > t$ and every $j > 0$. Notice now that $(A, T_0)$ is a P-ring, and $I := b_i A$ is an ideal of definition of $A$, for every $i > 0$, due to assumptions (a) and (b); moreover, any such $I$ fulfills the conditions of (16.3.53). In light of theorem [16.3.62] it then suffices to show that $\overline{\Phi}_{A/b_i A}$ is bijective for every $i > t$. This aim, from the snake lemma and assumption (a), we are easily reduced to checking that $\Phi_{A/b_i A}$ induces a bijection $J/b_i A \sim J/b_{i-1} A$ for every $i > t$. Then, since $J$ is the union of its subideals $b_k A$ (for all $k \in \mathbb{N}$), we are further reduced to checking that $\Phi_{A/b_k A}$ induces a bijection $b_k A/b_i A \sim b_{k-1} A/b_{i-1} A$ for every $k \geq i$. By considering the filtration

$$0 \subset b_{i+1} A/b_i A \subset b_{i+2} A/b_i \subset \cdots \subset b_k A/b_i A$$

an easy induction then reduces to the case where \( k = i + 1 \). Lastly, a similar induction argument, using the filtration \( 0 \subset b_{i+1}^p / b_i \subset b_{i+1}^{p-2} / b_i \subset \cdots \subset b_{i+1} / b_i \) further reduces the assertion to the surjectivity of \( \varphi_{i,j} \) for every \( j = 1, \ldots, p - 1 \), which is already known, by the foregoing.

Conversely, if (e) holds, then we get both (b) and (d), by virtue of proposition [16.3.57], then, notice that the direct limit of the system of maps \( (\overline{\Phi}_A/b_{i+1}A \mid i \geq t) \) is the Frobenius endomorphism of \( A/J \), whence (a). Next, let \( x \in A \) with \( b_0x = 0 \); it follows that \( (b_nx)^{p^n} = 0 \) for every \( n \in \mathbb{N} \), and since \( A \) is reduced (corollary [16.3.61](i)), we get \( b_nx = 0 \), whence (c).

Lastly, suppose that (c) and (d) hold; then we get a commutative diagram whose horizontal arrows are restrictions of \( \Phi_A/b_0A \), and are therefore bijections:

\[
\begin{array}{ccc}
  b_{t+1}^2A/b_1A & \xrightarrow{\sim} & b_t^2A/b_0A \\
  j_{t+1} \downarrow & & \downarrow j_t \\
  b_{t+1}A/b_1A & \xrightarrow{\sim} & b_tA/b_0A
\end{array}
\]

and whose vertical arrows are the natural injections; hence, we get an induced isomorphism \( \text{Coker } j_{t+1} \xrightarrow{\sim} \text{Coker } j_t \), whence (b). It has already been remarked that (d) implies (a), so the proof of the stated equivalences is complete.

Next, suppose that \( A \) is perfectoid, so all conditions (a), \ldots, (e) hold, and let us notice that

\[
(16.3.72) \quad \text{Ann}_A(b_0) \cap b_nA = 0 \quad \text{for every } n \in \mathbb{N}.
\]

Indeed, if \( x \in A \) and we have \( b_0 \cdot (b_nx) = 0 \), then \( b_nx = 0 \) by (c). This means that \( \mathcal{S}_0 \) induces the discrete topology on \( \text{Ann}_A(b_0) \), so \( \overline{A} := A/\text{Ann}_A(b_0) \) is complete and separated for its \( b_0 \)-adic topology. Consider now the commutative diagram:

\[
\begin{array}{ccc}
  A/b_{t+1}A & \xrightarrow{\overline{\Phi}_A/b_{t+1}A} & A/b_tA \\
  f_{1,t+1} \downarrow & & \downarrow f_{1,t} \\
  b_{t+1}A/b_{t+1}^2A & \longrightarrow & b_tA/b_t^2A
\end{array}
\]

whose left (resp. right) vertical arrow is induced by multiplication by \( b_{t+1} \) (resp. by \( b_t \)), and whose top (resp. bottom) horizontal arrow is induced by the Frobenius endomorphism of \( A/b_tA \) (resp. of \( A/b_t^2A \)). Due to (b), (d) and (16.3.72), we see that \( \overline{\Phi}_A/b_{t+1}A \) restricts to a bijection

\[
\text{Ann}_A(b_{t+1}) = \text{Ker } f_{1,t+1} \xrightarrow{\sim} \text{Ker } f_{1,t} = \text{Ann}_A(b_t)
\]

and combining with (c) we deduce that the Frobenius endomorphism of \( A/b_tA \) restricts to a bijection \( \text{Ann}_A(b_i) \xrightarrow{\sim} \text{Ann}_A(b_0) \) for every \( i \in \mathbb{N} \). Then, using (d) we conclude that the Frobenius endomorphism of \( \overline{A}/b_tA \) induces an isomorphism \( \overline{\Phi}_A/b_tA : \overline{A}/b_{t+1}A \xrightarrow{\sim} \overline{A}/b_tA \) for every \( i \in \mathbb{N} \). Lastly, it is easily seen that \( \text{Ann}_A(b_i) = 0 \) for every \( i \in \mathbb{N} \). Summing up, we have shown that the ring \( \overline{A} \) fulfills conditions (c) and (d), so it is perfectoid for its \( b_0 \)-adic topology, by the foregoing. Now, by virtue of (16.3.72), we may naturally identify \( \text{Ann}_A(b) \) with its image in \( A/b_0A \), and likewise one easily sees that \( \text{Ann}_{E(A)}(\beta) \cap \beta E(A) = 0 \), hence we may identify \( \text{Ann}_{E(A)}(\beta) \) with its image in \( E(A)/\beta E(A) \). By claim [16.3.60](ii), we have a commutative diagram of \( A_0/b_0A \)-modules

\[
\begin{array}{ccc}
  E(A)/\beta E(A) & \longrightarrow & \beta E(A)/\beta^2 E(A) \\
  \downarrow & & \downarrow \\
  A/b_0A & \longrightarrow & b_0A_0/b_0^2A_0
\end{array}
\]
whose top (resp. bottom) horizontal arrow is induced by multiplication by \( \beta \) (resp. by \( b_0 \)), and whose vertical arrows are induced by \( \overline{\pi}_A \). To conclude, it suffices to remark that the kernel of the top (resp. bottom) horizontal arrow is \( \text{Ann}_{E(A)}(\beta) \) (resp. \( \text{Ann}_{A}(b_0) \)).

Let us point out the following variant of corollary 16.3.69:

**Corollary 16.3.73.** Let \( A \) be a ring, \( b \in A \) an element such that \( p \in b^p A \), and such that the \( b \)-adic topology \( \mathcal{T} \) of \( A \) is complete and separated. Then \( (A, \mathcal{T}) \) is perfectoid if and only if the following two conditions hold:

1. The Frobenius endomorphism \( \Phi_{A/b^p A} \) of \( A/b^p A \) induces a bijection \( A/bA \cong A/b^p A \).
2. \( \text{Ann}_{A}(b^p) = \text{Ann}_{A}(b^{p-1}) \).

**Proof.** If \( A \) is perfectoid, then \( \overline{\pi}_{A/pA} : E(A) \to A/pA \) is surjective (lemma 16.2.7(i)), so there exists \( (b_n \mid n \in \mathbb{N}) \in E(A) \) such that \( b_0 - b \in pA_0 \), and it follows easily that \( b_0/b \in A^\times_0 \). Thus, we may replace \( b \) by \( b_0 \), in which case the assumptions of corollary 16.3.69 are fulfilled, and we deduce that both (a) and (b) hold.

Conversely, if (a) holds, then \( A \) is a \( B \)-ring, and if also (b) holds, arguing as in the foregoing we may again assume that \( b = b_0 \) for some \( (b_n \mid n \in \mathbb{N}) \in E(A) \); then we have, more generally:

**Claim 16.3.74.** If (a) holds and there exists \( t \in \mathbb{N} \) such that \( \text{Ann}_{A}(b^p) = \text{Ann}_{A}(b^p/b_1) \), then \( A \) is perfectoid.

**Proof of the claim.** In light of theorem 16.3.62 it suffices to show that the Frobenius endomorphism of \( A/b_iA \) induces bijections

\[ \Phi_i : \text{gr}_i(t+1) := b_{i+1}^t A/b_{i+1}^{t+1} A \cong \text{gr}_i(t) := b_i^t A/b_i^{t+1} A \quad \text{for every } i \in \mathbb{N}. \]

However, (a) easily implies that \( \Phi_i \) is an isomorphism for every \( i = 0, \ldots, p^{t+1} - 1 \). We then argue by induction on \( i \geq p^{t+1} - 1 \). Thus suppose that \( \Phi_i \) is an isomorphism for such \( i \); we consider the commutative diagram

\[
\begin{array}{ccc}
\text{gr}_i(t+1) & \xrightarrow{\Phi_i} & \text{gr}_i(t) \\
\downarrow \overline{\pi}_{i+1} & & \downarrow \overline{\pi}_i \\
\text{gr}_i(t+1) & \xrightarrow{\Phi_{i+1}} & \text{gr}_{i+1}(t) 
\end{array}
\]

whose vertical arrows are induced by scalar multiplication by \( b_{i+1} \) and respectively \( b_i \). Clearly both vertical arrows are surjections; thus, we are reduced to checking that \( \overline{\pi}_i \) is injective. Hence, say that for some \( a \in A \), the class of \( b_i^t a \) in \( \text{gr}_i(t) \) lies in the kernel of \( \overline{\pi}_i \); this means that there exists \( c \in A \) with \( b_i^{t+1} a = b_i^{t+2} c \), so that \( b_i^{t+1}(a - b_i c) = 0 \), and since \( i + 1 \geq p^{t+1} \), our assumption easily implies that \( b_i^t(a - b_i c) = 0 \) as well. So, the class of \( b_i^t a \) vanishes in \( \text{gr}_i(t) \), as required.

Proposition 16.3.8 shows that the completion of a perfectoid ring for the topology defined by a \( p \)-adically open and finitely generated ideal, is again perfectoid for the \( p \)-adic topology. We now wish to prove that the same still holds for a general finitely generated ideal.

16.3.75. Namely, let \( A \) be a perfectoid ring, \( I \subset A \) (resp. \( J \subset E := E(A) \)) a finitely generated ideal such that the topology of \( A \) (resp. of \( E \)) agrees with the \( I \)-adic topology \( \mathcal{T}_I \) (resp. with the \( J \)-adic topology \( \mathcal{T}_J \)). Let also \( \beta_n := \beta_n(\beta_1, \ldots, \beta_n) \) be any finite system of elements of \( E \) and \( J \subset E \) (resp. \( J \subset A \)) the ideal generated by \( \beta_n \) (resp. by \( \overline{\pi}_A(\beta_1), \ldots, \overline{\pi}_A(\beta_n) \)). Denote by \( \mathcal{T}_J \) (resp. \( \mathcal{T}_J \)) the \( J \)-adic on \( A \) (resp. the \( J \)-adic topology on \( E \)), and let

\[ (A_J, \mathcal{T}_J) \quad \text{and} \quad (E_J, \mathcal{T}_J). \]
respectively the completion of \((A, \mathcal{I}_I)\) and of \((E, \mathcal{I}_J)\). Lastly, let \(\mathcal{I}_J^\wedge\) (resp. \(\mathcal{I}_J^\wedge\)) be the \(IA_J^\wedge\)-adic topology on \(A_J^\wedge\) (resp. the \(IE_J^\wedge\)-adic topology on \(E_J^\wedge\)).

**Theorem 16.3.76.** In the situation of (16.3.75), the following holds:

(i) \((A_J^\wedge, \mathcal{I}_J^\wedge)\) is perfectoid.

(ii) There is a natural isomorphism of topological rings \(E(A_J^\wedge, \mathcal{I}_J^\wedge) \cong (E_J^\wedge, \mathcal{I}_J^\wedge)\).

**Proof.** Let \(J_A \subset A := W(E)\) be the ideal generated by \(\tau_E(\beta_1), \ldots, \tau_E(\beta_n)\), set \(J_A^\prime := J_A + pA\) and denote by \(A_J^\prime\) (resp. \(A_J^\prime\)) the \(J_A\)-adic (resp. \(J_A^\prime\)-adic) completion of \(A\). Moreover, pick any finite system of generators \((\gamma_1, \ldots, \gamma_k)\) for \(\mathcal{I}\), let \(I_A \subset A\) be the ideal generated by the system \((p, \tau_E(\gamma_1), \ldots, \tau_E(\gamma_k))\), and denote by \(\mathcal{I}_I^\wedge\) indifferently the \(I_A\)-adic topologies on \(A_J^\wedge\) and on \(A_J^\prime\), and by \(\mathcal{I}_I^\wedge\) the \(I_A\)-adic topology on \(A_J^\wedge\). With this notation, we have natural isomorphisms of topological \(A\)-algebras

\[
W(E_J^\wedge, \mathcal{I}_J^\wedge) \cong (A_J^\wedge, \mathcal{I}_J^\wedge, A) \quad \text{and} \quad W(E_J^\wedge, \mathcal{I}_J^\wedge) \cong (A_J^\prime, \mathcal{I}_J^\wedge, A)
\]

(proposition 9.3.78 (ii) and lemma 9.3.33 (iv)). On the other hand, since the \(J_A\)-adic topology is finer than the \(J_A^\prime\)-adic topology, the completion map \(A \rightarrow A_J^\prime\) factors through a unique map of \(A\)-algebras

\[
A_J^\prime \rightarrow A_J^\wedge.
\]

**Claim 16.3.79.** The map (16.3.78) is a ring isomorphism.

**Proof of the claim.** Quite generally, consider any abelian group \(M\), endowed with two topologies \(\mathcal{I}\) and \(\mathcal{I}'\) defined by cofiltered systems of subgroups \((M_\lambda, \mu \in \Lambda)\) respectively \((M_\mu' | \mu \in \Lambda')\). Endow each quotient \(Q_\lambda := M/M_\lambda\) with the quotient topology \(\mathcal{I}_\lambda\) induced by \(\mathcal{I}\) via the projection map \(M \rightarrow Q_\lambda\), and suppose moreover that \(\mathcal{I}\) is finer than \(\mathcal{I}'\) and \((Q_\lambda, \mathcal{I}_\lambda)\) is separated and complete for every \(\lambda \in \Lambda\). Then it follows that the natural map

\[
(M, \mathcal{I})^\wedge \rightarrow (M, \mathcal{I}')^\wedge
\]

(that extends the completion map \(M \rightarrow (M, \mathcal{I})^\wedge\), is an isomorphism of abelian groups. Indeed, clearly the family \((M_\lambda, \mu \in \Lambda, \mu \in \Lambda')\) is still a fundamental system of open neighborhoods of zero in \(M\) for the topology \(\mathcal{I}'\), so we have natural isomorphisms

\[
(M, \mathcal{I}')^\wedge \cong \lim_{(\lambda, \mu) \in \Lambda \times \Lambda'} M/(M_\lambda + M_\mu') \cong \lim_{\lambda \in \Lambda} \lim_{\mu \in \Lambda'} M/(M_\lambda + M_\mu') \cong \lim_{\lambda \in \Lambda} (Q_\lambda, \mathcal{I}_\lambda)^\wedge
\]

(where the second isomorphism follows from example 1.5.14 (ii)) but \((Q_\lambda, \mathcal{I}_\lambda)^\wedge = Q_\lambda\) under the current assumptions, whence the assertion.

Recall now that the family \((W(J^{(h)}) | \lambda \in \mathbb{N}[1/p])\) is a fundamental system of open neighborhoods of zero in \(W(J^{(h)})\), and hence \((W(J^{(h)}) | \lambda \in \mathbb{N}[1/p])\) is a fundamental system of open neighborhoods of zero in \(J_A\)-adic topology on \(A\) (proposition 9.3.78 (i) and lemma 9.3.33 (iv)). In view of the foregoing, the claim will then follow, once we have shown that the quotients \(A/W(J^{(h)})\) are complete and separated for the \(J_A\)-adic topology. Moreover, it is clear that \(J_A\)-adic topology on \(A/W(J^{(h)})\) agrees with the \(p\)-adic topology, so – taking into account proposition 9.3.45 (ii) – we come down to checking that \(W(J^{(h)})\) is a closed ideal for the \(p\)-adic topology \(\mathcal{I}_p\) on \(A\). But notice that if \(\mathcal{I}_p\) denotes the discrete topology on \(E\), then \(W(E, \mathcal{I}_p) = (A, \mathcal{I}_p, A)\), so the assertion is a special case of remark 9.3.28 (iv).

**Claim 16.3.80.** \((E_J^\wedge, \mathcal{I}_J^\wedge)\) is perfectoid.

**Proof of the claim.** Since \(E\) is a perfect topological ring, the same holds for \((E, \mathcal{I}_p)\), hence also for \((E_J^\wedge, \mathcal{I}_J^\wedge)\) (remark 9.4.9 (v) and example 9.3.49 (ii)), and by the same token, \((E_J^\wedge, \mathcal{I}_J^\wedge)\) is a perfect topological \(\mathbb{Z}_p\)-algebra. By example 16.3.2 (i), it then remains only to check that the topology \(\mathcal{I}_J^\wedge\) is complete and separated. However, since \(E\) is complete and separated for
the $\mathcal{I}$-adic topology, $E^\wedge_{\mathcal{I}}$ is complete and separated for the $(\mathcal{I} + \mathcal{J})$-adic topology (lemma 16.3.15(ii.b)) and then the assertion follows from lemma 8.3.12.

Let $\alpha := (\alpha_n \mid n \in \mathbb{N}) \in \text{Ker } u_A$ be any distinguished element; clearly $\alpha$ is still distinguished in $W(E^\wedge_{\mathcal{J}}, \mathcal{F}^\wedge_{\mathcal{J}})$, hence $W(E^\wedge_{\mathcal{J}}, \mathcal{F}^\wedge_{\mathcal{J}}) \otimes_A A$ is perfectoid (example 16.3.2(ii)). From (16.3.77) and claim 16.3.79 we deduce that both (i) and (ii) will follow, once we have shown

**Claim 16.3.81.** There is a natural isomorphism of topological rings:

$$(A^\wedge_{\mathcal{J}}, \mathcal{F}^\wedge_{A, \mathcal{J}}) \otimes_A A \xrightarrow{\sim} (A^\wedge_{\mathcal{J}}, \mathcal{F}^\wedge_{\mathcal{J}}).$$

**Proof of the claim.** By construction, the $J_A$-adic topology induces the $J$-adic topology on $A$, via the projection $u_A : A \to A$. Therefore, $u_A$ extends to a surjective map $u_A^\wedge : A^\wedge_J \to A^\wedge_J$ whose kernel is the topological closure of $\alpha A$ in the $J_A$-adic topology of $A^\wedge_J$ (proposition 8.2.13(i.v) and lemma 8.3.32(iv)). On the other hand, by proposition 9.3.78(ii) and lemma 16.2.7(i), the $I_A$-adic topology on $A$ induces the $I$-adic topology on $A$ via $u_A$, so the topology $\mathcal{F}^\wedge_{I, A}$ induces the topology $\mathcal{F}^\wedge_{I, J}$ on $A^\wedge_J$, via $u_A$. Thus, we are reduced to checking that $\alpha A^\wedge_J$ is a closed ideal in the $J_A$-adic topology of $A^\wedge_J$. By claim 16.3.79, it then further suffices to show that $\alpha A^\wedge_J$ is closed for the topology $\mathcal{F}^\wedge_{I, A}$. But in light of (16.3.77), the latter assertion follows from corollary 16.1.12.

As an application we get the following generalization of theorem 16.3.21(ii):

**Corollary 16.3.82.** Let $(A, \mathcal{F})$ be a perfectoid ring, $\beta_\bullet := (\beta_1, \ldots, \beta_k)$ and $\gamma_\bullet := (\gamma_1, \ldots, \gamma_l)$ two finite sequences of elements of $E := E(A)$, and denote by $I$ (resp. $J$) the ideal of $A$ generated by the system $(\pi_A(\beta_1), \ldots, \pi_A(\beta_k))$ (resp. by $\pi_A(\gamma_1), \ldots, \pi_A(\gamma_l)$). Then the resulting map (16.3.14) is an isomorphism.

**Proof.** Let $A'$ be the $I$-adic completion of $A$, and for every $k \in \mathbb{N}$, denote by $(J^k)^c$ the topological closure of the ideal $J^k A'$ relative to the $I A'$-adic topology; arguing as in the proof of lemma 16.3.15(ii.b), we are easily reduced to showing that the $J A'$-adic topology on $A'$ agrees with the linear topology defined by the system of ideals $((J^k)^c \mid k \in \mathbb{N})$. However, let $K$ be an ideal of definition of $A$, and and endow $A'$ with its $K A'$-adic topology $\mathcal{F}'$; by theorem 16.3.76, the topological ring $(A', \mathcal{F}')$ is also perfectoid. Moreover, for every $i \leq l$, denote by $\gamma_i' \in E := E(A')$ the image of $\gamma_i$ under the homomorphism $E \to E'$ induced by the completion map $A \to A'$; then clearly $J A'$ is the ideal generated by the system $(\pi_A(\gamma_i'), \ldots, \pi_A(\gamma_l'))$. Hence, we may replace $A$ by $A'$, after which we may assume that $A$ is complete and separated for its $I$-adic topology. To conclude, it then suffices to show:

**Claim 16.3.83.** In the situation of the corollary, suppose moreover that $A$ is complete and separated for the $I$-adic topology. Then the $J$-adic topology of $A$ agrees with the linear topology induced by the system of ideals $((J^k)^c \mid k \in \mathbb{N})$.

**Proof of the claim.** From lemma 9.3.70(iv) we know already that the $J$-adic topology on $A$ agrees with the linear topology defined by the system of ideals $\{[\gamma_\bullet]^{(\lambda)} A \mid \lambda \in \mathbb{N}[1/p]\}$ so it suffices to check that

$$([\gamma_\bullet]^{(\lambda)} A)^c \subset [\gamma_\bullet]^{(\lambda')} A \quad \text{for every } \lambda, \lambda' \in \mathbb{N}[1/p] \text{ with } \lambda' < \lambda.$$

Now, any element of $([\gamma_\bullet]^{(\lambda)} A)^c$ can be written as an $I$-adically convergent series $\sum_{n \in \mathbb{N}} x_n$, where $x_n \in [\gamma_\bullet]^{(\lambda)} A \cap [\beta_\bullet]^{(n)} A$ for every $n \in \mathbb{N}$ (again by lemma 9.3.70(iv)). Fix $\lambda'', \varepsilon \in \mathbb{N}[1/p]$ with $\lambda' < \lambda'' < \lambda$, and $0 < \varepsilon < 1 - \lambda''/\lambda$; by corollary 16.3.49(iii) we get

$$x_n \in [\gamma_\bullet]^{(\lambda'')} : [\beta_\bullet]^{(n\varepsilon)} A \quad \text{for every } n \in \mathbb{N}.$$

Now we argue as in the proof of claim 16.3.20: by definition, for every $n \in \mathbb{N}$ there exist
• a finite set $S_n \subset \mathbb{N}[1/p]^{\geq 1}$ with $\mu_1 + \cdots + \mu_l = \lambda''$ for every $\mu := (\mu_1, \ldots, \mu_l) \in S_n$

• a system $(a_\mu \mid \mu \in S_n)$ of elements of $[\beta_\bullet]^{(\mu)} A$ such that

$$x_n = \sum_{\mu \in S_n} a_\mu \cdot \overline{\alpha}(\gamma_\mu^\nu) \quad \text{where} \quad \gamma_\mu^\nu := \gamma_1^{\mu_1} \cdots \gamma_l^{\mu_l} \quad \text{for every} \quad \mu \in S_n.$$

Choose $N \in \mathbb{N}$ such that $\lambda'' - \lambda' > lp^{-N}$, and define $\overline{\alpha}$ and $\mu^*$ as in the proof of proposition 9.3.78 so that $\overline{\alpha} \in S := \{\nu \in p^{-N}\mathbb{N}^{\geq 1} \mid \lambda'' \geq \nu_1 + \cdots + \nu_l > \lambda'\}$ for every $n \in \mathbb{N}$ and every $\mu \in S_n$. It follows that

$$x = \sum_{\nu \in S} c_\nu \cdot \overline{\alpha}(\gamma_\nu^\mu) \quad \text{where} \quad c_\nu := \sum_{n \in \mathbb{N}} \sum_{\mu \in S_n} a_\mu \cdot \overline{\alpha}(\gamma_\nu^\mu).$$

Clearly $\overline{\alpha}(\gamma_\nu^\mu) \in [\gamma_\bullet]^{(\lambda')} A$, and by lemma 9.3.70(iv) the series $c_\nu$ converges in the $I$-adic topology of $A$ for every $\nu \in S$; also it is easily seen that $S$ is a finite set, whence the contention. □

16.4. **Homological theory of perfectoid rings.** This section gathers some results on the homological properties of perfectoid rings. The first result is a simplification of the criterion of theorem 16.3.62 valid in the case where a regular sequence generates a special ideal of definition of the $P$-ring $A$.

**Theorem 16.4.1.** Let $A$ be a $P$-ring, and $(a_1, \ldots, a_k)$ a regular sequence of elements of $A$ that generates a special ideal of definition $I$ of $A$. Then the following conditions are equivalent:

(a) The Frobenius endomorphism of $A/pA$ induces an isomorphism $A/I \cong A/I^p$.

(b) $A$ is perfectoid.

**Proof.** We know already that (b)⇒(a), by corollary 16.3.3. Suppose that (a) holds. Then $E := E(A)$ is perfectoid (proposition 16.2.9 and example 16.3.2(i)). Arguing as in the proof of theorem 16.3.62 we may then find elements $\beta_1, \ldots, \beta_k$ in $E$, which generate an ideal of definition of $E$, and such that $\overline{\alpha}(\beta_i)$ equals the image of $a_i$ in $A/pA$, for $i = 1, \ldots, k$; moreover, $\overline{\alpha}(A/pA)$ induces an isomorphism $16.3.63$.

Next, since $p \in I^p$, we may find – again as in the proof of theorem 16.3.62 – a distinguished element $\alpha' \in \ker u_A$ such that $\alpha'_i \in \Phi_p(\mathcal{J})$. We let $B := W(E)/\mathcal{J} W(E)$, and we notice, as in loc. cit. that $B$ is perfectoid for the quotient topology inherited from $W(E)$, and $u_A$ factors through a surjective ring homomorphism $v : B \to A$. We define the ideal $I_B \subset B$ as in the proof of theorem 16.3.62 so (16.3.66) holds as well in the current situation, and arguing as in loc. cit. we also see that $p \in I_B^p$. Set $B_0 := B/I_B$ and $A_0 := A/I$; there follows a commutative diagram

$$
\begin{array}{ccc}
\text{Sym}^\bullet_{B_0}(I_B/I_B^2) & \longrightarrow & \text{gr}^I_{I_B} B \\
\downarrow & & \downarrow \\
\text{Sym}^\bullet_{A_0}(I/I^2) & \longrightarrow & \text{gr}^I_{I} A
\end{array}
$$

(16.4.2)

where $\text{gr}^I A$ is the graded ring associated to the $I$-adic filtration on $A$, and likewise for $\text{gr}^I_{I_B} B$. The top horizontal arrow of this diagram is surjective, and by assumption, the bottom horizontal arrow is an isomorphism. Furthermore, we notice:

**Claim 16.4.3.** The maps $\overline{\alpha}_{A/pA}$, $\overline{\alpha}_{B/pB}$ and $v$ induce ring isomorphisms

$$E/\mathcal{J}^2 \cong B/I_B^2 \cong A/I^2.$$
Proof of the claim. We have a commutative diagram

\[
\begin{array}{ccc}
E/\mathcal{J} & \longrightarrow & A/I \\
\Phi_{E/\mathcal{J}} & \downarrow & \Phi_{A/I} \\
E/\mathcal{J}^{(p)} & \longrightarrow & A/I^{(p)}
\end{array}
\]

whose horizontal arrows are induced by \(\Phi_{A/pA}\). Now, the vertical arrows are isomorphisms, and we have already remarked that the top horizontal arrow is also an isomorphism. Thus, the same holds for the bottom horizontal arrow; since \(\Phi_{A/pA}(\mathcal{J}^2) = I^2/pA\), we deduce already that \(\Phi_{A/pA}\) induces an isomorphism \(E/\mathcal{J}^2 \sim A/I^2\). Similarly, since \(B\) is perfectoid, \(\Phi_{B/pB}\) induces an isomorphism \(E/\alpha'_0 E \sim B/pB\); however, \(\alpha'_0 \in \mathcal{J}^2, p \in I_B^2\), and \(\Phi_{B/pB}(\mathcal{J}^2) = I_B^2/pB\), so \(\Phi_{B/pB}\) induces an isomorphism \(E/\mathcal{J}^2 \sim B/I_B^2\). By construction, it is then clear that \(v\) induces an isomorphism \(B/I_B^2 \sim A/I^2\). \(\Box\)

From claim \ref{16.4.3} we see that \(v\) induces an isomorphism \(B_0 \sim A_0\), and we get as well isomorphisms of \(E\)-modules

\[
\mathcal{J}/\mathcal{J}^2 \sim I_B/I_B^2 \sim I/I^2.
\]

Thus, the left vertical arrow of \ref{16.4.2} is an isomorphism; therefore the same holds for the top horizontal arrow, and hence also for the right vertical arrow. Since \(B\) is complete and separated for its \(I_B\)-adic topology, and \(A\) is complete and separated for its \(I\)-adic topology, we conclude that \(v\) is an isomorphism of topological rings, whence (b). \(\square\)

16.4.4. For every \(n, r \in \mathbb{N}\), set (see also example \ref{4.8.55}[iii])

\[P_r := \mathbb{N}[1/p]^{\geq r} \quad R_{r,n} := \mathbb{Z}[P_r] = \mathbb{Z}[T_1^{1/p^\infty}, \ldots, T_r^{1/p^\infty}]\]

so, actually \(R_{r,n}\) is independent of \(n\), but we also consider the ring homomorphism

\[v_{r,n} : R_{r,n} \rightarrow R_{r,0} \quad T_i^n \mapsto T_i^{n/p^n} \quad \text{for every } a \in \mathbb{N}[1/p] \text{ and } i = 1, \ldots, r\]

for every \(r, n \in \mathbb{N}\). Let also \(T_r P_r \subset P_r\) be the ideal generated by \(\mathbb{N}^{\geq r}\), and set

\[I_{r,n} := (T_r P_r) \cdot R_{r,n} \quad I_{r,s} := (T_s P_r)^{[s]} \cdot R_{r,n} \quad \text{for every } s \in \mathbb{R}^+\]

(notation of remark \ref{9.3.71}[ii]). Thus \(I_{r,s}\) is an ideal of \(R_{r,n}\), for every \(s \in \mathbb{R}^+\) and every \(r, n \in \mathbb{N}\). Next, let \(A\) be any ring, \(u_0 : R_{r,0} \rightarrow A\) any ring homomorphism, and for every \(n \in \mathbb{N}\) set

\[u_n := u_0 \circ v_{r,n} : R_{r,n} \rightarrow A, \text{ denote by } f^{(n)} \text{ the sequence } (u_n(T_1), \ldots, u_n(T_r)) \text{ of elements of } A; \text{ for } n = 0, \text{ we shall also write just } f \text{ instead of } f^{(0)} \text{ and denote by } J \text{ the ideal generated by } f. \]

We may then state :

Lemma 16.4.5. In the situation of \ref{16.4.4}, suppose furthermore that

\[\text{Tor}^i_{R_{r,n}/I_{r,n}^{[s]}}, A = 0 \quad \text{for every } i > 0 \text{ and every } s \in \mathbb{R}^+.
\]

Then the following holds :

(i) The ring \(A\) satisfies condition (a)\(^\text{un}\) of \ref{7.8.21} with step \(\leq r\), for every \(n \in \mathbb{N}\).
(ii) \(\text{Ann}_A(J^k) = \text{Ann}_A(I_{r,0}^{[0]} \cdot A)\) for every \(k > 0\).
(iii) \(\text{Ann}_A(J) \cap I_{r,0}^{[0]} \cdot A = 0\).

Proof. (i): In case \(r = 0\), there is nothing to prove, so we assume henceforth that \(r > 0\). For every \(n \in \mathbb{N}\), endow \(A\) with the \(R_{r,n}\)-module structure induced by \(u_n\).

Claim 16.4.6. \(\text{Tor}^i_{R_{r,n}/I_{r,n}^{[s]}}, A = 0 \quad \text{for every } i > 0 \text{ and every } s \in \mathbb{R}^+\).
Proof of the claim. The base change change \(\nu_{r,n} : R_{r,n} \to R_{r,0}\) yields a spectral sequence
\[
E_{ij}^2 := \text{Tor}^{R_0}_i(R^n_j(R_{r,n}/I_{r,n}^s, R_{r,0}), A) \Rightarrow \text{Tor}^{R_0}_i(R_{r,n}/I_{r,n}^s, A).
\]
But since \(\nu_{r,n}\) is an isomorphism and \(\nu_{r,n}(I_{r,n}^s) = I_{r,0}^{|s/p^n|}\), we see that \(E_{ij}^2 = 0\) for every \(j > 0\), and \(E_{i0}^2 = \text{Tor}^{R_0}_i(R_{r,0}/I_{r,0}^s, A)\). Thus, \(E_{i0}^2 = 0\) for \(i > 0\), whence the claim.

In view of claim \(16.4.6\) we may replace \(u_0\) by \(u_n\), and reduce to checking condition (a)\(\overline{m}\) for \(A\). To this aim, define \(A_r, I_r\) and the ring homomorphism \(\beta_r : A_r \to A\) as in \((7.8.21)\); endow also \(R_{r,0}\) with the \(A_r\)-module structure induced by the inclusion map \(A_r \to R_{r,0}\), and consider the change of ring spectral sequence
\[
E(n)^2_{pq} := \text{Tor}^{R_0}_p((\text{Tor}^A_q(A_r/I_r^n, R_{r,0}), A) \Rightarrow \text{Tor}^{A_r}_p(A_r/I_r^n, A) \quad \text{for every } n \in \mathbb{N}.
\]
It is easily seen that \(R_{r,0}\) is a free \(A_r\)-module, hence \(E(n)^2_{pq} = 0\) whenever \(q > 0\), and \(E(n)^2_{j0} = R_{r,0}/I_{r,0}^n\). There follows a natural isomorphism
\[
\text{Tor}^{R_0}_p(R_{r,0}/I_{r,0}^n, A) \cong \text{Tor}^{A_r}_p(A_r/I_r^n, A) \quad \text{for every } p, n \in \mathbb{N}.
\]
Now, recall that \(I_{r,0}^{n+r} \subset I_{r,0}^{n+r-1} \subset I_{r,0}^n\) for every \(n \in \mathbb{N}\) (lemma \(9.3.70\)(iv)); then our assumption implies immediately that the inverse system \((\text{Tor}^{A_r}_p(A_r/I_r^n, A) \mid n \in \mathbb{N})\) is uniformly essentially zero, with step \(\leq r\).

(iii): We have just seen that condition (a)\(\overline{m}\) holds for every \(n\), with step bounded by \(r\). For every \(n \in \mathbb{N}\), let \(J_n \subset A\) be the ideal generated by \(f^n\), according to remark \(7.8.34\)(ii), it follows that there exists a sequence of integers \((d(i) \mid i \in \mathbb{N})\) such that inverse system \((H_{i+1}(f^n), J_{n,k}^i) \mid k \in \mathbb{N})\) is uniformly essentially zero, with step bounded by \(d(i)\), for every \(i, n \in \mathbb{N}\). Especially, for \(d := d(r)\) we get
\[
\text{Ann}_A(J_n) \cap J_n^d = 0 \quad \text{for every } n \in \mathbb{N}.
\]
By a simple induction argument, we deduce that \(\text{Ann}_A(J_{n+1}) \cap J_n^d = 0\) for every \(n, k \in \mathbb{N}\). But clearly, for every \(n \in \mathbb{N}\) there exists \(k \in \mathbb{N}\) such that \(J_{n+1}^k \subset J\), whence
\[
\text{Ann}_A(J) \cap J_n^d = 0 \quad \text{for every } n \in \mathbb{N}
\]
which yields easily the contention.

(ii) is an easy consequence of (iii). \(\square\)

Proposition 16.4.7. Let \(f : A \to B\) be any homomorphism of perfect \(\mathbb{F}_p\)-algebras, \(I \subset A\) any ideal. Then the natural morphism
\[
A/I^s A \xrightarrow{L} A \otimes_A B \to A/I^s A \otimes A B[0]
\]
is an isomorphism in \(\mathcal{D}(A\text{-Mod})\), for every \(s \in \mathbb{R}_+\) (notation of remark \(9.3.71\)(i)).

Proof. We reduce easily to the case where \(I\) is finitely generated, and \(f = E^*(f_0)\) for a map \(f_0 : A_0 \to B_0\) of \(\mathbb{F}_p\)-algebras of finite type (where \(A_0\) and \(B_0\) are endowed with their discrete topologies : notation of \(9.4.7\)). Then we may also assume that \(I = I_0 A\) for some finitely generated ideal \(I_0 \subset A_0\), and it suffices to show:

Claim 16.4.8. In the foregoing situation, for every \(\lambda, \lambda' \in \mathbb{N}[1/p]\) with \(\lambda' < \lambda\), the inclusion \(I(\lambda) A \subset I(\lambda') A\) induces the zero map
\[
\text{Tor}^A_i(A/I(\lambda) A, B) \to \text{Tor}^A_i(A/I(\lambda') A, B) \quad \text{for every } i > 0.
\]

Proof of the claim. Under the current assumptions, \(A\) is the colimit of the system of \(\mathbb{F}_p\)-algebras \((A_n \mid n \in \mathbb{N})\) such that \(A_n := A_0\) for every \(n \in \mathbb{N}\), with transition maps \(\varphi_n : A_n \to A_{n+1}\) given
by the Frobenius map $\Phi_{A_n}$, and likewise for $B$. Moreover, say that $\lambda = ap^h$ and $\lambda' = bp^h$ for some $a, b, k \in \mathbb{N}$, and for every $n \in \mathbb{N}$ define ideals of $A_n$ by the rules:

$$I_n := \begin{cases} 0 & \text{for } n < k \\ I_0 ap^{n-k} & \text{for } n \geq k \end{cases} \quad \text{and} \quad I'_n := \begin{cases} 0 & \text{for } n < k \\ I'_0 bp^{n-k} & \text{for } n \geq k. \end{cases}$$

Then it is easily seen that $\varphi^*(I_n) \subset I_{n+1}$, and likewise for $I'_n$, for every $n \in \mathbb{N}$. Furthermore, the colimit of the system $(I_n | n \in \mathbb{N})$ (resp. $(I'_n | n \in \mathbb{N})$) is $I^{(\lambda)}A$ (resp. $I^{(\lambda')}A$). By claim [7.11.37](i), we are therefore reduced to showing that the map induced by the inclusion $I_n \subset I'_n$

\[
\text{Tor}^{A_0}(A_0/I_n, B_0) \to \text{Tor}^{A_0}(A_0/I_n', B_0)
\]

vanishes, for every sufficiently large $n \in \mathbb{N}$. Since $a > b$, the latter assertion follows from claim [7.9.18](ii) (applied with $M := A$ and $N := B$).

16.4.9. We are going now to apply the general setup of (16.4.4) to the case where $A$ is a perfectoid ring, and

$$f := (\overline{\pi}_A(\beta_1), \ldots, \overline{\pi}_A(\beta_r))$$

for a given sequence $\beta_* := (\beta_1, \ldots, \beta_r)$ of elements of $\mathbb{E} := E(A)$. To ease notation, we shall simply write $P$ instead of $P_r$, and $R$ instead of $R_{r,0}$. Also, we shall write $I, I^{[s]} \subset R$ instead of $I_{r,0}$, and respectively $I^{[s]}_{r,0}$, for every $s \in \mathbb{R}_+$. Likewise, we shall write $u$ instead of $u_0$; hence $u : R \to A$ is the unique ring homomorphism such that $u(T_i) = \overline{\pi}_A(\beta_i)$ for $i = 1, \ldots, r$.

**Proposition 16.4.10.** With the notation of (16.4.9), the natural morphism

$$R/I^{[s]} \otimes_R A \to A/I^{[s]} A[0]$$

is an isomorphism in $D(R\text{-Mod})$, for every $s \in \mathbb{R}_+$.

**Proof.** Notice that $R_0 := R \otimes \mathbb{F}_p$ is a perfect $\mathbb{F}_p$-algebra, and $I^{[s]}R_0 = I_0^{[s]}R_0$, where $I_0 \subset R_0$ is the ideal generated by $(T_1, \ldots, T_r)$. In light of proposition [16.4.7] we deduce

$$\text{Tor}^R(R_0/I^{[s]}R_0, \mathbb{E}) = 0 \quad \text{for every } s \in \mathbb{R}_+ \text{ and every } i > 0.$$  

On the other hand, we have a standard 2-spectral sequence

$$E_{pq}^2 := \text{Tor}_p^R(\text{Tor}_q^R(R/I^{[s]}, R_0), \mathbb{E}) \Rightarrow \text{Tor}_{p+q}^R(R/I^{[s]}, \mathbb{E})$$

([25] Th.5.6.6). However, by construction $I^{[s]}$ is a direct summand of the free $\mathbb{Z}$-module $R$, so $R/I^{[s]}$ is also a free $\mathbb{Z}$-module, and then a standard calculation shows that $E_{pq}^2 = 0$ whenever $q > 0$. From (16.4.11) we see as well that $E_{p0}^2 = 0$ for every $p > 0$, so we conclude

$$\text{Tor}^R(R/I^{[s]}, \mathbb{E}) = 0 \quad \text{for every } s \in \mathbb{R}_+ \text{ and every } i > 0.$$  

Next, an easy induction argument using the short exact sequences of $W(\mathbb{E})$-modules

$$0 \to \mathbb{E} \simeq p^n W_{n+1}(\mathbb{E}) \to W_{n+1}(\mathbb{E}) \to W_n(\mathbb{E}) \to 0 \quad \text{for every } n \in \mathbb{N}$$

shows more generally that

$$\text{Tor}^R(R/I^{[s]}, W_n(\mathbb{E})) = 0 \quad \text{for every } s \in \mathbb{R}_+, \text{ every } i > 0 \text{ and every } n \in \mathbb{N}.$$  

For every $n \in \mathbb{N}$, set $J_n := p^n(T^*_nP)$, where $p_P$ denotes the $p$-Frobenius automorphism of $P$ (see definition [4.8.40](ii)), and consider the projection

$$\pi_{n(a,b)} : R/J^a_nR \to R/J^b_nR \quad \text{for every } a, b, n \in \mathbb{N} \text{ with } a \geq b.$$  

**Claim 16.4.13.** With the foregoing notation, we have:

(i) $\text{Tor}^R(\pi_{n(a,b)}, W_m(\mathbb{E})) = 0$ for every $a, b, i, m, n \in \mathbb{N}$ with $a - b \geq r$ and $i > 0$.  

(ii) For every $a, n \in \mathbb{N}$ there exists a complex of free $R$-modules of finite type $L_{a,n}$ with a quasi-isomorphism $L_{a,n} \to R/J_n^a[0]$ of complexes of $R$-modules.

(iii) $\text{Tor}_i^R(\pi_n^{(a,b)}, W(E)) = 0$ for every $a, b, i, n \in \mathbb{N}$ with $a - b \geq 2r$ and $i > 0$.

Proof of the claim. If $r = 0$ there is nothing to prove, so we may assume that $r > 0$.

(i) Notice that $J_n$ is generated by a system of $r$ elements of $P$, for every $n \in \mathbb{N}$; in view of [9.3.70(ii),(i)], we deduce

$$J_n^0 \subset J_n^{(a)} \subset (T_i P)((b+r-1)p^{-n}) \subset J_n^{(b+r-1)} \subset J_n^b$$

so the assertion follows from (16.4.12).

(ii) The ideal $J_n R$ is generated by the system $(T_1^{1/p^n}, \ldots, T_r^{1/p^n})$ of elements of the subring $S_n := \mathbb{Z}[T_1^{1/p^n}, \ldots, T_r^{1/p^n}]$; since $S_n$ is noetherian, we may find a complex $L_{a,n}^*$ of free $S_n$-modules of finite type, with a quasi-isomorphism $L_{a,n}^* \to S_n/J_n S_n[0]$, and since the inclusion map $S_n \to R$ is flat, the complex $L_{a,n} := L_{a,n}^* \otimes_{S_n} R$ will do.

(iii) For given $a, n \in \mathbb{N}$, let $L_{a,n}^*$ be as in (ii); it is easily seen that the natural map

$$\lim_{m \in \mathbb{N}} L_{a,n}^* \otimes_R W_m(E) \to L_{a,n}^* \otimes_R W(E)$$

is an isomorphism in $\mathbb{C}(R\text{-Mod})$. To ease notation, set $\mathcal{F}_{i,a,n} := \text{Tor}_i^R(R/J_n^aR, W_m(E))$ for every $i, m, n \in \mathbb{N}$; in light of [125, Th.3.5.8] we deduce natural short exact sequences

$$0 \to R^1 \lim_{m \in \mathbb{N}} \mathcal{F}_{i-1,a,n} \to \text{Tor}_i^R(R/J_n^aR, W(E)) \to \lim_{m \in \mathbb{N}} \mathcal{F}_{i,a,n} \to 0$$

for every $i, a, n \in \mathbb{N}$. Then the assertion follows from (i).

Now, for any $s \in \mathbb{R}_+$, let $S_s$ be the set of all pairs $(a, n) \in \mathbb{N} \times \mathbb{N}$ such that $ap^{-n} > s$; we define a partial ordering on $S_s$ by the rule: $(a, n) \geq (b, m)$ if and only if $n \geq m$ and $ap^{-n} \leq bp^{-m}$. With this notation, notice that $J_n^b \subset J_n^a$ whenever $(a, n) \geq (b, m)$, and $I^{[s]}$ is the union of its filtered system of subideals $(J_n^a R \mid (a, n) \in S_s)$. Taking into account claim [16.4.13(iii)] we deduce that

$$\text{Tor}_i^R(R/I^{[s]} R, W(E)) = 0 \quad \text{for every } s \in \mathbb{R}_+ \text{ and every } i > 0.$$ 

Next, from remark [16.1.7] we get a short exact sequence of $R$-modules

$$0 \to W(E) \xrightarrow{\alpha} W(E) \to A \to 0$$

where $\alpha$ is any distinguished element in $\text{Ker}_{uA}$. Then, by the induced long exact Tor-sequence, [16.4.14] implies already that $\text{Tor}_i^R(R/I^{[s]} A)$ vanishes for every $i > 1$. By the same token, we also see that $\text{Tor}_i^R(R/I^{[s]} A)$ is isomorphic to the kernel of scalar multiplication by $\alpha$ on the $R$-module $W(E)/I^{[s]} W(E)$; to conclude the proof, it then suffices to remark:

Claim 16.4.15. $\alpha W(E) \cap I^{[s]} W(E) = \alpha I^{[s]} W(E)$.

Proof of the claim. Denote by $\mathcal{F} \subset E$ the ideal generated by $\beta_*$; from proposition [9.3.78(i)] we easily deduce that $I^{[s]} W(E) = \bigcup_{s' > s} W(\mathcal{F}^{[s']})$, and in view of proposition [16.1.11(ii)] we get

$$\alpha W(E) \cap I^{[s]} W(E) = \bigcup_{s' > s} (\alpha W(E) \cap W(\mathcal{F}^{[s']})) = \bigcup_{s' > s} \alpha W(\mathcal{F}^{[s']}) = \alpha I^{[s]} W(E)$$

as stated.

Corollary 16.4.16. In the situation of [16.4.9], set $J := 1A$, and denote by $A_J^* \mathcal{C}$ the $J$-adic completion of $A$. Let also $\mathcal{C}_* \subset E$ be any bounded above complex of flat $A$-modules such that for every $i \in \mathbb{Z}$ there exists $c(i) \in \mathbb{N}$ with $J^{c(i)} H_i \mathcal{C}_* = 0$. Then the natural morphism

$$\mathcal{C}_* \to A_J^* \otimes_A \mathcal{C}_*$$

is an isomorphism in $D(A\text{-Mod})$. 
Proof. It is an immediate consequence of lemma 16.4.5(i), proposition 16.4.10 and corollary 16.3.31(ii) yields a natural isomorphism \[ \in \] may then replace \( \beta \) is a radical ideal; then it follows that the same holds for \( x \supseteq \) suppose that \( \alpha \) have \( (\beta_1, \ldots, \beta_n) \) is completely secant in \( E \). Set as usual \( J := IA \), and let \( A_j \) be the \( J \)-adic completion of \( A \). In view of corollary 16.4.16, we see that the sequence \( b_\bullet := (\overline{u}_A(\beta_1), \ldots, \overline{u}_A(\beta_n)) \) is completely secant in \( A \).

Proof. Set as usual \( J := IA \), and let \( A_j \) be the \( J \)-adic completion of \( A \). In view of corollary 16.4.16, we see that the sequence \( b_\bullet := (\overline{u}_A(\beta_1), \ldots, \overline{u}_A(\beta_n)) \) is completely secant in \( A \). Moreover, if \( \mathcal{J} \subset E \) denotes the ideal generated by \( \beta_\bullet \), we have a natural ring isomorphism \( E(A_j) \approx E_\mathcal{J} \) (theorem 16.3.76(ii)), and by the same token the sequence \( \beta_\bullet \) is completely secant in the perfectoid ring \( E \) if and only if the same holds for its image in \( E_\mathcal{J} \). Thus, we may replace \( A \) by \( A_j \), and assume from start that \( A \) is \( J \)-adically complete and separated. Next, let \( (\alpha_n \mid n \in \mathbb{N}) \) be any distinguished element in \( \text{Ker} \ u_A \); since \( \mathcal{J} \) is open, we have \( \alpha_n \in \mathcal{J} \) for some integer \( n \in \mathbb{N} \), and then we may find \( k \in \mathbb{N} \) such that \( \alpha_0 \) is contained in the ideal generated by the sequence \( \beta_\cdot := (\beta_1^{1/p^k}, \ldots, \beta_n^{1/p^k}) \). In light of corollary 7.8.8, we may then replace \( \beta_\cdot \) with \( \beta'_\cdot \), and assume that \( \alpha_0 \in \mathcal{J} \). Notice now that \( \{ J^n \} = J^n \) for every \( n \in \mathbb{N} \) (remark 16.3.28 viii)), and the inclusion \( J^{n+1} \subset J^n \) is taut for every \( n \in \mathbb{N} \), so theorem 16.3.31(ii) yields a natural isomorphism \[ \tau : \bigoplus_{n \in \mathbb{N}} J^n / J^{n+1} \approx \bigoplus_{n \in \mathbb{N}} J^n / J^{n+1}. \]

Moreover, a simple inspection shows that \( \tau \) is an isomorphism of \( A/pA \)-algebras; it follows immediately that the sequence \( \beta_\cdot \) is \( E \)-quasi-regular if and only if the sequence \( b_\cdot \) is \( A \)-quasi-regular (see remark 7.10.34[iii])). To conclude, it suffices now to invoke proposition 7.10.37. □

16.4.18. Let \( A \) be a perfectoid ring, set \( E := E(A) \), and denote by \( \alpha := (\alpha_n \mid n \in \mathbb{N}) \) any distinguished element of \( \text{Ker} \ u_A \). Set \( I_1 := \text{Ann}_{E}(\alpha_0) \), let \( I_2 \subset E \) be the radical of the ideal \( \alpha_0 E \), and \( I_3 := I_1 + I_2 \); let also \( E_i := E/I_i \) for \( i = 1, 2, 3 \). We claim that the resulting diagram of ring homomorphisms \[ \mathcal{E} : \quad \begin{array}{ccc} E & \longrightarrow & E_1 \\ \downarrow & & \downarrow \\ E_2 & \longrightarrow & E_3 \end{array} \]

is cartesian. Indeed, it is clear the induced map \( E \rightarrow E_1 \times E_3 E_2 \) is surjective; for the injectivity, suppose that \( x \in I_1 \cap I_2 \); then \( x^n \in \alpha_0 A \) for some \( n \in \mathbb{N} \), and \( \alpha_0 x = 0 \), so that \( x^{n+1} = 0 \), and therefore \( x = 0 \), since \( E \) is perfect. Notice also that the \( \alpha_0 \)-adic topology agrees with the discrete topology on \( E_2 \) and \( E_3 \), and by arguing as in remark 16.3.39(ii) we see that \( I_1 \) is a closed ideal for the \( \alpha_0 \)-adic topology of \( E \). Moreover, since \( E \) is perfect, it is easily seen that \( I_1 \) is a radical ideal; then it follows that the same holds for \( I_3 \), since we have already observed that the latter equals \( I_1 \oplus I_2 \). Summing up, we deduce that \( E_i \), endowed with its \( \alpha_0 \)-adic topology, is a perfectoid ring for \( i = 1, 2, 3 \). Consequently, the same holds for the rings \[ A_i := A \otimes_{W(E)} W(E_i) \quad i = 1, 2, 3 \]

and \( E(A_i) = E_i \), provided we endow each \( A_i \) with its \( p \)-adic topology (proposition 16.2.21[i]). Furthermore, arguing as in the proof of claim 16.3.22 we easily see that the resulting diagram...
of ring homomorphisms:

\[
A(\varphi) : \begin{array}{ccc}
A & \longrightarrow & A_1 \\
& & \\
A_2 & \longrightarrow & A_3
\end{array}
\]

is still cartesian. Set as well

\[X_E := \text{Spec } E \quad X_A := \text{Spec } A \quad \text{and} \quad X_{E_k} := \text{Spec } E_k \quad X_{A_k} := \text{Spec } A_k \quad \text{for } k = 1, 2, 3\]

and denote the resulting closed immersions by

\[i_{E_k} : X_{E_k} \rightarrow X_E \quad i_{A_k} : X_{A_k} \rightarrow X_A \quad \text{for } k = 1, 2, 3.\]

According to (16.1.3), we get moreover a continuous and spectral map

\[\varphi := (\text{Spec } \pi_A) : X_A \rightarrow X_E\]

**Remark 16.4.19.** In the situation of (16.4.18), we notice that:

(i) The image of \(\alpha_0\) is regular on \(E_1\), hence the induced isomorphism \(E \sim E_1 \times_{E_3} E_2\) identifies \(I_1\) with \(0 \times_{E_3} E_2\), i.e. with \(\text{Ker } (E_2 \rightarrow E_3)\).

(ii) Therefore, the image of \(\pi_A(\alpha_0)\) is regular in \(A_1\) (proposition 16.4.17), and consequently, also \(p\) is regular in \(A_1\).

(iii) For \(i = 2, 3\), the image of \(\alpha\) in \(W(E_i)\) equals \(pu\), for some \(u \in W(E_i)^\times\), so \(u_{A_2}\) and \(u_{A_3}\) induce isomorphisms of topological rings

\[E_2 \sim A_2 \quad E_3 \sim A_3\]

that identify the projection \(E_2 \rightarrow E_1\) in \(\varphi\) with the map \(A_2 \rightarrow A_3\) in \(A(\varphi)\).

(iv) Consequently, the isomorphism \(A \sim A_1 \times_{A_3} A_2\) induced by \(A(\varphi)\) identifies \(\text{Ann}_A(p)\) with \(0 \times_{A_3} A_2\), i.e. with \(\text{Ker } (A_2 \rightarrow A_3)\), and summing up, we get a natural \(W(E)\)-linear identification

\[\text{Ann}_E(\alpha_0) \sim \text{Ann}_A(p) : \beta \mapsto \pi_A(\beta).\]

(v) Let \(I\) be an ideal of adic definition of \(A\), and \(J \subset A\) another ideal such that \(IJ = 0\). Since \(A\) is reduced (corollary 16.3.61(i)), we deduce that \(I^n \cap J = 0\) for every \(n \in \mathbb{N}\), whence \(J + I^n = J + I^n \cap J = J\) for every such \(n\). It follows that

\[\bigcap_{n \in \mathbb{N}} (J + I^n) = \bigcap_{n \in \mathbb{N}} (J \cap I^n) = J + \bigcap_{n \in \mathbb{N}} I^n = J\]

which means that \(J\) is closed in the topology of \(A\).

**Proposition 16.4.20.** With the notation of (16.4.18), the following holds:

(i) The map \(\varphi\) is surjective.

(ii) For every quasi-coherent \(\mathcal{O}_{X_A}\)-module \(\mathcal{F}\) and every integer \(i > 0\) we have

\[R^i \varphi_* \mathcal{F} = 0.\]

**Proof.** (i): Consider any \(q \in X_E\), set

\[J := \sum_{x \in q} \pi_A(x) \cdot A \quad S := \{\pi_A(x) \mid x \in E \setminus q\}\]

and notice that \(S\) is a multiplicative subset of \(A\). Let \(p \in X_A\) be any prime ideal; it is easily seen that \(\varphi(p) = q\) if and only if \(S \cap p = \emptyset\) and \(J \subset p\). Thus, we come down to showing that \(JA_S \neq A_S\). Suppose this fails; then there exist \(y \in E \setminus q\) and sequences \(x_\bullet := (x_1, \ldots, x_k)\), \(a_\bullet := (a_1, \ldots, a_k)\) of elements of \(q\) and respectively \(A\), such that

\[\overline{u}_A(y) = \sum_{i=1}^k \overline{u}_A(x_i) \cdot a_i.\]
Especially, \([y]^{(1)} A \subset [x]^{(1)} A\). Set \(\mathcal{I} := \sum_{i=1}^{k} E_t^i \subset E\); by corollary \([16.3.49]\) we deduce
\[y \in \mathcal{I}^{(1-1/p)} E \subset q\]
a contradiction.

(ii): Let \(f \in E\) any element, and set \([f] := \overline{\alpha}_{A}(f)\); in light of \([9.3.68]\) we get
\[\varphi^{-1}(\text{Spec } E_f) = \text{Spec } A_{[f]}\].

Now, recall that \(R^i \varphi_* \mathcal{I}\) is naturally isomorphic to the sheaf associated to the presheaf
\[U \mapsto H^i(\varphi^{-1} U, E)\]
for every open subset \(U \subset X_E\).

Then the assertion follows immediately from \([16.4.21]\). □

### 16.4.22

In the situation of \([16.4.18]\), let \(\alpha := (\alpha_n \mid n \in \mathbb{N})\) be any distinguished element of \(\text{Ker } u_A\); notice the commutative diagram of topological spaces
\[X_0^E := \text{Spec } A/pA \xrightarrow{\varphi_0} X_0^E := \text{Spec } E/\alpha_0 E\]
whose vertical arrows are the inclusion maps, and with \(\varphi_0 := \text{Spec } \omega\), where \(\omega : E/\alpha_0 E \xrightarrow{\sim} A/pA\) is the ring isomorphism deduced from \(u_A \otimes \mathbb{Z} \mathbb{F}_p\) as in remark \([16.3.7]\). Denote also
\[\mathcal{O}_{X_E}^x \subset \mathcal{O}_{X_E}^t \text{ and } \mathcal{O}_{X_A}^x \subset \mathcal{O}_{X_A}^t\]
respectively the subsheaf of \(\alpha_0\)-torsion sections and the subsheaf of \(p\)-torsion sections. Notice that \(\mathcal{O}_{X_E}^x\) is independent of the choice of \(\alpha\) (remark \([16.1.7]\)); more precisely, corollary \([16.3.61]\) implies that
\[\mathcal{O}_{X_E}^x = \sum_{1}^{n} \mathcal{O}_{X_E}^x = \text{Ker } (\mathcal{O}_{X_E} \to i_{E_1} \mathcal{O}_{X_E_1})\]
\[\mathcal{O}_{X_A}^x = \sum_{1}^{n} \mathcal{O}_{X_A}^x = \text{Ker } (\mathcal{O}_{X_A} \to i_{A_1} \mathcal{O}_{X_A_1})\].

**Lemma 16.4.23.** In the situation of \([16.4.22]\), the following holds:

(i) The corresponding isomorphism of sheaves \(\varphi^x : \mathcal{O}_{X_E}^x \xrightarrow{\sim} \varphi_0 \mathcal{O}_{X_A}^x\) lifts to a map of sheaves of monoids
\[\varphi^x : \mathcal{O}_{X_E}^x \to \varphi_* \mathcal{O}_{X_A}^x\].

(ii) \(\varphi^x\) restricts to an isomorphism of sheaves of abelian groups
\[\mathcal{O}_{X_E}^x \xrightarrow{\sim} \varphi_* \mathcal{O}_{X_A}^x\].

(iii) For every open subset \(U \subset X_E\) we have
\[\varphi^x_U(x + y) = \varphi^x_U(x) + \varphi^x_U(y)\]
for every \(x \in \mathcal{O}_{X_E}^x(U)\) and \(y \in \mathcal{O}_{X_E}^x(U)\).

(iv) For every closed subset \(W_A \subset X_A^0\), the \(\mathcal{O}_{X_A}^x\)-module \(\sum_{W_A} \mathcal{O}_{X_A}^x\) is quasi-coherent.

**Proof.** (i): For every \(f \in E\), set \(D(f) := \text{Spec } E_f\) and \([f] := \overline{\alpha}_{A}(f)\), and let
\[\varphi_f^x := (\overline{\alpha}_{A})_f : E_f \to A_{[f]}\]
(notation of \([4.8.33]\)). Now, let \(g \in E\) be any other element, and suppose that \(D(g) \subset D(f)\); there follows a commutative diagram
\[
\begin{array}{ccc}
E & \longrightarrow & E_f \\
\varpi_A & \varphi_f^x & \downarrow \varphi_f^x \\
A & \longrightarrow & A_{[f]} \\
\end{array}
\]
then we have commutative diagrams of topological spaces and of sheaves of monoids: rings, and

\[
\begin{array}{ccc}
\mathcal{O}_{X_E} & \xrightarrow{\varphi} & \varphi_* \mathcal{O}_{X_A} \\
\downarrow & & \downarrow \\
\iota_{E*} \mathcal{O}_{X_E} & \xrightarrow{(\iota_{E*} \nu_E^0)} & \iota_{E*} \varphi_0 \mathcal{O}_{X_A} 
\end{array}
\]

commutes.

(iii): It suffices to check the stated identity for \( U \) of the form \( \text{Spec} E_f \), where \( f \in E \) is any element. Then, in light of (16.4.24), we easily reduce to the case where \( x, y \in \text{Im} (E \to E_f) \). Then, we are further reduced to checking that \( \pi_A(x + y) = \pi_A(x) + \pi_A(y) \) for every \( x, y \in E \) such that \( a_0 \cdot x = 0 \). The latter follows easily from proposition 9.3.63 and lemma 16.2.7(iii); details left to the reader.

(ii): Lemma 16.2.7(ii) easily implies that \( \varphi^0 \) sends \( \mathcal{O}_{X_E} \) into \( \varphi_* \mathcal{O}_{X_A} \). In light of (iii), it then suffices to check that the map \( \varphi_f^0 \) restricts to an isomorphism \( \text{Ann}_{E_f}(a_0) \xrightarrow{\sim} \text{Ann}_{A_f}(p) \) for every \( f \in E \). However

\[ (16.4.24) \quad \text{Ann}_{E_f}(a_0) = \text{Ann}_E(a_0) \quad \text{and} \quad \text{Ann}_{A_f}(p) = \text{Ann}_A(p) \quad \text{for} \quad f \in E \]

so the assertion follows from remark 16.4.19(iv).

(iv): Set \( W_E := \varphi_0(W_A) \); from (ii) we see that \( \varphi^0 \) induces an isomorphism

\[
\Gamma(W_A) \mathcal{O}_{X_A} = \Gamma(W_A) \circ \Gamma(X_A^0) \mathcal{O}_{X_A} \cong \Gamma(W_A) (\iota_{A*} \varphi_0 \mathcal{O}_{X_E}^0) = \iota_{A*} \varphi_0 \mathcal{O}_{X_E}^0
\]

of \( \mathcal{O}_{X_A} \)-modules (lemma 10.4.13(v)). Since the functor \( \iota_{A*} \) sends quasi-coherent \( \mathcal{O}_{X_A}^0 \)-modules to quasi-coherent \( \mathcal{O}_{X_A} \)-modules ([44, Ch.I, Cor.9.2.2]), we are then reduced to checking that \( \iota_{A*} \varphi_0 \mathcal{O}_{X_E}^0 \) is a quasi-coherent \( \mathcal{O}_{X_A} \)-module. However, it was already remarked in (16.4.22) that \( \Gamma(W_E) \mathcal{O}_{X_E}^0 = \Gamma(W_E) \mathcal{O}_{X_E}^0 \) is an \( \iota_{E*} \mathcal{O}_{X_E^0} \)-module, so we are further reduced to checking that \( \Gamma(W_E) \mathcal{O}_{X_E}^0 \) is a quasi-coherent \( \mathcal{O}_{X_A} \)-module.

Thus, let \( f \in E \) be any element, and \( s \in \Gamma(W_E) \mathcal{O}_{X_E}^0(f) \); we pick a subset \( S \subset E \) such that \( U_E := X_E \setminus W_E = \bigcup_{g \in S} D(g) \). By assumption, \( s|_{D(fg)} = 0 \) for every \( g \in S \); and there exist \( n \in \mathbb{N} \) and \( t \in E \) such that \( s = f^{-n} t \); it follows that for every \( g \in S \) there exists an integer \( m_g \in \mathbb{N} \) such that \( (fg)^{m_g} t = 0 \) in \( E \). Since \( E \) is perfect, we deduce that \( f g t = 0 \) for every \( g \), hence \( (fg)|_{U_E} = 0 \), so finally \( s \in (\Gamma(W_E) \mathcal{O}_{X_E}^0)|_{U_E} \); whence the contention. \( \square \)

**Remark 16.4.25.** (i) Keep the notation of lemma 16.4.23. Notice that the rule \( A \mapsto (\varphi, \varphi^0) \) is functorial in \( A \). Namely, if \( g : A' \to A'' \) is any continuous ring homomorphism of perfectoid rings, and \( (\varphi', \varphi'^0) (\varphi'', \varphi''^0) \) the pairs attached to \( A' \) and respectively \( A'' \) as in lemma 16.4.23, then we have commutative diagrams of topological spaces and of sheaves of monoids:

\[
\begin{array}{ccc}
X_{A''} & \xrightarrow{\varphi''} & X_{E''} \\
\downarrow \psi_A & & \downarrow \psi_E \\
X_{A'} & \xrightarrow{\varphi'} & X_{E'} \\
\end{array}
\quad
\begin{array}{ccc}
\mathcal{O}_{X_{A''}} & \xrightarrow{\psi''} & \psi_{E''} \mathcal{O}_{X_{E''}} \\
\downarrow \psi_{A*} & & \downarrow \psi_{E*} \mathcal{O}_{X_{E''}} \\
\mathcal{O}_{X_{A'}} & \xrightarrow{\varphi'_*} & \varphi'_* \mathcal{O}_{X_{A'}} \\
\end{array}
\]

where \( X_{A'} := \text{Spec} A', X_{E'} := \text{Spec} E(A') \) and similarly for \( X_{A''} \) and \( X_{E''} \), and \( \psi_E := \text{Spec} g \), \( \psi_E := \text{Spec} E(g) \). The verification shall be left to the reader.

(ii) The short exact sequence of \( \mathcal{O}_{X_E} \)-modules

\[
\begin{array}{ccc}
\mathcal{O}_{X_E} & \xrightarrow{\iota_{E*} \nu_E^0} & \iota_{E*} \mathcal{O}_{X_E}^0 \\
\end{array}
\]

where \( X_{A'} := \text{Spec} A', X_{E'} := \text{Spec} E(A') \) and similarly for \( X_{A''} \) and \( X_{E''} \), and \( \psi_E := \text{Spec} g \), \( \psi_E := \text{Spec} E(g) \). The verification shall be left to the reader.
induces a commutative ladder for every open subset $\Omega \subset X_E$:

$$
\begin{array}{cccccc}
0 & \longrightarrow & H^0(\Omega, \mathcal{O}_{X_E}^\lambda) & \longrightarrow & H^0(\Omega, \mathcal{O}_{X_E}) & \longrightarrow & H^0(\Omega, i_{E_1*}\mathcal{O}_{X_{E_1}}) \\
& & \beta & \downarrow & & \beta_1 & \downarrow \\
0 & \longrightarrow & H^0(\varphi^{-1}\Omega, \mathcal{O}_{X_A}) & \longrightarrow & H^0(\varphi^{-1}\Omega, \mathcal{O}_{X_A}) & \longrightarrow & H^0(\varphi^{-1}\Omega, i_{A_1*}\mathcal{O}_{X_{A_1}}) \\
& & & & & \gamma & \\
\end{array}
$$

whose rows are the initial terms of the long exact cohomology sequence attached to $\mathcal{E}$, and where $\beta$ is induced by $\varphi$. The map $\beta_1$ is induced by $i_{E_1*}\varphi_1^\lambda$, where $\varphi_1^\lambda : \mathcal{O}_{X_{E_1}} \to \varphi_1^*\mathcal{O}_{X_{A_1}}$ is the morphism associated with the perfectoid ring $A_1$ and the induced continuous map $\varphi_1 : X_{E_1} \to X_{A_1}$ as in Lemma 16.4.23(iii). Lastly, $\beta^t$ and $\gamma$ are deduced from the restriction $\mathcal{O}_{X_E}^\lambda \to \mathcal{O}_{X_A}$ of $\varphi^\lambda$, which is an isomorphism of abelian sheaves (Lemma 16.4.23(ii,iii)); furthermore, these subsheaves are supported on the closed subsets $X_E^\lambda$ and respectively $X_A^\lambda$, and $\varphi$ restricts to a homeomorphism $\varphi_0 : X_E^\lambda \to X_A^\lambda$, so $\beta^t$ and $\gamma$ are isomorphisms of abelian groups. The commutativity of the left square subdiagram is clear, and that of the central one follows from (i). To show the commutativity of the right square subdiagram, pick any $\sigma \in H^0(\Omega, i_{E_1*}\mathcal{O}_{X_{E_1}})$, and find a covering $\Omega = \bigcup_{i,j} \Omega_{ij}$ consisting of open subsets, such that $\sigma|_{\Omega_{ij}}$ is the image of some $s_{ij} \in H^0(\Omega_{ij}, \mathcal{O}_{X_E})$, for every $i,j \in I$. Set $\Omega_{ij} := \Omega_i \cap \Omega_j$ for every $i,j \in I$, and let $s_{ij} := s_{i|\Omega_{ij}} - s_{j|\Omega_{ij}}$, and notice that $s_{ij} \in H^0(\Omega_{ij}, \mathcal{O}_{X_E})$ for every such $i,j$. Then the image of $\sigma$ in $H^1(\Omega, \mathcal{O}_{X_E})$ is the class of the Čech cocycle $(s_{ij} | i,j \in I)$, and the latter maps to the class of the cocycle $(\varphi_{X_{E}}^\lambda(s_{ij}) | i,j \in I)$ in $H^1(\varphi^{-1}\Omega, \mathcal{O}_{X_A})$. On the other hand, set $\tilde{\sigma} := \beta(\sigma)$; for every $i \in I$, the restriction of $\tilde{\sigma}$ to $\varphi^{-1}\Omega_i$ is the image of $\varphi_{X_{E}}^\lambda(s_{ij}) \in H^0(\Omega_{ij}, \mathcal{O}_{X_A})$, hence the image of $\tilde{\sigma}$ in $H^1(\varphi^{-1}\Omega, \mathcal{O}_{X_A})$ is the class of the cocycle $(t_{ij} | i \in I)$ with $t_{ij} := t_{ij|\varphi^{-1}\Omega_i} - t_{ij|\varphi^{-1}\Omega_j}$ for every $i,j \in I$. Lemma 16.4.23(iii) implies that $t_{ij} = \varphi_{X_{A}}^\lambda(s_{ij})$ for every $i,j \in I$, whence the assertion.

The following result shows that if $A$ is a perfectoid ring, proposition 8.3.30 holds even in case the open subset $U$ of Spec $A$ is not quasi-compact.

**Lemma 16.4.26.** Let $A$ be a perfectoid ring, and $U \subset X_A := \text{Spec } A$ an open subset containing the analytic locus of $X_A$. We have:

(i) There exists a unique topology $\mathcal{T}_U$ on $A_U := \mathcal{O}_{X_A}(U)$ such that $(A_U, \mathcal{T}_U)$ is $f$-adic and the restriction map $\rho_U : A \to A_U$ is open.

(ii) $(A_U, \mathcal{T}_U)$ is complete and separated.

(iii) Let $f : A \to B$ be any morphism of $f$-adic topological rings, such that the image of $Spec f$ lies in $U$. Then the resulting map $f_U : (A_U, \mathcal{T}_U) \to B$ is continuous.

**Proof.** (i): We pick a system of elements $(\beta_1, \ldots, \beta_r)$ of $E(A)$ such that the system $(f_i := \pi_A(\beta_i) | i = 1, \ldots, r)$ generates an ideal $I$ of adic definition of $A$. Like in the proof of proposition 8.3.30(i), there exists a unique topology $\mathcal{T}_U$ on $A_U$ such that $(A_U, \mathcal{T}_U)$ is a topological group for its additive group structure, and we need to check the following. For every $a \in A_U$ and every $n \in \mathbb{N}$ there exists $k \in \mathbb{N}$ such that

$$a \cdot \rho_U(I^k) \subset \rho_U(I^n).$$

Now, for $i = 1, \ldots, r$, let $a_i \in \text{Spec } A_{f_i}$ be the image of $a$ under the restriction map $\rho_i : A_U \to A_{f_i}$; we may find $m \in \mathbb{N}$ and $b_1, \ldots, b_r \in A$ such that $a_i = f_i^{-m} b_i$, hence $f_i^m a - b_i \in \text{Ker } \rho_i$ for $i = 1, \ldots, r$. Pick a family $(g_{\lambda} | \lambda \in \Lambda)$ of elements of $A$ such that $U = \bigcup_{\lambda \in \Lambda} V_\lambda$, where $V_\lambda := \text{Spec } A_{f_{i_{\lambda}}}$ for every $\lambda \in \Lambda$. Notice that $(f_i^m a - b_i)|_{V_\lambda}$ lies in the kernel of the restriction map $\mathcal{O}_U(V_\lambda) \to \mathcal{O}_U(V_\lambda \cap \text{Spec } A_{f_{i_{\lambda}}})$, for every $i = 1, \ldots, r$ and every $\lambda \in \Lambda$. Thus, for every such $\lambda$ and $i$ there exist $t_{\lambda, i} \in \mathbb{N}$ and $c_{i, \lambda} \in A$ such that

$$g_{\lambda}^s \cdot (f_i^m a - b_i)|_{V_\lambda} = \rho_{\lambda}(c_{i, \lambda}) \quad \text{and} \quad f_i^t c_{i, \lambda} = 0 \quad \text{in } A$$
where \( \rho_\lambda : A \to A_{g_\lambda} \) is the localization map. From corollary \([16.3.61](i)\) we then deduce that
\[
(f_i^{m+1}a - f_ib_i)|_{V_\lambda} = 0
\]
for every \( \lambda \in \Lambda \) and every \( i = 1, \ldots, r \)
\[i.e. \] \( f_i^{m+1}a = \rho_U(f_ib_i) \) for every \( i = 1, \ldots, r \). From this, we may argue as in the proof of proposition \([8.3.30](i)\), to derive the assertion.

(ii): It suffices to show that \( \text{Ker } \rho_V \) is a closed ideal of \( A \). However, clearly \( I \cdot \text{Ker } \rho_U = 0 \), so the assertion follows from remark \([16.4.19](v)\).

(iii) is proven as proposition \([8.3.30](iii)\).

We wish next to show that the formula for the Teichmüller representative of a sum obtained in proposition \([9.3.63]\) is still valid in f-adic rings of the type considered in lemma \([16.4.26]\).

16.4.27. Indeed, resume the situation of \([16.4.22]\), and let \( U \subset X_E \) be an open subset containing \( X_E \setminus \text{Spec } E/E^{\infty} \); from \([16.4.21]\) we easily see that \( X_A \setminus \text{Spec } A/A^{\infty} \subset \varphi^{-1}U \), so
\[
E_U := \mathcal{O}_{X_E}(U) \quad \text{and} \quad A_U := \mathcal{O}_{X_A}(\varphi^{-1}U)
\]
deserve the f-adic topologies \( \mathcal{T}_U \) and respectively \( \mathcal{T}_{\varphi^{-1}U} \) furnished by lemma \([16.4.26]\).

**Proposition 16.4.28.** With the notation of \([16.4.27]\), the following holds :

(i) The map \( \varphi_U^\flat : (E_U, \mathcal{T}_U) \to (A_U, \mathcal{T}_{\varphi^{-1}U}) \) of lemma \([16.4.23](i)\) is continuous.

(ii) For every \( x := (x_0, \ldots, x_k) \in E_U^{k+1} \) we have the identity
\[
\varphi_U^\flat(x_0 + \cdots + x_k) = \sum_{n \in \mathbb{N}} p^n \cdot \sum_{\sigma \in \Sigma_n^{(k)}} c_\sigma \cdot \varphi_U^\flat(x^\sigma)
\]
where \( \Sigma_n^{(k)} \) is defined as in \([9.3.62]\) for every \( n \in \mathbb{N} \), and \( c_\sigma \in \mathbb{Z}_p \) is provided by proposition \([9.3.63]\) for every \( \sigma \in \bigcup_{n \in \mathbb{N}} \Sigma_n^{(k)} \), the convergence of the series is relative to the topology \( \mathcal{T}_{\varphi^{-1}U} \).

**Proof.** (Recall that \( x^\sigma := x_0^{n_0} \cdots x_k^{n_k} \) for every \( \sigma := (\sigma_0, \ldots, \sigma_k) \in \mathbb{N}[1/p]^{k+1} \).

(ii): Let \( (\alpha_n \mid n \in \mathbb{N}) \) be any distinguished element in \( \text{Ker } u_A \); since \( \alpha_0 \) is topologically nilpotent in \( E \), its image is topologically nilpotent in \( E_U \), hence there exists \( c \in \mathbb{N} \) such that \( \alpha_0^n \cdot x_i \in \text{Im } (E \to E_U) \) for \( i = 0, \ldots, k \). In light of lemma \([16.2.7](iii)\), we deduce that
\[
y_n(x) := \sum_{\sigma \in \Sigma_n^{(k)}} p^n \cdot c_\sigma \cdot \varphi_U^\flat(x^\sigma) \in p^n\cdot \text{Im } (A \to A_U) \quad \text{for every integer } n \geq c.
\]
Taking into account lemma \([16.4.26](ii)\), it follows that the series \( \sum_{n \in \mathbb{N}} y_n(x) \) converges for the topology \( \mathcal{T}_{\varphi^{-1}U} \) to a well determined element \( y \in A_U \), and it remains only to check that
\[
y = \varphi_U^\flat(x_0 + \cdots + x_k).
\]
To this aim, pick a family \( (g_\lambda \mid \lambda \in \Lambda) \) of elements of \( E \), such that
\[
U = \bigcup_{\lambda \in \Lambda} V_\lambda, \quad \text{where } V_\lambda := \text{Spec } E_{g_\lambda} \quad \text{for every } \lambda \in \Lambda.
\]
Then, for every such \( \lambda \) we may find \( n_\lambda \in \mathbb{N} \) such that \( (g_\lambda^{n_\lambda} \cdot x_i)|_{V_\lambda} \in \text{Im } (E \to E_{g_\lambda}) \) for \( i = 0, \ldots, k \), and it suffices to check that
\[
([g_\lambda^{n_\lambda}] \cdot \varphi_U^\flat(x_0 + \cdots + x_k))|_{\varphi^{-1}V_\lambda} = ([g_\lambda^{n_\lambda}] \cdot y)|_{\varphi^{-1}V_\lambda},
\]
where \( [g_\lambda^{n_\lambda}] := \overline{\rho}_A(g_\lambda^{n_\lambda}) \) for every such \( \lambda \).

However, we have
\[
[g_\lambda^{n_\lambda}] \cdot \varphi_U^\flat(x_0 + \cdots + x_k) = \varphi_U^\flat(g_\lambda^{n_\lambda} \cdot x_0 + \cdots + g_\lambda^{n_\lambda} \cdot x_k) \quad \text{and} \quad [g_\lambda^{n_\lambda}] \cdot y = \sum_{n \in \mathbb{N}} y_n(g_\lambda^{n_\lambda} \cdot x)
\]
where \( g_\lambda^{n_\lambda} \cdot x := (g_\lambda^{n_\lambda} \cdot x_0, \ldots, g_\lambda^{n_\lambda} \cdot x_k) \). Hence, we may replace \( x \) by \( g_\lambda^{n_\lambda} \cdot x \), after which we may assume that \( x_i \in \text{Im } (\rho_U : E \to E_U) \) for \( i = 0, \ldots, k \). In this case, say that \( x_i = \rho_U(z_i) \) for \( i = 0, \ldots, k \) and for certain \( z_0, \ldots, z_k \in E \); we have
\[
\varphi_U^\flat(x_0 + \cdots + x_k) = \rho_{\varphi^{-1}U} \circ \varphi_{X_E}^\flat(z_0 + \cdots + z_k) = \rho_{\varphi^{-1}U} \circ \overline{\rho}_A(z_0 + \cdots + z_k)
\]
where \(\rho_{\varphi^{-1}U} : A \to A_U\) is the corresponding restriction map; on the other hand, since \(\rho_{\varphi^{-1}U}\) is continuous for the topology \(\mathcal{T}_{\varphi^{-1}U}\), we have as well

\[
y = \sum_{n \in \mathbb{N}} p^n \cdot \sum_{\sigma \in \Sigma_n} c_{\sigma} \cdot \rho_{\varphi^{-1}U} \circ \varphi_{X_E}^\sigma (\xi_{\sigma}) = \rho_{\varphi^{-1}U} \left( \sum_{n \in \mathbb{N}} p^n \cdot \sum_{\sigma \in \Sigma_n} c_{\sigma} \cdot \varphi_{X_E}^\sigma (\xi_{\sigma}) \right)
\]

so the sought identity follows from proposition [9.3.63].

(i): Fix \(x_0 \in U_E\); the proof of (ii) shows that for every \(k \in \mathbb{N}\) there exists \(n \in \mathbb{N}\) such that \(y_r(x_0 + x) \in p^k \cdot \text{Im}(A \to A_U)\) for every \(r \geq n\) and every \(x \in \text{Im}(E \to U_E)\). On the other hand, clearly the mappings \(y_i\) are continuous for every \(i \in \mathbb{N}\), relative to the topologies \(\mathcal{T}_U\) and \(\mathcal{T}_{\varphi^{-1}U}\). The assertion follows immediately. \(\square\)

16.4.29. Keep the notation of (16.4.22), let \(U_E \subseteq X_E\) be any open subset, and set \(U_A := \varphi^{-1}U_E, Z_E := X_E \setminus U_E, Z_A := X_A \setminus U_A\). Denote by \(j_E : U_E \to X_E\) and \(j_A : U_A \to X_A\) the open immersions; the map \(\varphi^b\) of lemma [16.4.23](i) induces a morphism of sheaves of monoids

\[
\psi : j_E^* \mathcal{O}_{X_E} \xrightarrow{j_E^* j_E^\epsilon(\varphi^b)} j_E^* j_E^* \mathcal{O}_{X_A} \xrightarrow{\varphi^b_* j_A^* \mathcal{O}_{X_A}} \mathcal{O}_{X_A}
\]

Moreover, let

\[
\mathcal{O}_{X_E} := \text{Im}(\mathcal{O}_{X_E} \to j_E^* \mathcal{O}_{X_E}) \quad \mathcal{O}_{X_A} := \text{Im}(\mathcal{O}_{X_A} \to j_A^* \mathcal{O}_{X_A})
\]

Denote by \(\pi_E : j_E^* \mathcal{O}_{X_E} \to R^1 \Gamma Z_E \mathcal{O}_{X_E}\) and \(\pi_A : j_A^* \mathcal{O}_{X_A} \to R^1 \Gamma Z_A \mathcal{O}_{X_A}\) the projections, set \(q := \pi_A(\alpha_0)\), and for every \(c \in \mathbb{N}[1/p]\) define

\[
\alpha_0^{-c} \mathcal{O}_{X_E} := \text{Ker} \alpha_0^{-c} \cdot \mathcal{O}_{X_E}
\]

\[
p^{-c} \mathcal{O}_{X_A} := \text{Ker} q^c \cdot \pi_A
\]

\[
\mathcal{O}_{U_E}^c := \pi_E(\alpha_0^{-c} \mathcal{O}_{X_E})
\]

\[
\mathcal{O}_{U_A}^c := \pi_A(p^{-c} \mathcal{O}_{X_A})
\]

Also, set

\[
\mathcal{R}^c := \text{Coker}(\varphi_* \mathcal{O}_{X_A} \to \varphi_*(p^{-c} \mathcal{O}_{X_A})) \quad \text{and let} \quad \lambda : \mathcal{R}^c \to \varphi_* \mathcal{O}_{U_A}^c
\]

be the natural morphism of \(\mathcal{O}_{X_A}\)-modules; lemma [16.2.7](iii) easily implies that \(\psi\) restricts to a morphism of sheaves of sets

\[
\psi^c : \alpha_0^{-c} \mathcal{O}_{X_E} \to \varphi_*(p^{-c} \mathcal{O}_{X_A}) \quad \text{for every} \quad c \in \mathbb{N}[1/p].
\]

**Proposition 16.4.30.** With the notation of (16.4.29), suppose moreover that:

(a) \(\text{Spec } E[\alpha_0^{-1}] \subseteq U_E\).

(b) \(U_E\) is quasi-compact.

(c) \(c \leq p/(p - 1)\).

Then we have:

(i) The map \(\psi^c\) descends to a morphism of sheaves of sets

\[
\overline{\psi^c} : \mathcal{O}_{U_E}^c \to \mathcal{R}^c \xrightarrow{\lambda} \varphi_* \mathcal{O}_{U_A}^c.
\]

(ii) There exist unique morphisms of sheaves of sets

\[
\overline{\rho}_E : \mathcal{O}_{U_E}^{c/p} \to \mathcal{O}_{U_E}^c \quad \text{and} \quad \overline{\rho}_A : \mathcal{O}_{U_A}^{c/p} \to \mathcal{O}_{U_A}^c
\]
fitting into commutative diagrams

\[ \begin{array}{ccc}
\alpha_{\sigma}^{-c/p} \mathcal{O}_{X_E} & \longrightarrow & \alpha_{\sigma}^{-c} \mathcal{O}_{X_E} \\
\Downarrow & & \Downarrow \\
\mathcal{Q}^{c/p} \mathcal{U}_E & \longrightarrow & \mathcal{Q}^c \mathcal{U}_E
\end{array} \]

\[ \begin{array}{ccc}
p^{-c/p} \mathcal{O}_{X_A} & \longrightarrow & p^{-c} \mathcal{O}_{X_A} \\
\Downarrow & & \Downarrow \\
\mathcal{Q}^{c/p} \mathcal{U}_A & \longrightarrow & \mathcal{Q}^c \mathcal{U}_A
\end{array} \]

whose vertical arrows are the projections, and whose top horizontal arrows are the restrictions of the \( p \)-Frobenius endomorphisms of the sheaves of monoids \( j_{E*} \mathcal{O}_{U_E} \) and respectively \( j_{A*} \mathcal{O}_{U_A} \) (with composition law given by multiplication).

(iii) Moreover, we have a commutative diagram of sheaves of sets:

\[ \begin{array}{ccc}
\mathcal{Q}^{c/p} \mathcal{U}_E & \longrightarrow & \mathcal{Q}^c \mathcal{U}_E \\
\Downarrow \varphi^c/p & & \Downarrow \varphi^c \\
\mathcal{Q}^{c/p} \mathcal{U}_A & \longrightarrow & \mathcal{Q}^c \mathcal{U}_A
\end{array} \]

(iv) If \( c \leq 1 \), the map \( \varphi^c \) is an isomorphism of sheaves of abelian groups.

Proof. (i): Let \( f \in \mathcal{E} \) be any element, and set \( V := \text{Spec} \mathcal{E}_f \); we easily come down to showing Claim 16.4.31. If \( c \leq p/(p-1) \), we have

\[ \psi_V^c(x + y) - \psi_V^c(x) \in \mathcal{O}_{X_A}(\varphi^{-1}V) \quad \text{for every} \quad x \in \alpha_{0}^{-c} \mathcal{O}_{X_E}(V) \quad \text{and} \quad y \in \mathcal{O}_{X_E}(V). \]

Proof of the claim. Since \( \mathcal{U}_E \) is quasi-compact, \( j_{E*} \mathcal{O}_{U_E} \) is a quasi-coherent \( \mathcal{O}_{X_E} \)-module ([44, Ch.I, Cor.9.2.2]), hence the same holds for \( \alpha_{0}^{-c} \mathcal{O}_{X_E} \), and consequently

\[ \alpha_{0}^{-c} \mathcal{O}_{X_E}(V) = \alpha_{0}^{-c} \mathcal{O}_{X_E}(X_E)_f. \]

We may therefore find \( n \in \mathbb{N} \) such that \( f^n x \) (resp. \( f^n y \)) is the restriction to \( V \) of a global section \( x' \in \alpha_{0}^{-c} \mathcal{O}_{X_E}(X_E) \) (resp. of an element \( y' \in \mathcal{E} \)), and it suffices to show that

\[ \psi_{X_E}^c(x' + y') - \psi_{X_E}^c(x') \in \text{Im} (A \to j_{A*} \mathcal{O}_{U_A}(X_A) = \mathcal{O}_{X_A}(U_A)). \]

Hence, we may replace \( V \) by \( X_E \), and assume from start that

\[ x \in \mathcal{O}_{X_E}(U_E) \quad \text{and} \quad \alpha_0 \cdot x, y \in \text{Im} (\mathcal{E} \to \mathcal{O}_{X_E}(U_E)) \]

and we have to show that \( \varphi_{U_E}^c(x + y) - \varphi_{U_E}^c(x) \in \text{Im} (A \to \mathcal{O}_{X_A}(U_A)). \) Notice that the assertion is independent of the topology \( \mathcal{T} \) of \( A \) such that \( (A, \mathcal{T}) \) is perfectoid; by virtue of proposition 16.3.8(i) we may then assume that \( \mathcal{T} \) is the \( p \)-adic topology on \( A \), and therefore the topology of \( \mathcal{E} \) agrees with the \( \alpha_0 \)-adic topology. In this case, assumption (a), proposition 16.4.28(ii) and lemma 16.2.7(iii) imply that \( \varphi_{U_E}^c(x + y) - \varphi_{U_E}^c(x) = \varphi_{U_E}^c(y) \) is a \( p \)-adically convergent series \( \sum_{n>0} z_n \), where \( z_n \) is a \( \mathbb{Z}_p \)-linear combination of terms of the form \( \varphi_{U_E}^c(\alpha_0^s \cdot x^\sigma \cdot y^{1-s}) \), with \( 1 - \sigma, \sigma \in p^{-n}\mathbb{N} \backslash p^{1-n}\mathbb{N} \), for every \( n \in \mathbb{N} \). Hence, it suffices to check that \( n \geq p \cdot \sigma/(p-1) \) for every such \( \sigma \) and every integer \( n > 0 \). We leave the easy verification to the reader.

(ii): The uniqueness of \( \overline{\mathcal{U}}_{A*} \) is clear. For the existence, let \( V \) be as in the foregoing; we come down to showing that

\[ (x + y)^p - x^p \in \mathcal{O}_{X_A}(V) \quad \text{for every} \quad x \in p^{-c/p} \mathcal{O}_{X_A}(V) \quad \text{and} \quad y \in \mathcal{O}_{X_A}(V). \]

However, \( (x + y)^p - x^p = y^p + \sum_{i=1}^{p-1} \binom{p}{i} x_i y^{p-i} \), and \( px_i \in \mathcal{O}_{X_A}(V) \) for every \( i = 1, \ldots, p-1 \), since \( c \leq p/(p-1) \), whence the contention. Assertion (iii) shall be left to the reader.

(iv): Let \( V \) be as in the foregoing; in order to prove that \( \overline{\varphi}^c \) is a morphism of abelian sheaves when \( c \leq 1 \), we come down to showing that

\[ \psi_V^c(x + y) - \psi_V^c(x) - \psi_V^c(y) \in \mathcal{O}_{X_A}(\varphi^{-1}V) \quad \text{for every} \quad x, y \in \alpha_{0}^{-1} \mathcal{O}_{X_E}(V). \]
and arguing as in the proof of claim \[16.4.31\] we reduce to the case where \( V = X_E \) and \( x, y \) are sections of \( \mathcal{O}_{X_E}(U_E) \) such that \( \alpha_0x, \alpha_0y \in \text{Im}(E \to \mathcal{O}_{X_E}(U_E)) \). Then, it suffices to check that

\[
\varphi^\flat_U(\alpha_0^n \cdot y^\sigma \cdot x^{1-\sigma}) \in \text{Im}(A \to \mathcal{O}_{X_A}(U_A)) \quad \text{whenever } n > 0 \text{ and } 1 - \sigma, \sigma \in \mathbb{N}[1/p]
\]

which is clear. Next notice that, by remark \[16.4.25\] the pair \((\varphi, \varphi^n)\) restricts to isomorphisms of schemes

\[
(\varphi_2, \varphi^h_2) : X_{A_2} \xrightarrow{\sim} X_{E_2} \quad (\varphi_3, \varphi^h_3) : X_{A_3} \xrightarrow{\sim} X_{E_3} \quad \text{such that } \varphi_2(Z_A) = Z_E.
\]

**Claim 16.4.32.** Assertion (iv) holds for \( U_E = \text{Spec } E[\alpha_0^{-1}] \).

**Proof of the claim.** We have commutative diagrams

\[
\begin{array}{ccc}
U_{E_1} & \xrightarrow{j_{E_1}} & U_E \\
\downarrow j_{E_1} & & \downarrow j_E \\
X_{E_1} & \xrightarrow{i_{E_1}} & X_E
\end{array}
\quad \begin{array}{ccc}
U_{A_1} & \xrightarrow{j_{A_1}} & U_A \\
\downarrow j_{A_1} & & \downarrow j_A \\
X_{A_1} & \xrightarrow{i_{A_1}} & X_A
\end{array}
\]

whose top horizontal arrows are isomorphisms of schemes, whence commutative diagrams of abelian sheaves

\[
\begin{array}{ccc}
\mathcal{O}_{X_E} & \xrightarrow{\sim} & i_{E_1*} \mathcal{O}_{X_{E_1}} \\
\downarrow j_{E*} & & \downarrow i_{E_1*} \circ j_{E_1*} \mathcal{O}_{U_{E_1}} \\
\mathcal{O}_{X_A} & \xrightarrow{\sim} & i_{A_1*} \mathcal{O}_{X_{A_1}}
\end{array}
\]

whose left (resp. right) vertical arrows are the inclusion maps (resp. are induced by the inclusion maps \( \mathcal{O}_{X_{E_1}} \to j_{E_1*} \mathcal{O}_{U_{E_1}} \) and \( \mathcal{O}_{X_{A_1}} \to j_{A_1*} \mathcal{O}_{U_{A_1}} \)). Moreover, denote by \( \varphi_1 : X_{A_1} \to X_{E_1} \) the continuous map associated with \( A_1 \), as in \[16.4.18\], and by

\[
\psi_1 : j_{E_1*} \mathcal{O}_{U_{E_1}} \to \varphi_1* j_{A_1*} \mathcal{O}_{U_{A_1}} \quad (\text{resp. } \psi_1^c : \mathcal{O}_{U_{E_1}} \to \varphi_1* \mathcal{O}_{U_{A_1}})
\]

the corresponding morphism of sheaves of monoids as in \[16.4.29\] (resp. morphism of sheaves of sets, as in (i)); then \( i_{E_1*} \circ \varphi_1 = \varphi \circ i_{A_1} \) (remark \[16.4.25\]).

So finally, \( \psi_1^c \) is identified with \( i_{E_1*} \psi_1^c \) for every \( c \leq p/(p - 1) \), and we may replace from start \( A \) by \( A_1 \), after which, we may assume that \( \alpha_0 \) (resp. \( p \)) is regular in \( E \) (resp. in \( A \)). In this case, for every \( c \leq 1 \) we have a commutative diagram of sheaves :

\[
\begin{array}{ccc}
\mathcal{O}_{X_E} & \xrightarrow{\sim} & \varphi_* \mathcal{O}_{U_A} \\
\downarrow & & \downarrow \\
\mathcal{O}_{X_A}/\alpha_0^c \mathcal{O}_{X_E} & \xrightarrow{\sim} & \varphi_* (\mathcal{O}_{X_A}/p^c \mathcal{O}_{X_A})
\end{array}
\]

whose left (resp. right) vertical arrow is the isomorphism induced by scalar multiplication by \( \alpha_0^c \) (resp. by \( q^c \)) and whose bottom horizontal arrow is the isomorphism induced by \( \varphi_0^\flat \) (notation of \[16.4.22\]). The claim follows.

**Claim 16.4.33.** We may assume that the natural maps \( \mathcal{O}_{X_E} \to \mathcal{O}_{X_E} \) and \( \mathcal{O}_{X_A} \to \mathcal{O}_{X_A} \) are isomorphisms.

**Proof of the claim.** Assumption (a) implies that \( Z_E \subset X_{E_2} \) and \( Z_A \subset X_{A_2} \), therefore

\[
\mathcal{J}_E := \text{Ker}(\mathcal{O}_{X_E} \to \mathcal{O}_{X_E}) = \Gamma_{Z_E} \mathcal{O}_{X_E}^\flat \quad \mathcal{J}_A := \text{Ker}(\mathcal{O}_{X_A} \to \mathcal{O}_{X_A}) = \Gamma_{Z_A} \mathcal{O}_{X_A}^\flat
\]

(notation of \[16.4.22\]), and lemma \[16.4.23\] (ii,iii) implies that \( \varphi^\flat \) restricts to an isomorphism of abelian sheaves

\[
\mathcal{J}_E \xrightarrow{\sim} \varphi_* \mathcal{J}_A.
\]

\[16.4.34\]
Notice that $J : = \Gamma(X_E, \mathcal{J}_E)$ is an ideal of both $E$ and $E_2$, and moreover $\Phi_E(J) = J$. Indeed, $J$ consists of all $x \in E$ whose images vanish in $E_f$, for every $f \in E$ such that $\text{Spec } E_f \subset U_E$: since $E_f$ is still a perfect $\mathbb{F}_p$-algebra, it follows easily that $x \in J$ if and only if $x^p \in J$, hence the assertion. Thus, both $E : = E/J$ and $E_2 : = E_2/J$ are still perfect $\mathbb{F}_p$-algebras, and are even perfectoid, with the quotient topologies induced by the projections $E \to E_1$ and $E_2 \to E_2$. Moreover, it is easily seen that the diagram $\mathcal{E}$ of (16.4.18) induces a natural identification

$$E \cong E_1 \times_{E_3} E_2.$$ 

Let $h_E : X_E : = \text{Spec } E \to X_E$ be the closed immersion, $j_E : U_E : = U_E \cap X_E \to X_E$ the open immersion, and consider the corresponding quasi-coherent $\mathcal{O}_{X_E}$-module $\mathcal{D}^*_{U_E}$ as in (16.4.29). Since $U_E$ is quasi-compact, $\mathcal{J}_E$ is a quasi-coherent $\mathcal{O}_{X_E}$-module (see (10.4.16)), so $\mathcal{J}_E = \text{Ker } (\mathcal{O}_{X_E} \to h_{E*}\mathcal{O}_{X_E})$; it follows that the induced map $\mathcal{O}_{X_E} \to j_{E*}\mathcal{O}_{U_E}$ is a monomorphism, and $h_E$ restricts to an isomorphism of open subschemes $U_E \cong U_E$, so the resulting map $j_{E*}\mathcal{O}_{U_E} \to h_{E*}j_{E*}\mathcal{O}_{U_E}$ is an isomorphism, and we get a natural identification

$$\omega_E : \mathcal{D}^*_{U_E} \cong h_{E*}\mathcal{D}^*_{U_E}.$$ 

Next, consider the cartesian diagram $A(\mathcal{E})$ of (16.4.18), and recall that the bottom horizontal arrow $A_2 \to A_3$ of $A(\mathcal{E})$ is naturally isomorphic to the bottom horizontal arrow $E_2 \to E_3$ of $\mathcal{E}$ (remark [16.4.18] iii)). There follows a commutative diagram

$$\begin{array}{ccc}
A & \longrightarrow & \overline{A} \\
\downarrow & & \downarrow \\
\pi_1 & \longrightarrow & \overline{A} \\
\pi_2 & \downarrow & \downarrow \\
E_2 & \longrightarrow & E_2 & \longrightarrow & E_3 \\
\end{array}$$

whose two square subdiagrams are cartesian. Especially, $J$ is naturally identified with the kernel of the projection $A \to \overline{A}$; moreover, we have an isomorphism of topological rings

$$E(\overline{A}) \cong E$$

that identifies $E(\pi_1)$ and $E(\pi_2)$ with the projections $\overline{E} \to E_1$ and $\overline{E} \to E_2$, and furthermore, $\overline{A}$ is perfectoid (proposition [16.3.25]). Let also

$$h_A : X_\overline{A} : = \text{Spec } \overline{A} \to X_A \quad \text{and} \quad j_\overline{A} : U_\overline{A} : = U_A \cap X_\overline{A} \to X_\overline{A}$$

be respectively the closed and the open immersion, and consider the corresponding quasi-coherent $\mathcal{O}_{X_\overline{A}}$-module $\mathcal{D}^*_{U_\overline{A}}$, defined as in (16.4.29); in light of (16.4.34), we see that $\mathcal{J}_A = \text{Ker } (\mathcal{O}_{X_A} \to h_{A*}\mathcal{O}_{X_\overline{A}})$, and $h_A$ restricts to an isomorphism of open subschemes $U_\overline{A} \cong U_A$, so the resulting map $j_{A*}\mathcal{O}_{U_A} \to h_{A*}j_{A*}\mathcal{O}_{U_\overline{A}}$ is an isomorphism, and we get a natural identification

$$\omega_A : \mathcal{D}^*_{U_A} \cong h_{A*}\mathcal{D}^*_{U_\overline{A}}.$$ 

Lastly, let $\varphi : X_\overline{A} \to X_E$ be the continuous map provided by (16.4.18), and $\varphi_* : \mathcal{D}^*_{U_\overline{A}} \to \varphi_*\mathcal{D}^*_{U_{E}}$ the morphism of abelian sheaves attached to $\overline{A}$ and $U_\overline{A}$ as in (i); a direct inspection yields a commutative diagram

$$\begin{array}{ccc}
\mathcal{D}^*_{U_\overline{A}} & \longrightarrow & \varphi_*\mathcal{D}^*_{U_A} \\
\downarrow & & \downarrow \\
h_{E*}\varphi_*\mathcal{D}^*_{U_\overline{A}} & \longrightarrow & h_{E*}\varphi_*\mathcal{D}^*_{U_{E}} = \varphi_*h_{A*}\mathcal{D}^*_{U_\overline{A}} \\
\end{array}$$

whence the claim. ◇
Henceforth we assume that $\mathcal{O}_{X_E} = \mathcal{O}_{X_A}$ and $\mathcal{O}_{X_A} = \mathcal{O}_{X_A}$. Set $U'_E := \text{Spec } \mathbb{E}[\alpha_0^{-1}]$, so that $U'_A := \varphi^{-1}U'_E$ is the open subset $\text{Spec } A[\rho^{-1}]$ of $X_A$, and let $j'_E : U'_E \to X_E$ and $j'_A : U'_A \to X_A$ be the open immersions. Set also $Z'_E := X_E \setminus U'_E$ and $Z'_A := X_A \setminus U'_A$. Notice that

$$i_{E1,*}\mathcal{O}_{X_E1} = \text{Im}(\mathcal{O}_{X_E} \to j'_E,*)\mathcal{O}_{U'_E}) \quad \text{and} \quad i_{A1,*}\mathcal{O}_{X_A1} = \text{Im}(\mathcal{O}_{X_A} \to j'_A,*\mathcal{O}_{U'_A})$$

and denote by $\bar{\psi}^c : \mathcal{P}^c_{U'_E} \to \mathcal{P}^c_{U'_A}$ the map of abelian sheaves associated as in (i) with $A$ and $U'_E$. Since $U'_E \subset U'_E$, the natural maps $j'_E,*\mathcal{O}_{U'_E} = \mathcal{J}'_{E} \mathcal{O}_{U'_E}$ and $j'_A,*\mathcal{O}_{U'_A} = \mathcal{J}'_A \mathcal{O}_{U'_A}$ induce morphisms $\rho_E : R^1\Gamma_{Z_E}\mathcal{O}_{X_E} \to R^1\Gamma_{Z'_E}\mathcal{O}_{X_E}$ and $\rho_A : R^1\Gamma_{Z_A}\mathcal{O}_{X_A} \to R^1\Gamma_{Z'_A}\mathcal{O}_{X_A}$, and notice that the image of $\rho_E$ (resp. of $\rho_A$) lies in $\Gamma_{Z_E} R^1\Gamma_{Z'_E}\mathcal{O}_{X_E}$ (resp. in $\Gamma_{Z_A} R^1\Gamma_{Z'_A}\mathcal{O}_{X_A}$); there follows a commutative diagram

$$\xymatrix{ \mathcal{P}^c_{U'_E} \ar[r]^-{\bar{\psi}^c} \ar[d]_{\mathcal{E}_{Z_E}\mathcal{P}^c_{U'_E}} & \mathcal{P}^c_{U'_A} \ar[d]_{\mathcal{E}_{Z_A}\mathcal{P}^c_{U'_A}} \\ \Gamma_{Z_E}\mathcal{P}^c_{U'_E} & \Gamma_{Z_E}\mathcal{P}^c_{U'_A} = \mathcal{E}_{Z_A}\mathcal{P}^c_{U'_A} \mathcal{E}_{Z_E}\mathcal{P}^c_{U'_E} \mathcal{P}^c_{U'_A}}$$

where $\mathcal{E}_{Z_E}\mathcal{P}^c_{U'_E}$ (resp. $\mathcal{E}_{Z_A}\mathcal{P}^c_{U'_A}$) is the restriction of $\rho_E$ (resp. $\rho_A$). From the snake lemma, we obtain natural identifications

$$\text{Ker } \mathcal{E}_{Z_E}\mathcal{P}^c_{U'_E} \simeq \text{Ker } (\mathcal{O}_{X_E} \to j'_E,*)\mathcal{O}_{X_E}) \quad \text{and} \quad \text{Ker } \mathcal{E}_{Z_A}\mathcal{P}^c_{U'_A} \simeq \text{Ker } (\mathcal{O}_{X_A} \to j'_A,*)\mathcal{O}_{X_A})$$

(16.4.22).

**Claim 16.4.35.** The map $\bar{\psi}^c$ restricts to an isomorphism of abelian sheaves

$$\text{Ker } \mathcal{E}_{Z_E}\mathcal{P}^c_{U'_E} \simeq \text{Ker } \mathcal{E}_{Z_A}\mathcal{P}^c_{U'_A} \simeq \text{Ker } \mathcal{E}_{Z_A}\mathcal{P}^c_{U'_A} \mathcal{E}_{Z_E}\mathcal{P}^c_{U'_E} \mathcal{P}^c_{U'_A}$$

Proof of the claim. Notice that

$$\Gamma_{X_{E2}} \mathcal{O}_{X_E} \simeq j'_E,\mathcal{O}_{X_{E}}^c \quad \text{and} \quad \Gamma_{X_{A2}} \mathcal{O}_{X_A} \simeq j'_A,\mathcal{O}_{X_{A}}^c.$$  

In view of lemma [16.4.23(ii)], we deduce that $\psi^c$ induces an isomorphism of abelian sheaves

$$\text{Ker } \mathcal{E}_{Z_E}\mathcal{P}^c_{U'_E} \simeq \text{Ker } \mathcal{E}_{Z_A}\mathcal{P}^c_{U'_A} \simeq \text{Ker } \mathcal{E}_{Z_A}\mathcal{P}^c_{U'_A} \mathcal{E}_{Z_E}\mathcal{P}^c_{U'_E} \mathcal{P}^c_{U'_A}$$

Now, proposition [16.4.20(ii)] implies that $\psi^c$ is an exact functor on the category of quasi-coherent $\mathcal{O}_{X_A}$-modules, and since both $U_A$ and $U'_A$ are quasi-compact (see (16.1.3)), the $\mathcal{O}_{X_A}$-modules $j'_A,\mathcal{O}_{X_{A}}^c$ and $\mathcal{O}_{X_A}$ are quasi-coherent ([44, Ch.I, Cor.9.2.2]) so $\lambda$ restricts to an isomorphism $\mathcal{B} \simeq \psi^c \mathcal{B}$, whence the claim.

Now, claim [16.4.32] implies that $\Gamma_{Z_E}\bar{\psi}^c$ is an isomorphism, and in light of claim [16.4.35] we see that $\bar{\psi}^c$ is a monomorphism, so we are reduced to showing that $\Gamma_{Z_E}\bar{\psi}^c$ induces an epimorphism $\text{Im } \mathcal{E}_{Z_E}\mathcal{P}^c_{U'_E} \to \text{Im } \mathcal{E}_{Z_A}\mathcal{P}^c_{U'_A} \mathcal{E}_{Z_E}\mathcal{P}^c_{U'_E} \mathcal{P}^c_{U'_A}$. To this aim, let $x \in X_E$ be any point, and let $s_x \in \text{Im } (\psi^c, \mathcal{P}^c_{U'_E}) = \psi^c, (\text{Im } \mathcal{E}_{Z_A}\mathcal{P}^c_{U'_A})$ any element; by proposition [16.4.20(ii)], the functor $\psi^c$ is exact on quasi-coherent $\mathcal{O}_{X_A}$-modules, so both maps

$$\psi^c (\mathcal{O}_{X_A})_{x} \twoheadrightarrow \psi^c (\mathcal{P}^c_{U'_A})_{x} \twoheadrightarrow \psi^c (\text{Im } \mathcal{E}_{Z_A}\mathcal{P}^c_{U'_A})_{x}$$

are surjective, hence we may find an open neighborhood $\Omega \subset X_E$ of $x$ such that $s_x$ lifts to a section $s \in \mathcal{O}_{X_A} (U_A \cap \varphi^{-1}\Omega)$ and $q' * s$ extends to a section of $\mathcal{O}_{X_A} (\varphi^{-1}\Omega)$ (where $q$ is as in (16.4.29)). Denote by $t_x \in (\Gamma_{Z_E}\mathcal{P}^c_{U'_E})_{x}$ the preimage of $s_x$. Notice that

$$\Gamma_{Z_E} R^1\Gamma_{Z'_E}\mathcal{O}_{X_E} = (j'_E,\mathcal{O}_{X_{E1}})/i_{E1,*}\mathcal{O}_{X_E}$$
so we may replace $\Omega$ by a smaller open neighborhood of $x$, and assume that $t_x$ is the image of a section $\bar{t} \in i_{E_x}^* \mathcal{O}_{X_{E_1}}(U \cap \Omega)$. Denote by $\overline{s} \in i_{A_1} \mathcal{O}_{X_{A_1}}(U_A \cap \varphi^{-1}\Omega)$ the image of $s$, and set

$$\overline{u} := i_{E_1} \varphi_1^*(\overline{t}) - \overline{s} \in j_{A_1} j_{\mathfrak{a}}^* i_{A_1} \mathcal{O}_{X_{A_1}}(\varphi^{-1}\Omega).$$

By construction, the image of $\overline{u}$ vanishes in $(\varphi_* R^1 \mathcal{H}^j_{X_1})_x$, thus $\overline{u}_x \in \varphi_*(i_{A_1} \mathcal{O}_{X_{A_1}})_x$. By proposition 16.4.20(ii), the natural map $\varphi_* (\mathcal{O}_{X_1})_x \to \varphi_*(i_{A_1} \mathcal{O}_{X_{A_1}})_x$ is surjective, so we may replace $\Omega$ by a smaller open neighborhood of $x$, and assume that $\overline{u}$ is the image of a local section $u \in \mathcal{O}_{X_1}(\varphi^{-1}\Omega)$. However, $s$ and $s' := s + u_{(x)} \varphi^{-1} \Omega$ have the same image in $\varphi_*(\mathcal{D}_u^c)_x$, so we may replace $s$ by $s'$, and assume that $i_{E_1} \varphi_1^*(\overline{t}) = \overline{s}$. In this situation, remark 16.4.25(ii) implies that $\bar{t}$ lifts to a section $t \in \mathcal{O}_{X_E}(U \cap \Omega)$ such that $\varphi^*(t) = s$, and we denote by $v \in R^1 \mathcal{H}^j_{X_E} (\Omega)$ the image of $t$. Clearly, the image of $v$ in $(\mathcal{H}^j_{X_E})_x$ agrees with $t_x$, hence it remains only to check that $v_x \in \mathcal{D}_u^c$. But notice that $\alpha_0 \cdot t_x = 0$, so $\alpha_0 \cdot v_x \in (j_{E_1} j_{x}^* \mathcal{O}_{X_{E_1}})_x$. Pick any $\varepsilon \in \mathbb{N}[1/p]$ such that $0 < \varepsilon \leq \min(p/(p-1) - c, 1)$; by virtue of corollary 16.3.61(ii), it follows that $\alpha_0 \cdot v_x = 0$ is the image of a $\varphi_*(\mathcal{D}_u^{c+\varepsilon})_x$, and therefore $\alpha_0 \cdot v_x = 0$, since we have already remarked that $\varphi^*$ is a monomorphism. The assertion follows.

16.5. **Perfectoid quasi-affinoid rings.** We wish now to merge the theory of perfectoid rings with that of affinoid rings of section 15.3. First, let us make the following definitions:

**Definition 16.5.1.**

(i) We say that a quasi-affinoid ring $(A, A^+, U)$ is perfectoid if $A$ is a perfectoid ring.

(ii) We say that a quasi-affinoid scheme $X$ is perfectoid, if there exists a perfectoid quasi-affinoid ring $A$ and an isomorphism $X \sim \text{Spec } A$.

(iii) We denote by

$$q_{\text{Afd.Ring}_{\text{perf}}} \quad \text{and} \quad q_{\text{Afd.Sch}_{\text{perf}}}$$

the subcategories of q.Afd.Ring and respectively q.Afd.Sch whose objects are the perfectoid quasi-affinoid rings (resp. schemes), and whose morphisms are the $f$-adic morphisms of quasi-affinoid rings (resp. schemes).

16.5.2. Clearly we have a well defined functor

$$q_{\text{Afd.Ring}_{\text{perf}}} \to q_{\text{Afd.Sch}_{\text{perf}}} \quad A \mapsto \text{Spec } A$$

and we will construct a right adjoint. To this aim, we need a few preliminaries : we consider any perfectoid quasi-affinoid ring $A := (A, A^+, U_A)$ and set $X_A := \text{Spec } A, Z_A := X_A \setminus U_A$. Let also $E := E(A)$, define the continuous map $\varphi : X_A \to X_E := \text{Spec } E$ as in (16.4.18), and set $Z_E := \varphi(Z_A)$ and $U_E := X_E \setminus Z_E$. Then it is easily seen that $U_E$ contains the analytic locus of $X_E$, so any choice of ring of integral elements $E^+ \subset E$ will give another perfectoid quasi-affinoid ring $E := (E, E^+, U_E)$, as well as the attached perfectoid quasi-affinoid schemes

$$(U_A, \mathcal{R}_A, A^+_A) := \text{Spec } A \quad (U_E, \mathcal{R}_E, E^+_E) := \text{Spec } E.$$ 

More precisely, let $\alpha := (\alpha_n \mid n \in \mathbb{N})$ be any distinguished element in $\text{Ker } u_A$; since $\varphi$ maps $\text{Spec } A/pA$ bijectively onto $\text{Spec } E/\alpha_0 E$, and maps $\text{Spec } A[p^{-1}]$ onto $\text{Spec } E/\alpha_0^{-1}$, it is easily seen that $U_E$ is the unique open subset of $X_E$ containing the analytic locus, and such that

$$\varphi^{-1}(U_E) = U_A.$$ 

Recall that, according to lemma 16.4.26 the topologies $\mathcal{R}_A$ on $A_U := \mathcal{O}_{X_A}(U_A)$ and $\mathcal{R}_E$ on $E_U := \mathcal{O}_{X_E}(U_E)$ are $f$-adic, complete and separated, and the restriction maps $A \to A_U$ and...
\[ \mathbb{E} \rightarrow \mathbb{E}_U \] are open. Especially the image \( \overline{A} \) of \( A \) (resp. \( \overline{E} \) of \( E \)) is open in \( A_U \) (resp. in \( E_U \)), and we endow this subring with the quotient topology induced by the projection \( \pi_A : A \rightarrow \overline{A} \) (resp. \( \pi_E : E \rightarrow \overline{E} \)). Moreover, we have a continuous map of (multiplicative) monoids

\[ \varphi_U^b : \mathbb{E}_U \rightarrow A_U \] (proposition \[16.4.28\]i). Let also

\[ j^b_E : \overline{E} \rightarrow \mathbb{E}_U^b \quad \text{and} \quad j^b_A : \overline{A} \rightarrow A_U^b \]

be the inclusion maps, and we endow \( A_U^b \) (resp. \( E_U^b \)) with the topology induced by the inclusion into \( A_U \) (resp. into \( E_U \)), so that \( j^b_A \) and \( j^b_E \) are open maps.

**Proposition 16.5.4.** In the situation of \((16.5.2)\), we have:

1. For every \( x \in A_U \), the following conditions are equivalent:
   1. \( x \) is power bounded in \( A_U \).
   2. The subset \( \{x^n \mid n \in \mathbb{N}\} \) is bounded in \( A_U \).
   3. The image of \( x \) in \( R^1 \Gamma_{Z_A} \mathcal{O}_{X_A} \) is annihilated by \( A_\infty \).
   4. \( x \cdot A_U^b \subset A_U^b \).
   5. \( v(x) \leq 1 \) for every analytic rank one valuation \( v \in \text{Spa} A \).
2. \( \overline{A} \) and \( \overline{E} \) are perfectoid rings, and there exists a unique isomorphism
   \[ \overline{\omega} : \mathbb{E} \xrightarrow{\sim} \mathbb{E}(\overline{A}) \]
   such that \( \overline{\omega} \circ \pi_E = \mathbb{E}(\pi_A) \).
3. The maps \( \pi_A \) and \( \pi_E \) restrict to bijections \( \mathbb{E}_U^\infty \xrightarrow{\sim} \mathbb{E}_U^b \) and \( A_U^\infty \xrightarrow{\sim} A_U^b \).
4. The map \( \varphi_U^b \) restricts to a continuous map of topological monoids
   \[ \varphi_U^{b_0} : \mathbb{E}_U^b \rightarrow A_U^b \]
   which induces an isomorphism of perfect \( \mathbb{F}_p \)-algebras
   \[ \varphi_U^{b_0} : \mathbb{E}_U^b / E_U^b \xrightarrow{\sim} A_U^b / A_U^\infty \].

**Proof.** We consider first the following special case:

**Claim 16.5.5.** In the situation of \((16.5.2)\), let \( \beta \in \mathbb{E} \) be any regular element such that \( \alpha_0 \in \beta \mathbb{E} \), set \( b := \pi_A(\beta) \in A \), and suppose moreover that \( bA \) is an ideal of adic definition for \( A \), and \( U_A \) is the analytic locus of \( X_A \). Then conditions (i.a)–(i.d) are equivalent in this case, and

\[ A_\infty = A_U^b = \bigcup_{\lambda \in \mathbb{N}[1/p] \setminus \{0\}} b^\lambda A \quad \text{with} \quad b^\lambda := \pi_A(\beta^\lambda) \quad \text{for every} \quad \lambda \in \mathbb{N}[1/p]. \]

**Proof of the claim.** First, notice that under the assumptions of the claim, \( p \in bA \) (lemma \[16.2.7\]iii) and \( b^\lambda \) is a regular element of \( A \) for every \( \lambda \in \mathbb{N}[1/p] \) (proposition \[16.4.17\]). Especially, the localization map \( A \rightarrow A[b^{-1}] \) is injective, and \( U_A = \text{Spec} A[b^{-1}] \), so that \( A_U = A[b^{-1}] \), \( R^1 \Gamma_{Z_A} \mathcal{O}_{X_A} = A[b^{-1}] / A \), and condition (i.c) implies:

1. \( \beta^\lambda x \in A \) for every \( \lambda \in \mathbb{N}[1/p] \) \( \setminus \{0\} \).
2. We show first the equivalence of (i.a), (i.b) and (i.f). Indeed, obviously (i.f) \( \Rightarrow \) (i.a) \( \Rightarrow \) (i.b), so we may assume that (i.b) holds, and we set

\[ \rho := \inf \{ \gamma \in \mathbb{N}[1/p] \mid b^\gamma x^p \in A \text{ for every} \ n \in \mathbb{N} \}. \]

Notice that (i.b) implies that \( \rho < +\infty \). We claim that \( \rho = 0 \). Indeed suppose, by way of contradiction, that \( \rho > 0 \) and pick any \( \gamma \in \mathbb{N}[1/p] \) such that \( \rho > \gamma > \max(\rho/p, \rho - 1/p) \). Then

\[ b^{1/p} b^\gamma x^p \in A, \]

and hence \( b^\gamma x^p \in b^{-1/p} A \) for every \( n \in \mathbb{N} \); on the other hand, we also see that \( b^\gamma x^p \in A \) for every \( n \in \mathbb{N} \). Now, by corollary \[16.3.3\] the Frobenius endomorphism of \( A/pA \) induces an isomorphism \( A/b^{1/p} A \rightarrow A/bA \); since \( b \) is regular, there follows a bijective map

\[ b^{-1/p} A/A \xrightarrow{\sim} b^{-1} A/A \quad (x \mod A) \mapsto (x^p \mod A). \]
We deduce that $b^nx^p^n \in A$ for every $n \in \mathbb{N}$, i.e. $\gamma \leq \rho$, which is absurd. This shows that (i.f) holds, whence the assertion. Next, say that $x \in A[b^{−1}]^\circ$; since $bA$ is open in $A[b^{−1}]$, we must have $x^p^n \in bA$ for some $n \in \mathbb{N}$, so if set $y := b^{−1/p^n}x$, we get $y^{p^n} \in A$, and therefore the subset $\{y^{p^n} \mid n \in \mathbb{N}\}$ is bounded in $A_t$. Pick any integer $r > n$; by the foregoing, it follows that $b^{1/p^r} y \in A$, and finally $x \in b^{1/p^n−1/p^r} A$. This also implies the equivalence of (i.c),(i.d) and (i.f), so the proof of the claim is complete. 

For the general case, pick a finite system $\beta := (\beta_0, \ldots, \beta_k)$ of elements of $E$ with $\beta_0 = \alpha_0$, and such that $\beta_k$ generates an ideal $I$ of adic definition for $E$. Then the ideal $I \subset A$ generated by $(\pi_A(\beta_0), \ldots, \pi_A(\beta_k))$ is of adic definition for $A$ (see remark [16.3.7](iii)). We notice :

Claim 16.5.6. The ideal $A^\circ$ is generated by $(\pi_A(\beta_i^k) \mid i = 0, \ldots, k, \lambda \in \mathbb{N}[1/p] \setminus \{0\})$.

**Proof of the claim.** Clearly $\pi_A(\beta_i^k) \in A^\circ$ for every $i = 0, \ldots, k$ and every strictly positive $\lambda \in \mathbb{N}[1/p]$. Conversely, let $c \in A^\circ$ be any element; then $c^{p^n} \in I$ for every sufficiently large $n \in \mathbb{N}$. By remark [16.3.7](iii) we may find $\gamma \in E$ such that $\pi_A(\gamma) − c \in pA$, and the image of $\gamma^{p^n}$ in $E/\alpha_0 E$ lies in $I/\alpha_0 E$, so $\gamma^{p^n} \in I$, hence $\gamma \in I^{(1/p^n)}E$, and therefore $c \in I^{(1/p^n)}A + pA = I^{(1/p^n)}A$ (notation of remark [9.3.7](i)), whence the claim.

(i.c)⇒(i.a): By assumption, $\pi_A(\beta_i^k) \cdot x \in \overline{A}$, for every $i = 0, \ldots, k$ and every strictly positive $\lambda \in \mathbb{N}[1/p]$; let $n > 0$ be any integer, and pick $t \in \mathbb{N}$ such that $p^t \geq n$; then $\pi_A(\beta_i^{p^t/k}) \cdot x^n = (\pi_A(\beta_i^{1/k})) \cdot x^n$ lies as well in $\overline{A}$, and we conclude that $\pi_A(\beta_i) \cdot x^n \in \overline{A}$ for every $n \in \mathbb{N}$, whence the assertion.

Obviously, (i.a)⇒(i.b). To show that (i.b)⇒(i.c), let $\mathcal{F}_{\mathcal{A},p}$ be the $p$-adic topology on $A$, and $\mathcal{F}_{U,p}$ the unique $p$-adic topology on $A_U$ such that the restriction map $(A, \mathcal{F}_{\mathcal{A},p}) \to (A_U, \mathcal{F}_{U,p})$ is open (lemma [16.4.26](i)). Suppose first that the topology of $A$ agrees with $\mathcal{F}_{\mathcal{A},p}$, and let

$$A_1 := A/\text{Ann}_A(p) \quad Z' := \text{Spec} A/pA \quad U' := X_A \setminus Z'.$$

Denote as well by $x_{U'} \in \mathcal{O}_{X_A}(U') = A[1/p]$ the image of $x$. We recall that $p$ is regular in $A_1$ (remark [16.4.19](ii)), and we endow $A_1$ with its $p$-adic topology $\mathcal{F}_{A_1,p}$, and $A[1/p]$ with the unique $p$-adic topology $\mathcal{F}_{U',p}$ such that the inclusion map $(A_1, \mathcal{F}_{A_1,p}) \to (A[1/p], \mathcal{F}_{U',p})$ is open, so that the subset $\{x_{U'}^{p^n} \mid n \in \mathbb{N}\}$ is bounded in $A[1/p]$. Let $q := \pi_A(\alpha_0)$; by claim 16.5.5 and lemma [16.2.7](iii), it then follows that $q^\lambda \cdot x_{U'}$ lies in $A_1$ for every $\lambda \in \mathbb{N}[1/p] \setminus \{0\}$. Denote also by $\pi \in R^1\Gamma_Z\mathcal{O}_{X_A}$ the image of $x$; we deduce that the image of $q^\lambda \cdot \pi$ vanishes in $R^1\Gamma_Z\mathcal{O}_{X_A}$, for every such $\lambda$. To conclude in this case, it suffices to remark :

Claim 16.5.7. The kernel of the natural map $R^1\Gamma_Z\mathcal{O}_{X_A} \to R^1\Gamma_Z\mathcal{O}_{X_A}$ is annihilated by $q^\lambda$ for every $\lambda \in \mathbb{N}[1/p] \setminus \{0\}$.

**Proof of the claim.** By the snake lemma, this kernel is a quotient of $\Gamma^*_Z,j_*\mathcal{O}_{U_A}$, where $j_A : U_A \to X_A$ is the open immersion. However, $\Gamma_Z,j_\mathcal{O}_{U_A} = H^0(U_A, \mathcal{O}_{X_A})$. Since $\mathcal{O}_{X_A}$ is a quasi-coherent $\mathcal{O}_{X_A}$-module (lemma [10.4.17](i)), we are reduced to checking that $\text{Ann}_A(p)$ is annihilated by $q^\lambda$ for every $\lambda \in \mathbb{N}[1/p] \setminus \{0\}$. The latter holds by corollary [16.3.61](i). 

Next, let $A$ be any perfectoid ring; let $j_E : U_E \to X_E$ be the open immersion, and for every $c \in \mathbb{N}[1/p]$ consider the $\mathcal{O}_{X_E}$-module $\mathcal{D}_E^c$ and the $\mathcal{O}_{X_A}$-module $\mathcal{D}_{U_A}^c$ as in (16.4.29). We set

$$\mathcal{D}_{U_A}^0 := \bigcap_{c > 0} \mathcal{D}_{U_A}^c \quad \text{and} \quad \mathcal{D}_{U_A}^0 := \bigcap_{c > 0} \mathcal{D}_{U_A}^c.$$

Condition (i.b) implies that the set $\{x_{U_A}^{p^n} \mid n \in \mathbb{N}\}$ is bounded also for the topology $\mathcal{F}_{U,p}$ of $A_U$, and since $(A, \mathcal{F}_{\mathcal{A},p})$ is perfectoid (proposition [16.3.8](i)), the foregoing case shows that $\pi$ lies in $\mathcal{D}_{U_A}^0(X_A)$. By proposition [16.4.30](iv), the map $\varphi^\circ$ of lemma [16.4.23](ii) induces an isomorphism

$$\varphi^\circ : \mathcal{D}_{U_A}^0 \sim \varphi_* \mathcal{D}_{U_A}^0.$$
of abelian sheaves, fitting into a commutative diagram

\[
\begin{align*}
\mathcal{D}_U^0 & \xrightarrow{\varphi_0} \mathcal{D}_A^0 \\
\mathcal{D}_U^0 & \xrightarrow{\varphi_0} \mathcal{D}_A^0
\end{align*}
\]

(16.5.8)

where \( \mathcal{P}_E \) (resp. \( \mathcal{P}_A \)) is induced by the \( p \)-Frobenius endomorphism of the sheaf of monoids \( j_{E*} \mathcal{O}_{U_E} \) (resp. \( j_A \mathcal{O}_{U_A} \)). With this notation, condition (i.b) says that for some \( n \in \mathbb{N} \) we have

\[
\pi_A(\beta_i^n \cdot \mathcal{P}_E(x)) = 0 \quad \text{for every } i = 0, \ldots, k \text{ and every } r \in \mathbb{N}.
\]

(16.5.9)

Let \( \tau \in \mathcal{D}_U^0(X_E) \) be the preimage of \( \tau \); then \( \beta_i^\lambda \cdot \tau \) is the preimage of the class of \( \pi_A(\beta_i^\lambda) \cdot x \) in \( \mathcal{D}_U^0(X_A) \), for every \( i = 0, \ldots, k \) and every \( \lambda \in \mathbb{N}[1/p] \). By virtue of claim 16.5.6, we are then reduced to checking that \( \beta_i^\lambda \cdot \tau = 0 \) for every such \( i \) and \( \lambda \), and (16.5.9) yields already

\[
\beta_i^\lambda \cdot \mathcal{P}_E(\tau) = 0 \quad \text{for every } i = 0, \ldots, k \text{ and every } r \in \mathbb{N}.
\]

(16.5.8)

Now, we may write \( \lambda = t \cdot p^{-r} \) for some integers \( t \geq n \) and \( r \in \mathbb{N} \); we deduce

\[
\pi_A(\beta_i^\lambda \cdot \mathcal{P}_E(\tau)) = \beta_i^r \cdot \pi_A(\beta_i^\lambda \cdot \mathcal{P}_E(\tau)) = 0.
\]

Lastly, since \( E \) is perfect, it is easily seen that \( \mathcal{P}_E \) is an isomorphism, whence the assertion.

(ii): This was already remarked in the proof of claim [16.4.33]. Let us add the following:

**Claim 16.5.10.** The map \( \pi_E \) and \( \pi_A \) restrict to bijections \( E^\infty \oslash \pi_E \) and \( A^\infty \oslash \pi_A \).

**Proof of the claim.** First, notice that the image of \( \beta_i \) in \( E \) generates an ideal of adic definition for \( E \); in view of (ii) and claim 16.5.6, we deduce immediately that \( A^\infty = \pi_A(A^\infty) \) and \( E^\infty = \pi_E(E^\infty) \). Next, if \( I \) is any ideal of adic definition for \( A \), clearly we have \( I \cdot \ker \pi_A = 0 \), whence \( I \cap \ker \pi_A = 0 \), since \( A \) is reduced (corollary 16.3.61); but \( A^\infty \) is the union of all ideals of adic definition for \( A \), so we conclude that \( A^\infty \cap \ker \pi_A = 0 \). Likewise, we see that \( E^\infty \cap \ker \pi_E = 0 \), whence the claim.

(iii): Let \( x \in A_U^\infty \) be any element; denote by \( \tau \in R^1 \Gamma_X \mathcal{O}_{X_A} \) the image of \( x \); from (i) we see that \( \tau \in Q_A := \mathcal{D}_U^0(X_A) \), and since \( A \) is open in \( A_U \), there exists \( n \in \mathbb{N} \) such that \( x^{p^n} \in A \), therefore \( \mathcal{P}_A(\tau) = 0 \). On the other hand, we have already remarked that the maps \( \varphi_0^\lambda \) and \( \mathcal{P}_E \) appearing in (16.5.8) are isomorphisms, so the same holds for \( \mathcal{P}_A \), and consequently \( \tau = 0 \), i.e. \( x \in A \); then the assertion follows from claim 16.5.10. Next, from claim 16.5.6, it is easily seen that the isomorphism \( E/\mathcal{O}_A E \oslash \pi_E \) of remark 16.3.7(ii) restricts to a natural identification

\[
E^\infty/\mathcal{O}_A E \oslash \pi_A \rightarrow A/pA
\]

(16.5.11)

therefore \( Z_E \subset X_E \setminus \Spec E/\mathcal{O}_E \), so the foregoing applies as well to the perfectoid ring \( E \) and its closed subset \( Z_E \), and the proof of (iii) is thus complete.

Now, taking into account (iii), we easily see that (i.d) \( \Rightarrow \) (i.c). Conversely, if (i.c) holds, we get \( x \cdot A^\infty \cdot A^\infty \subset A_U^\infty \), but claim 16.5.6 implies that \( A^\infty \cdot A^\infty = A^\infty \), whence (i.d). Lastly, from remark 15.4.15(iv) it is clear that (i.a) \( \Rightarrow \) (i.e). Conversely, suppose (i.e) holds; then we have as well 

\[v(xa) < 1 \quad \text{for every } a \in A_U^\infty \text{ and every rank one analytic valuation } v \in \Spec A,\]

Taking into account lemma 15.3.14(v), it follows that \( v(xa) < 1 \) for every \( a \in A_U^\infty \) and every \( v \in (\Spec A)_a \). On the other hand, we have \( v(xa) = 0 \) for every \( v \in (\Spec A)_{\text{max}} \), and we conclude that \( xa \in A_U^\infty \), by corollary 15.4.27(ii). This shows that (i.e) \( \Rightarrow \) (i.d), and completes the proof of (i).

(iv): Set also \( Q_E := \mathcal{D}_U^0(X_E) \); in light of (16.5.11), it is easily seen that the isomorphism \( \varphi_0^\lambda \) restricts to a natural identification

\[
\text{Ann}_{Q_E}(E^\infty) \oslash \text{Ann}_{Q_A}(A^\infty)
\]
and taking into account (i) we deduce that $\varphi_{U}^\varnothing((\mathcal{E}_U^\varnothing)) \subset A_U^\varnothing$, so the sought map $\varphi_{U}^\varnothing$ is well defined, and it is continuous, by proposition [16.4.28](ii); combining with (iii), we also see that $\varphi_{U}^\varnothing$ induces bijections

$$E_U^\varnothing/\mathcal{E} \cong A_U^\varnothing/\mathcal{A} \quad \mathcal{E}/E_U^\varnothing \cong \mathcal{A}/A_U^\varnothing.$$  

On the other hand, we remark:

**Claim 16.5.12.** (i) For every $x, y \in E_U^\varnothing$ we have $\varphi_{U}^\varnothing(x + y) - \varphi_{U}^\varnothing(x) - \varphi_{U}^\varnothing(y) \in A_U^\varnothing$.

(ii) $\varphi_{U}^\varnothing(E_U^\varnothing) \subset A_U^\varnothing$.

**Proof of the claim.** (i) By proposition [16.4.28](ii), the difference in the claim can be written as a $p$-adically convergent series $\sum_{n \in \mathbb{N}(\{0\})} p^n \cdot c_n$, where each summand $c_n$ is a finite $\mathbb{Z}_p$-linear combination of terms of the form $\varphi_{U}^\varnothing(x^\lambda y^{1-\lambda})$, where $\lambda, 1 - \lambda \in \mathbb{N}/p[1/p]$. It is easily seen that $x^\lambda y^{1-\lambda} \in E_U^\varnothing$ for every such $\lambda$, and obviously $p \in A_U^\varnothing$, whence the contention.

(ii) is obvious, since $\varphi_{U}^\varnothing$ is a continuous morphism of multiplicative monoids. \hfill \Box

**Theorem 16.5.13.** In the situation of [16.5.2], the following holds:

(i) $E_U^\varnothing$ and $A_U^\varnothing$ are both perfectoid, and there exists an isomorphism of topological rings

$$\omega : E_U^\varnothing \xrightarrow{\sim} \mathcal{E}(A_U^\varnothing) \quad \text{such that} \quad \omega \circ \iota_E = \mathcal{E}(j_A^\varnothing).$$

(ii) The rule $D \mapsto \mathcal{E}(D)$ establishes a bijection from the set $\mathcal{I}_A$ of open integrally closed subrings of $A_U^\varnothing$ to the set $\mathcal{I}_E$ of open integrally closed subrings of $E_U^\varnothing$.

(iii) Moreover, every open integrally closed subring of $A_U^\varnothing$ is perfectoid (for the topology induced by $A_U^\varnothing$).

**Proof.** (i): First, notice that $E_U^\varnothing$ (resp. $A_U^\varnothing$) is a bounded open ideal of $E_U^\varnothing$ (resp. of $A_U^\varnothing$), by virtue of proposition [16.5.4](iii); it follows that $E_U^\varnothing$ and $A_U^\varnothing$ are bounded, so their topologies are both adic and $f$-adic (corollary [8.3.19](iii)). Moreover, since $E_U$ and $A_U$ are complete and separated (lemma [16.4.26](ii)), the same holds for $E_U^\varnothing$ and $A_U^\varnothing$. Furthermore, since $E_U$ is a perfect $\mathbb{F}_p$-algebra, proposition [16.5.4](i) easily implies that the same holds for $E_U^\varnothing$, so the latter is perfectoid (example [16.3.2](i)). Next, let $I \subset A$ be any ideal of definition; proposition [16.5.4](iii) implies that $I_U := IA_U^\varnothing \subset A_U^\varnothing$, so $I_U$ is a finitely generated ideal of adic definition for $A_U^\varnothing$ (corollary [8.3.19](iii)), and clearly $p \in I_U^\varnothing$. Furthermore, $I_U \subset \mathcal{A}$ (by claim [16.5.10]), and the Frobenius endomorphism $\Phi_{A_U}/I_U$ of $A_U/I_U$ induces surjective endomorphisms of both $\mathcal{A}/I_U$ and $A_U/\mathcal{A}$ (proposition [16.5.4](iv)); thus, $\Phi_{A_U}/I_U$ is surjective, which shows that $A_U$ is a $P$-ring. Next, endow $A_U^\varnothing/pA_U^\varnothing$ with the quotient topology induced by the projection $\pi_U : A_U^\varnothing \rightarrow A_U^\varnothing/pA_U^\varnothing$, and let $\varphi_{U}^\varnothing : E_U^\varnothing \rightarrow A_U^\varnothing$ and $\omega : \mathcal{E} \xrightarrow{\sim} \mathcal{E}(A)$ be respectively the continuous morphism of topological monoids and the isomorphism of topological rings provided by proposition [16.5.4](iii,iv); in light of proposition [16.4.28](ii) it is easily seen that $\pi_U \circ \varphi_{U}^\varnothing : E_U^\varnothing \rightarrow A_U^\varnothing/pA_U^\varnothing$ is a continuous ring homomorphism fitting into a commutative diagram

$$\begin{align*}
E & \xrightarrow{\pi_U \circ \varphi_{U}^\varnothing} A_U^\varnothing/pA_U^\varnothing \\
\mathcal{E} & \xrightarrow{j_A^\varnothing \otimes \mathbb{F}_p} \mathcal{E}(A) \\
E_U^\varnothing & \xrightarrow{\pi_U \circ \varphi_{U}^\varnothing} A_U^\varnothing/pA_U^\varnothing.
\end{align*}$$
By proposition 9.3.53(iii), there follows a continuous ring homomorphism $\nu_U : W(E_U^0) \to A_U^0$ fitting into a commutative diagram

$$W(\overline{E}) \xrightarrow{u_\overline{A} \circ W(\overline{\varpi})} \overline{A}$$

$$W(j_E^0) \downarrow \downarrow j_\overline{A}$$

$$W(E_U^0) \xrightarrow{\nu_U} A_U^0.$$ 

Since both $u_\overline{A}$ and $j_\overline{A}$ are open, the same holds for $\nu_U$, and since $\overline{A}$ is perfectoid (proposition 16.5.4(iii)), the kernel of $u_\overline{A} \circ W(\overline{\varpi})$ is a distinguished ideal, so it remains only to check

**Claim 16.5.14.** $\nu_U$ induces a ring isomorphism

$$\overline{\nu}_U : W(E_U^0) \otimes_{W(E)} \overline{A} \xrightarrow{\sim} A_U^0.$$ 

**Proof of the claim.** Let $\Phi_{E_U^0}$ be the Frobenius endomorphism of $E_U^0$, and notice that

$$\Phi_{E_U^0}(E_U^0) = E_U^0.$$ 

Moreover, $W(E_U^0)$ is a closed ideal of both $W(\overline{E})$ and $W(E_U^0)$ (remark 9.3.28(iv)); there follows a commutative ladder with exact rows:

$$\begin{array}{c}
0 \rightarrow W(E_U^0) \rightarrow W(\overline{E}) \rightarrow W(\overline{E}/E_U^0) \rightarrow 0
\end{array}$$

Let $\omega$ be any distinguished element of $\text{Ker } u_A$; since the image of $\omega$ is a regular element in both $W(E_U^0/E_U^0)$ and $W(E_U^0)$, we have

$$\text{Tor}_1^W(E)(W(E_U^0/E_U^0), A) = 0 \quad \text{Tor}_1^W(E)(W(E_U^0), A) = 0$$

so the rows of the ladder $\mathcal{L} \otimes_{W(E)} \overline{A}$ are still exact. Furthermore, since the topologies of $\overline{E}/E_U^0$ and $E_U^0/E_U^0$ are discrete, the isomorphism $\overline{\nu}_U$ of proposition 16.5.4(iv) induces identifications

$$W(\overline{E}/E_U^0) \otimes_{W(E)} \overline{A} \xrightarrow{\sim} \overline{A}/A_U^0 \quad W(E_U^0/E_U^0) \otimes_{W(E)} \overline{A} \xrightarrow{\sim} A_U^0/A_U^0.$$ 

Summing up, we obtain the commutative diagram with exact rows:

$$\begin{array}{c}
0 \rightarrow A_U^0 \rightarrow \overline{A} \rightarrow A_U^0 \rightarrow 0
\end{array}$$

and to conclude, it suffices to check that $\overline{\nu}_U \circ w = j_A^0$. To this aim, it suffices to show that $\overline{\nu}_U \circ w \circ u_\overline{A} = j_A^0 \circ u_\overline{A} : W(E(\overline{A})) \to A_U^0$. However, by construction we have

$$\overline{\nu}_U \circ w \circ u_\overline{A} = \nu_U \circ W(j_\overline{E} \circ \overline{\varpi}^{-1}) \quad \text{and} \quad j_A^0 \circ u_\overline{A} \circ W(\overline{\varpi}) = \nu_U \circ W(j_\overline{E})$$

whence the claim. \(\Diamond\)

(ii): Let $D \subset A_U^0$ be any open integrally closed subring; it is easily seen that $A_U^0 \subset D$, so $A_U^0$ is an ideal of $D$ (remark 8.3.10(iv)) and we set $\overline{D} := D/A_U^0 \subset C_A := A_U^0/A_U^0$.

**Claim 16.5.15.** With the foregoing notation, the rule $D \mapsto \overline{D}$ establishes a bijection from the set of open integrally closed subrings of $A_U^0$ to the set of integrally closed subrings of $C_A$. 

Proof of the claim. Let us check that \( \overline{D} \) is integrally closed in \( C_A \). Indeed, let \( \overline{x} \in C_A \), and \( P(T) \in D[T] \) a monic polynomial such that \( P(\overline{x}) = 0 \) in \( C_A \); if \( x \in A_U^\circ \) is any representative for the class \( \overline{x} \), we get \( P(x) \in A_U^\circ \). Set \( Q(T) := P(T) - P(x) \); then \( Q(T) \in D[T] \) and \( Q(x) = 0 \), so \( x \in D \), and therefore \( \overline{x} \in \overline{D} \), which shows the contention. Conversely, if \( \overline{D} \subset C_A \) is any integrally closed subring, let us show that the preimage \( D \subset A_U^\circ \) of \( \overline{D} \) is integrally closed in \( A_U^\circ \). Indeed, say that \( x \in A_U^\circ \) is integral over \( D \); then the class \( \overline{x} \in C_A \) of \( x \) is integral over \( \overline{D} \), hence \( \overline{x} \in \overline{D} \), and the claim follows. \( \square \)

Claim 16.5.15 also implies that if \( D \subset E_U^0 \) is any open and integrally closed subring, then \( E_U^\circ \subset D \), and the rule \( D \mapsto D/E_U^\circ \) establishes a bijection between the set of all open integrally closed subrings of \( E_U^\circ \) and the set of all integrally closed subrings of \( E := E_U^0/E_U^\circ \). However, proposition 16.5.4(iv) yields a natural ring isomorphism \( \varphi_U^\circ : C_A \to E \), whence a bijection \( \mathcal{A} \to \mathcal{E} \), and it remains to check that this bijection is realized by the rule \( D \mapsto E(D) \). To this aim, notice that every integrally closed subring of \( C_A \) is a perfect \( \mathbb{F}_p \)-algebra; then the assertion follows easily from proposition 16.3.25 which also gives (iii).

16.5.16. In the situation of (16.5.2), pick a finitely generated ideal \( J_E \subset E \) with \( \alpha_0 \in J_E \) and \( Z_E = \text{Spec} E/J_E \). From (16.5.3), it follows easily that \( Z_A = \text{Spec} A/J_E(1)A \) (notation of remark 9.3.71(i)). Also, we easily see that \( J_E^{(0)} \) is the radical of \( J_E \); on the other hand, \( p_A \) induces an isomorphism \( E/J_E^{(0)} \to A/J_E^{(0)} A \), so \( A/J_E^{(0)} A \) is reduced, i.e. \( J_E^{(0)} A \) is the radical of \( J_E^{(1)} A \).

Corollary 16.5.17. With the notation of (16.5.16), suppose moreover that \( A = A^+ \). Then:

\[
J_E^{(0)} A^+_U = J_E^{(0)} A .
\]

Proof. Notice that it suffices to show that \( J_E^{(0)} A^+_U \subset \overline{A} \). Indeed, suppose that the latter holds; since we have as well \( (J_E^{(0)})^2 = J_E^{(0)} \), we deduce that \( J_E^{(0)} A^+_U \subset J_E^{(0)} \overline{A} \), and the converse inclusion is obvious. Notice that \( E_U^\circ \) is the integral closure of \( \overline{E} \) in \( E_U^\circ \), so that theorem 16.8.2(ii) implies that the assertion holds for \( E_U^\circ \), i.e.

\[
J_E^{(0)} E_U^\circ \subset \overline{E} .
\]

Next, recall that proposition 16.5.4(iv) yields a ring isomorphism \( \varphi_U^\circ : E_U^\circ/E_U^\circ \to A_U^\circ/A_U^\circ \) restricting to an isomorphism \( \overline{E}/E_U^\circ \to \overline{A}/A_U^\circ \). Moreover, claim 16.5.15 shows that the subring \( E_U^\circ/E_U^\circ \) is the integral closure of \( \overline{E}/E_U^\circ \) in \( E_U^\circ/E_U^\circ \), and likewise, \( A_U^\circ/A_U^\circ \) is the integral closure of \( A_U^\circ/A_U^\circ \) in \( A_U^\circ/A_U^\circ \). Hence, \( A_U^+/A_U^\circ = \varphi_U^\circ(E_U^\circ/E_U^\circ) \), and taking into account (16.5.18), the assertion follows easily.

16.5.19. Keep the notation of (16.5.2). By virtue of lemma 15.6.10(i,iii) we may identify naturally \( U_A \) with an open subset of \( X_A^\circ := \text{Spec} A_U^\circ \), and we have a well defined quasi-affinoid ring \( A_U^\circ := (A_U^+, A_U^+, U_A) \), which is perfectoid, by theorem 16.5.13(i). Set

\[
(U_A, \mathcal{T}_{U_A}^\circ, A_U^+) := \text{Spec} A_U^\circ .
\]

since, by definition, the continuous maps \( A \to A_U^\circ \to A_U \) are both f-adic, we see that the topology \( \mathcal{T}_{U_A}^\circ \) agrees with \( \mathcal{T}_{U_A} \), i.e. we have a natural identification

\[
\text{Spec} A_U^\circ \to \text{Spec} A .
\]

Lastly, it is clear that \( A_U^\circ \) depends only on \( \text{Spec} A \), and we claim that the rule \( \text{Spec} A \mapsto A_U^\circ \) extends to a well defined functor

\[
\Gamma^\circ : \text{q.Afd.Sch}_{\text{perf}} \to \text{q.Afd.Ring}_{\text{perf}}^\circ
\]

with a natural isomorphism \( \varepsilon_X : \text{Spec} \Gamma^\circ(X) \to X \) for every object \( X \) of \( \text{q.Afd.Sch}_{\text{perf}} \). Indeed, if \( \overline{X} := (X, \mathcal{T}_X, A_X^\circ) \) and \( \overline{Y} := (Y, \mathcal{T}_Y, A_Y^+) \) are any two perfectoid quasi-affinoid schemes,
and \( \psi : X \rightarrow Y \) any f-adic morphism of quasi-affinoid schemes, then the corresponding map 
\( \psi^\circ : \mathcal{O}_Y(Y) \rightarrow \mathcal{O}_X(X) \) induces a morphism 
\( \psi^{\circ \circ} : (\mathcal{O}_Y(Y)^\circ, A_Y^+) \rightarrow (\mathcal{O}_X(X)^\circ, A_X^+) \) of affinoid rings (lemma [8.3.24(iii.a)]), which is obviously also f-adic, and the resulting diagram

\[
\begin{array}{ccc}
\text{Spec } \mathcal{O}_X(X) & \xrightarrow{\text{Spec } \psi^\circ} & \text{Spec } \mathcal{O}_Y(Y) \\
\downarrow j_X & & \downarrow j_Y \\
\text{Spec } \mathcal{O}_X(X)^\circ & \xrightarrow{\text{Spec } \psi^{\circ \circ}} & \text{Spec } \mathcal{O}_Y(Y)^\circ
\end{array}
\]

shows that \( \text{Spec } \psi^{\circ \circ} \) restricts to a morphism 
\( j_X(X) \rightarrow j_Y(Y) \), whence a well defined morphism of perfectoid quasi-affinoid rings:

\[
\Gamma^\circ(\psi) : \Gamma^\circ(Y) \rightarrow \Gamma^\circ(X).
\]

Moreover, if \( A := (A, A^+, U) \) is any perfectoid quasi-affinoid ring, the natural map 
\( A \rightarrow \mathcal{O}_A(U)^\circ \) induces a morphism of quasi-affinoid rings 
\( \eta_A : A \rightarrow \Gamma^\circ \circ \text{Spec } (A) \) which is f-adic, and therefore it is a morphism of perfectoid quasi-affinoid rings. Lastly, it is easily seen that the pair \((\varepsilon_\bullet, \eta_\bullet)\) fulfills the triangular conditions of (1.1.13), so \( \Gamma^\circ \) is right adjoint to \( \text{Spec } \).

### 16.5.20

We also want to upgrade the functor \( E \) to well defined functors

\[
E : \text{q.Afd.Ring}_{\text{perf}} \rightarrow \text{q.Afd.Ring}_{\text{perf}} \quad E : \text{q.Afd.Sch}_{\text{perf}} \rightarrow \text{q.Afd.Sch}_{\text{perf}}.
\]

Namely, let \( A := (A, A^+, U) \) be any perfectoid quasi-affinoid ring, and set \( E := E(A) \); by applying theorem [16.5.13(ii)] to the perfectoid quasi-affinoid ring \((A, A^+, \text{Spec } A)\), we see that \( E^+ := E(A^+) \) is a subring of integral elements of \( E \), so we get a perfectoid quasi-affinoid ring

\[
E(A) := (E, E^+, E(U))
\]

where \( E(U) \subset \text{Spec } E \) is defined as in (16.5.2) : namely, it is the unique open subset of \( \text{Spec } E \) containing the analytic locus and such that \( \varphi^{-1}E(U) = U \), where \( \varphi : \text{Spec } A \rightarrow \text{Spec } E \) is the continuous map given by (16.4.18). Moreover, if \( p \) is any distinguished element in \( \text{Ker } u_A \), endow \( A_0 := A/pA \) and \( E_0 := E/o_0E \) with the ring topologies induced by \( A \) and respectively \( E \); from remark [16.3.7(ii)] we see as well that the map \( u_A : A \rightarrow E \) induces a natural isomorphism of quasi-affinoid rings (notation of example [15.4.7(i)]):

\[
(16.5.21)
\]

Furthermore, for every morphism \( f : A \rightarrow B := (B, B^+, V) \) of perfectoid quasi-affinoid rings, it follows easily from [16.1.4] that the morphism of schemes \( \text{Spec } E(f) : \text{Spec } E(B) \rightarrow \text{Spec } E \) maps \( E(V) \) into \( E(U) \). Moreover, the ring homomorphism \( E(f) : E \rightarrow E(B) \) is adic (theorem [16.3.42(i)]) , whence a well defined morphism of perfectoid quasi-affinoid rings

\[
E(f) : E(A) \rightarrow E(B).
\]

Let also \( B_\text{-q.Afd.Ring}_{\text{perf}} := B/\text{q.Afd.Ring}_{\text{perf}} \) for every perfectoid quasi-affinoid ring \( B \); just as in remark [16.3.7(i)], this new functor \( E \) restricts to an equivalence

\[
A_\text{-q.Afd.Ring}_{\text{perf}} \xrightarrow{\sim} E(A)_\text{-q.Afd.Ring}_{\text{perf}}
\]

which admits a natural quasi-inverse functor

\[
A : E(A)_\text{-q.Afd.Ring}_{\text{perf}} \xrightarrow{\sim} A_\text{-q.Afd.Ring}_{\text{perf}} \quad (E, E^+, V) \mapsto (A(E), A(E^+), A(V))
\]

with \( A(E) := W(E) \otimes_{W(A)} A \) and correspondingly for \( A(E^+) \), and where \( A(V) := \varphi^{-1}V \). Likewise, for every perfectoid quasi-affinoid scheme \( U \) we define

\[
E(U) := \text{Spec } \circ E \circ \Gamma^\circ(U) \quad \text{and} \quad U_\text{-q.Afd.Sch}_{\text{perf}} := q.Afd.Sch_{\text{perf}}/U.
\]
Then, the resulting functor $\mathcal{E}$ on quasi-affinoid schemes restricts to an equivalence

$$U\text{-q.Afd.Sch}_{\text{perf}} \xrightarrow{\sim} \mathcal{E}(U)\text{-q.Afd.Sch}_{\text{perf}}$$

with quasi-inverse given by the rule: $V \mapsto \text{Spec} \circ A \circ \Gamma^\circ(V)$ (details left to the reader). Lastly, say that $U = \Gamma^\circ(V)$, and set $U_0 := \text{Spec} (A_0 \otimes_A A)$ and $\mathcal{E}(U)_0 := \text{Spec} (E_0 \otimes_E E)$; then we deduce from (16.5.21) a natural isomorphism of quasi-affinoid schemes

(16.5.22) \quad $U_0 \times_U V \xrightarrow{\sim} \mathcal{E}(U)_0 \times_{\mathcal{E}(U)} \mathcal{E}(V)$ \quad for every $V \in \text{Ob}(U\text{-q.Afd.Sch}_{\text{perf}})$.

(see example 15.4.8).

16.5.23. Next, we wish to extend the results of section 16.4 to the perfectoid quasi-affinoid case. Consider any perfectoid quasi-affinoid ring $A := (A, A^+, U_A)$, and let $(E, E^+, U_E) := E(A)$ (notation of 16.5.20). Let also $\overline{A}$ and $\overline{E}$ be the images of the restriction maps $A \to A_U := \mathcal{O}_{U_A}(U_A)$ and respectively $E \to E_U := \mathcal{O}_{U_E}(U_E)$. We endow $\overline{A}$ and $\overline{E}$ with the quotient topologies induced by the projections $A \to \overline{A}$ and respectively $E \to \overline{E}$. Pick any finitely generated ideal of definition $I$ of $E$; we get a descending filtration on $E_U$ and $A_U$ by the rules:

$$\text{Fil}^s E_U := I^s \overline{E} \quad \text{Fil}^s A_U := I^s \overline{A}$$

for every $s \in \mathbb{N}[1/p]$. As in example 9.1.9(i) we associate with $I$ an angular order function

$$\nu : E_U \to \mathbb{R} \cup \{+\infty\} \quad x \mapsto \sup \{s \in \mathbb{Z}[1/p] \mid x \in \text{Fil}^s E_U\}.$$ Notice that, since the topology of $E_U$ is separated, we have $\nu(x) = +\infty$ if and only if $x = 0$. Then, we fix $\rho \in ]0, 1[$, and set

$$|x|_I := \rho^{\nu(x)} \quad \text{for every } x \in E_U$$

(with the convention that $\rho^{+\infty} := 0$).

**Lemma 16.5.24.** With the notation of (16.5.23), we have:

(i) The mapping $| \cdot |_I$ is the asymptotic Samuel function on $E_U$ associated with $I$ (see example 9.1.9(i)). Especially, it is a real-valued power-multiplicative norm on $E_U$.

(ii) $\varphi_U^b(\text{Fil}^s E_U) \subseteq \text{Fil}^s A_U$ for every $s \in \mathbb{Z}[1/p]$ (notation of proposition 16.4.28(i)).

**Proof.** (i): Let $| \cdot |_I$ be the asymptotic Samuel function attached to $I$ (and the real number $\rho$), let $x \in E_U$ be any element, and $s \in \mathbb{Z}[1/p]$ any rational number; consider the following conditions:

(a) $|x|_I \leq \rho^s$.

(b) For every $t < s$ in $\mathbb{Z}[1/p]$ we have $x \in \text{Fil}^t E_U$.

(c) For every $t < s$ in $\mathbb{Z}[1/p]$ we may find $n \in \mathbb{N}$ such that $p^n t \in \mathbb{Z}$ and $xp^n \in I^{p^n t}$, where the integral power $I^{p^n t}$ is defined as in example 9.1.9(i).

(d) $|x|_I^s \leq \rho^s$.

It is easily seen that each of these conditions is equivalent to the following one, whence the assertion.

(ii): Suppose first that $s \geq 0$; in this case, by definition we have $\varphi_U^b(I^s) \subseteq \text{Fil}^s A_U$. On the other hand, proposition 16.4.28(ii) implies that $\varphi_U^b(\text{Fil}^s E_U)$ lies in the topological closure of the $\overline{A}$-submodule of $A_U$ generated by $\varphi_U^b(I^s)$, and since $\text{Fil}^s A_U$ is an open $\overline{A}$-submodule of $A_U$, the assertion follows.

Lastly, suppose that $s < 0$, and let $x \in \text{Fil}^s E_U$ be any element; the condition means that $I^s x \subseteq \overline{E}$, whence $\varphi_U^b(x) \cdot \varphi_U^b(I^s) \subseteq \overline{A}$, and finally $\varphi_U^b(x) \in \text{Fil}^s A_U$, as stated. □
16.5.25. The norm $| \cdot |_1$ in turns induces a mapping
\[ | \cdot |_1 : W(E_U) \to \mathbb{R}_+ \cup \{+\infty\} \]
\[ (a_n \mid n \in \mathbb{N}) \mapsto \sup_{n \in \mathbb{N}} |a_n|_1^{-n} \]
as in (9.3.80), such that the subset
\[ W(E_U, 1) := \{ a \in W(E_U) \mid |a|_1 \in \mathbb{R}_+ \} \]
is a subring of $W(E_U)$, and the restriction of $| \cdot |_1$ is a real-valued norm on $W(E_U, 1)$ (proposition 9.3.82(ii)). We endow $W(E_U, 1)$ with the topology defined by the norm $| \cdot |_1$. Then clearly $W(E_U, 1)$ is a separated topological ring, and it is independent of the choice of $I$ (see example 9.1.9 iv)). Furthermore, for every $s \in \mathbb{Z}[1/p]$ we set
\[ W(s) := \{ (x_n \mid n \in \mathbb{N}) \in W(E_U) \mid x_n \in \text{Fil}^{p^n}E_U \text{ for every } n \in \mathbb{N} \} \subset W(E_U, 1). \]
Recall that the $\mathfrak{p}$-adic topologies of $E_U$ and $A_U$ agree with the $\mathbb{Z}$-linear topologies defined by $\text{Fil}^nE_U$ and respectively $\text{Fil}^nA_U$ (lemma 9.3.70(iv) and corollary 16.3.40(ii)). Moreover, $\text{Fil}^nA_U$ and $\text{Fil}^nE_U$ are bounded subsets of $A_U$ and respectively $E_U$, for every $s \in \mathbb{Z}[1/p]$. It follows easily that for every $a := (a_n \mid n \in \mathbb{N}) \in W(E_U, 1)$, the series
\[ \sum_{n \in \mathbb{N}} p^n \cdot \varphi^\flat_U(a_n^{1/p^n}) \]
converges to a unique element $u_U(a)$ of $A_U$. Moreover, just as in definition 16.3.27(v), for any $E$-submodule $\mathscr{K}$ of $E_U$ we denote by $\{ \mathscr{K} \}$ the topological closure in $A_U$ of the $A$-submodule generated by $(\varphi^\flat_U(x) \mid x \in \mathscr{K})$. We also define filtrations on $\mathscr{K}$ and $\{ \mathscr{K} \}$ by the rules:
\[ \text{Fil}^n\mathscr{K} := \mathscr{K} \cap \text{Fil}^nE_U \quad \text{and} \quad \text{Fil}^n\{ \mathscr{K} \} := \{ \text{Fil}^n\mathscr{K} \} \quad \text{for every } s \in \mathbb{Z}[1/p]. \]

**Proposition 16.5.26.** With the notation of (16.5.25), we have:
\begin{enumerate}
  \item The resulting mapping $u_U : W(E_U, 1) \to A_U$ is a morphism of topological rings.
  \item $u_U(W(s)) = \{ \text{Fil}^nE_U \} \subset \text{Fil}^nA_U$ for every $s \in \mathbb{Z}[1/p]$.
  \item $pW(E_U) \cap W(s) = pW(s)$ for every $s \in \mathbb{Z}[1/p]$.
  \item The topological ring $W(E_U, 1)$ is complete and separated.
\end{enumerate}

**Proof.** (i): The continuity of $u_U$ follows from the continuity of $\varphi^\flat_U$ (proposition 16.4.28(i)) and a simple inspection of the definition. Next, we remark:

**Claim 16.5.27.** For every $a \in E_U$ and every $\underline{x} \in W(E_U, 1)$ we have
\[ \tau_{E_U}(a) \cdot \underline{x} \in W(E_U, 1) \quad \text{and} \quad u_U(\tau_{E_U}(a) \cdot \underline{x}) = \varphi^\flat_U(a) \cdot u_U(\underline{x}). \]

**Proof of the claim.** Say that $\underline{x} = (x_n \mid n \in \mathbb{N})$; by proposition 9.3.37(i) we have $\tau_{E_U}(a) \cdot \underline{x} = (a^{p^n}x_n \mid n \in \mathbb{N})$, whence the first assertion. By the same token, since $\varphi^\flat_U$ is a continuous morphism of multiplicative monoids, we may compute
\[ u_U(\tau_{E_U}(a) \cdot \underline{x}) = \sum_{n \in \mathbb{N}} p^n \cdot \varphi^\flat_U(ax_n^{1/p^n}) = \varphi^\flat_U(a) \cdot \sum_{n \in \mathbb{N}} p^n \cdot \varphi^\flat_U(x_n^{1/p^n}) = \varphi^\flat_U(a) \cdot u_U(\underline{x}) \]
as stated. \hfill \diamond

To conclude, we have to check that
\[ u_U(\underline{x} + \underline{y}) = u_U(\underline{x}) + u_U(\underline{y}) \quad \text{and} \quad u_U(\underline{x} \cdot \underline{y}) = u_U(\underline{x}) \cdot u_U(\underline{y}) \]
for every $\underline{x} := (x_n \mid n \in \mathbb{N})$, $\underline{y} := (y_n \mid n \in \mathbb{N}) \in W(E_U, 1)$. However, pick $s \in \mathbb{Z}[1/p]$ such that $\underline{x}, \underline{y} \in W(s)$, and notice that $u_U$ restricts to a map $W(s) \to \text{Fil}^nA_U$; set $\underline{x}^{(k)} := \sum_{n=0}^k p^n \cdot \tau_{E_U}(x_n)$ and define likewise $\underline{y}^{(k)}$ for every $k \in \mathbb{N}$. The sequences $(\underline{x}^{(k)} \mid n \in \mathbb{N})$ and $(\underline{y}^{(k)} \mid n \in \mathbb{N})$ lie in $W(s)$ and converge $p$-adically to $\underline{x}$ and respectively $\underline{y}$; moreover, the $p$-adic topology is separated on $\text{Fil}^nA_U$, so it suffices to check the sought identities with $\underline{x}$ and
as required. Especially it suffices to show that $W(\mathfrak{I})$ is a topology induced by the norm $|\cdot|_I$. To this aim, let $x_1, \ldots, x_n$ be any finite system of generators of $I\mathfrak{E}$, and denote by $\mathfrak{I} \subset W(\mathfrak{E})$ the ideal generated by $\tau(\mathfrak{E}(x_1)), \ldots, \tau(\mathfrak{E}(x_n))$. Taking into account proposition 9.3.78(i) and lemma 9.3.70(iv), it is easily seen that $\mathfrak{I}$ agrees with the $\mathfrak{I}$-adic topology on $W(\mathfrak{E})$. However, let also $\mathfrak{T}$ be the $I\mathfrak{E}$-adic topology on $\mathfrak{E}$ and $\mathfrak{T}_W(\mathfrak{E})$ the topology of $W(\mathfrak{E}, \mathfrak{T})$ (as in definition 9.3.14); then $\mathfrak{T}_W(\mathfrak{E})$ agrees with the $(pW(\mathfrak{E}) + \mathfrak{I})$-adic topology (proposition 9.3.78(ii)). On the other hand, since
\[ \mathcal{F}_E \] is complete and separated, the same holds for \( \mathcal{F}_{W(E)} \) (lemma \ref{lem:9.3.33}(ii)). To conclude, we may now appeal to lemma \ref{lem:8.3.12}.

16.5.28. In the situation of (16.5.23), let \( \mathcal{K}, \mathcal{J} \subset E_U \) be any two \( E \)-submodules; we let \( \mathcal{K} \mathcal{J} \subset E_U \) be the \( E \)-submodule generated by the system \( (xy \mid x \in \mathcal{K}, y \in \mathcal{J}) \). Especially, we have well defined \( E \)-submodules \( \mathcal{K}^n \) of \( E_U \), defined inductively by the rule : \( \mathcal{K}^0 := E \) and \( \mathcal{K}^{n+1} := \mathcal{K}^n \cdot \mathcal{K} \) for every \( n \in \mathbb{N} \). Next, suppose that \( \mathcal{J} \subset \mathcal{K} \), and let \( \beta \in E \) be any element; as in definition 16.3.27, we shall say that the inclusion of \( \mathcal{J} \) in \( \mathcal{K} \) is \( \beta \)-taut if

\[ \beta \cdot \Phi_{E_U}^{-1}(\mathcal{K}^p) \subset \mathcal{J} \]

where \( \Phi_{E_U} \) is the Frobenius automorphism of \( E_U \). For \( \beta = \alpha_0 \) (where \( (\alpha_n \mid n \in \mathbb{N}) \) is a fixed distinguished element in \( \text{Ker} u_A \)), we just say that the inclusion is \( taut \). Likewise, we say that \( \mathcal{K} \) is \( \beta \)-taut (resp. \( taut \)) if the identity map of \( \mathcal{K} \) is a \( \beta \)-taut (resp. \( taut \)) inclusion. Just as in (16.3.30), for any \( taut \) inclusion \( \mathcal{J} \subset \mathcal{K} \), the quotients \( \mathcal{K} / \mathcal{J} \) and \( \{ \mathcal{K} \} / \{ \mathcal{J} \} \) are both \( \overline{A}/p\overline{A} \)-modules. Also, just as in remark 16.3.28(v), if the inclusion \( \mathcal{J} \subset \mathcal{K} \) is \( taut \), then both \( \mathcal{J} \) and \( \mathcal{K} \) are \( taut \). With this terminology, we have the following extension of theorem 16.3.31.

**Lemma 16.5.29.** In the situation of \( (16.5.25) \), the following holds :

(i) Every \( taut \) inclusion \( \mathcal{K}_1 \subset \mathcal{K}_2 \) of \( E \)-submodules of \( E_U \) induces an \( \overline{A}/p\overline{A} \)-linear map

\[ \mathcal{K}_2/\mathcal{K}_1 \to \{ \mathcal{K}_2 \} / \{ \mathcal{K}_1 \} : (x \mod \mathcal{K}_1) \mapsto (\varphi_U^0(x) \mod \mathcal{K}_1). \]

(ii) If \( \mathcal{K}_1 \) and \( \mathcal{K}_2 \) are topologically closed in \( E_U \), the map of (i) is an isomorphism.

(iii) For every \( taut \) \( E \)-submodule \( \mathcal{K} \) of \( E_U \) and every \( t \in \mathbb{Z}[1/p] \) we have

\[ \{ \mathcal{K} \} \cap \{ \text{Fil}^t E_U \} = \text{Fil}^t \{ \mathcal{K} \}. \]

**Proof.** (i): The proof is the same as that of theorem \ref{thm:16.3.31}(i) : the only difference is that instead of using proposition \ref{prop:9.3.63}(ii) one must appeal to the more general proposition \ref{prop:16.4.28}(ii).

Next, we prove the following special case of (ii) :

**Claim 16.5.30.** Pick any strictly positive \( \varepsilon \in \mathbb{N}[1/p] \) such that \( \alpha_0 \in I^{(\varepsilon)}E \). Then we have :

(i) For every \( s, t \in \mathbb{Z}[1/p] \) such that \( t - \varepsilon \leq s \leq t \), the inclusion \( \text{Fil}^s E_U \subset \text{Fil}^t E_U \) is \( taut \), and the map of (i) is an isomorphism

\[ \tau_{s,t} : \text{Fil}^s E_U / \text{Fil}^t E_U \cong \{ \text{Fil}^s E_U \} / \{ \text{Fil}^t E_U \}. \]

(ii) Moreover, the inclusion \( \{ \text{Fil}^t E_U \} \subset \text{Fil}^s A_U \) induces an injection

\[ \mu_{s,t} : \{ \text{Fil}^t E_U \} / \{ \text{Fil}^s E_U \} \to \text{Fil}^s A_U / \text{Fil}^t A_U. \]

**Proof of the claim.** (i): First notice that, since \( \overline{A} \) is perfectoid and \( E(\overline{A}) = E \), the assertion in case \( s \geq 0 \) is a special case of theorem \ref{thm:16.3.31}(ii). Thus, we assume henceforth that \( s < 0 \). Next, suppose that \( t > 0 \); in this case, we know already that \( \tau_{0,t} \) is an isomorphism, and therefore the 5-lemma implies that \( \tau_{s,t} \) is an isomorphism if and only if the same holds for \( \tau_{s,0} \) (details left to the reader). Hence, we may further assume that \( t \leq 0 \) as well. Then, notice that the map \( \tau_{s,t} \) has dense image, for the quotient topology on the target; however, \( \{ \text{Fil}^t E_U \} \) is an open \( E_U \)-submodule of \( \{ \text{Fil}^t E_U \} \), so this quotient topology is discrete, and thus \( \tau_{s,t} \) is surjective. To conclude, it then suffices to check that \( \mu_{s,t} \circ \tau_{s,t} \) is injective. Hence, let \( x \in \text{Fil}^s E_U \) be any element, and suppose that \( \varphi_U^0(x) \in \text{Fil}^t A_U \); we need to show that \( x \in \text{Fil}^t E_U \), i.e. that for every \( b \in I^{(-t)} \) we have \( z := bx \in E \). However, for such \( z \) we have

\[ \varphi_U^0(z) = \varphi_U^0(b) \cdot \varphi_U^0(x) \in I^{(-t)} \cdot \text{Fil}^t A_U \subset \overline{A}. \]
Notice that $z \in \text{Fil}^{s-t} E_U$, and let $\varepsilon \in \text{Fil}^{s-t} E_U / \text{Fil}^0 E_U = \text{Fil}^{s-t} E_U / \bar{E}$ be the class of $z$. Since $s - t \geq -\varepsilon$, and since $\alpha_0 \in I^{(0)} E$, we see that $\text{Fil}^{s-t} E_U / \bar{E} \subset \text{Ann}_{E_U / \bar{E}}(\alpha_0)$; on the other hand, proposition 16.4.30(iv) implies that $\varphi^\beta_U$ induces an isomorphism

$$\text{Ann}_{E_U / \bar{E}}(\alpha_0) \xrightarrow{\sim} \text{Ann}_{A_U / \bar{A}}(p)$$

whence the contention. Assertion (ii) is an immediate consequence.

(iii): Let $\varepsilon, s, t \in \mathbb{Z}[1/p]$ be as in claim 16.5.30(i), and notice that the composition

\[ M := \frac{\text{Fil}^s \mathcal{X}}{\text{Fil}^t \mathcal{X}} \xrightarrow{\beta} M' := \frac{\text{Fil}^s \mathcal{X}}{\text{Fil}^t \mathcal{X}} \to \frac{\mathcal{X} \cap \{ \text{Fil}^s E_U \}}{\mathcal{X} \cap \{ \text{Fil}^t E_U \}} \to \frac{\{ \text{Fil}^s E_U \}}{\{ \text{Fil}^t E_U \}} \]

factors through an injective map $M \to \text{Fil}^s E_U / \text{Fil}^t E_U$ and the isomorphism $\tau_{s,t}$. Hence, $\beta$ is injective; moreover, $\beta$ has dense image, and the quotient topologies on $M$ and $M''$ are discrete, so $\beta$ is an isomorphism, by claim 16.3.34. We deduce that $\gamma$ is injective.

Claim 16.5.31. Assertion (iii) holds if there exists $s \in \mathbb{Z}[1/p]$ such that $\mathcal{X} \subset \text{Fil}^s E_U$.

Proof of the claim. Notice that $\mathcal{X} \cap \text{Fil}^s E_U$ is still taut for every $r \in \mathbb{Z}[1/p]$. Now, if $t < s$ there is nothing to prove. In case $t \geq s$, let $n \in \mathbb{N}$ be the unique integer such that $t - n \varepsilon - s \in [0, \varepsilon]$; arguing by induction on $n$, we are easily reduced to the case where $n = 0$, i.e. we may assume that $t - \varepsilon < s \leq t$. In this case, clearly $\gamma$ is an isomorphism, and the sought identity follows immediately.

Now, for a general $\mathcal{X}$, clearly $\{ \mathcal{X} \}$ is the topological closure of $\bigcup_{s \in \mathbb{Z}[1/p]} \{ \mathcal{X} \cap \text{Fil}^s E_U \}$ in $A_U$, and since $\{ \text{Fil}^t E_U \}$ is open in $A_U$, we deduce that $\{ \mathcal{X} \} \cap \{ \text{Fil}^t E_U \}$ is the topological closure of $\bigcup_{s \in \mathbb{Z}[1/p]} \{ \mathcal{X} \cap \text{Fil}^s E_U \} \cap \{ \text{Fil}^t E_U \})$. But for every $s \leq t$, we have $\{ \mathcal{X} \cap \text{Fil}^s E_U \} \cap \{ \text{Fil}^t E_U \} = \{ \mathcal{X} \cap \text{Fil}^t E_U \}$, by virtue of claim 16.5.31 whence (iii).

We may now complete the proof of (ii) arguing as in the proof of theorem 16.3.31(ii): namely, we may assume that $\alpha_0 \in I$, and for every $E$-submodule $\mathcal{X}$ of $E_U$ we set

$$\text{gr}^n \mathcal{X} := \text{Fil}^n \mathcal{X} / \text{Fil}^{n+1} \mathcal{X} \quad \text{gr}^n \{ \mathcal{X} \} := \text{Fil}^n \{ \mathcal{X} \} / \text{Fil}^{n+1} \{ \mathcal{X} \} \quad \text{for every } n \in \mathbb{Z}.$$

Moreover, for every $n \in \mathbb{Z}$ we let $\text{Fil}^n (\mathcal{X}_2 / \mathcal{X}_1)$ (resp. $\text{Fil}^n \{ \mathcal{X}_2 / \mathcal{X}_1 \}$) be the image of $\text{Fil}^n \mathcal{X}_2$ in $\mathcal{X}_2 / \mathcal{X}_1$ (resp. of $\text{Fil}^n \{ \mathcal{X}_2 / \mathcal{X}_1 \}$ in $\{ \mathcal{X}_2 / \mathcal{X}_1 \}$) and we denote again by $\text{gr}^n (\mathcal{X}_2 / \mathcal{X}_1)$ and $\text{gr}^n \{ \mathcal{X}_2 / \mathcal{X}_1 \}$ the respective associated graded modules. There follows for every $n \in \mathbb{Z}$ a commutative diagram with exact rows

\[
\begin{array}{cccccc}
0 & \rightarrow & \text{gr}^n \mathcal{X}_1 & \rightarrow & \text{gr}^n \mathcal{X}_2 & \rightarrow & \text{gr}^n (\mathcal{X}_2 / \mathcal{X}_1) & \rightarrow & 0 \\
0 & \rightarrow & \text{gr}^n \{ \mathcal{X}_1 \} & \rightarrow & \text{gr}^n \{ \mathcal{X}_2 \} & \rightarrow & \text{gr}^n (\{ \mathcal{X}_2 \} / \{ \mathcal{X}_1 \}) & \rightarrow & 0 \\
\end{array}
\]

and since both $\mathcal{X}_1$ and $\mathcal{X}_2$ are taut, we know already from the proof of (iii) that the leftmost and central vertical arrows are isomorphisms, hence the same holds for the rightmost vertical arrow. Now, notice that the filtration $\text{Fil}^n (\mathcal{X}_2 / \mathcal{X}_1)$ defines a separated and complete topology on $\mathcal{X}_2 / \mathcal{X}_1$, since $\mathcal{X}_2$ and $\mathcal{X}_1$ are closed $E$-submodules of $E$. The same holds for the topology on $\{ \mathcal{X}_2 / \mathcal{X}_1 \}$ determined by the filtration $\text{Fil}^n (\{ \mathcal{X}_2 / \mathcal{X}_1 \})$, since $\{ \mathcal{X}_2 \}$ and $\{ \mathcal{X}_1 \}$ are closed $\bar{A}$-submodules in $A$. Then (ii) follows directly from [28 Ch.III, §2, n.8, Cor.3].

Theorem 16.5.32. In the situation of 16.5.25, we have:

(i) The continuous ring homomorphism $u_U$ is surjective and open.

(ii) $\text{Ker} u_U = \mathbb{A} W (E_U, 1)$. 
Proof. (ii): Clearly \( \alpha \in \text{Ker} u_U \); thus, it suffices to check that \( u_U \) induces an isomorphism

\[
\pi_s : W(s)/\langle \alpha \rangle W(s) \xrightarrow{\sim} \{\text{Fil}^s E_U\} \quad \text{for each } s \in \mathbb{Z}[1/p]
\]

and by virtue of proposition [16.5.26] (ii) we know already that \( \pi_s \) is surjective for every such \( s \). Now, if \( s \geq 0 \), we have \( W(s) = W(I(s)E) \subset W(E) \), and the assertion follows from theorem [16.3.36] (iv). For the general case, we may assume that \( \alpha_0 \in I \), and then an easy induction argument then reduces to checking :

Claim 16.5.33. Suppose that \( \alpha_0 \in I \). Then, if \( \pi_{s+1} \) is injective, the same holds for \( \pi_s \).

Proof of the claim. We consider the commutative diagram

\[
\begin{array}{c}
W(s+1)/\langle \alpha \rangle W(s+1) \\
\downarrow \pi_{s+1} \quad \downarrow j \\
\{\text{Fil}^{s+1} E_U\} \\
\downarrow i \\
\{\text{Fil}^s E_U\}
\end{array}
\]

where \( i \) is the inclusion map, and \( j \) is induced by the inclusion \( W(s+1) \subset W(s) \). Since \( \pi_{s+1} \) is injective by assumption, the same holds for \( j \). Next, let us write \( \alpha = \tau E(\alpha_0) + p \cdot u \) for some invertible element \( u \) of \( W(E) \); from proposition [9.3.37] (ii) and our assumption on \( \alpha_0 \), we deduce that \( \tau E(\alpha_0) \cdot W(s) \subset W(s+1) \), hence the cokernel of \( j \) is annihilated by \( p \). Taking into account proposition [16.5.26] (iii), it follows that \( \tau U_0 \) is naturally identified with the cokernel of the natural map \( j' : (\text{Fil}^{s+1} E_U)/\langle \alpha_0(\text{Fil}^{s+1} E_U) \rangle \rightarrow (\text{Fil}^s E_U)/\langle \alpha_0(\text{Fil}^s E_U) \rangle \). But by the same token we see that \( \alpha_0(\text{Fil}^s E_U) \subset \text{Fil}^{s+1} E_U \), so \( \text{Coker} j' = \text{Fil}^s E_U/\text{Fil}^{s+1} E_U \). Moreover, a simple inspection of the definitions shows that the map \( \text{Coker} j' \rightarrow \text{Coker} i \) resulting from (16.5.34) is the same as the isomorphism \( \tau_{s+1} \) of claim [16.5.30] (i). Then the assertion follows from the 5-lemma. \( \diamond \)

(i): By proposition [16.5.26] (ii) we know already that \( u_U \) is an open map. Next, we remark :

Claim 16.5.35. To prove that \( u_U \) is surjective, we may assume that the topology of \( E \) is \( \alpha_0 \)-adic.

Proof of the claim. Notice that the image \( R \) of \( u_U \) contains \( u_{U'}(W(E)) = u_{U'}(W(E)) = A \) (lemma [16.2.7] (i)). Especially, \( R \) is an open subring of \( A_U \); by the same token, \( R \) contains the \( A \)-subalgebra \( R' \) of \( A_U \) generated by \( \varphi^U(U'_E) \), and proposition [16.5.26] (ii) implies that \( R' \) is dense in \( R \). However, \( R' \) is also open in \( A_U \), so \( R = R' \). Furthermore, a simple inspection shows that the definition of \( \varphi^U \) depends only on the ring \( A \) and the open subset \( U \) (and is independent of the topology of \( A \) or of \( E \)). This shows that the image of \( u_{U'} \) is independent of the topology of \( E_U \). Lastly, let \( \mathcal{F}_{\alpha_0} \) be the \( \alpha_0 \)-adic topology of \( E \); it follows easily from example [16.3.2] (i) and lemma [8.3.12] that the topological ring \( (E, \mathcal{F}_{\alpha_0}) \) is perfectoid, and \( U_E \) contains the analytic locus of \( \text{Spec} E \), relative to the topology \( \mathcal{F}_{\alpha_0} \), whence the claim. \( \diamond \)

Henceforth, we assume that the topology of \( E_U \) is \( \alpha_0 \)-adic. Set \( J_1 := \text{Ann}_E(\alpha_0) \), let \( J_2 \subset E \) be the radical of the ideal \( \alpha_0 E \), and \( J_3 := J_1 + J_2 \); let \( X_E := \text{Spec} E, X_A := \text{Spec} A, X_{E,i} := \text{Spec}(E_i) \otimes W(\mathbb{T}), X_{A,i} := \text{Spec}(E_i) \), and for \( i = 1, 2, 3 \) set \( E_{E,i} := E/J_i, \mathcal{A}_i := W(E_i) \otimes W(\mathbb{T}) A, \mathcal{X}_{E,i} := \text{Spec} E_i, \mathcal{X}_{A,i} := \text{Spec} A_i \). Lastly, let \( j_{E,i} : \mathcal{X}_{E,i} \rightarrow X_E \) and \( j_{A,i} : \mathcal{X}_{A,i} \rightarrow X_A \) be the induced closed immersions and set \( E_{U,i} := j_{E,i}^* \mathcal{O}_{X_{E,i}}(U_E), A_{U,i} := j_{A,i}^* \mathcal{O}_{X_{A,i}}(U_A) \) for \( i = 1, 2, 3 \). According to (16.4.18) we have cartesian diagrams of quasi-coherent \( \mathcal{O}_E \)-modules

\[
\begin{array}{ccc}
\mathcal{O}_{X_{E,1}} & \rightarrow & j_{E,1,*} \mathcal{O}_{X_{E,1}} \\
\downarrow & & \downarrow \\
\mathcal{O}_{X_{E,2}} & \rightarrow & j_{E,2,*} \mathcal{O}_{X_{E,2}} \\
\downarrow & & \downarrow \\
\mathcal{O}_{X_{E,3}} & \rightarrow & j_{E,3,*} \mathcal{O}_{X_{E,3}} \\
\downarrow & & \downarrow \\
\mathcal{O}_{X_{A,1}} & \rightarrow & j_{A,1,*} \mathcal{O}_{X_{A,1}} \\
\downarrow & & \downarrow \\
\mathcal{O}_{X_{A,2}} & \rightarrow & j_{A,2,*} \mathcal{O}_{X_{A,2}} \\
\downarrow & & \downarrow \\
\mathcal{O}_{X_{A,3}} & \rightarrow & j_{A,3,*} \mathcal{O}_{X_{A,3}}
\end{array}
\]
whence cartesian diagrams of ring homomorphisms
\[
\begin{align*}
E_U & \longrightarrow E_{U,1} & A_U & \longrightarrow A_{U,1} \\
E_{U,2} & \longrightarrow E_{U,3} & A_{U,2} & \longrightarrow A_{U,3}.
\end{align*}
\] (16.5.36)

We endow each \(E_{U,i}\) with its \(a_0\)-adic topology \(\mathcal{J}_i\); then \(\mathcal{J}_i\) is the discrete topology for \(i = 2, 3\), and the topological ring \((E_{U,i}, \mathcal{J}_i)\) is perfectoid for \(i = 1, 2, 3\) (see [16.4.18]). We also define the power-multiplicative norms \(|·|_{i,i} : E_{U,i} \rightarrow \mathbb{R}_+\) associated with the ideal \(I_{E_{U,i}}\) as in [16.5.23], and we get consequently the normed topological rings \(W(E_{U,i}, 1)\) as in [16.5.25].

**Claim 16.5.37.** The induced diagrams of rings
\[
\begin{align*}
W(E_U) & \longrightarrow W(E_{U,1}) & W(E_{U,1}) & \longrightarrow W(E_{U,1}, 1) \\
W(E_{U,2}) & \longrightarrow W(E_{U,3}) & W(E_{U,2}, 1) & \longrightarrow W(E_{U,3}, 1)
\end{align*}
\]
are cartesian.

**Proof of the claim.** The assertion is clear for the left diagram. Next, set
\[
E_U^+ := \{ x \in E_U \mid |x|_f \leq 1 \}
\]
and define likewise the subring \(E_{U,i}^+ \subset E_{U,i}\) for \(i = 1, 2\). For every \(x \in E_U\) and \(i = 1, 2\), denote by \(x^{(i)} \in E_{U,i}\) the image of \(x\); since we already know that diagram \(\mathcal{W}(E)\) is cartesian, the assertion for \(\mathcal{W}(E, 1)\) comes down to checking that if \(x \in E_U\) and \(|x^{(i)}|_{i,i} \leq \rho^{-s}\) for \(i = 1, 2\) and some \(s \in \mathbb{N}[1/p]\), then \(|x|_f \leq \rho^{-s}\). The latter is equivalent in turn to the following. Suppose that for every strictly positive \(\varepsilon \in \mathbb{N}[1/p]\) and every \(b \in I^{(s+\varepsilon)}\) we have \(b^{(i)} x^{(i)} \in \mathcal{I}_i\); then \(z := b x \in E_U^+\). Now, for such \(x\) and \(b\) pick \(y_1 \in \mathcal{E}\) with \(y_1^{(i)} = b^{(i)} x^{(i)}\) for \(i = 1, 2\); then \((z - y_1)(z - y_2) \in J_1 \cap J_2 = 0\), and especially, \(z\) is integral over \(\mathcal{E}\). But \(\mathcal{E} \subset E_U^+\), and \(E_U^+\) is integrally closed in \(E_U\) (remark [9.1.4](vi)), whence the claim.

**Claim 16.5.38.** The diagram of rings \(\mathcal{W}(E, 1) \otimes_{W(E)} A\) is cartesian.

**Proof of the claim.** Consider the complex in \(\mathbb{C}^{[0,1]}(W(E)\)-Mod\)
\[
K^* : 0 \rightarrow W(E_{U,1}, 1) \oplus W(E_{U,2}, 1) \rightarrow W(E_{U,3}, 1) \rightarrow 0
\]
whose differential is deduced from \(\mathcal{W}(E, 1)\), so that \(H^0 K^* = W(E_U, 1)\). Taking into account proposition [9.3.48](i), we have a short exact sequence
\[
0 \rightarrow K^* \xrightarrow{\alpha^*} K^* \rightarrow K^*/\alpha K^* \rightarrow 0
\]
and by the same token, scalar multiplication is injective on \(H^0 K^*\), so we get a long exact cohomology sequence
\[
0 \rightarrow H^0(K^*)/\alpha \rightarrow H^0(K^*) \rightarrow H^1 K^*/\alpha K^* \rightarrow H^1 K^* \xrightarrow{\alpha} H^1 K^*
\]
and the claim comes down to checking that \(f_{\alpha}\) is an isomorphism, or equivalently, that scalar multiplication by \(\alpha\) is injective on \(H^1 K^*\). However, notice that \(H^1 K^*\) is a quotient of the \(W(E)\)-module \(W(E_{U,3}, 1)\) and the latter is annihilated by \(\tau_E(\alpha_0)\). Since \(\alpha = \tau_E(\alpha_0) + p\mu\) for an invertible element \(\mu\) of \(W(E)\), we are reduced to checking that scalar multiplication by \(p\) is injective on \(H^1 K^*\), i.e. we may assume that \(\alpha = p\), and then it suffices to show that \(f_p\) is an isomorphism. However, it follows easily from proposition [16.5.26](iii) that
\[
P W(E_{U,i}) \cap W(E_{U,i}, 1) = p W(E_{U,i}, 1) \quad \text{for } i = 1, 2, 3
\] (16.5.39)
and likewise for \( W(\mathbf{E}_U, 1) \). Therefore, \( H^0(K^*)/p \cdot H^0(K^*) = \mathbf{E}_U \), and \( K^*/pK^* \) is the complex
\[
0 \to \mathbf{E}_{U,1} \oplus \mathbf{E}_{U,2} \to \mathbf{E}_{U,2} \to 0
\]
deduced from the cartesian diagram \(\text{(16.5.36)}\). The claim follows.\( \diamond \)

From claim \(\text{16.5.38}\) we deduce a commutative diagram of rings

\[
\begin{array}{ccc}
A_U & \xrightarrow{u_U} & A_{U,i} \\
\downarrow & & \downarrow \\
W(\mathbf{E}_U, 1) \otimes W(\mathbf{E}) A & \xrightarrow{u_{U,1}} & W(\mathbf{E}_{U,1}, 1) \otimes W(\mathbf{E}) A \\
\downarrow & & \downarrow \\
W(\mathbf{E}_{U,2}, 1) \otimes W(\mathbf{E}) A & \xrightarrow{u_{U,2}} & W(\mathbf{E}_{U,3}, 1) \otimes W(\mathbf{E}) A \\
\downarrow & & \downarrow \\
A_{U,2} & \xrightarrow{u_{U,3}} & A_{U,3} \\
\end{array}
\]

whose two square subdiagrams are both cartesian. Recall that the topologies of \( \mathbf{E}_{U,2} \) and \( \mathbf{E}_{U,3} \) are discrete; taking into account theorem \(\text{16.5.13(i)}\) it follows that \( \mathbf{E}_{U,i} = \mathbf{E}_{U,i}^0 = A_{U,i} \) and \( W(\mathbf{E}_{U,i}, 1) = W(\mathbf{E}_{U,i}) \) for \( i = 2, 3 \), which easily implies that \( u_{U,2} \) and \( u_{U,3} \) are isomorphisms. Thus, to conclude the proof it suffices to show that \( u_{U,1} \) is an isomorphism. Hence, we may replace \( \mathbf{E} \) by \( \mathbf{E}_1 \) and assume from start that \( \alpha_0 \) is a regular element of \( \mathbf{E} \) and the topology of \( \mathbf{E} \) is \( \alpha_0 \)-adic. Let \( R \) be the image of \( u_{U,1} \) under the current assumptions, \( p \) is a regular element of \( A \) (remark \(\text{16.4.19(ii)}\)), and therefore
\[
A \subset R \subset A_U \subset A[1/p]
\]

Moreover, we notice:

Claim 16.5.40. The inclusion \( R \subset A \) induces an injective map \( R/pR \to A_U/pA_U \).

Proof of the claim. From (ii) and \(\text{(16.5.39)}\) we get a natural identification
\[
R/pR \cong W(\mathbf{E}_U, 1)/\alpha W(\mathbf{E}_U, 1) + pW(\mathbf{E}_U, 1)) \cong \mathbf{E}_U/\alpha_0 \mathbf{E}_U
\]
and from the short exact sequence of \( \mathcal{O}_{\mathbf{E}_k} \)-modules
\[
0 \to \mathcal{O}_{\mathbf{E}_k}/\alpha_0 \to \mathcal{O}_{\mathbf{E}_k} \to \mathcal{O}_{\mathbf{E}_k}/\alpha_0 \mathcal{O}_{\mathbf{E}_k} \to 0
\]
we see that the natural map
\[
\mathbf{E}_U/\alpha_0 \mathbf{E}_U \to \mathbf{E}_U^0 := H^0(U_\mathbf{E} \cap \text{Spec } \mathbf{E}/\alpha_0 \mathbf{E}, \mathcal{O}_{\mathbf{E}_k}/\alpha_0 \mathcal{O}_{\mathbf{E}_k})
\]
is injective. Likewise, we see that the same holds for the natural map
\[
A_U/pA_U \to A_U^0 := H^0(U_A \cap \text{Spec } A/pA, \mathcal{O}_{U_A}/p \mathcal{O}_{U_A}).
\]
On the other hand, recall that the ring homomorphism \( u_A : W(\mathbf{E}) \to A \) induces an isomorphism of schemes \( \varphi_0 : \text{Spec } A/pA \cong \text{Spec } \mathbf{E}/\alpha_0 \mathbf{E} \) (see \(\text{16.4.22}\)), whence a ring isomorphism \(\varphi_{0,U} : \mathbf{E}_U^0 \cong A_U^0 \) and a simple inspection of the definitions shows that the resulting diagram
\[
\begin{array}{ccc}
\mathbf{E}_U/\alpha_0 \mathbf{E}_U & \xrightarrow{u_{U} \otimes_W A/pA} & A_U/pA_U \\
\downarrow & & \downarrow \\
\mathbf{E}_U^0 & \xrightarrow{\varphi_{0,U}} & A_U^0
\end{array}
\]
commutes. But it is easily seen that the isomorphism \(\text{(16.5.41)}\) identifies \( u_{U} \otimes_W A/pA \) with the map \( R/pR \to A_U/pA_U \) induced by the inclusion \( R \subset A \), whence the claim.\( \diamond \)
Now, let \( a \in A_U \) be any element, and pick \( n \in \mathbb{N} \) such that \( p^n a \in A \); then there exists \( \bar{x} \in W(E) \) such that \( u_U(\bar{x}) = u_A(\bar{x}) = p^n a \). To conclude, we shall show, by induction on \( i = 0, \ldots, n \) that \( p^{n-i} a \in R \). Indeed, we have just shown that \( p^n a \in R \). Suppose that \( i \geq 0 \) and \( p^{n-i} a \in R \); if \( i = n \), we are done, and if \( i < n \), the image of \( p^{n-i} a \) vanishes in \( A_U/pA_U \), hence also in \( R/pR \), i.e. there exists \( b \in R \) with \( pb = p^{n-i} a \); since \( p \) is regular in \( R \), it follows that \( b = p^{n-i-1} a \), as required. \( \square \)

**Corollary 16.5.42.** In the situation of (16.5.25), we have:

(i) \( \{ \text{Fil}^s E_U \} = \text{Fil}^s A_U \) for every \( s \in \mathbb{Z}[1/p] \).

(ii) The map \( \varphi_U \) induces a ring isomorphism \( E_U/\alpha_0 E_U \cong A_U/pA_U \).

**Proof.** (i): Let us first remark that \( \{ \text{Fil}^{s-n} E_U \} \cap \text{Fil}^s A_U = \{ \text{Fil}^s E_U \} \) for every \( n \in \mathbb{N} \) and every \( s \in \mathbb{Z}[1/p] \).

Indeed, the case where \( n = 1 \) follows immediately from claim (16.5.30)ii), and then the general case follows by a simple induction on \( n \in \mathbb{N} \): details left to the reader. But theorem (16.5.32)i) shows that \( A_U = \bigcup_{n \in \mathbb{N}} \{ \text{Fil}^{s-n} E_U \} \), whence the assertion.

(ii) follows directly from theorem (16.5.32)i) and (16.5.41). \( \square \)

As an application, we point out the following criterion:

**Corollary 16.5.43.** Let \( A \) be any perfectoid ring, \( U_E \subset V_E \subset X_E := \text{Spec} E(A) \) two constructible open subsets that contain the analytic locus. Set also \( U_A := \varphi^{-1} U_E \) and \( V_A := \varphi^{-1} V_E \), where \( \varphi : X_A := \text{Spec} A \to X_E \) is the continuous map of (16.4.18). Then we have:

(i) \( U_A \) is an affine scheme if and only if the same holds for \( U_A \).

(ii) More generally, the inclusion map \( U_E \to V_E \) is an affine morphism of schemes if and only if the same holds for the inclusion map \( U_A \to V_A \).

**Proof.** (i): Set \( E_U := \mathcal{O}_{X_E}(U_E) \) and \( A_U := \mathcal{O}_{X_A}(U_A) \); by lemma (15.6.10)i), we get commutative diagrams of schemes

\[
\begin{array}{ccc}
U_E & \xrightarrow{j_E} & \text{Spec} E_U \\
\downarrow{i_E} & & \downarrow{j'_E} \\
X_E & & X_E
\end{array}
\quad
\begin{array}{ccc}
U_A & \xrightarrow{j_A} & \text{Spec} A_U \\
\downarrow{i_A} & & \downarrow{j'_A} \\
X_A & & X_A
\end{array}
\]

where \( i_E, i_A, j_E \) and \( j_A \) are open immersions. We have to show that \( j_E \) is an isomorphism if and only if the same holds for \( j_A \). To this aim, set \( Z_E := X_E \setminus U_E \) and \( Z_A := X_A \setminus U_A \); equivalently, we have to check that \( j'_E^{-1} Z_E = \emptyset \) if and only if \( j'^{-1} Z_A = \emptyset \). Now, since \( U_E \) contains the analytic locus of \( X_E \), we may assume that \( Z_E \subset X_E^0 := \text{Spec} E/\alpha_0 E \), where \( (\alpha_n \mid n \in \mathbb{N}) \) is any fixed distinguished element of \( \text{Ker} u_A \), and likewise \( Z_A \subset X_A^0 := \text{Spec} A/pA \). On the other hand, by corollary (16.5.42)ii) we have a commutative diagram of schemes

\[
\begin{array}{ccc}
\text{Spec} A_U/pA_U & \xrightarrow{} & \text{Spec} E_U/\alpha_0 E_U \\
\downarrow{} & & \downarrow{} \\
X_A^0 & \xrightarrow{\varphi_0} & X_E^0
\end{array}
\]

whose horizontal arrows are isomorphisms induced by \( \varphi \) and by the map \( \varphi_U : E_U \to A_U \) of proposition (16.4.28)i), and whose vertical arrows are the restrictions of \( j'_E \) and \( j'_A \). Lastly, by construction we have \( \varphi_0^{-1} Z_E = Z_A \), whence the contention.

(ii) is analogous: the open immersion \( U_E \to V_E \) is affine if and only if for every affine open subset \( W \subset V_E \), the intersection \( W \cap U_E \) is still affine. The latter condition means that \( \text{Spec} \mathcal{O}_{X_E}(W \cap U_E) \times_W Z_E = \emptyset \) for every such \( W \).
which in turns is equivalent to the condition:

\[(16.5.44) \quad j_E^{-1}(Z_E \cap V_E) = \emptyset.\]

Likewise, we easily see that the inclusion \(U_A \subset V_A\) is affine if and only if \(j_A^{-1}(Z_A \cap V_A) = \emptyset\), and since \(Z_E \subset X_E^\nu\), this latter condition is equivalent to \((16.5.44)\) : details left to the reader. \(\square\)

**Lemma 16.5.45.** In the situation of \((16.5.23)\), let \(\mathcal{K}\) be any \(E\)-submodule of \(E_U\), and set:

\[W(\mathcal{K}) := \{(x_n \mid n \in \mathbb{N}) \mid x_n \in \mathcal{K}^\nu \text{ for every } n \in \mathbb{N}\} \quad W(\mathcal{K}, 1) := W(\mathcal{K}) \cap W(E_U, 1).\]

(Notation of \((16.5.23)\).) Denote also by \((\mathcal{K}^n)^c\) the topological closure of \(\mathcal{K}^n\) in \(E_U\), for every \(n \in \mathbb{N}\), and by \(W(\mathcal{K}, 1)^c\) the topological closure of \(W(\mathcal{K}, 1)\) in \(W(E_U, 1)\). We have:

(i) \(W(\mathcal{K})\) and \(W(\mathcal{K}, 1)\) are \(\mathcal{K}\)-submodules of respectively \(W(E_U)\) and \(W(E_U, 1)\).

(ii) \(W(\mathcal{K}, 1)^c = M := \{(x_n \mid n \in \mathbb{N}) \in W(E_U, 1) \mid x_n \in (\mathcal{K}^\nu)^c \text{ for every } n \in \mathbb{N}\}\).

(iii) If \(\mathcal{K}\) is taut, \(u_U(W(\mathcal{K}, 1)^c) = \{\mathcal{K}\}\).

(iv) If \(\mathcal{K}\) is 1-taut and topologically closed in \(E_U\), then \(u_U\) induces an isomorphism

\[W(\mathcal{K}, 1)/\alpha W(\mathcal{K}, 1) \cong \{\mathcal{K}\}.\]

**Proof.** (i): This is analogous to remark \(9.3.28\), details left to the reader.

(ii): Let \(x := (x_n \mid n \in \mathbb{N}) \in M\) be any element, and fix any \(\varepsilon \in \mathbb{R}_{>0}\). We shall exhibit inductively a sequence \(y := (y_n \mid n \in \mathbb{N})\) of elements of \(E_U\) such that

\[|y_1| \leq \varepsilon \quad \text{and} \quad x + y \in W(\mathcal{K}, 1).\]

Indeed, let \(n \in \mathbb{N}\), and suppose that we have already exhibited \(y_i \in (\mathcal{K}^\nu)^c\) for \(i = 0, \ldots, n - 1\) such that \(y^{(n)} := \sum_{i=0}^{n-1} p^i \cdot \tau_{E_U}(y_i)\) has norm \(< \varepsilon\) and such that if we set \((z_i^{(n)} \mid i \in \mathbb{N}) := x + y^{(n)}\), we have \(z_i^{(n)} \in \mathcal{K}^\nu\) for every \(i = 0, \ldots, n - 1\). It follows easily that \(z_i^{(n)} \in (\mathcal{K}^\nu)^c\) for every \(i \in \mathbb{N}\). We may then pick \(y_{n+1} \in (\mathcal{K}^\nu)^c\) such that \(|y_{n+1}| < \varepsilon^p\) and \(z_n^{(n)} + y_n \in \mathcal{K}^\nu\). Set \(y^{(n+1)} := y^{(n)} + p^n \cdot \tau_{E_U}(y_n)\) and \((z_i^{(n+1)} \mid i \in \mathbb{N}) := x + y^{(n+1)}\). In light of lemma \(9.3.27\) i) and claim \(9.3.31\) it is easily seen that \(z_i^{(n+1)} = z_i^{(n)}\) for every \(i = 0, \ldots, n - 1\), and \(z_n^{(n+1)} = z_n^{(n)} + y_n\). Then, it is clear that the element \(y := \sum_{n \in \mathbb{N}} p^n \cdot \tau_{E_U}(y_n)\) will do.

This shows that \(M \subset W(\mathcal{K}, 1)^c\). The converse inclusion is obvious, since \(\prod_{n \in \mathbb{N}} (\mathcal{K}^\nu)^c\) is a closed subset of \(W(E_U, 1)\) and the topology of \(W(E_U, 1)\) is finer than the one induced by \(W(E_U)\).

(iii): Recall that \(\varphi_U(\alpha_0) = \tau_{\mathcal{K}}(\alpha_0) = pv\) for an element \(v \in \mathcal{K}^\nu\). Then, since \(\mathcal{K}\) is taut, we see that \(p^n \cdot \varphi_U(x^{1/p^n}) = v^{-n} \varphi_U(\alpha_0^n x^{1/p^n}) \in (\mathcal{K}^\nu)^c\) for every \(x \in \mathcal{K}^\nu\). It follows easily that \(u_U(\mathcal{K}) \subset \{\mathcal{K}\}\) for every \(\mathcal{K} \in W(\mathcal{K}, 1)^c\), and thus \(u_U(W(\mathcal{K}, 1)^c) \subset \{\mathcal{K}\}\).

For the converse inclusion, pick a strictly positive \(\varepsilon \in \mathbb{N}_{[1/p]}\) such that \(\alpha_0 \in I^{(\varepsilon)}\); it was observed in the proof of lemma \(16.5.29\) iii) that \(\varphi_U^{(\varepsilon)}\) induces an \(\mathcal{A}/p\mathcal{A}\)-linear isomorphism

\[\left(\text{Fil}^s \mathcal{K} \right) / \left(\text{Fil}^{s+\varepsilon} \mathcal{K}\right) \cong \left(\text{Fil}^s \{\mathcal{K}\} \right) / \left(\text{Fil}^{s+\varepsilon} \{\mathcal{K}\} \right) \quad \text{for every } s \in \mathbb{Z}[1/p] \]

and moreover \(\text{Fil}^s \mathcal{K} = \{\mathcal{K}\} \cap \text{Fil}^s E_U = \{\mathcal{K}\} \cap \text{Fil}^s A_U = \text{Fil}^s A_U\) for every \(s \in A_U\) (lemma \(16.5.29\) iii) and corollary \(16.5.42\), hence the filtration \(\text{Fil}^s \{\mathcal{K}\}\) is exhaustive and separated on \(\{\mathcal{K}\}\). Thus, say that \(x \in \text{Fil}^s \mathcal{K}\) for some \(s \in \mathbb{Z}[1/p]\); it follows easily that we may find a sequence \((y_n \mid n \in \mathbb{N})\) of elements of \(E_U\) such that \(y_n \in \text{Fil}^{s+\varepsilon} \mathcal{K}\) for every \(n \in \mathbb{N}\), and the series \(\sum_{n \in \mathbb{N}} \varphi_U(\alpha_0^n x^{1/p^n})\) converges to \(x\) in the topology of \(A_U\). Clearly \(\tau_{E_U}(y_n) \in W(\mathcal{K})\) and \(\tau_{E_U}(y_n) \leq p^{s+\varepsilon}\) for every \(n \in \mathbb{N}\), so the series \(\sum_{n \in \mathbb{N}} \tau_{E_U}(y_n)\) converges in \(W(E_U, 1)\) to an element \(x \in W(\mathcal{K})^c\), and finally \(u_U(z) = \sum_{n \in \mathbb{N}} u_U(\mathcal{K} \cap \tau_{E_U}(y_n)) = x\).

(iv): The assumptions on \(\mathcal{K}\) imply that \(\mathcal{K}^\nu\) is topologically closed in \(E_U\), for every \(n \in \mathbb{N}\); combining with (ii) and (iii), it follows already that the induced map \(W(\mathcal{K}, 1)/\alpha W(\mathcal{K}, 1) \to \{\mathcal{K}\}\) is surjective. Next, say that \(\alpha_0 \in I^{(\varepsilon)}\) for some element \(\varepsilon > 0\) of \(\mathbb{Z}[1/p]\); notice that
Fil^e \mathcal{K} is still 1-taut and topologically closed in E_U for every s ∈ \mathbb{Z}[1/p]; taking into account lemma \textbf{16.5.29} (iii), we may therefore reduce to the case where \mathcal{K} ⊂ \text{Fil}^{n,e}E_U for some n ∈ \mathbb{N}. We argue by induction on n: indeed, the assertion for n = 0 is already known, by theorem \textbf{16.3.36} iv. Thus, suppose that n > 0, and that the assertion is already known for \mathcal{K} ∩ \text{Fil}^{(1-n)e}E_U; let \( z := (x_n \mid n \in \mathbb{N}) \in W(\mathcal{K}, 1) \) be an element in the kernel of u_U. This means that \( \sum_{n \in \mathbb{N}} p^i \cdot \varphi^\mathcal{K}_U(x_n^{1/p^n}) = 0 \) in A_U, and we need to check that \( x \in \alpha W(\mathcal{K}, 1) \). Now, since \( n > 0 \), we have \( z := (x_n^{1/p^{n+1}} \mid n \in \mathbb{N}) \in W(\mathcal{K}, 1) \) as well, so that

\[ \varphi^\mathcal{K}_U(x_0) = - \sum_{n \in \mathbb{N}} p^{n+1} \cdot \varphi^\mathcal{K}_U(x_n^{1/p^{n+1}}) \in \text{Fil}^{(1-n)e}A_U. \]

In view of claim \textbf{16.5.30} (ii), we deduce that \( x_0 \in \text{Fil}^{(1-n)e} \mathcal{K} \). Moreover, \( x = \tau_{E_U}(x_0) + p \cdot \bar{u} \), and recall that \( \bar{a} = \tau_\mathcal{E}(\alpha_0) + p \cdot \bar{u} \) for an invertible element \( \bar{u} \in W(\mathcal{E}) \); we conclude that \( x \) is the sum of

\[ \tau_{E_U}(x_0) - \bar{u}^{-1} \cdot \tau_\mathcal{E}(\alpha_0) \cdot \bar{z} \in W(\text{Fil}^{(1-n)e} \mathcal{K}, 1) \quad \text{and} \quad \bar{u}^{-1} \cdot \bar{a} \cdot \bar{z} \in \alpha W(\mathcal{K}, 1). \]

Especially, \( \tau_{E_U}(x_0) - \bar{u}^{-1} \cdot \tau_\mathcal{E}(\alpha_0) \cdot \bar{z} \) lies as well in the kernel of u_U; by inductive assumption it is therefore an element of \( \alpha W(\text{Fil}^{(1-n)e} \mathcal{K}, 1) \), and the proof is concluded.

\[ \square \]

**Proposition 16.5.46.** Let \( A \) be any complete and separated topological ring, whose topology is linear and coarser than the \( p \)-adic topology, and \( v \in \text{Cont}(A) \) any valuation. We have:

(i) The mapping \( v \circ \overline{\pi}_A \) is a continuous valuation of the topological ring \( E := E(A) \) (see Remark \textbf{9.4.12} (ii)).

(ii) The rule : \( v \mapsto v \circ \overline{\pi}_A \) defines continuous maps

\[ \text{Cont}(\overline{\pi}_A) : \text{Cont}(A) \to \text{Cont}(E) \quad \text{Cont}^+(\overline{\pi}_A) : \text{Cont}^+(A) \to \text{Cont}^+(E). \]

(iii) The diagrams of continuous maps

\[
\begin{array}{ccc}
\text{Spec}(A) & \xrightarrow{\text{Cont}(\overline{\pi}_A)} & \text{Spec}(E) \\
\downarrow & & \downarrow \\
\text{Spec} A & \xrightarrow{\text{Spec} \overline{\pi}_A} & \text{Spec} E
\end{array}
\]

\[
\begin{array}{ccc}
\text{Cont}(A) & \xrightarrow{\text{Cont}(\overline{\pi}_A)} & \text{Cont}(E) \\
\downarrow & & \downarrow \\
\text{Spec} A & \xrightarrow{\text{Spec} \overline{\pi}_A} & \text{Spec} E
\end{array}
\]

\[
\begin{array}{ccc}
\text{Cont}^+(A) & \xrightarrow{\text{Cont}^+(\overline{\pi}_A)} & \text{Cont}^+(E) \\
\downarrow & & \downarrow \\
\text{Spec} A & \xrightarrow{\text{Spec} \overline{\pi}_A} & \text{Spec} E
\end{array}
\]

commute, where \( \text{Spec} \overline{\pi}_A \) is defined as in \textbf{16.1} and the vertical arrows in the left (resp. right) diagram are the restrictions of the support maps \( \sigma_A \) and \( \sigma_E \) (resp. of the center maps \( \sigma_A^+ \) and \( \sigma_E^+ \)) : see Remark \textbf{9.2.4} (iii,v).

(iv) If \( v' \in \text{Cont}(A) \) is a primary (resp. secondary) specialization of \( v \), then \( \text{Cont}(\overline{\pi}_A)(v') \) is a primary (resp. secondary) specialization of \( \text{Cont}(\overline{\pi}_A)(v) \).

(v) The map \( \text{Cont}(\overline{\pi}_A) \) restricts to a surjection from the set of secondary specializations of \( v \) onto the set of secondary specializations of \( \text{Cont}(\overline{\pi}_A)(v) \).

(vi) If \( A \) is a P-ring, \( \text{Cont}(\overline{\pi}_A) \) also restricts to a surjection from the set of secondary specializations of \( v \) onto the set of secondary generalizations of \( \text{Cont}(\overline{\pi}_A)(v) \).

**Proof.** (i): Since both \( v \) and \( \overline{\pi}_A \) are continuous morphisms of pointed monoids, the same holds for \( v \circ \overline{\pi}_A \). Thus, it remains only to check that

\[ v(\overline{\pi}_A(a_* + b_*)) \leq \max(v(a_0), v(b_0)) \quad \text{for every} \quad a_*, b_* \in E. \]

However, recall that

\[ \overline{\pi}_A(a_* + b_*) = \lim_{n \to +\infty} (a_n + b_n)^{p^n}. \]
Since the pointed monoid $\Gamma_{v_0}$ is separated for its topology $\mathcal{B}_v$ (notation of definition 15.3.12(i)), it follows that $v(\bar{\pi}_A(a_\bullet + b_\bullet))$ is the unique limit point of the sequence $(v(a_n + b_n) p^n)_{n \in \mathbb{N}}$. However:

$$v(a_n + b_n) p^n \leq \max(v(a_n) p^n, v(b_n) p^n) = \max(v(a_0), v(b_0))$$

whence the assertion.

(ii): Let $a_\bullet, b_\bullet \in E$ be any two elements, and set $U := \{ v \in \text{Cont}(E) \mid v(a_\bullet) \leq v(b_\bullet) \neq 0 \}$; directly from the definition we find:

$$\text{Cont}(\bar{\pi}_A)^{-1}U = \{ w \in \text{Cont}(A) \mid w(a_0) \leq w(b_0) \neq 0 \}$$

whence the assertion.

(iii) and (iv) are immediate from the definitions.

(v): Set $w := \text{Cont}(\bar{\pi}_A)(v)$ and notice that $\mathfrak{p} := \sigma_A(v)$ is a closed subset in the $p$-adic topology of $A$; we remark the following:

**Claim 16.5.47.** Denote by $\overline{\pi}$ (resp. $\overline{\pi}$) the residual valuation of $\nu$ (resp. of $w$). Then we have:

(i) The map $\overline{\pi}_\nu : \nu(w) \to \nu(v)$ of lemma 16.1.5 restricts to a local morphism of multiplicative monoids $\overline{\pi}_\nu^+ : (\nu(w), \nu) \to (\nu(v), \nu)^+$.

(ii) Let also $\overline{\pi}(v)$ (resp. $\overline{\pi}(w)$) be the residue field of $\nu(v)^+$ (resp. of $\nu(w)^+$). There exists a unique ring homomorphism $\overline{\psi}_v : \overline{\pi}(w) \to \overline{\pi}(v)$ fitting into a commutative diagram

$$\begin{array}{ccc}
\nu(w) & \xrightarrow{\overline{\pi}_\nu} & \nu(v) \\
\downarrow & & \downarrow \\
\overline{\pi}(w) & \xrightarrow{\overline{\psi}_v} & \overline{\pi}(v)
\end{array}$$

whose vertical arrows are the projections.

**Proof of the claim.** (i): Indeed, a simple inspection of the definitions yields a commutative diagram of monoids

$$\begin{array}{ccc}
\nu(w) & \xrightarrow{\overline{\pi}_\nu} & \nu(v) \\
\downarrow & & \downarrow \\
\Gamma_v & \xrightarrow{\nu} & \Gamma_v
\end{array}$$

whence the assertion: details left to the reader.

(ii): Let $\overline{\pi}_w : \nu(v)^+ \to \overline{\pi}(v)$ be the projection; since $\overline{\pi}_w^+$ is local, we are easily reduced to checking that the composition $\psi := \overline{\pi}_w \circ \overline{\pi}_w^+$ is a ring homomorphism. However, $\psi$ is obviously a morphism of multiplicative monoids, so it suffices to show that

$$\overline{\pi}(\overline{\pi}_w^+(x_1 + x_2) - \overline{\pi}_w^+(x_1) - \overline{\pi}_w^+(x_2)) < 1$$

for every $x_1, x_2 \in \nu(w)^+$. However, let $\pi_w : E \to \nu(w)$ and $\pi_v : A \to \nu(v)$ be the projections; we may write

$$x_1 = \pi_w(\beta_1)/\pi_w(\gamma) \quad \text{and} \quad x_2 = \pi_w(\beta_2)/\pi_w(\gamma) \quad \text{for some } \beta_1, \beta_2, \gamma \in E$$

with $w(\beta_1), w(\beta_2) \leq w(\gamma) \neq 0$. Set $x_3 := x_1 + x_2$ and $\beta_3 := \beta_1 + \beta_2$; then

$$\overline{\pi}_w^+(x_i) = \pi_v \circ \overline{\pi}_A(\beta_i)/\pi_v \circ \overline{\pi}_A(\gamma) \quad \text{for } i = 1, 2, 3.$$
Since $v$ is a continuous valuation and $v(p)$ is final in $\Gamma_v$, the contention follows easily: details left to the reader.

Now we argue as in the proof of lemma 9.2.25 (iii). Namely, let $w'$ be a secondary specialization of $w$; then $\kappa(w') = \kappa(w)$, and $\kappa(w')^+ \subset \kappa(w)^+$. The image $W$ of $\kappa(w')^+$ in $\pi(w)$ is a valuation ring, and by corollary 9.1.24 there exists a valuation ring $V$ of $\pi(v)$ that dominates $\varpi_v(W)$. The preimage of $V$ in $\kappa(v)^+$ is a valuation ring of $\kappa(v)$, and the corresponding valuation $v'$ is a secondary specialization of $v$. Lastly, $v'$ is continuous, by remark 15.3.13 (iv), and by construction we have $\text{Cont}(\pi_A)(v') = w'$.

(vi): Clearly $\pi_A$ induces an injective morphism of ordered groups $i : \Gamma_w \to \Gamma_v$, and $\text{Spec} i$ is surjective, by remark 9.1.2 (v). Now, let $w'$ be a secondary generalization of $w := \text{Cont}(\pi_A)(v)$, so that $w' = w_\Delta$ for a convex subgroup $\Delta \subset \Gamma_w$, and we may write $\Delta = i^{-1}\Delta'$ for some convex subgroup $\Delta' \subset \Gamma_v$. If $\Delta' \neq \Gamma_v$, the projection $\Gamma_{v_0} \to (\Gamma_v/\Delta')_0$ is continuous (remark 15.3.13 (iii)), so $v' := v_{\Delta'}$ is a secondary specialization of $v$ in $\text{Cont}(A)$ with $\text{Cont}(\pi_A)(v') = w'$. Hence, we may assume that $w'$ is a trivial valuation. It follows easily that $E^{v_0} \subset \text{Ker} w'$. On the other hand, we may find finitely many elements $\beta_1, \ldots, \beta_k \in E^{v_0}$ such that the system $\pi_A(\beta_1), \ldots, \pi_A(\beta_k)$ generates an open ideal of $A$ (see the proof of lemma 16.2.7 (i)). Summing up, we see that $v'$ is an analytic valuation of $A$, especially $v' \in \text{Cont}(A)$, and the proof is concluded.

Remark 16.5.48. Keep the notation of proposition 16.5.46 for every $v \in \text{Cont}(A)$ we have the commutative diagram of topological monoids

\[
\begin{array}{ccc}
E & \xrightarrow{\pi_A} & A \\
\downarrow{E(v)} & & \downarrow{v} \\
E(\Gamma_{v_0}) & \xrightarrow{\pi_{\Gamma_{v_0}}} & \Gamma_{v_0}
\end{array}
\]

(where $\Gamma_{v_0}$ is endowed with its natural topology $\mathcal{T}_{\Gamma_v}$ as in definition 15.3.12 (i)) and under the natural identification $E(\Gamma_{v_0}) \xrightarrow{\sim} E(\Gamma_v)_0$, the map $\pi_{\Gamma_{v_0}}$ corresponds to $(\pi_{\Gamma_v})_0$. Then $E(\Gamma_v)$ inherits from $\Gamma_v$ a unique ordering such that $\pi_{\Gamma_v}$ is an injective morphism of ordered abelian groups. Moreover, since the $p$-Frobenius endomorphism of $\Gamma_v$ is injective, it is easily seen that the topology of $E(\Gamma_{v_0}, \mathcal{T}_{\Gamma_v})$ is the same as the topology $\mathcal{T}_{E(\Gamma_v)}$ provided by definition 15.3.12 (i) (details left to the reader). In view of proposition 16.5.46 (i), it follows that $E(v)$ is a continuous valuation on $E(v)$, and we have

\[
\text{Cont}(\pi_A)(v) = E(v) \quad \text{in} \quad \text{Cont}(E).
\]

Proposition 16.5.49. Let $A$ be any perfectoid ring. We have:

(i) $A$ is a valuation ring if and only if the same holds for $E := \text{Cont}(A)$.

(ii) Suppose that $A$ is a valuation ring, and let

$\gamma_A : \Gamma_A \cong \Gamma_A$.

$\gamma_A : \Gamma_A \cong \Gamma_A$

fitting into a commutative diagram

\[
\begin{array}{ccc}
E & \xrightarrow{\pi_A} & A \\
\downarrow{v_E} & & \downarrow{v_A} \\
\Gamma_{E_0} & \xrightarrow{\pi_A} & \Gamma_{A_0}
\end{array}
\]

be the valuations of $A$ and $E$ (see remark 9.1.13 (iv)). Then:

(a) $v_A \in \text{Cont}(A)$ and $v_E \in \text{Cont}(E)$.

(b) The map $\pi_A$ induces an isomorphism of ordered abelian groups:

\[
\gamma_A : \Gamma_A \cong \Gamma_A
\]

fitting into a commutative diagram

\[
\begin{array}{ccc}
E & \xrightarrow{\pi_A} & A \\
\downarrow{v_E} & & \downarrow{v_A} \\
\Gamma_{E_0} & \xrightarrow{\pi_A} & \Gamma_{A_0}
\end{array}
\]

be the valuations of $A$ and $E$ (see remark 9.1.13 (iv)). Then:

(a) $v_A \in \text{Cont}(A)$ and $v_E \in \text{Cont}(E)$.

(b) The map $\pi_A$ induces an isomorphism of ordered abelian groups:

$\gamma_A : \Gamma_A \cong \Gamma_A$.
(c) More precisely, if \((\alpha_n \mid n \in \mathbb{N})\) is any distinguished element of Ker \(u_A\), the map 
\[ \text{Frac}(E)^\times/(1 + \alpha_0E) \cong \text{Frac}(A)^\times/(1 + pA). \]

(iii) Let \(V\) be a valuation ring, and \(\mathcal{V}\) a linear, complete, separated and \(f\)-adic topology on \(V\) that is coarser than the \(p\)-adic topology. Suppose that:

(a) The value group of \(V\) is \(p\)-divisible.

(b) The Frobenius endomorphism of \(V/pV\) is surjective.

Then \((V, \mathcal{V})\) is a perfectoid ring.

**Proof.** (i): We remark:

**Claim 16.5.50.** If \(E\) is a valuation ring, then for every \(a \in A\) there exist \(t \in A^\times\) and \(e \in E\) such that \(a = t \cdot \pi_A(e)\).

**Proof of the claim.** Fix any distinguished element \((\alpha_n \mid n \in \mathbb{N})\) of Ker \(u_A\), and recall that \(p = w \cdot \pi_A(\alpha_0)\) for some \(w \in A^\times\) (lemma 16.2.7[iii]). Since the \(p\)-adic topology is separated on \(A\), there exists \(n \in \mathbb{N}\) such that \(a \in p^nA \setminus p^{n+1}A\), so that \(a = p^n b\) for some \(b \in A \setminus pA\). Then there exists \(\beta \in E\) such that \(b - \pi_A(\beta) = p z\) for some \(z \in A\) (lemma 16.2.7[i]), and notice that \(\beta \notin \alpha_0 E\), since otherwise we would have \(\pi_A(\beta) \in pA\), whence \(b \in pA\), a contradiction. Thus, \(\alpha_0 = \beta \cdot \gamma\) for some element \(\gamma\) of the maximal ideal of \(E\), and we may write

\[ x = p^n b = p^n \cdot (\pi_A(\beta) + p z) = w^n \cdot \pi_A(\alpha_0^n \beta) \cdot (1 + \pi_A(\gamma) \cdot w z). \]

We need to check that \(u := 1 + \pi_A(\gamma) \cdot w z\) is invertible in \(A\); to this aim, since \(p\) lies in the Jacobson radical of \(A\), it suffices to show that the image of \(u\) is invertible in \(A/pA\), and we are further reduced to checking that the image \(\overline{\pi}_A(\gamma)\) lies in the Jacobson radical of \(A/pA\). However, \(u_A\) induces a ring isomorphism \(E/\alpha_0 E \cong A/pA\) (remark 16.3.7[ii]), and \(\omega^{-1}(\overline{\pi}_A)\) is the class of \(\gamma\), whence the contention.

Now, suppose that \(E\) is a valuation ring; directly from claim 16.5.50 and corollary 16.3.61 we deduce that \(A\) is a domain. Then, let \(a_1, a_2 \in A\) be any two elements, and write \(a_i = t_i \cdot \pi_A(e_i)\) with \(t_i \in A^\times\) and \(e_i \in E\) for \(i = 1, 2\); we may assume that \(e_1 \in e_2 E\), whence \(a_1 \in a_2 A\), which easily implies that \(A\) is a valuation ring.

Conversely, suppose that \(A\) is a valuation ring; if the field of fractions \(K\) of \(A\) has characteristic \(0\), we know already from lemma 9.4.16 that \(E\) is a valuation ring. If the characteristic of \(K\) equals \(p\), the ring \(E\) is isomorphic to \(A\), whence the assertion.

(ii.a): In light of proposition 9.1.15[i, ii) we see that either the topology \(\mathcal{V}_A\) of \(A\) is discrete, or else it agrees with the valuation topology of \(A\). In either case, it is clear that \(v_A \in \text{Cont}(A)\). The same applies to \(E\), since the latter is perfectoid as well.

(ii.b): From claim 16.5.50 we immediately see that \(\gamma_A\) is surjective, and the injectivity follows from remark 16.5.48.

(ii.c): By (ii.b) and the snake lemma, we are reduced to showing that \(\pi_A\) induces a group isomorphism

\[ E^\times/(1 + \alpha_0 E) \cong A^\times/(1 + pA). \]

However, \(\pi_A\) induces a ring isomorphism \(E/\alpha_0 E \cong A/pA\) (remark 16.3.7[ii]), whence a group isomorphism \((E/\alpha_0 E)^\times \cong (A/pA)^\times\), and it remains only to observe that the natural maps

\[ E^\times/(1 + \alpha_0 E) \to (E/\alpha_0 E)^\times \quad A^\times/(1 + pA) \to (A/pA)^\times \]

are isomorphisms, since \(\alpha_0 E\) (resp. \(pA\)) lies in the Jacobson radical of \(E\) (resp. of \(A\)).

(iii): In light of proposition 9.1.15[i), we see that \(\mathcal{V}_V\) is either the discrete topology or the valuation topology on \(V\). If \(\mathcal{V}_V\) is discrete and coarser than the \(p\)-adic topology, then \(V\) must be an \(\mathbb{F}_p\)-algebra, so in this case the assertion is a special case of example 16.3.2(i). If \(\mathcal{V}_V\) is the
valuation topology, let us endow $K := \text{Frac} V$ with its valuation topology $\mathcal{S}_K$; then $(K, \mathcal{S}_K)$ is a Tate ring, by proposition [9.1.15(ii)], hence $V$ admits an ideal of adic definition of the form $I := aV$, for a non-zero topologically nilpotent element $a \in V$ (corollary 8.3.20(ii)). Since the value group of $V$ is $p$-divisible, and $p$ is topologically nilpotent in $V$, we may assume that $p \in I^p$, in which case, assumption (iii.b) implies that the Frobenius endomorphism of $V/pV$ induces an isomorphism $V/I \cong V/pV$. By the same token, we easily see that $(V, \mathcal{S}_V)$ is a $P$-ring, so the assertion follows from theorem [16.4.1].

**Remark 16.5.51.** Let $A, A'$ be two perfectoid valuation rings with valuations $v : A \to \Gamma_{A_0}$, $v' : A' \to \Gamma_{A_0'}$, and $f : A \to A'$ a continuous ring homomorphism; according to proposition [16.5.49(i)], both $E := E(A)$ and $E' := E(A')$ are valuation rings, and we denote by $v_E : E \to \Gamma_{E_0}$, $v_{E'} : E' \to \Gamma_{E_0'}$ their respective valuations. Then it follows easily from proposition [16.5.49(ii.c)] that $f$ is injective if and only if the same holds for $E(f) : E \to E'$. Moreover, if $f$ is injective there exist unique group homomorphisms $\varphi_E : \Gamma_E \to \Gamma_{E_0'}$, $\varphi_A : \Gamma_A \to \Gamma_{A_0'}$ fitting into a commutative diagram:

$$
\begin{array}{ccccccccc}
\Gamma_{E_0} & \xrightarrow{v_E} & E & \xrightarrow{E(f)} & E' & \xrightarrow{v_{E'}} & \Gamma_{E_0'} \\
\gamma_{A_0} & \searrow & \nearrow & \pi_A & & & \nearrow & \gamma_{A_0'} \\
\Gamma_A & \xrightarrow{v_A} & A & \xrightarrow{f} & A' & \xrightarrow{v_{A'}} & \Gamma_{A_0'} \\
& \nearrow & & & \varphi_A & & & \nearrow & \gamma_{A'}
\end{array}
$$

where $\gamma_A$ and $\gamma_{A'}$ are the group isomorphisms provided by proposition [16.5.49(ii.b)]:

**Theorem 16.5.52.** Let $A$ be any perfectoid ring, and set $E := E(A)$. We have:

(i) The induced map $\text{Cont}(\overline{\pi}_A)$ of proposition [16.5.46(ii)] is a homeomorphism.

(ii) For every rational subset $R$ of $\text{Cont}(E)$, the preimage $\text{Cont}(\overline{\pi}_A)^{-1}R$ is a rational subset of $\text{Cont}(A)$ (see [15.3.16]).

(iii) $\text{Cont}(\overline{\pi}_A)$ restricts to bijections

$$
\text{Cont}(A)_a \xrightarrow{\sim} \text{Cont}(E)_a \quad \text{and} \quad \text{Cont}(A)_{an} \xrightarrow{\sim} \text{Cont}(E)_{an}.
$$

(iv) Let $w \in \text{Cont}(A)$ be any valuation, and set $v := \text{Cont}(\overline{\pi}_A)(w)$. Then $\overline{\pi}_A$ induces group isomorphisms

$$
\gamma_w : \Gamma_v \xrightarrow{\sim} \Gamma_w \quad \text{and} \quad c\Gamma_v \xrightarrow{\sim} c\Gamma_w.
$$

**Proof.** (ii): If $A$ is perfectoid, both $\text{Cont}(A)$ and $\text{Cont}(E)$ are spectral spaces, and their rational subsets form a basis of constructible open subsets. Thus, let $(e_i | i = 0, \ldots, n)$ be any finite system of elements of $E$ that generate an open ideal, and set $R := R_E(e_i, \ldots, e_n) \cap \text{Cont}(E)$. Let also $a_i := \overline{\pi}_A(e_i)$ for every $i = 0, \ldots, n$. Then

$$
\text{Cont}(\overline{\pi}_A)^{-1}R = R_A(a_i/a_0) \cap \text{Cont}(A).
$$

However, the system $(a_i | i = 0, \ldots, n)$ generates an open ideal of $A$ (corollary [16.3.40(ii)]), whence the assertion.

(iii): Let $\alpha := (\alpha_n | n \in \mathbb{N})$ be any distinguished element of $\text{Ker } u_A$; since $\alpha_0$ is topologically nilpotent, it lies in every open prime ideal of $E(A/pA)$. Likewise, $pA$ is contained in every
open prime ideal of \( A \), and due to lemmata 16.2.7(i,iii) and 16.1.1(iv), the map \( \pi_A \) induces an isomorphism
\[
\omega : E/\alpha_0 E \xrightarrow{\sim} A/pA
\]
of topological rings, so that \( \text{Cont}(\pi_A) \) agrees with \( \text{Cont}(\omega) \) on the closed subset \( \text{Cont}(E/\alpha_0 E) \) of \( \text{Cont}(E) \), and induces a homeomorphism
\[
\text{Cont}(E/\alpha_0 E) \xrightarrow{\sim} \text{Cont}(A/pA).
\]
It is also clear that \( \text{Cont}(\omega) \) maps \( \text{Cont}(E/\alpha_0 E)_{na} = \text{Cont}(E)_{na} \) homeomorphically onto \( \text{Cont}(A/pA)_{na} = \text{Cont}(A)_{na} \), so we need only to check that the restriction
\[
C(A) := \text{Cont}(A) \cap R_A \left( \frac{p}{p} \right) \to C(E) := \text{Cont}(E) \cap R_E \left( \frac{\alpha_0}{\alpha_0} \right)
\]
of \( \text{Cont}(\pi_A) \) is a bijection. Set \( C^+(A) := C(A) \cap \text{Spv}^+ A \) and \( C^+(E) := C(E) \cap \text{Spv}^+ E \). Clearly \( \text{Cont}(\pi_A) \) restricts to a mapping \( C^+(A) \to C^+(E) \), and we shall first exhibit an inverse mapping
\[
\sigma : C^+(E) \to C^+(A)
\]
for \( \text{Cont}(\pi_A)|_{C^+(A)} \). To this aim, let \( v \in C^+(E) \) be any valuation; then \( v \) factors through a ring homomorphism \( \pi : E \to V := \kappa(v)^+ \) and the residual valuation \( \nu : V \to \Gamma_{\nu} \) of \( v \). Since \( E \) is a perfect \( \mathbb{F}_p \)-algebra, the field \( \kappa(v) \) is perfect, hence \( V \) is a perfect \( \mathbb{F}_p \)-algebra as well: indeed, it is clear that \( x^p \in V \) if and only if \( x \in V \), for every \( x \in \kappa(v) \). Let us endow \( V \) with its valuation topology \( \mathcal{T}_V \), so that \( \nu \) is continuous for the topology \( \mathcal{T}_V \) (remark 15.3.13(i)).

**Claim 16.5.53.** The completion \( (V^\wedge, \mathcal{T}_V^\wedge) \) of \( (V, \mathcal{T}_V) \) is a perfectoid valuation ring.

**Proof of the claim.** We know that \( V^\wedge \) is a valuation ring, by proposition 9.1.15(iii), and its topology \( \mathcal{T}_V^\wedge \) is adic with a principal ideal of adic definition, since the same holds for \( \mathcal{T}_V \) (lemma 15.3.14(ii)). Moreover, it is easily seen that the Frobenius endomorphism \( \Phi_V \) of \( V \) is a homeomorphism for the topology \( \mathcal{T}_V \), hence it induces a homeomorphism \( \Phi_V^\wedge \) on \( V^\wedge \); but clearly \( \Phi_V^\wedge \) is just the Frobenius endomorphism of \( V^\wedge \), so the latter is a perfect topological \( \mathbb{F}_p \)-algebra, and the assertion follows (see example 16.3.2(i)).

Let \( \pi^\wedge : E \to V^\wedge \) be the composition of \( \pi \) with the completion map \( V \to V^\wedge \); since \( \pi^\wedge \) is a continuous map of perfectoid \( \mathbb{F}_p \)-algebras (remark 15.3.13(i)), the image of \( \pi^\wedge \), under the map \( W(\pi^\wedge) \) is still distinguished in \( W(V^\wedge) \), so claim 16.5.53 and proposition 16.5.49(i,ii) say that
\[
A_V := W(V^\wedge) \otimes_{W(E)} A
\]
is a perfectoid valuation ring whose valuation \( v_{A_V} \), is continuous, and the map \( \pi_{A_V} \) induces an isomorphism of ordered abelian groups from the value group of \( V^\wedge \) onto that of \( A_V \)
\[
\gamma_{V^\wedge} : \Gamma_{V^\wedge} \xrightarrow{\sim} \Gamma_{A_V} \text{ such that } v_{A_V} \circ \pi_{A_V} = \gamma_{V^\wedge} \circ \nu^\wedge
\]
where \( \nu^\wedge \) is the valuation of \( V^\wedge \). Moreover, we get a continuous map of perfectoid rings
\[
\varphi := W(\pi^\wedge) \otimes_{W(E)} A : A \to A_V
\]
and \( w := v_{A_V} \circ \varphi \) is a continuous valuation of \( A \) such that
\[
\text{Cont}(\pi_A)(w) = w \circ \pi_A = v_{A_V} \circ \pi_{A_V} \circ \pi^\wedge = \gamma_{V^\wedge} \circ \nu^\wedge \circ \pi^\wedge = \gamma_{V^\wedge} \circ v.
\]
Since \( v(\alpha_0) \neq 0 \), we have \( w(p) \neq 0 \) as well, so we obtain the sought map \( \sigma \), by setting \( \sigma(v) := w \), and we already see that \( \sigma \) is a right inverse for \( \text{Cont}(\pi_A)|_{C^+(A)} \). We notice that since \( v(E) \cap \Gamma_v \) generates the group \( \Gamma_v \), the subset \( w \circ \pi_A(E) \cap \Gamma_{A_V} \) generates the group \( \Gamma_{A_V} \), so that \( \pi_A \) induces an isomorphism
\[
(16.5.54) \quad \Gamma_v \xrightarrow{\sim} \Gamma_{\sigma(v)} \text{ for every } v \in C^+(E).
\]
Next, we check that \( \sigma \) is a left inverse as well. To this aim, let \( v' \in C^+(A) \) be any valuation; then \( v' \) factors through a ring homomorphism \( \pi' : A \to V' := k(v')^+ \) and the residual valuation \( \pi' : V' \to \Gamma_{v'0} \). By lemma \[15.3.14(ii)\], the map \( \pi' \) is continuous for the valuation topology \( \mathcal{R}_{V'} \) of \( V' \), and \( \mathcal{R}_{V'} \) is adic with a principal ideal of adic definition. Since \( pV' \neq 0 \) and \( p \) is topologically nilpotent in \( A \), the ideal \( pV' \) is open and topologically nilpotent in \( V' \), so \( \mathcal{R}_{V'} \) agrees with the \( p \)-adic topology on \( V' \). Let \( (V'^\wedge, \mathcal{R}_{V'^\wedge}) \) be the completion of \((V', \mathcal{R}_{V'})\); then \( V'^\wedge \) is a valuation ring whose valuation \( \pi'^\wedge : V'^\wedge \to \Gamma_{v'0} \) extends \( \pi' \) (proposition \[9.1.15(iii,v)]), and we let \( \pi'^\wedge : A \to V'^\wedge \) be the composition of \( \pi' \) with the completion map \( V' \to V'^\wedge \). Then \( V'_E := E(V'^\wedge) \) is a valuation ring whose valuation is

\[
\pi'_E := \pi'^\wedge \circ \pi_{V'^\wedge} : V'_E \to \Gamma_{v'0}
\]

(lemma \[9.4.16\] and \( E(\pi'^\wedge) : E \to V'_E \) is a continuous ring homomorphism. Since \( \pi'^\wedge \circ \pi_A = \pi_{V'^\wedge} \circ E(\pi'^\wedge) \), we deduce that

\[
(16.5.55) \quad v'_E := \pi'_E \circ E(\pi'^\wedge) = \text{Cont}(\pi_A)(v') \quad \text{in Cont}(E).
\]

Claim 16.5.56. (i) The topology of \( V'_E \) agrees with the valuation topology \( \mathcal{R}_{V'_E} \).

(ii) \( (V'_E, \mathcal{R}_{V'_E}) \) is a perfectoid ring.

Proof of the claim. (i): Since the quotient topology induced by \( \mathcal{R}_{V'} \) on \( V'/pV' \) is discrete, the topology of \( V'_E \) is linear, complete and separated (remark \[9.4.9(ii)\]), so it suffices to check that this topology is not discrete (proposition \[9.1.15(i)\]). To this aim, since \( \alpha_0 \) is topologically nilpotent in \( E \), it suffices to check that \( \nu := E(\pi'^\wedge)(\alpha_0) \neq 0 \). However:

\[
\pi_{V'^\wedge}(\nu) = \pi'^\wedge \circ \pi_A(\alpha_0) = \pi'^\wedge(pu) \quad \text{for some } u \in A^\times
\]

(lemma \[16.2.7(iii)\]), and since \( v'(p) \neq 0 \), we must have \( \pi'^\wedge(p) \neq 0 \), whence the claim.

(ii): We have just seen that \( \nu \) is a non-zero topologically nilpotent element of \( V'_E \), so \( \mathcal{R}_{V'_E} \) agrees with the \( \nu \)-adic topology on \( V'_E \); then the assertion follows from example \[16.3.2(i)\]. \( \diamond \)

Arguing as in the foregoing we see that the image of \( \omega \) in \( W(V'_E) \) is still distinguished, so

\[
A_{V'} := W(V'_E) \otimes_{W(E)} A
\]

is a perfectoid valuation ring whose value group is naturally identified with the value group \( \Gamma_{v'_E} \) of \( v'_E \) (proposition \[16.5.49(i,ii.b)\] and claim \[16.5.56(ii)\]); by the same token, we get a natural isomorphism

\[
\beta : E(A_{V'}) \xrightarrow{\sim} V'_E \quad \text{such that} \quad \pi_{V'_E} \circ W(\beta) = u_{A_{V'}}
\]

where \( \pi_{V'_E} : W(V'_E) \to A_{V'} \) is the projection (proposition \[16.2.16(iv)\]). Moreover, in light of the commutative diagram

\[
\begin{array}{ccc}
W(E) & \xrightarrow{u_A} & A \\
\downarrow & & \downarrow \pi'^\wedge \\
W(E(\pi'^\wedge)) & \xrightarrow{u_{V'^\wedge}} & V'^\wedge \\
\end{array}
\]

we get a unique homomorphism of \( A \)-algebras

\[
\psi : A_{V'} \to V'^\wedge \quad \text{such that} \quad u_{V'^\wedge} = \psi \circ \pi_{V'_E}.
\]
There follows a diagram:

\[
\begin{array}{ccc}
\psi & \xleftarrow{\pi_{A_{V'}} \circ \beta^{-1}} & \psi' \\
\downarrow{\Gamma'_{E_{V'}}} & & \downarrow{\Gamma'_{E_{V'}}} \\
A_{V'} & \xrightarrow{\pi_{V'}} & V''
\end{array}
\]

whose two square subdiagrams commute, where \( v'_A \) is the valuation of \( A_{V'} \) and \( j \) the inclusion map of \( \Gamma'_{E_{V'}} \) into \( \Gamma'_{V'} \). Let also \( \varphi' : A \to A_{V'} \) be the structure map of the \( A \)-algebra \( A_{V'} \).

**Claim 16.5.57.** (i) The top subdiagram commutes as well.

(ii) The external subdiagram also commutes, i.e. \( \pi'' \circ \psi = j \circ v'_A \).

(iii) The topology of \( A_{V'} \) agrees with its valuation topology.

(iv) \( \psi \) is an isomorphism of topological rings and \( \Gamma'_{E_{V'}} = \Gamma'_{V'} \).

**Proof of the claim.** (i): Indeed, taking into account lemma [16.1.1](iv) we may compute:

\[
\begin{align*}
\psi \circ \pi'_{A_{V'}} &= \psi \circ u_{A_{V'}} \circ \tau_{E(A_{V'})} \\
&= \psi \circ \pi'_{E_{V'}} \circ W'(\beta) \circ \tau_{E(A_{V'})} \\
&= u_{V'} \circ W'(\beta) \circ \tau_{E(A_{V'})} \\
&= u_{V'} \circ \tau'_{E_{V'}} \circ \beta \\
&= \pi'' \circ \psi \circ \tau_{E} \circ \beta \\
&= \pi'' \circ \psi \circ \tau_{E}(y) = j \circ \pi'_E(y) = j \circ v'_A(x),
\end{align*}
\]

as stated.

(ii): Let \( x \in A_{V'} \) be any element; since the left square subdiagram commutes, we may find \( y \in V'_E \) such that \( \pi_{A_{V'}} \circ \beta^{-1}(y) \cdot u = x \) for some \( u \in A_{V'} \), and therefore \( \psi(x) = \pi'' \circ (y) \cdot \psi(u) \). Obviously, \( \psi(u) \) is invertible in \( V'' \), so that \( \pi'' \circ \psi(x) = \pi'' \circ \pi_{V''}(y) = j \circ \pi'_E(y) = j \circ v'_A(x) \), as stated.

(iii): In light of proposition [9.1.15](i), it suffices to check that the topology of \( A_{V'} \) is not discrete. However, notice that by construction \( \varphi' \) is a continuous map; thus, if the topology of \( A_{V'} \) were discrete, \( \ker \varphi' \) would be an open ideal, and then the same would hold for \( \ker \pi'' \).

But this is absurd, since \( v' \) is analytic.

(iv): As an immediate consequence of (ii), we already see that \( \psi \) is injective. Then it is clear that \( \varphi' \) factors uniquely through \( \pi' \) and an injective map \( V' \to A_{V'} \), whose composition with \( \psi \) equals the completion map. Thus, the image of \( \psi \) is a dense subring of \( V'' \); combining with (ii), we deduce already the stated equality of value groups. Then by (iii) the topology of \( A_{V'} \) agrees with the topology induced by \( V'' \) via \( \psi \). Since \( A_{V'} \) is complete and separated, theorem [8.2.8](iii) implies that \( \psi \) is an isomorphism.

From claim [16.5.57](ii) we get the following equalities in \( \text{Cont}(A) \):

\[
\sigma \circ \text{Cont}(\pi_A)(v') = \sigma(\pi'' \circ \pi_{V''} \circ E(\pi'_E))
\]

\[
= \sigma(\pi'_E \circ E(\pi''))
\]

\[
= v'_A \circ \varphi'
\]

\[
= \pi'' \circ \psi \circ \varphi'
\]

\[
= \pi'' \circ \pi''
\]

\[
= v'
\]

as required. Let \( \kappa(v'_E)^{\pm} \) be the completion of \( \kappa(v'_E)^{\pm} \) for its valuation topology, \( \pi'_E : E \to \kappa(v'_E)^{\pm} \) the natural ring homomorphism (whose composition with the valuation \( \kappa(v'_E)^{\pm} \to \Gamma'_{v'_E} \) yields \( v'_E \)), and \( \pi'' \circ \pi'' : E \to \kappa(v'_E)^{\pm} \) the completion of \( \pi'_E \); we notice as well:
Claim 16.5.58. There exists a ring isomorphism

$$\omega_E^\wedge : \kappa(v'_E)^\wedge \cong V'_E$$

such that

$$\omega_E^\wedge \circ \pi_E^\wedge = E(\pi^\wedge).$$

Proof of the claim. The map $E(\pi^\wedge)$ factors through $\pi'_E$ and a unique injective ring homomorphism $\omega_E : \kappa(v'_E)^\wedge \to V'_E$ such that $\pi'_E \circ \omega_E = \kappa(v'_E)^\wedge \to \Gamma_\nu \cdot$ is the residual valuation. Thus, the valuation topology of $\kappa(v'_E)^\wedge$ agrees with the topology induced from $V'_E$ via $\omega_E$, so the latter extends to a continuous ring homomorphism $\omega_E^\wedge : \kappa(v'_E)^\wedge \to V'_E$ such that $\pi'_E \circ \omega_E^\wedge$ is the valuation of $\kappa(v'_E)^\wedge$. The map $\omega_E^\wedge$ is injective (proposition [8.2.13]), and clearly $\omega_E^\wedge \circ \pi_E^\wedge = E(\pi^\wedge)$, so it remains only to check that $\omega_E^\wedge$ is bijective. To this aim, set $V'' := W(\kappa(v'_E)^\wedge) \otimes_{W(E)} A$; by the foregoing we know already that $V''$ is a perfectoid valuation ring with value group $\Gamma_\nu$, and it suffices to show that

$$\omega_A^\wedge := W(\omega_E^\wedge) \otimes_{W(E)} A : V'' \to A_{\nu'},$$

is an isomorphism. However, set $\pi''_A := W(\pi''_E) \otimes_{W(E)} A$; by remark [16.5.51] we know already that $\omega_A^\wedge$ is injective, and moreover we have a commutative diagram

$$\begin{array}{ccc}
A & \xrightarrow{\pi''_A} & V'' \\
\downarrow{v''} & & \downarrow{\Gamma_\nu'} \\
A_{\nu'} & \xrightarrow{\pi''_A} & \Gamma_\nu',
\end{array}$$

where $v''$ is the valuation of $V''$. It follows that the valuation topology of $V''$ is induced by the valuation topology of $A_{\nu'}$ via $\omega_A^\wedge$. Furthermore, we deduce that $v'' \circ \pi''_A = v'_A \circ \varphi' = v'$, so $\pi''_A$ factors through $\pi' : A \to V'$ and an injective map $V' \to V''$ whose composition with $\omega_A^\wedge$ has dense image, by virtue of claim [16.5.57] (iv). Since $V''$ is complete, it follows that $\omega_A^\wedge$ is surjective, whence the claim.

Next, let $A^+$ be the smallest subring of integral elements of $A$ (remark [15.4.2] (iv)); by theorem [16.5.13] (ii,iii), the ring $A^+$ is perfectoid, and $E(A^+)$ is naturally identified with the smallest ring $E^+$ of integral elements of $E$. Moreover, we get a commutative diagram

$$\begin{array}{ccc}
\text{Cont}(A) & \xrightarrow{\text{Cont}(\pi_A)} & \text{Cont}(E) \\
\downarrow{\text{Cont}(j_A)} & & \downarrow{\text{Cont}(j_E)} \\
\text{Cont}(A^+) & \xrightarrow{\text{Cont}(\pi_A^+)} & \text{Cont}(E^+),
\end{array}$$

where $j_A : A^+ \to A$ and $j_E : E^+ \to E$ are the inclusion maps. Since $A^+$ is the integral closure in $A$ of the $\mathbb{Z}$-subalgebra generated by $A^{\text{o}}$, it is easily seen that $\text{Cont}(A^+) = \text{Cont}^+(A^+)$, and likewise for $\text{Cont}(E^+)$. Therefore, $C(A^+) = C^+(A^+)$ and $C(E^+) = C^+(E^+)$, and the foregoing shows that $\text{Cont}(\pi_A^+)$ restricts to a bijection

$$C(E^+) \cong C(A^+).$$

Lastly, proposition [15.3.18] (ii) says that $\text{Cont}(j_A)$ restricts to a bijection from the analytic valuations of $A$ to those of $A^+$, and likewise for $\text{Cont}(j_E)$, whence (iii).

(iv): Let $\pi_A : A \to A/pA$ and $\pi_E : E \to E/\alpha_0E$ be the projections; if $w(p) = 0$, then $w = \text{Cont}(\pi_A)(w')$ for a unique $w' \in \text{Cont}(A/pA)$, and $v = \text{Cont}(\pi_E)(v')$, where $v' := \text{Cont}(\omega)(w')$. Since $\pi_A$ and $\pi_E$ are surjective, obviously $\Gamma_w = \Gamma_w'$ and $\Gamma_v = \Gamma_v'$, and likewise for the characteristic subgroups; since $\omega$ is a ring isomorphism, it induces a group isomorphism $\Gamma_\nu' \cong \Gamma_\nu'$ that identifies the respective characteristic subgroups, whence the assertion, in this case. Next, suppose that $w \in C(A)$, and set $w' := \text{Cont}(j_A)(w)$, $v' := \text{Cont}(\pi_A)(w')$.
then $w' \in C^+(A^+)$, and from (iii) and (16.5.54) we see that $\pi_{A^+}$ induces an isomorphism $\gamma_{w'}: \Gamma_{w'} \xrightarrow{\sim} \Gamma_{v'}$. Moreover, we have a commutative diagram of groups

$$
\begin{array}{ccc}
\Gamma_{w'} & \xrightarrow{\gamma_{w'}} & \Gamma_{v'} \\
\downarrow{i_w} & & \downarrow{i_v} \\
\Gamma_w & \xrightarrow{\gamma_w} & \Gamma_v
\end{array}
$$

where $i_w$ and $i_v$ are the injective maps induced by $j_A$ and $j_E$. In order to prove that $\gamma_w$ is an isomorphism, it suffices therefore to check that $i_w$ and $i_v$ are surjective. To this aim, it suffices to show that $S_{A^+} := w(A^+) \cap \Gamma_w$ generates $\Gamma_w$ and $S_{E^+} := v(A^+) \cap \Gamma_v$ generates $\Gamma_v$. However, notice that $pA \subset A^+$ and $\alpha_0 E \subset E^+$; since $w(p) \neq 0$ and $v(\alpha_0) \neq 0$, it follows easily that $S_{A^+}$ and $S_A := w(A) \cap \Gamma_w$ generate the same subgroup of $\Gamma_w$, and likewise for $S_{E^+}$. To conclude, it suffices to remark that $S_A$ generates $\Gamma_w$, and likewise for $\Gamma_v$.

Next, obviously $\gamma_w$ restricts to an injective group homomorphism $c_{\Gamma_w} \rightarrow c_{\Gamma_{w'}}$. To show that this map is surjective, consider any $a \in A$ such that $w(a) > 1$; since $\pi_{A/pA}$ is surjective (lemma 16.2.7(i)), we may write $a = \pi_A(\beta) + pb$ for some $\beta \in E$ and $b \in A$, and since $pb \in A^{\infty}$, we have $w(pb) < 1$, so that $w(a) = v(\beta)$, whence the contention.

(i): We argue as in the proof of proposition 15.3.19: by (ii) and (iii) we know already that $\text{Cont}(\pi_A)$ is a spectral and bijective map of spectral spaces, so it suffices to check that $\text{Cont}(\pi_A)$ is a closed map, and by proposition 8.1.44(i) and corollary 8.1.47(i) we are further reduced to showing that $\text{Cont}(\pi_A)$ is specializing. Hence, let $w \in \text{Cont}(A)$ be any valuation, and $\nu' \in \text{Cont}(A)$ any specialization of $\nu := \text{Cont}(\pi_A)(w)$; we may find a valuation $\nu''$ of $E$ that is both a secondary specialization of $\nu$ and a primary generalization of $\nu'$, and $\nu'' \in \text{Cont}(E)$, by remark 15.3.13(iv). By proposition 16.5.46(v), there exists a secondary specialization $\nu''$ of $w$ such that $\text{Cont}(\pi_A)(\nu'') = \nu''$. By (iv) we know that $\nu''$ and $\nu''$ have the same value groups and characteristic subgroups, so we may find a primary specialization $\nu'$ of $w$ such that $\text{Cont}(\pi_A)(\nu') = \nu'$, whence the assertion. 

16.5.59. Let $X$ be any perfectoid quasi-affinoid scheme, and with the notation of (16.5.19) and (16.5.20), let us set

$$
A := (A_X^\circ, A_X^+) := \Gamma^\circ(X) \quad \text{and} \quad E := (E_X^\circ, E_X^+) := E(A).
$$

Especially, $E_X^\circ = E(A_X^\circ)$ and $E_X^+ = E(A_X^+)$; it is then clear that $\text{Cont}(\pi_{A_X^\circ})$ maps the subset $\text{Spa}(A_X^\circ, A_X^+)$ into $\text{Spa}(E_X^\circ, E_X^+)$. Conversely, let $v : A_X^\circ \rightarrow \Gamma_v$ be any continuous valuation such that $v \circ \pi_{A_X^\circ} \in \text{Spa}(E_X^\circ, E_X^+)$, and $a_0$ any distinguished element of $\text{Ker} u_{A_X^\circ}$: for every $a \in A_X^\circ$ there exists $b \in A_X^+$ and $e \in E_X^+$ such that $a = \pi_{A_X^\circ}(e) + a_0 b$, and since $a_0 b \in A_X^\circ$, we deduce that $v(a) \leq 1$, so $v \in \text{Spa}(A_X^\circ, A_X^+)$. Combining with proposition 16.5.46(iii), we deduce that $\text{Cont}(\pi_{A_X^\circ})$ restricts to a homeomorphism

$$
\text{Spa}(\pi_A) : \text{Spa} A \xrightarrow{\sim} \text{Spa} E
$$

and taking into account the natural identifications $\text{Spa} A \xrightarrow{\sim} \text{Spa} X$ and $\text{Spa} E \xrightarrow{\sim} \text{Spa} E(X)$, we get as well an induced homeomorphism

$$
\text{Spa}(\pi_X) : \text{Spa} X \xrightarrow{\sim} \text{Spa} E(X).
$$
Moreover, it is easily seen that every morphism \( f : Y \to X \) of perfectoid quasi-affinoid schemes yields a commutative diagram

\[
\begin{array}{ccc}
\text{Spa} Y & \xrightarrow{\text{Spa}(\pi_X)} & \text{Spa} E(Y) \\
\downarrow{\text{Spa} f} & & \downarrow{\text{Spa} E(f)} \\
\text{Spa} X & \xrightarrow{\text{Spa}(\pi_Y)} & \text{Spa} E(X).
\end{array}
\]

(16.5.60)

**Corollary 16.5.61.** In the situation of (16.5.59), let \( x \in \text{Spa} X \) be any element and set \( y := \text{Spa}(\pi_X)(x) \). Denote also by \( \pi_x^+ : A_X^+ \to \kappa(x)^+ \) and \( \pi_y^+ : E_X^+ \to \kappa(y)^+ \) the natural maps (notation of (15.5.12)), and endow \( \kappa(x)^+ \) and \( \kappa(y)^+ \) with the unique ring topologies \( T^+_{x} \) and \( T^+_{y} \) such that \( \pi_x^+ \) and \( \pi_y^+ \) are adic ring homomorphisms. We have:

(i) The topological rings \( (\kappa(x)^+, T^+_{x}) \) and \( (\kappa(y)^+, T^+_{y}) \) are perfectoid valuation rings.

(ii) There exists a unique isomorphism of topological rings:

\[
\omega^+ : E(\kappa(x)^+) \sim \kappa(y)^+ \quad \text{such that} \quad \omega^+ \circ E(\pi_x^+) = \pi_y^+.
\]

**Proof.** Suppose first that \( p \in \text{Ker} \pi_x^+ \); in this case \( x \) corresponds to a continuous ring homomorphism \( \pi_x : A_X^0/pA_X^0 \to \kappa(x) \) and \( y \) corresponds to the continuous ring homomorphism \( \pi_y := \pi_x \circ \varphi : E_X^0/\alpha_0 E_X^0 \to \kappa(x) \), where \( \alpha_0 \) is as in (16.5.59) and \( \varphi : E_X^0/\alpha_0 E_X^0 \sim A_X^0/pA_X^0 \) is the isomorphism of topological rings induced by \( \pi_{A_X^0} \). There follows a unique isomorphism of valued fields \( \omega : \kappa(y) \sim \kappa(x) \) fitting into the commutative diagram

\[
\begin{array}{ccc}
E_X^0/\alpha_0 E_X^0 & \xrightarrow{\varphi} & A_X^0/pA_X^0 \\
\downarrow{\pi_y} & & \downarrow{\pi_x} \\
\kappa(y) & \xrightarrow{\omega} & \kappa(x).
\end{array}
\]

Let us now endow \( \kappa(x)^+ \) and \( \kappa(y)^+ \) with the unique ring topologies such that the natural maps \( \pi_x^+ : A_X^+ \to \kappa(x)^+ \) and \( \pi_y^+ : E_X^+ \to \kappa(y)^+ \) are adic; then clearly \( \omega \) restricts to an isomorphism \( \omega^+ : \kappa(y)^+ \sim \kappa(x)^+ \) of topological rings, and assertion (ii) follows straightforwardly in this case. Moreover, since \( E \) is a perfect \( \mathbb{F}_p \)-algebra, the same holds for its quotient \( E/\text{Ker} \pi_y \), and then also for \( \kappa(y) = \text{Frac}(E/\text{Ker} \pi_y) \), and for \( \kappa(y)^+ \) as well (example 9.4.9(ii)). By Remark 9.4.9(v), it follows easily that \( \kappa(y)^+ \) is a perfect adic and \( f \)-adic topological ring (details left to the reader), and hence it is perfectoid (example 16.3.2(ii)); the same then holds for \( \kappa(x)^+ \).

Next, if \( \pi_x^+(p) \neq 0 \), the point \( x \) is analytic, and the same then holds for \( y \). In this case, it is easily seen that the topologies \( T^+_{x} \) and \( T^+_{y} \) are separated and not discrete, so they coincide with the respective valuation topologies (proposition 9.1.15(i)). Recall that the inclusion map \( i : A_X^+ \to A_X^0 \) induces a homeomorphism \( \text{Cont}(i)_0 : \text{Cont}(A_X^0)_0 \sim \text{Cont}(A_X^+) \); and likewise for \( \text{Cont}(E_X^+) \) (proposition 15.3.18(ii)); moreover, if \( x' := \text{Cont}(i)(x) \), we have a unique isomorphism of valued fields \( \kappa(x') \sim \kappa(x) \) fitting into the commutative diagram

\[
\begin{array}{ccc}
A_X^+ & \xrightarrow{i} & A_X^0 \\
\downarrow{\pi_x^+} & & \downarrow{\pi_x^0} \\
\kappa(x')^+ & \sim & \kappa(x).
\end{array}
\]

where \( \pi_x^0 \) and \( \pi_x^+ \) are the natural maps, and likewise for \( y \) and its image \( y' \in \text{Cont}(E_X^+) \). Hence we may regard \( x \) and \( y \) as elements of \( \text{Cont}(A_X^+) \) and respectively \( \text{Cont}(E_X^+) \), and in this case assertions (i) and (ii) follow from claims 16.5.57(iv) and 16.5.58.
16.6. **Graded perfectoid rings.** This section is mainly dedicated to the construction and investigation of certain angular Rees algebras that shall be useful in the study of blowing up morphisms of perfectoid formal schemes.

**Proposition 16.6.1.** Let \((\Gamma, +, 0)\) be a monoid, \((A, B)\) a \(\Gamma\)-graded structure on the topological ring \((A, \mathcal{T})\), and \(i_0 : \text{gr}_0 B \to A\) the inclusion map. Suppose that \(A\) is a \(P\)-ring. Then we have:

(i) If the \(p\)-Frobenius endomorphism \(p_\Gamma\) of \(\Gamma\) is injective, there exists a finitely generated graded ideal \(J\) of \(B\) such that \(J A\) is an ideal of definition of \(A\).

(ii) Suppose that \(i_0\) is \(c\)-adic and \(p_\Gamma\) is injective. Then \(\text{gr}_0 B\) is a \(P\)-ring, and if \(A\) is perfectoid, the same holds for \(\text{gr}_0 B\).

(iii) If \(A\) is a perfectoid ring, \(\text{Ker} u_A\) is generated by a distinguished element in \(A(\text{gr}_0 B)\).

**Proof.** (i): By lemma [16.2.3](iv), we may write \(p = b^p u\) for some \(u \in A^\times\) and \(b \in A\), and by the same token, \(u = x^p + py\) for some \(x, y \in A\), so that \(p = a^p + p^2 w\), with \(a := bx\) and \(w := u^{-1} y\). Let now \((a_{\gamma} \mid \gamma \in \Gamma)\) be the sequence attached to \(a\), as in remark [8.5.2](iii), and \(c\) (resp. \(d\)) the limit of the Cauchy net \((c_S \mid S \supseteq \Gamma)\) (resp. \((d_S \mid S \supseteq \Gamma)\)) provided by lemma [8.5.6](i), where \(S\) ranges over the finite subsets of \(\Gamma\), and \(a^p_S = c_S + p \cdot d_S\) for every such \(S\) (with \(a_S\) defined as in remark [8.5.2](iii)). In light of proposition [8.5.3](ii), we deduce that \(a^p = c + pd\), whence \(p = c + pd + p^2 w\). Moreover, since the \(p\)-Frobenius map of \(\Gamma\) is injective, we have \(\pi_{\eta_\gamma}(c) = a^p_\gamma\) for every \(S \supseteq \Gamma\) and every \(\gamma \in S\); therefore \(\pi_{\eta_\gamma}(c) = a^p_\gamma\) for every \(\gamma \in \Gamma\), and especially, \(\pi_0(c) = a^p_0\). Consequently

\[p = a^p_0 + p \cdot d_0 + p^2 w_0\]

where \((d_\gamma \mid \gamma \in \Gamma)\) and \((w_\gamma \mid \gamma \in \Gamma)\) are the sequences attached to \(d\) and respectively \(w\). Next, notice that \(a\) is topologically nilpotent in \(A\), hence \(a_\gamma\) is topologically nilpotent in \(B\), for every \(\gamma \in \Gamma\) (lemma [8.5.6](ii)), and then the same holds for \(d_0\). Thus \(v := 1 - d_0 - pw_0\) is invertible in \(A\), with inverse given by the convergent series \(\sum_{n \in \mathbb{N}}(d_0 + pw_0)^n\), and since \(\text{gr}_0 B\) is closed in \(A\), we conclude that \(v \in (\text{gr}_0 B)^\times\). Summing up, we arrive at the identity

\[pv = a^p_0\quad \text{with } v \in (\text{gr}_0 B)^\times\] and \(a_0 \in \text{gr}_0 B\).

Lastly, by proposition [8.5.11](i,a) we know already that \(A\) admits an ideal of adic definition of the form \(J' A\), for some graded ideal \(J' \subseteq B\), and we set \(J := J' + a_0 B\); then it is easily seen that \(J A\) is an ideal of definition for the \(P\)-ring \(A\).

(ii): We remark:

**Claim 16.6.2.** In the situation of the proposition, suppose that \(p_\Gamma\) is injective. Then we have:

(i) The Frobenius endomorphism of \(B/pB\) restricts to surjective maps

\[\text{gr}_\gamma B \otimes_{\mathbb{Z}} \mathbb{F}_p \to \text{gr}_{p\gamma} B \otimes_{\mathbb{Z}} \mathbb{F}_p\]

for every \(\gamma \in \Gamma\).

(ii) \(\text{gr}_\gamma B = 0\) for every \(\gamma \in \Gamma \setminus E(\Gamma)\).

**Proof of the claim.** (i): Say that \(b \in \text{gr}_\gamma B\); by lemma [16.2.3](iv) there exists \(x \in A\) such that \(x^p - b \in pA\). Let \((x_\gamma \mid \gamma \in \Gamma)\) be the system attached to \(x\) as in remark [8.5.2](iii); it was remarked in the proof of (i) that the system \((x_\gamma^p \mid \gamma \in \mathbb{N})\) is a Cauchy net in \(B\), and if \(y \in A\) denotes the limit of this net, then \(x^p - y \in pA\), so that \(y - b \in pA\) as well. Consequently,

\[b = \pi_{\eta_\gamma}(b) = \pi_{\eta_\gamma}(y) = x_{p^{-1}\gamma}^p \quad (\text{mod } p \cdot \text{gr}_\gamma B)\]

if \(\gamma \in p\Gamma\), and otherwise \(b \in p \cdot \text{gr}_\gamma B\).Assertion (i) follows already. Next, using part (i) of the claim it is easily seen that, if \(\gamma \in \Gamma \setminus E(\Gamma)\), we have \(\text{gr}_\gamma B \otimes_{\mathbb{Z}} \mathbb{F}_p = 0\), whence (ii), since the \(p\)-adic topology is separated on \(B\).

Claim [16.6.2] says especially that the Frobenius endomorphism of \(\text{gr}_0 B \otimes_{\mathbb{Z}} \mathbb{F}_p\) is surjective. On the other hand, we already know by proposition [8.5.11](iii) that the topology of \(\text{gr}_0 B\) is adic.
with a finitely generated ideal of adic definition $I$. Moreover, the proof of (i) shows that there exists $a_0 \in \text{gr}_0 B$ such that $p = a_0^p u$ for some $u \in (\text{gr}_0 B)^\times$; then, it is easily seen that $\text{gr}_0 B$ is a $\mathbb{P}$-ring with ideal of definition $I + a_0 \cdot \text{gr}_0 B$.

Lastly, suppose that $A$ is perfectoid, and to ease notation set $B_0 := \text{gr}_0 B$. By the foregoing, we know already that $B_0$ is a $\mathbb{P}$-ring, and then $i_0$ is adic, by lemma 8.3.24(i.c). Pick any ideal of definition $I_0$ of $B_0$, and say that $I_0$ is generated by $k$ elements, for some $k \in \mathbb{N}$; by remark 16.3.56 we can assume that $p \in I_0^{(k-1)+1}$, and therefore $I := I_0 A$ is an open ideal of $A$ that fulfills the same condition. Set $J_0 := I_0(p)$ and $J := I_p = J_0 A$; it follows that the Frobenius endomorphism of $A/pA$ induces an isomorphism $\Phi_I : \text{gr}_I A \to \text{gr}_J A$ (propositions 16.3.8(i) and 16.3.57(ii)).

**Claim 16.6.3.** The natural maps
\[
\text{gr}_I^n B := I_0^n B/I_0^{n+1} B \to \text{gr}_I^n A \quad \text{gr}_J^n B := J_0^n B/J_0^{n+1} B \to \text{gr}_J^n A
\]
are bijective for every $n \in \mathbb{N}$.

**Proof of the claim.** By claim 8.3.26 we have $(I^n)^c = I^n A$, so that $I^n = I^n B + I^{n+1}$, whence the surjectivity of the first map. For the injectivity, we need to show that $I_0^{n+1} B = I_0^n B \cap I^{n+1}$. Hence, let $x \in I_0^n B \cap I^{n+1}$; then $x = \sum r_i x_i a_i$ for some $r_i \in \mathbb{N}$ and certain $x_i \in I_0^{n+1}$ and $a_i \in A (i = 1, \ldots, r)$. Say that $x \in \text{gr}_S B := \bigoplus_{\gamma \in S} \text{gr}_B$ for some finite subset $S \subset \Gamma$, and let $\pi_S : A \to \text{gr}_S B$ be the induced projection (the sum of the canonical $\gamma$-projections as in remark 8.5.2(iii), for $\gamma$ ranging over the subset $S$). Then $x = \pi_S(x) = \sum_{i=0}^r x_i \cdot \pi_S(a_i)$, whence the contention. The same argument applies to the second map.\hfill\qed

From claim 16.6.3 we conclude that the map $\Phi_I : \text{gr}_I B \to \text{gr}_J B$ is also an isomorphism. But then, since $p_\gamma$ is injective, clearly the direct summand $\text{gr}_0 \Phi_I := \Phi_I 0 : \text{gr}_0 B_0 \to \text{gr}_0 B_0$ is still an isomorphism, and therefore $B_0$ is perfectoid, by theorem 16.3.62.

(iii): By proposition 16.3.8(i), we may assume that $\mathcal{P}$ is the $p$-adic topology of $A$. Let $j_A : A \to B'$ be as in remark 8.5.2(iii); clearly $p^n B' \cap B_0 = p^n B_0$ and $p^n A \subset j_A^{-1}(p^n B')$, so $B_0 \cap p^n A = p^n B_0$ for every $n \in \mathbb{N}$, and therefore the topology of $B_0$ agrees with its $p$-adic topology. It follows that $i_0$ is an adic map, and therefore $B_0$ is even perfectoid, by (ii); then any distinguished element of $\text{Ker } u_{B_0}$ generates $\text{Ker } u_A$, by proposition 16.2.24(ii). \hfill\Box

16.6.4. Let $(\Gamma, 0, +)$ be a $p$-perfect monoid, $(A, B)$ a perfectoid ring with $\Gamma$-graded structure, and set $\langle E, B_E \rangle := E(A, B)$. Let also $\beta_1, \ldots, \beta_r$ (resp. $\gamma_1, \ldots, \gamma_r$) be a finite system of elements of $E$ (resp. of $\Gamma$), such that $\beta_i \in \text{gr}_0 B_E$ for every $i = 1, \ldots, r$. Set $f := (\pi_\beta(\beta_1), \ldots, \pi_\beta(\beta_r))$ and define the ring $R_{r,0}$ and its ideals $I_{r,s}$ for every $s \in \mathbb{R}_+$. In (16.4.4), we endow $B$ with the $R_{r,0}$-module structure induced by the unique ring homomorphism $u : R_{r,0} \to B$ such that $u(T_i^{(1/p^n)}) := \pi_\beta(\beta_i^{1/p^n})$ for every $i = 1, \ldots, r$ and every $n \in \mathbb{N}$.

**Proposition 16.6.5.** In the situation of (16.6.4), suppose moreover that the translation map $\Gamma \to \gamma : \gamma \mapsto \gamma + \gamma_i$ is injective for every $i = 1, \ldots, r$. Then we have:

(i) $\text{Tor}_{R_{r,0}}^1 (R_{r,0}/I_{r,0}^{[s]}, B) = 0$ for every $i > 0$ and every $s \in \mathbb{R}_+$.

(ii) The ring $B$ satisfies condition $(a)_{\text{un}}$ of (7.8.21).

**Proof.** (i): Denote by $\Gamma_0 \subset \Gamma$ the submonoid generated by $(\gamma_1/p^n, \ldots, \gamma_r/p^n | n \in \mathbb{N})$, and let $B_0 := \Gamma_0 \times_p B$. Recall that $R_{r,0} := \mathbb{Z}[P_{r,s}]$, where $P_r := \mathbb{N}[1/p]^{[p^n]}$, and let $\varphi : P_r \to \Gamma_0$ be the unique morphism of monoids such that $\varphi(e_i) := \gamma_i$ for $i = 1, \ldots, r$, where $(e_1, \ldots, e_r)$ is the standard minimal system of generators of $\mathbb{N}^{[p^n]}$. With this notation, $R_{r,0}$ is a $P_r$-graded $\mathbb{Z}$-algebra, and we set $S := (R_{r,0})_{\Gamma_0}$ (see definition 7.6.9(v)). Then clearly $u$ induces a morphism of $\Gamma_0$-graded $\mathbb{Z}$-algebras $S \to B_0$, and $B$ can be regarded naturally as a $\Gamma$-graded $S_{\Gamma_0}$-module. We remark, quite generally:
Claim 16.6.6. Let \((\Delta, 0, +)\) be a monoid, \(\Delta_0 \subset \Delta\) a submonoid such that the translation maps \(\Delta \to \Delta : \delta \mapsto \delta + \delta_0\) are injective for every \(\delta_0 \in \Delta_0\). Let also \(S = (S, \text{gr}_s S)\) be a \(\Delta_0\)-graded \(\mathbb{Z}\)-algebra, \(N\) a \(\Delta_0\)-graded \(S\)-module, and \(M\) a \(\Delta\)-graded \(S/\Delta\)-module. Then we have:

(i) The product \(M' := \prod_{\delta \in \Delta} \text{gr}_\delta M\) carries a natural \(S\)-module structure such that the natural map \(M \to M'\) is \(S\)-linear.

(ii) The induced map \(\tau_i : \text{Tor}_i^S(N, M) \to \text{Tor}_i^S(N, M')\) is injective, for every \(i \in \mathbb{N}\).

Proof of the claim. (i): We define a \(\mathbb{Z}\)-bilinear map

\[
\mu_{\delta_0} : \text{gr}_{\delta_0} S \times M' \to M'
\]

by the rule : \((s, (m_\delta | \delta \in \Delta)) \mapsto (m_\delta | \delta \in \Delta)\), where \(m_\delta' := s \cdot m_\gamma\) if there exists a (necessarily unique) \(\gamma \in \Delta\) with \(\gamma + \delta_0 = \delta\), and otherwise \(m_\delta' := 0\). The sum of the maps \(\mu_{\delta_0}\) yields a well defined \(\mathbb{Z}\)-bilinear map

\[
\mu : S \times M' \to M'
\]

and it is easily seen that \(\mu\) defines an \(S\)-module structure on \(M'\) with the sought property.

(ii): In view of remark [7.6.30(i)], we may find a resolution \(L_* \to N\) by free \(S\)-modules such that \(L_i\) is a \(\Delta_0\)-graded \(S\)-module, and the differential \(d_{i+1} : L_{i+1} \to L_i\) is a morphism of \(\Delta_0\)-graded \(S\)-modules, for every \(i \in \mathbb{N}\). Then, for every \(i \in \mathbb{N}\) the tensor product \(P_i := L_i \otimes_S M\) carries a natural structure of \(\Delta\)-graded \(S/\Delta\)-module : namely

\[
\text{gr}_\delta P_i := \text{Im} \left( \bigoplus_{(\delta_0, \gamma) \in D(\delta)} \text{gr}_{\delta_0} L_i \otimes_D \text{gr}_\gamma M \to P_i \right)
\]

where \(D(\delta)\) is the set of all pairs \((\delta_0, \gamma) \in \Delta_0 \times \Delta\) such that \(\gamma + \delta_0 = \delta\). With this definition, it is then easily seen that the differential \(d^p_{i+1} := d_{i+1} \otimes_S 1_M\) of \(P_*\) is a morphism of \(\Delta\)-graded \(S/\Delta\)-modules, whence an induced \(\Delta\)-graded \(S/\Delta\)-module structure on \(\text{Tor}_i^S(N, M)\), for every \(i \in \mathbb{N}\). Moreover, we get a \(\mathbb{Z}\)-bilinear map

\[
\psi : L_i \times M' \to P'_i := \prod_{\delta \in \Delta} \text{gr}_\delta P_i
\]

namely, the unique one whose restriction \(\text{gr}_{\delta_0} L_i \times M' \to P'_i\) for every \(\delta_0 \in \Delta_0\) is given by the rule : \((l, (m_\delta | \delta \in \Delta)) \mapsto (l \otimes m_\delta' | \delta \in \Delta)\), where \(m_\delta' := m_\gamma\) if \(\gamma + \delta_0 = \delta\), and \(m_\delta' := 0\) if there is no such \(\gamma\). Then it is easily seen that \(\psi\) is \(S\)-bilinear, so it induces an \(S\)-linear map

\[
L_i \otimes_S M' \to P'_i \quad \text{for every } i \in \mathbb{N}.
\]

Furthermore, the resulting diagram of \(S\)-linear maps

\[
\begin{array}{ccc}
L_{i+1} \otimes_S M' & \longrightarrow & P'_{i+1} \\
\downarrow d_{i+1} \otimes_S 1_M & & \downarrow \prod_{\delta \in \Delta} \text{gr}_\delta d^p_{i+1} \\
L_i \otimes_S M' & \longrightarrow & P'_i
\end{array}
\]

commutes for every \(i \in \mathbb{N}\), and we deduce an \(S\)-linear map

\[
\text{Tor}_i^S(N, M') \to \prod_{\delta \in \Delta} \text{gr}_\delta \text{Tor}_i^S(N, M)
\]

whose composition with \(\tau_i\) is the natural injection. The claim follows. \(\diamondsuit\)

Now, set \(B' := \prod_{\delta \in \Delta} \text{gr}_\delta B\), endow \(B'\) with the linear topology defined as in remark [8.5.2(ii)], and recall that the inclusion map \(j : B \to B'\) factors through the inclusion map \(B \to A\) and a continuous map \(j_A : A \to B'\) (remark [8.5.2(iii)]). Endow \(B'\) with the \(S\)-module structure provided by claim [16.6.6(i)]; a direct inspection of the proof of loc.cit. shows that scalar multiplication by any homogeneous element \(s\) of \(S\) defines a continuous endomorphism of \(B'\), and on the other hand we have \(j(s \cdot b) = s \cdot j(b)\) for every such \(s\) and every \(b \in B\); since \(j\) is
also a continuous map, we deduce that the same identity holds more generally for every \( b \in A \), i.e. \( j_A \) is an \( S \)-linear map. Lastly, notice that the ideal \( I_r^{[s]} \) of \( S \) is \( \Gamma_0 \)-graded, so \( R_{r,0}/I_r^{[s]} \) is a \( \Gamma_0 \)-graded \( S \)-module for every \( s \in \mathbb{R}_+ \). By claim \[16.6.6\] it follows that the composition of the two natural maps

\[
\text{Tor}_i^{R_{r,0}}(R_{r,0}/I_r^{[s]}, B) \to \text{Tor}_i^{R_{r,0}}(R_{r,0}/I_r^{[s]}, A) \to \text{Tor}_i^{R_{r,0}}(R_{r,0}/I_r^{[s]}, B')
\]

is injective for every \( i \in \mathbb{N} \); on the other hand, the middle term vanishes for \( i > 0 \), due to proposition \[16.4.10\] whence the contention.

(ii) follows from (i) and lemma \[16.4.5\] \qed

16.6.7. We consider now a perfectoid quasi-affinoid ring \((A, A^+, U_A)\), and let \((E, E^+, U_E) := E(A, A^+, U_A)\) (see \[16.5.20\]). Set as well \( X_A := \text{Spec} A \), \( X_E := \text{Spec} E \), and define as usual the \( f \)-adic rings \( A_U := \mathcal{O}_{X_A}(U_A) \) and \( E_U := \mathcal{O}_{X_E}(U_E) \), so that the restriction maps \( A \to A_U \) and \( E \to E_U \) are open, hence the image \( \overline{A} \) of \( A \) (resp. \( \overline{E} \) of \( E \)) is open in \( A_U \) (resp. in \( E_U \)), and we endow it with the topology induced by the projection \( A \to \overline{A} \) (resp. \( E \to \overline{E} \)). Suppose we are given a family \((\mathcal{K}_\gamma \mid \gamma \in \Gamma)\) consisting of topologically closed 1-taut bounded \( \overline{E} \)-submodules of \( E_U \), indexed by a \( p \)-perfect monoid \((\Gamma, +, 0)\), and such that (notation of \[16.5.28\]):

(a) \( 1 \in \mathcal{K}_0 \)

(b) \( \mathcal{K}_{\gamma \gamma'} = \mathcal{K}_\gamma \) for every \( \gamma \in \Gamma \)

(c) \( \mathcal{K}_\gamma \cdot \mathcal{K}_\mu \subset \mathcal{K}_{\gamma + \mu} \) for every \( \gamma, \mu \in \Gamma \)

(\text{notice that, in terms of the descending filtration } \text{Fil}^s E_U \text{ defined in } \[16.5.23\], a subset of } E_U \text{ is bounded if and only if it lies in } \text{Fil}^s E_U \text{, for some } s \in \mathbb{Z}[1/p]) \text{. Set } \mathcal{E} := \bigoplus_{\gamma \in \Gamma} \mathcal{K}_\gamma \quad \mathcal{A} := \bigoplus_{\gamma \in \Gamma} \{ \mathcal{K}_\gamma \}.

It is easily seen that the multiplication of \( E_U \) (resp. of \( A_U \)) induces a \( \Gamma \)-graded \( \overline{E} \)-algebra structure (resp. \( \overline{A} \)-algebra structure) on \( \mathcal{E} \) (resp. on \( \mathcal{A} \)). Choose ideals of definition \( J \) for \( A \) and \( \mathcal{J} \) for \( E \), and endow \( \mathcal{E} \) (resp. \( \mathcal{A} \)) with its \( \mathcal{J} \)-adic (resp. \( \mathcal{J} \)-adic) topology. Let also \( \mathcal{E}^\wedge \) (resp. \( \mathcal{A}^\wedge \)) be the separated completion of \( \mathcal{E} \) (resp. of \( \mathcal{A} \)).

**Lemma 16.6.8.** The pairs

\[
(\mathcal{E}^\wedge, \mathcal{E}) \quad \text{and} \quad (\mathcal{A}^\wedge, \mathcal{A})
\]

are topological rings with \( \Gamma \)-graded structures.

**Proof.** Indeed, the assertion comes down to checking that \( \mathcal{K}_\gamma \) (resp. \( \{ \mathcal{K}_\gamma \} \)) is a closed subset of \( \mathcal{E}^\wedge \) (resp. \( \mathcal{A}^\wedge \)) for every \( \gamma \in \Gamma \), and notice that the topological closure of \( \mathcal{K}_\gamma \), in \( \mathcal{E}^\wedge \) (resp. of \( \{ \mathcal{K}_\gamma \} \) in \( \mathcal{A}^\wedge \)) is the \( \mathcal{J} \)-adic (resp. \( \mathcal{J} \)-adic) completion of \( \mathcal{K}_\gamma \) (resp. of \( \{ \mathcal{K}_\gamma \} \)). Now, by assumption \( \mathcal{K}_\gamma \) is bounded in \( E_U \), so \( \{ \mathcal{K}_\gamma \} \) is bounded in \( A_U \), for every \( \gamma \in \Gamma \); it follows that the topology \( \mathcal{T}_\gamma \) on \( \mathcal{K}_\gamma \) (resp. on \( \{ \mathcal{K}_\gamma \} \)) induced by the inclusion into \( E_U \) (resp. into \( A_U \)) is coarser than the \( \mathcal{J} \)-adic (resp. \( \mathcal{J} \)-adic) topology; on the other hand, \( \mathcal{T}_\delta \) is complete and separated, since the same holds for the topology of \( E_U \) (resp. of \( A_U \)). Then lemma \[8.3.12\] implies that \( \mathcal{K}_\gamma \) (resp. \( \{ \mathcal{K}_\gamma \} \)) is complete and separated for its \( \mathcal{J} \)-adic (resp. \( \mathcal{J} \)-adic) topology, whence the contention. \qed

**Proposition 16.6.9.** With the notation of \[16.6.7\], the following holds :

(i) The rings \( \mathcal{E}^\wedge \) and \( \mathcal{A}^\wedge \) are perfectoid.

(ii) There is a natural isomorphism of topological rings with \( \Gamma \)-graded structures

\[
E(\mathcal{A}^\wedge, \mathcal{A}) \cong (\mathcal{E}^\wedge, \mathcal{E}).
\]
Proof. Taking into account remark[9.4.9](v) and example[9.3.49](ii), it is easily seen that $\mathcal{E}^\wedge$ is a perfect topological $\mathcal{E}$-algebra, hence it is perfectoid (see example[16.3.2](i)). Set

$$\mathcal{W} := \mathcal{W}(\mathcal{E}, \mathcal{E}) \quad (\mathcal{W} := \mathcal{W}(\mathcal{E}, \mathcal{E}))$$

To prove both assertions, it will therefore suffice to exhibit isomorphisms

$$(16.6.10) \quad (\mathcal{W} := \mathcal{W}(\mathcal{E}, \mathcal{E}))$$

of topological $A$-algebras with $\Gamma$-graded structures. We shall first exhibit a continuous map

$$u_{\gamma} : (\mathcal{W}, \mathcal{W}) \to (\mathcal{A}, \mathcal{A})$$

To this aim, define $W(\mathcal{X}_{\gamma})$ as in lemma[16.5.45] and notice that condition (b) of [16.6.7] yields:

$$\text{gr}_\gamma \mathcal{W} = W(\mathcal{X}_{\gamma}) \quad \text{for every } \gamma \in \Gamma$$

and the multiplication law of $\mathcal{W}$ is the unique bilinear map $\mathcal{W} \times \mathcal{W} \to \mathcal{W}$ whose restriction

$$W(\mathcal{X}_{\gamma}) \times W(\mathcal{X}_{\mu}) \to W(\mathcal{X}_{\delta + \gamma})$$

is induced by the multiplication law of $W(\mathcal{E}_U)$, for every $\gamma, \mu \in \Gamma$. Also, since $\mathcal{X}_{\gamma}$ is closed and 1-taut, lemma[16.5.45](iv) says that $u_\gamma$ restricts to a well defined surjective map

$$\text{gr}_\gamma u_{\gamma} : W(\mathcal{X}_{\gamma}) \to \text{gr}_\gamma \mathcal{A} \quad \text{for every } \gamma \in \Gamma$$

whose kernel is $\alpha W(\mathcal{X}_{\gamma})$, for any distinguished element $\alpha$ of Ker $u_{\gamma}$. Summing up, we conclude that the direct sum of the system of maps $(\text{gr}_\gamma u_{\gamma} \mid \gamma \in \Gamma)$ is a well defined surjective ring homomorphism $\text{gr}_\gamma u_{\gamma}$ that makes commute the diagram

$$(16.6.11) \quad W(\mathcal{E}) \xrightarrow{u_{\gamma}} A \quad \text{via} \quad \mathcal{W} \xrightarrow{\text{gr}_\gamma u_{\gamma}} \mathcal{A}$$

and with kernel equal to $\alpha W(\mathcal{E})$. Moreover, it follows easily from propositions[9.3.78](ii) and [8.5.11](i.b) that the left vertical map of [16.6.11] is an adic ring homomorphism, and the same obviously holds for the right vertical map. Since $u_{\gamma}$ is an open map, we deduce that $\text{gr}_\gamma u_{\gamma}$ is continuous and open as well; especially, it extends to a well defined continuous surjective ring homomorphism $u_{\gamma}$ as sought, whose kernel is the topological closure of $\alpha W(\mathcal{E})$ in $\mathcal{W}^\wedge$ (proposition[8.2.13]). However, recall that $\alpha W(\mathcal{E})$ is an closed ideal of $\mathcal{W}^\wedge$ (proposition[16.2.21](ii)), and obviously $\alpha W(\mathcal{E})$ is dense in it, hence the kernel of $u_{\gamma}$ is $\alpha W(\mathcal{E})$, as required. Lastly, since $\text{gr}_\gamma u_{\gamma}$ is an open map, the same holds for $u_{\gamma}$, and the proof is concluded.

Example 16.6.12. In the situation of [16.6.7], let $\varphi_U : \mathcal{E}_U \to A_U$ be the continuous morphism of topological monoids furnished by proposition[16.4.28](i). Let also $\beta_\lambda := (\beta_\lambda \mid \lambda \in \Lambda)$ be any bounded system of elements of $\mathcal{E}_U$. We consider the unique morphism of monoids

$$\varphi_E : P := \mathbb{N}[1/p](\Lambda) \to \mathcal{E}_U \quad e_\lambda \mapsto \beta_\lambda \quad \text{for every } \lambda \in \Lambda$$

where $e_\lambda := (e_\lambda \mid \lambda \in \Lambda)$ is the standard minimal set of generators of $\mathbb{N}(\Lambda)$. Let also $I \subset P$ be the ideal generated by $e_\lambda$. The composition $\varphi_A : \varphi_U \circ \varphi_E : P \to A$ is also a morphism of monoids, and we let $I(\delta)\bar{E}$ (resp. $I(\delta)\bar{A}$) be the $\bar{E}$-submodule of $\mathcal{E}_U$ generated by $\varphi_E(I(\delta))$ (resp. the $\bar{A}$-submodule of $A_U$ generated by $\varphi_A(I(\delta))$), for every $\delta \in \Delta := \mathbb{N}[1/p]$ (notation of [9.3.69]). We denote by $\text{gr}_\delta \mathcal{E}$ (resp. $\text{gr}_\delta \mathcal{A}$) the topological closure of $I(\delta)\bar{E}$ in $\mathcal{E}_U$ (resp. of $I(\delta)\bar{A}$ in $A_U$) for every $\delta \in \Delta$ (notation of remark[9.3.71](i)). We set

$$\mathcal{E}(\beta_\lambda) := \bigoplus_{\delta \in \Delta} \text{gr}_\delta \mathcal{E} \quad \text{and} \quad \mathcal{A}(\beta_\lambda) := \bigoplus_{\delta \in \Delta} \text{gr}_\delta \mathcal{A}.$$
Hence, $\mathcal{E}(\beta_\bullet)$ is a $\Delta$-graded $E$-algebra, and $\mathcal{A}(\beta_\bullet)$ is a $\Delta$-graded $A$-algebras. We endow $\mathcal{E}(\beta_\bullet)$ with the $\mathcal{J}$-adic topology and $\mathcal{A}(\beta_\bullet)$ with the $J$-adic topology, and let $\mathcal{E}(\beta_\bullet)^{^\wedge}$ and $\mathcal{A}(\beta_\bullet)^{^\wedge}$ be the respective separated completion. It is easily seen that $\text{gr}_\delta\mathcal{E}$ is $1$-taut and bounded in $E_U$, and moreover $\text{gr}_\delta\mathcal{E} = (\text{gr}_\delta\mathcal{E})^p$ for every $\delta \in \Delta$; furthermore, $\text{gr}_\delta\mathcal{A} = \{\text{gr}_\delta\mathcal{E}\}$ for every such $\delta$. Then proposition 16.6.9 shows that $(\mathcal{E}(\beta_\bullet)^{^\wedge}, \mathcal{A}(\beta_\bullet))$, and $(\mathcal{E}(\beta_\bullet)^{^\wedge}, \mathcal{A}(\beta_\bullet))$ are perfectoid rings with $\Delta$-graded structures, and we have a natural isomorphism of topological rings with $\Delta$-graded structures:

$E(\mathcal{A}(\beta_\bullet)^{^\wedge}, \mathcal{A}(\beta_\bullet)) \sim (\mathcal{E}(\beta_\bullet)^{^\wedge}, \mathcal{E}(\beta_\bullet)).$

**Example 16.6.13.** In the situation of (16.5.23), let $\Gamma := \mathbb{Z}[1/p]$; the family $(\text{Fil}^\Gamma E_U \mid \gamma \in \Gamma)$ fulfills conditions (a)–(c) of (16.6.7), and taking into account corollary 16.5.42 and proposition 16.6.9 we get perfectoid rings with $\Gamma$-graded structures $(\mathcal{E}_\Gamma^{^\wedge}, \mathcal{A}_U^{^\wedge})$, and for every $\gamma \in \Gamma$, as well as a natural isomorphism of topological rings with $\Gamma$-graded structures

$E(\mathcal{A}_U^{^\wedge}, \mathcal{A}_U^{^\wedge}) \sim (\mathcal{E}_\Gamma^{^\wedge}, \mathcal{E}_\Gamma^{^\wedge}).$

Moreover, by inspecting the proof of proposition 16.6.9 it is easily seen that – under the identification (16.6.14) – the restriction $\text{gr}_\gamma\mathcal{E}_\Gamma \rightarrow \text{gr}_\gamma\mathcal{A}_U$ of the map $\overline{\pi}_A : \mathcal{E}_U \rightarrow \mathcal{A}_U$ agrees with the restriction $\text{Fil}^\Gamma E_U \rightarrow \text{Fil}^\Gamma A_U$ of the map $\varphi_U : E_U \rightarrow A_U$, for every $\gamma \in \Gamma$.

16.6.15. Let $\Gamma$ be a $p$-perfect monoid, $(A^\wedge, A)$ a perfectoid ring with $\Gamma$-graded structure, set $(E^\wedge, E) := E(A^\wedge, A)$ and let $\alpha \in W(\text{gr}_0 E)$ be a distinguished element of $\text{Ker} \, u_A$ (see proposition 16.6.1(iii)). We denote by $\overline{\pi}_A : E \rightarrow A$ the restriction of the map $u_{A^\wedge} : E^\wedge \rightarrow A^\wedge$. For every integer $n > 0$ let

$$\lambda_n := \sum_{i=0}^{n-1} p^{-i} \quad S_n := \{ (i, j) \in \mathbb{N}[1/p]^{\oplus 2} \mid \lambda_n \leq i < n \quad \text{and} \quad 1 > j > 1 - i/n \}$$

and for every $\gamma \in \Gamma$ and every $e \in \text{gr}_\gamma E$, define the $\text{gr}_0 A$-module

$$\mathcal{I}(e, n, \gamma) := \sum_{(i, j) \in S_n} \text{gr}_{(1-j)\gamma} A \cdot \overline{\pi}_A(\alpha_0^i \cdot e^j).$$

**Proposition 16.6.16.** With the notation of (16.6.15), let $\gamma \in \Gamma$ and $a \in \text{gr}_\gamma A$ be any elements. Then, for every integer $n > 0$ there exists $e \in \text{gr}_\gamma E$ such that

$$a - \overline{\pi}_A(e) \in \mathcal{I}(e, n, \gamma) + p^n \cdot \text{gr}_\gamma A.$$

**Proof.** Notice that the assertion is independent of the topology $\mathcal{T}_{A^\wedge}$ of $A^\wedge$, so we may assume that $\mathcal{T}_{A^\wedge}$ is the $p$-adic topology of $A^\wedge$ (proposition 16.3.8(i)). We argue by induction on $n \in \mathbb{N}$. For $n = 1$, we have $S_1 = \emptyset$, and the assertion means that there exists $e \in \text{gr}_\gamma E$ such that $a - \overline{\pi}_A(e) \in p \cdot \text{gr}_\gamma A$. Hence, let $\pi : A \rightarrow A/pA$ be the projection; it suffices to remark:

**Claim 16.6.17.** The map $\pi \circ \overline{\pi}_A : E \rightarrow A/pA$ is surjective.

**Proof of the claim.** The assertion follows easily from claim 16.6.2(i). \(\diamondsuit\)

Thus, suppose that the proposition has already been proven for some $n \geq 1$, for every $\gamma \in \Gamma$ and every $a \in \text{gr}_\gamma A$. We notice:

**Claim 16.6.18.** (i) For every $\delta \in \Gamma$, every $b \in \text{gr}_\delta A$ and every $k \in \mathbb{N}$ there exist a sequence $(\beta_0, \ldots, \beta_k)$ of elements of $\text{gr}_\delta E$, and an element $d \in \text{gr}_{\delta} A$ such that

$$b = \sum_{i=0}^{k} p^i \cdot \overline{\pi}_A(\beta_i) + p^{k+1}d.$$
(ii) There exist elements \( c \in \text{gr}_0 A, e_n \in \text{gr}_1 E \), a finite set \( \Lambda \), a system of positive integers \( (k_\lambda \mid \lambda \in \Lambda) \), a mapping \( \Lambda \to S_n : \lambda \mapsto (i_\lambda, j_\lambda) \), a system \( (f_\lambda \mid \lambda \in \Lambda) \) with \( f_\lambda \in \text{gr}_{(1-j_\lambda)} E \) for every \( \lambda \in \Lambda \), such that

\[
(16.6.20) \quad a = \pi_A(e_n) + \sum_{\lambda \in \Lambda} k_\lambda \cdot \pi_A(f_\lambda \cdot \alpha_0^{i_\lambda} \cdot e_n^{j_\lambda}) + p^n c.
\]

(iii) There exists \( f \in \text{gr}_0 E \) such that \( p^n - \pi_A(\alpha_0 \cdot f)^n \in p^{n+1} \text{gr}_0 A \) for every \( n \in \mathbb{N} \).

**Proof of the claim.** (i): We argue by induction on \( k \), and notice that the assertion for \( k = 0 \) follows from the case \( n = 1 \) of the proposition, which is already known. Thus, suppose that \( k \in \mathbb{N} \), and that we have already found a sequence \( (\beta_0, \ldots, \beta_k) \) such that \((16.6.19)\) holds. Then we may also find \( \beta_{k+1} \in \text{gr}_j E \) and \( d' \in \text{gr}_s A \) such that \( d = \pi_A(\beta_{k+1}) + pd' \), and replacing this expression for \( d \) in \((16.6.19)\) we get the sought identity for \( k+1 \).

(ii): By inductive assumption, there exist a finite subset \( T \subset S_n \) and for every \((i, j) \in T\) an element \( b_{(i, j)} \in \text{gr}_{(1-j)} \gamma_1 A \) such that

\[
a = \pi_A(e_n) + \sum_{(i, j) \in T} b_{(i, j)} \cdot \pi_A(\alpha_0^i \cdot e_n^j) + p^n d \quad \text{for some } e_n \in \text{gr}_1 E \text{ and } d \in \text{gr}_0 A.
\]

By (i), we may then find, for every \((i, j) \in T\), a system \( (f_{(i,j),0}, \ldots, f_{(i,j),n-1}) \) of elements of \( \text{gr}_{(1-j)} \gamma_1 A \) and an element \( c_{(i,j)} \in \text{gr}_{(1-j)} \gamma_1 A \) such that \( b_{(i, j)} = \sum_{i=0}^{n-1} p^i \cdot \pi_A(f_{(i,j),i}) + p^n c_{(i,j)} \).

Hence, the sought identity holds with

\[
c := d + \sum_{(i, j) \in T} c_{(i,j)} \cdot \pi_A(\alpha_0^i \cdot e_n^j) \quad \Lambda := T \times \{0, \ldots, n-1\} \quad k_{(t, s)} := p^s \quad \text{for every } (t, s) \in \Lambda
\]

and with the mapping \( \Lambda \to S_n : (t, k) \mapsto t \).

(iii): By lemma \([16.2.7](iii)\), there exists \( x \in A^\epsilon \) such that \( p = \pi_A(\alpha_0 \cdot x) \). Let \( \pi_0^* : A^\epsilon \to \text{gr}_0 A \) be the canonical 0-projection (see remark \([8.5.2](iii)\)); it follows that \( p = \pi_A(\alpha_0 \cdot \pi_0^*(x)) \), so we may assume that \( x \in \text{gr}_0 A \). By (i), we have \( y_0 := x - \pi_A(f) \in p \cdot \text{gr}_0 A \) for some \( f \in E \), and we check, by induction on \( n \), that such \( f \) will do. Indeed, for \( n = 0 \) the assertion is trivial, and for \( n = 1 \) we have

\[
p = \pi_A(\alpha_0 \cdot (y_0 + \pi_A(f))) = \pi_A(\alpha_0 \cdot f) + y_0 \cdot \pi_A(\alpha_0)
\]

and \( y_1 := y_0 \cdot \pi_A(\alpha_0) = py_0 \cdot \pi_0^*(x^{-1}) \in p^2 \cdot \text{gr}_0 A \), again by lemma \([16.2.7](iii)\). Suppose now that \( n \geq 1 \), and that we have already shown that \( y_n := p^n - \pi_A(\alpha_0 \cdot f)^n \in p^{n+1} \text{gr}_0 A \). We compute

\[
py_n = p^{n+1} - p \cdot \pi_A(\alpha_0 \cdot f)^n
\]

\[
= p^{n+1} - (y_1 + \pi_A(\alpha_0 \cdot f)) \cdot \pi_A(\alpha_0 \cdot f)^n
\]

\[
= p^{n+1} - \pi_A(\alpha_0 \cdot f)^{n+1} - y_1 \cdot \pi_A(\alpha_0 \cdot f)^n
\]

Since both \( py_n \) and \( y_1 \cdot \pi_A(\alpha_0 \cdot f)^n = p^ny_1 \cdot \pi_A(f)^n \cdot \pi_0^*(x^{-n}) \) lie in \( p^{n+2} \text{gr}_0 A \), the assertion follows for \( n+1 \).

Pick any identity \((16.6.20)\) as provided by claim \([16.6.18](ii)\), and any \( f \in \text{gr}_0 E \) such that claim \([16.6.18](iii)\) holds; by claim \([16.6.18](i)\) we may also find \( g \in \text{gr}_E \) such that \( c = \pi_A(g) \in p \cdot \text{gr}_1 A \), and notice that, after replacing the set \( \Lambda \) by \( \bigcup_{\lambda \in \Lambda} \{\lambda\} \times \{1, \ldots, k_\lambda\} \), we may also assume that \( k_\lambda = 1 \) for every \( \lambda \in \Lambda \), so that

\[
a = \pi_A(e_n) + \sum_{\lambda \in \Lambda} \pi_A(f_\lambda \cdot \alpha_0^{i_\lambda} \cdot e_n^{j_\lambda}) + \pi_A(g \cdot \alpha_0^n \cdot f^n) + p^{n+1} d \quad \text{for some } d \in \text{gr}_1 A.
\]

We let \( S'_n := \{(i, j) \in \mathbb{N}[1/p]^{\geq 2} \mid \lambda_{n+1} \leq i < n + 1, \ n j + i \geq 1 + n \ \text{and} \ j < 1\} \) and we set

\[
\delta := \sum_{\lambda \in \Lambda} f_\lambda \cdot \alpha_0^{i_\lambda} \cdot e_n^{j_\lambda} \quad \text{and} \quad e_{n+1} := e_n + \delta + g \cdot \alpha_0^n \cdot f^n.
\]
Claim 16.6.21. There exists a finite subset \( \Lambda' \) with a mapping \( \Lambda' \to S'_n : \lambda \mapsto (i'_\lambda, j'_\lambda) \), and for every \( \lambda \in \Lambda' \) an element \( z_\lambda \in \text{gr}_{(1-j'_\lambda)} \) such that
\[
a = \pi_A(e_{n+1}) + \sum_{\lambda \in \Lambda'} z_\lambda \cdot \pi_A(\alpha_0 \cdot i'_\lambda) + p^{n+1}d' \quad \text{for some } d' \in \text{gr}_A.
\]

Proof of the claim. For every \( r = 1, \ldots, n \), let \( \Lambda'_r \) be the subset of all sequences \( e := (\sigma_0, \sigma_1, \sigma_\lambda \mid \lambda \in \Lambda) \) of elements of \( p^{-r} \mathbb{N} \setminus p^{1-r} \mathbb{N} \) such that \( \sigma_0 + \sigma_1 + \sum_{\lambda \in \Lambda} \sigma_\lambda = 1 \), and set \( \Lambda' := \bigcup_{r=1}^n \Lambda'_r \). Let also \( x := a - \pi_A(e_{n+1}) \); according to proposition 9.3.63, there exist a mapping \( \Lambda' \to \mathbb{Z}_p : e \mapsto \sigma'_e \) and an element \( d' \in \text{gr}_A \) such that
\[
x = \sum_{r=1}^n p^r \cdot \sum_{e \in \Lambda'_r} z'_e \cdot \pi_A(e_\sigma) + p^{n+1}d'
\]
where
\[
f'_e := g^{\sigma_1} \cdot f^{\sigma_\lambda} \quad i'_e := n \sigma_1 + \sum_{\lambda \in \Lambda} \sigma_\lambda \quad j'_e := \sigma_0 + \sum_{\lambda \in \Lambda} \sigma_\lambda \quad \text{for every } e \in \Lambda'.
\]
Let us remark that
\[
(16.6.22) \quad j'_e + \frac{i'_e}{n} = \sigma_0 + \sigma_1 + \sum_{\lambda \in \Lambda} \sigma_\lambda \geq \sigma_0 + \sigma_1 + \sum_{\lambda \in \Lambda} \sigma_\lambda = 1 \quad \text{for every } e \in \Lambda'.
\]
Moreover, we notice that
\[
(16.6.23) \quad 1 > j'_e \quad \text{and} \quad n > i'_e \quad \text{for every } e \in \Lambda'.
\]
Indeed, the first inequality is immediate, since \( \sigma_0 < 1 \); the second inequality is clear if \( \sigma_\lambda \neq 0 \) for at least one index \( \lambda \in \Lambda \), since in this case \( \sigma_\lambda \geq p^{-r} \) and \( i'_e < n \sigma_1 + n \sum_{\lambda \in \Lambda} \sigma_\lambda < n \). If \( \sigma_\lambda = 0 \) for every \( \lambda \in \Lambda \), we must have \( 1 > \sigma_1 > 0 \), since otherwise we would get \( \sigma_0, \sigma_1 \in \mathbb{N} \), which is absurd; hence, in this case \( 1 > \sigma_1 \geq p^{-r} \), so \( n > i'_e \geq n/p^r \geq \lambda_n/p^r \).

Next, for every \( r = 1, \ldots, n \) and every \( e \in \Lambda' \), we may find \( z_e \in \text{gr}_{(1-j'_e)} \) such that
\[
p^r \cdot z_e = \pi_A(f'_e) = z_e \cdot \pi_A(\alpha_0)
\]
(cp. the proof of claim 16.6.18(iii)). Hence, we set
\[
i'_e := i'_e + r \quad \text{for every } e \in \Lambda'.
\]
we get an expression for \( a \) of the sought type, and it remains only to check that \( (i'_e, j'_e) \in S'_n \) for every \( e \in \Lambda' \). However, from (16.6.23) we see that \( i'_e \geq 1 + \lambda_n/p = \lambda_{n+1} \) if \( e \in \Lambda' \), and \( i'_e \geq 2 + \lambda_n/p^2 > \lambda_{n+1} \) if \( e \in \Lambda'_r \) for some \( r > 1 \). Lastly, from (16.6.22) we get \( i'_e + j'_e \cdot n \geq n \) for every \( e \in \Lambda', \) whence \( i'_e + j'_e \cdot n \geq n + 1 \), and the proof is complete.

Let \( I \) (resp. \( J \)) be the ideal of \( E \) generated by the system \( (\alpha_0, e_n) \) (resp. by \( (\alpha_0, e_n + \delta) \)) and set \( q := \min(j + i/n \mid (i, j) \in \Lambda) \); then \( d \in i.c.(I, E, q) \), and the radical of \( I \) equals the radical of \( J \). Since \( q > 1 \), lemma 9.3.75(ii) shows therefore that
\[
I^{(q)} = J^{(q)} \quad \text{and consequently } \quad e_t^q \in J^{(q)} \quad \text{for every } \quad t \in \mathbb{N}/[1/p].
\]
and consequently \( e_t^q \in J^{(q)} \) for every \( t \in \mathbb{N}/[1/p] \). Notice that \( (\alpha_0, e_{n+1}) \) is another system of generators for \( J \). Since the topology of \( A \) is \( p \)-adic, it follows that for every \( t \in \mathbb{N}/[1/p] \) there
exist a finite subset \( T_i \subset \mathbb{N}[1/p] \) with \( 0 \leq \sigma \leq t \) for every \( \sigma \in T_i \), and a system \( \langle h'_\sigma \mid \sigma \in T_i \rangle \) of elements of \( A^\wedge \) such that
\[
\pi_A(e'_n) = \sum_{\sigma \in T_i} h'_\sigma \cdot \pi_A(\alpha_0^{n\sigma} \cdot e_{n+1}^{t-\sigma})
\]
(corollary [16.3.40(ii)]); after replacing \( h'_\sigma \) with its canonical \( \sigma \gamma \)-projection, we may also assume that \( h'_\sigma \in \text{gr}_{\sigma \gamma} A \) for every \( \sigma \in T_i \). Now, pick an expression for \( a \) as in claim [16.6.21] to conclude the proof, it suffices to show that \( \pi_A(\alpha_0^{n\sigma} \cdot e_{n+1}) \in \mathcal{I}(e_{n+1}, n + 1, \gamma) + p^{n+1} \cdot \text{gr}_{\lambda' \gamma} A \) for every \( \lambda \in A' \). To ease notation, set \((s, t) := (\lambda', \lambda)\); we see that
\[
\pi_A(\alpha_0^{n\sigma} \cdot e_{n+1}^{t-\sigma}) = \sum_{\sigma \in T_i} h'_\sigma \cdot \pi_A(\alpha_0^{n\sigma} \cdot e_{n+1}^{t-\sigma}).
\]
Now, since \((s, t) \in S'_n\), we have \( s + n\sigma \geq s \geq \lambda_{n+1} \) for every \( \sigma \in T'_i \). Moreover:
\[
s + n\sigma + (t - \sigma) \cdot (n + 1) = s + nt + t - \sigma \geq n + 1 + t - \sigma.
\]
Recall also that \( s + nt \geq n + 1 \); therefore, if \( s + n\sigma < n + 1 \), we must have \( t - \sigma > 0 \), so the pair \((s + nt, t - \sigma)\) lies in \( S_{n-1} \); lastly, if \( s + n\sigma \geq n + 1 \), the term \( \pi_A(\alpha_0^{n\sigma} \cdot e_{n+1}) \) lies in \( p^{n+1} \cdot \text{gr}_{(t-\sigma)\gamma} A \), whence \( h'_\sigma \cdot \pi_A(\alpha_0^{n\sigma} \cdot e_{n+1}) \in p^{n+1} \cdot \text{gr}_{t\gamma} A \) and the assertion follows.

**Remark 16.6.24.** (i) One can show by a direct computation that the element \( e_n \) appearing in the proof of proposition [16.6.16] is integral over the ideal generated by \( e_{n+1} \) and \( \alpha_0^{n} \); as a consequence, the proof of loc. cit. can be made in principle completely effective, so that one can extract from it an algorithm that exhibits an element \( e \) with the sought properties, for any given \( a \in \text{gr}_A \).

(ii) In [116], Scholze proves theorem [16.5.52] (for his perfectoid rings, that are a special case of our perfectoid quasi-affinoid rings) by means of his “approximation lemma” (see [116 Lemma 6.5]). With proposition [16.6.16] we can give an alternative proof of theorem [16.5.52] that generalizes to quasi-affinoid perfectoid rings, along the lines of Scholze’s original argument. The first step is the following extension of proposition [16.5.46] to quasi-affinoid perfectoid rings.

**Lemma 16.6.25.** In the situation of [16.5.23], let \( v \) be any continuous valuation on \( A_U \). Then:

(i) The mapping \( v \circ \varphi_U^y \) is a continuous valuation of \( E_U \).

(ii) The rule \( v \mapsto v \circ \varphi_U^y \) defines a continuous map
\[
\text{Cont}(\varphi_U^y) : \text{Cont}(A_U) \to \text{Cont}(E_U).
\]

**Proof.** (i): Since both \( v \) and \( \varphi_U^y \) are morphisms of pointed monoids, the same holds for \( v \circ \varphi_U^y \). Thus, it remains only to check that
\[
v(\varphi_U^y(x + y)) \leq M(x, y) := \max(v \circ \varphi_U^y(x), v \circ \varphi_U^y(y)) \quad \text{for every } x, y \in E_U.
\]
However, from proposition [16.4.28(ii)] we know that \( \varphi_U^y(x + y) \) is the sum of \( \varphi_U^y(x) + \varphi_U^y(y) \) and a \( p \)-adically convergent series, whose \( n \)-th term can be written as \( p^n \cdot z_n \), where \( z_n \) is in turn a finite \( \mathbb{Z}_p \)-linear combination of elements of the form \( \varphi_U^y(x^\sigma y^{1-\sigma}) \), with \( \sigma \) ranging over the elements of \( \Sigma_n := p^{-n} \mathbb{N} \cap [0, 1] \). It follows that
\[
v(z_n) \leq \max(\sigma \cdot v(\varphi_U^y(x)) + (1 - \sigma) \cdot v(\varphi_U^y(y)) \mid \sigma \in \Sigma_n) \leq M(x, y).
\]
On the other hand, \( v(p) \) is cofinal in the value group of \( v \), since the latter is continuous (see [15.3.1]). The assertion is an immediate consequence.

The proof of (ii) is similar to that of proposition [16.5.46(ii)] : details left to the reader.

Next, we remark the following corollary of proposition [16.6.16] that generalizes and improves slightly Scholze’s “approximation lemma” in [116 Lemma 6.5]. The same improvement appears in [90, Cor.3.6.7].
Corollary 16.6.26. Resume the notation of (16.5.23). For every \( \gamma \in \mathbb{Z}[1/p] \), every \( a \in \Fil^\gamma A_U \), every \( m \in \mathbb{N} \) and every \( \beta \in \mathbb{N}[1/p] \) with \( \beta < p/(p-1) \) there exists \( e \in \Fil^\gamma E_U \) such that

\[
v(a - \varphi_U^\gamma(e)) \leq v(p)^\beta \cdot \max(v(\varphi_U^\gamma(e)), v(p)^m) \quad \text{for every } v \in \Cont(A_U).
\]

Proof. (Notice that the value group \( \Gamma_v \) is \( p \)-divisible, due to theorem [16.5.52](iv), but even discounting loc.cit., the term \( v(p)^\beta \) is still well defined as an element of \( (\mathbb{Q} \otimes_{\mathbb{Z}} \Gamma_v)_v \), so the above inequality makes sense in any case.) Fix \( v, m, \beta \) as in the corollary, and a distinguished element \( \alpha := (\alpha_n \mid n \in \mathbb{N}) \in \Ker u_A \), and define the sequence of rational numbers \( (\lambda_n+1 \mid n \in \mathbb{N}) \) as in [16.6.15], as well as the subset \( S_n \subset \mathbb{N}[1/p]^{\geq 0} \) and the \( \mathcal{A} \)-submodule \( \mathcal{J}(\epsilon, n, \gamma) \) of \( \Fil^\gamma A_U \), for every \( e \in \Fil^\gamma E_U \) and every integer \( n > 0 \). Notice that

\[
\lim_{n \to +\infty} \lambda_n = p/(p-1).
\]

We apply proposition [16.6.16] to the perfectoid rings with \( \mathbb{Z}[1/p] \)-graded structure \( E_U \) and \( \mathcal{A}_U \) given by example [16.6.13]: for every integer \( n > 0 \) we then get \( e_n \in \Fil^\gamma E_U \), \( d_n \in \Fil^\gamma A_U \), a finite subset \( T_n \subset S_n \), and for every \( (i, j) \in T_n \) an element \( b_{i,j,n} \in \Fil^{(1-j)\gamma} A_U \) such that

\[
a = \varphi_U^\gamma(e_n) + \sum_{(i,j) \in T_n} b_{i,j,n} \cdot \varphi_U^\gamma(\alpha_0^i \cdot e_n^j) + p^m d_n.
\]

Pick also \( \epsilon \in \mathbb{N}[1/p] \setminus \{0\} \) such that \( \alpha_0 \in \Fil^\gamma E_U \), and \( k \in \mathbb{N} \) large enough so that \( \gamma + k \epsilon > 0 \).

Claim 16.6.28. We have \( v(p^m d_n) \leq v(p)^{\beta+m} \) for every sufficiently large \( n \in \mathbb{N} \).

Proof of the claim. We have \( p^m d_n \in \Fil^{\gamma+k \epsilon} A_U \), and notice that \( \Fil^\gamma A_U \subset A_U^0 \) for every \( \delta > 0 \). It follows that \( v(p^m d_n) < 1 \), so the claim holds for every \( n \geq k + m + \beta \).

Recall that \( pu = \varphi_U^\gamma(\alpha_0) \) for some \( u \in \mathcal{A}_U^\times \); suppose first that there exists \( n_0 \in \mathbb{N} \) such that \( v(\varphi_U^\gamma(e_n)) \leq v(p)^m \) for every \( n \geq n_0 \). Then we have

\[
v(b_{i,j,n} \cdot \varphi_U^\gamma(\alpha_0^i \cdot e_n^j)) \leq v(b_{i,j,n}) \cdot v(u)^i \cdot v(p)^{m+j} \quad \text{for every } n \geq n_0 \text{ and every } (i, j) \in T_n
\]

and on the other hand \( b_{i,j,n} \cdot \varphi_U^\gamma(\alpha_0^{(1-j)k}) \in \Fil^{(1-j)(\gamma+k \epsilon)} A_U^0 \), and \( v(u)^i \cdot v(x) < 1 \) for every \( x \in A_U^0 \), whence

\[
v(u)^i \cdot v(b_{i,j,n} \cdot \varphi_U^\gamma(\alpha_0^{(1-j)k})) < 1 \quad \text{for every } n \in \mathbb{N} \text{ and every } (i, j) \in T_n.
\]

By the same token, we have \( v(u)^{- (1-j) k} \cdot v(p)^{\delta} < 1 \) for every \( \delta > 0 \), whence

\[
v(p)^{\delta} \leq v(\varphi_U^\gamma(\alpha_0^{(1-j)k})) \quad \text{for every } \delta > (1-j)k.
\]

Summing up we obtain, for every \( (i, j) \in T_n \), the inequality

\[
v(b_{i,j,n} \cdot \varphi_U^\gamma(\alpha_0^i \cdot e_n^j)) \leq v(p)^{\beta+m} \quad \text{whenever } i + m + (1-j)k > m + \beta.
\]

The latter condition is the same as the inequality \( i > (1-j)(m+k) + \beta \). However, notice that \( 1-j < i/n \), so this inequality holds provided \( i > i \cdot (m+k)/n + \beta \), i.e. when

\[
(16.6.29) \quad i \cdot (1 - (m+k)/n) > \beta.
\]

Lastly, from (16.6.27) we see that \( \beta < \lambda_n \) for every sufficiently large \( n \), and since \( i \geq \lambda_n \), we may find \( n \) large enough so that (16.6.29) is verified for every \( (i, j) \in T_n \); taking into account claim 16.6.28 we get the corollary, in this case.

Thus, we may assume that there exists an infinite subset \( \Sigma \subset \mathbb{N} \) such that \( v(p)^m < v(\varphi_U^\gamma(e_s)) \) for every \( s \in \Sigma \), and taking into account claim 16.6.28 we are reduced to checking that

\[
v(b_{i,j,s} \cdot \varphi_U^\gamma(\alpha_0^i \cdot e_s^j)) \leq v(p)^{\delta} \cdot v(\varphi_U^\gamma(e_s)) \quad \text{for some } s \in \Sigma \text{ and every } (i, j) \in T_s.
\]

However, arguing as in the foregoing we easily see that

\[
v(\varphi_U^\gamma(\alpha_0^i)) \leq v(p)^{\delta} \quad \text{for every } \delta < i.
\]
Hence, after replacing $\beta$ by some $\beta' \in \mathbb{N}[1/p]$ with $p/(p-1) > \beta' > \beta$, we reduce to checking that there exists $s \in \Sigma$ such that

$$v(b_{i,j,s}) \cdot v(p)^{i-\beta} \leq v(p)^{(1-j)m}$$

for every $(i,j) \in T_s$.

On the other hand, we have $b_{i,j,n} \cdot \varphi_U^b(a_0^{(1-j)k}) \in A_U^{p_0}$, and $v(u)^{(1-j)k} \cdot v(x) < 1$ for every $x \in A_U^{p_0}$, whence

$$v(b_{i,j,n}) \cdot v(p)^{(1-j)k} < 1$$

for every $n \in \mathbb{N}$ and every $(i,j) \in T_n$.

Thus, it suffices to show that there exists $s \in \Sigma$ such that

$$i - \beta > (1-j)k + (1-j)m = (1-j)(m+k)$$

for every $(i,j) \in T_s$.

This condition is equivalent to (16.6.29), so we may argue as in the foregoing to conclude. □

16.6.30. Now, in the situation of corollary (16.6.26) let

$$C(f_*) := \text{Cont}(A_U) \cap R_{A_U}(\frac{f_{0}}{f_{0}}, \ldots, \frac{f_{n}}{f_{0}})$$

and

$$S(f_*) := C(f_*) \cap \text{Spa} \overline{A}$$

for a sequence $f_* := (f_0, \ldots, f_n)$ of elements of $A_U$ that generates an open ideal. There exist $a_0, \ldots, a_n \in A_U$ and an integer $m > 0$ such that $p^m - 1 = \sum_{i=0}^{n} a_i f_i$, and after replacing each $a_i$ by $p^v a_i$ for a suitable $v \in \mathbb{N}$, and $m$ by $m + \beta$, we may even assume that $a_0, \ldots, a_n \in \overline{A}$ (recall that $\overline{A}$ is the image of $A$ in $A_U$, and $\overline{E}$ is the image of $E$ in $E_U$) whence

$$v(p)^{m} \leq \max(v(pa_i) \cdot v(f_i) \mid i = 0, \ldots, n) \leq \max(v(f_i) \mid i = 0, \ldots, n)$$

for every $v \in \text{Cont}(A_U)$. It follows that

$$v(f_0) \geq v(p)^{m}$$

for every $v \in C(f_*)$.

By corollary (16.6.26) we may find $e_0, \ldots, e_n \in E_U$ such that for every $i = 1, \ldots, n$ we have:

$$v(f_i - \varphi_U^0(e_i)) \leq v(p) \cdot \max(v(\varphi_U^0(e_i)), v(p)^{m})$$

for every $v \in \text{Cont}(A_U)$.

We may now state the announced generalization of theorem (15.5.2):

**Proposition 16.6.34.** **With the notation of (16.6.30), we have:**

(i) The map $\text{Cont}(\varphi_U^0)$ of lemma (16.6.25) is a homeomorphism.

(ii) The system $e_* := (e_0, \ldots, e_n)$ generates an open ideal of $E_U$.

(iii) $C(f_*) = \text{Cont}(\varphi_U^0)^{-1}C(e_*)$, where $C(e_*) := R_{E_U}(\frac{e_0}{e_0}, \ldots, \frac{e_n}{e_0}) \cap \text{Cont}(E_U)$.

(iv) $\varphi_U^0(e_0) \in \mathcal{O}_{\text{Spa} \overline{A}}^\text{loc}((S(f_*))^\times) \text{ and } f_i/f_0 - \varphi_U^0(e_i)/\varphi_U^0(e_0) \in \mathcal{O}_{\text{Spa} \overline{A}}^\text{loc}(S(f_*))^\times$ for $i = 1, \ldots, n$ (notation of (15.5.11)).

**Proof.** (ii) Set $\varphi_U^0(e_*) := (\varphi_U^0(e_0), \ldots, \varphi_U^0(e_n))$; to begin with, we remark:

**Claim 16.6.35.** (ii) holds if and only if the system $\varphi_U^0(e_*)$ generates an open ideal of $A_U$.

**Proof of the claim.** Let $b_1, \ldots, b_r$ be a finite system of elements of $\overline{E}$ that generates an ideal of definition. Then we may find $k \in \mathbb{N}$ large enough so that $b_i^k e_j \in \overline{E}$ for every $i = 1, \ldots, r$ and every $j = 1, \ldots, n$. Clearly the system $b_i^k e_* := (b_i^k e_j \mid i \leq r, j \leq n)$ generates an open ideal of $E_U$ if and only if the same holds for $e_*$. Likewise; $\varphi^0(e_*)$ generates an open ideal of $A_U$ if and only if the same holds for $\varphi_U^0(b_i^k e_*)$. So we may replace $e_*$ by $b_i^k e_*$, and assume from start that $e_i \in \overline{E}$ for $i = 1, \ldots, n$, in which case $\varphi^0_U(e_i) = \pi_T(e_i) \in \overline{A}$ for $i = 1, \ldots, n$. Now, let $I_E \subset \overline{E}$ be the ideal generated by $e_*$; then $I_E$ is open in $\overline{E}$ if and only if $Z := \text{Spec} \overline{E}/I_E$ lies in the non-analytic locus $X$ of $\text{Spec} \overline{E}$; likewise, $I_E E_U$ is open in $E_U$ if and only if $Z' := \text{Spec} E_U/I_E E_U$ lies in the non-analytic locus $X'$ of $\text{Spec} E_U$ (lemma 8.3.29)). On the other hand, let $j : \overline{E} \to E_U$ be the inclusion map; then $Z' = (\text{Spec} j)^{-1} Z$, and lemma 8.3.29) implies that $Z$ lies in $X$ if and only if $Z'$ lies in $X'$. Summing up, we see that $I_E$ is open in $\overline{E}$ if and only if $I_E E_U$ is open in $E_U$. Likewise, let $I_A \subset \overline{A}$ be the ideal
generated by $\varphi_U^\flat(e_\bullet)$; then $I_A$ is open in $\overline{A}$ if and only if $I_A A_U$ is open in $A_U$. Thus, we are further reduced to showing that $e_\bullet$ generates an open ideal of $\overline{E}$ if and only if $\varphi_U^\flat(e_\bullet)$ generates an open ideal of $\overline{A}$. The latter assertion follows from corollary [16.3.40](ii).

By claim [16.6.35] it suffices to show that the system $\varphi_U^\flat(e_\bullet)$ generates an open ideal of $A_U$. To this aim, we apply the criterion of lemma [15.3.25], which reduces to checking that for every $v \in \text{Cont}(A_U)_a$ there exists $i \in \{0, \ldots, n\}$ such that $v(\varphi_U^\flat(e_i)) \neq 0$. However, from [16.6.33] we deduce that for every $i = 0, \ldots, n$ and every such $v$ we have:

- either $v(f_i) = v(\varphi_U^\flat(e_i))$
- or else $v(p) > 0$ and $v(f_i), v(\varphi_U^\flat(e_i)) < v(p)^m$.

Now, since the system $f_\bullet$ generates an open ideal of $A_U$, lemma [15.3.25] implies that $v(f_i) \neq 0$ for some $i \leq n$. If $v(p) = 0$ we deduce that $v(\varphi_U^\flat(e_i)) \neq 0$, as required.

Thus, suppose $v(p) > 0$; from [16.6.31] we know that $v(f_i) \geq v(p)^m > 0$ for some $i \leq n$, whence $v(\varphi_U^\flat(e_i)) = v(f_i) \neq 0$, again as needed.

(iii): In view of [16.6.32] and the foregoing, it follows that

\[(16.6.36) \quad v(f_0) = v(\varphi_U^\flat(e_0)) \geq v(p)^m \quad \text{for every } v \in C(f_\bullet).\]

Now, let $v \in C(f_\bullet)$ and $i \in \{0, \ldots, n\}$; if $v(f_i) \geq v(p)^m$, the foregoing also implies that

\[
v(\varphi_U^\flat(e_i)) = v(f_i) \leq v(f_0) = v(\varphi_U^\flat(e_0)).
\]

If $v(f_i) < v(p)^m$, likewise we get $v(\varphi_U^\flat(e_i)) < v(p)^m \leq v(\varphi_U^\flat(e_0))$, so $v \in \text{Cont}(\varphi_U^\flat)^{-1}C(e_\bullet)$.

Lastly, let $v \in \text{Cont}(A_U) \setminus C(f_\bullet)$; if $v(p) = 0$, we know that $v(f_i) = v(\varphi_U^\flat(e_i))$ for every $i = 0, \ldots, n$, whence $v \notin \text{Cont}(\varphi_U^\flat)^{-1}C(e_\bullet)$. Otherwise, [16.6.31] says that $v(f_j) \geq v(p)^m$ for some $j \leq n$, whence $v(\varphi_U^\flat(e_j)) \geq v(p)^m$. If now $v(f_0) < v(p)^m$, we get $v(\varphi_U^\flat(e_0)) < v(p)^m$, so $v \notin \text{Cont}(\varphi_U^\flat)^{-1}C(e_\bullet)$. Hence, suppose $v(\varphi_U^\flat(e_0)) = v(f_0) \geq v(p)^m > 0$. Then there exists $k \leq n$ such that $v(f_k) > v(f_0)$, whence $v(f_k) = v(\varphi_U^\flat(e_k))$, and again we conclude that $v \notin \text{Cont}(\varphi_U^\flat)^{-1}C(e_\bullet)$.

(i): First, let us show that the continuous map $\text{Cont}(\varphi_U^\flat)$ is bijective. Indeed, a simple inspection yields a commutative diagram of continuous maps

\[
\begin{array}{ccc}
\text{Cont}(A_U) & \xrightarrow{\text{Cont}(\varphi_U^\flat)} & \text{Cont}(E_U) \\
\downarrow & & \downarrow \\
\text{Cont}(A) & \xrightarrow{\text{Cont}(\pi)} & \text{Cont}(E)
\end{array}
\]

where the vertical arrows are induced by the open inclusion maps $A \to A_U$ and $E \to E_U$ (notation of [16.5.22]). Therefore, combining theorem [16.5.52](iii) and proposition [15.3.18](ii) we already see that $\text{Cont}(\varphi_U^\flat)$ restricts to a bijection $\text{Cont}(A_U)_a \xrightarrow{\sim} \text{Cont}(E_U)_a$. On the other hand, proposition [16.5.43](iv) implies easily that $\text{Cont}(\varphi_U^\flat)$ restricts as well to a bijection $\text{Cont}(A_U)_a \xrightarrow{\sim} \text{Cont}(E_U)_a$, whence the contention. Lastly, (ii) and (iii) imply easily that the topology of $\text{Cont}(A_U)$ is induced by the topology of $\text{Cont}(E_U)$, via the map $\text{Cont}(\varphi_U^\flat)$; the assertion follows.

(iv): Since $f_0$ is invertible in $C_{\text{Sp}A}(S(f_\bullet))$, combining [16.6.36] and proposition [15.4.30] we see that the same holds for $\varphi_U^\flat(e_0)$. For the second assertion, in view of corollary [15.4.27](ii) it suffices to show:

**Claim 16.6.37.** $v(f_i/f_0 - \varphi_U^\flat(e_i)/\varphi_U^\flat(e_0)) < 1$ for every $i = 1, \ldots, n$ and every $v \in C(f_\bullet)$.

**Proof of the claim.** From [16.6.33] we easily deduce that

\[
v(1/f_0 - 1/\varphi_U^\flat(e_0)) \leq v(p/f_0) \quad \text{for every } v \in C(f_\bullet)
\]
whence \( v(f_i/f_0 - f_i/\varphi_V'(e_i)) \leq v(p f_i/f_0) < 1 \) for every \( v \in C(f_*) \) and every \( i = 1, \ldots, n \). We are then reduced to checking that \( v(f_i/\varphi_V'(e_0) - \varphi_S'(e_i)/\varphi_V'(e_0)) < 1 \), or equivalently, that \( v(f_i - \varphi_S'(e_i)) < v(\varphi_S'(e_0)) \) for every such \( v \) and \( i \). Now, if \( v(f_i) < v(p)^m \), we know already that \( v(\varphi_S'(e_i)) < v(p)^m \), whence \( v(f_i - \varphi_S'(e_i)) < v(p)^m \), and the assertion follows from (16.6.36) in this case. Otherwise, we have \( v(f_i) = v(\varphi_S'(e_i)) \), whence \( v(\varphi_S'(e_i)) \leq v(f_0) = v(\varphi_S'(e_0)) \), and thus \( v(f_i - \varphi_S'(e_i)) \leq v(p) \cdot \max(v(\varphi_S'(e_0), v(p)^m) = v(p \cdot \varphi_S'(e_0)) < v(\varphi_S'(e_0)). \quad \square \)

16.6.38. Let \( \Gamma, \Delta \) be two monoids and \((A, B)\) a topological ring with \( \Delta \)-graded structure. Then we may form the complete topological ring with \( \Delta \oplus \Gamma \)-graded structure \[
(A, B)[\Gamma]^{\wedge}\]
by combining the constructions of example [8.5.7](i) and remark [8.5.2](iv). Explicitly, a direct inspection shows that \((A, B)[\Gamma]^{\wedge}\) is the pair \((A[\Gamma]^{\wedge}, B[\Gamma]^{\wedge})\), where \(B[\Gamma]^{\wedge}\) is the \( \Delta \)-graded ring such that \(\text{gr}_sB^c\) is the topological closure of \(\text{gr}_sB\) in the completion \(A^c\) of \(A\), and \(A[\Gamma]^{\wedge}\) is the completion of \(A[\Gamma]\), for the unique topology on the latter ring such that the inclusion map \(A \to A[\Gamma]\) is adic. Notice that if \(A\) is complete and separated, then \(B^c = B\), hence in this case \((A, B)[\Gamma]^{\wedge} = (A[\Gamma]^{\wedge}, B[\Gamma])\).

**Lemma 16.6.39.** In the situation of (16.6.38), suppose furthermore that \(A\) is perfectoid, and \(\Delta, \Gamma\) are both \(p\)-perfect, and let
\[
A \xrightarrow{\lambda_A} A[\Gamma]^{\wedge} \xleftarrow{\lambda_A^{-1}} \Gamma \quad \text{and} \quad E(A) \xrightarrow{\lambda_{E(A)}} E(A)[\Gamma]^{\wedge} \xleftarrow{\lambda_{E(A)}^{-1}} \Gamma
\]
be the natural inclusion maps. Then we have:

(i) \(A[\Gamma]^{\wedge}\) is perfectoid.

(ii) There exists a natural isomorphism of topological rings with \(\Delta \oplus \Gamma\)-graded structures
\[
\omega : E(A, B)[\Gamma]^{\wedge} \xrightarrow{\sim} E((A, B)[\Gamma]^{\wedge})
\]
fitting into a commutative diagram

\[
\begin{array}{ccc}
E(A) & \xrightarrow{\lambda_{E(A)}} & E(A)[\Gamma]^{\wedge} \\
\downarrow \omega & & \downarrow \omega \\
E(A[\Gamma]^{\wedge}) & \xleftarrow{\lambda_{E(A)}^{-1}} & \Gamma
\end{array}
\]

**Proof.** (Here \(\Gamma\) is identified with the source \(E(\Gamma)\) of the morphism \(E(i_A), \text{via } \eta_{E}\).)

(i): Indeed, by remark [16.3.56] we may find an ideal of definition \(I \subset A\) fulfilling the conditions of [16.3.53], and we let \(J := I(p)\); by proposition [16.3.57](ii), the corresponding map \(\Phi_I : \text{gr}_s^\bullet A \to \text{gr}_s^\bullet A\) is a ring isomorphism. Set \(I' := IA[\Gamma]^{\wedge}\) and \(J' := JA[\Gamma]^{\wedge}\); by construction, the topology of \(A[\Gamma]^{\wedge}\) agrees with the \(I'\)-adic topology, and the natural map \((A/I^2)[\Gamma] \to A[\Gamma]^{\wedge}/I^2\) is an isomorphism (remark [8.3.3](ii) and lemma [8.3.32](iv)). Since \(\Gamma\) is \(p\)-perfect, the diagram follows easily that the Frobenius endomorphism of \((A/I^2)[\Gamma]^{\wedge}/I^2\) is surjective, so \(A[\Gamma]^{\wedge}\) is a \(P\)-ring. On the other hand, notice the natural identifications:
\[
\text{gr}_s^\bullet A[\Gamma]^{\wedge} \xrightarrow{\sim} (\text{gr}_s^\bullet A)[\Gamma] \quad \text{gr}_s^\bullet (A[\Gamma]^{\wedge}) \xrightarrow{\sim} (\text{gr}_s^\bullet A)[\Gamma]
\]
which identify the ring homomorphism \(\Phi_I\) of proposition [16.3.57](i) with the map induced by \(\Phi_I\) and the \(p\)-Frobenius endomorphism of \(\Gamma\). Especially, \(\Phi_I\) is an isomorphism, so the assertion follows from theorem [16.3.62].

(ii): According to proposition [16.6.1](i), we may find a \(\Delta\)-graded ideal \(I_B\) of \(B\) such that \(I_A := I_B A\) is an ideal of definition of \(A\); then notice that the topological closure \(I_B^{\wedge}\) of \(I_B\) in \(A\) lies in \(I_A\) and \(I_B \cap B\) is the topological closure \(I_B^{\wedge}\) of \(I_B\) in \(B\), therefore \(I_B^{\wedge} = I_A\) and \(I_B = B \cap I_A\), which says especially that \(I_B\) is open in \(B\). Set \(A_0 := A/I_A\) and \(B_0 := B/I_B^{\wedge};\)
since \( I_B \) is a \( \Delta \)-graded ideal as well (remark 8.5.2(i)), we may form the quotient of \((A, B)[\Gamma]^\wedge\) by the open ideal \( I_B[\Gamma] \) of \( B[\Gamma] \) as in example 8.5.4(iii), and get a natural isomorphism:

\[
(16.6.40) \quad (A, B)[\Gamma]^\wedge \otimes_B B_0 \xrightarrow{\sim} (A_0[\Gamma], B_0[\Gamma]).
\]

However, the projections \((A, B) \rightarrow (A_0, B_0)\) and \((A, B)[\Gamma]^\wedge \rightarrow (A, B)[\Gamma]^\wedge \otimes_B B_0\) induce morphisms (see (9.4.24))

\[
(16.6.41) \quad E(A, B) \rightarrow E(A_0, B_0) \quad E((A, B)[\Gamma]^\wedge) \rightarrow E((A, B)[\Gamma]^\wedge \otimes_B B_0).
\]

On the other hand, the projections \(A \rightarrow A_0\) and \(A[\Gamma] \rightarrow A_0[\Gamma]\) induce isomorphisms

\[
E(A) \xrightarrow{\sim} E_0 := E(A_0) \quad \text{and} \quad E(A[\Gamma]) \xrightarrow{\sim} E(A_0[\Gamma])
\]

of topological rings (see (16.1)). Denote

\[
A_0 \xrightarrow{j_{A_0}} A_0[\Gamma]^\wedge \xleftarrow{i_{A_0}} \Gamma \quad \text{and} \quad E_0 \xrightarrow{j_{E_0}} E_0[\Gamma]^\wedge \xleftarrow{i_{E_0}} \Gamma
\]

the natural inclusion maps; taking into account example 8.5.7(iii), it follows that (16.6.41) are isomorphisms of topological rings with graded structures, and in view of (16.6.40) it suffices to exhibit an isomorphism \(\omega_0 : (E_0[\Gamma], E(B_0)[\Gamma]^\wedge) \xrightarrow{\sim} E(A_0[\Gamma], B_0[\Gamma])\) such that

\[
\omega_0 \circ j_{E_0} = E(j_{A_0}) \quad \text{and} \quad \omega_0 \circ i_{E_0} = E(i_{A_0})
\]

(where again, \(\Gamma\) is identified with the source \(E(\Gamma)\) of \(E(i_{A_0})\) via \(\eta_{\Gamma}\)). To this aim, set

\[
J := \text{Ker} \left( \varpi_{A_0[\Gamma]} : E_0[\Gamma] \rightarrow A_0[\Gamma] \right)
\]

and notice that, since \(A_0\) is a discrete topological ring, the topology of \(E_0[\Gamma]\) agrees with the \(J\)-adic topology (remark 9.4.9(ii)); moreover, \(J\) is finitely generated, since \(A\) is perfectoid (details left to the reader). By corollary 9.4.14 and remark 9.4.9(v) we deduce a natural isomorphism of topological rings

\[
\omega_0 : E_0[\Gamma]^\wedge \xrightarrow{\sim} E(A_0[\Gamma]) \quad \text{such that} \quad \varpi_{A_0[\Gamma]} \circ \omega_0 = \varpi_{A_0[\Gamma]^\wedge}
\]

where \(\varpi_{A_0[\Gamma]} : E_0[\Gamma]^\wedge \rightarrow A_0[\Gamma]\) is the completion of \(\varpi_{A_0[\Gamma]}\), and a simple inspection shows that \(\omega_0\) is a morphism \((E_0[\Gamma], E(B_0)[\Gamma]^\wedge) \rightarrow E(A_0[\Gamma], B_0[\Gamma])\), which then must be an isomorphism, again by example 8.5.7(iii). Let us check that \(\omega_0 \circ i_{E_0} = E(i_{A_0})\). Indeed, we have

\[
\varpi_{A_0[\Gamma]} \circ \omega_0 \circ i_{E_0} = \varpi_{A_0[\Gamma]^\wedge} \circ i_{E_0} = i_{A_0} = \varpi_{A_0[\Gamma]} \circ E(i_{A_0})
\]

whence the sought identity, by adjunction. A similar argument proves the remaining sought identity. \(\square\)

We conclude this section with a sample of other graded perfectoid rings that are analogous to certain constructions found in [116], and might be interesting for other purposes, but shall not be needed in the rest of this treatise.

**Example 16.6.42.** (i) Let \((\Delta, 0, +)\) be a monoid, \((A, B)\) a topological ring with \(\Delta\)-graded structure, and consider two morphisms of \(\Delta\)-graded monoids

\[
\Gamma_2 \xleftarrow{\varphi} \Gamma_1 \xrightarrow{\psi} B^\ast
\]

where \(B^\ast\) is the \(\Delta\)-graded monoid defined as in (9.4.21). Hence, \(B[\Gamma_2]\) is a \(\Delta \oplus \Gamma_2\)-graded \(\mathbb{Z}\)-algebra, and we may form the \(\Delta\)-graded \(\mathbb{Z}\)-algebra \(B[\Gamma_2]/\Delta\) corresponding to the morphism

\[
\eta : \Delta \oplus \Gamma_2 \rightarrow \Delta \quad (\delta, \gamma) \mapsto \delta + |\gamma| \quad \text{for every} \ \delta \in \Delta \ \text{and} \ \gamma \in \Gamma_2
\]

where \(|\cdot| : \Gamma_2 \rightarrow \Delta\) is the \(\Delta\)-grading of \(\Gamma_2\). It follows easily that

\[
I := \text{Ker} \left( B[\Gamma_2] \rightarrow \Gamma_2 \otimes \Gamma_1, B \right)
\]
is a $\Delta$-graded ideal of $B[\Gamma_2]/\Delta$, and by combining the constructions of examples $8.5.4$ (i) and $8.5.7$ (i, ii) we may define the topological ring with $\Delta$-graded structure

$$\Gamma_2 \otimes_{\Gamma_1} (A, B) := (A, B)[\Gamma_2]/\Delta/I.$$ 

Explicitly, this is the pair $(A', B')$, such that $A'$ (resp. $B'$) is the maximal separated quotient of $\Gamma_2 \otimes_{\Gamma_1} A$ (resp. of $\Gamma_2 \otimes_{\Gamma_1} B$), where the latter is endowed with the unique linear topology such that the natural map

$$A \to \Gamma_2 \otimes_{\Gamma_1} A \quad \text{(resp. } B \to \Gamma_2 \otimes_{\Gamma_1} B)$$

is adic. Then, $gr_\delta B'$ is the topological closure of the image of $gr_\delta B[\Gamma_2]/\Delta$ in $A'$, for each $\delta \in \Delta$. By construction, we have a natural morphism of topological rings with $\Delta$-graded structures (resp. of monoids)

$$j_{(A, B)} : (A, B) \to \Gamma_2 \otimes_{\Gamma_1} (A, B) \quad \text{(resp. } i_{(A, B)} : \Gamma_2 \to \Gamma_2 \otimes_{\Gamma_1} A \text{).}$$

(ii) Suppose now that $\Delta$ is $p$-perfect, and the topology of $A$ is complete, separated and coarser than the $p$-adic topology. Then the topological ring with $\Delta$-graded structure $E(A, B)$ is well defined as in $(9.4.24)$. Moreover, from the morphisms $\varphi$ and $\psi$ we derive two morphisms of monoids

$$E(\Gamma_2) \xleftarrow{\varphi_{E}} E(\Gamma_1) \xrightarrow{\psi_{E}} E(B^*)$$

where $\varphi_{E} := E(\varphi)$ and $\psi_{E} := E(\psi)$

so the considerations of (i) can be repeated on $E(A, B)$, and we get a topological ring with $E(\Delta)$-graded structure

$$E(\Gamma_2) \otimes_{E(\Gamma_1)} E(A, B).$$

**Proposition 16.6.43.** In the situation of example $16.6.42$ suppose moreover that $A$ is perfectoid, and $\Delta, \Gamma_1, \Gamma_2$ are $p$-perfect. We have:

(i) The completion $(\Gamma_2 \otimes_{\Gamma_1} A)^!$ of $\Gamma_2 \otimes_{\Gamma_1} A$ is perfectoid.

(ii) There exists a natural isomorphism of topological rings with $\Delta$-graded structures:

$$\omega : E((\Gamma_2 \otimes_{\Gamma_1} (A, B))^!) \xrightarrow{\sim} (\Gamma_2 \otimes_{\Gamma_1} E(A, B))^!$$

(notification of $(9.4.24)$) fitting into the commutative diagrams

$$
\begin{array}{ccc}
\text{E}(A, B) & \xrightarrow{E(j_{(A, B)})} & \text{E}((\Gamma_2 \otimes_{\Gamma_1} (A, B))^!)
\\
\downarrow{j_{E(A, B)}} & & \downarrow{\omega}
\\
(\Gamma_2 \otimes_{\Gamma_1} E(A, B))^! & \xrightarrow{E(i_{(A, B)})} & (\Gamma_2 \otimes_{\Gamma_1} E(A))^!
\end{array}
$$

$$
\begin{array}{ccc}
\Gamma_2 & \xrightarrow{E(i_{(A, B)})} & \text{E}((\Gamma_2 \otimes_{\Gamma_1} A)^!)
\\
\downarrow{i_{E(A, B)}} & & \downarrow{\omega}
\\
(\Gamma_2 \otimes_{\Gamma_1} E(A))^! & \xrightarrow{E(i_{E(A, B)})} & (\Gamma_2 \otimes_{\Gamma_1} E(A))^!.
\end{array}
$$

**Proof.** (Here we identify $\Gamma_1$ and $\Gamma_2$ with $E(\Gamma_1)$ and $E(\Gamma_2)$, via the isomorphisms $\pi_{\Gamma_1}$ and $\pi_{\Gamma_2}$.) Let us form as well the topological ring with $\Delta$-graded structure

$$(A', \mathcal{D}) := ((A, B)[\Gamma_2]^!)/\Delta.$$ 

Explicitly, $A'$ is the completion of $A[\Gamma_2]$, where the latter is endowed with the unique linear topology such that the natural map $A \to A[\Gamma_2]$ is adic; then $gr_\delta D$ is the topological closure in $A'$ of $gr_\delta (B[\Gamma_2]/\Delta)$, for every $\delta \in \Delta$. Here, as in example $16.6.42$ (i), the $\Delta$-graded $\mathbb{Z}$-algebra $B[\Gamma_2]/\Delta$ is obtained from the $\Delta \oplus \Gamma_2$-graded $\mathbb{Z}$-algebra $B[\Gamma_2]$ via the morphism $\eta$. With this notation, from proposition $8.2.13$ (i, v) and a simple inspection we get a natural identification

$$\text{E}(\Gamma_2) \otimes_{\text{E}(\Gamma_1)} (A, B)^! \xrightarrow{\sim} (A', \mathcal{D})/\mathcal{D}. $$

Set $(E, B_E) := E(A, B)$; from lemma $16.6.39$ and proposition $9.4.22$ (iii), we know already that $A'$ is perfectoid, and there exists an isomorphism

$$ \text{E}'(A', \mathcal{D}) := E(A', \mathcal{D}) \xrightarrow{\sim} ((E, B_E)[\Gamma_2]^!)/\Delta$$

(16.6.44)
of topological rings with $\Delta$-graded structures. Set

$$\mathcal{I} := \text{Ker } (B_E[\Gamma_2] \to \Gamma_2 \otimes_{\Gamma_1} B_E).$$

**Claim 16.6.46.** (i) $\Phi_E(\mathcal{I}E') = \mathcal{I}E'$.

(ii) $\{\mathcal{I}E'\} = (IA')^c$.

**Proof of the claim.** Let $\overline{\psi}_E := E(i) \circ \psi_E : \Gamma_1 \to E$ where $i : B^+ \to A$ is the natural map. Clearly, the ideals $IA'$ and $\mathcal{I}E'$ are generated respectively by the systems

$$\mathcal{I}_A := (\varphi(\gamma) - \psi(\gamma) \mid \gamma \in \Gamma_1) \quad \text{and} \quad \mathcal{I}_E := (\varphi_E(\gamma) - \overline{\psi}_E(\gamma) \mid \gamma \in \Gamma_1).$$

Since $\Gamma_1$ is perfect, assertion (i) follows already, and for (ii) we come down to showing that the topological closure of the ideal generated by the system $\overline{\pi}_A(\mathcal{I}_E)$ equals the topological closure of the ideal generated by $\mathcal{I}_A$. Now, proposition 9.3.63 says that each generator $\overline{\pi}_A((\varphi_E(\gamma) - \overline{\psi}_E(\gamma))$ can be written as a $p$-adically convergent series $\sum_{n \in \mathbb{N}} p^n c_{\gamma,n}$ where

$$c_{\gamma,0} = \overline{\pi}_A(\varphi_E(\gamma)) - \overline{\pi}_A(\overline{\psi}_E(\gamma))$$

and for every $n > 0$, the term $c_{\gamma,n}$ is a finite $\mathbb{Z}_p$-linear combination of elements of the form

$$\overline{\pi}_A((\varphi_E(\gamma)^s \cdot \overline{\psi}_E(\gamma)^{s'}) - \overline{\pi}_A(\varphi_E(\gamma)^{s'} \cdot \overline{\psi}_E(\gamma)^s))$$

where $s, s' \in p^{-n}\mathbb{N}$ and $s + s' = 1$. However, lemma 16.6.39(ii) implies that

$$\overline{\pi}_A(\varphi_E(\gamma)) = \varphi(\gamma) \quad \text{and} \quad \overline{\pi}_A(\overline{\psi}_E(\gamma)) = \psi(\gamma)$$

for every $\gamma \in \Gamma_1$.

Thus $\{\mathcal{I}E'\}$ lies in the topological closure of the ideal generated by the elements $t_{\gamma,s} := \varphi(\gamma)^s \cdot \psi(\gamma)^{s'} - \varphi(\gamma)^{s'} \cdot \psi(\gamma)^s$ for every $\gamma \in \Gamma_1$ and $s, s' \in \mathbb{N}[1/p]$ with $s + s' = 1$.

To ease notation, set $\lambda := \varphi(\gamma)$ and $\mu := \psi(\gamma)$; we notice that

$$(\lambda^s - \mu^s) \cdot (\mu^{1-s} + \lambda^{1-s}) - (\lambda - \mu) = t_{\gamma,s}$$

and since $\lambda^s - \mu^s, \lambda - \mu \in \mathcal{I}_A$, we conclude that $t_{\gamma,s} \in IA$. By the same token, from (16.6.47) we get $c_0 = \lambda - \mu$, so finally $(IA')^c = \{\mathcal{I}E'\} + p(IA')^c$. From this, an easy induction yields

$$(IA')^c = \{\mathcal{I}E'\} + p^n(IA')^c \quad \text{for every } n \in \mathbb{N}$$

whence the claim, since $\{\mathcal{I}E'\}$ is a closed ideal.

From claim 16.6.46 and corollary 16.3.38 we deduce that $A'/(IA')^c$ is perfectoid and there exists an isomorphism of topological rings $\omega' : E(A'/(IA')^c) \xrightarrow{\sim} E'/(\mathcal{I}E')^c$ such that

$$\omega' \circ E(\pi_A) = \pi_{E'}$$

where $\pi_A : A' \to A'/(IA')^c$ and $\pi_{E'} : E' \to E'/(\mathcal{I}E')^c$ are the projections. This completes the proof of (i), and we also see that the projection $(E', D_E) \to (E', D_E)/\mathcal{I}D_E$ factors through a morphism

$$E((A', D)/1D) \to (E', D_E)/\mathcal{I}D_E$$

which must be an isomorphism, by example 8.5.7(iii). On the other hand, from (16.6.45) we get a natural identification

$$E((A', D_E)/\mathcal{I}D_E) \xrightarrow{\sim} (\Gamma_2 \otimes_{\Gamma_1} E(A, B))^\wedge.$$

Lastly, combining (16.6.48), (16.6.49) and (16.6.44) we get the sought isomorphism $\omega$. The commutativity of the diagrams in (ii) follows by direct inspection, taking into account the corresponding properties of the isomorphism (16.6.45) stated in lemma 16.6.39(ii): details left to the reader. \qed
16.6.50. Let $\Lambda$ be any (small) set and $(\Delta, +, 0, \leq)$ any ordered abelian group; we set
\[
\Delta^+ = \{ \delta \in \Delta \mid \delta \geq 0 \} \quad P := \Delta^+(\Lambda) \quad Q := \Delta^+(\Lambda \times \Lambda)
\]
(cp. definition 9.1.1(i)). Denote by $I \subset P$ the ideal generated by the canonical system of generators $e_\lambda := (e_\lambda | \lambda \in \Lambda)$ for $P$, i.e. $e_\lambda := (\delta_\mu | \mu \in \Lambda)$, where $\delta_\mu := 1$ for $\lambda = \mu$, and $\delta_\mu := 0$ otherwise, for every $\lambda, \mu \in \Lambda$. Likewise, we let
\[
(f_\lambda, f'_\lambda | \lambda \in \Lambda) \quad \text{(resp. } (e_{\lambda,\lambda'}, | \lambda, \lambda' \in \Lambda))
\]
be the canonical system of generators of $P \times P$ (resp. of $Q$).

- With this notation, we define $\Delta$-gradings on $P$, $P \times P$ and $Q$ by the rules:
  \[
  |\delta e_\lambda|_P := \delta \quad |\delta f_\lambda + \delta' f'_\lambda|_{P \times P} := \delta \quad |\delta e_{\lambda,\lambda'}|_Q := \delta
  \]
for every $\lambda, \lambda' \in \Lambda$ and every $\delta, \delta' \in \Delta$ (see definition 4.8.8(i)), and we set
\[
I(\delta) := \{ x \in P \mid |x|_P \geq \delta \} \quad \text{for every } \delta \in \Delta.
\]
Notice that, in case $\Delta = \mathbb{Z}/[1/p]$, the ideals $I(\delta)$ of $P$ are the same as the ones introduced in (9.3.69), so the notation does not conflict with loc.cit. Lastly, we define
\[
\Gamma_I^+ := \bigcup_{\delta \in \Delta^+} I(\delta) \times \{ \delta \} \quad \Gamma_I := \bigcup_{\delta \in \Delta} I(\delta) \times \{ \delta \}
\]
and notice that $\Gamma_I^+$ (resp. $\Gamma_I$) is a submonoid of $P \times \Delta^+$ (resp. of $P \times \Delta$), so it inherits a natural $\Delta$-grading, given by the projection on the factor $\Delta$. We have morphisms of $\Delta$-graded monoids
\[
(16.6.51) \quad Q \xrightarrow{\psi} P \times P \xrightarrow{\varphi} \Gamma_I^+
\]
such that
\[
\varphi(\delta f_\lambda + \delta' f'_\lambda) := ((\delta + \delta') e_\lambda, \delta) \quad \psi(\delta e_{\lambda,\lambda'}) := \delta (f_\lambda + f'_\lambda) \quad \psi'(\delta e_{\lambda,\lambda'}) := \delta (f'_\lambda + f_\lambda)
\]
for every $\lambda, \lambda' \in \Lambda$ and every $\delta, \delta' \in \Delta$.

Lemma 16.6.52. With the notation of (16.6.50), we have:

(i) (16.6.51) is a presentation for $\Gamma_I^+$, i.e. $\varphi$ identifies $\Gamma_I^+$ with the coequalizer of $\psi$ and $\psi'$.

(ii) Define a $\Delta$-grading of $P \times \Delta^+$ by the rule: $(x, \delta) \mapsto |x|_P - \delta$ for every $x \in P$ and $\delta \in \Delta^+$. Then the mapping
\[
P \times \Delta^+ \to \Gamma_I \quad (x, \delta) \mapsto (x, |x|_P - \delta)
\]
is an isomorphism of $\Delta$-graded monoids.

Proof. (i): Indeed, say that
\[
g := \sum_{\lambda \in \Lambda} (r_\lambda f_\lambda + r'_\lambda f'_\lambda) \quad \text{and} \quad h := \sum_{\lambda \in \Lambda} (s_\lambda f_\lambda + s'_\lambda f'_\lambda)
\]
are two elements of $P \times P$ whose images agree in $\Gamma_I^+$, so that $r_\lambda, r'_\lambda, s_\lambda, s'_\lambda \in \Delta^+$ and
\[
(16.6.53) \quad r_\lambda + r'_\lambda = s_\lambda + s'_\lambda \quad \text{for every } \lambda \in \Lambda \quad \text{and} \quad \sum_{\lambda \in \Lambda} r_\lambda = \sum_{\lambda \in \Lambda} s_\lambda.
\]
Let $\sim$ be the equivalence relation defined by the pair $(\psi, \psi')$; we have to check that $g \sim h$. Now, consider any $\lambda \in \Lambda$, and suppose that $r_\lambda \leq s_\lambda$; then we may write $g = g' + r_\lambda f_\lambda, h = h' + r_\lambda f_\lambda$ for elements $g', h' \in P \times P$ such that $\varphi(g') = \varphi(h')$; it then suffices to check that $g' \sim h'$, and we are reduced to the case where $r_\lambda = 0$. In case $r_\lambda > s_\lambda$, we argue symmetrically, to reduce to the case where $s_\lambda = 0$. Likewise, we can reduce to the case where either $r'_\lambda = 0$ or $s'_\lambda = 0$. 

Repeating the argument for every $\lambda \in \Lambda$, and taking (16.6.53) into account, we may suppose from start that
\[
g = \sum_{\lambda \in A} r_\lambda f_\lambda + \sum_{\mu \in B} r_\mu f'_\mu \quad h = \sum_{\lambda \in A} r_\lambda f'_\lambda + \sum_{\mu \in B} r_\mu f_\mu
\]
for some finite subsets $A, B \in \Lambda$ with $A \cap B = \emptyset$, and a system $(r_\lambda | \lambda \in A \cup B)$ of elements of $\Delta^+ \setminus \{0\}$ such that
\[
\sum_{\mu \in B} r_\mu = \sum_{\lambda \in A} r_\lambda.
\]

Next, we argue by induction on the cardinality $c$ of $A \cup B$. If $c = 0$, there is nothing to prove. Suppose then that $c > 0$ and that the assertion is already known whenever the cardinality of $A \cup B$ is strictly smaller than $c$. Notice that $A \neq \emptyset$, since otherwise (16.6.54) would imply that $\Delta = \emptyset$, contradicting the assumption that $c > 0$; likewise, we must have $B \neq \emptyset$. Thus, pick any $\lambda \in A$ and $\mu \in B$, set $A' := A \setminus \{\lambda\}$, $B' := B \setminus \{\mu\}$, and suppose first that $r_\lambda \leq r_\mu$, we set
\[
g' := \sum_{\lambda \in A'} r_\lambda f_\lambda + \sum_{\mu \in B'} r_\mu f'_\mu + (r_\mu - r_\lambda) \cdot f'_\mu \quad h' := \sum_{\lambda \in A'} r_\lambda f'_\lambda + \sum_{\mu \in B'} r_\mu f_\mu + (r_\mu - r_\lambda) \cdot f_\mu
\]
so that $g = g' + r_\lambda \cdot (f_\lambda + f'_\mu)$ and $h = h' + r_\lambda \cdot (f'_\lambda + f_\mu)$. However, $r_\lambda \cdot (f_\lambda + f'_\mu) \sim r_\lambda \cdot (f'_\lambda + f_\mu)$, so we are reduced to checking that $g' \sim h'$. The latter is known by our inductive assumption. A symmetric argument will do, in case $r_\lambda > r_\mu$.

(ii) shall be left to the reader. \hfill \Box

16.6.55. In the situation of (16.6.50), take $\Delta := \mathbb{Z}[1/p]$ with its standard ordering, so that $\Delta^+ = \mathbb{N}[1/p]$. In this case, it is easily seen that $P, \Gamma^+_I$ and $\Gamma_I$ are $p$-perfect monoids. In this paragraph, it will be convenient to switch to a multiplicative notation for the composition laws of these monoids: in other words, we shall hereafter replace $(P, +, 0)$ by $(\exp P, \cdot, 1)$, and likewise for $\Gamma^+_I$ and $\Gamma_I$ (notation of (6.1)). Correspondingly, the product $\delta \cdot x$ of an element $\delta \in \Delta^+$ and an element $x \in P$ shall be replaced by the exponential $x^\delta$.

Let also $A$ be any perfectoid set, set $E := E(A)$ and denote by $A$ the topological ring with $\Delta$-graded structure $(A, A, \Delta)$, such that $\gr_\delta A = A$ and $\gr_\delta A = 0$ for every $\delta \neq 0$ in $\Delta$; define likewise the topological ring with $\Delta$-graded structure $E := (E, \Delta)$. Choose an ideal of definition $J$ for $A$, and set $\mathscr{J} := \pi_A^{-1}(J/pA)$, which is an ideal of definition for $E$. Let $\beta_* := (\beta_\lambda | \lambda \in \Lambda)$ be any system of elements of $E$; then $\beta_*$ determines a unique morphism of monoids
\[
\varphi_E : P \to E \quad \text{such that} \quad e^\delta \mapsto \beta_\delta \quad \text{for every } \lambda \in \Lambda \text{ and } \delta \in \Delta
\]
and composing with the map $\pi_A : E \to A$ we get also a morphism $\varphi_A : P \to A$. Moreover, notice that $I^{(0)} = P$, so we have as well a morphism $i_0 : P \to \Gamma_I^+$, and we can define the rings
\[
\mathcal{E}_+ := \Gamma_I^+ \otimes P A \subset \mathcal{E} := \Gamma_I \otimes P E \quad \text{and} \quad \mathcal{A}_+ := \Gamma_I^+ \otimes P A \subset \mathcal{A} := \Gamma_I \otimes P A
\]
as well as the topological rings with $\Delta$-graded structures
\[
(\mathcal{E}_+^\wedge, \mathcal{E}_+^\natural) := (\Gamma_I^+ \otimes P E)^\wedge \subset (\mathcal{E}^\wedge, \mathcal{E}_+^\natural) := (\Gamma_I \otimes P E)^\wedge
\]
\[
(\mathcal{A}_+^\wedge, \mathcal{A}_+^\natural) := (\Gamma_I^+ \otimes P A)^\wedge \subset (\mathcal{A}^\wedge, \mathcal{A}_+^\natural) := (\Gamma_I \otimes P A)^\wedge
\]
(notation of (6.1.34) and example (6.6.42). We endow $\mathcal{E}$ and $\mathcal{E}_+$ with their $\mathcal{J}$-adic topologies, and $\mathcal{A}$, $\mathcal{A}_+$ with their $J$-adic topologies; then $\mathcal{E}_+^\wedge$ (resp. $\mathcal{E}^\wedge$) is the completion of $\mathcal{E}_+$ (resp. of $\mathcal{E}$) and $\mathcal{A}_+^\wedge$ (resp. $\mathcal{A}^\wedge$) is the completion of $\mathcal{A}_+$ (resp. of $\mathcal{A}$). Furthermore, the rings $\mathcal{A}$ and $\mathcal{E}$ inherit natural $\Delta$-gradings from $\Gamma_I$, such that
\[
I^{(0)} \otimes P E = \gr_\delta \mathcal{E} \quad I^{(0)} \otimes P A = \gr_\delta \mathcal{A} \quad \text{for every } \delta \in \Delta.
and by restricting to $\Delta^+$, we get corresponding $\Delta^+$-gradings on $\mathcal{A}_+$ and $\mathcal{E}_+$. Then, a direct inspection shows that $\text{gr}_0^\mathcal{E}c$ (resp. $\text{gr}_0^\mathcal{A}c$) is the separated completion of $\text{gr}_0^\mathcal{E}$ (resp. of $\text{gr}_0^\mathcal{A}$), for every $\delta \in \Delta$. Let $i_\Gamma : \Gamma^+_I \to \Gamma_I$ be the inclusion map; as in example 16.6.42(i), we point out the commutative diagram of monoids and of topological rings with $\Delta$-graded structures:

$$
\begin{array}{c}
\xymatrix{
E & \xrightarrow{j_E} & (E^\wedge_+, E^c_+) \xrightarrow{i_E^+} \Gamma^+_I \xrightarrow{i_A^+} (E^\wedge_+, E^c_+) \xrightarrow{j_A^+} A \\
 & \downarrow j_E & \downarrow (i_\Gamma \otimes 1) & \downarrow i_\Gamma & \downarrow (i_\Gamma \otimes 1) \\
& (E^\wedge_+, E^c_+) \xrightarrow{i_E^-} \Gamma^- I \xrightarrow{i_A^-} (E^\wedge_+, E^c_+). 
\end{array}
$$

**Remark 16.6.56.** In the situation of $(16.6.55)$, suppose furthermore that the system $\beta_*$ generates an open ideal of $E$. Then, combining corollaries 8.6.40(ii) and 16.3.40(ii) together with proposition 16.5.5(ii), we deduce that $\Gamma^+_I \otimes_P E$ and $\Gamma_I \otimes_P E$ are already $\mathcal{I}$-adically complete and separated, and $\Gamma^+_I \otimes_P A$ and $\Gamma_I \otimes_P A$ are $J$-adically complete and separated.

**Corollary 16.6.57.** With the notation of $(16.6.55)$, the rings $\mathcal{E}^\wedge_+, \mathcal{E}^\wedge_+, \mathcal{A}^\wedge_+$ and $\mathcal{A}^\wedge_+$ are perfectoid, and we have natural isomorphisms of topological rings with $\Delta$-graded structures

$$
\begin{align*}
\omega_+ : E(\mathcal{A}^\wedge_+, \mathcal{E}^c_+) & \xrightarrow{\sim} (\mathcal{E}^\wedge_+, \mathcal{E}^c_+) \\
\omega : E(\mathcal{A}^\wedge_+, \mathcal{E}^c_+) & \xrightarrow{\sim} (\mathcal{E}^\wedge_+, \mathcal{E}^c_+) 
\end{align*}
$$

fitting into the commutative diagrams

$$
\begin{array}{c}
\xymatrix{
E & \xrightarrow{E(j_E^+)} & (E^\wedge_+, E^c_+) \ar[r]^-{E(i_E^+)} & \Gamma^+_I \ar[d]^-{j_E^-} & \xrightarrow{E(j_A)} & (E^\wedge_+, E^c_+) \ar[r]^-{E(i_A)} & \Gamma_I \\
& \downarrow \omega & \downarrow i_E & & & \downarrow i_E \\
& (E^\wedge_+, E^c_+) & & (E^\wedge_+, E^c_+). 
\end{array}
$$

**Proof.** Clearly we have $E(A) = E$. The corollary then becomes a special case of proposition 16.6.43 after we have shown

**Claim 16.6.58.** $\varphi_E \circ \pi_P = E(\pi_A \circ \varphi_E)$.

**Proof of the claim.** Clearly $\varphi_E \circ \pi_P = \pi_E \circ E(\varphi_E)$, so we are reduced to checking the identity $\pi_E = E(\pi_A)$, and the latter holds by remark 9.4.5(ii). \qed

16.6.59. From lemma 16.6.52(i) we deduce a corresponding coequalizer presentation for $\mathcal{E}_+$ in the category of $\Delta$-graded $\mathbb{Z}$-algebras:

$$
\begin{array}{c}
\xymatrix{
\mathbb{Z}[Q] & \ar[r] & \mathbb{Z}[P \times P] \otimes \mathbb{Z}[P] \ar[r] & E = E[P] \ar[r] & \mathbb{Z}[\Gamma^+_I] \otimes \mathbb{Z}[P] \ar[r] & E = \mathcal{E}_+ 
\end{array}
$$

where $E$ and $\mathbb{Z}[P \times P]$ are regarded as $\mathbb{Z}[P]$-algebras via $\varphi_E$ and respectively via the morphism of monoids $P \to P \times P$ given by the rule $e^\lambda_\delta \mapsto f^\lambda_\delta$ for every $\lambda \in \Lambda$ and every $\delta \in \Delta^+$. Likewise we may present $\mathcal{A}_+$, and there follow natural isomorphisms

$$
\mathcal{E}_+ \xrightarrow{\sim} E[P] / \mathcal{I}_E \quad \mathcal{A}_+ \xrightarrow{\sim} A[P] / \mathcal{I}_A
$$

where $\mathcal{I}_E \subset E[P]$ is the ideal generated by the system

$$
(\beta^\lambda_\mu \cdot e^r_\mu - \beta^r_\mu \cdot e^\lambda_\mu \mid \lambda, \mu \in \Lambda; \ r \in \mathbb{N}[1/p]).
$$

and $\mathcal{I}_A \subset A[P]$ is the ideal generated by the system

$$
(\pi_A(\beta^\lambda_\mu) \cdot e^r_\mu - \pi_A(\beta^r_\mu) \cdot e^\lambda_\mu \mid \lambda, \mu \in \Lambda; \ r \in \mathbb{N}[1/p]).
$$

Especially, notice that $\mathcal{I}_E$ (resp. $\mathcal{I}_A$) is a graded ideal of the $\Delta$-graded ring $E[P] / \Delta$ (resp. $A[P] / \Delta$), arising via the grading $| \cdot | : P \to \Delta$, and

$$
gr_\delta \mathcal{E}_+ = (gr_\delta E[P] / \Delta) / gr_\delta \mathcal{I}_E = E[gr_\delta P] / gr_\delta \mathcal{I}_E \quad \text{for every } \delta \in \Delta.
We can then form the topological rings with $\Delta$-graded structure
\[(\mathcal{E}^s_+^\times, \mathcal{E}^s_+) := (\mathcal{E}[P]\langle \Delta \rangle)/\mathcal{I} \quad (\mathcal{A}^s_+^\times, \mathcal{A}^s_+) := (\mathcal{A}[P]\langle \Delta \rangle)/\mathcal{I}^\times\]
that are the maximal separated quotients $\mathcal{E}^s_+^\times$ of $\mathcal{E}_+$ and $\mathcal{A}^s_+^\times$ of $\mathcal{A}_+$, endowed with the $\Delta$-graded $\mathbb{Z}$-algebra structures
\[\mathcal{E}^s_+^\times := \bigoplus_{\delta \in \Delta^+} (I^{(\delta)} \otimes_P \mathcal{E})^s \quad \text{and} \quad \mathcal{A}^s_+^\times := \bigoplus_{\delta \in \Delta^+} (I^{(\delta)} \otimes_P \mathcal{A})^s\]
where $(I^{(\delta)} \otimes_P \mathcal{E})^s$ denotes the maximal separated quotient of $I^{(\delta)} \otimes_P \mathcal{E}$, for every $\delta \in \Delta$, and likewise for $(I^{(\delta)} \otimes_P \mathcal{A})^s$. It is now straightforward that the completion maps $\mathcal{E}^s_+ \to \mathcal{E}^c_+$ and $\mathcal{A}^s_+ \to \mathcal{A}^c_+$ factor through natural isomorphisms
\[(\mathcal{E}^s_+^\times, \mathcal{E}^c_+) \xrightarrow{\sim} (\mathcal{E}_+^\times, \mathcal{E}_+^c) \quad \text{and} \quad (\mathcal{A}^s_+^\times, \mathcal{A}^c_+) \xrightarrow{\sim} (\mathcal{A}_+^\times, \mathcal{A}_+^c).

16.7. Perfectoid spaces. Some basic verifications concerning perfectoid spaces will employ a certain amount of formal algebraic geometry, that we collect hereafter.

16.7.1. Quite generally, let $R$ be any $\mathbb{Q}_+$-graded ring. We associate with $R$ a projective scheme
\[\text{Proj } R\]
as follows. For every $\gamma \in \mathbb{Q}_{>0}$, let $R^{(\gamma)} := \bigoplus_{k \in \mathbb{N}} R_{k\gamma}$, which we regard as an $\mathbb{N}$-graded ring, whose $k$-graded direct summand is $R_{k\gamma}$, for every $k \in \mathbb{N}$. Set $Y^{(\gamma)} := \text{Proj } R^{(\gamma)}$ for every such $\gamma$. If $n > 0$ is any integer, the discussion of (10.6.11) yields a natural isomorphism
\[Y^{(\gamma)} \xrightarrow{\Omega^{(\gamma)}_p} Y^{(n\gamma)}\]
of $R_0$-schemes, and it is easily seen that
\[\Omega^{(n\gamma)}_p \circ \Omega^{(\gamma)}_n = \Omega^{(p\gamma)}_{pn} \quad \text{for every integers } n, p > 0.
Thus, the rule $\gamma \mapsto Y^{(\gamma)}$ yields a well defined filtered system of isomorphisms, and we let $\text{Proj } R$ be any choice of an $R_0$-scheme representing the colimit of this system; e.g. $\text{Proj } R := Y^{(\gamma_0)}$, for some fixed $\gamma_0 \in \mathbb{Q}_{>0}$, together with the cocone $(\Omega^{(\gamma)} : Y^{(\gamma)} \to \text{Proj } R | \gamma \in \mathbb{Q}_{>0})$ resulting from the filtered system of morphisms $\Omega^{(\gamma)}_n$.

16.7.2. To ease notation, we shall let $Y := \text{Proj } R$. For every $\gamma \in \mathbb{Q}_{>0}$, every $n \in \mathbb{N}$, and every $f \in R_{n\gamma}$ we have the open subset $D_+(f) \subset Y^{(\gamma)}$ defined as in (10.6.1), and we denote also $D_+(f) \subset Y$ the image of this open subset under $\Omega^{(\gamma)}$. It is easily seen that the resulting open subset of $Y$ is independent of the choice of $\gamma$. We also set $\mathcal{O}_Y(0) := \mathcal{O}_Y$ and
\[\mathcal{O}_Y(\gamma) := \Omega^{(\gamma)}_p \mathcal{O}_Y((\gamma)/\gamma) \quad \text{for every } \gamma \in \mathbb{Q} \setminus \{0\}\]
and we notice that – according to (10.6.16) – the quasi-coherent $\mathcal{O}_Y$-module $\mathcal{O}_Y(\gamma)$ restricts to an invertible $\mathcal{O}_Y$-module on the open subset
\[U_\gamma(R) := \bigcup_{f \in R_{n\gamma}} D_+(f) \quad \text{for every } \gamma \in \mathbb{Q} \setminus \{0\}.

Remark 16.7.3. Let $\Gamma \subset \mathbb{Q}_+$ be any submonoid, and suppose that $R = \mathbb{Q}_+ \times \Gamma R'$ for a $\Gamma$-graded ring $R'$. Then it is easily seen that $\mathcal{O}_Y(\gamma) = 0$ and $U_\gamma(R) = \emptyset$ for every $\gamma \in \mathbb{Q} \setminus \Gamma^{\text{gp}}$. 
16.7.4. In view of the isomorphisms \((10.6.14)\), we get natural identifications
\[
\mathcal{O}_Y(n\gamma) \xrightarrow{\sim} \Omega^\gamma(\mathcal{O}_Y(n)) \quad \text{for every } n \in \mathbb{Z} \text{ and every } \gamma \in \mathbb{Q}_{>0}.
\]
For every \(\gamma, \gamma' \in \mathbb{Q}\) there exists as well a natural morphism
\[
\mathcal{O}_Y(\gamma) \otimes_{\mathcal{O}_Y} \mathcal{O}_Y(\gamma') \to \mathcal{O}_Y(\gamma + \gamma')
\]
that generalizes \((10.6.21)\). Namely, pick a common divisor, \textit{i.e.} a rational number \(\delta \in \mathbb{Q}_{>0}\) and integers \(p, q \in \mathbb{N}\) such that \(p\delta = \gamma\) and \(q\delta = \gamma'\); we have first a natural identification
\[
\mathcal{O}_Y(\gamma) \otimes_{\mathcal{O}_Y} \mathcal{O}_Y(\gamma') \xrightarrow{\sim} \Omega^\delta(\mathcal{O}_Y(p) \otimes_{\mathcal{O}_Y} \mathcal{O}_Y(q)) \xrightarrow{\sim} \Omega^\delta(\mathcal{O}_Y(p) \otimes_{\mathcal{O}_Y} \mathcal{O}_Y(q))
\]
which we combine with the map
\[
\Omega^\delta(\mathcal{O}_Y(p) \otimes_{\mathcal{O}_Y} \mathcal{O}_Y(q)) \to \Omega^\delta(\mathcal{O}_Y(p + q)) \xrightarrow{\sim} \mathcal{O}_Y(\gamma + \gamma')
\]
deduced from \((10.6.21)\) and the inverse of the isomorphism \((16.7.5)\), to obtain \((16.7.6)\), and it is easily seen that the resulting map is independent of the choice of \(\delta\); details left to the reader. Especially, \((16.7.6)\) restricts to an isomorphism on \(U_{\gcd(\gamma, \gamma')}(R)\), where \(\gcd(\gamma, \gamma')\) is the greatest common divisor of \(\gamma\) and \(\gamma'\) (here we let \(\gcd(0, 0) := 0\); actually, it is not difficult to show that \((16.7.6)\) is an isomorphism on the open subset \(U_\gamma(R) \cup U_{\gamma'}(R)\)). Furthermore, let
\[
\pi(\gamma) : Y(\gamma) \to \text{Spec } R_0 \quad \text{and} \quad \pi : Y \to \text{Spec } R_0
\]
be the structure morphisms; the morphism \((10.6.22)\) induces a natural map
\[
\pi^* R_\gamma^\gamma \xrightarrow{\sim} \Omega^\gamma(\pi)^* R_1^\gamma \to \Omega^\gamma(\mathcal{O}_Y(\gamma)) = \mathcal{O}_Y(\gamma) \quad \text{for every } \gamma \in \Gamma \setminus \{0\}
\]
which restricts to an epimorphism on \(U_\gamma(R)\).

16.7.7. Let \(R'\) be another \(\mathbb{Q}_+\)-graded ring, and \(\varphi : R \to R'\) a morphism of \(\mathbb{Q}_+\)-graded rings; set \(Y' := \text{Proj } R', Y'(\gamma) := \text{Proj } R'(\gamma)\), and denote by \(\Omega^\gamma(\gamma) : Y'(\gamma) \to Y'\) and \(\Omega^\gamma(n\gamma) : Y'(\gamma) \to Y'(n\gamma)\) the induced morphism, for every \(\gamma \in \mathbb{Q}_{>0}\) and every integer \(n > 0\). The restriction of \(\varphi\)
\[
\varphi(\gamma) : R(\gamma) \to R'(\gamma) \quad \text{for every } \gamma \in \mathbb{Q}_{>0}
\]
is a morphism of \(\mathbb{N}\)-graded rings, whence a morphism \(\text{Proj } \varphi(\gamma) : G(\varphi(\gamma)) \to Y'(\gamma)\) (notation of \((10.6.5)\)). Moreover, it is easily seen that
\[
\Omega^\gamma(n\gamma) G(\varphi(\gamma)) = G(\varphi(\gamma)) \quad \text{for every } \gamma \in \mathbb{Q}_{>0} \text{ and every integer } n > 0.
\]
Furthermore, the resulting diagram of schemes
\[
\begin{array}{ccc}
G(\varphi(\gamma)) & \xrightarrow{\text{Proj } \varphi(\gamma)} & Y'(\gamma) \\
\Omega^\gamma(n\gamma) \downarrow & & \Omega^\gamma(n\gamma) \downarrow \\
G(\varphi(\gamma)) & \xrightarrow{\text{Proj } \varphi(\gamma)} & Y'(n\gamma)
\end{array}
\]
commutes for every such \(\gamma\) and \(n\). Thus, we may set
\[
G(\varphi) := \Omega^\gamma(\gamma) G(\varphi(\gamma)) \quad \text{for any } \gamma \in \mathbb{Q}_{>0}
\]
and the colimit of the system \((\text{Proj } \varphi(\gamma) \mid \gamma \in \mathbb{Q}_+)\) is a well defined morphism
\[
\text{Proj } \varphi : G(\varphi) \to Y.
\]
Remark 16.7.8. (i) Set \( R_+ := \bigoplus_{\gamma \in \mathbb{Q}_{>0}} R_\gamma \), and define likewise \( R'_+ \). Let also \( f' \in R'_+ \) be any homogeneous element; we claim that \( D_+(f') \subset G(\varphi) \) if and only if \( f' \) lies in the radical \( J \) of the ideal of \( R' \) generated by \( \varphi(R_+) \). Indeed, say that \( f' \in R'_+ \) for some \( \gamma \in \mathbb{Q}_{>0} \); if \( D_+(f') \subset G(\varphi) \), then \( D_+(f') \subset G(\varphi(\gamma)) \) as well, so \( f' \) lies in the radical of the ideal of \( R(\gamma) \) generated by \( \varphi(\gamma)(\gamma) \) (see the discussion of \( \mathbf{10.6.5} \)), and therefore \( f' \) lies in \( J \) as well. Conversely, if \( f' \in J \), we may find \( n, k \in \mathbb{N} \), and elements \( \nu(i) \in \mathbb{Q}_{>0} \), \( a_i \in R_{\nu(i)} \), \( f_i \in R'_{\nu(i)} \) for \( i = 1, \ldots, k \), such that \( f^m = \sum_{i=1}^k f_i \cdot \varphi(a_i) \). Then, pick any common divisor \( \delta \) of \( \gamma, \nu(1), \ldots, \nu(k) \) in \( \mathbb{Q}_{>0} \); it follows that \( f' \) lies in the radical of the ideal of \( R(\delta) \) generated by \( \varphi(\delta)(\delta) \), whence \( D_+(f') \subset G(\varphi(\delta)) \), and finally \( D_+(f') \in G(\varphi) \).

(ii) Especially, if \( \varphi(R_+) \) generates the ideal \( R'_+ \) of \( R' \), then \( G(\varphi) = Y' \).

16.7.9. We shall apply the foregoing constructions to the situation contemplated in \( \mathbf{16.4.4} \); we let \( (A, u_0) \) be a pair consisting of a ring \( A \), and a ring homomorphism

\[
u_0 : R_{0,0} := \mathbb{Z}[T_1^{1/p^\infty}, \ldots, T_r^{1/p^\infty}] \to A.
\]

Also, we denote by \( T_s P_r \subset P_r := \mathbb{N}[1/p]^\mathbb{N} \) the ideal generated by \( N^\mathbb{N} \), we set \( \Gamma := \mathbb{N}[1/p] \), and we consider the \( \Gamma \)-graded angular Rees algebra

\[R(A) := \bigoplus_{\gamma \in \Gamma} T_\gamma A.
\]

Hence, for every \( \gamma \in \Gamma \), the direct summand \( R(A)_\gamma \) is the ideal of \( A \) generated by all products of the form \( u_0(T_1^{a_1} \cdots T_r^{a_r}) \), where \( (a_1, \ldots, a_r) \in P_r \) is any sequence of exponents such that \( a_1 + \cdots + a_r = \gamma \). The angular blowing up of the ideal \( T_\bullet A_0 \) is the morphism

\[Y := \text{Proj} (R(A)/Q_+) \to X := \text{Spec} A
\]

(notation of definition \( \mathbf{7.6.9}(v) \)). Notice that \( U_\gamma(R(A)/Q_+) = Y \) for every \( \gamma \in \Gamma \setminus \{0\} \).

Theorem 16.7.10. In the situation of \( \mathbf{16.7.9} \), suppose furthermore that the ring \( A \) fulfills the condition of lemma \( \mathbf{16.4.5} \). Then, for every \( s \in \mathbb{R} \) we have :

(i) The natural maps \( T_\bullet [s] \cdot A \to T_\bullet [s] \cdot H^0(Y, O_Y) \to H^0(Y, T_\bullet [s] O_Y) \) are isomorphisms.

(ii) \( H^p(Y, T_\bullet [s] O_Y) = 0 \) for every \( p > 0 \).

(iii) The ring \( R(A) \) fulfills the condition of lemma \( \mathbf{16.4.5} \).

(iv) For every \( t \in \mathbb{R} \), the natural map

\[T_\bullet [s] A \otimes_A T_\bullet [t] A \to T_\bullet [t+s] A
\]

is an isomorphism.

Proof. Notice first that \( T_\bullet [s] \cdot H^0(Y, O_Y) \) and \( H^0(Y, T_\bullet [s] O_Y) \) are \( A \)-submodules of \( H^0(Y, O_Y) \); hence, the map \( T_\bullet [s] \cdot H^0(Y, O_Y) \to H^0(Y, T_\bullet [s] O_Y) \) is injective, and in order to show (i), it suffices to prove that the composition \( T_\bullet [s] A \to H^0(Y, T_\bullet [s] O_Y) \) is an isomorphism.

Now, for every \( k \in \mathbb{N} \) we set \( \Gamma_k := \{n/k^k \mid n \in \mathbb{N} \} \subset \Gamma \), and consider the \( \Gamma_k \)-graded ring

\[S_k := \bigoplus_{\gamma \in \Gamma_k} I_{k^\gamma} A \quad \text{and the \( \mathbb{Q} \)-graded ring} \quad S'_k := (S_k)/Q_+
\]

where \( I_k \subset R_{r,0} \) denotes the ideal generated by \( (T_1^{1/p^k}, \ldots, T_r^{1/p^k}) \). The natural inclusion map is a morphism of \( \mathbb{Q}_- \)-graded rings \( S_k \to S'_k \) for every \( k \in \mathbb{N} \), and the colimit of the resulting system \( (S'_k \mid k \in \mathbb{N}) \) is \( R(A)/\gamma_+ \). Set as well

\[Y_k := \text{Proj} S'_k \quad \text{for every} \ k \in \mathbb{N}.
\]
There follows a system of affine morphisms of $X$-schemes $(Y_k \mid k \in \mathbb{N})$, and in view of [50, Ch.IV, Prop.8.2.3] it is easily seen that its limit is $Y$. For every $k \in \mathbb{N}$, let $\pi_k : Y \to Y_k$ be the natural projection. Notice that the direct summand $S^\prime_{k,\gamma}$ of $S'$ is an ideal of $A$, and

$$\bigcup_{k \in \mathbb{N}} S^\prime_{k,\gamma} = T^{(\gamma)} A \quad \text{for every } \gamma \in \Gamma.$$ 

We deduce natural identifications as in remark 10.6.39(iv) for every $\gamma \in \Gamma$ and every $k \in \mathbb{N}$

$$\mathcal{O}_{Y_k}(\gamma) \overset{\sim}{\to} S^\prime_{k,\gamma} \mathcal{O}_{Y_k} \quad \text{colim}_{i \in \mathbb{N}} \pi_i^{-1} \mathcal{O}_{Y_i}(\gamma) \overset{\sim}{\to} \mathcal{O}_Y(\gamma) \overset{\sim}{\to} T^{(\gamma)} \mathcal{O}_Y$$

whence, by proposition 10.1.10(ii), a natural isomorphism of $A$-modules:

$$(16.7.11) \quad H^p(Y, T^{(\gamma)} \mathcal{O}_Y) \overset{\sim}{\to} \colim_{i > s} H^p(Y, \mathcal{O}_Y(\gamma)) \quad \text{for every } p \in \mathbb{N} \text{ and every } \gamma \in \Gamma.$$ 

By the same token, we have as well a natural isomorphism

$$(16.7.12) \quad H^p(Y, T^{[s]} \mathcal{O}_Y) \overset{\sim}{\to} \colim_{\gamma > s} H^p(Y, T^{(\gamma)} \mathcal{O}_Y) \quad \text{for every } p \in \mathbb{N} \text{ and every } s \in \mathbb{R}.$$ 

**Claim 16.7.13.** There exists an integer $c > 0$ such that for every $k \in \mathbb{N}$ and every $\gamma \in \Gamma_k$, the inclusion map $i : S^\prime_{k,\gamma+c/p^k} \mathcal{O}_{Y_k} \to S^\prime_{k,\gamma} \mathcal{O}_{Y_k}$ induces the zero map in cohomology:

$$0 = H^p(Y_k, i) : H^p(Y_k, \mathcal{O}_{Y_k}(\gamma + c/p^k)) \to H^p(Y_k, \mathcal{O}_{Y_k}(\gamma)) \quad \text{for every } p > 0$$

and moreover the kernel and cokernel of the natural morphism of inverse systems

$$(S^\prime_{k,n/p^k}) \to H^0(Y_k, \mathcal{O}_{Y_k}(n/p^k)) \quad \text{for every } n \in \mathbb{N}$$

is uniformly essentially zero with step $\leq c$.

**Proof of the claim.** Recall that $Y_k$ is the colimit of the filtered system $(Y^\cdot_k(\gamma) \mid \gamma \in \Gamma_k)$ defined as in (16.7.1). By inspecting the construction, it is easily seen that $Z_k := Y^\cdot_k(1/p^k)$ is the blowing up morphism of the ideal of $\mathcal{O}_X$ generated by the sequence $\ell^{(k)} := (u_0(T^1_1/p^k), \ldots, u_0(T^1_k/p^k))$. Say now that $\gamma = a/p^k$; according to (16.7.5), we have a natural identification

$$\mathcal{O}_{Y_k}(\gamma + d/p^k) \overset{\sim}{\to} \Omega^{(1/p^k)} \mathcal{O}_{Z_k} (a + d) \quad \text{for every } d \in \mathbb{N}.$$ 

On the other hand, lemma 16.4.5(i) implies that the ring $A$ satisfies condition (a)$_{\ell^{(k)}}$ with step $\leq r$. Then, by theorem 10.6.50 and remark 10.6.57 there exists a constant $c \in \mathbb{N}$ independent of $k$ and $a$, such that the inclusion map $\mathcal{O}_{Z_k}(a) \to \mathcal{O}_{Z_k}(a + c)$ induces the zero map in cohomology

$$H^p(Z_k, \mathcal{O}_{Z_k}(a + c)) \to H^p(Z_k, \mathcal{O}_{Z_k}(a)) \quad \text{for every } p > 0$$

and moreover, the kernel and cokernel of the morphism of inverse systems

$$(I^k_a A \to H^0(Z_k, \mathcal{O}_{Z_k}(n))) \quad \text{for every } n \in \mathbb{N}$$

are uniformly essentially zero with step $\leq c$. Both assertions of the claim are an immediate consequence. \hfill \Box

Now, in view of (16.7.12), in order to prove (ii), it suffices to show that for every $\gamma > s$ there exists $\gamma' \in \mathbb{Q}_+$ with $s < \gamma' < \gamma$, and such that the natural map

$$H^p(Y, T^{(\gamma)} \mathcal{O}_Y) \to H^p(Y, T^{(\gamma')} \mathcal{O}_Y)$$

vanishes. To this aim, pick any $k \in \mathbb{N}$ such that $c/p^k < \gamma - s$, where $c \in \mathbb{N}$ is as in claim 16.7.13, by virtue of (16.7.11), we get the sought vanishing with $\gamma' := \gamma - c/p^k$. A similar argument proves also assertion (i) : details left to the reader.

(iii): It suffices to check that for every $\gamma' < \gamma$ in $\mathbb{N}[1/p]$ the inclusion $I^{(\gamma')}_{r_0} \subset I^{(\gamma)}_{r_0}$ induces the zero morphism

$$\text{Tor}^R_{i,\gamma}(R_{r_0}/I^{(\gamma)}_{r_0}, \mathbb{R} \langle A \rangle) \to \text{Tor}^R_{i,\gamma}(R_{r_0}/I^{(\gamma')}_{r_0}, \mathbb{R} \langle A \rangle) \quad \text{for every } i > 0.$$
However, for every $k \in \mathbb{N}$ set $A_{r,k} := \mathbb{Z}[T_1^{1/p^k}, \ldots, T_r^{1/p^k}]$ and let $J_{r,k} \subset A_{r,k}$ be the ideal generated by $(T_1^{1/p^k}, \ldots, T_r^{1/p^k})$; we regard $A$ as an $A_{r,k}$-algebra for every $k \in \mathbb{N}$, via restriction of scalars along the inclusion map $A_{r,k} \to R_{r,0}$, and we let $R_k(A)$ be the Rees $A$-algebra associated with the $J_{r,k}A$-adic filtration of $A$. Now, say that $\gamma = c/p^n$ and $\gamma' = c'/p^n$ for some $c, c', n \in \mathbb{N}$; in view of claim \[7.11.37\](i) it suffices to show that for every $i > 0$ there exists $k_0 \in \mathbb{N}$ such that the inclusion $J_{r,p^{k_0}+k} \subset J_{r,p^{k_0}+k}$ induces the zero morphism

\[
\text{Tor}_i^{A_{r,n+k}}(A_{r,n+k}/J_{r,n+k}^c, R_{n+k}(A)) \to \text{Tor}_i^{A_{r,n+k}}(A_{r,n+k}/J_{r,n+k}^c, R_{n+k}(A))
\]

for every $k \geq k_0$. However, for every $k \in \mathbb{N}$ let $f^{(k)} := (u_0(T_1^{1/p^k}), \ldots, u_0(T_r^{1/p^k}))$, and denote by $g^{(k)}$ the image of $f^{(k)}$ under the natural ring homomorphism $A \to R_k(A)$. By lemma \[16.4.5\](i) we know that $A$ fulfills condition (a) of $\text{Tor}_i^{A_{r,n+k}}$ with step $< r$; then corollary \[7.9.20\](ii) and remark \[7.9.25\] imply that $R_k(A)$ fulfills condition (a) of $\text{Tor}_i^{A_{r,n+k}}$ with a step independent of $k$; explicitly, the latter means that the inverse system $(\text{Tor}_i^{A_{r,k}}(A_{r,k}/J_{r,k}^c, R_k(A)) \mid t \in \mathbb{N})$ is uniformly essentially zero for every $k \in \mathbb{N}$ and every $i > 0$, with a step independent of $k$. The assertion is an immediate consequence.

(iv): It suffices to show that the natural map

\[
T^{(s)}_0 A \otimes_A T^{(t)}_0 A \to T^{(t+s)}_0 A
\]

is an isomorphism for every $t \in \mathbb{R}_+$. However, (iii) easily implies that the natural map

\[
T^{(s)}_0 R_{r,0} \otimes_{R_{r,0}} T^{(t)}_0 A \to T^{(t+s)}_0 A
\]

is an isomorphism, and the latter factors through \[\text{16.7.14}\] and a surjection $T^{(s)}_0 R_{r,0} \otimes_{R_{r,0}} T^{(t)}_0 A \to T^{(s)}_0 A \otimes_A T^{(t)}_0 A$, whence the contention. \qed

16.7.15. In the situation of \[16.7.9\], suppose that $A$ fulfills the condition of lemma \[16.4.5\] and is endowed with a $\mathbb{Q}_+$-grading which makes it an $A_0$-subalgebra of $A_0[\mathbb{Q}_+]$ (where $A_0 \subset A$ is the subring of homogeneous elements of degree zero), and moreover suppose that the image of $\varphi_0$ lies in $A_0$. In this case, the foregoing considerations apply to $A_0$ as well, and we get a well defined $\Gamma$-graded subring $R(A_0)$ of $R(A)$, as well the angular blowing up morphism

\[
Y_0 := \text{Proj} (R(A_0)/\mathbb{Q}_+) \to X_0 := \text{Spec} A_0.
\]

Notice also that $R(A)$ carries a natural $(\Gamma \times \mathbb{Q}_+)$-graded ring structure: namely,

\[
\text{gr}_{\gamma,t}(R(A)) := T^{(\gamma)}_\bullet A_t \quad \text{for every } (\gamma, t) \in \Gamma \times \mathbb{Q}_+
\]

which is an ideal in $A_0$, for every such $(\gamma, t)$, and we set

\[
R(A_t) := \bigoplus_{\gamma \in \Gamma} T^{(\gamma)}_\bullet A_t = A_t R(A_0) \quad \text{for every } t \in \mathbb{Q}_+.
\]

**Corollary 16.7.16.** In the situation of \[\text{16.7.15}\], for every $s \in \mathbb{R}_+$ and every $t \in \mathbb{Q}_+$ we have:

(i) The natural maps $T^{(s)}_0 A_t \to T^{(s)}_0 A_t \cdot H^0(Y_0, \mathcal{O}_{Y_0}) \to H^0(Y_0, T^{(s)}_0 A_t \mathcal{O}_{Y_0})$ are isomorphisms.

(ii) $H^p(Y_0, T^{(s)}_0 A_t \mathcal{O}_{Y_0}) = 0$ for every $p > 0$.

**Proof.** Let $i : A_0 \to A$ and $R(i) : R(A_0) \to R(A)$ be the inclusion maps; since $i(R(A_0)_+)$ generates the ideal $R(A)_+$ of $R(A)$, then $i$ induces a morphism of schemes $\text{Proj} R(i) : Y \to Y_0$
(remark 16.7.8(ii)) fitting into the commutative diagram

$$
\begin{array}{ccc}
Y & \xrightarrow{\text{Proj} R(i)} & Y_0 \\
\pi & \downarrow & \downarrow \pi_0 \\
X & \xrightarrow{\text{Spec} i} & X_0.
\end{array}
$$

To ease notation, we let $\varphi_X := \text{Spec} i$ and $\varphi_Y := \text{Proj} R(i)$. Notice that

$$
T_{*}^{[r]} R(\langle A \rangle_{(f)}) = T_{*}^{[r]} \left( \bigoplus_{t \in \mathbb{Q}^+} R(\langle A_{t} \rangle_{(f)}) \right) = \bigoplus_{t \in \mathbb{Q}^+} T_{*}^{[r]} A_t \langle A \rangle_{(f)}
$$

for every homogeneous element $f \in R(\langle A_{0} \rangle)$, which shows that

$$
\varphi_Y T_{*}^{[r]} \mathcal{O}_Y = \bigoplus_{t \in \mathbb{Q}^+} T_{*}^{[r]} A_t \mathcal{O}_{Y_0}.
$$

Since $\varphi_Y$ is an affine morphism, we deduce

$$
H^p(Y, T_{*}^{[r]} \mathcal{O}_Y) = H^p(Y_0, \varphi_Y T_{*}^{[r]} \mathcal{O}_Y) = \bigoplus_{t \in \mathbb{Q}^+} H^p(Y_0, T_{*}^{[r]} A_t \mathcal{O}_{Y_0})
$$

and combining with theorem 16.7.10 we get the corollary.

\[\square\]

**Example 16.7.17.** (i) According to proposition 16.4.10, theorem 16.7.10 applies especially to the case where $A$ is perfectoid. In this case there exist unique $\beta_1, \ldots, \beta_r \in E := E(A)$ such that $u_0(T_0^{1/p^k}) = \prod_{i=1}^r (\beta_i^{1/p^k})$ for every $i = 1, \ldots, r$ and every $k \in \mathbb{N}$, so we may regard as well $E$ as an $\mathcal{R}_{r,0}$-algebra via the unique ring homomorphism

$$
R_{r,0} \to E : T_i \mapsto \beta_i \quad \text{for every } i = 1, \ldots, r.
$$

(ii) More generally, proposition 16.6.5 shows that theorem 16.7.10 applies to the case where $A$ is the graded subring of a perfectoid ring $(A^\wedge, A)$ with $\Delta$-graded structure, where $\Delta$ is an integral $p$-perfect monoid, provided the elements $\beta_1, \ldots, \beta_r$ as in (i) are homogeneous elements of the $\Delta$-graded subring of $E(A)$.

(iii) A ring $A$ as in (ii) is given by example 16.6.12: we take a perfectoid ring $A_0$, a second finite family $\beta'_0 := (\beta'_1, \ldots, \beta'_{r'})$ of elements of $E_0 := E(A_0)$, we set $I := \beta'_0 E_0$, and let $A_t$ be the topological closure in $A_0$ of $I^{(t)} A_0$ for every $t \in \Delta := \mathbb{N}[1/p]$. Then, clearly corollary 16.7.16 shall apply to the $\mathbb{Q}_+^\text{-graded}$ ring $A/\mathbb{Q}_+^*$.

(iv) Let $A_0, E_0, \beta'_0$ and $A$ be as in (iii), and suppose that also the sequence $\beta'_0$ lies in $E(A_0)$. Suppose moreover that $I$ is an ideal of adic definition for $E_0$. In this case, the ideal $I^{(t)} A_0$ is also open in $A_0$ (corollary 16.3.40(ii)), and therefore it coincides with $A_t$ for every $t \in \mathbb{N}[1/p]$. Especially, $\text{gr}_{(\gamma, t)} R(A) = T_{*}^{(\gamma, t)} I^{(t)} A_0$ for every $(\gamma, t) \in \Gamma \times \mathbb{N}[1/p]$.

(v) In the situation of (iv), suppose furthermore that the ideal $T_{*}^{0} E_0 \subset E_0$ generated by $\beta_0$ is open. Notice that $T_{*}^{(0)} E_0$ is the radical of $T_{*} E_0$ (details left to the reader). It follows that for every $s \in \mathbb{N}[1/p] \setminus \{0\}$ there exists $s' > 0$ such that $I^{(s)} E_0 \subset T_{*}^{(s')} E_0$, whence $I^{(s)} A_0 \subset T_{*}^{(s')} A_0$ (corollary 16.3.49(ii)). Therefore :

$$
I^{(t+s)} A_0 \subset I^{(t)} T_{*}^{(0)} A_0 \subset I^{(t)} A_0 \quad \text{for every } t, s \in \mathbb{N}[1/p] \text{ with } s > 0.
$$

**Corollary 16.7.18.** In the situation of 16.7.9, suppose that $A$ is perfectoid, and let $I$ be any finitely generated ideal of adic definition of $E := E(A)$. With the notation of example 16.7.17(v), for every $t \in \mathbb{R}_+$ we have :

(i) The natural maps $I^{[t]} A \to I^{[k]}$, $H^0(Y, \mathcal{O}_Y) \to H^0(Y, I^{[t]} \mathcal{O}_Y)$ are isomorphisms.

(ii) $H^p(Y, I^{[t]} \mathcal{O}_Y) = 0$ for every $p > 0$. 

Proof. With the notation of example [16.7.17](v), notice that
\[ H^p(Y, I^t \mathcal{T}_{\bullet}^0 \mathcal{O}_Y) = \colim_{s \geq t} H^p(Y, I^s \mathcal{T}_{\bullet}^0 \mathcal{O}_Y). \]

On the other hand, example [16.7.17](v) implies that \( I^t A = I^t \mathcal{T}_{\bullet}^0 A \) for every \( t \in \mathbb{R}_+ \). To conclude, it suffices to invoke corollary [16.7.16] as in example [16.7.17](iii,iv): i.e. with \( A_0 \) and \( Y_0 \) replaced by the current \( A \) and respectively \( Y \), and with \( A \) replaced by the \( \mathbb{Q}_+ \)-graded ring \( A_{q/+} \), where \( A_{q/+} := I^s A \) for every \( s \in \mathbb{N}[1/p] \).

Definition 16.7.19. We say that a topological ring \((A, \mathcal{T})\) is a formal \( P \)-ring (resp. a formal perfectoid ring) if it is adic with a finitely generated ideal of adic definition, and the separated completion of \((A, \mathcal{T})\) is a \( P \)-ring (resp. a perfectoid ring).

Remark 16.7.20. Let \((A, \mathcal{T})\) be any topological ring.

(i) Suppose that \((A, \mathcal{T})\) is a \( P \)-ring. Then, any ideal of definition of the \( P \)-ring \( A \) is also an ideal of adic definition of the adic ring \( A \). Remark [16.2.4] implies that the converse holds if and only if \( A \) is an \( \mathbb{F}_p \)-algebra. Indeed, if \( I \) is any ideal of adic definition of \( A \), then any power \( I^n \) is also an ideal of adic definition, but if \( p \) does not vanish in \( A \), then one such power will not contain \( p \), whence the contention.

(ii) Let \( \varphi : (A, \mathcal{T}) \to (A', \mathcal{T}') \) be an adic morphism of topological rings, and suppose that \( \varphi \) is a weakly étale ring homomorphism. Then [59] Lemma 3.1.2(i) implies that \( \varphi \) is adically weakly étale (see definition [8.3.23](iii)).

Theorem 16.7.21. Let \( f : A \to B \) be a \( c \)-adically weakly étale morphism of topological rings.

(i) If \( A \) and \( B \) are \( f \)-adic and \( A \) is a formal \( P \)-ring (resp. a formal perfectoid ring), the same holds for \( B \).

(ii) If \( f \) is \( c \)-adically faithfully flat, the following holds:

(a) If \( B \) is \( f \)-adic and \( A \) and \( B \) are complete and separated, \( A \) is \( f \)-adic and \( f \) is adic.

(b) If \( B \) is a formal \( P \)-ring (resp. a formal perfectoid ring), the same holds for \( A \).

Proof. (i): In light of lemma [8.3.32](iii,iv), we may assume that \( A \) and \( B \) are complete and separated, in which case \( A \) is a \( P \)-ring (resp. a perfectoid ring), \( f \) is adically weakly étale (lemma [8.3.23](1.c)), and we have to show that \( B \) is a \( P \)-ring (resp. perfectoid).

Suppose first that \( A \) is a \( P \)-ring, and let \( I \) be any ideal of definition of \( A \). It suffices to check that \( IB \) is an ideal of definition of \( B \). However, the natural map \( B/I^2 B \to B/IB \) is an isomorphism, by remark [8.3.3](ii), so we come down to checking that the Frobenius endomorphism of \( B/I^2 B \) is surjective. However, the induced ring homomorphism \( A/I^2 \to B/I^2 B \) is weakly étale by assumption; since the Frobenius endomorphism of \( A/I^2 \) is surjective by assumption, the assertion then follows easily from [59] Th.3.5.13(ii).

Next, suppose that \( A \) is perfectoid. Due to remark [16.3.56], we may assume that \( p \in I' \), where \( t \in \mathbb{N} \) is defined as in [16.3.53], in terms of the length of a system of generators for \( I \).

Set \( J := I^{(t)} \); taking into account (i) and theorem [16.3.62], we are then reduced to checking that the morphism of graded rings
\[ \Phi_{IB} : \text{gr}^* IB \to \text{gr}^* JB \]

is an isomorphism. However, since \( f \otimes_A A/I^n \) is flat for every \( n \in \mathbb{N} \), we get induced graded ring isomorphisms
\[ \varphi_I : B \otimes_A \text{gr}^* IA \to \text{gr}^* IB \quad \varphi_J : B \otimes_A \text{gr}^* JA \to \text{gr}^* JB \]
and \( \varphi_I \) identifies the map
\[ \text{gr}^* f : \text{gr}^* IA \to \text{gr}^* IB \]
with the base change \( f \otimes_A \gr^*_A \). Especially, since \( f \otimes_A A/I \) is weakly étale, the same holds for \( \gr^*_f \) ([59] Lemma 3.1.2(ii)). Moreover, denote by \( (\gr^*_A)_{\Phi} \) the \( \gr^*_A \)-algebra whose underlying ring is \( \gr^*_f \) and whose structure map is the Frobenius endomorphism \( \Phi_{\gr^*_A} \), and define likewise \( (\gr^*_B)_{\Phi} \); by [59] Th.3.5.13(ii), the maps \( \psi_J \) and \( \gr^*_f \) induce an isomorphism

\[
\psi_J : B \otimes_A (\gr^*_A)_{\Phi} \simto \gr^*_f B \otimes_{\gr^*_A} (\gr^*_f)_{\Phi} \simto (\gr^*_f B)_{\Phi} \quad b \otimes a \mapsto b^p \cdot \gr^*_f(a).
\]

Summing up, we get a commutative diagram of ring homomorphisms

\[
(16.7.22)
\]

whose vertical arrows are isomorphisms. Lastly, since \( A \) is a formal perfectoid ring, \( \Phi_f \) is an isomorphism as well (theorem 16.3.62), whence the assertion.

(ii.a): Let \( J \) be any finitely generated ideal of adic definition of \( B \), and \( (I_\lambda | \lambda \in \Lambda) \) a cofiltered system of ideals that defines the linear topology of \( A \). By assumption, \( (I_\lambda B)^{^c} \) is open in \( B \), hence \( I_\lambda B = (I_\lambda B)^{^c} \) for every \( \lambda \in \Lambda \) (lemma 8.3.21(ii.b)); then the induced map

\[
f_\lambda : A_\lambda := A/I_\lambda \rightarrow B_\lambda := B/I_\lambda B
\]

is weakly étale and faithfully flat for every \( \lambda \in \Lambda \). Also by assumption, we may find \( \mu \in \Lambda \) such that \( I_\mu B \subset J^2 \). Hence, \( JB_\mu \) is contained in the nilradical \( \text{nil}(B_\mu) \) of \( B_\mu \), and it follows easily from claim 14.3.27(i) that

\[
\text{nil}(B_\mu) = \text{nil}(A_\mu) \cdot B_\mu.
\]

Therefore, we may find a finitely generated ideal \( K' \subset \text{nil}(A_\mu) \) such that \( JB_\mu \subset K'B_\mu \). Pick a finitely generated ideal \( K \subset A \) such that \( KA_\mu = K' \). It follows easily that \( J \subset KB + J^2 \). However, \( B \) is complete and \( J \) is topologically nilpotent in \( B \), so \( J \) lies in the Jacobson radical of \( B \), and consequently \( J \subset KB \), by Nakayama’s lemma. On the other hand, by construction, we may find \( n \in \mathbb{N} \) such that \( K^n = 0 \), whence \( K^n \subset I_\mu \), and therefore \( K^n B \subset J^2 \).

Summing up, we conclude that \( KB \) is an ideal of adic definition of \( B \). For every \( n \in \mathbb{N} \), pick \( \nu(n) \in \Lambda \) such that \( I_{\nu(n)} B \subset J^n \); then \( I_{\nu(n)} B_\lambda \subset K^n B_\lambda \) for every \( \lambda \in \Lambda \), so that \( I_{\nu(n)} A_\lambda \subset K^n A_\lambda \) as \( f_\lambda \) is faithfully flat. We deduce that the topological closure \( (K^n)^{^c} \) in \( K^n \) contains \( I_{\nu(n)} \), and especially, it is an open ideal of \( A \), for every \( n \in \mathbb{N} \). On the other hand, for every \( \lambda \in \Lambda \) we may find \( k(\lambda) \in \mathbb{N} \) such that \( J^{2k(\lambda)} \subset I_\lambda B_\lambda \), so that \( K^{n-k(\lambda)} A_\nu B_\nu \subset I_\lambda A_\nu B_\nu \) again since \( f_\nu \) is faithfully flat; then, since \( f_\nu \) is closed in \( A \), we deduce that \( K^{n-k(\lambda)} \subset I_\lambda , \) for every \( \lambda \in \Lambda \). Summing up, we see that the topology of \( A \) is c-adic, hence \( f \)-adic, by lemma 8.3.21(ii.a). Then \( f \) is adic, by lemma 8.3.24(i.c).

(ii.b): In light of lemma 8.3.32(iii), we may replace \( f \) by \( f^\wedge \), and assume from start that \( A \) and \( B \) are complete and \( B \) is a P-ring (resp. perfectoid), and we need to show that the same holds for \( A \). However, (ii.a) already says that \( A \) is f-adic, and \( f \) is adic. Suppose first that \( B \) is a P-ring, and pick any finitely generated ideal of adic definition for \( A \); without loss of generality we may assume that \( J \) is an ideal of definition for the P-ring \( B \), and that \( IB \subset J \). Set \( A_n := A/I^{n+1} \) and \( B_n := B/I^{n+1}B \) for every \( n \in \mathbb{N} \), and notice that \( JB_0 \) is nilpotent ideal of \( B_0 \); arguing as in the proof of (ii.a), we deduce that there exists a finitely generated ideal

\[
(16.7.23)
\]

such that \( JB_0 \subset K_0 B_0 \). Then, the preimage \( K \) of \( K_0 \) in \( A \) is a finitely generated ideal such that \( JB \subset KB \); hence \( p^2 \in K^2 B_n \) for every \( n \in \mathbb{N} \). Since the induced map \( A_n \rightarrow B_n \) is faithfully flat, it follows that \( p \in K^2 A_n \) for every \( n \in \mathbb{N} \), so \( p \) lies in the topological closure of \( K^2 \) in \( A \); but \( (K^2)^{^c} = K^2 \), since \( K \) is open in \( A \) by construction. Lastly, (16.7.23) implies that \( K^n \subset I \)
for some sufficiently large \( n \in \mathbb{N} \); thus, \( K \) is also an ideal of adic definition of \( A \), and we are reduced to checking that the Frobenius endomorphism \( \Phi_{A/J} \) of \( A/J^2 \) is surjective. However, by lemma \( [16.2.3] \) the Frobenius endomorphism \( \Phi_{B/JB} \) is surjective; by [59, Th.3.5.13(ii)], it follows that \( \Phi_{A/J} \otimes_{A/J} B/J^2B \) is also surjective. But the induced map \( A/J^2 \to B/J^2B \) is faithfully flat, whence the contention.

Lastly, suppose that \( B \) is perfectoid; by the foregoing, we know already that \( A \) is a \( P \)-ring, and by remark \([16.3.56]\) we may find an ideal of definition \( I \) of \( A \) such that \( p \in I^t \), where \( t \in \mathbb{N} \) is defined as in \([16.3.55]\). We set \( J := I^{(p)} \); arguing as in the proof of (i), we get a commutative diagram \([16.7.22]\), whose vertical arrows are isomorphisms. Now, notice that, since \( f \) is adic, \( IB \) is an ideal of definition of \( B \), so the bottom horizontal arrow of \([16.7.22]\) is an isomorphism; hence the same holds for \( B \otimes_{A} \Phi_I = (B/IB) \otimes_{A/I} \Phi_I \). But by assumption, \( f \) induces a faithfully flat map \( A/I \to B/IB \), so \( \Phi_I \) is an isomorphism, and therefore \( A \) is perfectoid, by theorem \([16.3.62] \).

16.7.24. Let \( \mathcal{U} := (U, \mathcal{F}, A_U^+) \) be any perfectoid quasi-affindoid scheme, and set \( U_{E} := E(U) \) (notation of \([16.5.20]\)), so that \( U_{E} := (E(U), \mathcal{F}, E_U^+, \text{where } E_U^+ := E(A_U^+) \). Let as well

\[
A_U := \mathcal{O}(U), \quad E_U := \mathcal{O}(E(U))
\]

and pick a perfectoid subring of definition \( A \) of \( A_U \) such that \( A_U^+ \) is the integral closure of \( A \) in \( A_U \) and such that the induced map \( U \to \text{Spec } A \) is an open immersion (by theorem \([16.5.13] \) and lemma \([15.6.10] \) (i)), the ring \( A_U^+ \) is one such subring of definition, and recall that \( E := E(A) \) is a ring of definition of \( E_U \). We denote as usual by \( \varphi_U^+ : E_U \to A_U \) the continuous map of monoids provided by proposition \([16.4.28] \), and recall that \( \varphi_U^+ \) restricts to a continuous map \( \pi_A : E \to A \). Now, let \( e_0, \ldots, e_n \) be a finite system of elements of \( E_U \) that generates an open ideal; according to claim \([16.6.35] \) the system \( (a_i := \varphi_U^+(e_i) \mid i = 0, \ldots, n) \) generates an open ideal of \( A_U \), so we may consider the rational subset

\[
R := R_A \left( \frac{a_1}{a_0}, \ldots, \frac{a_n}{a_0} \right) \cap \text{Spa } U
\]

and the corresponding topological rings \( \mathcal{O}_{\text{Spa } U}^\wedge(R) \) and \( \mathcal{O}_{\text{Spa } U}^\wedge+(R) \), defined as in \([15.5.11] \). Recall the construction of \( \mathcal{O}_{\text{Spa } U}^\wedge(R) \) : first, there is a natural \( f \)-adic topology on the localization \( A_R := A_U[1/a_0] \) such that the localization map \( A_U \to A_R \) is \( f \)-adic; and the subring

\[
B_R := A[a_i/a_0 \mid i = 1, \ldots, n] \subset A_R
\]

is a ring of definition of \( A_R \); hence \( A_R \) induces on \( B_R \) the unique linear topology such that the natural map \( A \to B_R \) is adic. We let \( A_R^+ \) be the integral closure of \( A_R[a_i/a_0 \mid i = 1, \ldots, n] \) in \( A_R \), set \( U_R := U \cap \text{Spec } A_R \), and define

\[
A_R := (A_R, A_R^+, U_R) \quad \text{and} \quad U_R^\wedge := (\text{Spec } A_R)^\wedge.
\]

Then (up to natural isomorphism) we have

\[
\Gamma(U_R^\wedge) = (\mathcal{O}_{\text{Spa } U}^\wedge(R), \mathcal{O}_{\text{Spa } U}^\wedge+(R), U_R^\wedge) \quad \text{where} \quad U_R^\wedge := U_R \times_{\text{Spec } A_R} \text{Spec } \mathcal{O}_{\text{Spa } U}^\wedge(R).
\]

Notice that \( A_R \) contains also the subrings

\[
C_R := A \left[ \frac{\varphi_U^+(e_i^{1/p^k})}{\varphi_U^+(e_0^{1/p^k})} \mid (i, k) \in \{1, \ldots, n\} \times \mathbb{N} \right]
\]

and

\[
D_R := A_U[ \frac{\varphi_U^+(e_i^{1/p^k})}{\varphi_U^+(e_0^{1/p^k})} \mid (i, k) \in \{1, \ldots, n\} \times \mathbb{N} ]
\]

and endow \( C_R \) and \( D_R \) with the topologies induced by the inclusion into \( A_R \). Let also \( C_R^+ := C_R \cap A_R \). The first observation is the following :

**Proposition 16.7.25.** With the notation of \([16.7.24] \), the following holds :

(i) The natural morphism \( A_R^\wedge \to \Gamma(U_R^\wedge) \) is an isomorphism.
(ii) The datum \( C_R := (C_R, C_R^+, U_R) \) is a quasi-affinoid ring, and the natural morphism \( \text{Spec } A_R \to \text{Spec } C_R \) is an isomorphism.

(iii) \( C_R^+ \) is a perfectoid quasi-affinoid ring, and \( \mathcal{U}_R^+ \) is a perfectoid quasi-affinoid scheme.

(iv) Suppose moreover that \( \beta_U(U_R) \subset \Omega_U \) (notation of definition \([15.6.1] \)). Then the datum \( D_R := (D_R, D_R, U_R) \) is a quasi-affinoid ring, and \( D_R^+ \) is perfectoid.

Proof. (ii): We consider the natural morphisms of schemes

\[
U_R \xrightarrow{f} \text{Spec } A_R \xrightarrow{g} \text{Spec } C_R \xrightarrow{h} \text{Spec } A
\]

whose composition is also the composition of the open immersion \( U_R \to U \) with the natural morphism \( i : U \to \text{Spec } A \). By assumption, \( i \) is an open immersion, and its image contains the analytic locus of \( \text{Spec } A \) (lemma \([8.3.29] \)). It follows that \( h \circ g \circ f \) is an open immersion; moreover, by construction, both \( f \) and \( g \) have schematically dense images. From claim \([15.6.5] \) we deduce that \( g \circ f \) is an open immersion, and \( f(U_R) = (h \circ g)^{-1}i(U_R) = (h \circ g)^{-1}i(U) \).

Now, \( U \) contains the analytic locus of \( \text{Spec } A \), and the natural map \( A \to A_R \) is f-adic; taking into account lemma \([8.3.29] \), it follows that \( f(U_R) \) contains the analytic locus of \( \text{Spec } A_R \).

Lastly, \( g \) identifies the analytic locus of \( \text{Spec } A_R \) with that of \( \text{Spec } C_R \) (lemma \([8.3.29] \)), so \( g \circ f(U_R) \) contains the analytic locus of \( \text{Spec } C_R \). Summing up, this shows that \( C_R \) is a quasi-affinoid ring. Then, a simple inspection shows that the inclusion map \( C_R \to A_R \) induces an isomorphism \( \text{Spec } A_R \to \text{Spec } C_R \).

(i): To begin with, we remark :

Claim 16.7.26. \( C_R \) and \( D_R \) are subrings of definition of \( A_R \).

Proof of the claim. Clearly \( C_R \) and \( D_R \) are open in \( A_R \), and \( D_R \subset C_R \); by virtue of proposition \([8.3.18] \), we have then only to check that \( C_R \) is bounded in \( A_R \). To this aim, since \( B_R \) is open and bounded in \( A_R \), it suffices to show that there exists an open ideal \( J \) of \( B_R \) such that \( J \cdot C_R \subset B_R \). However, pick any finite system \( f_1, \ldots, f_r \) of generators for an ideal of definition of \( E \); since the system \( e_0, \ldots, e_n \) generates an open ideal of \( E_U \), we may find an integer \( k \in \mathbb{N} \) large enough so that the \( f_i^*e_j \in E \) for every \( i = 1, \ldots, r \) and every \( j = 0, \ldots, n \), and then it is clear that the system \( (f_i^*e_j) \mid i \leq r, j \leq n \) generates an open ideal of \( E \). By claim \([16.6.35] \) it follows that the system \( (e_j^*e_\nu) \mid i \leq r, j \leq n \) generates an open ideal \( J_{0, \nu} \) of \( A \), and therefore \( J := J_{0, \nu}B_R \) is open in \( B_R \). To conclude, it suffices to show that \( f_i^*e_j^*e_\nu \in B_R \) for every \( i = 1, \ldots, r \), \( j = 0, \ldots, n \), and every \( \nu \in \mathbb{N}/p \). Moreover, we may easily reduce to the case where \( 0 < \nu < 1 \). Then we see that

\[
f_i^*e_j^*e_\nu = e_j^* \frac{e_\nu}{e_0} \cdot (f_i^*e_\nu) \cdot (f_i^*(1-\nu)e_0^{-1})
\]

where both \( f_i^*e_\nu \) and \( f_i^*(1-\nu)e_0^{-1} \) lie in \( E \), since the latter is a perfect \( \mathbb{F}_p \)-algebra. The assertion follows.

Pick a finite system \( \beta_* := (\beta_1, \ldots, \beta_s) \) of elements of \( E \) that generates an ideal of adic definition, and set \( f_i := \pi_A(\beta_i) \) for \( i = 1, \ldots, s \), so that the system \( f_* := (f_1, \ldots, f_s) \) generates an ideal of adic definition of \( A \). By claim \([16.7.26] \) it then follows that the system \( f_* \) also generates an ideal of adic definition \( J \) for \( C_R \). Denote by \( C_R^\alpha \) the separated completion of \( C_R \); we notice :

Claim 16.7.27. The ring \( C_R \) fulfills condition (a) of \([7.8.21] \), and \( C_R^\alpha \) is perfectoid.

Proof of the claim. Set \( \Delta := \mathbb{N}/p \); recall that example \([16.6.12] \) attaches to the sequence \( e_* := (e_0, \ldots, e_n) \) of elements of \( E_U \), two perfectoid rings with \( \Delta \)-graded structure

\[
(\mathcal{E}(e_*), \mathcal{F}(e_*)) \quad \text{and} \quad (\mathcal{A}(e_*), \mathcal{A}(e_*)).
\]
Moreover, $\text{gr}_0\mathcal{E}(e_*) = E$, $\text{gr}_0\mathcal{A}(e_*) = A$, and we have a natural isomorphism

$$E(\mathcal{A}(e_*), \mathcal{A}(e_*)) \sim (\mathcal{E}(e_*), \mathcal{E}(e_*)).$$

Furthermore, since $e_*$ generates an open ideal of $E_U$, the $E$-module $\text{gr}_0\mathcal{E}(e_*)$ (resp. the $A$-module $\text{gr}_0\mathcal{A}(e_*)$) is the submodule of $E_U$ (resp. of $A_U$) generated by the elements of the form $e_0^{\nu_0} \cdots e_n^{\nu_n}$ (resp. $e_0^{\nu_0} \cdots e_n^{\nu_n}$), where $(\nu_0, \ldots, \nu_n)$ ranges over all elements of $\Delta^{\oplus n+1}$ such that $\nu_0 + \cdots + \nu_n = \delta$ (see remark 16.3.28(viii)). Especially, we may regard $\beta_*$ as a sequence of elements of $\text{gr}_0\mathcal{E}(e_*)$, whose image under the map $\pi_{\mathcal{E}(e_*)} : \mathcal{E}(e_*) \rightarrow \mathcal{A}(e_*)$ is (naturally identified with) the sequence $f_*$. Next, let us endow $\mathcal{A}' := \mathcal{A}(e_*)[a^{-1}]$ with its $J\mathcal{A}'$-adic topology; since we are inverting an element $a_0 \in \text{gr}_0\mathcal{A}(e_*)$, the $A$-algebra $\mathcal{A}'$ is also $\Delta$-graded, and a simple inspection yields a natural isomorphism of $C_R \sim \text{gr}_0\mathcal{A}'$ of topological rings, which identifies the sequences $f_*$ in these two rings. Lastly, by virtue of proposition 16.6.5(ii), we deduce that $\mathcal{A}(e_*)$ satisfies condition (a)\ref{tight} of (7.8.21), and then the same holds for $\text{gr}_0\mathcal{A}'$, whence the first assertion.

In order to show that $C_R^\wedge$ is perfectoid, notice that $J^n\mathcal{A}' = \bigoplus_{\delta \in \Delta} J^n\text{gr}_0\mathcal{A}'$ for every $n \in \mathbb{N}$. It follows easily that the maximal separated quotient $\mathcal{A}''$ of $\mathcal{A}'$ is also a $\Delta$-graded ring (so that the projection $\mathcal{A}' \rightarrow \mathcal{A}''$ is a homomorphism of $\Delta$-graded rings), and $\text{gr}_0\mathcal{A}''$ is the maximal separated quotient of $\text{gr}_0\mathcal{A}'$: details left to the reader. Hence $(\mathcal{A}'', \mathcal{A}'')^\wedge$ is a topological ring with $\Delta$-pre-graded structure, and therefore $(\mathcal{C}^\wedge, \mathcal{C}) := (\mathcal{A}'', \mathcal{A}'')^\wedge$ is a topological ring with $\Delta$-graded structure (proposition 8.5.3(iii)), and the induced map $C_R^\wedge \rightarrow \text{gr}_0\mathcal{E}$ is an isomorphism of topological rings. On the other hand, since $\mathcal{A}(e_*)$ is perfectoid, and since the localization map $\mathcal{A}(e_*) ightarrow \mathcal{A}'$ is an adic ring homomorphism, theorem 16.7.21(i) implies that $\mathcal{C}^\wedge$ is perfectoid as well. To conclude, it suffices now to invoke proposition 16.6.1(ii).

As the morphism $i : U \rightarrow \Spec A$ is an open immersion whose image contains the analytic locus of Spec $A$, we may find an open ideal $I \subset A$ such that $\Spec A \setminus U = \Spec A/I$, and we pick a finite system $g_* := (g_1, \ldots, g_r)$ of generators of $I$. On the other hand, $i$ factors through the natural open immersion $j : U \rightarrow \Spec A_U$ and the morphism $\varphi : \Spec A_U \rightarrow \Spec A$ induced by the inclusion map $A \rightarrow A_U$; by claim 15.6.5(ii), it follows that $\varphi^{-1}(U) = j(U)$, whence $\Spec A_U/IA_U = \Spec A_U \setminus j(U)$, and therefore

$$Z := \Spec A_U/IA_U = \Spec A_U \setminus U_R.$$

In view of claim 16.7.26 remark 15.4.13(ii) and proposition 8.3.33(iii), we are then reduced to showing that

$$\text{depth}_Z A_R \otimes_{C_R} C_R^\wedge > 1.$$

However, set $Q^* := \text{Cone}(C_R[0] \rightarrow C_R^\wedge[0])$; clearly we have $\text{depth}_{IA_U} A_U > 1$, whence $\text{depth}_Z A_R > 1$, and thus it suffices to check that

$$R\Gamma_Z (A_R \otimes_{C_R} Q^*) = 0.$$

In light of proposition 10.4.32(i), we are then reduced to showing that the Koszul complex $K^*(g_*, A_R \otimes_{C_R} Q^*)$ is acyclic. We remark :

**Claim** 16.7.28. The natural map $A_R \otimes_{C_R} Q^* \rightarrow A_R \otimes_{C_R} Q^*$ is an isomorphism in $D(C_R\text{-Mod})$.

**Proof of the claim.** We have a natural morphism of distinguished triangles

$$
\begin{align*}
A_R[0] &\rightarrow A_R[0] \otimes_{C_R} C_R^\wedge[0] \rightarrow A_R \otimes_{C_R} Q^* \rightarrow A_R[1] \\
A_R[0] &\rightarrow A_R \otimes_{C_R} C_R^\wedge[0] \rightarrow A_R[0] \otimes_{C_R} Q^* \rightarrow A_R[1]
\end{align*}
$$
in light of which, we are reduced to checking that \( T_i := \text{Tor}_i^C(\mathcal{F}_R, \mathcal{F}_R^\hat{\otimes}) = 0 \) for every \( i > 0 \). However, clearly the natural map \( T_i \to \text{Tor}_i^C(\mathcal{F}_R/\mathcal{F}_R^\frac{\hat{\otimes}}{\otimes}, \mathcal{F}_R^\frac{\hat{\otimes}}{\otimes}) \) is an isomorphism for \( i > 1 \), and is injective for \( i = 1 \), and moreover \( \mathcal{F}_R/\mathcal{F}_R^\frac{\hat{\otimes}}{\otimes} = \bigcup_{n \in \mathbb{N}} \text{Ann}_{\mathcal{F}_R/\mathcal{F}_R^\frac{\hat{\otimes}}{\otimes}}(J^n) \). Hence, the assertion follows from claims \([8.6.36] \) and \([16.7.27] \).

Taking into account lemma \([7.8.2(v)] \) and claim \([16.7.28] \), we are further reduced to showing that \( \mathcal{K}_\bullet(g_\bullet) \otimes_{\mathcal{F}_R} \mathcal{F}_R^\frac{\hat{\otimes}}{\otimes} Q^\bullet \) is acyclic, and to this aim it suffices to check that the same holds for the complex \( \mathcal{K}_\bullet(g_\bullet) \otimes_{\mathcal{F}_R} Q^\bullet \). The latter follows easily from lemma \([7.8.2(ii)] \), claim \([16.7.27] \) and corollary \([8.6.34(i)] \).

(iii): From claim \([16.7.27] \) we know already that \( \mathcal{F}_R^\hat{\otimes} \) is perfectoid, and from (i) and (ii) we get isomorphisms of quasi-affinoid schemes

\[
U_R^\hat{\otimes} \sim \text{Spec} (\mathcal{A}_R^+) \sim \text{Spec} (\mathcal{C}_R^+)
\]

whence the contention.

(iv): We consider the natural morphisms of schemes:

\[
U_R \xrightarrow{f} \text{Spec} \mathcal{A}_R \xrightarrow{g} \text{Spec} \mathcal{D}_R \to \text{Spec} \mathcal{A}_U^+
\]

whose composition is the same as the restriction of \( \beta_U \) to \( U_R \), hence it is an open immersion. Notice also that \( \beta_U \) is in turn the composition of the open immersion \( i : U \to \text{Spec} \mathcal{A} \) and the natural morphism \( \text{Spec} \mathcal{A} \to \text{Spec} \mathcal{A}_U^+ \); the latter identifies the analytic locus of \( \text{Spec} \mathcal{A} \) with that of \( \text{Spec} \mathcal{A}_U^+ \) (lemma \([8.3.29] \) iii)), hence the image of \( \beta_U \) contains the analytic locus of \( \text{Spec} \mathcal{A}_U^+ \). We may then argue as in the proof of (ii) to conclude that \( g \circ f \) is an open immersion and \( g \circ f(U_R) \) contains the analytic locus of \( \text{Spec} \mathcal{D}_R \). Together with claim \([16.7.26] \) this already shows that \( \mathcal{D}_R \) is a quasi-affinoid ring. Moreover, we also know that \( \mathcal{A}_U^+ \) is a perfectoid ring (theorem \([16.5.13(iii)] \)), and our assumptions imply that \( \mathcal{A} := (\mathcal{A}_U^+, \mathcal{A}_U^+, U) \) is another perfectoid quasi-affinoid ring with \( \mathcal{A} = U \). We may then argue as in the proof of claim \([16.7.27] \) to see that the separated completion \( \mathcal{D}_R^\hat{\otimes} \) of \( \mathcal{D}_R \) is perfectoid, and the proof is complete. \( \square \)

**Remark 16.7.29.** (i) Let \( X \) be any perfectoid quasi-affinoid scheme; taking into account proposition \([16.6.34(iii)] \) we deduce that the continuous map \( \text{Spa}(\pi_X) \) of \((16.5.59)\) induces a natural isomorphism of sites (notation of \([15.5.33] \)):

\[
\mathcal{E} : \mathcal{R}(X) \sim \mathcal{R}(\mathcal{E}(X)) \quad \mathcal{R} \mapsto \text{Spa}(\pi_X)(\mathcal{R}).
\]

(ii) Moreover, proposition \([16.7.25(iii)] \) says that for every \( R \in \text{Ob}(\mathcal{R}(X)) \) the sub-presheaf \( h^\mu_R \) of \( h^\mu_X \) is represented by a perfectoid quasi-affinoid scheme \( Y \) (notation of remark \([15.5.9(i)] \)), and taking into account \([16.5.60] \) together with the equivalence of categories

\[
\mathcal{X}_{-q,Afd,Sch_{perf}} \xrightarrow{\sim} \mathcal{E}(\mathcal{X}){-q,Afd,Sch_{perf}}
\]

described in \([16.5.20] \), we deduce easily that \( \mathcal{E}(Y) \) represents the sub-presheaf \( h^\mu_{E(R)} \) of \( h^\mu_X \) (details left to the reader).

**Theorem 16.7.30.** For every perfectoid quasi-affinoid scheme \( X \), the following holds:

(i) The presheaves \( \mathcal{O}_X^\L(P) \), \( \mathcal{O}_X^\L(O) \) and \( \mathcal{O}_X^\L(+) \) are sheaves of topological rings on the site \( \mathcal{R}(X) \) (notation of \([15.5.33] \)).

(ii) For every rational subset \( R \) of \( \text{Spa} X \) and every finite covering \( \mathcal{U} \) of \( R \) consisting of rational subsets, the augmented alternating \( \acute{C}ech \) complex \( C^\cdot_{\mathcal{R}}(\mathcal{U}, \mathcal{E}_\mathcal{R}^\L) \) has strict differentials, and its cohomology has the discrete topology.

**Proof.** (i): By virtue of corollary \([15.4.27(i)] \) and proposition \([16.5.4(i)] \), if \( \mathcal{O}_X^\L(+) \) is a sheaf, the same holds for \( \mathcal{O}_X^\L(O) \) and \( \mathcal{O}_X^\L(P) \), so it suffices to check the assertion for \( \mathcal{O}_X^\L(+) \). Now, say that \( X = (X, \mathcal{S}_X, A_X) \). Notice first that, for every rational subset \( R \) of \( \text{Spa} X \), and every morphism \( \varphi_{Y/X} : \mathcal{Y} \to \mathcal{X} \) representing the sub-presheaf \( h_R \) of \( h_X \), the quasi-affinoid scheme
\(\mathcal{Y}\) is also perfectoid (proposition 16.7.25 iii)). Moreover, lemmata 15.4.17 iv) and 15.5.10 and proposition 16.7.25 i) imply that \(\varphi_{\mathcal{Y}/\mathcal{X}}\) induces equivalences of categories (16.7.31)

\[
\mathcal{B}(\mathcal{Y}^\wedge) \xrightarrow{\sim} \mathcal{B}(\mathcal{Y}) \xrightarrow{\sim} \mathcal{B}(\mathcal{X})/R.
\]

Hence, let \(A_\mathcal{X} := \mathcal{O}_\mathcal{X}(\mathcal{X})\) and \(A := A_\mathcal{X}^\wedge\), so that \(\Gamma^0(\mathcal{X}) = (A, A_\mathcal{X}^\wedge, \mathcal{X})\) (notation of (16.5.19)); according to lemma 15.5.21, every open covering of \(\text{Spa} \mathcal{X}\) can be refined by the standard covering \(R_* := (R_0, \ldots, R_n)\) attached to a given sequence \(a_* := (a_0, \ldots, a_n)\) of elements of \(A\) that generates an (open) ideal \(J \subset A\) such that \(\text{Spec} A/J \subset \text{Spec} A \setminus \mathcal{X}\); for every subset \(\Lambda \subset \{0, \ldots, n\}\) we define the rational subset \(R_\Lambda \subset R\) and the quasi-affinoid ring \(A_{X,\Lambda} := (A_{X,\Lambda}, A_{X,\Lambda}^+, X_\Lambda)\) as in remark 15.5.25 i), so that \(R_\Lambda = \text{Spa} A_{X,\Lambda}\) for every such \(\Lambda\). As in the proof of theorem 15.5.26, we are then reduced to checking that the natural map

(16.7.32)

\[
\mathcal{O}_{\text{Spa} \mathcal{X}}(\text{Spa} \mathcal{X}) \to \text{Equal}(\prod_{i=0}^n \mathcal{O}_{\text{Spa} \mathcal{X}}(R_i) \xrightarrow{\sim} \prod_{i,j=0}^n \mathcal{O}_{\text{Spa} \mathcal{X}}(R_{i,j}))
\]

is an isomorphism of topological rings. To this aim, set \(E := E(A)\); by proposition 16.6.34 we may assume that there exists a sequence \(e_* := (e_0, \ldots, e_n)\) of elements of \(E\) such that \(a_i = \pi_A(e_i)\) for \(i = 0, \ldots, n\). Then, for every subset \(\Lambda \subset \{0, \ldots, n\}\), we consider the subring

\[
C_{R,\Lambda} := A\left[\frac{\pi_A(e_j^{1/p^k})}{\pi_A(e_i^{1/p^k})}\big| (j, i, k) \in \{0, \ldots, n\} \setminus \Lambda \times \Lambda \times \mathbb{N}\right] \subset A_{X,\Lambda}.
\]

Claim 16.7.33. For every \(\Lambda \subset \{0, \ldots, n\}\) the following holds:

i) \(C_{R,\Lambda}\) is a ring of definition of \(A_{X,\Lambda}\).

ii) The natural map \(\omega_{\Lambda}^* : A_{X,\Lambda}^\wedge \to \mathcal{O}_{\text{Spa} \mathcal{X}}(R_\Lambda)\) of remark 15.5.25 ii) is an isomorphism of topological \(A\)-algebras.

Proof of the claim. Both assertions are clear when \(\Lambda = \{i\}\), for any \(i = 0, \ldots, n\), due to proposition 16.7.25 i) and claim 16.7.26. We reduce to this case as follows. Let \(r\) be the cardinality of \(\Lambda\), and set

\[
\Sigma := \{e_{i_1} \cdots e_{i_r} \mid 0 \leq i_1 \leq i_2 \leq \cdots \leq i_r \leq n\}.
\]

It is easily seen that the family \((\pi_A(e) \mid e \in \Sigma)\) generates an open ideal of \(A\) whose radical equals the radical of \(J\). Set also \(e_\Lambda := \prod_{e \in \Lambda} e_i \in \Sigma\), and notice that

\[
R_\Lambda = R_\Lambda\left(\frac{\pi_A(e)}{\pi_A(e_\Lambda)}\big| e \in \Sigma\right) C_{R,\Lambda} = A\left[\frac{\pi_A(e_i^{1/p^k})}{\pi_A(e_\Lambda^{1/p^k})}\big| e \in \Sigma, k \in \mathbb{N}\right].
\]

After replacing \(e_0\) by \(e_\Lambda\), and the system \((e_0, \ldots, e_n)\) by \(\Sigma\), we are therefore reduced to the case where \(R = R_0\), to which proposition 16.7.25 i) and claim 16.7.26 apply.

In view of claim 16.7.33, we may now proceed as in remark 15.5.25 iv): we set

\[
B := A[T_0^{1/p^\infty}, \ldots, T_n^{1/p^\infty}]
\]

and consider the homomorphism of \(\mathbb{N}[1/p]\)-graded \(A\)-algebras

\[
u : B \to \mathcal{X}[Y^{1/p^\infty}] \quad T_i^{1/p^k} \mapsto \pi_A(e_i^{1/p^k} \cdot Y^{1/p^k}) \quad \text{for} \ i = 0, \ldots, n \text{and every} \ k \in \mathbb{N}.
\]

Set also \(S := \text{Spec} A_{\mathcal{X}}^\wedge\); according to (16.7.7), the map \(\nu\) induces a well defined morphism of \(S\)-schemes

\[
\text{Proj} (\nu) : \mathcal{X} \to \text{Proj} B.
\]

Recall also that the inclusion map \(A[T_0, \ldots, T_n] \to B\) induces an affine morphism of schemes \(\psi : \text{Proj} B \to \text{Proj} \mathbb{P}_S^n\). Let \(\mathbb{P}_S^n = \lim_{\to} \lim_{\to} \Omega_{\mathcal{X}}\), be the standard affine covering by complements of hyperplanes, as in remark 15.5.25 iv), set \(\Omega_i := \psi^{-1} \Omega_i\) and \(U_i := (\text{Proj} \psi)^{-1} \Omega_i\) for \(i = 0, \ldots, n\); there follows an affine open covering of \(\text{Proj} B\) and an open covering of \(\mathcal{X}\):

\[
\text{Proj} B = \Omega_0' \cup \cdots \cup \Omega_n' \quad \mathcal{X} = U_0 \cup \cdots \cup U_n.
\]
Set also $U_\Lambda := \bigcap_{i \in \Lambda} U_i$ for every non-empty $\Lambda \subset \{0, \ldots, n\}$; by remark \[15.5.25\] \[i\] we have

\[(16.7.34) \quad \mathcal{O}_X(U_\Lambda) = A_{X,\Lambda} \quad \text{for every non-empty } \Lambda \subset \{0, \ldots, n\}.\]

Let $V$ be the schematic image of $\text{Proj } u$ (see remark \[15.5.25\] \[v\]); a simple inspection shows that

$$V = \text{Proj } \mathcal{A}(e_\bullet)$$

where $\mathcal{A}(e_\bullet)$ is the $\mathbb{N}[1/p]$-graded algebra associated with the sequence $e_\bullet$ via example \[16.6.12\]. Especially, we see that $V_\Lambda := \bigcap_{i \in \Lambda} \Omega_i = \text{Spec } C_{R,\Lambda}$ for every non-empty subset $\Lambda \subset \{0, \ldots, n\}$.

Fix a finitely generated ideal $I$ of adic definition for $E$, and for every $t \in \mathbb{R}_+$, denote by $C_t^i$ the augmented alternating Čech complex of $I^{[t]} \mathcal{O}_V$, relative to the open covering $(V_i | i = 0, \ldots, n)$. Notice that if $\Lambda \neq \emptyset$, the scheme $V_\Lambda$ is affine, hence we have $I^{[t]} C_{R,\Lambda} = H^0(V_\Lambda, I^{[t]} \mathcal{O}_V)$. Moreover, by corollary \[16.7.18\] \[(i)\] and (theorem \[10.2.28\] \[ii\]), the complex $C_t^i$ is acyclic, and the natural map $I^{[t]} A \to C_t^{-1}$ is an isomorphism, for every $t \in \mathbb{R}_+$. It follows that

$$I^{[s]} C_t^i = C_{t+s}^i \quad \text{for every } i \in \mathbb{Z} \text{ and every } s, t \in \mathbb{R}_+$$

and we endow $C_t^i$ with the $I$-adic topology, so that $(C_{t+s}^i \mid s \in \mathbb{R}_+)$ is a fundamental system of open submodules of $C_t^i$, for every $i \in \mathbb{Z}$ and every $t \in \mathbb{R}_+$.

Furthermore, denote by $A_X^\bullet$, the augmented alternating Čech complex of $\mathcal{O}_X$ relative to the open covering $(U_i | i = 0, \ldots, n)$, and for every $i \in \mathbb{Z}$ endow $A_X^i$ with the topology deduced from the topologies of the rings $A_{X,\Lambda}$, via the identifications \[16.7.34\], as in \[15.5.33\]. There follows a natural monomorphism of complexes of topological $A$-modules

$$C_t^i \to A_X^\bullet \quad \text{for every } t \in \mathbb{R}_+$$

and the image of $C_t^i$ is open in $A_X^i$, for every $i \in \mathbb{Z}$. Denote by $(A_X^\bullet, d_X^\bullet)$ and $(C_t^i, d_t^i)$ the complexes obtained by termwise completion of $A_X^\bullet$ and $C_t^i$; for every $t \in \mathbb{R}_+$ the induced map

$$C_t^i \to A_X^\bullet$$

is still a monomorphism. By the foregoing, we have a natural isomorphism of complexes

$$C_t^i \cong \lim_{s \in \mathbb{R}_+} C_t^i / C_{t+s+t} \quad \text{for every } t \in \mathbb{R}_+$$

and moreover $C_t^i / C_{t+s+t}^i$ is acyclic for every $s, t \in \mathbb{R}_+$. By virtue of \[125\] Th.3.5.8, it follows that $C_t^i$ is acyclic for every $t \in \mathbb{R}_+$. Next, notice that the induced morphism

$$A_X^\bullet / C_t^i \to A_X^\bullet / C_t^i$$

is an isomorphism of complexes, for every $t \in \mathbb{R}_+$; we conclude that

$$H^n A_X^\bullet = H^n(A_X^\bullet / C_t^i) = H^n(A_X^\bullet / C_t^i) = H^n A_X^\bullet \quad \text{for every } n \in \mathbb{Z}.$$  

On the other hand, claim \[16.7.33\] \[ii\] and remark \[15.5.25\] \[iii\] yield an isomorphism of complexes of topological $A$-modules

$$A_X^\bullet \cong C_{ah}(R_\bullet, \mathcal{O}_{\text{Spa } A}^\bullet).$$

Since $H^0 A_X^\bullet = 0$, we conclude that \[16.7.32\] is a ring isomorphism. Lastly, let $E$ be the equalizer appearing in \[16.7.32\], and endow it with the topology induced by the inclusion into $\prod_{i=0}^n \mathcal{O}_{\text{Spa } A}(R_i)$; we have to check that the resulting map $\mathcal{O}_{\text{Spa } A}(\text{Spa } A) \to E$ is open. In view of the isomorphism \[16.7.35\], the assertion will follow from the following:

**Claim 16.7.36.** The differentials of the complex $(A_X^\bullet, d_X^\bullet)$ are strict and its cohomology has the discrete topology.
Proof of the claim. For every \( i \in \mathbb{Z} \), the family \((\text{Ker} \, d^{i}_{t} \mid t \in \mathbb{R}_{+})\) yields a fundamental system of open submodules of \( \text{Ker} \, d^{i}_{X} \). But we have already noticed that \( C^{\Lambda}_{t} \) is acyclic, so this system is the image of \( (C^{\Lambda}_{t} \mid t \in \mathbb{R}_{+}) \), which is a fundamental system of open subgroups of \( A^{i}_{X} \), whence the contention.

(ii): We may argue as in the proof of theorem \( \text{15.5.34\,(ii)} \) : we choose a standard covering \( \mathcal{U}' \) that refines \( \mathcal{U} \) and we apply lemma \( \text{8.6.15\,(i)} \) and corollary \( \text{8.6.12} \) to the double complex \( C^{\Lambda}_{\text{alt}}(\mathcal{U}, \mathcal{U}') \) (details left to the reader). \( \square \)

16.7.37. Let \( X := (X, \mathcal{A}, A^{+}_{X}) \) be any perfectoid quasi-affinoid scheme; in light of theorem \( \text{16.7.30} \) we may now argue as in \( \text{15.5.43} \) to first extend \( \mathcal{O}^{\wedge}_{\text{Spa} \, X} \) to a sheaf of topological rings on the topological space \( \text{Spa} \, X \), and then show that the stalks of the latter sheaf are local rings. There follows a well defined morphism of locally ringed spaces

\[
\sigma_{X} : (\text{Spa} \, X, \mathcal{O}^{\wedge}_{\text{Spa} \, X}) \to (X, \mathcal{O}_{X})
\]

whose induced map on global sections is the identity map \( \mathcal{O}_{X}(X) \to \mathcal{O}^{\wedge}_{\text{Spa} \, X}(\text{Spa} \, X) \), and whose underlying continuous map \( \text{Spa} \, X \to X \) is the restriction of the support map of remark \( \text{9.2.4\,(iii)} \). Also corollary \( \text{15.5.45} \) extends to the perfectoid case:

**Corollary 16.7.38.** With the notation of \( \text{(16.7.37)} \), the morphism \( \sigma_{X} \) induces an isomorphism

\[
H^{i}(X, \mathcal{O}_{X}) \sim H^{i}(\text{Spa} \, X, \mathcal{O}^{\wedge}_{\text{Spa} \, X}) \quad \text{for every } i \in \mathbb{N}.
\]

**Proof.** We proceed as in the proof of corollary \( \text{15.5.45} \): first we show the following

**Claim 16.7.39.** In the situation of the corollary, suppose moreover that \( X \) is affinoid. Then \( H^{i}(\text{Spa} \, X, \mathcal{O}^{\wedge}_{\text{Spa} \, X}) = 0 \) for every \( i > 0 \).

**Proof of the claim.** Arguing as in the proof of claim \( \text{15.5.46} \) we reduce to checking that for every standard covering \( \mathcal{U} \) of \( \text{Spa} \, X \) the Čech cohomology \( H^{i} := H^{i}_{\text{alt}}(\mathcal{U}, \mathcal{O}^{\wedge}_{\text{Spa} \, X}) \) vanishes for every \( i > 0 \); but the proof of theorem \( \text{16.7.30\,(i)} \) shows that \( H^{i} \) is naturally isomorphic to the Čech cohomology \( H^{i}_{\text{alt}}(U_{\bullet}, X) \), relative to a certain affine open covering \( U_{\bullet} \) of \( X \). Then the assertion follows from theorem \( \text{10.2.28} \). \( \square \)

Now, set \( A_{X} := \mathcal{O}_{X}(X) \), say that \( X = \text{Spec} \, A_{X} \setminus \text{Spec} \, A_{X}/J \) for some finitely generated ideal \( J \subset A_{X} \), and pick a finite system of generators \( f_{\bullet} := (f_{0}, \ldots, f_{n}) \) for \( J \). Let \( R_{\bullet} := (R_{0}, \ldots, R_{n}) \) be the standard covering of \( \text{Spa} \, X \) associated with \( f_{\bullet} \), and set as well \( U_{i} := \text{Spec} \, A_{X}[f^{-1}_{i}] \) for every \( i = 0, \ldots, n \), so that \( U_{\bullet} := (U_{0}, \ldots, U_{n}) \) is an affine open covering of \( X \), and moreover \( R_{i} = \sigma_{X}^{-1}(U_{i}) \) for every \( i = 0, \ldots, n \). There follows a commutative diagram

\[
\begin{array}{ccc}
H^{i}_{\text{alt}}(U_{\bullet}, \mathcal{O}_{X}) & \longrightarrow & H^{i}_{\text{alt}}(R_{\bullet}, \mathcal{O}^{\wedge}_{\text{Spa} \, X}) \\
\downarrow & & \downarrow \\
H^{i}(X, \mathcal{O}_{X}) & \longrightarrow & H^{i}(\text{Spa} \, X, \mathcal{O}^{\wedge}_{\text{Spa} \, X})
\end{array}
\]

where the vertical arrows are isomorphisms, by virtue of claim \( \text{16.7.39} \) and corollary \( \text{10.2.21\,(ii)} \). We are then reduced to checking that the top horizontal arrow is an isomorphism; but as already pointed out, the latter assertion was shown in the proof of theorem \( \text{16.7.30\,(i)} \). \( \square \)

16.7.40. Let again \( X \) be as in \( \text{(16.7.37)} \); set \( A_{X} := \mathcal{O}_{X}(X) \), and let \( V \subset X^{+} := \text{Spec} \, A^{+}_{X} \) be any quasi-compact open subset containing the analytic locus of \( X^{+} \), and such that \( X \) spreads over \( V \) (see definition \( \text{15.6.1\,(i)} \)). Let also \( J_{V} \subset A^{+}_{X} \) be the unique radical ideal such that \( \text{Spec} \, A^{+}_{X}/J_{V} = X^{+} \setminus V \). We consider the sheaf of ideals

\[
\mathcal{J}_{V} \subset \mathcal{O}^{\wedge}_{\text{Spa} \, X} \quad \text{on } \mathcal{R}(X)
\]
defined as the sheaf associated to the presheaf given by the rule : \( R \mapsto J_V \mathcal{O}^+_{\text{Spa} \hat{X}}(R) \) for every rational subset \( R \subset \text{Spa} \hat{X} \).

**Theorem 16.7.41.** In the situation of (16.7.40), we have :

(i) \( J_V(R) = J_V \mathcal{O}^+_{\text{Spa} \hat{X}}(R) \) for every \( R \in \text{Ob}(\mathcal{R}(X)) \) (notation of (15.6.1)).

(ii) \( H^i(X, J_V) = 0 \) for every \( i > 0 \).

**Proof.** To begin with, we remark :

**Claim 16.7.42.** Let \( R \in \text{Ob}(\mathcal{R}(X)) \), and \( Y \) any topologically local quasi-affinoid scheme representing the sub-presheaf \( h_R \) of \( h_{\text{Spa} \hat{X}} \). Say that \( Y^\wedge := (Y^\wedge, \mathcal{J}^\wedge_Y, A^+_Y) \). We have :

(i) The completion \( Y^\wedge \) spreads over the preimage \( W \) of \( V \) in \( Y^\wedge := \text{Spec} A^+_Y \).

(ii) Let \( J_W \subset A^+_Y \) be the unique radical ideal such that \( \text{Spec} A^+_Y/J_W = Y^\wedge \setminus W \). Then \( J_W = J_V A^+_Y \).

**Proof of the claim.** (i): Since \( Y \) spreads over \( V \), the assertion follows from proposition (15.6.6)(i).

(ii): We may find a finitely generated open ideal \( J_E \subset E^+ \) such that \( J_E A^+_Y = J_V \) (see (16.5.16)); then we have \( \text{Spec} A^+_Y/J_W A^+_Y = Y^\wedge \setminus W \), and on the other hand, arguing as in (16.5.16) we see that \( J_E^0 A^+_Y \) is a radical ideal of \( A^+_Y \), whence the claim. \( \diamond \)

**Claim 16.7.43.** In order to prove the theorem it suffices to show that for every \( X \) and \( V \) as in (16.7.40) we have \( H^0(\mathcal{R}(X), J_V \mathcal{O}^+_{\text{Spa} \hat{X}}) = J_V \) and \( H^i(\mathcal{R}(X), J_V \mathcal{O}^+_{\text{Spa} \hat{X}}) = 0 \) for every \( i > 0 \).

**Proof of the claim.** Indeed, in light of proposition (15.6.8)(i,ii), both (i) and (ii) will follow once we show that the presheaf \( J_V \mathcal{O}^+_{\text{Spa} \hat{X}} \) is a sheaf on the site \( \mathcal{R}(X) \), and \( H^i(\mathcal{R}(X), J_V \mathcal{O}^+_{\text{Spa} \hat{X}}) = 0 \) for every \( i > 0 \). Next, in view of theorem (10.2.24) in order to prove the latter assertions it suffices to show that for every \( R \in \text{Ob}(\mathcal{R}(X)) \) we have \( H^0(\mathcal{R}(X)/R, J_V \mathcal{O}^+_{\text{Spa} \hat{X}}) = J_V \mathcal{O}^+_{\text{Spa} \hat{X}}(R) \) and \( H^i(\mathcal{R}(X)/R, J_V \mathcal{O}^+_{\text{Spa} \hat{X}}) = 0 \) for every \( i > 0 \). Proposition (15.6.8)(iii) then further reduces to showing both identities, with \( \mathcal{R}(X) \) replaced by \( \mathcal{R}(X) \). Lastly, for such a rational subset \( R \), define \( Y \) and \( W \) as in claim (16.7.42)(i); in light of claim (16.7.42)(ii), and taking into account the equivalences (16.7.31), we may then replace \( X \) by \( Y^\wedge \), and \( V \) by \( W \), and reduce to prove the foregoing identities for \( R = \text{Spa} \hat{X} \), whence the claim. \( \diamond \)

We consider first the case where the induced morphism \( \beta_X : X \to X^\wedge := \text{Spec} A^+_X \) is an open immersion, so that \( \Omega_X \) is the image of \( \beta_X \) (notation of definition (15.6.1)), and we take \( V := \Omega_X \). By theorem (16.5.13)(iii) we have the perfectoid quasi-affinoid ring

\[ \Gamma^+(X) := (A^+_X, A^+_X, V) \]

and clearly \( \text{Spec} (\Gamma^+(X)) \) is isomorphic to \( X \). In view of lemma (15.5.21) we deduce that every open covering of \( \text{Spa} \hat{X} \) can be refined by the standard covering \( \mathfrak{U}_n := (\mathfrak{U}_0, \ldots, \mathfrak{U}_n) \) associated to some sequence \( (a_0, \ldots, a_n) \) of elements of \( A^+_X \) that generates an ideal \( K \) with \( \text{Spec} A^+_X/K \subset X^\wedge \setminus V \), and notice that \( \mathfrak{U}_n \) is a covering family of the site \( \mathcal{R}(X) \), due to proposition (15.6.6)(ii). We shall show more precisely that the augmented alternating Čech complex \( C^+_\text{alt}(\mathfrak{U}, J_V \mathcal{O}^+_{\text{Spa} \hat{X}}) \) is acyclic. To this aim, set \( E^+ := E(A^+_X) \); in view of proposition (16.6.34), we may assume that there exists a sequence \( e_* := (e_0, \ldots, e_n) \) of elements of \( E^+ \) such that \( a_i = \pi_{A^+_X}(e_i) \) for \( i = 0, \ldots, n \), and we let \( K_E \subset E^+ \) be the open ideal generated by \( e_* \) (proposition (16.6.34)(ii)). Notice that \( J_E^{[0]} \) and \( K_E^{[0]} \) are the radicals of \( J_E \) and respectively \( K_E \); we deduce that

\[ (16.7.44) \]

\[ J_E^{[0]} = K_E^{[0]} J_E^{[0]} < K_E^{[0]} J_E^{[0]} < J_E^{[0]} \]

We consider the \( \mathbb{N}[1/p] \)-graded \( A^+_X \)-algebra \( \mathcal{A} \) associated as in example (16.6.12) to the sequence \( e_* \), i.e. such that

\[ \mathcal{A}_0 := A^+_X \quad \text{and} \quad \mathcal{A}_\gamma := [e_*^{(\gamma)} A^+_X \quad \text{for every} \quad \gamma \in \mathbb{N}[1/p] \setminus \{0\} \]
(with multiplication induced by that of $A^+_\mathcal{X}$). We have then a ring homomorphism as in (16.7.9)

\[ \varphi: \mathbb{Z}[T_0^{1/p\infty}, \ldots, T_n^{1/p\infty}] \to \mathcal{A} \quad T_i^{1/p^r} \mapsto \pi_{A^+_X}(e_i^{1/p^r}) \quad \text{for } i = 0, \ldots, n \text{ and every } r \in \mathbb{N} \]

whose image lies in $\mathcal{A}^0 = A^+_X$, whence corresponding angular Rees algebras $R\langle A^+_X \rangle$ and $R\langle \mathcal{A} \rangle$.

Set $Y_0 := \text{Proj } R\langle A^+_X \rangle$; the map $\varphi$ induces a morphism of schemes

\[ \text{Proj } \varphi: Y_0 \to \mathbb{P}^n := \text{Proj } \mathbb{Z}[T_0^{1/p\infty}, \ldots, T_n^{1/p\infty}] \]

Let $\mathbb{P}^n = \Omega_0 \cup \ldots \cup \Omega_n$ be the standard affine open covering by complements of hyperplanes, set $U_i := (\text{Proj } \varphi)^{-1}\Omega_i$ for $i = 0, \ldots, n$, and let

\[ C^\bullet := C^\bullet_{\text{alt}}(U_\bullet, \mathcal{O}_{Y_0}) \]

be the augmented alternating Čech complex relative to the covering $U_\bullet := (U_0, \ldots, U_n)$. Taking into account (16.7.44) and corollary 16.7.16 (as well as theorem 10.2.28(ii)), we deduce that

\[ C^\bullet_{\text{alt}}(U_\bullet, J_V \mathcal{O}_{Y_0}) = J_V C^\bullet \]

and moreover this second augmented alternating Čech complex is acyclic. Furthermore, let $I_E$ be any finitely generated ideal of definition for $E^+$; corollary 16.7.18 shows likewise that

\[ C^\bullet_{\text{alt}}(U_\bullet, I_E^{[t]} \mathcal{O}_{Y_0}) = I_E^{[t]} C^\bullet \quad \text{for every } t \in \mathbb{R}_+ \]

and also these complexes are acyclic. We may describe the terms of $C^\bullet$ as in the proof of theorem 16.7.30: for every $i = 0, \ldots, n$, the $A^+_X$-module $C_i$ is a direct sum $\bigoplus_{\Lambda \subseteq \{0, \ldots, n\}} \mathcal{O}_{Y_0}(U_\Lambda)$, where $\Lambda$ ranges over the set of subsets of cardinality equal to $i + 1$, and $U_\Lambda := \bigcap_{j \in \Lambda} U_j$ for every such $\Lambda$.

Then

\[ \mathcal{O}_{Y_0}(U_\Lambda) = A^+_X[e_0^{1/p\infty}] / \pi_{A^+_X}(e_i^{1/p\infty}) \mid (i, j) \in \{0, \ldots, n\} \times \Lambda \subseteq \{0, \ldots, n\} \]

for every non-empty $\Lambda \subseteq \{0, \ldots, n\}$. If we set likewise $U_\Lambda := \bigcap_{j \in \Lambda} U_j$ for every such $\Lambda$, we see that $\mathcal{O}_{Y_0}(U_\Lambda) \subseteq \mathcal{O}_{\text{Spa} X}(\Lambda)$. Set as usual $A_X := \mathcal{O}_X(X)$; in light of claim 16.7.33 we see that there exists for every $\Lambda \neq \emptyset$ a (unique) $f$-adic topology on $A_X[a_j^{-1} \mid j \in \Lambda]$ for which the localization map $A_X \to A_X[a_j^{-1} \mid j \in \Lambda]$ is $f$-adic and $\mathcal{O}_{Y_0}(U_\Lambda)$ is a subring of definition. Especially, the induced topology on $\mathcal{O}_{Y_0}(U_\Lambda)$ is adic, and the natural map $A^+_X \to \mathcal{O}_{Y_0}(U_\Lambda)$ is an adic ring homomorphism. Let us endow $C^i$ with the corresponding product topology, for every $i = 0, \ldots, n$; then $(I_E^{[t]} C^i \mid t \in \mathbb{R}_+)$ is a fundamental system of open submodules of $C^i$, and hence also of $J_V C^i$, for every such $i$. Moreover, we know that the natural maps $J_V A^+_X \to J_V C^i$ and $I_E^{[t]} A^+_X \to I_E^{[t]} C^i$ are isomorphisms (again, by corollaries 16.7.16(i) and 16.7.18(i)), so $(I_E^{[t]} C^i \mid t \in \mathbb{R}_+)$ is a fundamental system of open submodules of $J_V C^i$.

Taking into account [22] Th.3.5.8], we conclude that the termwise completion of $J_V C^i$ is still acyclic. Furthermore, the latter is isomorphic to $J_V C^{\Lambda^i}$, where $C^{\Lambda^i}$ is the termwise completion of $C^\bullet$; indeed, $J_V C^{\Lambda^i}$ is dense and open in the completion of $J_V C^i$ for every $i = 0, \ldots, n$, so the assertion is clear.

**Claim** 16.7.45. Set $W_\Lambda := U_\Lambda \cap \text{Spec } \mathcal{O}_{Y_0}(U_\Lambda)[a_j^{-1} \mid j \in \Lambda]$ for every non-empty $\Lambda \subseteq \{0, \ldots, n\}$. The datum $(\mathcal{O}_{Y_0}(U_\Lambda), \mathcal{O}_{Y_0}(U_\Lambda), W_\Lambda)$ is a quasi-affinoid ring, and its completion is a perfectoid quasi-affinoid ring

\[ \mathcal{R}_\Lambda := (\mathcal{O}_{Y_0}(U_\Lambda)^\wedge, \mathcal{O}_{Y_0}(U_\Lambda)^\wedge, W_\Lambda^\wedge := W_\Lambda \times_{U_\Lambda} \text{Spec } \mathcal{O}_{Y_0}(U_\Lambda)^\wedge) \]

**Proof of the claim.** Arguing as in the proof of claim 16.7.33, we may assume that $\Lambda = \{i\}$, for some $i \in \{0, \ldots, n\}$, in which case it suffices to invoke proposition 16.7.25(iv).\[\Box\]

With the notation of claim 16.7.45 we see that

\[ \Gamma(\text{Spec } \mathcal{R}_\Lambda) = (\mathcal{O}_{Y_0}(U_\Lambda)^\wedge[a_j^{-1} \mid j \in \Lambda], \mathcal{O}_{Y_0}(U_\Lambda)^\wedge, W_\Lambda^\wedge) \]
where \( \mathcal{O}_{Y_0}(U_\Lambda)^{[a^{-1}_j \mid j \in \Lambda]} \) carries the unique f-adic topology such that the localization map \( \mathcal{O}_{Y_0}(U_\Lambda)^{[a^{-1}_j \mid j \in \Lambda]} \to \mathcal{O}_{Y_0}(U_\Lambda)^{[a^{-1}_j \mid j \in \Lambda]} \) is open (proposition 8.3.30(ii)), and \( \mathcal{O}_{Y_0}(U_\Lambda)^{\Lambda^+} \) is the integral closure of \( \mathcal{O}_{Y_0}(U_\Lambda)^{[a^{-1}_j \mid j \in \Lambda]} \). In other words, \( \mathcal{O}_{Y_0}(U_\Lambda)^{\Lambda^+} \) is represented by an f-adic morphism \( A \to X \). We have

\[
\mathcal{O}_{Y_0}(U_\Lambda)^{\Lambda^+} = A_X^{[a^{-1}_j \mid j \in \Lambda]},
\]

where the latter is endowed with the unique f-adic topology such that the localization map \( \mathcal{O}_{Y_0}(U_\Lambda) \to A_X^{[a^{-1}_j \mid j \in \Lambda]} \) is open (proposition 8.3.33). It follows that \( \mathcal{O}_{Y_0}(U_\Lambda)^{\Lambda^+} \) is also the completion of the integral closure of \( \mathcal{O}_{Y_0}(U_\Lambda)^{[a^{-1}_j \mid j \in \Lambda]} \) in \( A_X^{[a^{-1}_j \mid j \in \Lambda]} \) (lemma 8.3.6), which is the same as the completion of the integral closure of \( A_X^{[a^{-1}_j \mid j \in \Lambda]} \). This means that

\[
\Gamma(\text{Spec } R_\Lambda) = (\mathcal{O}_{\text{Spa} X}(\Lambda), \mathcal{O}_{\text{Spa} X}(\Lambda), W^{\Lambda}).
\]

We have already observed that \( J \mathcal{O}_{\text{Spa} X}(\Lambda) \) is a radical ideal of \( \mathcal{O}_{\text{Spa} X}(\Lambda) \); combining with corollary 16.5.17 we conclude that

\[
J \mathcal{O}_{\text{Spa} X}(\Lambda) = J \mathcal{O}_{Y_0}(U_\Lambda)^{\Lambda} \quad \text{for every non-empty } \Lambda \subset \{0, \ldots, n\}
\]

which implies that the natural map of complexes \( J \mathcal{O}_{\text{Spa} X}(\Lambda) \to C^{\bullet}_{\ast}(\Lambda); J \mathcal{O}_{\text{Spa} X}(\Lambda) \) is an isomorphism, so the proof of the theorem is complete in this case.

For the general case, let us set

\[
(X, E, \mathcal{E}_X, E_X) := (E(\Lambda), X, E_X, X_X).
\]

(see example 15.4.4). Say that \( X' := (X', E_X', \mathcal{E}_X') \); then \( X' \) spreads over the preimage \( V' \) of \( V \) in \( X'^{+} := \text{Spec } A_X^{+} \) (proposition 15.6.6(iv)); on the other hand, by construction the image of \( \beta_X : X' \to X'^{+} \) lies in \( V' \), so \( \beta_X \) is an open immersion and \( V' = \Omega X_X \). Therefore we have as well the perfectoid quasi-affinoid ring \( \Gamma(X') := (A_X, A_X^{+}, V') \), and \( \text{Spec } \Gamma(X') \) is isomorphic to \( X' \); especially, the latter is a perfectoid quasi-affinoid scheme of the type considered in the foregoing case. Next, since the natural morphism \( \pi : X' \to X \) is f-adic, proposition 15.4.22(iii.a) says that \( \text{Spa } \pi : \text{Spa } X' \to \text{Spa } X \) induces a functor

\[
\mathcal{R}(X) \to \mathcal{R}(X') \quad R \mapsto (\text{Spa } \pi)^{-1} R
\]

which restricts to a functor

\[
\mathcal{R}_V(\Lambda) \to \mathcal{R}_V'(\Lambda).
\]

Indeed, let \( R \) be any rational subset of \( \text{Spa } X \), and say that the corresponding sub-presheaf \( h_R \) of \( h_{\text{Spa } X} \) is represented by an f-adic morphism \( Y \to X \) of quasi-affinoid schemes. Then \( (\text{Spa } \pi)^{-1} R \) is represented by the induced morphism \( Y' := (Y \times_X X')_{\text{loc}} \to X' \) (see remark 15.5.9(iii)). Now, if \( Y \) spreads over \( V \), proposition 15.6.6(iii,iv) implies that \( Y' \) spreads over \( V' \), whence the contention. Furthermore, let \( J \mathcal{V}_X \subset A_{X_X}^{+} \) be the unique radical ideal such that \( \text{Spec } A_X^{+}/J_\mathcal{V}_X = X'^{+} \setminus V' \); we have :

**Claim 16.7.46.** For every \( R \in \text{Ob}(\mathcal{R}_V(\Lambda)) \), the induced map

\[
(16.7.47) \quad J_\mathcal{V}_X \mathcal{O}_{\text{Spa} X}(\Lambda) \to J_\mathcal{V}_X \mathcal{O}_{\text{Spa} X}(\Lambda), ((\text{Spa } \pi)^{-1} R)
\]

is an isomorphism.

**Proof of the claim.** We consider first the case where \( R = \text{Spa } X \): arguing as in the proof of claim 16.7.42(ii) we easily see that \( J_\mathcal{V}_X = J_\mathcal{V}_X A_{X_X}^{+} \). Therefore, let \( \overline{A_{X_X}^{+}} \) be the image of \( A_{X_X}^{+} \) in \( A_{X_X}^{+} \); combining with corollary 16.5.17 it follows that

\[
J_\mathcal{V}_X = J_\mathcal{V}_X \overline{A_{X_X}^{+}}
\]

which already shows that the natural ring homomorphism \( \rho : A_{X_X}^{+} \to \overline{A_{X_X}^{+}} \) restricts to a surjection \( J_\mathcal{V}_X \to J_\mathcal{V}_X \). Next, notice that the support of \( \text{Ker } \rho \) lies in the closed subset \( X'^{+} \setminus V \), and therefore \( J_\mathcal{V}_X \cap \text{Ker } \rho \) is contained in the nilradical of \( A_{X_X}^{+} \); but \( A_{X_X}^{+} \) is reduced (corollary 16.3.61)), whence the claim, in this case. Next, let \( R \in \text{Ob}(\mathcal{R}_V(\Lambda)) \) be a general rational subset; to ease notation,
set $R' := (\text{Spa} \pi)^{-1} R$, and let $Z$ be any topologically local quasi-affinoid scheme representing the sub-presheaf $h_{R'}$ of $h_{\text{Spa} X'}$. Define $Y^\wedge, Y', Y^{\wedge, +}, W \subset Y^{\wedge, +}$ and $J_W$ as in claim $16.7.42$. Let also $Y' := \beta_Y^1(W)$ and $\tilde{Y}' := Y' \times_{Y^{\wedge, +}} Y^\wedge$. Say that $Y' = (Y', \mathcal{O}_{Y'}, A_{Y'})$, and let moreover $W'$ be the preimage of $W$ in $Y^{\wedge, +} := \text{Spec} A_{Y'}$, and $J_{W'} \subset A_{Y'}^+$, the unique radical ideal such that $\text{Spec} A_{Y'}/J_{W'} = Y^{\wedge, +} \setminus W'$; arguing as in the foregoing, we see that $Y'$ is a perfectoid quasi-affinoid scheme that spreads over $W'$, and a direct inspection of the constructions shows that $Y'$ is the completion of $Z$. Thus, the image of $\text{Spa} Y^\wedge$ (resp. of $\text{Spa} Y'$) in $\text{Spa} X$ (resp. in $\text{Spa} X'$) agrees with $R$ (resp. with $R'$), and taking into account claim $16.7.42$ (ii) we conclude that $16.7.47$ is naturally identified with the map

$$J_W \to J_{W'}$$

induced by the projection $Y' \to Y^\wedge$. By the previous case, we know already that this map is bijective, whence the claim. 

We may now conclude the proof of the theorem: indeed, we have already remarked that every covering family of $\mathcal{R}(X)$ can be refined by a standard covering $\{U_i := (U_0, \ldots, U_n)\}$ which is also a covering family of $\mathcal{R}_V(X)$. It follows that $\{U_i := ((\text{Spa} \pi)^{-1} U_i | i = 0, \ldots, n\}$ is a standard covering of $\text{Spa} X'$ which is also a covering family of $\mathcal{R}_V(X')$. By the previous case, we know already that $H^i(U_i, J_{V'} \mathcal{O}_{\text{Spa} X'}^{\wedge, +}) = J_{V'}$ and $H^i(U_i, J_{V'} \mathcal{O}_{\text{Spa} X'}^{\wedge, +}) = 0$ for every $i > 0$. In view of claim $16.7.46$ it follows that $H^0(U_i, J_{V'} \mathcal{O}_{\text{Spa} X'}^{\wedge, +}) = J_{V'}$ and $H^i(U_i, J_{V'} \mathcal{O}_{\text{Spa} X'}^{\wedge, +}) = 0$ for every $i > 0$, and taking into account claim $16.7.43$ the theorem follows. 

16.8. **Almost purity.** To begin with, let $p$ be a prime integer; we consider a perfect $\mathbb{F}_p$-algebra $V$ and a radical ideal $m \subset V$. Since $V$ is perfect, $(V, m)$ is clearly a basic setup, in the sense of [59] §2.1.1]. Our first observation is the following:

**Lemma 16.8.1.** In the situation of (16.8), let $A \subset B$ be an inclusion of perfect $V$-algebras, and $m_0 \subset m$ a subideal whose radical is $m$. We set

$$A' := \{x \in B | m \cdot x \subset A\} \quad B' := \{x \in B | \text{ there exists } n \in \mathbb{N} \text{ with } m_0^n \cdot x \subset A\}.$$

Then $A'$ and $B'$ are perfect $V$-algebras, and $A'$ is integrally closed in $B'$.

**Proof.** It is easily seen that $A'$ and $B'$ are $V$-subalgebras of $B$, and obviously $A \subset A' \subset B'$. Next, let $x \in B$, and say that $x^p \in A'$; thus, $m \cdot x^p \subset A$, and therefore $(ax)^p \in A$ for every $a \in m$. Since $A$ is perfect, it follows that $ax \in A$ for every such $a$, so that $x \in A'$; this shows that $A'$ is perfect. Likewise one checks that $B'$ is perfect.

Next, let $x \in B'$, and suppose that $x^n + a_1 x^{n-1} + \cdots + a_n = 0$ for some $a_1, \ldots, a_n \in A'$. Then $A'[x] = A' + A'x + \cdots + A'x^{n-1} \subset B'$. By assumption, there exists $k \in \mathbb{N}$ with $m_0^k \cdot x \subset A$, and it follows easily that $m_0^k A'[x] \subset A$. Now, let $a \in m$; by assumption, there exists $M \in \mathbb{N}$ such that $a^M \in m_0^k$, whence $(ax)^{M^*} \in A$, and since $A$ is perfect, we conclude that $ax \in A$ for every such $a$, i.e. $x \in A'$. This shows that $A'$ is integrally closed in $B'$. 

We may now state the following generalization of [59, Th.3.5.28]:

**Theorem 16.8.2.** In the situation of (16.8), set $S := \text{Spec} V$ and $Z := \text{Spec} V/m$. Then:

(i) The pair $(S, Z)$ is almost pure, relative to the basic setup $(V, m)$.

(ii) If $Z$ is constructible in $S$, the pair $(S, Z)$ is normal, for the basic setup $(V, m)$.

**Proof.** (ii): Denote by $j : U \to S$ the open immersion; the kernel $\mathcal{K}$ of the natural map $\mathcal{O}_S \to j_* \mathcal{O}_U$ is the largest $\mathcal{O}_S$-submodule such that $m \mathcal{K} = 0$, so the induced morphism $\mathcal{O}_S^\wedge \to j_* \mathcal{O}_U^\wedge$ is a monomorphism. It remains to check that the image of $\mathcal{O}_S^\wedge$ is integrally closed in $j_* \mathcal{O}_U^\wedge$, and since $Z$ is constructible, we are reduced to showing that $V^\wedge$ is integrally closed in $\mathcal{O}_S(U)^\wedge$ ([44, Ch.I, Prop.9.2.1]). The latter follows from lemma $16.8.1$ and [59, Lemma 8.2.28].
(i): Let \((Z_\lambda \mid \lambda \in \Lambda)\) be the cofiltered system of closed constructible subsets of \(S\) containing \(Z\), and for every \(\lambda \in \Lambda\) let \(m_\lambda \subset m\) be the unique radical ideal such that \(\text{Spec} \, V/m_\lambda = Z_\lambda\). Set also \(U := S \setminus Z\) and \(U_\lambda := S \setminus Z_\lambda\) for every \(\lambda \in \Lambda\). Then \(m_\lambda = m_\lambda^2\) and notice that both \(m_\lambda\) (for every \(\lambda \in \Lambda\)) and \(m\) trivially fulfill condition (B) of \([59, \S 2.1.6]\), since \(V\) is perfect. We then get an essentially commutative diagram

\[
\begin{array}{ccc}
(O_S, mO_S)^{\alpha}\text{-}\check{\text{Et}}_{\text{aff}} & \xrightarrow{\rho} & O_U\text{-}\check{\text{Et}} \\
\downarrow & & \downarrow \\
(O_S, m_O S)^{\alpha}\text{-}\check{\text{Et}}_{\text{aff}} & \xrightarrow{\rho_0} & O_{U_\lambda}\text{-}\check{\text{Et}}
\end{array}
\]

for every \(\lambda \in \Lambda\).

However, on the one hand, proposition \([14.2.3]\) and corollary \([14.2.5]\) imply that the category \((O_S, mO_S)^{\alpha}\text{-}\check{\text{Et}}_{\text{aff}}\) is equivalent to the 2-limit of the system \(((O_S, m_O S)^{\alpha}\text{-}\check{\text{Et}}_{\text{aff}} \mid \lambda \in \Lambda)\); on the other hand, it is clear that \(O_U\text{-}\check{\text{Et}}\) is equivalent to the 2-limit of the system \((O_{U_\lambda}\text{-}\check{\text{Et}} \mid \lambda \in \Lambda)\). Thus, we are reduced to checking that for every \(\lambda \in \Lambda\), and we may therefore assume from start that \(Z\) is constructible. In view of (ii) and lemma \([14.4.5]\) (ii), we are then reduced to showing that for every finite étale \(O_U\text{-}\text{algebra}\) \(B\) there exists an étale \(O_S\text{-}\text{algebra}\) \(A\) of almost finite rank such that \(\rho(A)\) is isomorphic to \(B\). Now, by applying proposition \([14.3.30]\) with \(X := S\) and \(m_0 = m := V\) (so, we consider here the “classical limit” almost ring structure) we obtain a quasi-coherent \(O_S\text{-}\text{algebra}\) \(\mathcal{R}_0\) which is finitely presented as an \(O_S\text{-}\text{module}\), with an isomorphism \(\mathcal{B} \xrightarrow{\sim} \mathcal{R}_{0\mid U}\) of \(O_U\text{-}\text{algebras}\).

Let \(\Phi_S : S \to S\) be the Frobenius endomorphism, and consider the directed system of quasi-coherent \(O_S\text{-}\text{algebras}\) \(\mathcal{R}_n \mid n \in \mathbb{N}\) with \(\mathcal{R}_n := \Phi^n_S \mathcal{R}_0\) for every \(n \in \mathbb{N}\); explicitly, \(\mathcal{R}_n(U') = \mathcal{R}_0(U')\) for every open subset \(U' \subset S\), and the \(O_S(U')\text{-}\text{algebra}\) structure on \(\mathcal{R}_n(U')\) is given by the composition of the Frobenius endomorphism \(O_S(U') \to O_S(U')\) with the structure morphism \(O_S(U') \to \mathcal{R}_0(U')\). The transition maps \(\varphi_n : \mathcal{R}_n \to \mathcal{R}_{n+1}\) are given on each such \(U'\) by the Frobenius endomorphism \(\mathcal{R}_0(U') \to \mathcal{R}_0(U')\), for every \(n \in \mathbb{N}\). We let

\[
\mathcal{R} := \text{colim}_{n \in \mathbb{N}} \mathcal{R}_n.
\]

Since \(V\) is perfect, \([59, \text{Th.3.5.13}]\) (applied again in the “classical limit” case with \(m = V\)) implies that \(\varphi_n|_{U'}\) is an isomorphism for every \(n \in \mathbb{N}\), so the natural morphism \(\mathcal{R}_0 \to \mathcal{B}\) induces an isomorphism of \(O_U\text{-}\text{algebras}\)

\[
\mathcal{B} \xrightarrow{\sim} \mathcal{R}_{0\mid U}.
\]

**Claim 16.8.3.** There exists a subideal \(m_0 \subset m\) whose radical is \(m\), and with

\[
m_0 \cdot \ker \varphi_0 = m_0 \cdot \text{Coker} \varphi_0 = 0.
\]

**Proof of the claim.** Since \(Z\) is constructible, there exist finitely many elements \(x_1, \ldots, x_n \in m\) such that \(U = \bigcup_{i=1}^n \text{Spec} \, V[x_i^{-1}]\). Notice that both \(\mathcal{R}_0\) and \(\mathcal{R}_1\) are finitely presented \(O_S\text{-}\text{modules}\) : indeed, this holds for assumption for \(\mathcal{R}_0\), and then it follows also for \(\mathcal{R}_1\), since \(\Phi_S\) is an automorphism of \(S\). Thus, since moreover \(\varphi_0|_U\) is an isomorphism, after replacing each \(x_i\) by a power \(x_i^N\) for some suitable \(N \in \mathbb{N}\), we may assume already that \(x_i \cdot \text{Coker} \varphi_0 = 0\) for every \(i = 1, \ldots, n\). Next, let \(R_i := \mathcal{R}_i(S)\) for \(i = 0, 1\), and denote by \(f : R_0 \to R_1\) the Frobenius map; the natural map

\[
V[x_i^{-1}] \otimes V \text{Hom}_V(R_1, R_0) \to \text{Hom}_V[x_i^{-1}](R_1[x_i^{-1}], R_0[x_i^{-1}])
\]

is bijective (\([59, \text{Lemma 2.4.29}(i.a)]\)) and \(V[x_i^{-1}] \otimes V f\) is an isomorphism, hence we may find for every \(i = 1, \ldots, n\) a \(V\text{-linear map}\) \(g_i : R_1 \to R_0\) such that \(V[x_i^{-1}] \otimes V (g \circ f) = 1_{R_0}\). Then there exists \(N \in \mathbb{N}\) such that \(x_i^N \cdot (g \circ f) = x_i^N \cdot 1_{R_0}\) for every \(i = 1, \ldots, n\), whence \(x_i^N \cdot \ker f = 0\) for every \(i = 1, \ldots, n\). The claim follows. \(\diamondsuit\)
Let \( m_0 \) be as in claim \([16.8.3]\), and for every \( n \in \mathbb{N} \) set \( m_n := \Phi_V^n(m_0) \), where \( \Phi_V : V \to V \) denotes the Frobenius automorphism; then \( m_n \cdot \operatorname{Ker} \varphi_n = m_n \cdot \operatorname{Coker} \varphi_n = 0 \) for every \( n \in \mathbb{N} \). Notice that

\[
m_n^2 \subset m_n \cdot m_{n+1} \cdots m_{n+k}
\]

and therefore \( m_n^2 \) annihilates the kernel and cokernel of the transition map \( \mathcal{R}_n \to \mathcal{R}_{n+k} \), for every \( n, k \in \mathbb{N} \); we conclude that

\[
(16.8.4) \quad m_n^2 \cdot \operatorname{Ker} (\mathcal{R}_n \to \mathcal{R}) = m_n^2 \cdot \operatorname{Coker} (\mathcal{R}_n \to \mathcal{R}) = 0 \quad \text{for every} \quad n \in \mathbb{N}.
\]

Especially, \( \mathcal{A} := \mathcal{R}^a \) is an almost finitely presented and uniformly almost finitely generated \( \mathcal{O}_S^a \)-module (\([59\text{ Cor.2.3.13}]\)). Next, pick again elements \( x_1, \ldots, x_n \in m \) such that \( U \) is the union of the affine open subsets \( U_i := \operatorname{Spec} V[x_i^{-1}] \) for \( i = 1, \ldots, n \); since \( \mathcal{B} \) is a projective \( \mathcal{O}_U \)-module of finite rank, for every \( i = 1, \ldots, n \) there exist \( N_i \in \mathbb{N} \) and \( \mathcal{O}_U \)-linear morphisms

\[
\mathcal{B}|_{U_i} \xrightarrow{f_{0,i}} \mathcal{O}_S^a|_{U_i} \xrightarrow{g_{0,i}} \mathcal{B}|_{U_i}
\]

such that \( g_i \circ f_i = 1_{\mathcal{B}|_{U_i}} \).

Then, arguing as in the proof of claim \([16.8.3]\) we find for every \( i = 1, \ldots, n \), an integer \( M_i \in \mathbb{N} \) and \( \mathcal{O}_S \)-linear morphisms

\[
\mathcal{B}_0 \xrightarrow{f_{0,i}} \mathcal{O}_S^a \xrightarrow{g_{0,i}} \mathcal{B}_0
\]

whence, for every \( k \in \mathbb{N} \), and every \( i = 1, \ldots, n \), a pair of \( \mathcal{O}_S \)-linear morphisms

\[
\mathcal{B}_k \xrightarrow{f_{k,i}} \mathcal{O}_S^a \xrightarrow{g_{k,i}} \mathcal{B}_k
\]

such that \( g_{k,i} \circ f_{k,i} = x_i^{M_i/p^k} \cdot 1_{\mathcal{B}_0} \).

It follows easily that \( x_i^{M_i/p^k} \cdot \operatorname{Tor}_j^{\mathcal{O}_S}(\mathcal{B}_k, \mathcal{N}) = 0 \) for every \( j > 0 \), every \( i = 1, \ldots, n \), every \( k \in \mathbb{N} \) and every quasi-coherent \( \mathcal{O}_S \)-module \( \mathcal{N} \). After taking colimits, we conclude that \( \mathcal{A} \) is a flat \( \mathcal{O}_S^a \)-module; then \( \mathcal{A} \) is also an almost projective \( \mathcal{O}_S \)-module of finite rank, in light of \([59\text{ Prop.2.4.18(ii) and Rem.4.3.10(i)]}\). Next, let \( e \) be the diagonal idempotent of the étale \( \mathcal{O}_U \)-algebra \( \mathcal{B} \) (see remark \([14.3.10]\)). Pick a finite system of elements \( \varepsilon_1, \ldots, \varepsilon_k \in m \) such that \( m \) is the radical of the ideal \( \sum_{i=1}^k V \varepsilon_i \); we may then find \( N \in \mathbb{N} \) and for every \( i = 1, \ldots, k \) an element \( e_i \in R_0 \otimes_V R_0 \) such that

\[
(16.8.5) \quad (e_i^N \cdot e_i)_{|\operatorname{Spec} V[1/e]} = (e_i^N \cdot e)_{|\operatorname{Spec} V[1/e]} \quad \text{and} \quad \mu_0(e_i) = \varepsilon_i^N
\]

where \( \mu_0 : \mathcal{R}_n \otimes_{\mathcal{O}_S} \mathcal{R}_n \to \mathcal{R}_n \) is the multiplication map, for every \( n \in \mathbb{N} \). Next, let \( a_1, \ldots, a_n \) be a finite system of generators for the \( V \)-module \( R_0 \); we may find \( N' \in \mathbb{N} \) such that

\[
\varepsilon_i^{N'} \cdot (a_j \otimes 1 - 1 \otimes a_j) \cdot e_i = 0 \quad \text{for every} \quad i = 1, \ldots, k \quad \text{and} \quad \text{every} \quad j = 1, \ldots, n
\]

and after replacing \( e_i \) by \( \varepsilon_i^{N'} e_i \) and \( N \) by \( N + N' \) we may therefore assume that \( (16.8.5) \) still holds, and additionally:

\[
e_i \cdot \operatorname{Ker} \mu_0 = 0 \quad \text{for every} \quad i = 1, \ldots, k.
\]

The same \( e_1, \ldots, e_k \) can also be regarded as elements of \( R_n \otimes_V R_n \), and we deduce that

\[
(16.8.6) \quad \mu_n(e_i) = \varepsilon_i^{N/p^n} \quad \text{and} \quad e_i \cdot \operatorname{Ker} \mu_n = 0 \quad \text{for} \quad i = 1, \ldots, k \quad \text{and every} \quad n \in \mathbb{N}.
\]

Set \( R := \mathcal{R}(S) \) and denote by \( e_{n,i} \in R \otimes_V R \) the image of \( e_i \) under the natural morphism \( \mathcal{R}_n \to \mathcal{R} \), for \( i = 1, \ldots, k \). Say that \( \varepsilon_i^{N''} \in m_0 \) for \( i = 1, \ldots, k \) (where \( m_0 \) is as in claim \([16.8.3]\)); then \( \varepsilon_i^{N''/p^n} \in m_n \) for every \( n \in \mathbb{N} \) and \( i = 1, \ldots, k \). Recall that the kernel of the multiplication map \( \mu : \mathcal{R} \otimes_{\mathcal{O}_S} \mathcal{R} \to \mathcal{R} \) is generated, as a \( \mathcal{R} \otimes_{\mathcal{O}_S} \mathcal{R} \)-module, by the system \( (a \otimes 1 - 1 \otimes a \mid a \in R) \); in light of \( (16.8.4) \) and \( (16.8.6) \) we deduce that

\[
\varepsilon_i^{2N''/p^n} \cdot e_{n,i} \cdot \operatorname{Ker} \mu = 0 \quad \text{for} \quad i = 1, \ldots, k.
\]
where $\mu : \mathcal{R} \otimes_{\mathcal{O}_S} \mathcal{R} \to \mathcal{R}$ is the multiplication map. After replacing $e_{n,i}$ by $\varepsilon^{N/n}_i \cdot e_{n,i}$ and $N$ by $N + 2N''$, we then obtain $\mathcal{R} \otimes_{\mathcal{O}_S} \mathcal{R}$-linear morphisms

$$\nu_{n,i} : \mathcal{R} \to \mathcal{R} \otimes_{\mathcal{O}_S} \mathcal{R} \quad x \mapsto (x \otimes 1) \cdot e_{n,i}$$

for every $n \in \mathbb{N}$ and $i = 1, \ldots, k$ such that $\mu \circ \nu_{n,i} = \varepsilon^{N/n}_i \cdot 1_{\mathcal{R}}$. Set $R := \mathcal{R}(S)$ for every $n \in \mathbb{N}$; it follows easily that $\mathcal{R}(S) = 0$ for every $i = 1, \ldots, k$, every $n \in \mathbb{N}$, every $j > 0$ and every $\mathcal{R} \otimes_{\mathcal{O}_S} \mathcal{R}$-module $M$, so $\mathcal{R}$ is an almost projective $\mathcal{R} \otimes_{\mathcal{O}_S} \mathcal{R}$-module, and the proof is concluded. \hfill $\square$

Notice next that, in the situation of (16.8), the ring $\mathcal{V}$ is reduced, hence every flat almost finitely presented $\mathcal{V}^a$-module has almost finite rank (lemma 14.3.4(ii)). We can generalize this observation as follows:

**Proposition 16.8.7.** Let $(\mathcal{V}, \mathfrak{m})$ be a basic setup as in (16.8), and consider ideals $I \subset J \subset \mathfrak{m}$ with $J$ finitely generated. Let $P$ be any flat almost finitely presented $(\mathcal{V}/I)^a$-module. We have:

(i) $P$ has almost finite rank.

(ii) If $\text{Spec} \mathcal{V}/\mathfrak{m}$ is a constructible subset of $S := \text{Spec} \mathcal{V}$, then $P$ has finite rank.

**Proof.** In light of corollary 14.2.5(iv) we may assume that $\mathfrak{m}$ is the radical of a finitely generated subideal $\mathfrak{m}_0$ containing $J$, in which case $\text{Spec} \mathcal{V}/\mathfrak{m}$ is constructible in $S$, and it suffices to show assertion (ii). Then we may even replace $J$ by $\mathfrak{m}_0$, and assume that $J^{[1]}(1) V = \mathfrak{m}$ (notation of remark 9.3.71(i)).

**Claim 16.8.8.** We may assume that $J$ lies in the Jacobson radical of $\mathcal{V}$.

**Proof of the claim.** Indeed, let $x_1, \ldots, x_k$ be a finite system of generators of $J$; the induced map

$$\mathcal{V} \to (1 + J)^{-1} \mathcal{V} \times \prod_{i=1}^k \mathcal{V}[x_i^{-1}]$$

is faithfully flat, and clearly $\mathcal{V}[x_i^{-1}] \otimes_{\mathcal{V}} P$ is a projective $\mathcal{V}[x_i^{-1}] \otimes_{\mathcal{V}} \mathcal{V}/I$-module of finite rank for every $i = 1, \ldots, k$, so we are reduced to checking that $(1 + J)^{-1} \mathcal{V} \otimes_{\mathcal{V}} P$ is an almost projective $(1 + J)^{-1} \mathcal{V} \otimes_{\mathcal{V}} (\mathcal{V}/I)^a$-module of finite rank, whence the claim. \hfill $\diamond$

Henceforth we assume that $J$ lies in the Jacobson radical of $\mathcal{V}$. Now, suppose that we have $\Lambda_{[V/J]^a}(P/JP) = 0$ for some $r \in \mathbb{N}$; then $J \cdot \Lambda_{[V/J]^a} P = \Lambda_{[V/J]^a} P$, and since $J$ is tight and $\Lambda_{[V/J]} P$ is almost finitely generated, we deduce that $\Lambda_{[V/J]^a} P = 0$, by [59] Lemma 5.1.7]. Thus, we are reduced to checking the assertion in case $I = J$. Next, notice that there exists $n \in \mathbb{N}$ such that $(J^{(1)})^a V = J^{(n)} V \subset J$ (lemma 9.3.70(ii.a,iv)), so $J^{(1)} V$ is also a tight ideal contained in the Jacobson radical of $\mathcal{V}$, and by the same token we are reduced to checking that $Q := P/J^{(1)} P$ is a $(\mathcal{V}/J^{(1)})^a$-module of finite rank. To this aim, let us consider the $S$-scheme

$$Y := \text{Proj} R \quad \text{where} \quad R := \bigoplus_{\gamma \in \mathbb{N}[1/p]} J^{(1)} V$$

as in (16.7.9), as well as the closed immersion

$$i : Y_0 := Y \times_S \text{Spec} \mathcal{V}/J^{(1)} V = \text{Proj} R/J^{(1)} R \to Y.$$

Let also $\mathcal{T}$ be the discrete topology on $V$, and notice that $(V, \mathcal{T})$ is a perfectoid ring. Notice furthermore that $(J^{(1)} V)^a = (J^{(1)} V)^a$; in light of example 16.7.9(i), theorem 16.7.10 and the short exact sequence of quasi-coherent $\mathcal{O}_Y$-modules

$$0 \to J^{(1)} \mathcal{O}_Y \to \mathcal{O}_Y \to i_* \mathcal{O}_{Y_0} \to 0$$
we then deduce an isomorphism of $V^a$-algebras

$$\frac{(V/J^{(1)}V)^a}{(V/J^{(1)}V)^a} \cong H^0(Y_0, \mathcal{O}_{Y_0})^a$$

(details left to the reader). Say that $J$ is generated by a finite system $x_1, \ldots, x_k$; then $Y$ admits a closed immersion $Y \to \mathbb{P}^{k-1}_S := \text{Proj} V[T_1^{1/p^n}, \ldots, T_k^{1/p^n}]$ (see example 4.8.55(iii)), whence an affine covering $Y = U_1, \ldots, U_k$ consisting of preimages of complements of hyperplanes of $\mathbb{P}^k_S$, as usual. Set $U_{0,i} := U_i \times_Y Y_0$ for $i = 1, \ldots, k$; we get an injective ring homomorphism

$$H^0(Y_0, \mathcal{O}_{Y_0}) \to A := \prod_{i=1}^k H^0(U_{0,i}, \mathcal{O}_{Y_0})$$

and on the other hand, natural identifications of $A$-modules of finite rank, the localization $A_i := \text{gr}_0 R[x_i^{-1}] \cong H^0(U_i, \mathcal{O}_Y)$ $A_i/J^{(1)}A_i \cong H^0(U_{0,i}, \mathcal{O}_{Y_0})$ $i = 1, \ldots, k$. Since $Q$ is a flat $(V/J^{(1)}V)^a$-module, the same holds for $\Lambda^r_{(V/J^{(1)}V)^a} Q$, for every $r \in \mathbb{N}$; hence the induced map

$$\Lambda^r_{(V/J^{(1)}V)^a} Q \to A^a \otimes_{V^a} \Lambda^r_{(V/J^{(1)}V)^a} Q = \Lambda^r_{A^a}(A^a \otimes_{V^a} Q)$$

is a monomorphism, and we are reduced to checking that $A_i^a \otimes_{V^a} Q$ is an $(A_i/J^{(1)}A_i)^a$-module of finite rank for every $i = 1, \ldots, k$. Now, let $(B_i, JB_i)$ be the henselization of the pair $(A_i, JA_i)$. The ideal $mB_i$ is generated by the system $(x_i^{1/p^n} \mid n \in \mathbb{N})$ consisting of regular elements of $B_i$; by [59, Th.2.1.12(ii,b)] we deduce that $mB_i$ is a $B_i$-module of homological dimension $\leq 1$. Lastly, since $B_i/J^{(1)}B_i = A_i/J^{(1)}A_i$, we may apply [59, Th.5.5.7(i)] to find a flat almost finitely presented $B_i^a$-module $Q'$ with an isomorphism $Q'/J^{(1)}Q' \cong A_i^a \otimes_{V^a} Q$; since the localization $B_i \to B_i[x_i^{-1}]$ is a monomorphism, and since $B_i[x_i^{-1}] \otimes_{B_i} Q'$ is a projective $B_i[x_i^{-1}]$-module of finite rank, the $B_i^a$-module $Q'$ has finite rank as well. But then obviously the same holds for the $(A_i/J^{(1)}A))^a$-module $A_i^a \otimes_{V^a} Q$, as required. \hfill \Box

16.8.9. Let $A$ be a perfectoid ring, $E := E(A)$, and $\omega \in W(E)$ a distinguished element in the kernel of $u_A : W(E) \to A$. Recall that $\overline{u}_A : E \to A$ induces an isomorphism of topological rings $\omega : E/\alpha_0 E \sim A/pA$ (remark 16.3.7(ii)); hence, for every ideal $I \subset A$ containing $pA$, there exists a unique ideal $I_E \subset E$ containing $\alpha_0 E$ such that $\omega(I_E/\alpha_0 E) = I/pA$.

**Definition 16.8.10.** In the situation of (16.8.9), let $(A, m)$ and $(E, n)$ be two basic setups. We say that $(A, m)$ and $(E, n)$ are **compatible** if there exists an ideal of definition $I \subset A$ such that $\omega$ induces a bijection $(n + I_E)/I_E \sim (m + I)/I$.

**Remark 16.8.11.** With the notation of definition 16.8.10, let $M, N$ be two $A/I$-modules, and $h : M \to N$ an $A$-linear map. By assumption, $\overline{u}_A : E \to A$ induces a ring isomorphism $\omega_I : E/IE \sim A/I$, and the compatibility of $(A, m)$ and $(E, n)$ means that $\omega_I$ is an isomorphism

$$\frac{(E/IE, (n + I_E)/I_E)}{(A/I, (m + I)/I)} \sim (A/I, (m + I)/I)$$

in the category $\mathcal{B}$ of basic setups as in [59, §3.5]. Hence $h^a$ is an isomorphism of $(A, m)^a$-modules if and only if $\omega_I^a(h^a) : \omega_I^a(M^a) \to \omega_I^a(N^a)$ is an isomorphism of $(E, n)^a$-modules.

**Lemma 16.8.12.** In the situation of (16.8.9), consider two compatible basic setups $(A, m)$ and $(E, n)$, and let also $f : B \to B'$ be any continuous map in $A$-$\text{Perf}$. Then the morphism $f^a : B^a \to B'^a$ is an isomorphism in $(A, m)^a$-$\text{Alg}$ if and only if $E(f)^a : E(B)^a \to E(B')^a$ is an isomorphism in $(E, n)^a$-$\text{Alg}$.
Proof. By assumption, there exists an ideal of definition \( I \subset A \) such that \( \omega \) induces a bijection \( (m + I)/I \xrightarrow{\sim} (n + I_E)/I_E \), and arguing as in the proof of lemma [16.2.7(i)], we find a sequence \( \beta_1, \ldots, \beta_k \) of elements of \( E \) such that \( I \) is generated by \( \overline{u}_A(\beta_1), \ldots, \overline{u}_A(\beta_k) \); then, after replacing each \( \beta_i \) by \( \beta_i^{1/p^r} \) for some large \( n \in \mathbb{N} \), we may also assume that \( p \in I', \) with \( t := k(p - 1) + 1 \).

In light of lemma [16.1.9(ii)], it follows easily that \( I_E \) is generated by \( \beta_1, \ldots, \beta_k \), and \( \alpha_0 \in I_E \).

Denote by \( \mathcal{T} \) and \( \mathcal{T}' \) the \( I \)-adic topologies of \( B \) and \( B' \); by lemma 8.3.12 and proposition 16.3.8, the topological rings \( (B, \mathcal{T}) \) and \( (B', \mathcal{T}') \) are still perfectoid. Now, let \( \text{gr} \mathbf{B} \) (resp. \( \text{gr} \mathbf{B}' \)) be the graded ring associated with the \( I \)-adic filtration on \( B \) (resp. on \( B' \)); likewise, let \( \text{gr} \mathbf{E}(B) \) (resp. \( \text{gr} \mathbf{E}(B') \)) be the graded ring associated with the \( I_E \)-adic filtration on \( E(B) \) (resp. on \( E(B') \)). By claim 16.3.60(ii), the maps \( \overline{u}_B \) and \( \overline{u}_{B'} \) induce graded ring isomorphisms

\[ \vartheta : \text{gr} \mathbf{E}(B) \xrightarrow{\sim} \text{gr} \mathbf{B} \quad \vartheta' : \text{gr} \mathbf{E}(B') \xrightarrow{\sim} \text{gr} \mathbf{B}' \]

On the other hand, \( f \) and \( E(f) \) induce graded ring homomorphisms

\[ \text{gr} \mathbf{B} \to \text{gr} \mathbf{B}' \quad \text{gr} \mathbf{E}(f) : \text{gr} \mathbf{E}(B) \to \text{gr} \mathbf{E}(B') \]

such that:

\[ (16.8.13) \quad \text{gr} \mathbf{B} \circ \vartheta = \vartheta' \circ \text{gr} \mathbf{E}(f). \]

Now, if \( f^a \) is an isomorphism, then the same holds for \( \text{gr} \mathbf{B}^a \); conversely, if \( \text{gr} \mathbf{B}^a \) is an isomorphism, then we easily see that \( f^a_n := (A/I^n \otimes_A f)^a : (B/I^n B)^a \to (B'/I^n B')^a \) is an isomorphism for every \( n \in \mathbb{N} \), and therefore \( f^a = \lim_{n \in \mathbb{N}} f^a_n \) is an isomorphism (recall that the functor \( (\cdot)^a \) commutes with limits, since it is a right adjoint). Likewise we see that \( E(f)^a \) is an isomorphism if and only if the same holds for \( \text{gr} \mathbf{E}(f)^a \). Thus, we are reduced to checking that \( \text{gr} \mathbf{B}^a \) is an isomorphism of \((A, m)^a\)-algebras if and only if \( \text{gr} \mathbf{E}(f)^a \) is an isomorphism of \((E, n)^a\)-algebras. However, notice that \( \text{gr} \mathbf{B} \) and \( \text{gr} \mathbf{B}' \) are \( A/I \)-modules, and let \( \omega_I : E/I_E \xrightarrow{\sim} A/I \) be the ring isomorphism deduced from \( \overline{u}_A \); we may then regard \( \vartheta \) as an isomorphism \( \text{gr} \mathbf{E}(B) \xrightarrow{\sim} \omega_I^*(\text{gr} \mathbf{B}) \) of \( E/I_E \)-modules, and likewise for \( \vartheta' \). Also, \( \text{gr} \mathbf{B} \) is an isomorphism of \((A, m)^a\)-algebras if and only if \( \omega_I^*(\text{gr} \mathbf{E}(f)) \) is an isomorphism of \((E, n)^a\)-algebras, by remark 16.8.11. Taking into account (16.8.13), the assertion follows.

16.8.14. Let now \( A \) be a perfectoid ring, and \( m \subset A \) an open radical ideal. It follows easily that \( A^{\omega} \subset m \); moreover, if \( m_E \subset E := E(A) \) is associated with \( m \) as in (16.8.9), then \( \overline{u}_A \) induces a ring isomorphism \( E/m_E \xrightarrow{\sim} A/m. \)

Proposition 16.8.15. In the situation of 16.8.14, let also \( f : B \to B' \) be any continuous map in \( A\text{-Perf}. \) The following holds:

(i) \((A, m)\) and \((E, m_E)\) are basic setups fulfilling condition (B) of \([59, \S 2.1.6]\).

(ii) More precisely, the multiplication maps \( \overline{m} := m \otimes_A m \to m \) and \( \overline{m}_E := m_E \otimes_E m_E \to m_E \) are isomorphisms.

(iii) The morphism \( f^a : B^a \to B'^a \) is an isomorphism in \((A, m)^a\)-Alg if and only if \( E(f)^a : E(B)^a \to E(B')^a \) is an isomorphism in \((E, m_E)^a\)-Alg.

(iv) \( mB \) is a radical ideal of \( B \).

Proof. (i): Let \( I \) be any ideal of definition of \( A \). Since \( A/m \) is reduced, the same holds for \( E/m_E \), so \( m_E \) is a radical ideal of \( E \), hence \( m_E^2 = m_E \), since \( E \) is perfect. Now, let \( \alpha \in \text{Ker } u_A \) be any distinguished element; by remark 16.3.7(ii), the map \( \overline{u}_A \) induces a ring isomorphism \( E/\alpha_0 E \xrightarrow{\sim} A/pA \), and it follows easily that \( m^2 + pA = m \). On the other hand, we have \( pA \subset I \subset m^2 \), so \( m^2 = m \). Next, it is clear that \( m_E \) fulfills condition (B), in particular \( m_E \) is generated by its \( p \)-th powers, therefore the same follows for the ideal \( m_E/\alpha_0 E \) of \( E/\alpha_0 E \), and then also for the ideal \( m/pA \) of \( A/pA \). Combining with lemma 16.2.3(iv), we deduce that \( m \) is
generated by its $p$-powers. If $l \neq p$ is any prime integer, we have $l \in A^\times$, hence $m/lm = 0$, and taking into account \[59\] Claim 2.1.9, it follows that $m$ fulfills condition (B).

(ii): Let us write $m$ as the union of a filtered system $(m_\lambda \mid \lambda \in \Lambda)$ of open radical subideals such that $\text{Spec } A/m_\lambda$ is constructible in $\text{Spec } A$ for every $\lambda \in \Lambda$; clearly it suffices to show that the corresponding map $m_\lambda \otimes_A m_\lambda \to m_\lambda$ is an isomorphism for every $\lambda \in \Lambda$. We may therefore assume that $m$ is the radical of an open ideal generated by finitely many elements $a_1, \ldots , a_r$ of $A$; moreover, we may also assume that there exist $\alpha_1, \ldots , \alpha_r \in E$ with $a_i = \pi_A(\alpha_i)$ for $i = 1, \ldots , r$ (see remark \[16.3.7\] (iii)). In this situation, we have a ring homomorphism $u_0 : R_{r, 0} \to A$ such that $u_0(\alpha_i^{1/p^k}) = \pi_A(\alpha_i^{1/p^k})$ for $i = 0, \ldots , r$ (notation of \[16.7.9\]), and then it is easily seen that $m = T_{r[0]}^i A$. Then the assertion follows from proposition \[16.4.10\] and theorem \[16.7.10\] (iv).

(iii): It is clear that the basic setups $(A, m)$ and $(E, m_E)$ are compatible, in the sense of definition \[16.8.10\] then the assertion follows from lemma \[16.8.12\]

(iv): The map $\overline{u}_B$ induces a ring isomorphism:

$E(B)/m_E E(B) \cong B/mB$

and we need to check that $B/mB$ is reduced; so we are reduced to showing that the same holds for $E(B)/m_E E(B)$, i.e. that $m_E E(B)$ is a radical ideal. But since $E(B)$ is perfect, this is equivalent to proving that $\Phi_E(B)(m_E B) = m_E B$ (where $\Phi_E(B)$ denotes the Frobenius automorphism of $E(B)$); the latter is clear, since we have already shown that $m_E$ is a radical ideal of $E$.

16.8.16. Let $A$ be a perfectoid ring, $E := E(A)$, and $m \subset A$ an open radical ideal; let also $B$ be any perfectoid $A$-algebra, and $m_E \subset E$ the unique open ideal such that $\pi_A : E \to A$ induces a ring isomorphism $E/m_E E \cong A/m$ (see \[16.8.9\]). According to proposition \[16.8.15\] (i), we have a well defined $(A, m)^a$-algebra $B^a$ and an $(E, m_E)^a$-algebra $E(B)^a$. We denote by

$\eta_B : B \to B^a_a$ and $\eta_{E(B)} : E(B) \to E(B)^a$

the units of adjunction, and endow $B^a$ (resp. $E(B)^a$) with the unique ring topology such that $\eta_B$ (resp. $\eta_{E(B)}$) is an adic morphism.

**Corollary 16.8.17.** With the notation of \[16.8.16\], the topological rings $B^a$ and $E(B)^a$ are perfectoid, and there exists an isomorphism of $E$-algebras

$\omega : E(B)^a \cong E(B^a)$ such that $\omega \circ \eta_{E(B)} = \eta_B$.

**Proof.** We consider first the case where the structure map $A \to B$ is adic, and $Z := \text{Spec } A/m$ is constructible in $X := \text{Spec } A$. Then, set $U := \text{Spec } B \times_X (X \setminus Z)$, $B_U := \mathcal{O}_U(U)$, and let $\overline{B} \subset B_U$ be the image of the restriction map $\rho : B \to B_U$. Notice that $B$ is reduced, by corollary \[16.3.61\] (i); it follows easily that

\[(16.8.18) \quad m \cdot \text{Ker } \rho = 0\]

(the details are left to the reader). We remark:

**Claim 16.8.19.** If $Z$ is constructible in $X$, we have a natural identification of $B$-algebras:

$B^a \cong C := \{ x \in B_U \mid m \cdot x \subset \overline{B} \}$.

**Proof of the claim.** Let $a_1, \ldots , a_n \in A$ be a finite system of elements that generate an ideal whose radical equals $m$; then :

$B_U = \text{Equal } \left( \prod_{i=1}^n B(a_i^{-1}) \longrightarrow \prod_{i,j=1}^n B(a_i^{-1}, a_j^{-1}) \right)$.

Now, obviously $B(a_i^{-1})^a = B(a_i^{-1})$, and likewise for $B(a_i^{-1}, a_j^{-1})$, for every $i, j = 1, \ldots , n$; since the functor of almost elements is left exact, we deduce that $B_U^a = B_U$. Therefore, $\rho$ induces a map of $B$-algebras $\rho^a : B^a \to B_U$, and notice that $\rho^a$ is a monomorphism, due to \[16.8.18\], so
the same holds for $\rho_\circ^a$ (proposition 13.3.18(i)). Obviously $\overline{B}^a = B^a$, hence $m \cdot \rho_\circ^a(B^a) = m\overline{B}$, i.e. the image of $\rho_\circ^a$ lies in the subring $C$. Moreover, $\rho$ induces an isomorphism $C^{\circ} \to B^a$, whence by adjunction, a unique map of $B$-algebras $C \to B^a$ whose composition with $\rho_\circ$ agrees with the inclusion map $C \to B_U$. This shows that $\rho_\circ$ maps $B^a_\circ$ onto $C$, whence the claim. \hfill\Box

Recall that $B_U$ carries a natural $f$-adic topology for which $\overline{B}$ is a subring of definition (lemma 16.4.26(i)), and $\overline{E}$ is an open ideal of $\overline{B}$, since the structure map $A \to B$ is adic; from claim 16.8.19 it then follows that $B^a_\circ$ is a bounded subring of $B_U$, and therefore its topology as defined in [16.8.16] agrees with the topology induced by the inclusion into $B_U$ (proposition 8.3.18(i,ii)).

Claim 16.8.20. If the structure map $A \to B$ is adic, and $Z$ is constructible in $X$, we have:

(i) $B^a_\circ/B^\circ_U$ is a perfect $\mathbb{F}_p$-algebra and it is integrally closed in $B^a_\circ/B_U^\circ$.

(ii) $B^a_\circ$ is perfectoid and integrally closed in $B^a_\circ$.

Proof of the claim. (i): Notice that $A/A^\circ$, $\overline{B}/B^\circ$ and $B^a_U/B^\circ_U$ are perfect $\mathbb{F}_p$-algebras; also, $m/A^\circ$ is a radical ideal of $A/A^\circ$, and since $Z$ is constructible, there exists a finitely generated ideal $m_0 \subset A/A^\circ$ whose radical is $m/A^\circ$. With this notation, $B_\circ^a/B^\circ_U$ is an $A/A^\circ$-algebra, and for every $x \in B_\circ^a/B^\circ_U$ there exists $k \in \mathbb{N}$ such that $m^k_0 \cdot x \subset \overline{B}/B^\circ$. Then the assertion follows from lemma [16.8.1].

(ii) follows from (i), claim 16.5.15 and theorem 16.5.13(iii). \hfill\Box

Next, set $Z_E := \text{Spec } E/m_{E}$, $X_E := \text{Spec } E$, and $U_E := \text{Spec } E(B) \times_{X_E} (X_E \setminus Z_E)$. The foregoing argument applies also to $E(B)_\circ$, and shows that the latter is a perfectoid subring of $E_U := \mathcal{O}_{U_E}(U_E)$; moreover, we get cartesian diagrams of topological rings:

$$
\begin{array}{ccc}
B^a_\circ & \xrightarrow{\iota_B^a} & B^a_U \\
\downarrow & & \downarrow \\
B^a_\circ/B^\circ_U & \xrightarrow{\iota_U^a} & B^a_U/B^\circ_U
\end{array}
\ 
\begin{array}{ccc}
E(B)^a_\circ & \xrightarrow{\iota_E^a} & E^a_U \\
\downarrow & & \downarrow \\
E(B)^a_\circ/E^\circ_U & \xrightarrow{\iota_E^a} & E^a_U/E^\circ_U.
\end{array}
$$

Furthermore, according to proposition [16.5.4]iv), the morphism of topological monoids $\varphi^a_U : E^a_U \to B^a_U$ induces a ring isomorphism $\varphi^a_U : E^a_U/E^\circ_U \to B^a_U/B^\circ_U$, which in turn restricts to a ring isomorphism $\overline{E}(B)/E^\circ_U \to \overline{B}/B^\circ$, where $\overline{E}(B)$ denotes the image of $E(B)$ into $E_U$. Notice also that claim 16.8.19 yields natural identifications:

$$
\begin{array}{c}
B^a_\circ/B^\circ_U \simeq \{ x \in B^a_U/B^\circ_U | m \cdot x \subset \overline{B}/B^\circ \} \\
E(B)^a_\circ/E^\circ_U \simeq \{ x \in E^a_U/E^\circ_U | m_{E} \cdot x \subset \overline{E}(B)/E^\circ \}.
\end{array}
$$

But clearly $\varphi^a_U(m_{E} \cdot x) = m \cdot \varphi^a_U(x)$ for every $x \in E^a_U/E^\circ_U$, so $\varphi^a_U$ restricts as well to a ring isomorphism

$$
E(B)^a_\circ/E^\circ_U \simeq B^a_\circ/B^\circ_U.
$$

Summing up, and invoking proposition 16.3.25, we obtain a unique isomorphism of topological rings $\omega : E(B)^a_\circ \to E(B)^a_\circ$ fitting into the commutative diagram:

$$
\begin{array}{ccc}
E(B)^a_\circ & \xrightarrow{\iota_E^a} & E^a_U \\
\downarrow \omega & & \downarrow \omega^a \\
E(B)^a_\circ & \xrightarrow{\iota_B^a} & E(B)_U
\end{array}
$$

where $\omega^a$ is the isomorphism provided by theorem 16.5.13(i). Lastly, denote by $\rho^a : B \to B^\circ_U$ and $\varphi^a_E : E(B) \to E^a_U$ the continuous ring homomorphisms induced by the restriction maps;
the isomorphism $\omega^\circ$ is characterized by the identity:

$$\omega^\circ \circ \rho^\circ_E = E(\rho^\circ).$$

Since $\rho^\circ$ and $\rho_E^\circ$ factor through $\eta_B$ and respectively $\eta_{E(B)}$, we conclude that $\omega \circ \eta_{E(B)} = E(\eta_B)$, as stated. This completes the proof of the corollary in case $Z$ is constructible.

Next, we consider the case where $Z$ can be an arbitrary closed subset of $X$, and the structure map $A \to B$ is still adic. Let us write $m$ as the filtered union of a system $(m_\lambda \mid \lambda \in \Lambda)$ of open radical subideals such that $Spec A/m_\lambda$ is constructible in $X$ for every $\lambda \in \Lambda$; correspondingly, we obtain a filtered system $(m_{E,\lambda} \mid \lambda \in \Lambda)$ of ideals in $E$ whose union is $m_E$. For every such $\lambda$ let $B_\lambda$ (resp. $E(B)_\lambda$) be the image of $B$ (resp. of $E(B)$) in the category $(A, m_\lambda)^a$-$Alg$ (resp. $(E, m_{E,\lambda})^{a}$-$Alg$); we endow $B_\lambda^{\circ}$ (resp. $E(B)_\lambda^{\circ}$) with the unique adic topology such that the unit of adjunction $\eta_{B,\lambda} : B \to B_\lambda^{\circ}$ (resp. $\eta_{E(B),\lambda} : E(B) \to E(B)_\lambda^{\circ}$) is adic. After replacing $\Lambda$ by a cofinal subset, we may assume that $\Lambda$ admits an initial element $\lambda_0$. The localization functors $(A, m))^a$-$Alg \to (A, m_\lambda)^a$-$Alg \to (A, m_\mu)^a$-$Alg$ induce natural maps of $B$-algebras

$$f_\lambda : B_\lambda^{\circ} \to B_\lambda^{\circ}$$

and

$$f_\mu : B_\mu^{\circ} \to B_\mu^{\circ}$$

for every $\lambda, \mu \in \Lambda$ with $\lambda \geq \mu$ which are clearly continuous. Moreover, clearly the images $f_\lambda$ and $f_\mu$ of $f_\lambda$ and $f_\mu$ in $(A, m_\lambda)^a$-$Alg$ are isomorphism, hence

$$m_\lambda \cdot Ker f_\lambda = m_\lambda \cdot Coker f_\lambda = 0 \quad m_\lambda \cdot Ker f_\mu = m_\lambda \cdot Coker f_\mu = 0$$

for every $\lambda \geq \mu$.

Claim 16.8.21. The maps $f_\lambda$ and $f_\mu$ induce bijections

$$m_\lambda B_\lambda^{\circ} \xrightarrow{\sim} m_\lambda B_\mu^{\circ} \xrightarrow{\sim} m_\mu B_\mu^{\circ}$$

for every $\lambda \geq \mu$.

Proof of the claim. By the foregoing, we see already that if $f_\lambda$ (resp. $f_\mu$) maps $m_\lambda B_\lambda^{a}$ onto $m_\lambda B_\lambda^{\circ}$ (resp. $m_\mu B_\mu^{\circ}$ onto $m_\mu B_\mu^{a}$). Moreover, by the previous case we also know that $B_\lambda^{a}/m_\lambda B_\lambda^{a}$ is perfectoid, and under our current assumptions $m_\lambda B_\lambda^{\circ}$ is an open ideal of $B_\lambda^{\circ}$, hence $B_\lambda^{a}/m_\lambda B_\lambda^{a} = B_\lambda^{\circ} \otimes_A m_\lambda$ is a discrete perfectoid $\mathbb{F}_p$-algebra (proposition [16.3.9](i)); especially, the latter is a reduced ring (corollary [16.3.6](i)). Now, let $x \in m_\lambda B_\lambda^{\circ} \cap Ker f_\mu$; then $m_\lambda \cdot x = 0$, whence $x^2 = 0$, and finally $x = 0$, which shows that $f_\mu$ is injective on $m_\lambda B_\lambda^{\circ}$ for every $\lambda \in \Lambda$. Next, from corollary [14.2.5](i) we know that $B_\lambda^{a}$ is the limit of the cofiltered system of $B$-algebras $(B_\lambda^{\circ} \mid \lambda \in \Lambda)$, hence the natural map

$$m_\lambda B_\lambda^{\circ} \to L := \lim_{\lambda \in \Lambda} m_\lambda B_\lambda^{\circ}$$

is injective. But we have also just seen that all the projections $L \to m_\lambda B_\lambda^{\circ}$ are isomorphisms, so the maps $m_\lambda B_\lambda^{a} \to m_\lambda B_\lambda^{\circ}$ are injective as well.

From claim [16.8.21] and [125] Lemma 3.5.3] we deduce that the natural map

$$B_\lambda^{a}/m_\lambda B_\lambda^{\circ} \to \lim_{\lambda \in \Lambda} B_\lambda^{\circ}/m_\lambda B_\lambda^{\circ}$$

is a ring isomorphism; since we have already observed that each quotient $B_\lambda^{\circ}/m_\lambda B_\lambda^{\circ}$ is a perfect $\mathbb{F}_p$-algebra, it follows easily that the same holds for $B_\lambda^{a}/m_\lambda B_\lambda^{a}$; especially, the latter is a discrete perfectoid ring. We then get for every $\lambda \in \Lambda$ a cartesian diagram of rings

$$
\begin{array}{ccc}
B_\lambda^{\circ} & \xrightarrow{f_\lambda} & B_\lambda^{a} \\
\downarrow & & \downarrow \\
B_\lambda^{a}/m_\lambda B_\lambda^{\circ} & \xrightarrow{f_\mu} & B_\lambda^{a}/m_\lambda B_\lambda^{a}
\end{array}
$$

which is also cartesian in the category of topological rings, by lemma [8.3.11] and proposition [16.3.25] implies that $B_\lambda^{a}$ is perfectoid. The same argument applies as well to the perfectoid
E-algebra $E(B)$, and it yields a cartesian diagram of perfectoid rings:

$$
\begin{array}{ccc}
E(B)^a_s & \xrightarrow{f_{E,\lambda}} & E(B)^a_{s*} \\
\downarrow & & \downarrow \\
E(B)^a_s/m_{E,\lambda_0} & \xrightarrow{E(B)^a_s/m_{E,\lambda_0}} & E(B)^a_{s*}/m_{E,\lambda_0}.
\end{array}
$$

By the same token, the system $(f_{E,\lambda} \mid \lambda \in \Lambda)$ induces a ring isomorphism

$$E(B)^a_s/m_{E,\lambda_0} \to \lim_{\lambda \in \Lambda} E(B)^a_{s*}/m_{E,\lambda_0}.$$

Furthermore, by the previous case we already have an isomorphism of topological rings

$$\omega_\lambda : E(B)^a_{s*} \xrightarrow{\sim} E(B^a_{\lambda_*})$$

such that $\omega_\lambda \circ \eta_{E(B),\lambda} = E(\eta_{B,\lambda})$ for every $\lambda \in \Lambda$.

We may then identify naturally the bottom row of $\mathcal{D}_\lambda$ with that of $\mathcal{D}_{E,\lambda}$, and by invoking again proposition [16.3.25] we obtain a natural isomorphism of topological rings $\omega : E(B)^a_s \xrightarrow{\sim} E(B^a_s)$ fitting into the commutative diagrams

$$
\begin{array}{ccc}
E(B)^a_s & \xrightarrow{f_{E,\lambda}} & E(B)^a_{s*} \\
\downarrow & & \downarrow \\
E(B^a_s) & \xrightarrow{e(f_\lambda)} & E(B^a_{s*})
\end{array}
$$

Then the sought identity $\omega \circ \eta_{E(B)} = E(\eta_B)$ follows from the corresponding ones for the isomorphisms $\omega_\lambda$, after taking limits (details left to the reader). This completes the proof, in case the topologies of $A$ and $B$ are $p$-adic.

For the general case, let $\mathcal{D}_{A,p}$ (resp. $\mathcal{D}_{B,p}$) be the $p$-adic topology on $A$ (resp. on $B$); then $(A, \mathcal{D}_{A,p})$ and $(B, \mathcal{D}_{B,p})$ are perfectoid topological rings as well (proposition [16.3.8](i)), and the rings underlying $E((B, \mathcal{D}_{B,p})_s^a)$ and $E(B, \mathcal{D}_{B,p})_s^a$ coincide with the rings underlying $E(B^a_s)$ and respectively $E(B^a_s)$, so the previous case already yields a ring isomorphism $\omega$ as sought. It remains to check that $B^a_s$ (resp. $E(B^a_s)$) is perfectoid for the topology such that $\eta_B$ (resp. $\eta_{E(B)}$) is adic, and that $\omega$ is also an isomorphism of topological rings for these topologies. However, let $I \subset B$ be any finitely generated ideal of definition; the natural map $B^a_s \to \lim_{n \in \mathbb{N}} (B/I^n)^a_s$ is an isomorphism, hence the same holds for the induced map $B^a_s \to \lim_{n \in \mathbb{N}} (B/I^n)^a_s$, and especially, $B^a_s$ is complete and separated for the linear topology for which $(J_n := \text{Ker} B^n_s \to (B/I^n)^a_s \mid n \in \mathbb{N})$ is a fundamental system of open submodules (corollary [8.2.16](i)). Clearly $I^n B^a_s \subset J_n$ for every $n \in \mathbb{N}$, so $B^a_s$ is also complete and separated for its $I$-adic topology (lemma [8.3.12]). Together with proposition [16.3.8](ii), this proves that $B^a_s$ is perfectoid, and the same applies to $E(B)^a_s$. Lastly, since $\eta_B$ is adic, the same holds for $E(\eta_B)$ (corollary [16.3.8]), but then the identity $\omega \circ \eta_{E(B)} = E(\eta_B)$ implies easily that $\omega$ is an isomorphism of topological rings. 

16.8.22. In the situation of (16.8.16), denote also by $\varepsilon_B : B^a_H \to B$ and $\varepsilon_{E(B)} : E(B)^a_H \to E(B)$ the counits of adjunction, and endow $B^a_H$ (resp. $E(B)^a_H$) with the unique topology such that the natural map $A \to B^a_H$ (resp. $E \to E(B)^a_H$) is adic.

**Corollary 16.8.23.** With the notation of (16.8.22), the topological rings $B^a_H$ and $E(B)^a_H$ are perfectoid and there exists an isomorphism of $E$-algebras

$$\omega : E(B)^a_H \xrightarrow{\sim} E(B^a_H),$$

such that $E(\varepsilon_B) \circ \omega = E(\varepsilon_{E(B)}).$
Proof. Notice that, by virtue of proposition\textsuperscript{[16.8.15]} ii) we have cartesian diagrams of rings

\[
\begin{array}{ccc}
B/J_0 & \xrightarrow{\varepsilon_B} & B \\
\downarrow & & \downarrow \\
E(B)/J_0 & \xrightarrow{\varepsilon_{E(B)}} & E(B)
\end{array}
\]

\[
\begin{array}{ccc}
A/m & \rightarrow & B/mB. \\
\downarrow & & \downarrow \\
E/m_E & \rightarrow & E(B)/m_E E(B).
\end{array}
\]

Moreover, clearly we may assume that the structure map \( A \rightarrow B \) is an adic ring homomorphism, in which case the same holds for the map \( E \rightarrow E(B) \) (theorem\textsuperscript{[16.3.42]} ii)), and the bottom rows of \( \mathcal{D} \) and \( \mathcal{D}_E \) consist of discrete perfectoid \( \mathbb{F}_p \)-algebras (cp. the proof of claim\textsuperscript{[16.8.21]}). Then \( \mathcal{D} \) and \( \mathcal{D}_E \) are cartesian in the category of topological rings as well (lemma\textsuperscript{[8.3.11]}), and the assertion follows from proposition\textsuperscript{[16.3.25]} \( \square \)

\textbf{Lemma 16.8.24.} In the situation of (16.8.16), let \( f : B \rightarrow C \) be a morphism of perfectoid \( A \)-algebras, \((b_\lambda \mid \lambda \in \Lambda)\) a system of elements of \( B \), and for every \( n \in \mathbb{N} \) denote by \( I_n \subset B \) the ideal generated by the system \((b_n^n \mid \lambda \in \Lambda)\). Suppose that \( p^kB \subset I_1 \) for some \( k \in \mathbb{N} \), and that \((f \otimes_B B/I_1)^a : (B/I_1)^a \rightarrow (C/I_1C)^a\) is a flat morphism of \((A, m)^a\)-algebras. Then the same holds for \((f \otimes_B B/I_n)^a\), for every \( n \in \mathbb{N} \).

\textbf{Proof.} Set \( J_n := p^nB + I_n \) for every \( n \in \mathbb{N} \); since \( p^kB \subset I_1 \), it is easily seen that for every \( n \in \mathbb{N} \) there exists \( n' \in \mathbb{N} \) such that \( J_n' \subset I_n \subset J_n \) (details left to the reader). Hence, it suffices to show that \((f \otimes_B B/J_n')^a\) is flat for every \( n \in \mathbb{N} \). Next, let \( \alpha \in \text{Ker } u_B \) be a distinguished element, and pick for every \( \lambda \in \Lambda \) elements \( e_\lambda \in E(B) \) and \( c_\lambda \in B \) such that \( b_\lambda = \pi_B(e_\lambda) + \pi_B(\alpha_0) \cdot c_\lambda \).

For every \( n \in \mathbb{N} \), denote by \( I'_n \subset B \) the ideal generated by \((\pi_B(e_\lambda^n) \mid \lambda \in \Lambda)\), and set \( J_n' := \pi_B(\alpha_0^n) \cdot B + I'_n \); it follows easily that

\[
J_{2n-1} \subset J'_n \quad \text{and} \quad J'_{2n-1} \subset J_n \quad \text{for every } n \in \mathbb{N}
\]

so \((f \otimes_B B/J'_n)^a\) is flat, and we are further reduced to checking that \((f \otimes_B B/J'_n)^a\) is flat for every \( n \in \mathbb{N} \). For every \( n \in \mathbb{N} \), denote by \( I_{E,n} \subset E(B) \) the ideal generated by \((e_\lambda^n \mid \lambda \in \Lambda)\), and set \( J_{E,n} := \alpha_0^n E(B) + I_{E,n} \), notice the natural identifications

\[
(16.8.25) \quad B/J'_1 = E(B)/J_{E,1} \quad \text{and} \quad C/J'_1C = E(C)/J_{E,1} E(C).
\]

Denote also by \( \Phi_{B/J'_1} \) and \( \Phi_{C/J'_1C} \) the Frobenius endomorphism of \( B/J'_1 \) and respectively \( C/J'_1C \). We remark:

\textbf{Claim 16.8.26.} The induced diagram of \( E \)-algebras

\[
\begin{array}{ccc}
B/J'_1 & \xrightarrow{f \otimes_B B/J'_1} & C/J'_1 C \\
\Phi_{B/J'_1} & \downarrow & \Phi_{C/J'_1 C} \\
B/J'_1 & \xrightarrow{f \otimes_B B/J'_1} & C/J'_1 C
\end{array}
\]

is cocartesian.

\textbf{Proof of the claim.} Indeed, since \( E(B) \) is perfect, it is easily seen that \( \Phi_{B/J'_1} \) is surjective, and its kernel is the ideal generated by the system \( \{\alpha_0^{1/p} \} \cup \{e_\lambda^{1/p} \mid \lambda \in \Lambda\} \), under the identifications\textsuperscript{[16.8.25]}; likewise, \( \Phi_{C/J'_1C} \) is surjective and its kernel is generated by the image in \( C/J'_1C \) of the same system, whence the claim. \( \diamond \)

For every \( n \in \mathbb{N} \), set \( n_n := \{a \in W_n E \mid a_0, \ldots, a_{n-1} \in m\} \); since \( m_E \) fulfills condition (B) of [59 \ §2.1.6], proposition\textsuperscript{[14.7.11]} says that \( n_n \) is the unique ideal \( n_n \subset W_n E \) with \( n_n^2 = n_n \).
and \( \varpi_i(n_n) = n_{E} \) for \( i = 0, \ldots, n - 1 \). From claim 16.8.26 and theorem 14.7.26(i) it follows that the induced morphism of \((W_n, E, n_n)\)-algebras

\[
W_n(f \otimes_B B/J_1) : W_n(E(B)/J_{E,1})^n \to W_n(E(C)/J_{E,1}E(C))^n
\]
is flat for every \( n \in \mathbb{N} \). Moreover, the Frobenius automorphisms of \( E(B) \) and \( E(C) \) induce isomorphisms \( E(B)/J_{E,1} \cong E(B)/J_{E,p^n} \) and \( E(C)/J_{E,1}E(C) \cong E(C)/J_{E,p^n}E(C) \) for every \( k \in \mathbb{N} \), whence a commutative diagram of \( W_nE \)-algebras

\[
\begin{array}{ccc}
W_n(E(B)/J_{E,1}) & \xrightarrow{W_n(f \otimes_B E(B)/J_{E,1})} & W_n(E(C)/J_{E,1}E(C)) \\
\downarrow & & \downarrow \\
W_n(E(B)/J_{E,p^n}) & \xrightarrow{W_n(f \otimes_B E(B)/J_{E,p^n})} & W_n(E(C)/J_{E,p^n}E(C))
\end{array}
\]

whose vertical arrows are isomorphisms, and where the rings on the bottom row are regarded as \( W_nE \)-algebras via restriction of scalars along the automorphism \( W_n(\Phi_E) : W_nE \to W_nE \).

Since we have

\[
W_n(\Phi_E)(n_n) = n_n \quad \text{for every } n \in \mathbb{N}
\]
it follows that \( W_n(f \otimes_B E(B)/J_{E,p^n})^n \) is a flat morphism of \((W_nE, n_n)\)-algebras, for every \( n, k \in \mathbb{N} \). We remark, quite generally:

**Claim 16.8.27.** Let \( R \) be any ring such that the Frobenius endomorphism \( \Phi_{R/pR} \) of \( R/pR \) is surjective, \( (x_\lambda \mid \lambda \in \Lambda) \) any set of elements of \( R \), and \( I \subset R \) the ideal generated by this set. Then, for every \( n \in \mathbb{N} \), the kernel of the projection \( \pi_n : W_nR \to W_nR/I \) is generated by

\[
(V^i(\lambda) \mid \lambda \in \Lambda, \ i = 0, \ldots, n - 1).
\]

**Proof of the claim.** Arguing by induction on \( n \in \mathbb{N} \), we are reduced to checking that the ideal \( V_nI := V_nR \cap \ker \pi_{n+1} \) is generated by \((V^n\lambda \mid \lambda \in \Lambda)\), for every \( n \in \mathbb{N} \). However, according to claim 9.3.31 we have an isomorphism of \( W_{n+1}R \)-modules : \( I \cong V_nI \), where \( I \) is regarded as a \( W_{n+1}R \)-module via restriction of scalars along the ring homomorphism \( \varpi_n : W_{n+1}R \to R \). Thus, we come down to showing that \( \varpi_n \) is a surjection for every \( n \in \mathbb{N} \). We argue by induction on \( n \) : the assertion is trivial for \( n = 0 \), so suppose that \( \varpi_n \) is already known to be surjective for some \( n \geq 0 \); since \( \Phi_{R/pR} \) is surjective, the same holds for \( \Phi_{R/pR}^n \) and taking into account (9.3.3) together with our inductive assumption, we easily deduce that \( \varpi_{n+1} \) is surjective as well. \( \diamond \)

In light of claim 16.8.27 we see that

\[
W_n(E(B)/J_{E,p^n}) = W(E(B))/(p^nW(E(B)) + \mathcal{J}_k)
\]

where \( \mathcal{J}_k \) is the ideal generated by \((p^i \cdot \tau_{E,(B)}(e_{\lambda})^{p^{k-1}}) \mid \lambda \in \Lambda, \ i = 0, \ldots, k) \). Taking into account lemma 16.1.1(iv), we deduce that

\[
A \otimes_{W(E)} W_n(E(B)/J_{E,p^n}) = B/(p^nB + I''_k)
\]

where \( I''_k \) is the ideal generated by \((p^i \cdot \varpi_B(e_{\lambda})^{p^{k-1}}) \mid \lambda \in \Lambda, \ i = 0, \ldots, k) \). Notice that

\[
(16.8.28) \quad J''_{2k-1} \subset I''_{2k-1} \subset J''_k \quad \text{for every } k \in \mathbb{N}
\]

We have as well \( A \otimes_{W(E)} W_n(f \otimes_B E(B)/J_{E,p^n}) = f \otimes_B B/(p^nB + I''_k) \), and furthermore, the ring homomorphism \( W_nE \to A/p^nA \) induced by \( u_A \) maps \( n_n \) onto \( m/p^nA \); therefore, \((f \otimes_B B)/(p^nB + I''_k))^n \) is a flat morphism of \((A, m)^n\)-algebras, for every \( n, k \in \mathbb{N} \). Combining with (16.8.28), the assertion follows. \( \square \)

**Proposition 16.8.29.** In the situation of (16.8.16), let \( f^a : B^a \to C \) be an étale morphism of \((A, m)^a\)-algebras such that \( C \) is an almost finitely presented \( B^a \)-module, and endow \( C_a \) with the unique ring topology such that the induced map \( B \to C_a \) is adic. Then \( C_a \) is perfectoid.
Proof. Let \( I \subset B \) be any ideal of definition, and \( I_E \subset E(B) \) the corresponding ideal such that \( \pi_A \) induces an isomorphism \( E(B)/I_E \xrightarrow{\sim} B/I \) (see remark \[16.3.7\](iii)); then \( f^a \otimes_B B/I : E(B)/I_E \rightarrow C/IC \) is an étale morphism of \((E, m_E)^a\)-algebras. By \[59\ Th.5.3.27\], the latter lifts uniquely to an étale morphism \( g : E(B)^a \rightarrow C' \) of \((E, m_E)^a\)-algebras such that \( C' \) is almost finitely presented as an \( E(B)^a \)-module. Since \( E(B) \) is perfect, \[59\ Th.3.5.13\] implies that the Frobenius morphism

\[
(\Phi_E, \Phi_{C'}) : (E(B), m_E), C') \rightarrow ((E(B), m_E), C')
\]
is cartesian in the fibred category \( \mathcal{B}^a_{\text{Alg}} \) of \[59\ §3.5.3\]. Since the functor \(-)_* \) on \( \mathcal{B}^a_{\text{Alg}} \) is cartesian (see \[59\ §3.5.4\]), it follows that the morphism

\[
(\Phi_E, \Phi_{C'_a}) : ((E(B), m_E), C'_a) \rightarrow ((E(B), m_E), C'_a)
\]
is cartesian as well, i.e. \( C'_a \) is a perfect \( \mathbb{F}_p \)-algebra. Let us endow \( C'_a \) with its \( I_E \)-adic topology.

We remark:

Claim 16.8.30. \( C'_a \) is perfectoid.

Proof of the claim. Since \( E(B)^a \) is complete and separated for its \( I_E \)-adic topology, \[59\ Claim 5.3.25\], implies that the natural morphism \( C' \rightarrow \lim_{n \in \mathbb{N}} C'/\mathbb{I}_E^n C' \) is an isomorphism, so the same holds for the induced map \( C'_a \rightarrow \lim_{n \in \mathbb{N}} (C'/\mathbb{I}_E^n C')_a \). Especially, \( C'_a \) is complete and separated for the linear topology defined by the system of ideals \( (J_n := \text{Ker} (C'_a \rightarrow (C'/\mathbb{I}_E^n C')_a) \mid n \in \mathbb{N}) \) (corollary \[8.2.16\](ii)). Clearly \( \mathbb{I}_E^n C'_a \subset J_n \) for every \( n \in \mathbb{N} \), so \( C'_a \) is also complete and separated for its \( I_E \)-adic topology (lemma \[8.3.12\]), whence the claim.

By claim \[16.8.30\] it follows that there exists a perfectoid \( A \)-algebra \( D \) with an isomorphism of perfectoid \( E \)-algebras \( C'_a \xrightarrow{\sim} E(D) \). We consider the composition

\[
h : E(B) \xrightarrow{\eta_E(B)} E(B)^a \xrightarrow{g} C'_a \xrightarrow{\sim} E(D)
\]

where \( \eta_{E(B)} \) is the unit of adjunction; since \( h \) is an adic ring homomorphism, there exists a unique adic map of \( A \)-algebras \( k : B \rightarrow D \) with \( E(k) = h \) (theorem \[16.3.42\](i)). By construction, we have also an isomorphism \( (C/IC)^a \xrightarrow{\sim} (D/ID)^a \) of \( (B/I)^a \)-algebras; especially, \( (k \otimes_B B/I)^a \) is a flat ring homomorphism, and therefore the same holds for \( (k \otimes_B B/I^n)^a : (B/I)^a \rightarrow (D/ID)^a \), for every \( n \in \mathbb{N} \) (lemma \[16.8.24\]). By virtue of \[59\ Cor.3.2.11\(\text{(ii,iii)} \) and remark \[14.1.91\] it follows that there exists a unique isomorphism of \( (B/I)^a \)-algebras

\[
\omega_n : C/I^n C \xrightarrow{\sim} (D/I^n D)^a \quad \text{for every } n \in \mathbb{N}.
\]

Notice that the uniqueness of the morphisms \( \omega_n \) implies that \( \omega_{n+1} \otimes_B B/I^n = \omega_n \) for every \( n \in \mathbb{N} \). However, \( D \) is complete and separated for its \( I \)-adic topology, since \( h \) is adic; the same holds for \( C \), since the latter is an almost projective \( B \)-module of almost finite presentation (\[59\ Claim 5.3.25\)). Hence, the limit of the inverse system \( (\omega_n \mid n \in \mathbb{N}) \) is an isomorphism \( \omega : C \xrightarrow{\sim} D^a \) of \( B^a \)-algebras, whence the isomorphism \( \omega_x : C_x \xrightarrow{\sim} D^a_x \) of \( B \)-algebras, and it suffices to invoke corollary \[16.8.17\] to conclude. \[\square\]

16.8.31. Let now \( A := (A, A^+, U) \) be any perfectoid quasi-affinoid ring, and set

\[
U := \text{Spec } A \quad U_E := \text{E(U)} \quad X_A := \text{Spec } A \quad Z_A := X_A \setminus U
\]

(notation of \[16.5.20\]). We let \( m \subset A \) be the unique radical ideal such that \( \text{Spec } A/m = Z_A \). Also, set \( E := E(A), X_E := \text{Spec } E \), and let \( m_E \subset E \) be the unique ideal such that \( \pi_A \) induces a ring isomorphism \( E/m_E \xrightarrow{\sim} A/m \) (see remark \[16.3.7\](iii)). According to proposition \[16.8.15\], both pairs \( (A, m) \) and \( (E, m_E) \) are basic setups.

Theorem 16.8.32. With the notation of \[16.8.31\], the pair \( (X_A, Z_A) \) is normal and almost pure, relative to the basic setup \( (A, m) \).
Proof. Let \( j_A : U \to X_A \) be the open immersion; since \( j_A, \mathcal{O}_U \) is a quasi-coherent \( \mathcal{O}_{X_A} \)-algebra (\([44]\) Ch.I, Prop.9.4.2(i))), in order to check that the pair \((X_A, Z_A)\) is normal, it suffices to show that the induced map \( A \to \mathcal{O}_{X_A}(U) \) is almost injective and the image of \( A^a \) is integrally closed in \( \mathcal{O}_{X_A}(U)^a \). These assertions follow from claim \([16.8.20]\)(ii).

Next, pick any ideal of definition \( I \subset A \), set \( E := \mathcal{E}(A) \), let \( I_E \subset E \) be the unique ideal of definition such that \( \pi_A \) induces a ring isomorphism \( E/I_E \xrightarrow{\sim} A/I \), and consider the following diagram of categories:

\[
\begin{array}{ccc}
\mathcal{Cov}(U) & \xleftarrow{j_A^*} & (A, m)^a.\mathcal{E}_{\text{af}} \xrightarrow{i_A^*} (A/I, m/I)^a.\mathcal{E}_{\text{af}} \\
\mathcal{D}_A & \xrightarrow{w_A} & \mathcal{Cov}(U_E) \xrightarrow{j_E^*} (E, m_E)^a.\mathcal{E}_{\text{af}} \xrightarrow{i_E^*} (E/I_E, m_E/I_E)^a.\mathcal{E}_{\text{af}}
\end{array}
\]

where \( j_A^* \) (resp. \( i_A^* \)) is induced by the open (resp. closed) immersion \( j_A : U \to X_A \) (resp. \( i_A : Z_A \to X_A \)) and likewise for \( j_E^* \) and \( i_E^* \). We need to show that \( j_A^* \) is an equivalence. However, according to \([59]\) Th.5.5.7(iii)), both \( i_A^* \) and \( i_E^* \) are equivalences, and the same holds for \( j_E^* \), by virtue of theorem \([16.8.2]\)(i). Then, choose an arbitrary quasi-inverse functor \( s_E \) for \( j_E^* \) and \( t_A \) for \( i_A^* \); we let the dotted arrow be the functor \( w_A := j_A^* \circ t_A \circ i_E^* \circ s_E : \mathcal{Cov}(U_E) \to \mathcal{Cov}(U) \), so that \( \mathcal{D}_A \) is essentially commutative, and we are reduced to checking that \( w_A \) is an equivalence.

Claim 16.8.33. We may assume that \( A = \Gamma^0(U) \) (notation of \([16.5.19]\)).

Proof of the claim. Say that \( \Gamma^0(U) = (A_0, A_+^0, U) \), set \( X_0 := \text{Spec} A_0^0 \), and denote by \( m_U \subset A_0^0 \) the unique radical ideal such that \( \text{Spec} A_0^0/m_U = X_0 \setminus U \). Likewise, say that \( \Gamma^0(U_E) = (E_0, E_+^0, U_E) \), set \( X_0 := \text{Spec} E_0^0 \), and denote by \( m_{E,U} \subset E_0^0 \) the unique radical ideal such that \( \text{Spec} E_0^0/m_{E,U} = X_0 \setminus U_E \). It follows easily that

\[
m_U \subset m A_0^0 \quad m_{E,U} \subset m E_0^0.
\]

Moreover, set \( I_U := IA_0^0 \) and \( I_{E,U} := I_E E_0^0 \); the map \( \pi_{A_0^0} : E_0^0 \to A_0^0 \) induces a ring isomorphism \( E_0^0/I_{E,U} \xrightarrow{\sim} A_0^0/I_U \). Also, as in the foregoing, the projection \( A_0^0 \to A_0^0/I_U \) and the open immersion \( j_{E,U} : U_E \to X_0 \) induce equivalences of categories

\[
\begin{array}{c}
(A_0^0, m_U)^a.\mathcal{E}_{\text{af}} \xrightarrow{i_U^*} (A_0^0/I_U, m_U/I_U)^a.\mathcal{E}_{\text{af}} \xrightarrow{j_U^*} \mathcal{Cov}(U_E) \\
(A_0^0/I_U, m_U/I_U)^a.\mathcal{E}_{\text{af}} \xrightarrow{j_E^*} (E_0^0, m_{E,U})^a.\mathcal{E}_{\text{af}} \xrightarrow{i_E^*} \mathcal{Cov}(U_E)
\end{array}
\]

After choosing quasi-inverse functors \( t_U \) for \( i_U^* \) and \( s_{E,U} \) for \( j_{E,U}^* \), there follows an essentially commutative diagram of functors

\[
\begin{array}{ccc}
(A, m)^a.\mathcal{E}_{\text{af}} & \xleftarrow{t_A} & (A/I, m/I)^a.\mathcal{E}_{\text{af}} \\
\mathcal{Cov}(U) & \xleftarrow{j_A} & \mathcal{Cov}(U_E) \xleftarrow{j_U} \mathcal{Cov}(U_E) \\
(A/I, m/I)^a.\mathcal{E}_{\text{af}} & \xrightarrow{i_E^*} & (E, m_E)^a.\mathcal{E}_{\text{af}} \\
\mathcal{Cov}(U_E) & \xrightarrow{s_{E,U}} & \mathcal{Cov}(U_E)
\end{array}
\]

whose unmarked vertical arrows are induced by the natural ring homomorphisms \( A \to A_0^0 \), \( A/I \to A_0^0/I_U \) and \( E \to E_0^0 \), and where \( j_{E,U}^* \) is induced by the open immersion \( j_U : U \to X_0 \).

The claim follows easily.

The restriction to the site \( \mathcal{R}(U) \) of the stack \( \mathcal{Cov}^\wedge_U \) of corollary \([15.7.26]\) along the inclusion \( \mathcal{R}(U) \subset \mathcal{D}(U) \) is a stack that we denote again

\[
\pi_U : \mathcal{Cov}^\wedge_U \to \mathcal{R}(U).
\]
Recall the construction: for every rational subset \( R \subset \text{Spa} U \) we choose a complete and separated quasi-affinoid scheme \( \mathcal{U}_R^\wedge := (U_R^\wedge, \mathcal{T}_R^\wedge, \mathcal{A}_R^\wedge^+) \) representing the sub-presheaf \( h^\wedge_R \) of \( h^\wedge_U \), then \( \pi_{\mathcal{U}_R^\wedge}(R) := \text{Cov}(U_R^\wedge) \). We shall consider similarly the quasi-affinoid schemes

\[
\mathcal{X}_A := \text{Spec} (A, A^+, X_A) \quad \text{and} \quad \mathcal{Y}_A := \text{Spec} A/I \otimes_A (A, A^+, X_A)
\]

(notation of example 15.4.7(i)) and the fibrations

\[
\pi_{\mathcal{X}_A} : \text{Cov}(\mathcal{X}_A, \mathcal{m}_A) \rightarrow \mathcal{R}(U) \quad \pi_{\mathcal{Y}_A} : \text{Cov}(\mathcal{Y}_A, \mathcal{m}_A) \rightarrow \mathcal{R}(U)
\]

defined as follows. For any \( R \in \text{Ob}(\mathcal{R}(U)) \), we know that \( (A_R^\wedge, A_R^\wedge^+, U_R^\wedge) := \Gamma^\circ(U_R^\wedge) \) is a perfectoid quasi-affinoid ring (proposition 16.7.25(iii) and (16.5.19)), and we set \( X_R := \text{Spec} A_R^\wedge^+ \); then, let \( m_R \subset A_R^\wedge \) be the unique radical ideal such that \( X_R \setminus U_R^\wedge = \text{Spec} A_R^\wedge/m_R \). Set also \( I_R := IA_R^\wedge \), by proposition 16.8.15(i), the pair \( (A_R^\wedge, m_R) \) is a basic setup, and we let

\[
\pi_{\mathcal{X}_A}^{-1}(R) := (A_R^\wedge, m_R)^a : \mathcal{E}_{\text{afp}} \quad \pi_{\mathcal{Y}_A}^{-1}(R) := (A_R^\wedge/I_R, m_R/I_R)^a : \mathcal{E}_{\text{afp}}
\]

If \( R' \subset R \) is another rational subset, the induced inclusion of sub-presheaves \( h^\wedge_{R'} \subset h^\wedge_R \) corresponds to a morphism \( U_R^\wedge \rightarrow U_{R'}^\wedge \) of quasi-affinoid schemes, which in turn yields a morphism \( \Gamma^\circ(U_{R'}^\wedge) \rightarrow \Gamma^\circ(U_R^\wedge) \) of perfectoid quasi-affinoid rings, and it follows easily that

\[
m_{R'} \subset m_R A_{R'}^\wedge
\]

whence, finally, induced functors

\[
j^*_{R'R'} : \pi_{\mathcal{X}_A}^{-1}(R) \rightarrow \pi_{\mathcal{X}_A}^{-1}(R') \quad j^\circ_{R'R'} : \pi_{\mathcal{Y}_A}^{-1}(R) \rightarrow \pi_{\mathcal{Y}_A}^{-1}(R').
\]

Moreover, for every further inclusion of rational subset \( R'' \subset R' \) we have a natural isomorphisms of functors

\[
j^*_{R'R''} \circ j^*_{R'R} \cong j^*_{R'R''} \circ j^*_{R'R} \quad j^\circ_{R'R''} \circ j^\circ_{R'R} \cong j^\circ_{R'R''} \circ j^\circ_{R'R}
\]

and the systems of such functors and isomorphisms of functors amount to well defined pseudofunctors \( \mathcal{R}(U)^a \rightarrow \text{Cat} \), whence the sought fibrations \( \pi_{\mathcal{X}_A} \) and \( \pi_{\mathcal{Y}_A} \). Furthermore, the system of open immersions \( j_R : U_R^\wedge \rightarrow X_R \) and the projections \( A_R^\wedge \rightarrow A_R^\wedge/I_R \) induce pseudonatural transformations

\[
(A_R^\wedge/I_R, m_R/I_R)^a : \mathcal{E}_{\text{afp}} \quad \text{and} \quad (A_R^\wedge, m_R)^a : \mathcal{E}_{\text{afp}}
\]

\[
\text{Cov}(\mathcal{Y}_A, \mathcal{m}_A) \leftarrow \text{Cov}(\mathcal{X}_A, \mathcal{m}_A) \rightarrow \text{Cov}(\mathcal{Y}_A, \mathcal{m}_A)
\]

whence morphisms of fibrations

\[
\text{Cov}(\mathcal{Y}_A, \mathcal{m}_A) \leftarrow \text{Cov}(\mathcal{Y}_A, \mathcal{m}_A) \rightarrow \text{Cov}(\mathcal{Y}_A, \mathcal{m}_A)
\]

Likewise, by repeating the foregoing with the quasi-affinoid schemes

\[
\mathcal{X}_E := \text{Spec} (E, E^+, X_E) \quad \text{and} \quad \mathcal{Y}_E := \text{Spec} E/I_E \otimes_E (E, E^+, X_E)
\]

we get the following fibrations and morphisms of fibrations over the site \( \mathcal{R}(U_E) \):
Furthermore, both $i^*_U$ and $i^*_U$ are fibrewise equivalences, by virtue of [59] Th.5.5.7(iii), and the same holds for $j^*_U$ by theorem [16.8.2]. We may then find morphisms of fibrations

$$s_U : \mathrm{Cov}_{U}^\wedge \to \mathrm{Cov}_{(X_m, m)^u}^\wedge \quad \text{and} \quad t_U : \mathrm{Cov}_{(X_m, m)^u}^\wedge \to \mathrm{Cov}_{(X_m, m)^u}^\wedge$$

that are quasi-inverse functors for $j^*_U$ and $i^*_U$ (corollary 3.1.28(i)). The composition of these functors yields a morphism of stacks

$$w_U : \mathrm{Cov}_{U}^\wedge \xrightarrow{s_U} \mathrm{Cov}_{(X_m, m)^u}^\wedge \xrightarrow{i_U} \mathrm{Cov}_{(X_m, m)^u}^\wedge \xrightarrow{t_U} \mathrm{Cov}_{(X_m, m)^u}^\wedge \xrightarrow{\beta_U} \mathrm{Cov}_{U}^\wedge$$

such that $(w_U)_{\mathrm{Spa}_U} : \mathrm{Cov}(U_E) \to \mathrm{Cov}(U)$ is isomorphic to $w_A$.

For every $x \in \mathrm{Spa}_U$, let $x_E := \mathrm{Spa}(w_X)(x) \in \mathrm{Spa}_U$; by propositions 5.2.9 and 5.6.37, we are then reduced to checking that the induced functor on stalks

$$w_U(x) : \mathrm{Cov}_{U}^\wedge(x_E) \to \mathrm{Cov}_{U}^\wedge(x)$$

is an equivalence, for every such $x$. To this aim, suppose first that $x$ is analytic; in this case, the completed residue field $\kappa(x)^\wedge$ is a Tate valued field (see (5.5.12)), so that the analytic locus of $\mathrm{Spec} \, \kappa(x)^\wedge$ is $\{\eta_x\}$, where $\eta_x$ is the generic point. We have a well defined quasi-affinoid ring

$$\kappa(x)^\wedge := (\kappa(x)^\wedge, \kappa(x)^\wedge, \{\eta_x\})$$

and the natural map $A \to \kappa(x)^\wedge$ yields a morphism of quasi-affinoid rings $\pi^\wedge_x : A \to \kappa(x)^\wedge$. Likewise we get a morphism of quasi-affinoid rings

$$\pi^\wedge_{x_E} : \mathrm{E}(A) \to \kappa(x_E)^\wedge := (\kappa(x_E)^\wedge, \kappa(x_E)^\wedge, \{\eta_{x_E}\})$$.

Moreover, by virtue of corollary [16.5.61] both $\kappa(x)^\wedge$ and $\kappa(x_E)^\wedge$ are perfectoid, and there exists a unique isomorphism of quasi-affinoid rings

$$(16.8.37) \quad \omega : \mathrm{E}(\kappa(x)^\wedge) \xrightarrow{\sim} \kappa(x_E)^\wedge \quad \text{such that} \quad \omega \circ \pi^\wedge_{x_E} = \pi^\wedge_{x_E}.$$

We may then repeat the foregoing constructions with $A$ replaced by $\kappa(x)^\wedge$ and $\kappa(x_E)^\wedge$ : we get first the quasi-affinoid schemes

$$U(x) := \mathrm{Spec} \, \kappa(x)^\wedge \quad U_E(x_E) := \mathrm{Spec} \, \kappa(x_E)^\wedge.$$

Then we set $A(x) := (\kappa(x)^\wedge, \kappa(x)^\wedge, \mathrm{Spec} \, \kappa(x)^\wedge)$, and

$$X_A(x) := \mathrm{Spec} \, A(x) \quad Y_A(x) := \mathrm{Spec} \, (A/I \otimes_A A(x))$$

and define likewise $X_E(x_E)$ and $Y_E(x_E)$. Also, let $m_x \subset \kappa(x)^\wedge$ and $m_{x_E} \subset \kappa(x_E)^\wedge$ be the maximal ideals. To these quasi-affinoid schemes we attach as in the foregoing fibrations over the sites $\mathcal{A}(U(x))$ and $\mathcal{A}(U_E(x_E))$. However, notice that the points of $\mathrm{Spa}_U(x)$ are (the equivalence classes of) the continuous valuations $v : \kappa(x)^\wedge \to \Gamma^\wedge_0$ with $\ker v = 0$ and $v(\kappa(x)^\wedge) \subset \Gamma^\wedge_0$; it is easily seen that there is only one such valuation, i.e. the one corresponding to the point $x$ of $\mathrm{Spa}_U$. Likewise, we have $\mathrm{Spa}_U := \{x_E\}$; hence, these fibrations amount to categories, or equivalently, they can be identified naturally with their stalks over the unique point $x$ of $\mathrm{Spa}_U$ and the unique point $x_E$ of $\mathrm{Spa}_U$. Then, a simple inspection yields an essentially commutative diagram of categories :

\[
\begin{array}{ccc}
\mathrm{Cov}_{(Y_m, m)^u}^\wedge(x) & \xrightarrow{i_U(x)} & \mathrm{Cov}_{(X_m, m)^u}^\wedge(x) & \xrightarrow{j_U(x)} & \mathrm{Cov}_U^\wedge(x) \\
\Downarrow & & \Downarrow & & \Downarrow \\
\mathrm{Cov}_{(Y_m(x), m_x)^u}^\wedge(x) & \xrightarrow{i_U(x_E)} & \mathrm{Cov}_{(X_m(x), m_x)^u}^\wedge(x) & \xrightarrow{j_U(x_E)} & \mathrm{Cov}_U^\wedge(x)
\end{array}
\]
whose right-most vertical arrow is an equivalence, by virtue of \([15.7.28]\). Likewise we have an essentially commutative diagram \(\mathcal{D}'_E\) for the corresponding fibrations over the site \(\mathcal{D}(U_E)\); moreover, in light of \([16.8.37]\) we have as well an essentially commutative diagram

\[
\begin{array}{ccc}
\text{Cov}^\wedge_{(Y_A,m_A)}(x) & \longrightarrow & \text{Cov}^\wedge_{(Y_A,m_A)}(x) \\
\downarrow & & \downarrow \\
\text{Cov}^\wedge_{(Y_A(x),m_A,x)} & \longrightarrow & \text{Cov}^\wedge_{(Y_A(x),m_A,x)}
\end{array}
\]

whose vertical arrows are the same as the left-most vertical arrows of \(\mathcal{D}'_A\) and \(\mathcal{D}'_E\), and whose horizontal arrows are induced by the equivalences \([16.8.36]\). Summing up, we are reduced to checking the following:

**Claim 16.8.38.** The functor \(j^*_U(x)\) is an equivalence.

**Proof of the claim.** By unwinding the definitions, we see that \(\text{Cov}^\wedge_{U(x)}\) is the category of étale \(\kappa(x)\)-algebras, \(\text{Cov}^\wedge_{(X_A(x),m_A)}\) is the category of étale \((\kappa(x)^\wedge,m_A)^a\)-algebras of almost finite rank, and \(j^*_U(x)\) is the natural restriction functor. In light of lemma \([14.4.3]\)(iii) and remark \([14.4.3](i)\), it follows already that \(j^*_U(x)\) is fully faithful. Next, let \(E\) be any finite separable field extension of \(\kappa(x)^\wedge\), and \(E^\wedge\) the integral closure of \(\kappa(x)^\wedge\) in \(E\); it suffices to check that \(E^\wedge\) is an étale \((\kappa(x)^\wedge)^a\)-algebra of finite rank. However, notice that \(\kappa(x)^\wedge\) is a valuation ring of rank one with field of fractions \(\kappa\); moreover, it is perfectoid for the ring topology such that the natural map \(A \to \kappa(x)^\wedge\) is adic (corollary \([16.5.61]\)1)), and therefore it is deeply ramified, by \([59]\) Prop.6.6.6] and lemma \([16.2.3]\)iv). Let also \(E^a\) be any separable closure of \(E\), and \(E^\wedge\) the integral closure of \(E^a\) in \(E^a\); by \([59]\) Prop.6.6.2 and Rem.6.1.12(iv) it follows that \((E^\wedge/\kappa(x)^\wedge)^a = 0\), and combining with \([59]\) Th.6.3.23) we deduce that \((\Omega_{E^\wedge/\kappa(x)^\wedge})^a = 0\) (cp. the proof of \([59]\) Prop.6.6.2)). By invoking again \([59]\) Th.6.3.23), it follows that \(\mathcal{D}_{E^\wedge/\kappa(x)^\wedge} = E^\wedge\). Then the assertion follows from \([59]\) Prop.6.3.8 and Lemma 4.1.27].

Lastly, in case \(x\) is non-analytic, set

\[
Y(x) := \text{Spec}(A/I \otimes_A \text{Spa}^\wedge_{X_A,x}) \quad Y_E(x) := \text{Spec}(E/I_E \otimes_E \text{Spa}^\wedge_{U_E,x})
\]

According to \([15.7.28]\) we have natural equivalences of categories

\[
\Psi : \text{Cov}^\wedge_U(x) \sim \text{Cov}(Y(x)) \quad \Psi_E : \text{Cov}^\wedge_U(x_E) \sim \text{Cov}(Y_E(x_E)).
\]

Recall the construction of these equivalences: an object of \(\text{Cov}^\wedge_U(x)\) is a pair \((R, \varphi)\) where \(R\) is a rational subset of \(\text{Spa}^\wedge U\) containing \(x\), and \(\varphi : V \to U^\wedge_R\) is a finite étale morphism of schemes; to such an object, the equivalence \(\Psi\) assigns the finite étale morphism \(Y(x) \times_{U^\wedge} \varphi\). Similarly we may describe \(\Psi_E\). We get likewise well defined functors

\[
\text{Cov}^\wedge_{(X_A,m_A)}(x) \xrightarrow{\Psi'} \text{Cov}(Y(x)) \xleftarrow{\Psi''} \text{Cov}^\wedge_{(Y_A,m_A)}(x).
\]

Namely, an object of \(\text{Cov}^\wedge_{(X_A,m_A)}(x)\) is a pair \((R,f : (A^\wedge,m_A)^a \to B^a)\) where \(R\) is as in the foregoing and \(f\) is an étale covering of almost rings, and notice that \(m_A \text{Spa}^\wedge_{X_A,x} = \text{Spa}^\wedge_{U_A,x}\), so \(f_x := A/I \otimes_A \text{Spa}^\wedge_{U_A,x} \otimes A^\wedge\) \(f\) is a homomorphism of (usual) rings; then the functor \(\Psi'\) assigns to the pair \((R,f)\) the finite étale covering \(\text{Spec} f_x\) of \(Y(x)\). Similarly we define \(\Psi''\), and it is easily seen that the resulting diagram of categories:

\[
\begin{array}{ccc}
\text{Cov}^\wedge_{(X_A,m_A)}(x) & \xrightarrow{j^*_U(x)} & \text{Cov}^\wedge_{(Y_A,m_A)}(x) \\
\downarrow & & \downarrow \\
\text{Cov}(Y(x)) & \xrightarrow{\Psi''} & \text{Cov}(Y(x))
\end{array}
\]

foundations for almost ring theory 1597
is essentially commutative. Correspondingly, we have an essentially commutative diagram $\mathcal{D}_E''$ for the stalks over $x_E$, and notice that all the arrows of $\mathcal{D}_E''$ are equivalences (details left to the reader). On the other hand, the system of isomorphisms \((16.8.35)\) induces an isomorphism of schemes

$$Y_A(x) \xrightarrow{\sim} Y_E(x_E)$$

whence an essentially commutative diagram

$$
\begin{array}{ccc}
\text{Cov}_{(Y_E,m_E)_y}^\wedge(x_E) & \xrightarrow{\Psi_E''} & \text{Cov}(Y_E(x_E)) \\
\downarrow & & \downarrow \\
\text{Cov}_{(\mathcal{L}_A,m)_y}^\wedge(x) & \xrightarrow{\Psi''} & \text{Cov}(Y(x))
\end{array}
$$

whose left vertical arrow is induced by the equivalence \((16.8.36)\), and the right vertical arrow is an equivalence as well. We conclude that $\Psi''$ is an equivalence; then the same holds for $j_{I^*}(x)$, and finally also for $w_{E}(x)$, as sought. The proof is complete. \hfill $\square$

16.8.39. **Almost purity in the formal perfectoid case.** We show now how to extend theorem \((16.8.32)\) to the case of formal perfectoid rings. We begin with some preliminary observations:

**Lemma 16.8.40.** Let $A$ be an adic topological ring that admits a finitely generated ideal $I$ of adic definition, $A^\wedge$ the completion of $A$, and $m \subset A$ an open ideal. The following holds:

(i) $m$ is a radical ideal of $A$ if and only if $mA^\wedge$ is a radical ideal of $A^\wedge$.

(ii) $m = m^2$ if and only if $mA^\wedge = m^2 A^\wedge$.

(iii) $m$ fulfills condition (B) of \cite{59}, §2.1.6 if and only if the same holds for $mA^\wedge$.

**Proof.** By assumption, $I^n \subset m$ for some integer $n > 0$; after replacing $I$ by $I^n$, we may then assume that $I \subset m$.

(i): Let $n$ be the radical ideal of $m$; since $I \subset m$, it is easily seen that $n/I$ is the radical ideal of $m/I$ in the quotient $A/I$. Since the completion map $A \rightarrow A^\wedge$ induces an isomorphism $A/I \xrightarrow{\sim} A^\wedge/IA^\wedge$, it follows that $nA^\wedge/IA^\wedge$ is the radical ideal of $mA^\wedge/IA^\wedge$; again, this easily implies that $nA^\wedge$ is the radical ideal of $mA^\wedge$, whence the assertion.

(ii): We have $m = m^2 \Leftrightarrow m/I^2 = m^2/I^2$, and since the completion map induces an isomorphism $A/I^2 \xrightarrow{\sim} A^\wedge/I^2 A^\wedge$, we have $m/I^2 = m^2/I^2 \Leftrightarrow mA^\wedge/I^2 A^\wedge = m^2/I^2 A^\wedge$. Again, the latter condition holds if and only if $mA^\wedge = m^2 A^\wedge$, whence the assertion.

(iii): In view of (ii), it is clear that if $m$ fulfills condition (B), then so does $mA^\wedge$. Conversely, suppose that $mA^\wedge$ fulfills condition (B); by (ii), it follows already that $m = m^2$, and it remains to check that for every integer $k > 0$, the ideal $m$ is generated by the system $x^k := (x^k | x \in m)$. However, let $a_1, \ldots, a_n$ be a finite system of generators of $I$, and choose $N \in \mathbb{N}$ such that $I^N$ lies in the ideal generated by $a_k^{b_k} := (a_1^{b_1}, \ldots, a_n^{b_n})$; by assumption $mA^\wedge$ is generated by the system $b^k := (b^k | b \in mA^\wedge)$, hence the same holds for $mA^\wedge/I^N A^\wedge$. The completion map induces an isomorphism $m/I^N \xrightarrow{\sim} mA^\wedge/I^N A^\wedge$ and maps $x^k$ onto the family $b^k$, so that $m/I^N$ is generated by $x^k$, and therefore the same holds for $m$, since the family $x^k$ contains $a^k$. $\square$

**Proposition 16.8.41.** Let $A$ be a formal perfectoid ring, $I \subset A$ a finitely generated ideal of adic definition, $m \subset A$ a radical ideal with $I \subset m$, and $U := \text{Spec} A \setminus \text{Spec} A/m$. We have:

(i) $(A, m)$ is a basic setup fulfilling condition (B) (see \cite{59}, §2.1.1, §2.1.6).

(ii) For every subideal $J \subset I$, every almost finitely generated almost projective $(A/J)^\wedge$-module $P$ has almost finite rank, for the almost structure induced by $(A, m)$.

(iii) In the situation of (ii), if moreover $U$ is quasi-compact, then $P$ has finite rank.
Proof. (i) follows from lemma [16.8.40] and proposition [16.8.15(i)].

(ii): After replacing \( I \) by \( I + pA \), we may assume that \( p \in I \). Set \( X := \text{Spec } A/J \) and \( U' := X \setminus \text{Spec } A/I \). Let \( S \subset A \) be the multiplicative subset \( 1 + I \), and \( B := S^{-1}(A/J) \). Let also \( \mathcal{P} \) be the quasi-coherent \( \mathcal{O}_X \)-module associated with the \( A/J \)-module \( P \). Then \( X = U' \cup \text{Spec } B \), and \( U' \) is quasi-compact, so that \( \mathcal{P}_{U'} \) is a locally free \( \mathcal{O}_{U'} \)-module of finite rank. Thus, it suffices to check that \( P_B := P \otimes_A B \) is almost projective \( B^a \)-module of almost finite rank. Now, the ideal \( I_B := I/J \) of \( B \) is obviously tight, and by construction \( I_B \subset \text{rad}(B) \); moreover, the localization \( A/J \rightarrow B \) induces a ring isomorphism \( A/I \sim B/I_B \), whence an isomorphism of \((A/I)^a\)-modules \( P_0 := P/IP \sim P_B/I_B P_B \). By lemma [14.3.17(ii)] we are then reduced to checking that \( P_0 \) is an \((A/I)^a\)-module of almost finite rank. To this aim, let \( E := E(A) \), and pick a distinguished element \( \alpha \in \text{Ker } u_A \); by remark [16.3.7(ii)], the map \( \pi_A \) induces a ring isomorphism \( \omega : E/\alpha_0 E \sim A/pA \), and we let \( m_E \) and \( I_E \) be the unique ideals of \( E \) with 
\[
\alpha_0 \in m_E \quad \alpha_0 \in I \quad m/pA \sim m_E/\alpha_0 E \quad I/pA \sim I_E/\alpha_0 E.
\]
In particular, \( I_E \) is finitely generated, and \( (E, m_E) \) is a basic setup, by proposition [16.8.15(i)]. Via the isomorphism \( \omega \), we may then regard \( P_0 \) as an almost finitely generated almost projective \((E/I_E)^a\)-module (for the almost structure given by \( (E, m_E) \)), and clearly it suffices to show that \( P_0 \) is of almost finite rank, when regarded as an \((E/I_E)^a\)-module. The latter follows from proposition [16.8.41(i)].

(iii): Arguing as in the proof of (ii), we reduce to showing that if \( U \) is quasi-compact, then \( P_0 \) is of finite rank, when regarded as a \((E/I_E)^a\)-module, and according to proposition [16.8.7(ii)], the latter will follow, once we show that \( Z := \text{Spec } E/m_E \) is constructible in \( \text{Spec } E \). However, \( (\text{Spec } A/pA) \setminus (\text{Spec } A/m) = U \cap \text{Spec } A/pA \) is quasi-compact, hence the same holds for \( W := (\text{Spec } E/\alpha_0 E) \setminus Z \). Thus, \( (\text{Spec } E) \setminus Z = W \cup \text{Spec } E[\alpha_0^{-1}] \) is constructible in \( \text{Spec } E \), and then the same follows for \( Z \).

16.8.42. Let \( A \) be a formal perfectoid ring, \( I \subset A \) a finitely generated ideal of adic definition, and \( m \subset A \) a radical ideal with \( I \subset m \). Set \( X := \text{Spec } A, Z := \text{Spec } A/m, \) and \( U := X \setminus Z \). According to proposition [16.8.41(i)], we may consider the almost structure associated with the basic setup \((A, m)\). We then have:

**Theorem 16.8.43.** In the situation of (16.8.42), let also \( r \in \mathbb{N} \). The following holds:

(i) The pair \((X, Z)\) is almost pure.

(ii) Let \( \mathcal{M} \) be any almost projective \( \mathcal{O}_X^a \)-module of almost finite rank. Then \( \mathcal{M} \) is a faithfully flat \( \mathcal{O}_X^a \)-module (resp. an \( \mathcal{O}_X^a \)-module of finite rank \( \leq r \)) if and only if the same holds for the \( \mathcal{O}_U^a \)-module \( \mathcal{M}_U \).

Proof. (i): Suppose first that \( Z \) is constructible in \( X \). Let \( A^h \) and \( A^\wedge \) be respectively the topological henselization and the completion of \( A \), and set \( X^h := \text{Spec } A^h \) and \( X^\wedge := \text{Spec } A^\wedge \). Let also \( U^h := X^h \times_X U \) and \( U^\wedge := X^\wedge \times_X U \). In light of theorem [16.8.32] it suffices to check that both square subdiagrams of the following induced diagram are 2-cartesian:

\[
\begin{array}{ccc}
\mathcal{O}_X^a \rightarrow \mathcal{O}_{X^h}^a & \rightarrow \mathcal{O}_{U^h}^a \rightarrow \mathcal{O}_{U^\wedge}^a \\
\downarrow \quad \downarrow \quad \downarrow \quad \downarrow \\
\mathcal{O}_X^{\text{fr}} & \rightarrow \mathcal{O}_{X^h}^{\text{fr}} & \rightarrow \mathcal{O}_{U^h}^{\text{fr}} & \rightarrow \mathcal{O}_{U^\wedge}^{\text{fr}}.
\end{array}
\]

Now, by [59 Prop.5.5.6(i)] it follows that the natural functor

\[
\mathcal{O}_X^a \rightarrow \mathcal{O}_X^{\text{fr}} \rightarrow \mathcal{O}_{X^h}^{\text{fr}} \rightarrow \mathcal{O}_{U^h}^{\text{fr}}
\]
is fully faithful. Thus, let $(\mathcal{E}^h, \mathcal{E}_U, \xi)$ be the datum of an object $\mathcal{E}^h$ of $\mathcal{O}_{X^h}^{\text{fr}}$, an object $\mathcal{E}_U$ of $\mathcal{O}_{U^h}^{\text{fr}}$, and an isomorphism $\xi$ in $\mathcal{O}_{U^h}^{\text{fr}}$. By loc.cit., there exists a quasi-coherent $\mathcal{O}_{X}^{\text{fr}}$-algebra $\mathcal{E}$ whose restriction to $X^h$ and to $U$ is isomorphic to $\mathcal{E}^h$ and respectively $\mathcal{E}_U$, and in view of proposition [16.8.41](iii), it remains to check that $\mathcal{E}$ is étale and almost finitely presented as an $\mathcal{O}_{X}^{\text{fr}}$-module. Since the induced morphism $U \cup X^h \to X$ is quasi-compact and faithfully flat, the assertion follows from lemmata [14.3.5](i) and [14.3.26](i). This shows that the left square subdiagram of the foregoing diagram is 2-cartesian.

Next, since both of the natural maps $A/I \to A^h/I A^h$ and $A/I \to A^\text{fr}/I A^\text{fr}$ are isomorphisms, [59] Th.5.5.7(iii)) implies that the top horizontal arrow of the right square subdiagram is an equivalence. To conclude the proof in this case, it then suffices to show :

**Claim 16.8.44.** The base change functor $\mathcal{O}_{U^h}^{\text{fr}} \to \mathcal{O}_{U^h}^{\text{fr}}$ is an equivalence.

**Proof of the claim.** According to proposition [8.3.30](i) there exists a unique $\mathfrak{f}$-adic topology on $B := \mathcal{O}_{U^h}(U^h)$ (resp. on $C := \mathcal{O}_{U}(U^\text{fr})$) such that the restriction map $A^h \to B$ (resp. $A^\text{fr} \to C$) is open. It follows easily that the induced map $B \to C$ is continuous and adic, since the same holds for the completion map $A \to A^\text{fr}$. Set $A^{h+} := A^{\text{fr}} \subset A^h$ and $A^{\text{fr}+} := A^{\text{fr}+} \subset A^h$; in view of lemma [8.3.24](iii.a), the integral closure in $B$ (resp. in $C$) of the image of $A^{h+}$ (resp. of $A^{\text{fr}+}$) is a subring of integral elements, that we denote $B^+$ (resp. $C'$). Recall also that the natural morphism of schemes $\text{Spec } B \to X^h$ (resp. $X^\text{fr} \to \text{Spec } C$) induces an isomorphism $U_B := U^h \times_{X^h} \text{Spec } B \cong U_h$ (resp. $U_C := U^\text{fr} \times_{X^\text{fr}} \text{Spec } C \cong U^\text{fr}$); combining with lemma [15.4.6] we deduce that the resulting diagram

$$
\begin{array}{ccc}
\text{Spec}(C, C^+, U_C) & \longrightarrow & \text{Spec}(B, B^+, U_B) \\
\varphi \downarrow & & \downarrow \\
\text{Spec}(A^\text{fr}, A^{\text{fr}+}, U^\text{fr}) & \longrightarrow & \text{Spec}(A^h, A^{h+}, U^h)
\end{array}
$$

is cartesian in the category of quasi-affinoid schemes. Furthermore, the quasi-affinoid scheme $\text{Spec}(C, C^+, U_C)$ is complete, by virtue of lemma [16.4.26](ii). By arguing with universal properties, it follows easily that the morphism $\varphi$ identifies $\text{Spec}(C, C^+, U_C)$ with the completion of $\text{Spec}(A^\text{fr}, A^{\text{fr}+}, U^\text{fr})$ : the details are left to the reader. Then the claim follows from theorem [15.7.17] and proposition [16.8.41](ii).

Lastly, we consider the case where $Z$ is an arbitrary closed subset in $X$. Then, let $(I_\lambda \mid \lambda \in \Lambda)$ be the filtered system of all finitely generated ideals of $A$ containing $I$ and contained in $m$. For every $\lambda \in \Lambda$, let also $m_\lambda$ be the radical of $I_\lambda$; then $Z_\lambda := \text{Spec } A/m_\lambda = \text{Spec } A/I_\lambda$ and

$$
U_\lambda := X \setminus Z_\lambda
$$

are constructible subsets of $X$, and $(A, m_\lambda)$ is a basic setup fulfilling condition (B), for every such $\lambda$ (proposition [16.8.41](i)). Both natural functors :

$$(A, m)^{\text{fr}} \dashv \mathcal{O}_{U^h}^{\text{fr}} \to 2\text{-lim}_{\lambda \in \Lambda}(A, m_\lambda)^{\text{fr}} \dashv \mathcal{O}_{U^h}^{\text{fr}} \to 2\text{-lim}_{\lambda \in \Lambda} \mathcal{O}_{U^h}^{\text{fr}}$$

are equivalences of categories (corollary [14.2.3](ii,iv,v)), hence we are reduced to prove the theorem for the pair $(X, Z_\lambda)$, relative to the almost structure $(A, m_\lambda)$, for every $\lambda \in \Lambda$. The latter is already known by the previous case, so the proof is concluded.

(ii): Again, we assume first that $Z$ is constructible, in which case $\mathcal{M}$ has finite rank (proposition [16.8.41](iii)). Let $A_{\text{loc}}$ be the topological localization of $A$ (see (8.4.8)); set also $X_{\text{loc}} := \text{Spec } A_{\text{loc}}$. Then $A_{\text{loc}}$ is a formal perfectoid ring, and the localization $A \to A_{\text{loc}}$ induces an isomorphism of the respective completions $A^h \cong A_{\text{loc}}^h$ (corollary [8.4.14](i)), and an isomorphism of $A$-schemes $\pi : U_{\text{loc}} := X_{\text{loc}} \times_X U \cong U$. Set $M := \mathcal{M} (X)$, $M_{\text{loc}} := A_{\text{loc}} \otimes_A M$, and let $\mathcal{M}_{\text{loc}}$ be the almost projective $\mathcal{O}_{X_{\text{loc}}}^{\text{fr}}$-module of finite rank corresponding to $M_{\text{loc}}$. Then $\pi$ induces a natural identification of $\mathcal{M}_{U}$ with $(\mathcal{M}_{\text{loc}})_{U_{\text{loc}}}$, so that the latter is a faithfully flat $\mathcal{O}_{U_{\text{loc}}}$-module. We notice :
Claim 16.8.45. In the situation of (16.8.31), let \( \mathcal{F} \) be any almost projective \( \mathcal{O}^{\circ}_{X_A} \)-module of finite rank. Then \( \mathcal{F} \) is a faithfully flat \( \mathcal{O}^{\circ}_{X_A} \)-module (resp. is an \( \mathcal{O}^{\circ}_{X_A} \)-module of finite rank \( \leq r \)) if and only if the same holds for the \( \mathcal{O}_U \)-module \( \mathcal{F}|_U \).

Proof of the claim. Since the pair \((X, Z)\) is normal (theorem 16.8.32), the assertion follows immediately from lemma 14.3.18.

From claim 16.8.45 it follows that \( A^{\circ}_{\text{loc}} \otimes_{A_{\text{loc}}} M_{\text{loc}} \) is a faithfully flat \( (A^{\circ}_{\text{loc}})^a \)-module of finite rank; consequently \( M_{\text{loc}}/IM_{\text{loc}} \) is a faithfully flat \( A^{\circ}_{\text{loc}} \otimes_{A_{\text{loc}}} M_{\text{loc}} \)-module of finite rank. By construction, \( I^{\text{loc}}_{\text{loc}} \subset \text{rad}(A^{\circ}_{\text{loc}}) \) is a tight ideal of \( A^{\circ}_{\text{loc}} \) (relative to the basic setup \((A, m)\)), hence \( M_{\text{loc}} \) is a faithfully flat \( A^{\circ}_{\text{loc}} \)-module (lemma 14.3.17(i)). Lastly, let \( Y \) be the disjoint union of \( U \) and \( \text{Spec} A_{\text{loc}} \); we have an obvious faithfully flat morphism of \( A \)-schemes \( f : Y \to X \), and the foregoing implies that \( f^* \mathcal{M} \) is a faithfully flat \( \mathcal{O}^{\circ}_{Y} \)-module, so \( \mathcal{M} \) is a faithfully flat \( \mathcal{O}^{\circ}_{X} \)-module, by lemma 14.3.5(i).

Next, for a general \( Z \), define the filtered system of subideals \( \langle m_\lambda \mid \lambda \in \Lambda \rangle \) of \( m \), and the corresponding filtered system of open constructible subsets \( \langle U_\lambda \mid \lambda \in \Lambda \rangle \) of \( U \), as in the proof of (i). Then if \( \mathcal{M}_{\text{loc}} \) is a faithfully flat \( \mathcal{O}_U \)-module (resp. if the rank of \( \mathcal{M} \) is \( \leq r \)), obviously the same holds for the \( \mathcal{O}_U \)-module \( \mathcal{M}|_{U_\lambda} \). For every \( \lambda \in \Lambda \), denote by \( M_\lambda \) the image of \( M \) in the category of \( (A, m_\lambda)^a \)-modules; by the foregoing case, \( M_\lambda \) is a faithfully flat \( (A, m_\lambda)^a \)-module (resp. has rank \( \leq r \)) for every such \( \lambda \). Then \( M \) is a faithfully flat \( (A, m)^a \)-module (resp. has rank \( \leq r \)), by corollary 14.2.5(iii,iv).

16.9. Perfectoid Tate rings and perfectoid Abhyankar’s lemma. In this section we introduce some special classes of perfectoid quasi-affinoid rings that will play an important role in the proof of Hochster’s direct summand conjecture. The main results are theorems 16.9.17 and 16.9.34 that generalize important results from Y.André’s papers [5] and [6].

Definition 16.9.1. Let \((A, \mathcal{O}_A)\) be a Tate ring (see definition 8.3.8(vi)).

(i) We say that \( A \) is a perfectoid Tate ring (resp. formal perfectoid Tate ring) if it has a subring of definition \( A_0 \) that is perfectoid (resp. formal perfectoid), for the topology induced by \( \mathcal{O}_A \) via the inclusion map \( A_0 \to A \).

(ii) We say that \( A \) is uniform, if \( A^\circ \) is a bounded subset of \( A \) (see definition 8.3.8(ii)). We let \( \text{Tate} \) and \( u.\text{Tate} \) be the full subcategories of \( \mathbb{Z}_-\text{TopAlg} \) (see definition 8.3.1(iii)) whose objects are the Tate rings and respectively the uniform Tate rings.

Lemma 16.9.2. (i) Let \((A, \mathcal{O}_A)\) be a Tate ring. The following conditions are equivalent:

(a) \( A \) is uniform.
(b) The completion \( A^\wedge \) of \( A \) is uniform.
(c) \( \mathcal{O}_A \) agrees with the topology given by a power-multiplicative semi-norm \( \| \cdot \| : A \to \mathbb{R} \).

(ii) Moreover, if the power-multiplicative semi-norm \( \| \cdot \| \) defines the topology \( \mathcal{O}_A \), we have:

\[ A^\circ = \{ a \in A \mid \| a \| \leq 1 \} \quad \text{and} \quad A^{\circ_0} = \{ a \in A \mid \| a \| < 1 \} . \]

(iii) The inclusion functor \( u.\text{Tate} \to \text{Tate} \) admits a left adjoint

\[ u : \text{Tate} \to u.\text{Tate} \quad A \mapsto u(A) . \]

We call \( u(A) \) the uniformization of the Tate ring \( A \).

Proof. (i.a)\(\Rightarrow\)(i.b): Indeed, if \( A^\circ \) is a bounded subset of \( A \), then its image \( B \) in \( A^\wedge \) is bounded in the latter ring; but then the same holds for the topological closure \( B^{\circ_0} \) of \( B \) in \( A^\wedge \) (remark 8.3.9(iii)). However, \( B^{\circ_0} = (A^\wedge)^{\circ_0} \) (corollary 8.4.14(ii) and proposition 8.2.13(iii)) whence the contention.

Proof.
(i.b)⇒(i.a): Let \( j : A \to A^\wedge \) be the completion map; we have \( j^{-1}((A^\wedge)^\circ) = A^\circ \), by corollaries \[8.4.14\] and \[8.2.17\]. Since the topology of \( A \) is induced by that of \( A^\wedge \) via \( j \), the assertion follows easily.

(i.a)⇒(i.c): Fix \( \rho \in [0,1] \) and pick \( t \in A^\times \cap A^{100} \). Notice that \( A^\circ \) is a subring of definition of \( A \) (proposition \[8.3.18\]). Denote by \( \nu : A \to \mathbb{Z} \cup \{+\infty\} \) the order function associated with the ideal \( tA^\circ \) (see example \[9.1.9\]), and set \( |a| := \rho^{\nu(a)} \) for every \( a \in A \). Moreover, let \( \| \cdot \| : A \to \mathbb{R} \) be the asymptotic Samuel function of \( tA^\circ \), i.e. \( \|a\| := \lim_{n \to +\infty} |a^n|^{1/n} \) for every \( a \in A \). Notice that \( \nu(t^k a) = k + \nu(a) \) for every \( k \in \mathbb{N} \) and \( a \in A \), whence : have :

\[
(16.9.3) \quad \|t^k a\| = \rho^k \cdot |a| \quad \text{for every } k \in \mathbb{N} \text{ and } a \in A.
\]

By construction, \( |a| \leq 1 \) for every \( a \in A^\circ \). On the other hand, if \( |a| > r > 1 \), then there exists \( k \in \mathbb{N} \) such that \( |a^n| > r^n \) for every \( n \geq k \), and it follows easily that \( a \notin A^\circ \). Combining with \((16.9.3)\), we conclude that \( t^k A^\circ = \{a \in A \mid |a| \leq \rho^k\} \) for every \( k \in \mathbb{N} \), whence (i.c).

(i.c)⇒(i.a): Clearly \( \{a \in A \mid |a| < 1\} = A^{100} \). Pick \( t \in A^\times \cap A^{100} \), so that \( r := \|t\| \in [0,1] \); then \( t^k A^{100} \) is an open ideal of \( A^\circ \) for every \( k \in \mathbb{N} \), and it lies in the subset \( \{a \in A \mid |a| < r^k\} \), whence (i.a).

(ii) follows by simple inspection of the definitions.

(iii): Let \( A_0 \subset A \) be a subring of definition, \( t \in A^\times \cap A^{100} \), and \( \nu : A \to \mathbb{Z} \cup \{+\infty\} \) the order function associated with the ideal \( tA_0 \). For given \( \rho \in [0,1] \), the map \( \cdot : A \to \mathbb{R} \) such that \( |a| : A \to \mathbb{R} \) is a semi-norm, and the topology defined by \( |a| \) agrees with \( \mathcal{T}_A \). Then, let \( \| \cdot \| : A \to \mathbb{R} \) be the asymptotic Samuel function of \( tA_0 \). Recall that \( \| \cdot \| : A \) is a multiplicative semi-norm, and let \( \mathcal{T}_A \) be the topology on \( A \) defined by \( |a| \). Lemma \[9.1.8\] implies that the identity map of \( A \) is a continuous ring homomorphism \( (A, \mathcal{T}_A) \to (A, \mathcal{T}_A) \); also, the discussion of example \[9.1.9\] shows that \( \mathcal{T}_A \) depends only on the original topology \( \mathcal{T}_A \) (and is independent of all auxiliary choices). Now, let \( (B, \mathcal{T}_B) \) be any uniform Tate ring, and \( f : (A, \mathcal{T}_A) \to (B, \mathcal{T}_B) \) a continuous ring homomorphism. By lemma \[8.3.29\], the map \( f \) is \( f \)-adic, hence it restricts to an \( f \)-adic ring homomorphism \( f_0 : A_0 \to B^\circ \) (lemma \[8.3.24\]), and the proof of (i) shows that \( \mathcal{T}_B \) agrees with the topology defined by the asymptotic Samuel function \( \| \cdot \| : B \to \mathbb{R} \) of the ideal \( f(t) \cdot B^\circ \). With this notation, it follows easily that \( f \) is a morphism of normed rings \( (A, | \cdot |) \to (B, \| \cdot \|) \) (see \[9.1.6\]), and then lemma \[9.1.8\] shows that \( f \) is also a morphism of uniform semi-normed rings \( (A, | \cdot |) \to (B, \| \cdot \|) \). In view of (i), we deduce that \( f : (A, \mathcal{T}_A) \to (B, \mathcal{T}_B) \) is a continuous ring homomorphism of uniform Tate rings. Thus the sought functor is obtained by the rule : \( (A, \mathcal{T}_A) \to (A, \mathcal{T}_A) \). \( \square \)

**Example 16.9.4.** Let \( A \) be a Tate ring, \( A_0 \subset A \) a subring of definition, and suppose there exists an integer \( n > 1 \) such that \( \{x \in A \mid x^n \in A_0\} \subset A_0 \). Then it follows easily that \( A^{100} \subset A_0 \), and since \( A^{100} \) is an ideal of \( A \), we deduce that \( A \) is uniform.

16.9.5. Let \( (A, \mathcal{T}_A) \) be a perfectoid Tate ring, and \( A_0 \subset A \) a perfectoid ring of definition, so that \( A = A_0[t^{-1}] \), for any \( t \in A^\times \cap A^{100} \). Moreover, \( tA_0 \) is an ideal of \( A \) (corollary \[8.3.20\]). Let also \( A^+ \) be the integral closure of \( A_0 \) in \( A \); it follows that \( U := \text{Spec} A \) is the analytic locus of \( \text{Spec} A_0 \), and

\[
U := (U, \mathcal{T}_A, A^+)
\]

is a perfectoid affinoid scheme (see definition \[16.5.1\]). Then, according to \(16.5.20\), theorem \[16.5.13\] and corollary \[16.5.43\]), we get a perfectoid affinoid scheme

\[
(U_E, \mathcal{E}_E, \mathcal{E}_E^+ := \mathcal{E}(U) \quad \text{with } \mathcal{E}_U := \mathcal{O}_{U_E}(U_E)
\]

so that \( \mathcal{E}_E \) is a complete \( f \)-adic ring, and its open subring \( \mathcal{E}_U^+ \) is perfectoid and naturally isomorphic to \( \mathcal{E}(A^+) \). Let \( (\alpha_n \mid n \in \mathbb{N}) \) be a distinguished element in \( \ker u_{A^+} \); then the isomorphism
of topological rings $E_U^0/\alpha_0 E_U^0 \to A^0/pA^0$ of remark 16.3.7 ii) induces an isomorphism

$\varpi : E_U^0/\alpha_0 E_U^0 \to A^0/A^0$. 

Recall also that the composition $E_U^0 \to A$ of $\pi_{A^0} : E_U^0 \to A^0$ with the localization $A^0 \to A$, factors through a continuous morphism of monoids

$\varphi_U : E_U^0 \to A$ 

(lemma 16.4.23 i) and proposition 16.4.28 i)). Let $\pi_A : A^0 \to A^0/A^0$ and $\pi_E : E_U^0 \to E_U^0/\alpha_0 E_U^0$ be the projections; denote by $\mathcal{P}_A$ and $\mathcal{P}_E$ the set of perfectoid subrings of adic definition of $A$ and respectively $E_U$, and by $\mathcal{P}_A$ the set of perfect subrings of $A^0/A^0$.

**Lemma 16.9.6.** In the situation of (16.9.5), the following holds:

(i) $(A, \mathcal{P}_A)$ is a uniform Tate ring.

(ii) $(E_U, \mathcal{P}_E)$ is a perfectoid Tate ring, and $U_E$ is the analytic locus of $\text{Spec } E_U^0$.

(iii) The rules: $B \mapsto \pi_A^{-1} B$ and $B \mapsto (\varpi \circ \pi_E)^{-1} B$ establish natural bijections

$\mathcal{P}_E \sim \mathcal{P}_A \sim \mathcal{P}_A$.

**Proof.** (i) follows immediately from theorem 16.5.13 i).

(ii) It is easily seen that $tA^0$ is an ideal of adic definition for $A^0$, and $A^0[t^{-1}] = A$, hence $U$ is the analytic locus of $\text{Spec } A^0$, and therefore $U_E$ is the analytic locus of $\text{Spec } E_U^0$. Pick $m \in \mathbb{N}$ such that $p^m/t \in A^0$; by applying corollary 16.6.26 to the quasi-affinoid ring $(A^0, A^0, U)$, we deduce that there exists $t' \in E_U^0$ such that

$v(t - \pi_A(t')) \leq v(p) \cdot \max(v(\pi_A(t')), v(p^m))$ 

for every $v \in \text{Cont}(A^0)$ where $\pi_A : E_U^0 \to A^0$ is the natural morphism of topological monoids as in (9.4). It follows that $v(t) = v(\pi_A(t'))$ for every $v \in \text{Cont}(A^0)$. We have $v(t) < 1$ for every $v \in \text{Cont}(A^0)$ and $v(t) \neq 0$ for every $v \in \text{Cont}(A)$, since $t \in A^0 \cap A^\infty$ (theorem 15.3.15 i)); hence $w(t') < 1$ for every $w \in \text{Cont}(E_U^0)$ (theorem 16.5.52 i)), and therefore $t' \in E_U^0$ (corollary 15.4.27 ii)). Also, combining with (16.5.59) we deduce that $w(t') \neq 0$ for every $w \in \text{Spa } E(U)$, hence $t' \in E_U^0$. 

(iii): For every $A' \in \mathcal{P}_A$, the inclusion map $A' \to A^0$ induces an open injective continuous ring homomorphism $E' := E(A') \to E_U^0$, and moreover we have $A^0 \subset A'$ and $E_U^0 \subset E'$, by theorem 16.3.42 ii, iii, a. As in (16.9.5), we deduce a ring isomorphism $E'/E_U^0 \to A'/A^0$, which shows that $A'/A^0 \in \mathcal{P}_A$. Conversely, let $B \in \mathcal{P}_A$; according to proposition 16.3.25 the open subring $\pi_A^{-1} B = B \times_{A^0/A^0} A^0$ of $A^0$ is perfectoid for the topology induced by the inclusion into $A^0$, and then $\pi_A^{-1} B \in \mathcal{P}_A$. Likewise one proves that the map $\mathcal{P}_A \to \mathcal{P}_E$ is a bijection. 

**16.9.7.** Let now $(A, \mathcal{P}_A)$ be a perfectoid Tate ring, $A_0 \subset A$ a perfectoid subring of definition, $(B, \mathcal{P}_B)$ an $f$-adic ring, and $f : A \to B$ a continuous ring homomorphism. Define the perfectoid affinoid schemes $\mathcal{U}$ and $(U_E, \mathcal{P}_E, \mathcal{E}_U^+)$ and the $f$-adic ring $E_U$ as in (16.9.5); by lemma 16.9.6 ii) we find $t' \in E_U^0 \cap \mathcal{E}_U^+$, and we let $t := \pi_A(t')$, which is a topologically nilpotent unit of $A$. Then more generally, the element $t' : = \varphi_U(t') \in A$ is well defined for every $\gamma \in \mathbb{Z}[1/p]$. Notice that $s := f(t)$ is a topologically nilpotent unit of $B$, hence $B$ is a Tate ring; especially, the non-analytic loci of both $\text{Spec } A$ and $\text{Spec } B$ are empty, so that $f$ is an $f$-adic ring homomorphism (lemma 8.3.29 iv)). By lemma 8.3.24 ii, c) there exists a subring of definition $B_0 \subset B$ such that $f$ restricts to a continuous ring homomorphism $f_0 : A_0 \to B_0$. Then $sB_0$ is an ideal of $B_0$, and $B = B_0[s^{-1}]$ (corollary 8.3.20 ii, b)). Let $s^\gamma := f(t^\gamma)$ for every $\gamma \in \mathbb{Z}[1/p]$. We fix $\rho \in ]0, 1[$ and consider the map

$| \cdot |_B : B \to \mathbb{R} \cup \{+\infty\}$ 

$b \mapsto \inf\{\rho^\gamma \mid b \in s^\gamma B_0\}$
(cp. (16.5.23)). Let also \(|b| : B \to \mathbb{R} \cup \{+\infty\}\) be the asymptotic Samuel function of \(sB_0\), as defined in example 9.1.9(ii). Recall furthermore that \(A^\circ\) is perfectoid for the topology induced by \(A\) (theorem 16.5.13(i)), and the pair \((A^\circ, A^{\omega\circ})\) is a basic setup verifying condition (B) of [59 §2.1.6] (proposition 16.8.15(i)). Hence, the \((A^\circ, A^{\omega\circ})\)-algebra \(B^{\omega}\) is well defined, and in view of proposition 16.8.15(ii) we see that:

\[
B^{\omega}_A = \text{Hom}_{A^\circ}(A^{\omega\circ}, B) = \text{Hom}_A(A \otimes_{A^\circ} A^{\omega\circ}, B) = \text{Hom}_A(A, B) = B.
\]

**Lemma 16.9.8.** (i) For every \(b \in B\) we have: \(\lim_{n \to +\infty} |b^n|_B^{1/n} = \|b\|_B\).

(ii) \(|s^n b|_B = \rho^n \cdot \|b\|_B\) for every \(\gamma \in \mathbb{Z}[1/p]\) and every \(b \in B\).

(iii) \(B^{\omega\circ} = \{b \in B \mid \|b\|_B < 1\}\).

(iv) \((B^{\omega})_A^\circ = \{b \in B \mid \|b\|_B \leq 1\}\).

**Proof.** (i): Recall that \(\|b\|_B := \lim_{n \to +\infty} \rho^n (|b^n|_B / \rho^n)^{1/n}\), where \(\nu(b) := \inf\{k \in \mathbb{Z} \mid b \in s^k B_0\}\). For every \(b \in B\), set \(\mu(b) := \sup\{\gamma \in \mathbb{Z}[1/p] \mid b \in s^\gamma B_0\}\), so that \(\|b\|_B = \rho^{\mu(b)}\). Clearly we have:

\[
\nu(b^n) < \mu(b^n) < \nu(b^n) + 1
\]

for every \(b \in B\) and \(n \in \mathbb{N}\).

It follows that \(\lim_{n \to +\infty} (|b^n|_B / \rho^n)^{1/n} = 1\), whence the contenton.

(ii): It suffices to observe that \(|s^n b|_B = \rho^n \cdot \|b\|_B\) for every such \(b\) and \(\gamma\), and apply (i).

(iii): It suffices to remark that \(\|b\|_B < 1\) if and only if \(x^n \in s B_0\) for some \(n \in \mathbb{N}\).

(iv): Notice that \((B^{\omega})^\circ_A \subseteq B^{\omega}_A = B\). On the other hand, we have \((B^{\omega})^\circ_A = \text{Hom}_{A^\circ}(A^{\omega\circ}, B^{\omega})\).

It then follows that \((B^{\omega})^\circ_A = \{b \in B \mid b A^{\omega\circ} \subseteq B^{\omega}\}\) = \(\{b \in B \mid b A^{\omega\circ} \subseteq B^{\omega}\}\). Especially, \(|s^n b|_B = \rho^n\) and \(\gamma \in N[1/p] \setminus \{0\}\), whence \(\rho^n \cdot \|b\|_B < 1\) for every such \(\gamma\), in view of (ii) and (iii): i.e. \(\|b\|_B \leq 1\). Conversely, if \(\|b\|_B \leq 1\), we get \(\|f(a)b\|_B \leq \|b\|_B \cdot \|f(a)\|_B < 1\) for every \(a \in A^{\omega\circ}\), due to (ii); then \(f(a)b \in B^{\omega\circ}\) for every such \(a\), again due to (iii), and finally, \(b \in (B^{\omega})^\circ_A\).

16.9.9. Keep the situation of (16.9.7), and set \(C := (B^{\omega})^\circ_A\); lemma 16.9.8(ii,iv) implies that

\[
s^n C = \{b \in B \mid \|b\|_B \leq \rho^n\}\] for every \(\gamma \in \mathbb{Z}[1/p]\).

In light of lemma 16.9.2(iii), we may now conclude that \(C\) is the subring of power bounded elements of the uniformization \(u(B)\) of \((B, \mathcal{T}_B)\), and the topology of \(u(B)\) is the \(f\)-adic topology such that \(C \subseteq B\) is a subring of definition, and \(s C\) is an ideal of adic definition. Notice that \(f : (A, \mathcal{S}_A) \to u(B)\) is still an \(f\)-adic ring homomorphism. Moreover, from lemmata 16.9.2(ii) and 16.9.8(iii) we see that

\[
u(B^{\omega\circ}) = B^{\omega\circ}.
\]

**Definition 16.9.11.** (i) With the notation of (16.9.7), we say that \(B\) is a pre-perfectoid \(A\)-algebra, if \(u(B)\) is a formal perfectoid Tate ring.

**Remark 16.9.12.** (i) With the notation of (16.9.9), endow \(C\) with its \(s C\)-adic topology \(\mathcal{T}_C\); from corollary 8.4.1(i) and theorem 16.5.13(i) we see that \(B\) is a pre-perfectoid \(A\)-algebra if and only if \((C, \mathcal{T}_C)^\wedge\) is a perfectoid ring.

(ii) Let \(D \subseteq C\) be any subring that is \(p\)-integrally closed in \(C\) (see definition 9.8.24(i)). From (16.9.10) we see that:

\[
D\] is open in \((B, \mathcal{T}_B)\) \iff \(B^{\omega\circ} \subseteq D \iff u(B)^{\omega\circ} \subseteq D \iff D\) is open in \(u(B)\).

Suppose then that \(D\) is open in \((B, \mathcal{T}_B)\), and denote by \(\mathcal{T}_D\) the topology of \(D\) induced by \(\mathcal{T}_C\); then we claim that \(B\) is a pre-perfectoid \(A\)-algebra if and only if \((D, \mathcal{T}_D)^\wedge\) perfectoid. Indeed, suppose that \(B\) is a pre-perfectoid \(A\)-algebra; since \(B^{\omega\circ} \subseteq D\), we see that \(D/B^{\omega\circ}\) is a subring of \(C/B^{\omega\circ}\), and in view of (16.9.10) we get natural identifications:

\[
C/B^{\omega\circ} = C/u(B)^{\omega\circ} = \overline{C} := (C, \mathcal{T}_C)^\wedge / (u(B)^\wedge)^{\omega\circ}.
\]
Then, (i) implies that \( C/B^\infty \) is a perfect ring, and \( D/B^\infty \) is a perfect subring, since \( D \) is \( p \)-integrally closed in \( C \). In light of (i), lemma [16.9.6(iii)] and proposition [8.2.13(i,ii)], we conclude that \( (D, \mathcal{J}_D)^\wedge = D/B^\infty \times_C (C, \mathcal{J}_C) \) is a perfectoid subring of definition of \( u(B)^\wedge \). Conversely, suppose that \( (D, \mathcal{J}_D)^\wedge \) is perfectoid; we know already that \( D \) is open in \( u(B) \), and then \( (D, \mathcal{J}_D)^\wedge \) is open in \( u(B)^\wedge \), and its topology is induced by the inclusion into \( u(B)^\wedge \) (proposition [8.2.13(i,ii)]); hence, \( B \) is a pre-perfectoid \( A \)-algebra.

(iii) Lastly, let \( D \subset B \) be an open subring, endow \( D \) with the topology induced by \( B \), and suppose that \( D \) is a formal perfectoid (definition [16.7.19]); then \( D \) is \( p \)-integrally closed in \( B \).

Conversely, suppose that the Frobenius endomorphism of \( D \) is adic, so \( D^\wedge \) is a perfectoid subring of definition of \( B^\wedge \), hence \( (B^\wedge)_0 \subset D^\wedge \), by virtue of lemma [16.9.6(iii)]; especially, \( s^\gamma D \subset D \) for every \( \gamma \in \mathbb{N}[1/p] \), and \( s^{-\gamma} p \in D \) for every sufficiently small \( \gamma \in \mathbb{N}[1/p] \) (corollary [8.2.17(ii)]). It then suffices to invoke the criterion of theorem [16.4.1] together with lemma [8.9.26(i)]

Example 16.9.13. Let us return to the situation of (16.6.30): we consider a quasi-affinoid perfectoid ring \( A := (A, A^+, U_A) \) and a sequence \( f_\bullet := (f_0, \ldots, f_n) \) of elements of \( A_U := \mathcal{O}_{U, U}(U_A) \) that generates an open ideal (for the \( f \)-adic topology on \( A_U \) as in lemma [16.4.26(i)]). Let \( (E, E^+, U_E) := (E(A), notation of (16.5.20)), and E_U := \mathcal{O}_{U, U}(U_E) \). As recalled in [16.9.5], the map \( \pi_A : E \to A \) extends to a continuous morphism of topological monoids \( \varphi_U^\wedge : E_U \to A_U \); we may then find \( m \in \mathbb{N} \) and \( e_0, \ldots, e_n \in E_U \) verifying the inequalities [16.6.32] and [16.6.33] for every \( i = 1, \ldots, n \). Let also \( A_0 \subset A_U \) be any subring of definition, and \( I_0 \subset A_0 \) an ideal of adic definition; recall that the \( I_0 \)-adic completion \( B(f_\bullet)^\wedge \) of \( B(f_\bullet) := A_0[f_1/f_0, \ldots, f_n/f_0] \subset A_U[1/f_0] \) is a subring of definition of \( \mathcal{O}_{U, U}^\wedge (S(f_\bullet)) \), with \( S(f_\bullet) := R_{A_U}(f_{0,1}, \ldots, f_{0,n}) \cap \text{Spa } A_U \). Moreover, the sequence \( \varphi_U^\wedge(e_0), \ldots, \varphi_U^\wedge(e_n) \) generates an open ideal of \( A_U \) as well, according to proposition [16.6.34(ii)] and claim [16.6.35] and [16.6.33] (iii). It follows that the \( I_0 \)-adic completion \( B(e_\bullet)^\wedge \) of \( B(e_\bullet) := A_0[\varphi_U^\wedge(e_1), \ldots, \varphi_U^\wedge(e_n)] \) is another subring of definition of \( \mathcal{O}_{U, U}^\wedge (S(f_\bullet)) \). Therefore, the \( p \)-integral closures \( D(f_\bullet) \) and \( D(e_\bullet)^\wedge \) of \( B(f_\bullet)^\wedge \) and \( B(e_\bullet)^\wedge \) in \( \mathcal{O}_{U, U}^\wedge (S(f_\bullet)) \) both contain \( \mathcal{O}_{U, U}^\wedge (S(f_\bullet))\circlearrowleft \). Combining with proposition [16.6.34(iv)], we conclude that \( D(f_\bullet) = D(e_\bullet) \).

(ii) In the situation of (i), notice that if \( f_0, \ldots, f_n \in A \), we may take \( e_0, \ldots, e_n \in E \), and by construction we shall then have \( f_i - \pi_A(e_i) \in pA \) for \( i = 0, \ldots, n \).

Theorem 16.9.14. In the situation of (16.9.7), pick \( \gamma \in \mathbb{N}[1/p] \setminus \{0\} \) with \( pB_0 \subset s^{p\gamma}B_0 \), and suppose that the Frobenius endomorphism of \( B_0/s^{p\gamma}B_0 \) is surjective. Then \( B \) is pre-perfectoid.

Proof. We exhibit an increasing chain of subrings

\[
B_0 \subset B_1 \subset B_2 \subset \cdots
\]

of the \( p \)-integral closure of \( B_0 \) in \( B \), verifying the following conditions for every \( i \in \mathbb{N} \):

(a) The Frobenius endomorphism \( \Phi_i \) of \( B_i/s^{p\gamma}B_i \) is surjective.

(b) Let \( \overline{\Phi}_i : B_i/s^{p\gamma}B_i \to B_{i+1}/s^{p\gamma}B_{i+1} \) be the ring homomorphism induced by \( \Phi_i \). Then the kernel of the induced map \( j_i : B_i/s^{p\gamma}B_i \to B_{i+1}/s^{p\gamma}B_{i+1} \) contains \( \text{Ker } \overline{\Phi}_i \).

To this aim, we argue by induction on \( i \in \mathbb{N} \). Hence, suppose that for a given \( i \in \mathbb{N} \) we have already exhibited a subring \( B_i \) fulfilling condition (a); we need to exhibit \( B_{i+1} \) so that condition (b) holds as well for \( B_i \), and moreover such that condition (a) holds for \( B_{i+1} \). Now, since (a) holds for \( B_i \), for every \( x \in \text{Ker } \overline{\Phi}_i \) we may find a sequence \( (a(x, n) \mid n \in \mathbb{N}) \) of elements of \( B_i \), such that the image of \( a(x, 0) \) in \( B_i/s^{p\gamma}B_i \) agrees with \( x \), and:

\[
a(x, n + 1)^p - a(x, n) \in s^{p\gamma}B_i \quad \text{for every } n \in \mathbb{N}.
\]
It follows easily that \(a(x, n)^{p^{n+1}} \in s^{p^n} B_i\), and therefore \(b(x, n) := a(x, n) \cdot s^{-\gamma/p^n}\) lies in the \(p\)-integral closure of \(B_i\) in \(B\), for every \(n \in \mathbb{N}\). Let us then set
\[
B_{i+1} := B [b(x, n) \mid (x, n) \in \operatorname{Ker} (\mathcal{P}_i) \times \mathbb{N}] \subseteq B.
\]
Since the image of \(b(x, 0) \cdot s^\gamma\) in \(B_i/s^\gamma B_i\) agrees with the image of \(x\), we see that \(j_i(x) = 0\) for every \(x \in \operatorname{Ker} \mathcal{P}_i\), hence condition (b) holds for \(B_i\). Lastly, notice that
\[
b(x, n + 1)^p - b(x, n) \in B_i \quad \text{for every } n \in \mathbb{N}.
\]
Since \(B_i/s^{p^n} B_i \subseteq \operatorname{Im} \mathcal{P}_{i+1}\), it follows easily that condition (a) holds for \(B_{i+1}\), as required.

Set \(B_\infty := \bigcup_{i \in \mathbb{N}} B_i = B_\infty\); by construction, the Frobenius endomorphism of \(B_\infty\) induces an isomorphism \(B_\infty/s^{p^n} B_\infty \cong B_\infty/s^{p^n} B_\infty\), hence \(B_\infty\) is the \(p\)-integral closure of \(B_0\) in \(B\), by lemma [9.8.26(i)]. Next, let \(B_\infty\) be the completion of \(B_\infty\) for its \(p\)-adic topology; the Frobenius endomorphism of \(B_\infty\) induces an isomorphism \(B_\infty/s^{\gamma} B_\infty \cong B_\infty/s^{\gamma} B_\infty\). Clearly \(B_\infty\) is a \(p\)-ring; by theorem [16.4.1], the ring \(B_\infty\) is then perfectoid, and the assertion follows from remark [16.9.12(ii)].

Corollary 16.9.15. In the situation of [16.9.7], let \(I \subseteq B\) be any ideal, and endow \(\overline{B} := B/I\) with the \(p\)-adic topology \(\mathcal{T}_{\overline{B}}\) induced by \(\mathcal{T}_B\) via the projection \(B \to \overline{B}\) (see example [8.3.27(iii)]). Then, if \(B\) is a pre-perfectoid \(A\)-algebra, the same holds for \(\overline{B}\).

Proof. Let \(\mathcal{T}_{\overline{B}}^u\) be the topology of \(u(B)\), and denote by \(\mathcal{T}_{\overline{B}}^u\) the \(\gamma\)-adic topology induced by \(\mathcal{T}_{\overline{B}}^u\) via the projection \(B \to \overline{B}\). If \(C\) is any uniform Tate ring, and \(f : (\overline{B}, \mathcal{T}_{\overline{B}}) \to C\) any continuous ring homomorphism, it is easily seen that \(f\) factors through the identity map \(1_{\overline{B}} : (\overline{B}, \mathcal{T}_{\overline{B}}) \to (\overline{B}, \mathcal{T}_{\overline{B}}^u)\), which is continuous, and the continuous ring homomorphism \(f : (\overline{B}, \mathcal{T}_{\overline{B}}^u) \to C\). By the universal property of uniformization, this implies that \(1_{\overline{B}}\) induces an isomorphism of uniform Tate rings
\[
u(\overline{B}, \mathcal{T}_{\overline{B}}) \cong u(\overline{B}, \mathcal{T}_{\overline{B}}^u)
\]
(whose underlying ring homomorphism is of course again the identity map of \(\overline{B}\)). Thus, it suffices to check that \((\overline{B}, \mathcal{T}_{\overline{B}}^u)\) is pre-perfectoid. However, since \(B\) is pre-perfectoid, \(C := u(B)^\circ\) is a perfectoid ring, hence for every \(\gamma \in \mathbb{N}[1/p] \setminus \{0\}\) such that \(pC \subseteq s^{p^n} C\), the Frobenius endomorphism of \(C/s^{p^n} C\) is surjective. By construction, the image \(\overline{C}\) of \(C\) in \(\overline{B}\) is a subring of definition for the topology \(\mathcal{T}_{\overline{B}}^u\); and it follows that the Frobenius endomorphism of \(\overline{C}/s^{p^n} \overline{C}\) is again surjective; then the assertion follows from theorem [16.9.14].

16.9.16. Let \(A\) be a formal perfectoid Tate ring, \(A_0 \subseteq A\) a formal perfectoid subring of definition, \(t \in A_0^{\infty} \cap A^x\), and \(P \in A_0[X] \setminus A_0\) a monic polynomial. We let \(B_0 := A_0[X^{1/p^n}] := \bigcup_{n \in \mathbb{N}} A_0[X^{1/p^n}]/(P)\) for every \(n \in \mathbb{N}\), and \(C_0 := B_0/\mathcal{P}_B\) and \(C := B/\mathcal{P}_B\). Clearly the natural map of \(A_0\)-algebras \(C_{0,m} \to C_{0,n}\) is injective for every \(n, m \in \mathbb{N}\) with \(n \geq m\), and \(C_{0,n}\) is a free \(A_0\)-module of rank \(p^n \cdot \deg_{X}(P)\) for every such \(n\). Hence \(C_0 = \bigcup_{n \in \mathbb{N}} C_{0,n}\) is a faithfully flat \(A_0\)-algebra, and the localization \(C_0 \to C\) is injective. Lastly, let \(D \subseteq C\) be the \(p\)-integral closure of \(C_0\) in \(C\) (see definition [9.8.24(ii)]), and endow \(D\) with its \(t\)-adic topology.

The following result and its proof are a generalization and refinement of [5] Th.2.5.2] (modulo powers of \(p\), as in [5] Rem.2.6.1(4)); see also [19] Th.2.3]. We also borrowed from a set of lecture notes of B.Bhatt the idea of stating the theorem for a general monic polynomial \(P\): see [20] Th.9.4.3] (whereas André’s original theorem would be the special case with \(P = X - a\), for any \(a \in A_0\).

Theorem 16.9.17. (i) In the situation of [16.9.16], \(D\) is a faithfully flat \(A_0\)-algebra.

(ii) Moreover, \(D\) is a formal perfectoid ring for its \(t\)-adic topology.
Proof. Clearly $D[1/t] = C$ is a faithfully flat $A$-algebra, and the image of $t$ is regular in $D$; by virtue of [59, Lemma 5.2.1], in order to show (i), it then suffices to check that $D/tD$ is a faithfully flat $A_0/tA_0$-algebra. Recall that the completion $A_0^\wedge$ is a subring of definition for the completion $A^\wedge$ of $A$ (proposition 8.3.33(ii)); set $C'_0 := A_0^\wedge \otimes_{A_0} C_0$, $C' := A^\wedge \otimes_A C$, and let $D'$ be the $p$-integral closure of $C'_0$ in $C'$. Endow also $C_0$ (resp. $C'_0$) with its $t$-adic topology, and $C$ (resp. $C'$) with the unique $f$-adic topology such that $C_0$ (resp. $C'_0$) is a subring of definition; let $\mathcal{T}_D$ (resp. $\mathcal{T}_{D'}$) be the topology induced by $C$ on $D$ (resp. by $C'$ on $D'$). Taking into account proposition 8.3.33, it is easily seen that the natural maps $T$ of (lemma 16.9.6(ii,iii)). We may also assume that $t$ recall that $E$ is a pre-perfectoid $A$-algebra, by theorem 16.9.14. Then the assertion follows from remark 16.9.12(ii).

Proof of the claim. Let also $C_0^\wedge$ be the completion of $C_0$; since $t^kC_0^\wedge$ is an open $A_0$-submodule of $D$, the map $u$ induces an isomorphism $A_0$-modules $\overline{\pi} : D/t^kC_0^\wedge \cong D^\wedge/t^kC_0^\wedge$. Hence, $\overline{\pi}(tD/tC_0) = t^k : \overline{\pi}(D/tC_0) = t^kD^\wedge/t^kC_0^\wedge$, whence the assertion.

By applying claim 16.9.18 to both $D^\wedge$ and the completion $D^\wedge$ of $(D', \mathcal{T}_{D'})$, we reduce to checking that $D'/tD'$ is a faithfully flat $A_0/tA_0$-algebra, and that $D'$ is perfectoid for its $t$-adic topology. Thus, we may replace $A$ by $A'$, and assume that $A$ is a perfectoid Tate ring.

(ii): By construction, the Frobenius endomorphism of $C_0$ is a surjection; hence $C$ is a pre-perfectoid $A$-algebra, by theorem 16.9.14. Then the assertion follows from remark 16.9.12(ii).

(i): Define the affinoid schemes $\mathcal{U} := (U, \mathcal{T}_{A}, A^+)$ and $\mathcal{U}_E := (U_E, \mathcal{T}_{E}, E^+_0)$ as in (16.9.5); recall that $E_0 := E(A_0)$ is a subring of definition of the Tate perfectoid ring $E_U := \mathcal{O}_{U_E}(U_E)$ (lemma 16.9.6(ii,iii)). We may also assume that $t := \pi A_0(t') \in A$ for some $t' \in E_U \cap E_0^\infty$.

We endow $B_0$ with its $t$-adic topology, and $B$ with the $f$-adic topology such that $B_0$ is a subring of definition. We have then a short exact sequence of flat $A_0$-modules

$$
\Sigma^\wedge : 0 \to PB_0 \to B_0^\wedge \xrightarrow{\pi_0^\wedge} C_0^\wedge \to 0.
$$

As in (16.9.7), we let $t^\gamma := \varphi(t^\gamma) \in A$ for every $t^\gamma \in \mathbb{Z}[1/p]$. With this notation, the sequence $A_0/t^\gamma A_0 \otimes_{A_0} \Sigma$ is still short exact, for every $t^\gamma \in \mathbb{N}[1/p]$, which means that $t^\gamma B_0 \cap PB_0 = t^\gamma PB_0$ for every such $t^\gamma$. Especially, the topology of $B_0$ induces the $t$-adic topology on the ideal $PB_0$, and after taking completions, we still get a short exact sequence:

$$
\Sigma^\wedge : 0 \to PB_0^\wedge \to B_0^\wedge \xrightarrow{\pi_0^\wedge} C_0^\wedge \to 0.
$$

Recall that the completion $C^\wedge$ of $C$ is naturally identified with $C_0^\wedge[t^{-1}]$, and $C_0^\wedge$ is a subring of definition for $C^\wedge$ (proposition 8.3.33(ii,iii)). Likewise, $B_0^\wedge$ is a subring of definition of $B^\wedge = B_0^\wedge[t^{-1}]$. We consider the affinoid ring $B^\wedge := (B^\wedge, B^\wedge_0)$, and the rational subset

$$
R_n := R B^\wedge \left( \frac{P^\wedge}{P^\wedge_n} \right) \cap \text{Spa } B^\wedge
$$

for every $n \in \mathbb{N}$.

Endow the subring $B_n := B_0^\wedge[P/t^n] \subset B^\wedge$ with its $t$-adic topology, and let $\mathcal{T}_n$ be the $f$-adic topology on $B^\wedge$ such that $B_n$ is a subring of definition; then the completion $B_n^\wedge$ of $B_n$ is a subring of definition of $\mathcal{O}_{\text{Spa } B^\wedge}(R_n) = (B^\wedge, \mathcal{T}_n)^\wedge$, for every $n \in \mathbb{N}$. Notice that the projection $\pi_0^\wedge$ extends to a continuous open ring homomorphism $\pi^\wedge : B^\wedge \to C^\wedge$, and for every $n \in \mathbb{N}$, the image of the induced continuous map

$$
\text{Spa } \pi^\wedge : \text{Spa} (C^\wedge, C^\wedge_0) \to \text{Spa } B^\wedge
$$

lies in $R_n$. It follows that $\pi^\wedge$ factors uniquely through a continuous ring homomorphism

$$
\psi_n : \mathcal{O}_{\text{Spa } B^\wedge}(R_n) \to C^\wedge
$$

for every $n \in \mathbb{N}$.
(see remark \[15.5.9\](i)). Moreover, we have \(R_{n+1} \subset R_n\) for every \(n \in \mathbb{N}\), and clearly the composition of \(\psi_{n+1}\) with the restriction map \(\mathcal{O}_{\text{Spa} B^\wedge}(R_n) \to \mathcal{O}_{\text{Spa} B^\wedge}(R_{n+1})\) agrees with \(\psi_n\).

Furthermore, a direct inspection shows that \(\psi_n(B^\wedge_n) = C^\wedge_0\) for every \(n \in \mathbb{N}\). Summing up, we deduce a commutative diagram of rings:

\[
\begin{array}{ccc}
B^\wedge := \text{colim}_{n \in \mathbb{N}} B^\wedge_n & \longrightarrow & \mathcal{O} := \text{colim}_{n \in \mathbb{N}} \mathcal{O}_{\text{Spa} B^\wedge}(R_n) \\
\downarrow & & \downarrow \\
n^\wedge \end{array}
\]

(16.9.19)

whose vertical (resp. horizontal) arrows are surjections (resp. injections).

**Claim 16.9.20.** The diagram (16.9.19) is cartesian.

**Proof of the claim.** The assertion means that the induced map \(\text{Ker } \alpha \to \text{Ker } \beta\) is bijective. However, this map is clearly injective, so it remains to check its surjectivity. To this aim, notice that for every \(n \in \mathbb{N}\) and every \(g_n \in \mathcal{O}_{\text{Spa} B^\wedge}(R_n)\) there exists \(N \in \mathbb{N}\) such that

\[t^N g_n = \sum_{i=0}^{\infty} b_i \cdot \left(\frac{P}{t^m}\right)^i \quad \text{with } b_i \in B^\wedge_0 \text{ for every } i \in \mathbb{N} \text{ and } \lim_{i \to +\infty} b_i = 0.\]

With this notation, it follows easily that \(g_n \in \text{Ker } \psi_n\) if and only if \(b_0 = 0\). Suppose then that \(\psi_n(g_n) = 0\); the image \(g_{n+N}\) of \(g_n\) in \(\mathcal{O}_{\text{Spa} B^\wedge}(R_{n+N})\) can be written as:

\[g_{n+N} = \sum_{i=1}^{\infty} t^{N(i-1)} b_i \cdot \left(\frac{P}{t^{m+N}}\right)^i\]

and we have \(t^{N(i-1)} b_i \in B^\wedge_0\) for every \(i \geq 1\), and \(\lim_{i \to +\infty} t^{N(i-1)} b_i = 0\). Hence \(g_{n+N} \in B^\wedge_{n+N}\), and clearly \(g_{n+N} \in \text{Ker } \psi_{n+N}\), whence the contention. \(\Diamond\)

Let \(\mathcal{D}\) be the \(p\)-integral closure of \(B^\wedge\) in \(\mathcal{O}\), and endow \(\mathcal{D}\) with its \(t\)-adic topology; it follows easily from claim (16.9.20) that \(\mathcal{D} = \beta^{-1} D\). Moreover, the induced ring homomorphism \(\beta|_{\mathcal{D}} : \mathcal{D} \to D\) is surjective, and its kernel is \(\text{Ker } \beta\). The latter is clearly \(t\)-divisible, hence \(\beta|_{\mathcal{D}}\) induces an isomorphism of \(A_0\)-algebras

\[\mathcal{D}/t^n \mathcal{D} \xrightarrow{\sim} D/t^n D \quad \text{for every } n \in \mathbb{N}.\]

Thus, it suffices to check that the natural ring homomorphism \(A_0 \to \mathcal{D}\) is adically faithfully flat. To this aim, let also \(\mathcal{D}_n\) be the \(p\)-integral closure of \(B^\wedge_n\) in \(\mathcal{O}_{\text{Spa} B^\wedge}(R_n)\), for every \(n \in \mathbb{N}\), and endow \(\mathcal{D}_n\) with its \(t\)-adic topology; in view of lemma \([9.8.26]\)(iii.b) we are reduced to checking that \(\mathcal{D}_n\) is an adically faithfully flat \(A_0\)-algebra for every \(n \in \mathbb{N}\).

Now, notice that \(B^\wedge_0\) is a perfectoid ring, by virtue of lemma \([16.6.39]\) and we have a natural identification of topological rings:

\[E(B^\wedge_0) \xrightarrow{\sim} E_0[X^{1/p\infty}]^\wedge \quad \text{such that } \bar{u}_{B^\wedge_0}(X^\gamma) = X^\gamma \quad \text{for every } \gamma \in \mathbb{N}[1/p]\]

where \(E_0[X^{1/p\infty}]^\wedge\) denotes the \(t\)'-adic completion of \(E_0[X^{1/p\infty}]\). Next, let \((\alpha_n \mid n \in \mathbb{N})\) be a distinguished element in the kernel of \(u_{A_0} : W(E_0) \to A_0\); after replacing \(t\)' by \(t^\gamma\) for some sufficiently small \(\gamma \in \mathbb{N}[1/p] \setminus \{0\}\), we may assume that \(\alpha_0 E_0 \subset t E_0\), in which case the isomorphism \(\omega\) of remark \([16.3.7]\)(ii) induces ring isomorphisms

(16.9.21)

\[E_0/t E_0 \xrightarrow{\sim} A_0/t A_0 \quad E(B^\wedge_0)/t E(B^\wedge_0) \xrightarrow{\sim} B^\wedge_0/t B^\wedge_0.\]

On the other hand, set \(U_B := \text{Spec } B^\wedge\); then \((B^\wedge_0, B^\wedge_0, U_B)\) is a perfectoid quasi-affinoid ring, and by example \([16.9.13]\) we may then find \(e_n \in E(B^\wedge_0)\) such that \(\mathcal{D}_n\) is the \(p\)-integral closure in \(\mathcal{O}_{\text{Spa} B^\wedge}(R_n)\) of the \(t\)-adic completion of \(B^\wedge_0/\bar{u}_{B^\wedge_0}(e_n)/t^n\), and moreover – after replacing
again \( t' \) by \( t^n \) for some small \( \gamma \in \mathbb{N}[1/p] \setminus \{0\} \) — we may assume that \( P - \bar{\pi}_{B_0^\circ}(e_n) \in tB_0^\circ \). Hence, there exist a monic polynomial \( Q_n \in E_0[X] \) and \( g_n \in E_0[X^{1/p\infty}]^\wedge \) with

\[
e_n = Q_n + t g_n.
\]

(16.9.22)

According to proposition \([16.7.25]\) (iii), the subring

\[
D_n := B_0^\circ[\bar{\pi}_{B_0^\circ}(e_n^{1/p^k})/t^n/p^k \mid k \in \mathbb{N}] \subset B^\wedge
\]
is formal perfectoid for the topology \( \mathcal{T}_n' \) induced by \( \mathcal{T}_n \). Then \( \mathcal{T}_n' \) is the \( t \)-adic topology, and combining with remark \([16.9.12]\) (iii) and lemma \([9.8.26]\) (ii), we deduce that

\[
(D_n, \mathcal{T}_n')^\wedge = \mathcal{D}_n.
\]

Thus, we are further reduced to checking that the \( A_0 \)-algebra \( D_{n,k} := B_0^\circ[\bar{\pi}_{B_0^\circ}(e_n^{1/p^k})/t^n/p^k] \) is adically faithfully flat for every \( n, k \in \mathbb{N} \) with \( n > 0 \) and \( n/p^k \leq 1 \). Since \( t \) is a regular element of \( D_{n,k} \), the local flatness criterion \(([100], \text{Th.}22.3)\) further reduces to showing that \( D_{n,k}/(t^n/p^k) \) is a faithfully flat \( A_0/(t^n/p^k) \)-algebra, for every such \( n \) and \( k \). To this aim, notice that \((16.9.21)\) induces an isomorphism \( E_{n,k} := E_0/(t^n/p^k) \cong A_0/(t^n/p^k) \), and \( B_0^\circ/(t^n/p^k) \) is isomorphic to the \( A_0 \)-algebra \( E_{n,k}[X^{1/p\infty}] \) (as \( n/p^k \leq 1 \)). Also, the image of \( \bar{\pi}_{B_0^\circ}(e_n^{1/p^k}) \) in \( E_{n,k}[X^{1/p\infty}] \) is the regular element \( Q_n/p^k \), due to \((16.9.22)\). Thus, the sequence \((t^n/p^k, \bar{\pi}_{B_0^\circ}(e_n^{1/p^k}))\) is regular in the ring \( B_0^\circ \); in particular, this sequence is completely secant \((\text{proposition} \ [7.8.7])\), so the natural map

\[
B_0^\circ[Y]/(\bar{\pi}_{B_0^\circ}(e_n^{1/p^k}) - t^n/p^k Y) \rightarrow D_{n,k}
\]
is an isomorphism of \( A_0 \)-algebras \((\text{lemma} \ [7.8.1])\). We are then further reduced to checking that for every \( n, k, r \in \mathbb{N} \) with \( n > 0 \), \( r \geq k \) and \( n/p^k \leq 1 \), the \( E_{n,k} \)-algebra

\[
E_{n,k}[X^{1/p^r}, Y]/(Q_n^{1/p^r})
\]
is faithfully flat. The latter follows from \([50, \text{Ch.IV, Prop.}11.3.7]\).

16.9.23. Let \( A \) be a perfectoid Tate ring, \( A_0 \subset A \) a perfectoid subring of definition, and \((A_0, m)\) a basic setup in the sense of \([59, \text{§2.1.1}]\), such that \( m \) is the filtered union of a countable system of principal subideals. If \( m \) is an open radical ideal of \( A_0 \), then we have attached to \( m \) an open radical ideal \( m_E \) of \( E_0 := E(A_0/pA_0) \), so that \((E_0, m_E)\) is a basic setup as well \((\text{see proposition} \ [16.8.15])\). One can show that here \( m \) is still a radical ideal; however, it is not necessarily open, but nevertheless we can construct a useful basic setup \((E_0, m_E)\) as follows. By assumption, \( m \) is the filtered union of a countable system of principal ideals; hence, we may find a generating system \((a_n \mid n \in \mathbb{N})\) for \( m \) such that for every \( n \in \mathbb{N} \) there exists an element \( c_n \in A \) with \( a_n = c_n a_{n+1}^p \). For every \( x \in A_0 \), let \( \bar{x} \in A_0/pA_0 \) be the class of \( x \); since \( A_0 \) is perfectoid, for every \( n \in \mathbb{N} \) there exists \((\bar{x}_{n,k} \mid k \in \mathbb{N}) \in E_0 \) with \( \bar{x}_{n,0} = \bar{x}_n \) (recall that \( \bar{x}_{n,k} = \bar{x}_{n,k} \) for every \( k \in \mathbb{N} \)). Set

\[
\alpha_{n,k} := \bar{x}_{n+k} \cdot \bar{x}_{n,k} \cdot \bar{x}_{n,k+1,k-1} \cdots \bar{x}_{n+k-1,1} \quad \text{for every} \ n \in \mathbb{N}.
\]

Thus, \( \alpha_{n,k} = \bar{x}_n \) and it is easily seen that \( \alpha_{n,k} := (\alpha_{n,k} \mid k \in \mathbb{N}) \in E_0 \) for every \( n \in \mathbb{N} \); moreover, \( \alpha_{n,k} \in \alpha_{n+1,k}^p E_0 \) for every \( n \in \mathbb{N} \). Let then \( m_E \subset E_0 \) be the ideal generated by the system \((\alpha_{n,k} \mid n \in \mathbb{N})\); it follows that \((E_0, m_E)\) is a basic setup.

**Remark 16.9.24.** (i) In the situation of \((16.9.23)\), we have:

\[
(16.9.25) \quad \bigcap_{n \in \mathbb{N}} (\bar{\pi}_{A_0}(m_E) \cdot A_0 + p^n A_0) = \bigcap_{n \in \mathbb{N}} (m + p^n A_0).
\]

Indeed, on the one hand, \( \bar{\pi}_{A_0}(\alpha_{n,k}) \) is the limit of the \( p \)-adically convergent sequence

\[
((a_{n+k} x_{n,k} \cdots x_{n+k-1,1})^{1/p^k} \mid k \in \mathbb{N})
\]
hence it lies in the $p$-adic topological closure of $m$. On the other hand, by construction for every $x \in m$ there exists $y \in \pi_{A_0}(m, E)$ such that $x - y \in pA_0$; then $xp^n - yp^n \in p^nA_0$ for every $n \in \mathbb{N}$ (lemma 9.3.4(i)), and since $m$ is generated by $(xp^n \mid x \in m)$, we deduce the converse inclusion.

(ii) Quite generally, let $(V, m)$ be a basic setup in the sense of [59, §2.1.1], such that $m$ is a filtered countable union of principal subideals; then it is easily seen that we may write $m = \bigcup_{n \in \mathbb{N}} V a_n$ for a system $(a_n \mid n \in \mathbb{N})$ of elements of $A$ such that $V a_n \subset m \cdot a_{n+1}$ for every $n \in \mathbb{N}$: the details are left to the reader. Hence, for every $n \in \mathbb{N}$ let $c_n \in m$ such that $a_n = a_n a_{n+1}$. We consider the inductive limit $L = \bigcup_{n \in \mathbb{N}} V a_n$ for a system $(a_n \mid n \in \mathbb{N})$ of elements of $A$ such that $V a_n \subset m \cdot a_{n+1}$ for every $n \in \mathbb{N}$: the details are left to the reader. Hence, for every $n \in \mathbb{N}$ let $c_n \in m$ such that $a_n = a_n a_{n+1}$. We consider the inductive limit $L_n := (L_n \mid n \in \mathbb{N})$ with $L_n := V$ for every $n \in \mathbb{N}$, with $V$-linear transition map $\varphi_n : L_n \to L_{n+1}$ such that $\varphi_n(1) := c_n$ for every $n \in \mathbb{N}$. The inductive limit $L$ of $L_n$ is the set of equivalence classes $[x, n]$ of all pairs $(x, n)$ with $n \in \mathbb{N}$ and $x \in L_n$. We have an obvious $V$-linear surjection

$$
\psi : L \to m \quad [x, n] \mapsto xa_n.
$$

Notice that if $[x, n] \in \text{Ker } \psi$, then $a_n \cdot [x, n] = [a_n x, n] = 0$; on the other hand, for every $k \geq n$ there exists $y \in V$ such that $[x, n] = [y, k]$, whence $a_k \cdot [x, n] = a_k \cdot [y, k] = 0$ as well. This shows that $m \cdot \text{Ker } \psi = 0$. Therefore, $m \otimes V \psi : m \otimes V L \to m := m \otimes V m$ is an isomorphism. But by construction, $L$ is a flat $V$-module, hence the natural map $m \otimes V L \to m L$ is an isomorphism; lastly, for every $[x, n] \in L$ we have $[x, n] = c_n [x, n + 1]$, so $m L = L$. Summing up, $m \otimes V \psi$ is naturally identified with the isomorphism:

$$
L \cong m \quad [x, n] \mapsto x \otimes a_n.
$$

(iii) Furthermore, the functor $E$ induces a functor on almost algebras

$$
E^a : (A_0, m)^a-\text{Alg} \to (E_0, m_E)^a-\text{Alg} \quad R^a \mapsto E(R/pR)^a.
$$

Indeed, let $f : R \to S$ be a homomorphism of $A_0$-algebras such that $f^a : R^a \to S^a$ is an isomorphism of $(A_0, m)^a$-algebras, and set $f_0 := f \otimes \mathbb{Z}/p\mathbb{Z}$; we need to check that $E(f_0)^a : E(R/pR)^a \to E(S/pS)^a$ is an isomorphism of $(E_0, m_E)^a$-algebras. However, $E(f_0)$ is the limit of the system of rings $(R_n \mid n \in \mathbb{N})$, with $R_n := R/pR$ for every $n \in \mathbb{N}$, and with transition map $R_{n+1} \to R_n$ given by the Frobenius endomorphism $\Phi_{R/pR}$. Now, if $g : A_0 \to R$ is the structure map of the $A_0$-algebra $R$, then $R_0$ is naturally an $E_0$-algebra, via the composition $g' : E_0 \to R_0$ of the projection $\pi_{A_0/pA_0} : E_0 \to A_0/pA_0$ and $g \otimes \mathbb{Z}/p\mathbb{Z} : A_0/pA_0 \to R_0$. Let $\Phi_{E_0}$ be the Frobenius automorphism of $E_0$; then for every $n \in \mathbb{N}$, the ring $R_n$ is an $E_0$-algebra with structure morphism $g' \circ \Phi_{E_0}^{-n} : E_0 \to R_n$, i.e. $R_n = (R_0)(\Phi_{E_0}^{-n})$, and $\Phi_{R/pR} : R_{n+1} \to R_n$ is a homomorphism of $E_0$-algebras, for these $E_0$-algebra structures. Likewise, $E(S/pS)$ is the limit of a system of $E_0$-algebras $(S_n \mid n \in \mathbb{N})$, and $f$ induces a system of maps of $E_0$-algebras $f_n := f_0 : R_n \to S_n$, whose inverse limit is $E(f_0)$. Since $f^a$ is an isomorphism, and since $\Phi_{E_0} : (E_0, m_E) \to (E_0, m_E)$ is an isomorphism of basic setups, it is easily seen that $f_n^a : R_n^a \to S_n^a$ is an isomorphism of $(E_0, m_E)^a$-algebras, for every $n \in \mathbb{N}$; on the other hand, the functor $(-)^a$ commutes with limits, since it has a left adjoint, whence the contention.

16.9.26. Let $A$ be a Tate ring, $A_0 \subset A$ a subring of definition, $p \in \mathbb{N}$ a prime integer, and $A_1 \subset A$ the $p$-integral closure of $A_0$ in $A$ (see definition 9.8.24(ii)). Moreover, suppose there exists $b \in A_0^\circ \cap A^\circ$ with $pA_0 \subset b^pA_0$, and let $A_0^b$ and $A_1^b$ be the $b$-adic completions of $A_0$ and $A_1$. Notice that the Frobenius endomorphism $\Phi_{A_0}$ of $A_i/b^pA_i$ induces a ring homomorphism

$$
\overline{\Phi}_{A_i} : A_i/bA_i \to A_i/b^pA_i \quad \text{for } i = 0, 1.
$$

Furthermore, let $(A_0, m)$ be a basic setup, such that $m$ is the filtered union of a countable system of principal subideals, and denote by $\overline{m}$ the image of $m$ in $\overline{A_0} := A_0/pA_0$. Then $m$ is generated by the system $(xp^i \mid x \in m)$ ([59, Prop.2.17]), and therefore the Frobenius endomorphism $\Phi$ of $\overline{A_0}$ is a morphism of basic setups in the sense of [59, §3.5]

$$
\Phi : (\overline{A_0}, \overline{m}) \to (\overline{A_0}, \overline{m}).
$$
As detailed in [59, §3.5.7], the latter induces a pull-back functor
\[(\mathcal{A}_0, \mathfrak{m})^\text{a}-\text{Alg} \to (\mathcal{A}_0, \mathfrak{m})^\text{a}-\text{Alg} \quad B \mapsto B(\phi).\]

**Definition 16.9.27.** In the situation of (16.9.26), we say that the basic setup \((A_0, m)\) is **almost perfectoid** if \(A_0\) is complete and separated, and the Frobenius endomorphism of \(A_0/b^pA_0\) induces an isomorphism of \((A_0, m)^\text{a}-\text{algebras} \overline{\mathcal{A}}_0 : (A_0/bA_0)^\text{a} \xrightarrow{\sim} (A_0/b^pA_0)^\text{a}_0(\phi).\]

**Remark 16.9.28.** The following proposition [16.9.29(i)] implies in particular that definition [16.9.27] is independent of the choice of the element \(b \in A_0\) such that \(p \in b^pA_0\): if \(b' \in A_0\) is another such element, and if the \(b\)-adic topology on \(A_0\) agrees with the \(b'\)-adic topology, then \(\overline{\mathcal{A}}_0\) is an isomorphism if and only if the same holds for the corresponding morphism of \((A_0, m)^\text{a}-\text{algebras} (A_0/bA_0)^\text{a} \xrightarrow{\sim} (A_0/b^pA_0)^\text{a}_0(\phi).\) See also lemma [17.5.10].

**Proposition 16.9.29.** (i) In the situation of (16.9.26), the following conditions are equivalent:

(a) The basic setup \((A_0, mA_0^0)\) is almost perfectoid.

(b) The basic setup \((A_1, mA_1^0)\) is almost perfectoid, and the inclusion map \(j : A_0 \to A_1\) induces isomorphisms of \((A_0, m)^\text{a}-\text{algebras} j^0 : A_0^0 \xrightarrow{\sim} A_1^0\).

(c) The topological closure \(\overline{C} \subset A_0\) of the subring \(C := \mathbb{Z}[a^p \mid a \in A_0]\) contains \(m\), and \(j\) induces an isomorphism of \((A_0, m)^\text{a}-\text{algebras} j^a : A_0^a \xrightarrow{\sim} A_1^a\).

(ii) If \(A_0\) is integrally closed (resp. \(p\)-integrally closed) in \(A\), then \(A_0^a\) is integrally closed (resp. \(p\)-integrally closed) in \(A_0^0[b^{-1}].\)

(iii) If \((A_0, m)\) is an almost perfectoid basic setup, the same holds for \((A_0^a, mA_0^a)\).

(iv) \((A_0, m)\) is an almost perfectoid basic setup, and the unit of adjunction \(A_0 \to (A_0)_a^a\) is an isomorphism, then \(A_0 = A_1\).

**Proof.** By simple inspection we see that (i.b)⟺(i.a). Conversely, suppose that (i.a) holds, and let also \(j^0 : A_0^0 \to A_1^0\) be the \(b\)-adic completion of \(j\); in order to show (i.b), it suffices to check:

**Claim 16.9.30.** \(\text{Ker } \overline{\mathcal{A}}_0 = 0 \iff j^a\) is an isomorphism \(\iff (j^a)^0\) is an isomorphism.

**Proof of the claim.** Suppose first that \(\text{Ker } \overline{\mathcal{A}}_0 = 0\). We can construct \(A_1\) as the increasing union of the ascending chain \((A_0,n)\) of subrings of \(A\) defined inductively as follows: \(A_{0,0} := A_0\) and \(A_{0,n} := A_{0,n-1}[\Sigma_n]\), with \(\Sigma_n := \{x \in A \mid x^p \in A_{0,n-1}\}\), for every \(n > 0\). Thus, we are reduced to showing that the inclusion \(A_0 \to A_{0,n}\) induces an isomorphism \(A_0^0 \xrightarrow{\sim} A_0^n\) for every \(n \in \mathbb{N}\). However, if for some \(n > 0\) the inclusion \(j_{n-1} : A_{0,n-1} \to A_{0,n}\) induces an isomorphism \(j_{n-1}^0 : A_{0,n-1}^0 \xrightarrow{\sim} A_{0,n}^0\), then the same holds for \(j_n : A_{0,n} \to A_{0,n+1}\) indeed, let \(x \in \Sigma_{n+1}\); since \(x^p \in A_{0,n}\), by assumption we have \((ax)^p \in A_{0,n-1}\) for every \(a \in m\), whence \(ax \in A_{0,n}\). Thus, we are further reduced to checking that \(j_0\) induces an isomorphism \(j_0^a : A_0^0 \xrightarrow{\sim} A_{0,1}^a\), i.e. that \((\text{Coker } j_0)^a = 0\). We argue as in the proof of lemma [9.8.26(i)] let \(x \in A_1 \setminus A_0\), and denote by \(m \in \mathbb{N}\) the smallest integer such that \(b^mx \cdot m \subseteq A_0\). Hence, \(y := b^mx^p \in A_0\), and \((b^{m+1}x)^p = b^py^p \in b^pA_0\). By assumption, for every \(a \in m\) we then have \(z \in A_0\) such that \(ab^mx \cdot z = bz\), contradicting the choice of \(m\).

Conversely, suppose that \(j^a\) is an isomorphism, and let \(x \in A_0\) be an element whose class \(\overline{x} \in A_0/bA_0\) lies in \(\text{Ker } \overline{\mathcal{A}}_0\); then \(x^p \in b^pA_0\), so \((x/b)^p \in A_0\), and our assumption implies that \(m \cdot x \in bA_0\), i.e. \(m \cdot \overline{x} = 0\).

Next, if \(j^a\) is an isomorphism, the same holds for \(j_k^a := A_0^0/b^kA_0 \otimes A_0^a j^a : A_0^0/b^kA_0^0 \to A_1^a/b^kA_1^a\), for every \(k \in \mathbb{N}\), and then also for the limit of the inverse system \((j_k^a | k \in \mathbb{N})\). But the functor \((-)^a\) commutes with limits, since it has a left adjoint, so \((j^a)^a\) is an isomorphism.

Conversely, if \((j^a)^a\) is an isomorphism, the induced map \(A_0^0[b^{-1}]/A_0^0 \to A_1^0[b^{-1}]/A_1^0\) is an almost isomorphism of \(A_0\)-modules. But proposition [8.3.33(iii)] easily implies that the natural
map $A_0[b^{-1}]/A_0 \to A_0^n[b^{-1}]/A_0^n$ is bijective, and similarly for $A_1$; hence $j$ induces isomorphisms $A_0^n[b^{-1}]/A_0^n \xrightarrow{\sim} A_1^n[b^{-1}]/A_1^n$ and $A_0[b^{-1}] \xrightarrow{\sim} A_1[b^{-1}]$. By the 5-lemma, it follows easily that $j^a$ is an isomorphism.

Next, let $m_\pi \subset \tilde{C}$ be the ideal generated by $(a^p \mid a \in m)$. Since $m$ is the filtered union of a countable system of principal subideals, the same holds for $\overline{m}C$; by the same token, since $m = m^2$, for every $a \in m$ there exist $b, c \in m$ such that $a = bc$, whence $a^p = b^p c^p$, which shows that $m_\pi = m_{\pi}^2$. Hence, $(\tilde{C}, m_\pi)$ is a basic setup; moreover, we have already remarked that $m = m_\pi A_0$, hence the inclusion $\tilde{C} \to A_0$ is a morphism of basic setups $(\tilde{C}, m_\pi) \to (A_0, m)$.

Notice then that the $\overline{C}$-module $A_0/\overline{C}$ is the limit of the inverse system

$$(M_n := A_0/(b^a A_0 + C) \mid n \in \mathbb{N}).$$

Hence, $m \subset \overline{C}$ if and only if the $(\overline{C}, m_\pi)^a$-module $(A_0/\overline{C})^a$ vanishes, if and only if $M_n^a = 0$ for every $n \in \mathbb{N}$. Now, for given $n \in \mathbb{N}$, consider the $b^a$-adic filtration on $M_n$, and let $\text{gr}_a M_n$ be the associated graded $\overline{C}$-module; clearly $\text{gr}_a M_n$ is a quotient of $M_p$, for every $i \in \mathbb{N}$. Hence, $m \subset \overline{C}$ if and only if $M_n^p = 0$; the latter in turns holds if and only if $\text{Coker} M_n^p = 0$. This already shows that (a) $\Rightarrow$ (b) $\Rightarrow$ (c). Concretely, if (c) holds, in order to deduce (a), it suffices to check that $\text{Ker} \overline{A}_n^0 = 0$; since $j^a$ is an isomorphism, the latter holds by claim 16.9.30.

(ii) Notice first that since $b \cdot 1_{A_0}$ is an injective map, the same holds for $(b \cdot 1_{A_0})^a = b \cdot 1_{A_0^n}$, since the functor $(-)^a$ commutes with limits. Thus, $A_0^n$ is naturally a subring of $A_0^n[b^{-1}]$. Now, let $x \in A_0^n[b^{-1}]$ be integral over $A_0^n$, hence there exist $n, k \in \mathbb{N}$ and $y, a_1, \ldots, a_k \in A_0^n$ such that $x = y/b^n$ and

$$(y/b^n)^k + a_1 \cdot (y/b^n)^{k-1} + \cdots + a_k = 0.$$  

Recall that $A_0^n = \text{Hom}_{A_0}(\tilde{m}, A_0)$, with $\tilde{m} := m \otimes_{A_0} m$. Then we get $(y(t)/b^n)^k + a_1(t) \cdot (y(t)/b^n)^{k-1} + \cdots + a_k(t) = 0$ for every $t \in \tilde{m}$, and if $A_0$ is integrally closed in $A$, it follows that $y(t)/b^n \in A_0$ for every such $t$, i.e. $x \in A_0^n$. One shows likewise that if $A_0$ is $p$-integrally closed in $A$, then $A_0^n$ is $p$-integrally closed in $A_0^n[b^{-1}]$.

(iii) By assumption, $b \cdot 1_{A_0}$ is an injective map, so the same holds for $b \cdot 1_{A_0^n}$, because the functor $(-)^a$ commutes with limits. This shows that $A_0^n$ has no $b$-torsion; next, we need to check that $A_0^n$ is $b$-adically complete and separated. This follows from the more general:

**Claim 16.9.31.** Let $(V, m_\pi)$ be a basic setup, $A$ a $V$-algebra, $I \subset A$ an ideal of finite type, $M$ an $A$-module whose $I$-adic topology is complete and separated. Then the same holds for the $I$-adic topology of $M^a$.

**Proof of the claim.** Both functors $(-)^a$ and $(-)^a$ commute with limits, since they are right adjoints, hence $M^a$ is the limit of the inverse system $((M/I^n M)^a \mid n \in \mathbb{N})$. For every $n \in \mathbb{N}$, let $M_n$ be the image of the natural map $\pi_n : M_n^a \to (M/I^n M)^a$; it follows that $M^a$ is also the limit of the induced inverse system $(M_n \mid n \in \mathbb{N})$, and therefore $M^a$ is complete and separated for the linear topology that admits the fundamental system of open submodules $(\text{Ker} \pi_n = (I^n M)^a \mid n \in \mathbb{N})$ (corollary 8.2.16(i)). Since $I^n M^a \subset (I^n M)^a$ for every $n \in \mathbb{N}$, the claim now follows from lemma 8.3.12.

It remains to check that the Frobenius endomorphism of $R := A_0^n$ induces an isomorphism $(R/bR)^a \xrightarrow{\sim} (R/b^a R)^a$; the latter is clear, since the same holds by assumption for the Frobenius endomorphism of $A_0$, and the natural map $A_0 \to A_0^n$ is an almost isomorphism.

(iv) Under the stated assumptions, $j$ induces an isomorphism $A_0 \xrightarrow{\sim} (A_0)^a \xrightarrow{\sim} (A_1)^a$, by (i), and on the other hand, $(A_1)^a$ is $p$-integrally closed in $A_0^n[b^{-1}] = A$, by (ii), hence $A_0$ is $p$-integrally closed in $A$, i.e. $A_0 = A_1$. □
16.9.32. Let $A$ be a perfectoid Tate ring, $A_0 \subset A$ a perfectoid subring of definition, and $b \in A_0^{\circ} \cap A^\times$, so that the topology of $A_0$ is $b$-adic. Let also $g_\bullet := (g_n \mid n \in \mathbb{N}) \in \mathbf{E}_0 := \mathbf{E}(A_0)$, and set $g := g_0 = \pi_{A_0}(g_\bullet)$. Hence, $g^*$ is well defined in $A_0$ for every $\gamma \in \mathbb{N}[1/p]$, and set
\[ m := \bigcup_{n \in \mathbb{N}} g_n A_0 \quad A'_0 := \text{Im}(A_0 \to A_0[1/g]) \quad \text{and} \quad A_1 := \{ a \in A_0[1/g] \mid m \cdot a \subset A'_0 \}. \]

Clearly $(A_0, m)$ is a basic setup fulfilling the conditions of (16.9.26).

**Lemma 16.9.33.** With the notation of (16.9.32), let $A'_0$ be the $(A_0, m)$-algebra associated with $A_0$. Then the natural map $A_0 \to A_1$ factors through the unit of adjunction $A_0 \to A_0^m$, and an isomorphism of $A_0$-algebras $A'_0 \sim A_1$.

**Proof.** We claim that the induced surjection $\pi : A_0 \to A'_0$ induces an isomorphism of $(A_0, m)$-algebras $\pi^* : A'_0 \sim A_0^m$. Indeed, if $a \in \text{Ker} \pi$, there exists $n \in \mathbb{N}$ such that $g^n a = 0$ in $A_0$; then $(g^{n/p^k} a)^p = 0$ in $A_0$, and consequently $g^n a = 0$ in $A_0$ for every $k \in \mathbb{N}$, due to corollary 16.3.61(i), whence the contention. Since the natural map $A_0 \to A_1$ factors through $\pi$ and the inclusion $i : A'_0 \to A_1$, and since $\pi^*$ is an isomorphism we are reduced to checking that $i$ factors through the unit of adjunction $A'_0 \to A'^m_0$ and an isomorphism $A'^m_0 \sim A_1$.

Next, we claim that the surjection $m \to m A'_0$ is bijective. Indeed, say that $x \in m$ and $\pi(x) = 0$; we may write $x = g^\gamma y$ for some $\gamma \in \mathbb{N}[1/p] \setminus \{0\}$, and then clearly $\pi(y) = 0$. But by the foregoing, it follows that $g^\gamma y = 0$, whence the contention.

Set $\bar{m} := m \otimes_{A_0} m$; by the foregoing, the isomorphism $\pi^*$ induces identifications:
\[ A'^m_0 = \text{Hom}_{A_0}(\bar{m}, A_0) \sim A^m_0 = \text{Hom}_{A_0}(\bar{m}, A'_0) = \text{Hom}_{A'_0}(m A'_0 \otimes_{A'_0} m, A'_0). \]

Notice that the multiplication map $m A'_0 \otimes_{A'_0} m A'_0 \to m A'_0$ is the colimit of the system of isomorphisms $(g^\gamma A'_0 \otimes_{A'_0} g^\gamma A'_0) \sim g^{2\gamma} A'_0 \mid \gamma \in \mathbb{N}[1/p] \setminus \{0\}$, and it is therefore an isomorphism. So, finally, we get a natural identification
\[ A'^m_0 \sim \text{Hom}_{A'_0}(m A'_0, A'_0) = A_1 \]
from which the lemma follows easily: details left to the reader. \(\square\)

The following result generalizes the “perfectoid Abhyankar’s lemma” of [6].

**Theorem 16.9.34.** In the situation of (16.9.32), let $B$ be a finite étale $A_0[1/g]$-algebra, $B_1$ the integral closure of $A_1$ in $B$, and endow $A_1$ and $B_1$ with their $b$-adic topologies. For the almost structure given by $(A_0, m)$, we have:

(i) The basic setup $(B_1, m B_1)$ is almost perfectoid, and $B_1$ is $p$-integrally closed in $B_1[1/b]$.
(ii) $(B_1/b^n B_1)^a$ is an étale $(A_0/b^n A_0)^a$-algebra of finite rank, for every $n \in \mathbb{N}$.
(iii) $B_1[b^n B_1]^a$ is a faithfully flat $(A_0/b^n A_0)^a$-algebra, for every $n \in \mathbb{N}$.
(iv) $A_1$ is complete and separated, and is integrally closed in $A_0[1/g]$.
(v) The unit of adjunction $B_1 \to B_1^a$ is an isomorphism.

**Proof.** Arguing as in (16.9.7), we may assume that $p A_0 \subset b^n A_0$, and $b = \pi_{A_0}(b_\bullet)$ for some $b_\bullet \in \mathbf{E}(A_0)$, so that $b^\gamma$ is well defined in $A$ for every $\gamma \in \mathbb{Z}[1/p]$. We let $I := A_0 b + A_0 g$, and $U := \text{Spec} A_0 \setminus \text{Spec} A_1 / I$; consider the quasi-affinoid ring $A_0 := (A_0, A_0, U)$, and the rational subsets of $X := \text{Spa} A_0$
\[ R_n := R_{A_0} \left( \frac{b^n}{g} \right) \cap X \quad R'_n := R_{A_0} \left( \frac{g}{b^n} \right) \cap X \quad \text{for every } n \in \mathbb{N} \]
(definition 15.4.14(iv)). Set $A_n := \theta_{X_{A_0}}^+(R_n)$ and $A'_n := \theta_{X_{A_0}}^+(R'_n)$ for every $n \in \mathbb{N}$; since $R_n \subset R_{n+1}$ for every $n \in \mathbb{N}$, we deduce a well defined inverse system of $A_0$-algebras $(A_n \mid n \in \mathbb{N})$.  

Claim 16.9.35. (i) The natural map $A_0 \to \mathcal{O}_X^{\pm}(X)$ induces an isomorphism $A_0^a \sim \mathcal{O}_X^{\pm}(X)^a$ of $(A_0, m)^a$-algebras.

(ii) For every $i \in \mathbb{N}$, the following holds:

(a) The induced inverse system $(A_n/b^nA_n | n \in \mathbb{N})$ is almost essentially constant, relative to the basic setup $(A_0, m)$ (see definition [14.2.11]iii).

(b) The natural cone $(\rho_n : A_0 \to A_n | n \in \mathbb{N})$ induces a universal cone $((A_0/b^iA_0)^a \to (A_n/b^nA_n)^a | n \in \mathbb{N})$ in the category of $(A_0, m)^a$-algebras.

Proof of the claim. (i): By construction, $\mathcal{O}_X^{\pm}(X)$ is the integral closure of the image of $A_0$ in $A_U := \mathcal{O}_U(U)$. On the other hand, $A_0^a$ is integrally closed in $A_U$ (claim 16.8.20[ii]), and recall that $A_0^a$ is integrally closed in $A_U$ (remark 8.3.10(iv)). It follows that the unit of adjunction $\eta : A_0 \to A_0^a$ factors through the inclusion map $\mathcal{O}_X^{\pm}(X) \to A_0^a$. Since $\eta^a$ is an isomorphism, the assertion follows.

(ii): In light of (i) and theorem 16.7.41, the following sequence of $(A_0, m)^a$-modules is short exact for every $n \in \mathbb{N}$:

$$0 \to A_0^a \to A_n^a \to (R_n \cap R'_n)^a \to 0.$$

Moreover, clearly the image of $b$ is a regular element in $\mathcal{O}_X^+(R_n \cap R'_n)$; by the snake lemma, we easily deduce, for every $n, i \in \mathbb{N}$, a short exact sequence of $(A_0, m)^a$-modules

$$0 \to A_0^a/b^iA_0^a \to A_0/b^iA_0 \otimes_{A_0} (A_n \otimes A_n)^a \to A_0/b^iA_0 \otimes_{A_0} (R_n \cap R'_n)^a \to 0.$$

Let us show that for every $\gamma \in \mathbb{N}[1/p] \setminus \{0\}$, every $n \in \mathbb{N}$ with $n\gamma \geq i$ and every $a \in A_0$ with $\rho_n(a) \in b^nA_n$, we have $g^{2\gamma}a \in b^iA_0$. Indeed, let $\overline{a} \in A_0/b^iA_0$ be the image of $a$; then $r_n(\overline{a}) = (0, \overline{\pi})$ for some $\overline{\pi} \in A_n$, and we notice that $g^{r_n(\overline{a})} = b^{n\pi} \cdot (g/b)^{\gamma} \cdot \pi$, whence $g^{\gamma} \cdot \pi = 0$, since $(g/b)^\gamma \in A_n$. It follows that $r_n(g^{\gamma} \cdot \overline{a}) = 0$, whence $g^{2\gamma} \cdot \overline{a} = 0$, as required. Lastly, let us check that for every $\gamma \in \mathbb{N}[1/p] \setminus \{0\}$, every $n \in \mathbb{N}$ with $n\gamma \geq i$ and every $\overline{\pi} \in A_n/b^nA_n$ there exists $\overline{a} \in A_0/b^iA_0$ with $\rho_n(\overline{a}) = g^{2\gamma} \cdot \overline{\pi}$. To this aim, set $\overline{\pi} := s_n(\overline{\pi}, 0)$; again, we notice that $g^{r_n(\overline{\pi})} = b^{n\pi} \cdot (g/b)^{\gamma} \cdot \overline{\pi} = 0$, so that $(g^2, 0) \in \text{Ker} s_n = \text{Im} r_n$, whence the contention. This completes the proof of (ii.a). Assertion (ii.b) follows from the proof of (ii.a) and lemma [14.2.14](iii).

Recall that $\mathcal{O}_X^+(R_n) = A_n[1/g]$, and set $B_n := A_n[1/g] \otimes_{A_0} B$ for every $n \in \mathbb{N}$; recall as well that $A_n$ is perfectoid for its $b$-adic topology (proposition 16.7.25[iii] and theorem 16.5.13[iii]). Since the functor $(-)^a$ commutes with limits, from claim 16.9.35 we deduce that also the cone $\rho_n | n \in \mathbb{N}$ is universal, i.e. we have an isomorphism of $(A_0, m)^a$-algebras:

$$A_0^a \sim \lim_{\longleftarrow} \lim_{n \in \mathbb{N}} A_n^a/b^nA_n^a \sim \lim_{\longleftarrow} \lim_{n \in \mathbb{N}} A_n^a.$$

Claim 16.9.37. $m_A$ is an open radical ideal of $A_n$, for every $n \in \mathbb{N}$.

Proof of the claim. Clearly $m_A$ is an open ideal of $A_n$, since $(b^n/g)^\gamma \in A_n$ for every $\gamma \in \mathbb{N}[1/p]$. Moreover, set $J := \bigcup_{\gamma \in \mathbb{N}[1/p]\setminus\{0\}} b^nA_n$; by corollary 16.3.69, the quotient $A_n/J$ is a perfect $\mathbb{F}_p$-algebra; it follows easily that $m/J$ is a radical ideal of $A_n/J$, whence the claim.

Say that $B$ is a projective $A_0[1/g]$-module of rank $\leq r$; from claim 16.9.37 and theorem 16.8.43, we deduce that for every $n \in \mathbb{N}$ there exists an étale $A_n$-algebra $C_n$ of rank $\leq r$, unique up to unique isomorphism, with an isomorphism of $A_n[1/g]$-algebras $C_n[1/g] \sim B_n$. From the uniqueness property of $C_n$, there follows a unique isomorphism of $A_n^a$-algebras:

$$(16.9.38) \quad A_0^a \otimes_{A_0} C_{n+1} \sim C_n$$

for every $n \in \mathbb{N}$.

Denote by $D$ (resp. by $E$) the inverse limit of the resulting system $(C_n | n \in \mathbb{N})$ of $A_0^a$-algebras (resp. $(B_n | n \in \mathbb{N})$ of $A_0$-algebras), and for every $i \in \mathbb{N}$ let as well $D_i$ (resp. $E_i$) be the limit of the induced system $(C_n/b^iC_n | n \in \mathbb{N})$ of $A_0^a/b^iA_0$-algebras. By proposition [14.2.32](ii,iii),
(C_n/b^n C_n \mid n \in \mathbb{N}) is almost essentially constant, and the projection \(D_i \to C_n/b^n C_n\) induces an isomorphism of \(A_0^n/b^n A_0^n\)-algebras:

\[(16.9.39)\quad A^n_0 \otimes_{A^n_0} D_i \xrightarrow{\sim} C_n/b^n C_n \quad \text{for every } n \in \mathbb{N}.
\]

Notice that \(b\) and \(g\) are regular elements of \(A_n\), and then they are also regular elements of \(C_{n^*}\), since \(C_n\) is a flat \(A^n_0\)-algebra; in view of the induced isomorphism

\[(16.9.40)\quad D_* \xrightarrow{\sim} \lim_{n \in \mathbb{N}} C_{n^*}
\]

(proposition \[1.3.25\] iii) it follows easily that \(b\) and \(g\) are regular elements of \(D_*\).

**Claim 16.9.41.** (i) For every \(n \in \mathbb{N}\), the ring \(C_{n^*}\) is perfectoid for its \(b\)-adic topology.

(ii) \(D_*\) is \(p\)-integrally closed in \(D_*[1/b]\) and is integrally closed in \(D_*[1/g]\).

(iii) The \(A_0^n/b^n A_0^n\)-algebra \(D_i\) is étale rank \(\leq r\) for every \(i \in \mathbb{N}\).

(iv) \(b\) is a faithfully flat \(A_0[1/g]\)-algebra, then \(D_i\) is a faithfully flat \(A_0^n/b^n A_0^n\)-algebra for every \(i \in \mathbb{N}\).

(v) \(B\) and \(D_*\) are integrally closed in \(E\).

(vi) The basic setup \((D_*, mD_*)\) is almost perfectoid for the \(b\)-adic topology of \(D_*\), and the projection \(D \to D_i\) factors through an isomorphism \(D/b^n D \xrightarrow{\sim} D_i\) for every \(i \in \mathbb{N}\).

**Proof of the claim.** (i) follows from proposition \[16.8.29\] and claim \[16.9.37\], since we have already recalled that \(A_n\) is perfectoid for its \(b\)-adic topology. Together with corollary \[16.3.73\] and lemma \[9.8.26\] we deduce that \(C_{n^*}\) is \(p\)-integrally closed in \(C_{n^*}[1/b]\), for every \(n \in \mathbb{N}\).

Then lemma \[9.8.26\] iii.a) and the isomorphism \[16.9.40\] imply that \(D_*\) is \(p\)-integrally closed in the limit \(L\) of the system \((C_{n^*}[1/b] \mid n \in \mathbb{N})\). However, the induced map \(D_* \to L\) factors through an injective map \(D_*[1/b] \to L\), so \(D_*\) is also \(p\)-integrally closed in \(D_*[1/b]\).

Similarly, \(C_{n^*}\) is integrally closed in \(C_{n^*}[1/g] = B_n\) for every \(n \in \mathbb{N}\), due to claim \[16.8.20\] ii); it follows easily that \(D_*\) is integrally closed in \(E\). But the induced map \(D_* \to E\) factors through an injective map \(D_*[1/g] \to E\), so \(D_*\) is also integrally closed in \(D_*[1/g]\).

(iii) follows from theorem \[14.2.39\] iii.iv).

(iv): If \(B\) is a faithfully flat \(A_0[1/g]\)-algebra, \(C_n\) is a faithfully flat \(A^n_0\)-algebra for every \(n \in \mathbb{N}\) (theorem \[16.8.43\] ii); then the assertion follows from theorem \[14.2.39\] ii).

(v): We have already observed that \(D_*\) is integrally closed in \(E\). Next, by construction, \(B_n = B \otimes_{A_0[1/g]} A_0[1/g]\) for every \(n \in \mathbb{N}\). Since \(B\) is a projective \(A_0[1/g]\)-module of finite rank, there follows a natural identification:

\[E \xrightarrow{\sim} B \otimes_{A_0[1/g]} \lim_{n \in \mathbb{N}} A_0[1/g].\]

Since \(B\) is an étale \(A_0[1/g]\)-algebra, by proposition \[14.3.25\] we are then reduced to showing that \(A_0[1/g]\) is integrally closed in the limit \(L\) of the system of \(A_0\)-algebras \((A_0[1/g] \mid n \in \mathbb{N})\). However, invoking again claim \[16.8.20\] ii) we see that \(A^n_0\) is integrally closed in \(A_0[1/g]\) for every \(n \in \mathbb{N}\), hence the limit \(L^*\) of the system \((A^n_0 \mid n \in \mathbb{N})\) is integrally closed in \(L\), and therefore \(L[1/g]\) is integrally closed in \(L\). But in view of \[16.9.36\], we have a natural identification of \(A_0\)-algebras: \(A_0[1/g] \xrightarrow{\sim} A_0^n[1/g] \xrightarrow{\sim} L[1/g]\), whence the assertion.

(vi): Since \(C_n\) is the limit of the inverse system \((C_n/b^n C_n \mid n \in \mathbb{N})\) for every \(n \in \mathbb{N}\), we obtain a natural isomorphism of \(A^n_0\)-algebras:

\[D_* \xrightarrow{\sim} \lim_{i \in \mathbb{N}} D_i.
\]

On the other hand, in view of \[16.9.39\] we have a natural isomorphism of \(A_0^n\)-algebras

\[(D_{i+1} \otimes_{A_0^n} A_0^n/b_i A_0^n) \otimes_{A_0^n} A_0^n \xrightarrow{\sim} C_n/b_i C_n \quad \text{for every } n, i \in \mathbb{N}.
\]
whence, again by theorem [14.2.39(i)], an induced isomorphism of $A_0$-algebras:

\[(16.9.42)\quad D_{i+1} \otimes_{A_0} A_0^n/b^iA_0^n \sim\sim D_i \quad \text{for every } i \in \mathbb{N}.\]

For every $i \in \mathbb{N}$, let $\pi_i : D \to D_i$ be the projection; notice that $I := \ker \pi_1 = bD + \ker \pi_{i+1}$ for every $i \in \mathbb{N}$, in light of the isomorphism $D_{i+1}/bD_{i+1} \sim\sim D_i$ deduced from (16.9.42). By [59, Lemma 5.3.5(i)], it follows that $I = \bigcap_{i \in \mathbb{N}} (bD + T^{i+1}) = bD$ (where $T$ denotes the closure of $J$, for every ideal $J \subset D$ : see [59, Def.5.3.1(iii)]). By [59, Lemma 5.3.8(iii)] we deduce that $I = bD$, and more generally $b^iD = \ker \pi_i$ for every $i \in \mathbb{N}$. On the other hand, $\pi_i$ is an epimorphism for every $i \in \mathbb{N}$, by lemma [14.2.24(i)], so it induces an isomorphism $D/b^iD \sim\sim D_i$, for every $i \in \mathbb{N}$. Hence, the natural morphism $D \to \lim_{i \in \mathbb{N}} D/b^iD$ is an isomorphism of $A_0$-algebras, so we have an induced isomorphism of $A_1$-algebras $D_* \sim\sim \lim_{i \in \mathbb{N}} (D/b^iD)_*$ (lemma [16.9.33]). As we have already noticed, $b$ is regular in $D_*$, so for every $i \in \mathbb{N}$ we get a short exact sequence of $A_0$-modules $0 \to D \to b^iD \to D/b^iD \to 0$ and since the functor $(\_)_*$ is left exact, we deduce an injective $A_1$-linear map

\[D_*/b^iD_* \to (D/b^iD)_* \quad \text{for every } i \in \mathbb{N}\]

from which it follows easily that also the induced map $D_* \to \lim_{i \in \mathbb{N}} D_*/b^iD_*$ is an isomorphism, hence $D_*$ is $b$-adically complete and separated. In order to show that $(D_*, m_{D_*})$ is almost perfectoid, it remains only to check that the Frobenius endomorphism of $D_*/pD_*$ induces an isomorphism $D/bD \sim\sim (D/b^iD)_*(\Phi)$ of $A_0^n/bA_0^n$-algebras (where $\Phi$ denotes the Frobenius endomorphism of $A_0/pA_0$). But we have already seen that $D/bD$ is the inverse limit of the system $(C_n/b^nC_n \mid n \in \mathbb{N})$, for every $i \in \mathbb{N}$, hence we are reduced to checking that the Frobenius endomorphism of $C_{ns}/pC_{ns}$ induces an isomorphism $C_n/b^nC_n \sim\sim (C_n/b^nC_n)_*(\Phi)$ of $A_0^n/bA_0^n$-algebras, for every $n \in \mathbb{N}$. The latter is clear, since we know already that $C_{ns}$ is perfectoid (corollary [16.3.3]).

Next, recall that for every $n \in \mathbb{N}$ we have $A_0$-algebras $A_{n,0}, \ldots, A_{n,r}$, and an isomorphism of $A_0$-algebras $A_n^a \sim\sim A_{n,0} \times \cdots \times A_{n,r}$ such that $C_n := A_{n,k} \otimes A_0^n$ is an $A_{n,k}$-module of constant rank $k$, for every $k = 0, \ldots, r$ ([59, Prop.4.3.27]). For every $n \in \mathbb{N}$ and $k = 0, \ldots, r$ consider the map of sets:

\[\chi^{(n,k)} : C_{n,k} \to A_{n,k}^a[X] \quad c \mapsto \chi_c(X)\]

which associates with every $c \in C_{n,k}$, the characteristic polynomial $\chi_c(X)$ of the $A_{n,k}$-linear endomorphism $c \cdot 1_{C_{n,k}}$ of $C_{n,k}$ (see [59, §4.4.29]); by [59, Prop.4.4.30] we have $\chi_c(c) = 0$ for every such $c$. By virtue of (16.9.38), we see that the restriction map $A_{n+1} \to A_n$ induces isomorphisms of $A_0$-algebras

\[A_n^a \otimes A_{n+1}^a \sim\sim A_{n,k} \quad \text{for every } k = 0, \ldots, r\]

and from the compatibility of traces with ring extensions ([59, Prop.4.1.8(ii)]), we deduce for every $n \in \mathbb{N}$ and $k = 0, \ldots, r$ a commutative diagram:

\[
\begin{array}{ccc}
C_{n+1,k} & \xrightarrow{\chi^{(n+1,k)}} & A_{n+1,k}^a[X] \\
\downarrow & & \downarrow \\
C_{n,k} & \xrightarrow{\chi^{(n,k)}} & A_{n,k}^a[X]
\end{array}
\]

whose vertical arrows are induced by the induced projection $A_{n+1,k} \to A_{n,k}$. For every $k = 0, \ldots, r$, let $A^{(k)}$ be the limit of the induced inverse system of $A_0$-algebras $(A_{n,k} \mid n \in \mathbb{N})$, and set $D^{(k)} := A^{(k)} \otimes A_0 D$; in view of (16.9.36), there follows an isomorphism of $A_0$-algebras $D \sim\sim D^{(0)} \times \cdots \times D^{(r)}$. Notice as well that $\chi_c(X)$ is a monic polynomial of degree $k$, for every
$n \in \mathbb{N}$, every $k = 0, \ldots, r$ and every $c \in C_{n,k}$; in light of (16.9.40), it follows easily that the limit of the system of maps $\chi^{(n,k)}: n \in \mathbb{N}$ is a well defined map of sets

$$\chi^{(k)}: D_s^{(k)} \rightarrow A_s^{(k)}[X] \quad d \mapsto \chi_d(X) \quad \text{for every} \ k = 0, \ldots, r.$$ 

Moreover, $\chi_d(X)$ is a monic polynomial with $\chi_d(d) = 0$ for every $k = 0, \ldots, r$ and every $d \in D_s^{(k)}$. Taking into account lemma [16.9.33], it follows that $D_s$ is an integral $A_1$-algebra. Since both $D_s$ and $B$ are integrally closed subrings of $E$ (claim [16.9.41]), and since $A_1 \subset A_0[1/g]$, we deduce that $D_s \subset B$, and hence $D_s$ is also the integral closure of $A_1$ in $B$, i.e. $D_s = B_1$. Then assertions (i), (ii) and (iii) of the theorem follow from claim [16.9.41].

(iv): By construction, $A_1$ is an open bounded subring of $A$, hence it is complete and separated for the topology induced by $A$, which agrees with the $b$-adic topology (proposition [8.3.18], i, ii)). In order to show that $A_1$ is integrally closed in $A_0[1/g]$, consider the case where $B = A_0[1/g]$; then $C_n = A_{0,n}$ for every $n \in \mathbb{N}$, so that $B_1 = D_s = A_{0,s} = A_1$, whence the assertion. 

**Remark 16.9.43.** (i) In the situation of theorem [16.9.34] let $g'_0 := (g'_0(n) \mid n \in \mathbb{N}) \in E_0$ be another element, and $g' := g'_0 = \overline{\pi}_B(g'_0)$. Let also $A'_0 := \text{Im}(A_0 \rightarrow A_0[1/(gg')])$ and set

$$m' := \bigcup_{n \in \mathbb{N}} g'_0 A_0 \quad m'' := m \cdot m' \quad A_2 := \{a \in A_0[1/(gg')] \mid m'' \cdot a \in A'_0\}.$$ 

Clearly $(A_0, m')$ and $(A_0, m'')$ are two basic setups; for every $A_0$-module $M$, let $(M, m') \in (A_0, m')^a$-$\text{Mod}$ (resp. $(M, m')^a \in (A_0, m')^a$-$\text{Mod}$, resp. $(M, m'')^a \in (A_0, m'')^a$-$\text{Mod}$) be the image of $M$. We may apply theorem [16.9.34] with $(A_0, m)$ and $B$ replaced respectively by $(A_0, m')$, and $B'[1/g'] := \text{hence, let } B_2 \text{ be the integral closure of } A_2 \text{ in } B'[1/g']$; then $B_2 = (B_2, m'')^a$ is an almost perfectoid $A_0$-algebra relative to $(A_0, m')$, and $(B_2/b^nB_2, m'')^a$ is an étale $(A_0/b^nA_0, m'')^a$-algebra of finite rank, for every $n \in \mathbb{N}$. The localizations $A_0[1/g] \rightarrow A_0[1/(gg')]$ and $B \rightarrow B'[1/g']$ clearly restrict to ring homomorphisms $A_1 \rightarrow A_2$ and $B_1 \rightarrow B_2$.

Now, $(A_0, m'')^a$ is integrally closed in $(A_0[1/(gg')], m'')^a$ (theorem [16.9.34] v) and lemma [16.9.33], hence the same holds for $(A_0[1/g], m'')^a$; since $B$ is a finite étale $A_0[1/g]$-algebra, it follows that $(B, m'')^a$ is integrally closed in $(B[1/g'], m''^a)$ (proposition [14.3.25]). Taking into account theorem [16.9.34] v, remark [14.2.7] ii) and [59] Lemma 8.2.28 we deduce :

$$B_2 = (B_2, m'')^a = \text{i.c.}.((A_0, m'')^a, (B[1/g'], m'')^a)_s = \text{i.c.}.((A_0, m')^a, (B[1/g'], m')^a)_s = (A_1, B, m'_s)$$

$$= (A_1, B, m''^a)_s = (B_1, m''^a)_s = (B_1, m')^a.$$ 

(ii) As a special case of (i), we may take $g'_0 := b_0$ such that $b := b_0 \in A^\infty \cap A_0^\infty$. Then, endow $B_1$ with its $b$-adic topology, so that $B_1$ is a subring of definition of the Tate ring $B_1[1/b]$, and by theorem [16.9.34] i) it is $p$-integrally closed in $B_1[1/b]$, hence $B_1[1/b]^\infty \subset B_1$ (example 16.9.4). It follows easily that $(B_1[1/b], m')^a = (B_1, m')^a$, so we have inclusions of rings :

$$B_1 \subset B^\circ \subset (B_1, m')^a \subset (B_1[1/b], m')^a \subset B_1[1/b].$$ 

On the other hand, it is easily seen that $B_1, m')^a \subset B_1[1/b]^\circ$, so $B_2 = (B_1, m')^a = B_1[1/b]^\circ$.

(iii) In the situation of theorem [16.9.34], suppose that $A$ is an $\mathbb{F}_p$-algebra; then $A_0 = E_0$ is a perfect $\mathbb{F}_p$-algebra, and it follows easily that the same holds for $A_1$. Then, set $X := \text{Spec} A_1$
and \( Z := \text{Spec} A_1/gA_1 \); by theorem \[16.8.2\] the pair \((X, Z)\) is normal and almost pure, hence \( B^*_1 \) is an étale \( A^n_1 \)-algebra of finite rank (proposition \[14.4.8\]).

(iv) If \( A \) is not an \( \mathbb{F}_p \)-algebra, we know neither whether \( A_1 \) is perfectoid, nor whether \( B^*_1 \) is an étale \( A^n_1 \)-algebra. However, by theorem \[16.9.34\]ii) and lemma \[14.3.15\]ii), for every \( n \in \mathbb{N} \) we have a well defined map

\[
\chi_{B_1/b^nB_1} : (B_1/b^nB_1)^{\infty} \to (A_0/b^nA_0)^{\infty}[T] \quad b \mapsto \det((1 + bT) \cdot 1_{B_1/b^nB_1})
\]

and clearly the inverse system of maps \( (\chi_{B_1/b^nB_1} \mid n \in \mathbb{N}) \) amounts to a well defined map

\[
\chi_{B_1} : B_1 \to A_1[T].
\]

By the same token, we may associate to the finite étale \( A_0[1/g] \)-algebra \( B \) the map

\[
\chi_B : B \to A_0[1/g, T] \quad b \mapsto \det((1 + bT) \cdot 1_B)
\]

and we claim that

\[
\chi_B(b) = \chi_{B_1}(b) \quad \text{for every } b \in B_1.
\]

For the proof, define the inverse system of \( A_0 \)-algebras \( A_{\bullet} := (A_n \mid n \in \mathbb{N}) \), and for every \( n \in \mathbb{N} \) the étale \( A^n_0 \)-algebra \( C_n \) of rank \( \leq r \), as in the proof of theorem \[16.9.34\] recall that \( A_1 \) (resp. \( B_1 \)) is the limit of \( A_{\bullet} \) (resp. of \( (C_{n^s} \mid n \in \mathbb{N}) \)). It follows easily that \( \chi_{B_1} \) is also the inverse limit of the system of similar maps \( (\chi_{C_n} \mid n \in \mathbb{N}) \). On the other hand, \( A_0[1/g] \) is integrally closed in the limit \( L \) of the induced inverse system \( (A_n[1/g] \mid n \in \mathbb{N}) \), and \( B \) is the integral closure of \( A_0[1/g] \) in the inverse system \( E \) of the induced inverse system \( (C_n[1/g] \mid n \in \mathbb{N}) \); also, the natural map \( E \to B \otimes_{A_0[1/g]} L \) is an isomorphism (see the proof of claim \[16.9.41\]). Thus, both \( \chi_E \) and \( \chi_{B_1} \) are restrictions of the corresponding map \( \chi_E : E \to L \), whence the assertion.

(v) Furthermore, set \( R := B_1 \otimes_{A_1} B_1 \), let \( R^\wedge \) be the \( b \)-adic completion of \( R \), and

\[
e_{B/A_0[1/g]} \in R[1/g] = B \otimes_{A_0[1/g]} B
\]

the diagonal idempotent of the \( A_0[1/g] \)-algebra \( B \); we notice:

**Corollary 16.9.44.** *In the situation of theorem \[16.9.34\] we have:*

(i) The following conditions are equivalent:

(a) \( g^n \cdot e_{B/A_0[1/g]} \in R' := \text{Im}(R \to R[1/g]) \) for every \( \gamma \in \mathbb{N}[1/p] \setminus \{0\} \).

(b) For every \( \gamma \in \mathbb{N}[1/p] \setminus \{0\} \) there exists \( N_{\gamma} \in \mathbb{N} \) such that \( b^{N_{\gamma}} \cdot g^n \cdot e_{B/A_0[1/g]} \in R' \).

(c) \( B^*_1 \) is an étale \( A^n_1 \)-algebra.

(d) \( B^*_1 \) is a weakly unramified \( A^n_1 \)-algebra.

(e) \( B^*_1 \) is an almost finitely generated \( A^n_1 \)-module.

(f) \( B^*_1 \) is an almost finite projective \( A^n_1 \)-module.

(g) \( B^*_1[1/b] \) is a weakly unramified \( A^n_1[1/b] \)-algebra.

(h) \( B^*_1[1/b] \) is an almost finitely generated \( A^n_1[1/b] \)-module.

(ii) There exists \( n \in \mathbb{N} \) such that \( g^n \) annihilates the kernel and cokernel of the completion map \( R \to R^\wedge \). Also, \( \text{Ann}_{R^\wedge}(g)^a = 0 \).

**Proof.** Obviously (c)⇒(a),(d); also (d)⇒(g), (a)⇒(b) and (f)⇒(c)⇒(h).

(a)⇒(c),(f): The assumption implies that \( e_{B/A_0[1/g]} \) lies in the image of the induced map

\[
R^a_+ \to B \otimes_{A_0[1/g]} B.
\]

Then the assertion follows from proposition \[14.3.21\] and theorem \[16.9.34\] (iv)).

(f)⇒(c): We consider the commutative diagram of \( A^n_1 \)-algebras:

\[
\begin{align*}
R^a & \xrightarrow{\mu} \lim_{n \in \mathbb{N}} R^a/b^nR^a \\
B^*_1 & \xrightarrow{\mu^a} \lim_{n \in \mathbb{N}} B^*_1/b^nB^*_1
\end{align*}
\]

\[\text{(16.9.45)}\]
where \( \mu^a \) is the multiplication law, and the right vertical arrow is the inverse limit of the system of multiplication laws \( \left( R^n/b^n R \to B^n_{1}/b^n B^n_{1} \mid n \in \mathbb{N} \right) \). According to theorem \([16.9.34](i)\), \( B_1 \) is \( b \)-adically complete and separated; then by lemma \([14.2.24](iii)\) the morphism \( \varphi \) is an isomorphism. By theorem \([16.9.34](ii)\), for each \( n \in \mathbb{N} \) we have a diagonal idempotent \( e_n \in (R/b^n R)_x \), and it is easily seen that the system \( (e_n \mid n \in \mathbb{N}) \) corresponds, under the isomorphism \( \varphi \), to an idempotent element \( e_{B_1/A_1} \in \hat{B}^\ast_{1} \) such that \( \mu(B_{1}/A_{1}) = 1 \) and \( x \cdot e_{B_{1}/A_{1}} = 0 \) for every \( x \in (Ker \mu)^\ast_{1} \). Then the assertion follows from \([59\), Prop.3.1.4].

\((d) \Rightarrow (a)\): Let \( J := \bigcup_{n \in \mathbb{N}} Ann_R(g^n) \) and \( \hat{R} := R/J \). By construction, \( g \) is a regular element of \( B_1 \), so that \( JB_1 = 0 \), for the \( R \)-algebra structure on \( B_1 \) given by the multiplication map \( \mu : R \to B_1 \). On the other hand, by assumption \( \mu^a \) is a flat morphism of \( A^n_1 \)-algebras; hence \( \mu^a \otimes_R \hat{R} : \hat{R} \to B_1 \) is still flat. Also, the localisation \( R \to R[1/g] \) of \( A^n_1 \)-algebras, and since \( B \) is an étale \( A_0[1/g] \)-algebra, \( B = B[1/g] \) is a projective \( R[1/g] \)-module of finite rank. By \([59\), Prop.2.4.19] it follows that \( B_1 \) is an almost finite \( \hat{R} \)-module, and therefore \( Ker (\mu^a \otimes_R \hat{R}) \) is generated by an idempotent almost element \( d \in \hat{R} \) \((59\), Rem.3.1.8). For every \( \gamma \in \mathbb{N}[1/p] \setminus \{0\} \), we then find \( e_{\gamma} \in R \) whose image in \( \hat{R}/J \) agrees with \( g^{\gamma} \cdot (1 - d) \). It follows easily that the image of \( e_{\gamma} \) in \( R[1/g] \) agrees with \( g^{\gamma} e_{B/A_0}[1/g] \), whence the contention.

\((g) \Rightarrow (b)\): The assumption means that \( \mu^a \otimes_{A_1} A_1[1/b] : R[1/b]^a \to B_1[1/b]^a \) is a flat morphism, hence the same holds for \( \mu^a \otimes_R \hat{R}[1/b] \), and arguing as in the foregoing we find for every \( \gamma \in \mathbb{N}[1/p] \setminus \{0\} \) an integer \( N_\gamma \in \mathbb{N} \) and \( e_{\gamma} \in R \) whose image in \( R[1/(gb)] \) agrees with the image of \( g^{\gamma} b^{N_\gamma} e_{B/A_0}[1/g] \). Notice that, since \( B_1[1/g] = B \) is a flat \( A_1[1/g] \)-algebra, and since \( b \) is regular in \( A_1 \), it follows that \( b \) is regular also in \( R[1/g] \), hence the localization \( R[1/g] \to R[1/(gb)] \) is injective, and we deduce that the image of \( e_{\gamma} \) agrees with \( g^{\gamma} b^{N_\gamma} e_{B/A_0}[1/g] \) already in \( R[1/g] \), as required.

\((b) \Rightarrow (a)\): Define the inverse system of \( A_0 \)-algebras \((A_n \mid n \in \mathbb{N})\) as in the proof of theorem \([16.9.34]\) and for every \( n \in \mathbb{N} \) let \( C_n \) be the unique étale \( A^n_0 \)-algebra up to unique isomorphism, such that \( C_n[1/g] \) is isomorphic to \( A_0[1/g] \otimes_{A_0} B \). By claim \([16.9.35](ii)\), for every \( i \in \mathbb{N} \) the induced inverse system \((A_n/b^n A_n \mid n \in \mathbb{N})\) is almost essentially constant relative to the basic setup \((A_0, m)\). In view of \([16.9.38]\) the same follows for the inverse system \((C_n/b^n C^n_0 \mid n \in \mathbb{N})\), for every \( i \in \mathbb{N} \); but the proof of theorem \([16.9.34]\) also shows that the inverse limit of the latter system is naturally isomorphic to \( B^n/b^n B^n_{1} \), for every \( i \in \mathbb{N} \). Thus, set \( R_n := C_n \otimes_{A^n_0} C_n \) for every \( n \in \mathbb{N} \); we deduce that for every \( i \in \mathbb{N} \) and there exists \( n(i, \gamma) \in \mathbb{N} \) such that \( g^{\gamma} \) annihilates the kernel of the induced morphism

\[
R^n/b^n R^a \to R_{n(i, \gamma)}/b^n R_{n(i, \gamma)}.
\]

Notice also that, since \( g \) is regular in \( A_n \), and \( C_n \) is a flat \( A^n_0 \)-algebra, then \( g \) is regular in \( C_n \), and the localization \( R_n \to R_n[1/g] \) is a monomorphism of \( A^n_0 \)-modules, for every \( n \in \mathbb{N} \). Moreover, the image of \( e_{B/A_0}[1/g] \) in \( R_n[1/g] \) is the diagonal idempotent of the étale \( A_0[1/g] \)-algebra \( C_n[1/g] \), and the latter agrees with the image of the diagonal idempotent \( e_{n} \in R_{nx} \) of the étale \( A^n_0 \)-algebra \( C_n \). Summing up, we conclude that for every \( \gamma \in \mathbb{N}[1/p] \setminus \{0\} \), the image of \( e_{\gamma} \) vanishes in \( R_{n(N_\gamma, \beta)}/b^{N_\gamma} R_{n(N_\gamma, \gamma)} \) and hence \( g^{2\gamma} e_{\gamma} \) vanishes in \( R/b^{N_\gamma} R \), i.e. \( g^{2\gamma} e_{\gamma} = b^{N_\gamma} e_{\gamma} \) for some \( e_{\gamma} \in R \). Since \( b \) is regular in \( R[1/g] \), it follows that the image of \( e_{\gamma} \) in \( R[1/g] \) agrees with \( g^{3\gamma} e_{B/A_0[1/g]} \), as required.

\((h) \Rightarrow (b)\): By assumption, for every \( \gamma \in \mathbb{N}[1/p] \setminus \{0\} \) there exists \( n(\gamma) \in \mathbb{N} \) and an \( A_1 \)-linear map \( f_{\gamma} : A_1^{|n(\gamma)} \to B_1 \) such that

\[
(16.9.46) \quad g^{\gamma} \cdot \text{Coker}(A_1[1/b] \otimes A_1 f_{\gamma}) = 0.
\]
Then, let $E_\gamma$ be the fibre product in the cartesian diagram of $A_1$-modules:

$$\begin{array}{ccc}
E_\gamma & \overset{f'_\gamma}{\longrightarrow} & B_1 \\
\downarrow & & \downarrow g^\gamma 1_{B_1} \\
A_1^{\oplus n(\gamma)} & \overset{f_\gamma}{\longrightarrow} & B_1.
\end{array}$$

By virtue of (16.9.46), the image of $A_1^{1/[b]} \otimes A_1 g^\gamma 1_{B_1}$ lies in the image of $A_1^{1/[b]} \otimes A_1 f_\gamma$; on the other hand, the diagram $A_1^{1/[b]} \otimes A_1 \mathcal{D}_\gamma$ is still cartesian, so the map $A_1^{1/[b]} \otimes A_1 f'_\gamma$ is surjective. Recall that $b$ is regular in both $A_1$ and $B_1$, therefore also in $E_\gamma$; then endow $A_1^{1/[b]}$ (resp. $B_1^{1/[b]}$) with the $f$-adic topology $\mathcal{T}_{A_1}$ (resp. $\mathcal{T}_{B_1}$) such that $A_1$ (resp. $B_1$) is a subring of definition, with ideal of definition $bA_1$ (resp. $bB_1$); since $A_1$ and $B_1$ are $b$-adically complete and separated (theorem 8.3.33), Endow also $A_1^{1/[b]} \otimes A_1 \mathcal{D}_\gamma$ with the product topology $\mathcal{T}_{A_1} \times \cdots \times \mathcal{T}_{A_1}$; it is easily seen that all the maps of $A_1^{1/[b]} \otimes A_1 \mathcal{D}_\gamma$ are continuous for these topologies, hence $A_1^{1/[b]} \otimes A_1 E_\gamma$ is a closed subset of $A_1^{1/[b]} \otimes A_1 (A_1^{\oplus n(\gamma)} \oplus B_1)$, and is therefore complete and separated for the topology induced by the inclusion in this $A_1$-module; moreover, since $A_1^{\oplus n(\gamma)}$ is open in $A_1^{1/[b]} \otimes A_1 \mathcal{D}_\gamma$ and $B_1$ is open in $B_1^{1/[b]}$, we see that $E_\gamma$ is open in $A_1^{1/[b]} \otimes A_1 E_\gamma$. By the Banach open mapping theorem ([80] Lemma 2.4), there exists therefore $N_\gamma \in \mathbb{N}$ such that $b^{N_\gamma} B_1 \subset \text{Im}(f'_\gamma)$. It follows easily that

(16.9.47)

$$g^\gamma b^{N_\gamma} B_1 \subset \text{Im}(f_\gamma).$$

By virtue of lemma 14.2.24(iv), we deduce that

(16.9.48)

$$g^\gamma b^{N_\gamma} \text{Coker } \varphi = 0,$$

where $\varphi$ is as in (16.9.45). On the other hand, since $A_1^{1/[gb]} \otimes A_1 f_\gamma : A_1^{1/[gb]} \otimes A_1 f_\gamma \rightarrow B_1^{1/[b]}$ is surjective, and since $B_1^{1/[b]}$ is a projective $A_1^{1/[gb]}$-module, there exists an $A_1^{1/[gb]}$-linear map $h : B_1^{1/[b]} \rightarrow A_1^{1/[gb]}(\gamma)$ such that $f_\gamma \circ h = 1_{B_1^{1/[b]}}$. Let $\varepsilon_1, \ldots, \varepsilon_n(\gamma)$ be the canonical basis of the free $A_1^{1/[gb]}$-module $A_1^{1/[gb]}(\gamma)$, and pick $k \in \mathbb{N}$ such that $h \circ f_\gamma(k g^\gamma e_1) \subset A_1^{\oplus n(\gamma)}$ for every $i = 1, \ldots, n(\gamma)$. In view of (16.9.47), we deduce an $A_1$-linear map:

$$h' : B_1 \rightarrow A_1^{\oplus n(\gamma)} \quad x \mapsto b^{N_\gamma+k} g^{k+\gamma} h(x)$$

and by construction we have $f_\gamma \circ h' = b^{N_\gamma+k} g^{k+\gamma} 1_{B_1}$. Then lemma 14.2.24(iv) implies that

(16.9.49)

$$b^{N_\gamma+k} g^{k+\gamma} \text{Ker } \varphi = 0.$$

Now, let $e_* := (e_n \mid n \in \mathbb{N}) \in \lim_{n \in \mathbb{N}} (R^n/b^a R^n)_*$ be the compatible system of diagonal idempotents of the étale $(A_0/b^n A_0)^a$-algebras $B^n_1/b^n B_1$, for every $n \in \mathbb{N}$; by (16.9.48) there exists $e' \in R$ such that $\varphi(e') = g^\gamma b^{N_\gamma} e_*$. Then we have

$$\varphi(x \cdot e') = 0 \quad \text{for every } x \in \text{Ker } \mu.$$

Combining with (16.9.49), it follows that $b^{N_\gamma+k} g^{k+\gamma} x \cdot e' = 0$ in $R$, for every $x \in \text{Ker } \mu$. But we have already observed that $b$ is regular in $R[1/g]$, so we easily conclude that the image of $e'$ in $R[1/g]$ agrees with $g^\gamma b^{N_\gamma} e_{B_1/A_0[1/g]}$.

(ii): Pick $n \in \mathbb{N}$ such that $g^{n} e_{B_1/A_0[1/g]}$ lies in the image of the localization $B_1 \otimes A_1 B_1 \rightarrow B \otimes A_0[1/g] B$. Arguing as in the proof of claim 14.3.23 we then find $k \in \mathbb{N}$ and $A_1$-linear maps $B_1 \rightarrow A_1^{\otimes k} \rightarrow B_1$ whose composition is $g^k \cdot 1_{B_1}$. Recall now that $R^\wedge$ is the limit of the inverse system $(B_1 \otimes A_1 B_1/b^i B_1 \mid i \in \mathbb{N})$; then the first assertion follows from lemma 14.2.24(iv).

In order to show the second assertion of (ii), let $C_n$ be the étale $A_n$-algebra of finite rank as in the proof of theorem 16.9.34 for every $n \in \mathbb{N}$. Since $A_n$ is $b$-adically complete and separated, the almost projective $A_n$-module of finite rank $S_n := C_n \otimes_{A_n} C_n$ is $b$-adically complete and
separated as well, for every \( n \in \mathbb{N} \), by [59, Claim 5.3.25], and moreover \( \text{Ann} \, S_n (g) = 0 \), since \( \text{Ann}_{A_n} (g) = 0 \); then we are easily reduced to checking:

**Claim 16.9.50.** \((R^n)^{\circ}\) represents the limit of the inverse system of \( A_0\)-algebras \((S_n \mid n \in \mathbb{N})\).

**Proof of the claim.** It suffices to show that the \( A_0^n / b A_0^n \)-algebra \((B_1 / b B_1 \otimes_{A_1 / b A_1} B_1 / b B_1)^{n}\) represents the limit of the induced inverse system \((C_n / b C_n \otimes_{A_n / b A_n^0} C_n / b C_n^0 \mid n \in \mathbb{N})\), for every \( k \in \mathbb{N} \). However, the proof of theorem [16.9.34] shows that the inverse system \((C_n / b C_n \mid n \in \mathbb{N})\) is almost essentially constant for every \( k \in \mathbb{N} \), and the same holds for the inverse system \((A_0^n / b A_0^n \mid n \in \mathbb{N})\), by claim [16.9.35](ii). Then the assertion follows from proposition [14.2.38].

We conclude with a discussion of some further constructions that we do not need (though, see remark [17.5.16]), but may be useful for other questions, and are related to some recent work of Y. André and others as well.

**16.9.51.** Let \( A \) be a perfectoid Tate ring, \( A_0 \subset A \) a perfectoid subring of definition, \( p \in \mathbb{N} \) a prime integer, and \( b \in A_0^n \cap A^k \) with \( pA_0 \subset b^p A_0 \). We consider the categories:

\[
A_0\text{-cp.Adic} \quad A_0\text{-Tate} \quad A_0\text{-Perf.Adic} \quad A_0\text{-Perf.Tate}
\]

such that:

- the objects of \( A_0\text{-cp.Adic} \) are the adic ring homomorphisms \( A_0 \to B_0 \) of complete separated topological rings, and the morphisms are the maps of \( A_0\)-algebras
- \( A_0\text{-Tate} \) is the full subcategory of \( A_0\text{-cp.Adic} \) whose objects are the \( A_0\)-algebras \( B_0 \) such that the localisation \( B_0 \to B_0[b^{-1}] \) is injective
- \( A_0\text{-Perf.Adic} \) (resp. \( A_0\text{-Perf.Tate} \)) is the full subcategory of \( A_0\text{-cp.Adic} \) (resp. of \( A_0\text{-Tate} \)) whose objects are the perfectoid \( A_0\)-algebras.

Notice that every morphism in these categories is adic. We wish to exhibit right adjoints for the inclusion functors

\[(16.9.52) \quad A_0\text{-Perf.Adic} \to A_0\text{-cp.Adic} \quad A_0\text{-Perf.Tate} \to A_0\text{-Tate}.
\]

Thus, consider any \( B_0 \in \text{Ob} (A_0\text{-cp.Adic}) \), set \( \overline{A_0} := A_0/pA_0 \), \( B_0 := B_0/pB_0 \), and let \( \overline{\beta}_n := (\overline{\beta}_n \mid n \in \mathbb{N}) \in E_0 := E(A_0) \) be any element such that \( \overline{\beta}_0 \in \overline{A_0} \) is the class of \( b \). Endow \( E(B_0) \) with its \( \overline{\beta}_n \)-adic topology \( \mathcal{T}_{E(B_0)} \); let also \( \mathcal{T}_{B_0} \) be the \( b \)-adic topology of \( B_0 \). Then the topology of \( E(B_0) \) is complete, separated, adic, and coarser than \( \mathcal{T}_{E(B_0)} \) (remark [9.4.9](ii)). By lemma [8.3.12] it follows that \( \mathcal{T}_{E(B_0)} \) is complete and separated. Then the \( A_0\)-algebra

\[B_0^n := A_0 \otimes_{W(E_0)} W(\mathcal{E}(B_0)) \to B_0\]

is a perfectoid ring for its \( b \)-adic topology (example [16.3.2](ii)). The structure map \( A_0 \to B_0 \) of \( B_0 \), and the map \( u_{B_0} : W(\mathcal{E}(B_0)) \to B_0 \) induce an adic map

\[
e_{B_0} : B_0^n \to B_0 \quad 1 \otimes (x_n \mid n \in \mathbb{N}) \mapsto \sum_{n \in \mathbb{N}} p^n \cdot \overline{\beta}_n (x_n^{p^{-n}})
\]

and notice that \( e_{B_0} \) is an isomorphism if \( B_0 \) is perfectoid. Next, let \( \beta_n := (\beta_n \mid n \in \mathbb{N}) \in E(A_0) \) be the preimage of \( \overline{\beta}_n \) under the isomorphism \( E(A_0) \cong E_0 \) induced by the projection \( A_0 \to \overline{A_0} \). Hence \( \beta_0 - b \in pA_0 \), so that \( \beta_0/b \in A_0^k \); if \( B_0 \in \text{Ob} (A_0\text{-Tate}) \), then the image of \( b \) is regular in \( B_0 \), so the same holds for the image of \( \beta_0 \), and finally, the image of \( \beta_n \) is a regular element of \( E(B_0) \) (proposition [16.4.17]); by the same token, the image of \( \beta_0 \) in \( B_0^n \) is then regular, and hence the same holds for the image of \( b \). Hence, in this case \( B_0^n \) is an object of \( A_0\text{-Perf.Tate} \). Moreover, every morphism \( g : B_0 \to C_0 \) of \( A_0\text{-Tate} \) induces an adic map of \( A_0\)-algebras

\[g^2 : B_0^n \to C_0^n \quad 1 \otimes (\overline{x}_n \mid n \in \mathbb{N}) \mapsto 1 \otimes (\mathcal{E}(\overline{g})(\overline{x}_n) \mid n \in \mathbb{N})
\]
with $\mathfrak{g} := g \otimes \mathbb{Z}/p\mathbb{Z} : \mathcal{B}_0 \to \mathcal{C}_0$. We have therefore well defined functors

$(-)^b : A_0{\text{-}}\text{cp.Adic} \to A_0{\text{-}}\text{Perf.Adic}$

$(-)^3 : A_0{\text{-}}\text{Tate} \to A_0{\text{-}}\text{Perf.Tate}$.

Now, let $C \in \text{Ob}(A_0{\text{-}}\text{Perf})$; to every adic map $f : C \to \mathcal{B}_0$ let us attach $f^* := \varepsilon_{\mathcal{B}_0} f : C \to \mathcal{B}_0$, and to every adic map $h : C \to \mathcal{B}_0$ let us attach $h^* := h^3 \circ \varepsilon_{\mathcal{C}_0}^{-1} : C \to \mathcal{B}_0^3$. By a simple inspection we get $h^{**} = h$. In order to check that $f^{**} = f$, it suffices to show that $\varepsilon_{\mathcal{B}_0} = \varepsilon_{\mathcal{B}_0}^3$.

Thus, let $\mathfrak{x}_n := (x_n \mid n \in \mathbb{N}) \in W(\mathbb{E}(\mathcal{B}_0^3))$ be any element; via the natural identification $\mathbb{E}(\mathcal{B}_0^3) \xhookrightarrow{\sim} \mathbb{E}(\mathcal{B}_0^3)$, we may view $\mathfrak{x}_n$ as a system $x_{\mathfrak{n}} := (x_{n,k} \mid n, k \in \mathbb{N})$ of elements of $\mathcal{B}_0^3$ such that $x_{n,k+1} = x_{n,k}$ for every $n, k \in \mathbb{N}$; then we have:

$$\varepsilon_{\mathcal{B}_0}^3(1 \otimes x_{\mathfrak{n}}) = \sum_{n \in \mathbb{N}} p^n x_{n,n} \quad \varepsilon_{\mathcal{B}_0}^3(1 \otimes x_{\mathfrak{n}}) = 1 \otimes (\mathbb{E}(\mathcal{B}_0^3)(\mathfrak{x}_n) \mid n \in \mathbb{N}).$$

But we have $\sum_{n \in \mathbb{N}} p^n \cdot \tau(\mathbb{E}(\mathcal{B}_0^3)(\mathfrak{x}_n)p^{-n}) = (\mathbb{E}(\mathcal{B}_0^3)(\mathfrak{x}_n) \mid n \in \mathbb{N})$ in $W(\mathbb{E}(\mathcal{B}_0^3))$, by virtue of (2.3.47), where $\tau$ denotes the Teichmuller representative. Hence, let $\mathfrak{y}_n := (y_k \mid k \in \mathbb{N}) \in \mathbb{E}(\mathcal{B}_0^3)$ be any element, which we identify with a unique element $(y_k \mid k \in \mathbb{N}) \in \mathbb{E}(\mathcal{B}_0^3)$; we come down to showing that $1 \otimes \tau(\mathfrak{y}_n) = y_0 = \tau(\mathfrak{y}_n)$ in $\mathcal{B}_0^3$. But we have $1 \otimes \tau(\mathfrak{y}_n) = u_{\mathcal{B}_0}(\tau(\mathfrak{y}_n))$, so the assertion follows from lemma [16.1.1 (iv)]. This shows that the rule $f \mapsto f^*$ yields the sought adjunctions between [16.9.52] and the functors $(-)^3$.

16.9.53. In the situation of [16.9.51], let also $(A_0, m)$ be a basic setup, such that $m$ is the filtered union of a countable system of principal subideals, and consider as well the categories

$(A_0, m)^a{\text{-}}\text{Perf.Adic} \quad (A_0, m)^a{\text{-}}\text{Perf.Tate}$

with the same objects as $A_0{\text{-}}\text{Perf.Adic}$ (resp. as $A_0{\text{-}}\text{Perf.Tate}$), and whose morphisms $B_0 \to C_0$ are the morphisms $B_0^a \to C_0^a$ of $(A_0, m)^a$-algebras. We have obvious forgetful functors:

$A_0{\text{-}}\text{Perf.Adic} \to (A_0, m)^a{\text{-}}\text{Perf.Adic}$

$(16.9.54)$

$A_0{\text{-}}\text{Perf.Tate} \to (A_0, m)^a{\text{-}}\text{Perf.Tate}$

$B_0 \mapsto B_0^a$.

As explained in [16.9.23], we may attach to $m$ an ideal $m_0 \subset E_0$, and remark [16.9.24 (i)] implies that $(E_0, m_0)$ is a basic setup compatible with $(A_0, m)$, in the sense of definition [16.8.10]. For every $B_0 \in \text{Ob}(A_0{\text{-}}\text{cp.Adic})$, we then let $B_0^a$ (resp. $E(B_0)^a$) be the $(A_0, m)^a$-algebra attached to $B$ (resp. the $(E_0, m_0)^a$-algebras attached to $E(B_0)$).

**Theorem 16.9.55.** Let $B_0 \in \text{Ob}(A_0{\text{-}}\text{cp.Adic})$, and endow $C := (B_0)_0^a$ with its $b$-adic topology, and $D := E(B_0)_0^a$ with its $\beta^a$-adic topology, as in [16.9.51]. We have:

(i) $(B_0)_0^a \in \text{Ob}(A_0{\text{-}}\text{cp.Adic})$, and if $B_0 \in \text{Ob}(A_0{\text{-}}\text{Tate})$, then $(B_0)_0^a \in \text{Ob}(A_0{\text{-}}\text{Tate})$.

(ii) There exists a natural isomorphism $E(B_0)_0^a \xrightarrow{\sim} (E(B_0))^a_0$ of $E_0$-algebras.

(iii) Suppose moreover that the basic setup $(B_0, mB_0)$ is almost perfectoid; then we have:

(a) $\varepsilon_{B_0}^a : (B_0)_0^a \to B_0^a$ is an isomorphism.

(b) The completions $C^\wedge$ and $D^\wedge$ of $C$ and $D$ are perfectoid.

(c) $C^\wedge/\text{Ann}_{C^\wedge}(b) \in \text{Ob}(A_0{\text{-}}\text{Perf.Tate})$.

(d) There exists a natural isomorphism $E(C^\wedge) \xrightarrow{\sim} D^\wedge$.

(iv) The natural morphisms $(C^\wedge)^a \to B_0^a$ and $(D^\wedge)^a \to E(B_0)^a$ are isomorphisms.

(v) If $B_0$ is perfectoid, the same holds for $C^\wedge$ and $D^\wedge$.

(vi) The functors (16.9.54) admit both left and right adjoints.

**Proof.** (i): If $b \cdot 1_{B_0}$ is an injective map, the same holds for $b \cdot 1_{B_0^a}$, because the functor $(-)_0^a$ commutes with limits; the assertion then follows from claim [16.9.31].

(ii): By remark [16.9.24 (iii)], the natural map $B_0 \to B_0^a$ induces an isomorphism $E(B_0)_0^a \xrightarrow{\sim} E(B_0^a)_0^a$; in light of (i), we may then replace $B_0$ by $B_0^a$, and assume from start that $B_0 = B_0^a$. 

...
in which case we show that the natural map $E(B_0) \to E(B_0)_a^a$ is an isomorphism. To this aim, consider the system of sets and maps of sets $S_{\bullet} := (S_{ij}, \varphi_{ij}^h, \varphi_{ij}^v | i, j \in \mathbb{N})$ with $S_{ij} := (B_0 / b^j B_0)_a^a$ for every $i, j \in \mathbb{N}$, and where:

- $\varphi_{ij}^h : S_{i+1, j} \to S_{ij}$ is given by the rule $x \mapsto x^p$ for every $x \in (B_0 / b^j B_0)_a^a$.
- $\varphi_{ij}^v : S_{i, j+1} \to S_{ij}$ is induced by the projection $B_0 / b^{j+1} B_0 \to B_0 / b^j B_0$.

We compute the inverse limit $L$ of the system $S_{\bullet}$ in two different ways:

$$L = \lim_{i \in \mathbb{N}} \lim_{j \in \mathbb{N}} S_{ij} \cong \lim_{j \in \mathbb{N}} \lim_{i \in \mathbb{N}} S_{ij}.$$ 

Notice that, for fixed $i \in \mathbb{N}$, the system $S_{\bullet} := (S_{ij}, \varphi_{ij}^v | j \in \mathbb{N})$ consists of rings and ring homomorphisms, and since the functor $(-)^a$ commutes with limits, the limit of $S_{\bullet}$ represents $L_i := B_0^a = B$; then, the system of maps $\varphi_{ij}^h$ is a natural transformation $S_{i+1, \bullet} \to S_{\bullet}$ whose limit $\varphi_i^h : L_{i+1} \to L_i$ is obviously the map given by the rule $x \mapsto x^p$ for every $x \in B$. Thus $L := \lim_{i \in \mathbb{N}} (S_{\bullet}, \varphi_i^h)$ represents the set underlying $E(B)$. Next, for every $j \in \mathbb{N}$, let $L_j^0$ be the limit of the system of sets $S_{\bullet} := (S_{ij}, \varphi_{ij}^v | i \in \mathbb{N})$; again, the system $(\varphi_{ij}^v | i \in \mathbb{N})$ is a natural transformation $S_{\bullet} \to S_{\bullet}$, inducing a map $\varphi_j^v : L_{j+1}^0 \to L_j$ and $L$ is also $\lim_{j \in \mathbb{N}} (L_j^0, \varphi_j^v)$. Notice now that $L_0$ is the set underlying $E(B_0 / b B_0)_a^a$, since the functor $(-)^a$ commutes with limits. We are therefore reduced to checking that $\varphi_j^v$ is bijective for every $j \in \mathbb{N}$.

To this aim, it suffices to exhibit a system of maps $(s_{ij} : S_{i+1, j} \to S_{ij+1} | i \in \mathbb{N})$ such that $s_{ij} \circ \varphi_{i+1, j}^v = \varphi_{i, j+1}^h \quad \varphi_{ij}^v \circ s_{ij} = \varphi_{ij}^h$ for every $i, j \in \mathbb{N}$ (details left to the reader). This in turn is achieved by the following more general:

**Claim 16.9.56.** Let $(V, m_V)$ be a basic setup such that $\tilde{m}_V := m_V \otimes_V m_V$ is a flat $V$-module, $R$ a $V$-algebra, $I \subset R$ an ideal with $p I = 0$ and $x^p = 0$ for every $x \in I$. Denote by $\pi : R \to R/I$ the projection. Then there exists a map $s$ that makes commute the diagram of sets:

$$
\begin{array}{ccc}
R^a_s & \xrightarrow{\Phi} & R^a_s \\
\downarrow{\pi^a_s} & & \downarrow{\pi^a_s} \\
(R/I)^a_s & \xrightarrow{\overline{\varphi}} & (R/I)^a_s
\end{array}
$$

where $\Phi$ is the map given by the rule $x \mapsto x^p$ for every $x \in R^a_s$, and likewise for $\overline{\varphi}$.

**Proof of the claim.** For every $V$-algebra $S$, denote by $\sigma_S : R/I \otimes_V S \to R \otimes_V S$ the map defined as follows. For every $x \in R/I \otimes_V S$, pick $x \in R \otimes_V S$ such that $\pi(x) = x$, and set $\sigma_S(x) := x^p$; it is easily seen that this map is independent of the choice of representatives, and moreover the rule $S \mapsto \sigma_S$ yields a homogeneous polynomial law $\sigma : R/I \sim R$ of degree $p$ (see definition 9.5.11(ii)). Thus, $\sigma$ factors through the universal homogeneous polynomial law $\chi^p_{R/I} : R/I \sim \Gamma^p_V(R/I)$ and a unique $R$-linear map $\sigma^* : \Gamma^p_V(R/I) \to R$ (see 9.5.19). On the other hand, since $\tilde{m}_V$ is a flat $V$-module, we have a $V$-linear isomorphism $\omega : \tilde{m}_V \sim \Gamma^p_V(\tilde{m}_V)$ (59 (2.1.11))); then the map given by the rule:

$$
\text{Hom}_V(\tilde{m}_V, R/I) \to \text{Hom}_V(\tilde{m}_V, R) \quad \varphi \mapsto (\tilde{m}_V \xrightarrow{\sim} \Gamma^p_V(\tilde{m}_V) \xrightarrow{\Gamma^p_V(\varphi)} \Gamma^p_V(R/I) \xrightarrow{\sigma^*} R)
$$

fulfills the required conditions (details left to the reader). \hfill \Box

(iii.a): Let $B_1$ be the $p$-integral closure of $B_0$ in $B_0[b^{-1}]$, endow $B_1$ with its $b$-adic topology, and let $B_1'$ be the completion of $B_1$. Since $b \cdot 1_{B_1}$ is injective, the same holds for $(b \cdot 1_{B_1})^\wedge = b \cdot 1_{B_1'}$ (proposition 8.2.13(i)). Then, according to claim 16.9.30 and proposition 16.9.29(ii), the basic setup $(B_1', mB_1)$ is almost perfectoid and the induced map $i : B_0 \to B_1'$ is an
almost isomorphism. Moreover, \( B_0^\wedge \) is \( p \)-integrally closed in \( B_1^\wedge[b^{-1}] \), by lemma \[9.8.26\] (ii) and proposition \[8.3.33\] (iii). We consider the commutative diagram

\[
\begin{array}{ccc}
B_0^\wedge & \xrightarrow{\varepsilon_B} & B_0 \\
\downarrow{i} & & \downarrow{i} \\
(B_1^\wedge)^\wedge & \xrightarrow{\varepsilon_B^\wedge} & B_1^\wedge.
\end{array}
\]

By remark \[16.9.24\] (iii), \( i \) induces an isomorphism \( E(i)^a : E(B_0)^a \to E(B_1^\wedge)^a \) of \((E, m_E)^a\)-algebras. Let \( n \subseteq A_0 \) be the ideal generated by \( \mathbb{A}_n(m_E) \); it is easily seen that \((A_0, n)\) is a basic setup, and then \( i_n : A_0 \otimes_{W(E_0)} W(E(\overline{i})) \) is an almost isomorphism relative to the almost structure furnished by \((A_0, n)\). Now, \( i_n \) is the inverse limit of the system of maps \( i_n \) : \( \mathbb{Z}/p^n \to \mathbb{Z}/p^m \), and in view of \[16.9.25\] we deduce that \( i_n \) is an almost isomorphism also relative to the original almost structure \((A_0, \mathfrak{m})\), for every \( n \in \mathbb{N} \), and finally, the same holds for \( i_n \). Summing up, we are therefore reduced to checking that \( \varepsilon_B^a \) is an isomorphism of \((A_0, \mathfrak{m})^a\)-algebras, so we may assume from start that \( B_0 \) is \( p \)-integrally closed. Denote by \( gr \) the graded ring associated with the \( b \)-adic filtration on \( B_0 \), and likewise define \( gr\big|B_0^\wedge \); since both \( B_0 \) and \( B_0^\wedge \) are \( b \)-adically complete and separated, we are further reduced to showing that the induced map \( gr \big|B_0^\wedge \to gr \big|B_0 \) is an almost isomorphism, and since \( b \) is regular in both \( B_0 \) and \( B_0^\wedge \), it suffices to prove that the same holds for

\[
gr \big|B_0^\wedge : B_0^\wedge/bB_0^\wedge \to B_0/bB_0.
\]

**Claim 16.9.57.** Define \( \beta_* \in E(A_0) \) as in \[16.9.51\]. Then we have:

(i) The Frobenius endomorphism of \( B_0/\beta_n B_0 \) induces an injective map

\[
B_0/\beta_{n+1} B_0 \to B_0/\beta_n B_0 \quad \text{for every} \quad n \in \mathbb{N}.
\]

(ii) The kernel of the projection \( E(B_0) \to B_0/bB_0 \) is \( \beta_* E(B_0) \).

(iii) We have a natural identification \( B_0^\wedge/bB_0^\wedge \cong E(B_0)/\beta_* E(B_0) \).

**Proof of the claim.** (i) follows straightforwardly from the assumption that \( B_0 \) is \( p \)-integrally closed in \( B_0[b^{-1}] \), and (ii) follows easily from (i) : the details are left to the reader.

(iii): Let \( \alpha_* \in W(E_0) \) be a distinguished element in the kernel of \( u_A : W(E_0) \to A_0 \); we have \( p \in b^p \) by assumption, and \( \alpha_0 \in \beta_0^p E_0 \), by lemma \[16.1.9\] (ii). But the natural isomorphism

\[
E(B_0)/\alpha_0 E(B_0) \cong E_0/\alpha_0 E_0 \otimes_{E_0} E(B_0) \cong A_0 \otimes_{W(E_0)} E(B_0) \cong B_0^\wedge/pB_0^\wedge
\]

maps the class of \( \beta_* \) to the class of \( b \), whence the contention. \( \diamond \)

By claim \[16.9.57\] (ii), the projection \( \overline{u}_{B_0/pB_0} : E(B_0) \cong E(B_0/pB_0) \to B_0/bB_0 \) induces an injective map

\[
j : E(B_0)/\beta_* E(B_0) \to B_0/bB_0
\]

and claim \[16.9.57\] (iii) yields a natural identification of \( j \) with \( gr \big|B_0 \). Thus, it remains only to check that \( \overline{u}_{B_0/pB_0} \) is an epimorphism of \((E_0, m_{E_0})^a\)-algebras. However, recall that \( E(B_0) \) is the limit of the system of rings \( (R_n : n \in \mathbb{N}) \), with \( R_n := B_0/bB_0 \) for every \( n \in \mathbb{N} \), and with transition maps given by the Frobenius endomorphism \( \Phi_{B_0/bB_0}^a \). Thus, \( \overline{u}_{B_0/pB_0} \) is the inverse limit of the system of maps \( \Phi_{B_0/bB_0}^a : R_n \to B_0/bB_0 \) for every \( n \in \mathbb{N} \), each of which is almost surjective, since \( (B_0, m B_0) \) is almost perfectoid (as usual, we regard \( \Phi_{B_0/bB_0}^a \) as a morphism of \((E_0, m_{E_0})^a\)-algebras \( R_{n,a}(\Phi_{B_0}^a) \to B_0^\wedge/bB_0^\wedge \) : cp. remark \[16.9.24\] (iii)). To conclude, it suffices now to invoke lemma \[14.2.24\].
(iii.b): We consider first the assertion for \( C^\perp \): set \( \overline{A}_0 := A_0/bA_0 \), and \( \overline{m} := \overline{m}A_0 \); by assumption, the Frobenius endomorphism of \( B_0/b^pB_0 \) induces an isomorphism \( \Phi^a_{B_0} : (B_0/bB_0)^a \cong (B_0/b^pB_0)^a_{(\varphi)} \) of \( (\overline{A}_0, \overline{m})^a \)-algebras, whence the isomorphism of \( \overline{A}_0 \)-algebras

\[
(\Phi^a_{B_0})_{!!} : (B_0/bB_0)^a_{!!} \cong ((B_0/b^pB_0)^a_{(\varphi)})_{!!}
\]

where \((-)_{!!}\) denotes the left adjoint of the localization functor \((-)^a : \overline{A}_0 \text{-Alg} \to (\overline{A}_0, \overline{m})^a \text{-Alg}.\) On the other hand, by a direct inspection of the construction of these left adjoints, one gets natural identifications

\[
C/bC \cong (B_0/bB_0)^a_{!!}, \quad C/b^pC \cong ((B_0/b^pB_0)^a_{(\varphi)})_{!!}
\]

where, however, the construction of \( C := (B_0)^a_{!!} \) refers to the left adjoint of the corresponding localization \((-)^a : A_0 \text{-Alg} \to (A_0, m)^a \text{-Alg}.\) It is then easily seen that, under these identifications, the map \((\Phi^a_{B_0})_{!!}\) corresponds to the ring homomorphism \(\Phi_C : C/bC \to C/b^pC\) induced by the Frobenius endomorphism of \( C/b^pC.\) The latter is therefore an isomorphism, and so the same holds for the corresponding ring homomorphism \(\Phi_{C^\perp} : C^\perp/bC^\perp \to C^\perp/b^pC^\perp.\) Then, according to corollary [16.3.73] in order to check that \( C^\perp \) is perfectoid, it remains only to show that \( \text{Ann}_{C^\perp}(b^p) = \text{Ann}_C(b^{p-1}) \), and in light of remark [8.6.39(iii)], we are reduced to proving that \( \text{Ann}_C(b^p) = \text{Ann}_C(b^{p-1}).\) Let \( \mu : \overline{m} \to A_0 \) be the \( A_0 \)-linear map such that \( \mu(x \otimes y) := xy \) for every \( x, y \in \overline{m};\) we notice:

**Claim 16.9.58.** \( \text{Ann}_C(b^p) \) is a quotient of \( \ker(\overline{m}/b^n\overline{m} \to A_0/b^nA_0) \), for all \( n \in \mathbb{N}.\)

**Proof of the claim.** We consider the commutative diagram of \( A_0 \)-modules with exact rows:

\[
0 \rightarrow n \rightarrow A_0 \oplus (\overline{m} \otimes A_0 B_0) \rightarrow (B_0)^a_{!!} \rightarrow 0
\]

\[
0 \rightarrow n \rightarrow A_0 \oplus (\overline{m} \otimes A_0 B_0) \rightarrow (B_0)^a_{!!} \rightarrow 0
\]

whose vertical arrows are scalar multiplication by \( b^n \), and where \( n \) denotes the image of the map \( \overline{m} \to A_0 \oplus (\overline{m} \otimes A_0 B_0) \) given by the rule: \( z \mapsto (\mu(z), z \otimes 1) \) for every \( z \in \overline{m}.\) By assumption, \( b \) is a regular element in both \( A_0 \) and \( B_0 \), and \( \overline{m} \) is a flat \( A_0 \)-module, by [59, Prop.2.1.7(i)]. Hence, the central vertical arrow is injective, and the assertion follows easily from the snake lemma.

In view of claim [16.9.58], we are reduced to showing that \( b \cdot \ker(A_0/b^nA_0 \otimes A_0 \mu) = 0 \) for every \( n \in \mathbb{N}.\) To this aim, write \( m = \bigcup_{n \in \mathbb{N}} A_0 a_i \) for a system \((a_i \mid i \in \mathbb{N})\) of elements of \( A_0 \) such that for every \( i \in \mathbb{N} \) we have \( a_i = c_i a^p_{i+1} \) for some \( c_i \in A_0 \) (see [16.9.23]); by remark [16.9.24(ii)], the \( A_0 \)-module \( m \) is then isomorphic to the inductive limit \( L \) of a system \((F_i \mid i \in \mathbb{N})\) of free rank one \( A_0 \)-modules \( F_i = A_0 e_i \), with transition maps \( f_i : F_i \to F_{i+1} \) such that \( f_i(e_i) = c_i a^p_{i+1} e_{i+1} \) for every \( i \in \mathbb{N}.\) Hence \( L \) is the set of equivalence classes \([x, y]\) of pairs \((x, y)\) with \( i \in \mathbb{N} \) and \( x \in F_i \), and with this notation, \( \mu \) corresponds to the \( A_0 \)-linear map \( L \to A_0 \) given by the rule: \([ye_i, i] \mapsto ya_i \) for every \( i \in \mathbb{N} \) and \( y \in A_0.\) Hence, let \([ye_i, i] \in L \) and suppose that \( ya_i \in b^nA_0;\) we need to show that \([ye_i, i] \in b^{n-1}L.\) Pick \( k \in \mathbb{N} \) with \( p^k \geq n;\) by a simple induction, we see that:

\[
[ye_i, i] = y_k[e_{i+k}, i + k] \quad \text{with} \quad y_k := yc_{i+1}^p \cdots c_{i+k-1}^p c_{i+k}^{p-1}.
\]

We are then reduced to checking that \( y_k \in b^{n-1}A_0, \) and by theorem [16.3.62], the latter is equivalent to the condition: \( y_k^{p^k} \in b(n-1)p^k A_0.\) But we have:

\[
y_k^{p^k} = y^{p^k} c_{i+1}^p \cdots c_{i+k-1}^{p^k-1} = y c_{i+1}^p \cdots c_{i+k-1}^{p^k-1} \cdot (ya_i)^{p^k-1} \in b(n-1)p^k A_0 \subset b(n-1)p^k A_0.
\]
Next, we consider the assertion concerning $D^\wedge$: the discussion of (16.9.51) already shows that $E(B_0)$ is a perfectoid ring, when endowed with its $\bar{\beta}_\bullet$-adic topology, and moreover the image of $\bar{\beta}_\bullet$ is regular in $E(B_0)$. Hence, the assertion for $D^\wedge$ follows from the foregoing case, after replacing the basic setup $(A_0, m)$ by $(E, m_E)$.

(iii.c): Arguing as in the proof of corollary [16.3.73] we may assume that $b = b_0$ for some $(b_n | n \in \mathbb{N}) \in E(A_0)$; notice also that $C^\wedge$ is reduced, due to (iii.b) and corollary [16.3.61]i), hence $\text{Ann}_{C^\wedge}(b) = \bigcup_{n \in \mathbb{N}} \text{Ann}_{C^\wedge}(b^n)$, so scalar multiplication by $b$ is an injective endomorphism of $C^\wedge/\text{Ann}_{C^\wedge}(b)$. Then the assertion follows from corollary [16.3.69].

(iv): The counit of adjunction for the pair of functors $((-)_\wedge, (-)^\wedge)$ is an almost isomorphism $\varepsilon_{B_0}: C \to B_0$, hence the same for its $b$-adic completion (cp. the proof of claim [16.9.30]). Likewise, recall that $E(B_0)$ is $\bar{\beta}_\bullet$-adically complete and separated (see (16.9.51)); then the same argument shows that the counit of adjunction $\varepsilon_{E(B_0)}: D \to E(B_0)$ induces, after taking $\bar{\beta}_\bullet$-adic completions, an almost isomorphism $D^\wedge \to E(B_0)$.

(v): We may assume that $b = \beta_0$, where $\beta_\bullet \in E(A_0)$ is as in (16.9.51); also, arguing as in the proof of (iii.b), we see that $\bar{\beta}_C$ is an isomorphism, and then claim [16.3.74] and remark 8.6.39(iii) reduce to showing that $\text{Ann}_C(b^n) = \text{Ann}_C(b^n/\beta_1) = \text{Ann}_C(b^n - 1)$. But, arguing as in the proof of claim [16.9.58] we obtain, for every $n \in \mathbb{N}$, an exact sequence of $A_0$-modules

$$\bar{m} \otimes_{A_0} \text{Ann}_C(b^n) \to \text{Ann}_C(b^n) \to M$$

where $M$ is a quotient of $\ker(A_0/b^n A_0 \otimes_{A_0} \mu)$. The proof of (iii.b) then shows that $bM = 0$, and on the other hand $\beta_1 \cdot \text{Ann}_C(b^n) = 0$, by corollary [16.3.69] thus $\beta_1^{p+1} \cdot \text{Ann}_C(b^n) = 0$, and since $p^2 - 1 \geq p + 1$, the assertion follows.

(vi): Let $X \in \text{Ob}(A_0, \text{Perf.Tate})$ and $Y \in \text{Ob}((A_0, m)^a, \text{Perf.Tate})$, and set $Z := (Y^a)^\wedge$; we know already from (i) and (iii.c) that $Y^a \in \text{Ob}(A_0, \text{Tate})$ and $Z/\text{Ann}_Z(b) \in \text{Ob}(A_0, \text{Perf.Tate})$. Then, in view of the discussion of (16.9.51) we get natural bijections

$$\text{Hom}_{(A_0, m)^a, \text{Perf.Tate}}(X^a, Y^a) \cong \text{Hom}_{A_0, \text{Tate}}(X, Y^a) \cong \text{Hom}_{A_0, \text{Perf.Tate}}(X, (Y^a)^\wedge)$$

$$\text{Hom}_{(A_0, m)^a, \text{Perf.Tate}}(Y^a, X^a) \cong \text{Hom}_{A_0, \text{Alg}}(Y^a, X) \cong \text{Hom}_{A_0, \text{Perf.Tate}}(Z/\text{Ann}_Z(b), X)$$

so the rule $Y \mapsto (Y^a)^\wedge$ (resp. $Y \mapsto Z/\text{Ann}_Z(b)$) yields the sought right (resp. left) adjoint for the functor $A_0, \text{Perf.Tate} \to (A_0, m)^a, \text{Perf.Tate}$. The same argument shows that the rule $Y \mapsto (Y^a)^\wedge$ also provides a right adjoint for the forgetful functor $A_0, \text{Perf.Adic} \to (A_0, m)^a, \text{Perf.Adic}$, and using (v) we easily see that the rule $Y \mapsto Z$ yields a left adjoint for the same functor.

(iii.d): To begin with, let us notice:

**Claim 16.9.59.** The functors (16.9.54) induce equivalences between $(A_0, m)^a, \text{Perf.Adic}$ (resp. $(A_0, m)^a, \text{Perf.Tate}$) and the localization of $A_0, \text{Perf.Adic}$ (resp. $A_0, \text{Perf.Tate}$) obtained by inverting all almost isomorphisms.

**Proof of the claim.** Recall that $\varepsilon_{B_0}: B_0^\wedge \to B_0$ is an isomorphism if $B_0$ is perfectoid (see (16.9.51)); we deduce for every $Y \in \text{Ob}(A_0, \text{Perf.Adic})$ an isomorphism $((Y^a)^\wedge)^a \cong (Y^a)^a \cong Y^a$ in the category $(A_0, m)^a, \text{Perf.Adic}$. Combining with (vi) and proposition [1.1.20](iii), we deduce that the right adjoints to both of the forgetful functors (16.9.54) are fully faithful. Then the claim follows from proposition [1.6.1].

From (vi) and remark [16.24](iii) we get a diagram of categories:

$$\begin{array}{c}
\text{A_0, Perf.Adic} \\
\downarrow \varepsilon(-) \downarrow \text{E_0, Perf.Adic} \downarrow \varepsilon(-) \\
\text{(A_0, m)^a, Perf.Adic} \\
\end{array}$$

$$\text{E(-)}$$
Thus, we are reduced to checking that the natural map $((\varphi)_{\alpha}\Gamma)^{\wedge}$ is an isomorphism. This in turn will follow, once we have shown that the natural map $(\varphi)_{\alpha}\Gamma^{\wedge} \rightarrow E(B_0)$, whence a ring isomorphism $\tau_{B_0} : (E((B_0^a)^{\wedge})_{\Gamma})^{\wedge} \cong (E(B_0^a))^{\wedge}$.

Lastly, $R := (B_0^a)^{\wedge}$ is perfectoid, by (v), whence the isomorphism $\tau_{B_0} \circ \omega_R : (E(R^{\wedge})^{\wedge}) \cong (E(B_0^a))^{\wedge}$.

Thus, we are reduced to checking that the natural map $(E((B_0^a)^{\wedge})^{\wedge}) \rightarrow (B_0^a)^{\wedge}$ is an isomorphism. This in turn will follow, once we have shown that the natural map $(E((B_0^{\wedge}))_{\Gamma}^{\wedge}) \rightarrow B_0^{\wedge}$ is an isomorphism. But the latter is a straightforward consequence of (iv).

17. Applications

17.1. Model algebras. We let $(K, | \cdot |)$ be a valued field of characteristic 0 with value group $\Gamma_K$ of rank one, such that the residue field $\kappa$ of $K^+$ has characteristic $p > 0$.

Definition 17.1.1. The category $\text{MA}_K$ of model $K^+$-algebras consists of all the pairs $(A, \Gamma)$, where $(\Gamma, +)$ is an integral monoid, and $A$ is a $\Gamma$-graded $K^+$-algebra $A$, fulfilling the following conditions:

(MA1) $\text{gr}_\gamma A$ is a torsion-free $K^+$-module, with $\dim_K \text{gr}_\gamma A \otimes K^+ = 1$, for every $\gamma \in \Gamma$.

(MA2) $\text{gr}_\alpha A \cdot \text{gr}_\beta A \neq 0$ for every $\alpha, \beta \in \Gamma$, and $(\text{gr}_\gamma A)^n = \text{gr}_{n\gamma} A$ for every $n \in \mathbb{N}$ and $\gamma \in \Gamma$.

(MA3) $\text{gr}_0 A = K^+$.

(MA4) $\Gamma$ is saturated and $\Gamma^{\text{gp}}$ is a $\mathbb{Z}[1/p]$-module.

The morphisms $(A, \Gamma) \rightarrow (A', \Gamma')$ in $\text{MA}_K$ are the pairs $(f, \varphi)$, where $\varphi : \Gamma \rightarrow \Gamma'$ is a morphism of monoids, and $f : A \rightarrow \Gamma \times_{\Gamma'} A'$ is a morphism of $\Gamma$-graded $K^+$-algebras (see (7.6.1)).

Example 17.1.2. Let $M$ be an integral monoid, $N \rightarrow M$ an exact and injective morphism of monoids, $N \rightarrow K^+ \setminus \{0\}$ a morphism of monoids, and suppose that:

- $M$ is divisible, i.e. the $k$-Frobenius endomorphism of $M$ is surjective for every $k > 0$
- $M^{\text{gp}}/N^{\text{gp}}$ is a $\mathbb{Q}$-vector space.

Let $(\Gamma, +)$ be the image of $M$ in $M^{\text{gp}}/N^{\text{gp}}$, and denote by $I$ the nilradical of the $K^+$-algebra $A := M \otimes_N K^+$; then $A$ is a $\Gamma$-graded $K^+$-algebra, and $I$ is a $\Gamma$-graded ideal (proposition [7.6.12](ii)). We claim that $I \otimes K^+$, $K = 0$ and $(A/I, \Gamma)$ is a model $K^+$-algebra. Indeed, (MA4) is immediate, and it is easily seen that $gr_n A = (gr_\gamma A)^n$ for every $\gamma \in \Gamma$ and $n \in \mathbb{N}$. Moreover, since the map $N \rightarrow M$ is exact, the kernel of the map $M \rightarrow M^{\text{gp}}/N^{\text{gp}}$ equals $N$, so $(A/I)_{\Gamma} = K^+$, i.e. (MA3) holds as well. The remaining assertions can be checked after tensoring with $K$; namely, we have to show that the $\Gamma$-graded $K^+$-algebra $A_K := M \otimes K^+$ is reduced, with $\dim_K gr_\gamma A_K = 1$ for every $\gamma \in \Gamma$, and $gr_\alpha A_K \cdot gr_\beta A_K \neq 0$ for every $\alpha, \beta \in \Gamma$. However, the morphism $N \rightarrow K^+$ extends uniquely to a group homomorphism $N^{\text{gp}} \rightarrow K^*$, and $A_K = (N^{-1} M) \otimes N^{\text{gp}} K$; hence, we may assume that $N$ is a group, in which case $\Gamma$ is the set-theoretic quotient of $M$ by the translation action of $N$ (lemma [4.8.31](iii)). In this case, choose a representative $\gamma^* \in M$ for every $\gamma \in \Gamma$; it follows easily that $(\gamma^* \otimes 1 | \gamma \in \Gamma)$ is a basis of the $K^*$-vector space $A_K$, whence (MA1), and $(\alpha^* \otimes 1 \cdot (\beta^* \otimes 1)$ is a non-zero multiple of $(\alpha + \beta)^* \otimes 1$, which yields (MA2). Lastly, since the nilradical $I_K$ of $A_K$ is $\Gamma$-graded (proposition [7.6.12](ii)), we also deduce that $I_K = 0$, as sought.
Remark 17.1.3. (i) The category MA$_K$ admits a tensor product, defined by the rule:

\[(A, \Gamma) \otimes (A', \Gamma') := (A \otimes_{K^+} A', \Gamma \oplus \Gamma').\]

(ii) Let \((A, \Gamma)\) be any model \(K^+\)-algebra, and suppose that \(\Gamma = \Gamma_1 \oplus \Gamma_2\) is a given decomposition of \(\Gamma\) as direct sum of monoids. Then it is easily seen that \(\Gamma_1\) and \(\Gamma_2\) are integral and saturated, and they fulfill axiom (MA4). There follows a morphism of model \(K^+\)-algebras:

\[(17.1.4) \quad (\Gamma_1 \times_\Gamma A, \Gamma_1) \otimes (\Gamma_2 \times_\Gamma A, \Gamma_2) \to (A, \Gamma)\]

(iii) In the situation of (ii), set \(A_K := A \otimes_{K^+} K\). Then it is easily seen that \((17.1.4)\) induces an isomorphism of \(K\)-algebras:

\[\Gamma_1 \times_\Gamma A_K \otimes_K (\Gamma_2 \times_\Gamma A_K) \simto A_K.\]

In general, \((17.1.4)\) need not be an isomorphism. However, \((17.1.4)\) is an isomorphism, if either \(\Gamma_1\) or \(\Gamma_2\) is a torsion abelian group. Indeed, in any case the induced maps

\[\text{gr}_\alpha A \otimes_{K^+} \text{gr}_\beta A \to \text{gr}_{\alpha+\beta} A \quad \text{for } a_1 \otimes a_2 \mapsto a_1a_2\]

will be injective for every \(\alpha \in \Gamma_1\) and \(\beta \in \Gamma_2\). To check surjectivity, let \(a \in \text{gr}_{\alpha+\beta} A\) be any element, and say that \(n_\beta = 0\); then \(a^n \in \text{gr}_n A\), and by (MA2) we know that there exist \(a_1 \in \text{gr}_\alpha A\) and \(x \in K^+\) such that \(a^n = a_1^n x\). It follows that \(a = a_1a_2\) for some \(a_2 \in \text{gr}_\beta A_K\) such that \(a_2^n \in K^+\). Then \(a_2 \in \text{gr}_\beta A\), whence the claim.

(iv) Let \((E, | \cdot |_E)\) be any valued field extension of \((K, | \cdot |)\), such that \(| \cdot |_E\) is also a valuation of rank one. Then we have an obvious base change functor:

\[\text{MA}_K \to \text{MA}_E : (A, \Gamma) \mapsto (A \otimes_{K^+} E^+, \Gamma).\]

17.1.5. Let \((A, \Gamma)\) be any model \(K^+\)-algebra. For any subset \(\Delta \subset \Gamma\), set

\[A_\Delta := \Delta \times_\Gamma A \quad A_{\Delta,K} := A_\Delta \otimes_{K^+} K \quad \Delta[1/p] := \bigcup_{n \in \mathbb{N}} \{\gamma \in \Gamma | p^n \gamma \in \Delta\}.\]

Clearly, if \(\Delta\) is a submonoid of \(\Gamma\), then \(A_\Delta\) is a \(K^+\)-subalgebra of \(A\), and \((A_\Delta, \Delta)\) is a subobject of \((A, \Gamma)\), provided \(\Delta\) satisfies (MA4). On the other hand, if \(\Delta\) is saturated, it is easily seen that the same holds for \(\Delta[1/p]\), and then the latter does satisfy (MA4).

Also, if \(\Delta\) is an ideal of \(\Gamma\), then clearly \(A_\Delta\) is an ideal of \(A\).

Set \(K^* := K^+ \setminus \{0\}\) and let \(A^*_\gamma := \text{gr}_\gamma A \setminus \{0\}\) for every \(\gamma \in \Gamma\); for any submonoid \(\Delta \subset \Gamma\), we deduce a sequence of morphisms of integral monoids:

\[1 \to K^* \xrightarrow{\varphi_\Delta} A^*_\Delta \to \Delta \to 1 \quad \text{where } A^*_\Delta := \bigoplus_{\gamma \in \Delta} A^*_\gamma\]

(where and where the direct sum is formed in the category of \(K^*\)-modules), such that \((17.1.6)\) is a short exact complex of abelian groups; then (MA1) implies that \(\varphi_\Delta\) is saturated (proposition 6.2.31). Also, (MA1) implies that each \(A^*_\gamma\) is a filtered union of free cyclic \(K^*\)-modules, hence \(\varphi_\Delta\) is also integral. Furthermore, (MA1) and (MA2) imply that \(A^*_\Delta\) is \(\Delta^{gp}\)-graded, and

\[(17.1.7) \quad \text{gr}_\gamma A^*_\Delta = A^*_\gamma \otimes_{K^*} K^* \quad \text{for every } \gamma \in \Delta.\]

(details left to the reader). We shall just write \(A^*\) and \(A_K\) instead of \(A^*_\gamma\), and respectively \(A_{\Gamma,K}\).

17.1.8. Let now \((A, \Gamma)\) be any model \(K^+\)-algebra; set \(S := \text{Spec } K^+, \quad X := \text{Spec } A\), and let \(\mathfrak{p}\) be any geometric point of \(X\), localized on the closed subset \(Z := X \times_{S} \text{Spec } K\). Let \(\mathcal{J}_{A,p}\) be the \(p\)-adic topology on \(A\). Suppose furthermore, that \(K^+\) is deeply ramified (see [59, Def.6.6.1]), and let \((K^+, \mathfrak{m}_K)\) be the standard setup associated with \(K^+\) (see [59, §6.1.15]); then we have the corresponding sheaf \(\mathcal{O}^a_{X,\mathfrak{p}}\) of \(K^{+a}\)-algebras on \(X(\mathfrak{p})\), and we may state the following almost purity theorem:

**Theorem 17.1.9.** With the notation of (17.1.8), the following holds:
(i) \((A, \mathcal{T}_A)\) is a formal perfectoid ring.
(ii) The pair \((X(\mathcal{T}), Z(\mathcal{T}))\) is almost pure.

**Proof.** (i) Let \(\pi \in K^+\) be any element such that \(\pi^n K^+ = pK^+\); denote by \(A^\wedge\) the completion of \((A, \mathcal{T}_A)\), and set \(I := \pi A^\wedge\). Then the topology of \(A^\wedge\) agrees with the \(I\)-adic topology (remark [8.3.3iv]), and the image of \(\pi\) is a regular element in \(A^\wedge\), by proposition [8.2.13](i) (the details shall be left to the reader). Moreover we have \(pA^\wedge = I^{(p)}\) (notation of definition [16.2.1]); by theorem [16.4.1] it then suffices to check that the Frobenius endomorphism \(\Phi_{A/pA}\) of \(A^\wedge/pA^\wedge = A/pA\) induces an isomorphism \(A/\pi A \sim A/pA\). We are then further reduced to showing that \(\Phi_{A/pA}\) restricts to a bijection
\[
{\mathrm{gr}_\gamma A/\pi \cdot {\mathrm{gr}_\gamma A} \sim {\mathrm{gr}_p A/\pi \cdot {\mathrm{gr}_p A}} \quad \text{for every } \gamma \in \Gamma.
\]
However, since \(\Gamma_K\) is of rank one, there exists a sequence \((a_n \mid n \in \mathbb{N})\) of elements of \(\mathrm{gr}_\gamma A\) such that \(K^+ a_n \subset K^+ a_{n+1}\) for every \(n \in \mathbb{N}\) and \(\mathrm{gr}_\gamma A = \bigcup_{n \in \mathbb{N}} K^+ a_n\). Then \(\mathrm{gr}_p A = \bigcup_{n \in \mathbb{N}} K^+ a_n^p\).
By [59] Prop.6.6(6) the Frobenius endomorphism of \(K^+\) induces an isomorphism \(K^+ / \pi K^+ \sim K^+ / pK^+\). It follows that \(\Phi_{A/pA}\) induces a bijection \((K^+ a_n)/\pi (K^+ a_n) \sim (K^+ a_n^p)/p(K^+ a_n^p)\) for every \(n \in \mathbb{N}\), whence the contention.
(ii) follows from (i), and theorems [16.7.21](i) and [16.8.43] \(\square\)

**17.1.10.** The inclusion map \(A^* \to A\) is a morphism of (multiplicative) monoids, hence induces a log structure on \(X := \text{Spec } A\) (see (12.1.15)). We shall denote
\[
\mathcal{S}(A, \Gamma) := (X, (A^\wedge_\wedge)_{\text{log}})
\]
the resulting log scheme. Clearly, every morphism \((f, \varphi) : (A, \Gamma) \to (A', \Gamma')\) of model algebras induces a morphism of log schemes
\[
\mathcal{S}(f, \varphi) : \mathcal{S}(A', \Gamma') \to \mathcal{S}(A, \Gamma).
\]
Especially, by lemma [12.1.13](iv), the map \(\varphi_T\) yields a saturated morphism
\[
\mathcal{S}(A, \Gamma) \to \mathcal{S}(K^+) := \mathcal{S}(K^+, \{1\}).
\]
Also, if \((K, | \cdot |) \to (E, | \cdot |_E)\) is an extension of rank one valued fields, the inclusion \(A^* \subset (A \otimes_{K^+} E^*)^*\) induces a morphism of log schemes
\[
\mathcal{S}(A \otimes_{K^+} E^+, \Gamma) \to \mathcal{S}(A, \Gamma)
\]
for any model \(K^+\)-algebra \((A, \Gamma)\), and we remark that the resulting diagram of log schemes
\[
\mathcal{S}(A \otimes_{K^+} E^+, \Gamma) \to \mathcal{S}(A, \Gamma)
\]
\[
\downarrow
\]
\[
\mathcal{S}(E^+) \to \mathcal{S}(K^+)
\]
is cartesian. Indeed, since (12.1.16) is right exact, it suffices to check that the natural map
\[
A^* \otimes_{K^+} E^* \to (A \otimes_{K^+} E^*)^*
\]
is an isomorphism, which is clear.

**Remark 17.1.12.** (i) Let \((A, \Gamma)\) be any model \(K^+\)-algebra, and suppose that \(\Delta_0 \subset \Gamma\) is a fine and saturated submonoid, such that \(\Delta_0^{\wedge_0}\) is torsion-free. In this case, \(\Delta_0^{\wedge_0}\) is a free abelian group of finite rank, hence (17.1.6) admits a splitting \(\sigma : \Delta_0^{\wedge_0} \to A^{*\wedge_0}\). Then, using (17.1.7) and (MA1), it is easily seen that the rule \(\gamma \mapsto \sigma(\gamma)\) extends to an isomorphism of \(\Delta_0\)-graded \(K\)-algebras
\[
K[\Delta_0] \sim A_{\Delta_0, K}.
\]
(ii) In the situation of (i), suppose furthermore, that $K$ is algebraically closed. Pick any $x \in K^\times$ such that $\gamma := |x| \neq 1$, and let $\langle \gamma \rangle \subset \Gamma_K$ be the subgroup generated by $\gamma$; we define a group homomorphism $\langle \gamma \rangle \to K^\times$ by the rule $\gamma^k \mapsto x^k$ for every $k \in \mathbb{Z}$. Since $K^\times$ is divisible, the latter map extends to a group homomorphism

$$\Gamma_K \to K^\times$$

and since $\Gamma_K$ is a group of rank one, it is easily seen that (17.1.13) is a right inverse for the valuation map $| \cdot | : K^\times \to \Gamma_K$, whence a decomposition :

$$K^\times \sim (K^+)^\times \oplus \Gamma_K.$$

On the other hand, set $A^*_{\Delta_0,K} := A^*_{\Delta_0} \otimes_{K^*} K^\times$; from (i) we deduce an isomorphism of $\Delta_0$-graded monoids :

$$A^*_{\Delta_0,K} \sim A^*_{\Delta_0} \oplus K^\times.$$

Combining these two isomorphisms, we deduce a surjection $\tau : A^*_{\Delta_0,K} \to (K^+)^\times$ which is a left inverse to the inclusion $(K^+)^\times \to A^*_{\Delta_0}$. Then, for every $\gamma \in \Delta_0$, let us set $C_\gamma := A^*_{\gamma} \cap \ker \tau$; there follows a (non-canonical) isomorphism of $\Delta$-graded monoids :

$$A^*_{\Delta_0} \sim (K^+)^\times \oplus C \quad \text{where} \quad C := \bigoplus_{\gamma \in \Delta_0} C_\gamma \subset A^*_{\Delta_0} \quad \text{and} \quad C^{\text{gp}} \simeq \Delta^{\text{gp}} \oplus \Gamma_K$$

(details left to the reader).

(iii) Suppose that $\Gamma^{\text{gp}}$ is torsion-free, and $K$ is still algebraically closed. Let us set :

$$\Delta_n := \{ \gamma \in \Gamma \mid p^n \gamma \in \Delta_0 \} \quad \text{for every} \ n \in \mathbb{N}.$$

It is easily seen that $\Delta_n$ is still fine and saturated, and since $K^\times$ is divisible, we may extend inductively the splitting $\sigma$ of (i) to a system of homomorphisms

$$\sigma_n : \Delta^{\text{gp}}_n \to A^{\text{gp}} \quad \text{such that} \quad \sigma_{n+1|\Delta^{\text{gp}}_n} = \sigma_n \quad \text{for every} \ n \in \mathbb{N}$$

whence a compatible system of isomorphisms

$$K[\Delta_n] \sim A_{\Delta_n,K} \quad \text{for every} \ n \in \mathbb{N}.$$

Proceeding as in (ii), we deduce a compatible system of isomorphisms of $\Delta_n$-graded monoids

$$A^*_{\Delta_n} \sim (K^+)^\times \oplus C^{(n)} \quad \text{such that} \ C^{(n)} \subset C^{(n+1)} \quad \text{for every} \ n \in \mathbb{N}.$$

In this situation, notice that the $p$-Frobenius automorphism of $\Gamma^{\text{gp}}$ restricts to an isomorphism

$$\Delta_{n+1} \sim \Delta_n \quad \text{for every} \ n \in \mathbb{N}.$$

Likewise, since $\Gamma_K$ is $p$-divisible, taking $p$-th powers induces isomorphisms

$$C^{(n+1)} \sim C^{(n)} \quad \text{for every} \ n \in \mathbb{N}.$$

Definition 17.1.15. Let $(B, \Delta)$ be model $K^+$-algebra. We say that $(B, \Delta)$ is small, if the following conditions hold :

(a) $\text{gr}_\gamma B$ is a finitely generated $K^+$-module for every $\gamma \in \Delta$.
(b) $\Delta = \Delta_0[1/p]$ for some fine and saturated submonoid $\Delta_0$.
(c) $\Delta_0 \times \Delta B$ is a finitely generated $K^+$-algebra.

Remark 17.1.16. Notice that condition (a) of definition 17.1.15 and axiom (MA1) imply that $\text{gr}_\gamma B$ is a free $K^+$-module of rank one, for every small model algebra $(B, \Delta)$ and every $\gamma \in \Delta$. Moreover, actually conditions (b) and (c) (together with axioms (MA1) and (MA2)) imply condition (a). Indeed, (c), (MA1) and proposition 7.6.23(ii) imply that $\text{gr}_\gamma B$ is a free $K^+$-module of rank one, for every $\gamma \in \Delta_0$. Now, in case $n\gamma \in \Delta_0$, (MA2) implies that $\text{gr}_{n\gamma} B$ is generated by an element of the form $z = x_1 \cdots x_n$, for certain $x_1, \ldots, x_n \in \text{gr}_\gamma B$. Suppose that $x_1 = ay$ for some $a \in K^+$ and $y \in \text{gr}_\gamma B$; then $z$ is divisible by $a$ in $\text{gr}_{n\gamma} B$, so $a \in (K^+)^\times$, i.e.
$x_1$ generates $gr_i B$. In view of (b), for every $\gamma \in \Delta$ we may find $k \geq 0$ such that $p^k \gamma \in \Delta_0$, so (a) follows.

**Remark 17.1.17.** Let $(B, \Delta)$ be any small model algebra, so that conditions (b) and (c) of definition [17.1.15] are satisfied for some submonoid $\Delta_0 \subset \Delta$.

(i) Choose a decomposition $\Delta^+ = G \oplus H$, where $G$ is a free abelian group, and $H$ is the torsion subgroup of $\Delta_0$; we have an isomorphism

$$\Delta_0 \simeq \Lambda \oplus H \quad \text{with} \quad \Lambda := \Delta_0^+ \oplus G$$

(lemma [6.2.10]), which induces a decomposition:

$$\Delta \simeq \Lambda[1/p] \oplus H$$

inducing, in turn, an isomorphism of model $K^+$-algebras:

$$(B, \Delta) \simto (B_{\Lambda[1/p], \Lambda[1/p]} \otimes (B_H, H))$$

Remark [17.1.3(iii)]. Notice that both $B_{\Lambda}$ and $B_H$ are finitely generated $K^+$-algebras (proposition [7.6.23](i)). In other words, every small model algebra can be written as the tensor product of two small model algebras $(B', \Delta')$ and $(B'', \Delta'')$, such that $\Delta'^{gp}$ is torsion-free, and $\Delta''$ is a finite abelian group whose order is not divisible by $p$.

(ii) For every $n \in \mathbb{N}$, set $\Delta_0 := \{ \gamma \in \Delta \mid p^n \gamma \in \Delta_0 \}$. Then $B_0 := \Delta_0 \times_{\Delta} B$ is a finitely generated $K^+$-algebra for every $n \in \mathbb{N}$. Indeed, in view of (i), it suffices to check the assertion in case $\Delta^{gp}$ is a torsion-free abelian group. Now, pick a system $x_1, \ldots, x_k$ of homogeneous generators of the $K^+$-algebra $B_0$, by (MA2), for every $i = 1, \ldots, k$ there exist a homogeneous element $y_i \in B_n$ and $u_i \in (K^+)^\times$ such that $u_i y_i^{p^i} = x_i$.

Let $z \in B_n$ be any homogeneous element; then $z^{p^n} = u_1^{t_1} \cdots u_k^{t_k}$ for some $v \in K$ and $t_1, \ldots, t_k \in \mathbb{N}$. Set $y := y_1^{t_1} \cdots y_k^{t_k}$ and $u := u_1^{t_1} \cdots u_k^{t_k} \in K^\times$; then $y^{p^n} u v = z^{p^n}$, and since $\Delta^{gp}$ is torsion-free, we deduce that $y v = z$ for some $w \in K^+$, i.e. the system $y_1, \ldots, y_k$ generates the $K^+$-algebra $B_n$.

(iii) Suppose that $\Delta$ is a finite group whose order is not divisible by $p$. Then we claim that $B$ is a finite étale $K^+$-algebra. Indeed, in view of remark [17.1.3(iii)], it suffices to verify the assertion for $\Delta$ a cyclic finite group, say of order $n$, with $(n, p) = 1$; in the latter case, (MA2) implies that $B \simeq K^+[X]/(X^n - u)$ for some $u \in (K^+)^\times$, whence the contention.

(iv) Let $F \subset \Delta$ be any face. Then $(B_F, F)$ is a small model algebra as well. Indeed, by (i), it suffices to consider the case where $\Delta^{gp}$ is a torsion-free abelian group. In this case, set $F_0 := F \cap \Delta_0$; it is easily seen that $F = F_0[1/p]$, and $F_0$ is a finite and saturated monoid, by lemma [6.1.21(ii)] and corollary [6.2.33](ii).

Moreover, $B_{F_0} = F_0 \times_{F} B_{\Delta_0}$ is a finitely generated $K^+$-algebra, by proposition [7.6.23](i), whence the contention.

(v) Suppose moreover, that $K$ is algebraically closed, and let $(B, \Delta)$ be any small model $K^+$-algebra. Then we have a (non-canonical) isomorphism:

$$K[\Delta] \simto B_K.$$

To exhibit such an isomorphism, we may – in light of (i) – assume that $\Delta^{gp}$ is either torsion-free, or a finite group of order not divisible by $p$. In the latter case, the assertion follows easily from (iii). In case $\Delta^{gp}$ is torsion-free, the sought isomorphism is the colimit of the system of isomorphisms $[17.1.14].$

**Lemma 17.1.18.** Let $(A, \Gamma)$ be a model $K^+$-algebra, and denote by $\mathcal{F}(\Gamma)$ the filtered family of all fine and saturated submonoids of $\Gamma$. We have:

(i) $A = \colim_{\Delta \in \mathcal{F}(\Gamma)} A_\Delta$.

(ii) Suppose that $\Gamma^{gp}$ is a torsion-free abelian group. Then $A$ is a normal domain.

**Proof.** (i) is an immediate consequence of corollary [6.4.1(ii)].

(ii): We show first the following:
Claim 17.1.19. Suppose that $\Gamma^{sp}$ is a torsion-free abelian group. Then $A_K$ is a normal domain.

Proof of the claim. In view of (i), it suffices to show that $A_{\Delta K}$ is a normal domain, when $\Delta \subset \Gamma$ is fine and saturated. The latter assertion follows from remark [17.1.12(i) and theorem 6.4.16(iii)].

Let $A'$ be the integral closure of $A$ in $A_K$; in view of claim 17.1.19 we are reduced to showing that $A = A'$. By proposition 7.6.15(ii), $A'$ is $\Gamma$-graded. Suppose now that $x \in A'$; we need to show that $x \in A$, and we may assume that $x \in \text{gr}_\gamma A'$ for some $\gamma \in \Gamma$. Hence, let

\[ x^n + a_1x^{n-1} + \ldots + a_n = 0 \quad \text{with } a_1, \ldots, a_n \in A \]

be an integral equation for $x$ over $A$. If we replace each $a_i$ by its homogeneous component in degree $i\gamma$, we still obtain an integral equation for $x$, so we may assume that $a_i \in \text{gr}_{\gamma_i}A$ for every $i = 1, \ldots, n$. Then, (MA2) implies that, for every $i = 1, \ldots, n$ there exist $u_i \in K^+$ and $b_i \in \text{gr}_{\gamma_i} A$, such that $|u_i| = 1$ and $a_i = u_ib_i$. Also, from (MA1) we deduce that there exists $b \in \text{gr}_\gamma A$ such that $b_1, \ldots, b_n \in K^+ b$. Set $y := b^{-1}x \in \text{gr}_0 A \otimes_{K^+} K$; clearly $y$ is integral over the subring $\text{gr}_0 A$. Lastly, (MA3) shows that $y \in K^+$, whence $x \in \text{gr}_\gamma A$, which proves the contention. \[ \square \]

Proposition 17.1.20. Let $(A, \Gamma)$ be a model $K^+$-algebra, and suppose that $\Gamma_K$ is divisible. Then $(A, \Gamma)$ is the filtered union of its small model $K^+$-subalgebras.

Proof. In view of lemma 17.1.18(i), we see that $(A, \Gamma)$ is the colimit of the filtered system of its subobjects $(A_{\Delta[1/p]}, \Delta[1/p])$, for $\Delta$ ranging over the fine and saturated submonoids of $\Gamma$. We may then assume from start that $\Gamma = \Gamma_0[1/p]$ for some fine and saturated submonoid $\Gamma_0$.

Next, in view of remark 17.1.17(i), we may consider separately the cases where $\Gamma_0^{sp}$ is a torsion-free abelian group, and where $\Gamma_0 = \Gamma_0$ is a finite abelian group.

Suppose first that $\Gamma_0^{sp}$ is torsion-free, and let $\gamma_0 := (\gamma_1, \ldots, \gamma_n)$ be a finite system of generators for $\Gamma_0$. For every $i = 1, \ldots, n$, choose $a_i \in A_{\gamma_i}^*$, and let $B(\gamma, a) \subset A$ be the $K^+$-subalgebra generated by $a := (a_1, \ldots, a_n)$. Clearly the grading of $A$ induces a $\Gamma_0^{sp}$-grading on $B(\gamma, a)$, and $\text{gr}_\beta B(\gamma, a)$ is a finitely generated $K^+$-module for every $\beta \in \Gamma_0$ (proposition 7.6.23(ii)); by virtue of (MA1), we know that $\text{gr}_\beta B(\gamma, a)$ is then even a free rank one $K^+$-module, for every $\beta \in \Gamma_0$. Furthermore, $a$ generates a fine submonoid of $A^*$, so – by proposition 6.6.35(ii) – there exists an integer $k > 0$ such that

\[ (\text{gr}_\beta B(\gamma, a))^n = \text{gr}_{nk\beta} B(\gamma, a) \quad \text{for every } \beta \in \Gamma_0 \text{ and every integer } n > 0. \]

Now, for any $\beta \in \Gamma$, let $t > 0$ be an integer such that $p^t\beta \in \Gamma_0$, and pick a generator $b$ of the $K^+$-module $\text{gr}_{p^t\beta} B(\gamma, a)$; in light of (MA2) we may find $x \in K^+$ and $c \in \text{gr}_{\beta} A$, such that $b = c^{p^t} x$. Since $\Gamma_K$ is divisible, we may write $x = y^{p^t} u$ for some $y, u \in K^+$ with $|u| = 1$.

It is easily seen that the $K^+$-submodule of $\text{gr}_\beta A$ generated by $cy$ does not depend on the choices of $c, y, t$ and $k$; hence we denote $\text{gr}_\beta C(\gamma, a)$ this submodule; a simple inspection shows that the resulting $\Gamma$-graded $K^+$-module

\[ C(\gamma, a) := \bigoplus_{\beta \in \Gamma} \text{gr}_\beta C(\gamma, a) \]

is actually a $\Gamma$-graded $K^+$-subalgebra of $A$, for which (MA2) holds, and therefore $(C(\gamma, a), \Gamma)$ is a small model algebra. Lastly, it is clear that the family of all such $(C(\gamma, a), \Gamma)$, for $\gamma$ ranging over all finite sets of generators of $\Gamma$, and $\gamma$ ranging over all the finite sequences of elements of $A$ as above, form a cofiltered system of subobjects, whose colimit is $(A, \Gamma)$. This concludes the proof of the proposition in this case.

Next, suppose that $\Gamma = \Gamma_0$ is a finite abelian group. In view of remark 17.1.3(iii), we are reduced to the case where $\Gamma$ is cyclic, say $\Gamma = \mathbb{Z}/n\mathbb{Z}$. Fix any generator $\gamma$ of $\Gamma$, and for every
$a \in \text{gr}_\gamma A$, let $C(a)$ be the $K^+$-subalgebra of $A$ generated by $a$; it is easily seen that the colimit of the filtered family $((C(a), \Gamma) \mid a \in \text{gr}_\gamma A)$ equals $(A, \Gamma)$. (Details left to the reader.)

17.1.21. Suppose now that $K$ is algebraically closed, let $(B, \Delta)$ be a small model $K^+$-algebra, with $\Delta^{gp}$ torsion-free, and write $\Delta = \Delta_0[1/p]$ for some fine and saturated submonoid $\Delta_0$ such that the $K^+$-algebra $B_0 := B_{\Delta_0}$ is finitely generated. Let us set

$$\Delta_n := \{ \gamma \in \Delta \mid p^n \gamma \in \Delta_0 \} \quad B_n := B_{\Delta_n} \quad Y_n := \text{Spec} B_n \quad \text{for every } n \in \mathbb{N}.$$

We wish to construct a ladder of log schemes

$$\cdots \xrightarrow{g_{n+1}} (Y_{n+1}, \mathcal{M}_{n+1}) \xrightarrow{g_n} (Y_n, \mathcal{M}_n) \xrightarrow{g_{n-1}} \cdots \xrightarrow{g_0} (Y_0, \mathcal{M}_0)$$

(17.1.22)

such that, for every $n \in \mathbb{N}$:

- $\varphi_n$ is smooth and saturated, and $\mathcal{M}_n$ admits a chart, given by a $\Delta_n$-graded fine monoid $P^{(n)}$, such that $P_0^{(n)}$ is sharp, and the inclusion map $P_0^{(n)} \to P^{(n)}$ is flat and saturated, and gives a chart for $\varphi_n$;
- the morphism of schemes underlying $h_n$ (resp. $g_n$) is the identity of $S$ (resp. is induced by the inclusion $B_n \subset B_{n+1}$);
- the morphism $g_n$ admits a chart, given by an injective map $P^{(n)} \to \Delta_n \times_{\Delta_{n+1}} P^{(n+1)}$ of $\Delta_n$-graded monoids, whose restriction $P_0^{(n)} \to P_0^{(n+1)}$ gives a chart for $h_n$.

This will be achieved in several steps, as follows:

- First, let $b_1, \ldots, b_k$ be a finite system of generators for $B_0$. By remark [17.1.12(it)], we have a decomposition $B_0^* = (K^+)^* \otimes C$ for some submonoid $C \subset B_0^*$, and we may suppose that each $b_i$ lies in $C$. Let $P^{(0)} \subset B_0^*$ be the submonoid generated by $b_1, \ldots, b_k$. The restriction of the surjection $B^*_0 \to \Delta_0$ is then still a surjection $\pi : P^{(0)} \to \Delta_0$. Notice that, for every $x \in \text{Ker} \pi^{gp}$, we have either $x \in K^+$ or $x^{-1} \in K^+$; especially, we may find a finite system $x_1, \ldots, x_n$ of generators for $\text{Ker} \pi^{gp}$, such that $x_i \in K^+$ for every $i = 1, \ldots, n$. Now, let $\Sigma \subset P^{(0)}$ be the submonoid generated by $x_1, \ldots, x_n$; after replacing $P^{(0)}$ by $P^{(0)} \cdot \Sigma$, we may assume that $\text{Ker} \pi^{gp} = P^{(0)}$, where $P^{(0)} := \text{Ker} \pi^{gp} \subset K^+$ is a fine submonoid.

- Next, by theorem 6.6.45 we may find a finitely generated submonoid $\Sigma' \subset P^{(0)} \cap K^+$ such that the induced morphism $P_0^{(0)} \cdot \Sigma' \to P^{(0)} \cdot \Sigma'$ is flat. Clearly

$$P_0^{(0)} \cdot \Sigma' = \text{Ker} \pi^{gp} \cap (P^{(0)} \cdot \Sigma')$$

hence, we may replace $P^{(0)}$ by $P^{(0)} \cdot \Sigma'$, and assume that the morphism $P_0^{(0)} \to P^{(0)}$ is also flat.

- We claim that the map $P_0^{(0)} \to P^{(0)}$ is also saturated. We shall apply the criterion of proposition 6.2.3: indeed, for given $\gamma \in \Delta_0$ and integer $n > 0$, let $x$ (resp. $y$) be a generator of the $P^{(0)}$-module $P^{(0)}_\gamma$ (resp. $P^{(0)}_{n\gamma}$). Then $x$ (resp. $y$) is also a generator of the $K^+$-module $\text{gr}_\gamma B$ (resp. $\text{gr}_{n\gamma} B$), and (MA2) implies that there exists $u \in (K^+)^*$ such that $uy = x^n$; but since $x, y \in C$, we must have $u = 1$ therefore $(P^{(0)}_\gamma)^n = P^{(0)}_{n\gamma}$, as required.

- Next, we claim that the induced map of $\Delta_0$-graded $K^+$-algebras

$$P^{(0)} \otimes_{P_0^{(0)}} K^+ \to B_0$$

(17.1.23)

is an isomorphism. Indeed, since $P^{(0)}$ contains a set of generators for the $K^+$-algebra $B$, the map (17.1.23) is obviously surjective. However, for every $\gamma \in \Delta_0$, the $P^{(0)}_\gamma$-module $P^{(0)}_\gamma$ is free of rank one (remark 6.2.5(iv)), therefore $(P^{(0)} \otimes_{P_0^{(0)}} K^+)_\gamma$ is a free $K^+$-module of rank one. It follows easily that (17.1.23) is also injective.
Now, denote by \( N_0 \) (resp. \( M_n \)) the fine log structure on \( S \) (resp. on \( X_0 \)) deduced from the inclusion map \( P_0^{(0)} \to K^+ \) (resp. \( P^{(0)} \to B_0 \)). By lemma 12.1.13(iv), the inclusion \( P_0^{(0)} \to P^{(0)} \) yields a chart for a morphism \( \varphi_0 : (Y_0, M_0) \to (S, N_0) \) that is saturated, as sought. Lastly, since (17.1.23) is an isomorphism, theorem 12.3.37 shows that \( \varphi_0 \) is also smooth.

Next, according to remark 17.1.12(iii), we have a compatible system of decompositions

\[ B_n^* = (K^+) \times \oplus C(n) \quad \text{for every } n \in \mathbb{N} \]

with \( C(0) = C \), and such that the \( p \)-Frobenius induces an isomorphism \( \tau_n : C(n+1) \cong C(n) \) for every \( n \in \mathbb{N} \). Hence, define inductively an increasing sequence of submonoids

\[ P^{(0)} \subset P^{(1)} \subset P^{(2)} \subset \cdots \subset B^* \quad \text{by letting } \quad P^{(n+1)} := \tau_n^{-1}P^{(n)} \quad \text{for every } n \in \mathbb{N}. \]

Clearly, the grading of \( B^* \) restricts to a \( \Delta_n \)-grading on \( P^{(n)} \), and induces a \( \Delta \)-grading on \( P \). We deduce isomorphisms of \( \Delta_{n+1} \)-graded monoids:

\[ P^{(n+1)} \cong \Delta_{n+1} \times_{\Delta_n} P^{(n)} \quad \text{for every } n \in \mathbb{N}. \]

Especially, the induced maps of monoids \( P^{(n)}_0 \to P^{(n)} \) are still flat and saturated, and \( P^{(n)}_0 \) is still sharp (remark 17.1.26). The inclusion maps \( P^{(n)} \to B_n \) and \( P^{(n)}_0 \to K^+ \) determine an isomorphism of \( \Delta_n \)-graded \( K^+ \)-algebras

\[ P^{(n)} \otimes_{P^{(n)}_0} K^+ \cong B_n \quad \text{for every } n \in \mathbb{N} \]

as well as fine log structures \( M_n \) on \( Y_n \), and \( N_n \) on \( S \), whence a morphism of log schemes \( \varphi_n : (Y_n, M_n) \to (S, N_n) \) which is again smooth and saturated. This completes the construction of (17.1.22).

**Remark 17.1.26.** (i) With the notation of (17.1.21), notice that, by construction, \( P^{(n)\mathbb{Z}_p} \subset C^{(n)\mathbb{Z}_p} \); especially, since \( \Delta^{\mathbb{Z}_p} \) is torsion-free, the same holds for \( P^{(n)\mathbb{Z}_p} \). Likewise, the construction shows that the induced map \( P^{(n)\mathbb{Z}_p}_0 \to \Gamma K \) is always injective; especially, \( P^{(n)\mathbb{Z}_p}_0 \) is a free abelian group of finite rank, and \( P^{(n)}_0 \) is sharp. It follows that the \( P^{(n)}_0 \)-module \( P^{(n)}_\gamma \) admits a unique generator \( g_\gamma \), for every \( \gamma \in \Delta_n \), and the saturation condition for the inclusion \( P^{(n)}_0 \to P^{(n)} \) translates as the system of identities:

\[ g_\gamma^k = g_{k\gamma} \quad \text{for every } k \in \mathbb{N} \text{ and every } \gamma \in \Delta_n. \]

Moreover, set \( P := \bigcup_{n \in \mathbb{N}} P^{(n)} \). Notice that the colimit of the maps (17.1.25) is an isomorphism of \( \Delta \)-graded \( K^+ \)-algebras

\[ P \otimes_{P_0} K^+ \cong B. \]

Furthermore, since the natural map \( P^{(n)}/P^{(n)}_0 \to \Delta \) is an isomorphism for every \( n \in \mathbb{N} \), we deduce that the grading of \( P \) induces an isomorphism:

\[ P/P_0 \cong \Delta. \]

(iii) We also obtain a commutative diagram of log schemes:

\[ \begin{array}{ccc}
S(B_n, \Delta_n) & \longrightarrow & (Y_n, M_n) \\
\downarrow & & \downarrow \varphi_n \\
S(K^+) & \longrightarrow & (S, N_n)
\end{array} \quad \text{for every } n \in \mathbb{N} \]

whose left vertical arrow is the saturated morphism (17.1.11), and whose bottom (resp. top) arrow is the identity of \( S \) (resp. of \( Y_n \)) on the underlying schemes, and is induced by the
inclusion map $P_n^{(0)} \to K^*$ (resp. $P^{(n)} \to B_n^*\). It is easily seen that (17.1.29) is cartesian: indeed, since the functor (12.1.16) is right exact, it suffices to check that the natural map

$$P^{(n)} \otimes_{P_0^{(n)}} K^* \to B_n^*$$

is an isomorphism, which is clear from (17.1.25).

(iv) Notice that the inclusion map $i_0 : P_0^{(0)} \to P^{(0)}$ is also local; then corollary 6.4.5 yields a decomposition

$$\vartheta_0 : P^{(0)} \to (P^{(0)}) \oplus (P^{(0)})$$

such that $\vartheta_0 \circ i_0 = i_0 \circ \lambda_0^\sharp$, where $i_0 : P^{(0)} \to (P^{(0)}) \oplus (P^{(0)})$ is the natural inclusion map. By means of the isomorphisms (17.1.24), we may then inductively construct decompositions

$$\vartheta_n : P^{(n)} \to (P^{(n)}) \oplus (P^{(n)})$$

for every $n \in \mathbb{N}$ fitting into a commutative diagram

\[
\begin{array}{ccc}
P_0^{(n)} & \xrightarrow{i_n} & P^{(n)} \\
\downarrow \varrho_n & & \downarrow \vartheta_n \\
P^{(n)} & \xrightarrow{\vartheta_n} & (P^{(n)}) \oplus (P^{(n)})
\end{array}
\]

where $i_n$, $\varrho_n$ and $\vartheta_n$ are the natural inclusion maps. Now, set

$$B'_n := K^+[P^{(n)}] \quad B''_n := P^{(n)} \otimes_{P_0^{(n)}} K^+$$

for every $n \in \mathbb{N}$ and let $\Delta'_n$ (resp. $\Delta''_n$) be the image of $P^{(n)}$ (resp. of $\vartheta_n^{-1} P^{(n)}$) in $\Delta_n$; since the grading of $P^{(n)}$ induces an isomorphism $P^{(n)}/P_0^{(n)} \sim \Delta_n$, we see that $\Delta_n = \Delta'_n \oplus \Delta''_n$, and by construction, for every $n \in \mathbb{N}$ we have isomorphisms

$$(B_n, \Delta_n) \sim (B'_n, \Delta'_n) \otimes (B''_n, \Delta''_n)$$

of model $K^+$-algebras, which identify the inclusions $B_n \to B_{n+1}$ with the tensor product of the induced inclusion maps $B'_n \to B'_{n+1}$ and $B''_n \to B''_{n+1}$. Furthermore, set $Y'_n := \text{Spec } B'_n$ and $Y''_n := \text{Spec } B''_n$ for every $n \in \mathbb{N}$. The induced map of monoids $P^{(n)} \to B''_n$ determines a fine log structure $\mathcal{M}'_n$ on $Y'_n$, the map $i_n^\sharp$ gives a chart for a smooth and saturated morphism of log schemes

$$\varphi''_n : (Y''_n, \mathcal{M}'_n) \to (S, \mathcal{N}_n)$$

and there follows an isomorphism of $(S, \mathcal{N}_n)$-schemes (lemma 12.1.4)

(17.1.30)

$$(Y_n, \mathcal{M}_n) \sim (Y'_n \times_S Y''_n, \mathcal{M}'_n \mathcal{M}''_n)$$

for every $n \in \mathbb{N}$.

(v) Starting with (17.1.31), we shall consider the strict henselization $B_{\text{sh}}$ of $B$ at a given geometric point $\pi$ of $\text{Spec } B \otimes_{K^+} \kappa$. In this situation, let $x \in Y := \text{Spec } B$ be the support of $\pi$, and $p_x \subset B$ the corresponding prime ideal. Let also $P$ be as in (ii), denote by $\beta : P \to B$ the natural map deduced from (17.1.27), and set $p := \beta^{-1} p_x$. Moreover, set $p_n := p \cap P^{(n)}$ and $Q^{(n)} := P^{(n)}$ for every $n \in \mathbb{N}$; clearly $p_n \subset p_{n+1}$ (so the isomorphism (17.1.24) maps $p_{n+1}$ onto $p_n$), and therefore

$$Q^{(n)} \subset Q^{(n+1)}$$

for every $n \in \mathbb{N}$.

Furthermore, the image of $Q^{(n)}$ in $\Delta''_n$ is a localization $\Gamma_n$ of $\Delta_n$, especially it is still saturated, and the maps (17.1.24) extend to isomorphisms of $\Gamma_{n+1}$-graded monoids

$$Q^{(n+1)} \sim \Gamma_{n+1} \times_{\Gamma_n} Q^{(n)}$$

for every $n \in \mathbb{N}$.

It is also clear that the $p$-Frobenius of $\Gamma_{n+1}$ factors through an isomorphism $\Gamma_{n+1} \sim \Gamma_{n}$, for every $n \in \mathbb{N}$. Set $F_n := P^{(n)} \setminus p_n$ for every $n \in \mathbb{N}$; notice that, by construction, $F_n \cap P_0^{(n)} = \{1\}$, hence $F_n \cap P_\gamma^{(n)}$ is either empty or else it contains exactly one element, namely the generator $g_{\gamma}$.
Moreover, arguing as in remark 17.1.12(iii), we get an isomorphism
\[ B_p := Q \otimes_{Q_0} K^+ \]

The foregoing shows that \((B_p, \Gamma)\) is still a small model algebra, and we also obtain a ladder of log schemes with the properties listed in
\[ (17.1.21) : \text{namely, set } B_{p,n} := B_p \cap_n = Q(n) \otimes_{Q_0(n)} K^+ \]

for every \(n \in \mathbb{N}\), and endow \(Y_{p,n} := \text{Spec } B_{p,n}\) with the log structure \(\overline{M}_{p,n}\) determined by the induced map \(Q(n) \to B_{p,n}\). Clearly the geometric point \(\varpi\) lifts uniquely to a geometric point \(\varpi_p\) of \(Y_p := \text{Spec } B_p\), and the localization map \(B \to B_p\) induces an isomorphism
\[ Y_p(\varpi_p) \sim Y(\varpi). \]

Hence, for the study of the scheme \(Y(\varpi)\), it shall be usually possible to replace the original small algebra \(B\) by its localization \(B_p\) thus constructed. In so doing, we gain one more property: indeed, notice that the new chart \(Q(n) \to B_{p,n}\) is local at the geometric point \(\varpi\), for every \(n \in \mathbb{N}\).

Now, choose a compatible system of decompositions
\[ (Y_{p,n}, \overline{M}_{p,n}) \sim Y''_{p,n} \times S (Y''_{p,n}, \overline{M}_{p,n}) \]
as in (iv), and denote by \(\varpi_{p,n}\) (resp. \(\varpi''_{p,n}\)) the image of \(\varpi_p\) in \(Y_{p,n}\) (resp. in \(Y''_{p,n}\), for every \(n \in \mathbb{N}\).

By inspecting the construction, it is easily seen that the chart \(Q(n)^{\sharp} \to B''_{p,n} := Q(n)^{\sharp} \otimes_{Q_0(n)} K^+\) is also local at \(\varpi''_{p,n}\).

17.1.31. Let us return to the situation of

\[ (17.1.21) : \text{namely, set } B_{p,n} := B_p \cap_n = Q(n) \otimes_{Q_0(n)} K^+ \]

for every \(n \in \mathbb{N}\), and endow \(Y_{p,n} := \text{Spec } B_{p,n}\) with the log structure \(\overline{M}_{p,n}\) determined by the induced map \(Q(n) \to B_{p,n}\). Clearly the geometric point \(\varpi\) lifts uniquely to a geometric point \(\varpi_p\) of \(Y_p := \text{Spec } B_p\), and the localization map \(B \to B_p\) induces an isomorphism
\[ Y_p(\varpi_p) \sim Y(\varpi). \]

For the next step, we shall apply the method of

\[ (14.5.60) \]
to construct a normalized length function for \(B^{\mathfrak{sh}}\)-modules. To this aim, we need an auxiliary model \(K^+\)-algebra, defined as follows. First, notice that the grading \(P \to \Delta\) extends to a morphism of monoids
\[ \pi_Q : P_Q \to \Delta_Q \]

(notation of \(6.3.20\)); i.e. \(P_Q\) is a \(\Delta_Q\)-graded monoid. Since \(K^\times\) is a divisible group, the inclusion map \(P_0 \to K^\times\) extends to a group homomorphism \(P_{Q,0}^{\mathfrak{sh}} \to K^\times\), and it is easily seen that the latter restricts to a morphism of monoids
\[ P_{Q,0} \to K^\times. \]

So finally, we may set
\[ A := P_Q \otimes_{P_{Q,0}} K^+. \]

Taking into account
\[ (17.1.27) \]
we deduce an isomorphism of \(\Delta\)-graded \(K^+\)-algebras
\[ (17.1.32) B \sim A_\Delta. \]

Moreover, arguing as in remark
\[ (17.1.12) \text{iii}, \]
we get an isomorphism
\[ (17.1.33) K[\Delta_Q] \sim A_K \]

fitting into a commutative diagram of \(K\)-algebras
\[ \begin{array}{ccc} K[\Delta] & \sim & B_K \\ \downarrow & & \downarrow \\ K[\Delta_Q] & \sim & A_K \end{array} \]
whose top horizontal arrow is the isomorphism of remark 17.1.17, and whose right (resp. left) vertical arrow is deduced from (17.1.32) (resp. is induced by the natural inclusion \( \Delta \subset \Delta_Q \)).

**Lemma 17.1.34.** With the notation of (17.1.31), we have:

(i) \( P_{Q,7} \) is a free \( P_{Q,0} \)-module of rank one, for every \( \gamma \in \Delta_Q \).

(ii) \( P_{Q,0} \) is a sharp monoid, and the inclusion map \( P_{Q,0} \to P_Q \) is flat and saturated.

*Proof.* (i): We can write \( (P_n; \mu_{P,n,m} : P_n \to P_{nm} \mid n, m \in \mathbb{N}) \) such that \( P_n := P(0) \) for every \( n \in \mathbb{N} \), and \( \mu_{P,n,m} \) is the \( m \)-Frobenius map of \( P(0) \), for every \( n, m \in \mathbb{N} \). Likewise, we may write \( \Delta_Q \) as colimit of a system of Frobenius endomorphisms \( (\Delta_{0,n} \mid n, m \in \mathbb{N}) \), and \( \pi_Q \) is the colimit of the corresponding system of maps \( (\pi_n : P_n \to \Delta_{0,n} \mid n \in \mathbb{N}) \) where \( \pi_n := \pi \) for every \( n \in \mathbb{N} \). Hence, for any \( \gamma \in \Delta_0 \) there exists \( n \in \mathbb{N} \) such that \( \gamma \) is the image of some \( \gamma_n \in \Delta_{0,n} \), and

\[
P_{Q,7} = \text{colim}_{k \in \mathbb{N}} P_{nk,k\gamma} = \text{colim}_{k \in \mathbb{N}} P_{k\gamma_7}.
\]

However, we know that \( P_{k\gamma_7} \) is free of rank one, generated by a unique element \( g_{k\gamma_7} \); moreover, the transition maps \( \mu_{P,n,k} \) send \( g_{\gamma_7} \) onto \( g_{k\gamma_7} \), for every \( k \in \mathbb{N} \) (remark 17.1.26). This implies that \( P_{Q,7} \) is generated by the image of \( g_7 \), whence (i).

(ii): The flatness follows from (i). Since the inclusion map \( P(0)^0 \to P(0) \) is saturated, it is easily seen that the same holds for the inclusion \( P_{Q,0} \to P_Q \). Lastly, the sharpness of \( P_{Q,0} \) is likewise deduced from the sharpness of \( P(0)^0 \) (details left to the reader). \( \square \)

**17.1.35.** Lemma 17.1.34(ii) implies that the pair \( (A, \Delta_Q) \) fulfills axiom (MA2), and we have thus our sought auxiliary model \( K^+ \)-algebra. Since \( P_{Q,0} \) is sharp, the \( P_{Q,0} \)-module \( P_{Q,7} \) admits a unique generator \( g_7 \), for every \( \gamma \in \Delta_Q \). The image \( g_7 \otimes 1 \) of \( g_7 \) in \( A \) is a generator of the direct summand \( A_\gamma \), which is a free \( K^+ \)-module of rank one; hence, there exists a unique \( a_\gamma \in K \) such that \( \gamma \otimes a_\gamma \) gets mapped to \( g_7 \otimes 1 \), under the isomorphism (17.1.33).

**14.5.63.** After choosing an order-preserving isomorphism, we may define a function

\[
f_A : \Delta_Q \to \mathbb{R} : \gamma \mapsto \log |a_\gamma|.
\]

The inclusion \( A_\gamma \cdot A_\delta \subset A_{\gamma+\delta} \) translates as the inequality

\[
f_A(\gamma) + f_A(\delta) \geq f_A(\gamma + \delta) \quad \text{for every } \gamma, \delta \in \Delta_Q.
\]

Likewise, the saturation condition of axiom (MA2) translates as the identity

\[
f_A(n\gamma) = n \cdot f_A(\gamma) \quad \text{for every } \gamma \in \Delta_Q \text{ and every } n \in \mathbb{N}.
\]

We also fix a (Banach) norm

\[
\Delta^\mathbb{R}_Q \to \mathbb{R} \quad \gamma \mapsto \|\gamma\|.
\]

We can then state the following

**Lemma 17.1.36.** With the notation of (17.1.35), we have:

(i) There exists a \( \Delta^\mathbb{R}_Q \)-rational subdivision \( \Theta \) of the convex polyhedral cone \( (\Delta^\mathbb{R}_Q, \Delta^\mathbb{R}) \), such that

\[
f_A(\sigma + \delta) = f_A(\sigma) + f_A(\delta) \quad \text{for every } \sigma \in \Theta \text{ and every } \gamma, \delta \in \sigma \cap \Delta_Q.
\]

(ii) Especially, the function \( f_A \) is of Lipschitz type, i.e. there exists a real constant \( C_A > 0 \) such that

\[
|f_A(\gamma) - f_A(\gamma')| \leq C_A \cdot \|\gamma - \gamma'\| \quad \text{for every } \gamma, \gamma' \in \Delta^\mathbb{R}_Q.
\]
Proof. (Here, \(\Delta^\text{gp}_\mathbb{R} := \Delta_\mathbb{R}^\text{gp} \otimes_\mathbb{Z} \mathbb{R}\) and \(\Delta_\mathbb{R} \subset \Delta^\text{gp}_\mathbb{R}\) is the cone spanned by \(\Delta_0\).) Combining proposition \(6.3.28\) and lemma \(6.3.33\), we find a \(\Delta_0^\text{gp}\)-rational subdivision \(\Theta\) of \(\Delta_\mathbb{R}\) such that

\[P_{Q,\gamma+\delta} = P_{Q,\gamma} + P_{Q,\delta}\]

for every \(\sigma \in \Theta\) and every \(\gamma, \delta \in \sigma \cap \Delta_Q\).

This means that \(g_\gamma : g_\delta = g_{\gamma+\delta}\) for every \(\sigma \in \Theta\) and every \(\gamma, \delta \in \sigma \cap \Delta_Q\), whence (i).

(ii): Clearly, for every \(\sigma \in \Theta\) we may find a constant \(C_\sigma\) such that the stated inequality holds—with \(C_A\) replaced by \(C_n\) for every \(\gamma, \gamma' \in \sigma \cap \Delta_Q\). It is easily seen that \(C_A := \max\{C_\sigma \mid \sigma \in \Theta\}\) will do (details left to the reader).

17.1.37. Fix \(n \in \mathbb{N}\), pick a subdivision \(\Theta\) of \((\Delta^\text{gp}_\mathbb{R}, \Delta_\mathbb{R})\) as in lemma \(17.1.36\) and let \(\Theta^* \subset \Theta\) be the subset of all \(\sigma \in \Theta\) that span \(\Delta^\text{gp}_\mathbb{R}\). Also, for every \(\gamma \in \Delta^\text{gp}_Q\), denote by \([\gamma]\) the class of \(\gamma\) in \(\Delta^\text{gp}_Q/\Delta^\text{gp}_n\). For any subset \(\Sigma \subset \Delta^\text{gp}_\mathbb{R}\) we let

\[A_\Sigma := A_{\Sigma \cap \Delta_Q}\]

(where the right-hand side is defined as in \((17.1.5)\)). In light of lemma \(6.3.26\) we obtain a decomposition of \(B_n = A_{\Delta_n} = A_{[0]}\) as sum of \(K^+\)-subalgebras:

\[B_n = \sum_{\sigma \in \Theta^*} A_{[0] \cap \sigma}\]

and a corresponding decomposition of the \(B_n\)-module \(A_{[\gamma]}\) as sum of \(A_{[0] \cap \sigma}\)-modules

\[A_{[\gamma]} = \sum_{\sigma \in \Theta^*} A_{[\gamma] \cap \sigma}\]

for every \(\gamma \in \Delta^\text{gp}_Q\).

Lemma 17.1.38. With the notation of \((17.1.37)\) and \((17.1.21)\), there exists \(N \in \mathbb{N}\) such that for every \(n \in \mathbb{N}\) and every \(\gamma \in \Delta^\text{gp}_Q\) the \(B_n\)-module \(A_{[\gamma]}\) admits a system of generators of cardinality at most \(N\).

Proof. According to proposition \(6.3.22\)(ii), for every \(\sigma \in \Theta^*\) and every \(\gamma \in \Delta^\text{gp}_Q\), the subset \(\Sigma_{\sigma, \gamma} := \Delta^\text{gp}_Q \cap (\sigma - \gamma)\) is a finitely generated \((\Delta^\text{gp}_Q \cap \sigma)\)-module; hence, let us fix a finite system of generators \(G_{\sigma, \gamma}\) for \(\Sigma_{\sigma, \gamma}\). In light of lemma \(17.1.36\)(i) we see that the finite set

\[G'_{\sigma, \gamma} := \{g_\delta \otimes 1 \mid \delta \in G_{\sigma, \gamma}\} \subset A\]

generates the \(A_{[0] \cap \sigma}\)-module \(A_{[\gamma] \cap \sigma}\). Consequently, the finite set \(\bigcup_{\sigma \in \Theta^*} G'_{\sigma, \gamma}\) generates the \(B_n\)-module \(A_{[\gamma]}\). On the other hand, since \(\mathcal{I}_{\Delta^\text{gp}_Q, \sigma}\) is a finitely generated \(\Delta^\text{gp}_Q\)-module (proposition \(6.3.35\)(ii)) it is clear that the cardinality of \(G_{\sigma, \gamma}\) is bounded by a constant \(N_{\sigma}\) that is independent of \(\gamma\), and then \(A_{[\gamma]}\) is generated by at most \(N_{\sigma} := \sum_{\sigma \in \Theta^*} N_{\sigma}\) elements. It remains to show that the estimate for \(N_{\sigma}\) is independent of \(n\). However, notice that, for every \(\sigma \in \Theta^*\), the automorphism of \(\Delta^\text{gp}_Q\) given by multiplication by \(p^\sigma\), induces a natural bijection

\[\mathcal{I}_{\Delta^\text{gp}_Q, \sigma} \cong \mathcal{I}_{\Delta^\text{gp}_n, \sigma}\]

that sends each \(\Delta_n\)-module \(\Delta_n^\text{gp} \cap (\sigma - v)\) onto the \(\Delta_0\)-module

\[\Delta_0^\text{gp} \cap (\sigma - p^n v) = \Delta_0 \otimes_{\Delta_n} (\Delta_n^\text{gp} \cap (\sigma - v))\]

(where the extension of scalars \(\Delta_n \rightarrow \Delta_0\) is the isomorphism given by the rule \(\gamma \mapsto p^n \gamma\) for every \(\gamma \in \Delta_n \cap \sigma\)). Thus, we see that \(N := N_0\) will already do. \(\square\)
17.1.39. Let us choose \( N \) as in lemma \( 17.1.38 \) and endow the set \( M_N(B^n_n) \) with the uniform structure defined in \( (14.5.85) \) (relative to the standard setup attached to \( K^+ \)). We consider the mapping

\[
\Delta^\text{gp}_Q \to M_N(B^n_n) \quad \gamma \mapsto A^{n}_{[\gamma]}.
\]

**Lemma 17.1.40.** Keep the notation of \( (6.3.34) \) and \( (14.5.85) \), and let also \( C_A > 0 \) be the constant appearing in lemma \( 17.1.36 \)(ii). Then:

\[
(A^{n}_{[\gamma]}, A^{n}_{[\gamma]}) \in E_C A_{\|\gamma - \gamma\|}^2
\]

for every \( \Sigma \in \mathcal{J}_{\Delta^\text{gp}, \Delta_R} \) and every \( \gamma, \gamma' \in \Omega(\Delta_R, \Sigma) \cap \Delta^\text{gp}_Q \).

**Proof.** By inspecting the definitions, we get an isomorphism of \( B_n \)-modules

\[
A_{[\gamma]} \cong \bigoplus_{\delta \in \Sigma} \left\{ \delta \otimes a \in K[\Delta^\text{gp}_n] \mid \log |a| \geq f_A(\gamma + \delta) \right\}
\]

for every \( \Sigma \in \mathcal{J}_{\Delta^\text{gp}, \Delta_R} \) and every \( \gamma \in \Omega(\Delta_R, \Sigma) \cap \Delta^\text{gp}_Q \). Hence, suppose more generally that \( \Sigma, \Sigma' \) are two elements of \( \mathcal{J}_{\Delta^\text{gp}, \Delta_R} \) such that \( \Sigma \subset \Sigma' \), and let \( \gamma \in \Omega(\Delta_R, \Sigma) \cap \Delta^\text{gp}_Q \). \( \gamma' \in \Omega(\Delta_R, \Sigma') \cap \Delta^\text{gp}_Q \) be any two elements; from lemma \( 17.1.36 \)(ii) we get, for any \( b \in K^+ \) with \( \log |b| \geq C_A \|\gamma' - \gamma\| \), a \( B_n \)-linear map

\[
\tau_{b, \gamma', \gamma} : A_{[\gamma]} \to A_{[\gamma']}
\]

which, under the identifications \( (17.1.41) \), corresponds to the map given by the rule: \( \delta \otimes a \mapsto \delta \otimes ba \) for every \( \delta \in \Sigma \) and every \( a \in K \) such that \( \log |a| \geq f_0(\gamma + \delta) \). In case \( \Sigma = \Sigma' \), also \( \tau_{b, \gamma', \gamma} \) is well defined, and clearly

\[
\tau_{b, \gamma', \gamma} \circ \tau_{b, \gamma, \gamma'} = b^2 \cdot 1_{A_{[\gamma]}} \quad \tau_{b, \gamma, \gamma'} \circ \tau_{b, \gamma', \gamma} = b^2 \cdot 1_{A_{[\gamma']}}
\]

whence the contention. \( \square \)

**Remark 17.1.42.** Let \( \gamma_1, \gamma_2, \gamma'_1, \gamma'_2 \in \Delta^\text{gp}_n \) be four elements, and set \( \gamma_3 := \gamma_1 + \gamma_2, \gamma'_3 := \gamma'_1 + \gamma'_2 \); suppose that

\[
\Delta^\text{gp}_n \cap (\Delta_R - \gamma_i) \subset \Delta^\text{gp}_n \cap (\Delta_R - \gamma'_i) \quad \text{for} \ i = 1, 2, 3.
\]

With the notation of the proof of lemma \( 17.1.40 \), for every \( b_1, b_2 \in K^+ \) such that

\[
\log |b_i| \geq C_A \|\gamma'_i - \gamma_i\| \quad (i = 1, 2)
\]

we obtain a commutative diagram of \( B_n \)-linear maps

\[
\begin{array}{ccc}
A_{[\gamma_1]} \otimes_{B_n} A_{[\gamma_2]} & \longrightarrow & A_{[\gamma_3]} \\
\tau_{b_1, \gamma'_1 - \gamma_1} \otimes \tau_{b_2, \gamma'_2 - \gamma_2} & \downarrow & \tau_{b_1 b_2, \gamma'_3 - \gamma_3} \\
A_{[\gamma_1]} \otimes_{B_n} A_{[\gamma'_2]} & \longrightarrow & A_{[\gamma'_3]}
\end{array}
\]

whose horizontal arrows are the restrictions of the multiplication map of the \( B_n \)-algebra \( B \): the detailed verification shall be left as an exercise for the reader.

**Theorem 17.1.43.** In the situation of \( (17.1.31) \), the \( K^+ \)-algebra \( B_{sh} \) is ind-measurable.

**Proof.** First, notice that, for every \( k \geq 0 \), the inclusion map \( B_n \to B_{n+k} \) induces a radicial morphism \( B_n \otimes_{K^+} \kappa \to B_{n+k} \otimes_{K^+} \kappa \), and therefore also an isomorphism of \( B_{n+k} \)-algebras

\[
B_{sh} \otimes_{B_n} B_{n+k} \cong B_{sh}^{n+k}
\]

(\[ Ch.IV, \text{Prop.18.8.10} \]). Notice as well, that \( B_{sh} \) is a measurable \( K^+ \)-algebra (see definition \( 14.5.3 \)(ii)), hence we have a well defined normalized length function \( \lambda_n \) on isomorphism classes of \( B_{sh}^{n+k} \)-modules, characterized as in theorem \( 14.5.43 \). Thus, our task is to exhibit a sequence \( (d_n : n \in \mathbb{N}) \) of normalizing factors fulfilling conditions (a) and (b) of definition \( 14.5.64 \) for
the directed system \((B_{n}^{sh} \mid n \in \mathbb{N})\), whose colimit is \(B^{sh}\). To this aim, let \(M\) be any object of \(B_{n}^{sh}\).Mod_{coh,\{a\}}; in view of (17.1.44), we need to estimate

\[
\lambda_{k+n}(B_{k+n} \otimes_{B_{n}} M) = \lambda_{k+n} \left( \bigoplus_{[\gamma] \in \Delta^{gp}_{k+n}/\Delta^{gp}_{k+n}} A_{[\gamma]} \otimes_{B_{n}} M \right).
\]

To this aim, let us introduce the function

\[
l_{M} : \Delta^{gp}_{Q} \to \mathbb{R} \quad \gamma \mapsto \lambda_{n}(A_{[\gamma]} \otimes_{B_{n}} M).
\]

**Claim 17.1.45.** Let \(\Sigma\) be as in lemma 17.1.40 set \(J := \text{Ann}_{B^{sh}}(M/mM)\), and suppose that \(M\) admits a generating set of cardinality \(k\). Then the restriction of \(l_{M}\) to \(\Omega(\Delta_{R}, \Sigma) \cap \Delta^{gp}_{Q}\) is of Lipschitz type, i.e. there exists a real constant \(C_{A} > 0\) independent of \(n, \Sigma\) and \(M\) such that

\[
|l_{M}(\gamma) - l_{M}(\gamma')| \leq C_{A} : k \cdot \text{length}_{B^{sh}}(B_{n}^{sh}/JB_{n}^{sh}) \cdot \|\gamma - \gamma'\|
\]

for every \(\gamma, \gamma' \in \Omega(\Delta_{R}, \Sigma) \cap \Delta^{gp}_{Q}\).

**Proof of the claim.** Let \(I \subset B_{n}^{sh}\) be any finitely generated \(m_{B^{sh}}\)-primary ideal contained in the annihilator of \(M\). Also, let \(N'\) be the cardinality of a finite set of generators for the \(B_{n}^{sh}\)-module \(M\), and \(N\) the constant provided by lemma 17.1.38. Then \(M\) admits a system of generators of cardinality \(\leq NN'\), for every \(\gamma \in \Delta^{gp}_{Q}\). Furthermore, an argument as in the proof of [59] Lemma 2.3.7(iv) shows that the induced mapping

\[
\mathcal{M}_{N}(B_{n}) \to \mathcal{M}_{N'}(B_{n}^{sh}/IB_{n}^{sh}) \quad L \mapsto L \otimes_{B_{n}} M
\]

is of Lipschitz type; more precisely, it sends the entourage \(E_{r}\) into \(E_{2r}\), for every \(r \in \mathbb{R}_{>0}\) (details left to the reader). Then the claim follows by combining lemmata 14.5.86 and 17.1.40.

From proposition 6.3.35(iv), we see that, for every \(\Sigma \in \mathcal{S}^{gp}_{\Delta_{R}},\Delta_{R}\) the subset \(\Omega(\Delta_{R}, \Sigma) \cap \Delta^{gp}_{Q}\) is dense in \(\Omega(\Delta_{R}, \Sigma)\); taking into account claim 17.1.45 it follows that \(l_{M}\) extends (uniquely) to a function \(l_{M,R} : \Delta^{gp}_{Q} \to \mathbb{R}\), whose restriction to every \(\Omega(\Delta_{R}, \Sigma)\) is continuous and still satisfies the same Lipschitz type estimate. Notice that \(l_{M,R}\) descends to a function on the torus

\[
l_{M} : T_{n} := \Delta^{gp}_{Q}/\Delta_{0}^{gp} \to \mathbb{R}.
\]

Hence, set \(r := \text{rk}_{2}\Delta^{gp}_{0}\), let us fix a basis \(e_{1}, \ldots, e_{r}\), for the free \(\mathbb{Z}\)-module \(\Delta^{gp}_{0}\), and define

\[
\Omega_{n} := \left\{ \sum_{i=1}^{r} t_{i}e_{i} \mid -\frac{1}{2^{p^{n}}} \leq t_{i} < \frac{1}{2^{p^{n}}} \quad \text{for} \quad i = 1, \ldots, r \right\}
\]

so \(\Omega_{n} \subset \Delta^{gp}_{n}\) is a fundamental domain for the lattice \(\Delta^{gp}_{n}\); in view of theorem 14.5.43(ii.b), we reach the following identity:

\[
\lambda_{k+n}(B_{k+n} \otimes_{B_{n}} M) = \frac{1}{[\kappa(B_{k+n}^{sh}) : \kappa(B_{n}^{sh})]} \cdot \sum_{\gamma \in \Delta^{gp}_{k+n} \cap \Omega_{n}} l_{M}(\gamma).
\]

Now, set

\[
d_{n} := p^{nr} \cdot [\kappa(B_{n}^{sh}) : \kappa(B_{0}^{sh})]^{-1} \quad \text{for every} \quad n \in \mathbb{N}.
\]

We claim that \((d_{n} \mid n \in \mathbb{N})\) is a suitable sequence of normalizing factors for \(B^{sh}\). Indeed, recall that \(\Omega(\Delta_{R}, \Sigma)\) is linearly constructible for every \(\Sigma \in \mathcal{S}^{gp}_{\Delta_{0}^{gp},\Delta_{R}}\) (proposition 6.3.35(iii)), especially, the bounded function \(l_{M}\) is continuous outside a subset of \(\Delta^{gp}_{Q}\) of measure zero, hence it is integrable on every bounded measurable subset of \(\Delta_{R}\). It follows that \(l_{M}\) is integrable
relative to the invariant measure \( d\mu_n \) on \( T_n \) of total volume equal to 1; lastly, a simple inspection yields
\[
\lambda(B \otimes_{B_n} M) := \lim_{k \to +\infty} d_{k+n}^{-1} \cdot \lambda_{k+n}(B_{k+n} \otimes_{B_n} M) = d_{n}^{-1} \int_{T_n} l_M d\mu_n
\]
which shows that condition (a) of definition 14.5.64 holds for this choice of normalizing factors.

In order to check condition (b), set \( \Delta_R(\rho) := \{ v \in \Delta_R \mid \|v\| \leq \rho \} \) for every \( \rho > 0 \). Notice that the automorphism of \( \Delta_{R,G}^{gp} \) given by multiplication by \( p^n \) restricts to a bijection
\[
\Omega(\Delta_R, \Delta_n) \xrightarrow{\sim} \Omega(\Delta_R, \Delta_0)
\]
for every \( n \in \mathbb{N} \).

Then, by claim 6.3.40, we see that there exists \( \rho_0 \) such that
\[
(17.1.47) \quad \Delta_R(p^{-n}\rho_0) \subset \Omega_n \cap \Omega(\Delta_R, \Delta_n) \quad \text{for all } n \in \mathbb{N}.
\]
Especially, for every \( \rho \leq \rho_0 \) we may regard \( \Delta_R(p^{-n}\rho) \) as a measurable subset of \( T_n \), whose measure \( \text{Vol}(\rho) \) is strictly positive and independent of \( n \).

**Claim 17.1.48.** Let \( I \subset B_n^{sh} \) be any finitely generated \( m_{B_n^{sh}} \)-primary ideal. Then there exists a real constant \( C_I > 0 \) such that
\[
d_n^{-1} \cdot \text{length}_{B_n^{sh}}(B_n^{sh} / (I + m)B_n^{sh}) \leq C_I \quad \text{for every } n \in \mathbb{N}.
\]

**Proof of the claim.** On the one hand, we may write \( B_n^{sh} \) as the direct sum of the \( B_n^{sh} \)-modules \( A_{\gamma} \otimes_{B_o} B_n^{sh} \), for \( \gamma \) ranging over the elements of \( \Delta_R^{gp} / \Delta_{R,G}^{gp} \). There are \( p^n \) such direct sums, and each of them admits a generating system of cardinality \( \leq N \), where \( N \) is the constant provided by lemma 17.1.38. It follows that
\[
\text{length}_{B_n^{sh}}(B_n^{sh} / (I + m)B_n^{sh}) \leq Np^n \cdot \text{length}_{B_0^{sh}}(B_0^{sh} / (I + mB_0^{sh})).
\]
On the other hand, say that \( l := \text{length}_{B_n^{sh}}(B_n^{sh} / (I + m)B_n^{sh}) \); this means that may find a filtration of \( B_n^{sh} / (I + m)B_n^{sh} \) of length \( l \), consisting of \( B_n^{sh} \)-submodules, whose graded subquotients are all isomorphic to \( \kappa(B_n^{sh}) \). Given such a filtration, we easily obtain a filtration of \( B_n^{sh} / (I + m)B_n^{sh} \) of length \( l \cdot [\kappa(B_n^{sh}) : \kappa(B_0^{sh})] \), consisting of \( B_0^{sh} \)-submodules, whose graded subquotients are all isomorphic to \( \kappa(B_0^{sh}) \). Therefore
\[
l \cdot [\kappa(B_n^{sh}) : \kappa(B_0^{sh})] = \text{length}_{B_n^{sh}}(B_n^{sh} / (I + m)B_n^{sh})
\]
whence the claim. \( \diamond \)

Now, fix \( \varepsilon > 0 \), and suppose there is given a finitely generated \( m_{B_0^{sh}} \)-primary ideal \( I \subset B_0^{sh} \), and a surjection of finitely presented \( B_n^{sh} / IB_n^{sh} \)-modules \( M \to M' \), generated by \( k \) elements, such that
\[
d_n^{-1} \cdot (\lambda_n(M) - \lambda_n(M')) > \varepsilon.
\]
Set \( C(I, k) := 2kC_A'C_I \), where \( C_A' \) and \( C_I \) are as in claims 17.1.45 and 17.1.48 since
\[
l_M(0) - l_{M'}(0) = \lambda_n(M) - \lambda_n(M')
\]
we may estimate:
\[
|\lambda(B_n^{sh} \otimes_{B_n^{sh}} M) - \lambda(B_n^{sh} \otimes_{B_n^{sh}} M')| \geq d_n^{-1} \cdot \int_{\Delta_R(p^{-n}\rho)} (l_M - l_{M'}) d\mu_n \geq \text{Vol}(\rho) \cdot (d_n^{-1} (l_M(0) - l_{M'}(0)) - C(I, k) \cdot p^{-n}\rho) \geq \text{Vol}(\rho) \cdot (\varepsilon - C(I, k) \cdot \rho)
\]
for every \( \rho \leq \rho_0 \). Therefore, if we set
\[
\rho(k, \varepsilon, I) := \min\{\rho_0, 2^{-1}C(I, k)^{-1}\varepsilon\}
\]
it is easily seen that the sought condition (b) holds with \( \delta(k, \varepsilon, I) := 2^{-1} \cdot \text{Vol}(\rho(k, \varepsilon, I)) \cdot \varepsilon. \) \( \square \)
17.2. **Almost purity: the log regular case.** In this section, we prove an almost purity theorem for certain towers of regular log schemes.

17.2.1. Let $M_0$ be a log structure on the Zariski site of a local scheme $X_0$, such that $(X_0, M_0)$ is regular at the closed point $x_0 \in X_0$, and say that $X_0 = \text{Spec } B_0$ for a local ring $B_0$ which is necessarily noetherian, normal and Cohen-Macaulay (corollary 12.5.13). Let also $\beta_0 : P \to B_0$ be a finite map. Indeed, in this case, for a suitable $\Phi := \text{Spec } X$, so the assertion follows from (i).

Notice that (b) implies that $B_0/pB_0$ is a finite dimensional $\kappa(x_0)$-vector space. Moreover, $(X_0, M_0)$ is a regular log scheme, by theorem 12.5.31.

**Example 17.2.2.** Let $(B, \beta)$ be a pair consisting of

(a) a local ring $B$ whose residue field $\kappa_B$ has positive characteristic

(b) a local morphism of monoids $\beta : P \to B$ from a fine, sharp and saturated monoid $P$.

Denote by $m_B$ the maximal ideal of $B$, by $M$ the logarithmic structure on the Zariski site of $X := \text{Spec } B$ induced by $\beta$, and suppose that $(X, M)$ is regular at the closed point of $X$.

(i) If moreover, $B$ is complete for the $m_B$-adic topology and $\kappa_B$ is perfect, then the Frobenius endomorphism $B/pB$ is a finite map. Indeed, in this case, for a suitable $d \in \mathbb{N}$ we have a surjective ring homomorphism

$$R[[P \times \mathbb{N}^d]] \to B$$

where $R$ is either $\kappa_B$, or a discrete valuation ring with an isomorphism $R/pR \cong \kappa_B$ (remark 12.5.12). The assertion is an immediate consequence.

(ii) It follows that for any such pair $(B, \beta)$ we may find a local ring $B_0$ and a local and flat ring homomorphism $f : B \to B_0$ such that the log scheme

$$(X_0, M_0) := \text{Spec } B_0 \times_X (X, M)$$

and its chart $\beta_0 := \beta \circ f : P \to B_0$ fulfill the conditions of (17.2.1). Indeed, according to [46 Ch.0, Prop.10.3.1] there exists a flat and local $B$-algebra $C$ such that $\kappa_B \otimes_B C$ is a perfect field, and we take $B_0$ to be the completion of $C$. By proposition 12.5.30(ii), the resulting log scheme $(X_0, M_0)$ is regular at the closed point of $X_0$, so the assertion follows from (i).

17.2.3. In the situation of (17.2.1), set

$$P^{(n)} := \{ \gamma \in P | \gamma^{p^n} \in P \} \quad \text{for every } n \in \mathbb{N}.$$  

The $p^n$-Frobenius map of $P^{(n)}$ identifies $P^{(n)}$ with its submonoid $P$; in other words, the inclusion map $P \to P^{(n)}$ is naturally identified with the $p^n$-Frobenius endomorphism of $P$. Fix a sequence $(f_1, \ldots, f_r)$ of elements of $B_0$ whose image in $A$ is maximal in the sense of remark 9.6.35(iii), in which case we say that $(f_1, \ldots, f_r)$ is maximal in $B_0$. Notice that $\dim_{\kappa(x_0)} m_A/m_A^2 = \dim A$, since $A$ is regular; it follows that

$$r = \dim A + \dim_{\kappa(x_0)} \Omega^1_{\kappa(x_0)/\mathbb{Z}}$$

by virtue of the short exact sequence (9.6.5), if $p \in m_A^2$, and otherwise, by virtue of proposition 9.6.17. Denote also by $\bar{f}_i \in A$ the image of $f_i$, for every $i = 1, \ldots, r$. According to corollary 9.6.34 the ring

$$A_n := A[T_1, \ldots, T_r]/(T_1^{p^n} - \bar{f}_1, \ldots, T_r^{p^n} - \bar{f}_r)$$
is a local ring, and we denote by \( m \) finite, so every point of \( \text{Spec} B \).

**Lemma 17.2.4.** The induced maps

\[
B_n \to B_{n+1} \quad \text{and} \quad B_n/pB_n \to B_{n+1}/pB_{n+1}
\]

are injective, for every \( n \in \mathbb{N} \).

**Proof.** The natural map \( B_n \to B_{n+1} \) factors as the composition

\[
B'_n \otimes_{B_0} B''_n \to B'_n \otimes_{B_0} B''_n \to B'_n \otimes_{B_0} B''_n + 1 \quad \text{for every} \ n \in \mathbb{N}.
\]

Notice that \( B_0 = B'_n \), and \( B_{n+1}'' \) is a free \( B''_n \)-module (of rank \( P^n \)) for every \( n \in \mathbb{N} \); we are then reduced to checking that the maps \( B'_n \to B''_n \) and \( B'_n/pB_n \to B''_n/pB_n + 1 \) are injective for every \( n \in \mathbb{N} \). However, set \( G := P^{(n+1)}/P^{(n)} \), and notice that \( P^{(n+1)} \) is a \( G \)-graded monoid, with \( P^{(n+1)} = P^{(n)} \), hence \( B''_n \) is a \( G \)-graded \( B''_n \)-algebra with \( (B''_n)_0 = B'_n \) for every \( n \in \mathbb{N} \). The assertion follows.

**17.2.5.** In view of lemma 17.2.4, we may set

\[
B^n := \bigcup_{n \in \mathbb{N}} B''_n \quad B := \bigcup_{n \in \mathbb{N}} B_n \quad P^{(\infty)} := \bigcup_{n \in \mathbb{N}} P^{(n)}
\]

and clearly

\[
B = P^{(\infty)} \otimes_{P} B'' \quad \text{for every} \ n \in \mathbb{N}
\]

from which we see that \( B \) is naturally a \( P^{(\infty)} / P^{(n)} \)-graded \( B_n \)-algebra, for every \( n \in \mathbb{N} \). Also, the induced morphism \( \text{Spec} B_{n+1}/pB_{n+1} \to \text{Spec} B_n/pB_n \) is radicial and surjective, so \( \text{Spec} B_n/pB_n \) is a local scheme for every \( n \in \mathbb{N} \); on the other hand, the map \( B_0 \to B_n \) is finite, so every point of \( \text{Spec} B_n \) specializes to a point of \( \text{Spec} B_n/pB_n \). We conclude that \( B_n \) is a local ring, and we denote by \( mB_0 \) its maximal ideal, for every \( n \in \mathbb{N} \). Let \( M_n \) be the log structure on the Zariski site of \( X_n := \text{Spec} B_n \) deduced from the natural map \( \beta : P^{(n)} \to B_n \); notice that \( B_n/mP^{(n)}B_n = A_n \) is a regular local ring of dimension equal to \( dim A \). Since we have as well \( dim P^{(n)} = dim P \), it follows that \( (X_n, M_n) \) is regular at the closed point \( x_n \in X_n \). Then theorem 12.5.31 shows that \( (X_n, M_n) \) is a regular log scheme. Thus, we have obtained a tower of finite morphisms of regular log schemes

\[
\cdots \to (X_{n+1}, M_{n+1}) \to (X_n, M_n) \to \cdots \to (X_0, M_0)
\]

which we call the maximal tower associated with the chart \( \beta_0 : P \to B_0 \) and the maximal sequence \((f_1, \ldots, f_r)\). The limit of the tower (17.2.6) is a log scheme \((X, \underline{M})\) whose log structure admits a chart \( P^{(\infty)} \to B \) which is sharp at the closed point.

**Remark 17.2.7.** Keep the notation of (17.2.5), and let \( s \in \mathbb{N} \) be any integer; from remark 9.6.35(iii) it is easily seen that the sequence \((X_{n+s}, M_{n+s}) \mid n \in \mathbb{N}\), obtained by removing from (17.2.6) the first \( s \) terms, is the maximal tower associated with the chart \( \beta_n \) and the maximal sequence \((f_1^{1/p}, \ldots, f_r^{1/p^n})\).

**17.2.8.** Let now \( y \in (X_0, \underline{M}_0)_t \) be any point, and \( n \in \mathbb{N} \) any integer. The chart \( \beta_0 \) extends uniquely to a morphism of monoids \( \beta_{0,y}^GP : P^{GP} \to B_{0,y} \), and we have a natural isomorphism

\[
B_n \otimes_{B_0} B_{0,y} \to P^{(n)GP} \otimes_{P^{GP}} B_{0,y} \otimes_{B_0} B_n
\]

Especially, \( B_n \otimes_{B_0} B_{0,y} \) is a free \( B_{0,y} \)-module of rank \( p^{nd} \), where

\[
d := \dim P + r = \dim P + dim A + dim_{\Omega_1^{(y)}} \Omega_{n(x_0)}^{(x_0)}/\mathbb{Z}.
\]
However, since \((X_0, M_0)\) is regular, we have \(\dim A + \dim P = \dim B_0\). Summing up, we find
\[
d = \dim B_0 + \dim \kappa(x_0) \Omega^1_{\kappa(x_0)/\mathbb{Z}}.
\]
Next, let \(z \in \text{Spec } B_0/pB_0 \subset X_0\) be any point, and \(p_z \subset B_0\) the corresponding prime ideal; as in the foregoing, the chart \(\beta_0\) extends uniquely to a morphism \(\beta_p : P_p \to B_{0,z} := \mathcal{O}_{X_0,z}\), where \(p := \beta_0^{-1}p_z\). As already remarked, the point \(z\) lifts uniquely to a point \(z_n \in X_n\), and on the other hand, there exists a unique prime ideal \(p^{(n)} \subset P^{(n)}\) containing \(p\), and the inclusion map \(j_p : P_p \to P^{(n)}\) is naturally identified with the \(p^n\)-Frobenius endomorphism of \(P_p\). By lemma 6.2.10 there exists an isomorphism of monoids \(P^{(n)} \iso G \times Q\), with \(G := P^{(n)}_p\) and \(Q := P^{(n)}_p\); we may then find a corresponding decomposition \(P^{(n)}_p = G^{(n)} \times Q^{(n)}\) that identifies \(j_p\) with the product of maps of monoids \(G \to G^{(n)}\) and \(Q \to Q^{(n)}\). Summing up, there follows an isomorphism of \(B_0\)-algebras
\[
\mathcal{O}_{X_n,z_n} \iso P^{(n)}_p \otimes_{P_p} B_{0,z} \otimes_{B_0} B''_n \iso (Q^{(n)} \otimes Q B_{0,z}) \otimes_{B_{0,z}} (G^{(n)} \otimes_G B_0,z) \otimes_{B_0} B''_n.
\]
Fix a basis \(g_1, \ldots, g_s\) of the free \(\mathbb{Z}\)-module \(G\), and set \(f_{r+i} := \beta_p(g_i)\) for \(i = 1, \ldots, s\); clearly
\[
(G^{(n)} \otimes_G B_{0,z}) \otimes_{B_0} B''_n = B_{0,z}[T_1, \ldots, T_{r+s}]/(T_1^{p^n} - f_1, \ldots, T_{r+s}^{p^n} - f_{r+s}).
\]
On the other hand, set \(A_z := B_0/QB_{0,z}\); we have
\[
\dim P = \dim B_0 + \dim Q + s \quad \text{(corollary 6.4.10(i))}
\]
\[
\dim B_{0,z} = \dim Q + \dim A_z \quad \text{(since \((X_0, M_0)\) is regular)}
\]
\[
\dim B_{0,z} = d - \dim \kappa(z) \Omega^1_{\kappa(z)/\mathbb{Z}} \quad \text{(proposition 9.7.20)}
\]
Therefore \(r + s = \dim A_z + \dim \kappa(z) \Omega^1_{\kappa(z)/\mathbb{Z}}\). However, \(A_{z_n} := \mathcal{O}_{X_n,z_n}/m_Q \mathcal{O}_{X_n,z_n}\) is a regular local ring, since \((X_n, M_n)\) is regular, and by inspecting the construction we see that
\[
A_{z_n} = A_z[T_1, \ldots, T_{r+s}]/(T_1^{p^n} - f_1, \ldots, T_{r+s}^{p^n} - f_{r+s})
\]
hence the image of the system \((f_1, \ldots, f_{r+s})\) yields a basis of either \(\Omega^1_{A_z/\mathbb{Z}} \otimes_{A_z} \kappa(z)\) or \(\Omega_{A_z}\), depending on whether or not \(p \in m^2\) (corollary 9.6.34). In conclusion, we see that the induced sequence of morphisms of log schemes
\[
\cdots \to (X_{n+1}(z_n), M_{n+1}(z_n)) \to (X_n(z_n), M_n(z_n)) \to \cdots \to (X_0(z), M_0(z))
\]
(notation of (12.7.11)) is the maximal tower associated with the induced chart \(Q \to \mathcal{O}_{X_0,z}\) and the maximal sequence \((f_1, \ldots, f_{r+s})\).

Remark 17.2.9. (i) Let \(\pi_0\) be any geometric point of \(X_0\), localized at \(x_0\), and denote by \(B_0^{\text{sh}}\) the strict henselization of \(B_0\) at the point \(\pi_0\). In light of [59] Th.3.5.13(ii)], we see that the log scheme \((X_0(\pi_0), M_0(\pi_0))\) still fulfills the conditions of (17.2.1). Moreover, the image in \(B_0^{\text{sh}}\) of the maximal sequence \((f_1, \ldots, f_n)\) is still maximal (remark 9.6.35(iv)). It follows easily that the induced tower of regular log schemes\
\[
\cdots \to X_0(\pi_0) \times_{X_0} (X_{n+1}, M_{n+1}) \to X_0(\pi_0) \times_{X_0} (X_n, M_n) \to \cdots \to (X_0(\pi_0), M_0(\pi_0))
\]
is (naturally isomorphic to) the maximal tower associated with the induced chart \(P_0 \to B_0^{\text{sh}}\) and the maximal sequence \((f_1, \ldots, f_n)\) of \(B_0^{\text{sh}}\).

(ii) In the same vein, let \(I \subset B_0\) be any proper ideal, \(B_0^I\), the \(I\)-adic completion of the local ring \(B_0\), and set \(X_0^I := \text{Spec } B_0^I\); according to claim 9.7.21(i), the log scheme \((X_0^I, M_0^I) := X_0^I \times_{X_0} (X_0, M_0)\) still fulfills the conditions of (17.2.1), and the image in \(B_0^{sh}\) of the maximal sequence \((f_1, \ldots, f_n)\) of \(B_0\) is still maximal (remark 9.6.35(iv)). It follows that the induced tower of log schemes
\[
\cdots \to X_0^I \times_{X_0} (X_{n+1}, M_{n+1}) \to X_0^I \times_{X_0} (X_n, M_n) \to \cdots \to (X_0^I, M_0^I)
\]
is (naturally isomorphic to) the maximal tower associated with the induced chart \( P_0 \to B_{0,1}^\wedge \) and the maximal sequence \( (f_1, \ldots, f_n) \) of \( B_{0,1}^\wedge \).

17.2.10. Let \( \Phi_{B_n} : B_n/pB_n \to B_n/pB_n \) be the Frobenius endomorphism of \( B_n/pB_n \); taking into account lemma 17.2.4, we see that \( \Phi_{B_{n+1}} \) factors through a unique ring homomorphism
\[
\Psi_{B_{n+1}} : B_{n+1}/pB_{n+1} \to B_n/pB_n \quad \text{for every } n \in \mathbb{N}.
\]

**Lemma 17.2.11.** The map \( \Psi_{B_{n+1}} \) is surjective for every \( n \in \mathbb{N} \).

**Proof.** Let us start out with the following general:

**Claim 17.2.12.** Let \( \varphi : R \to S \) be an injective, finite and radicial ring homomorphism. Then \( \varphi \) is an isomorphism if and only if \( \Omega_{S/R}^1 = 0 \).

**Proof of the claim.** We may assume that \( \Omega_{S/R}^1 = 0 \), and we show that \( \varphi \) is an isomorphism. To this aim, it suffices to show that
\[
\varphi \otimes_R R/m : R' := R/m \to S' := S/mS
\]
is an isomorphism for every maximal ideal \( m \subset R \). However, \( \Omega_{S/R}^1 = \Omega_{S/R}^1 \otimes_R R' = 0 \), so we may replace \( R \) by \( R' \) and \( S \) by \( S' \), and assume from start that \( R \) is a field. In this case, \( S \) is a local unramified \( R \)-algebra, so \( S \) must be a finite separable field extension of \( R \), by [51] Ch.IV Cor.17.4.2. But \( S \) is also a radical extension of \( R \), so \( S = R \).

**Claim 17.2.13.** Let \( p > 0 \) be a prime integer, \( R \) a local \( \mathbb{F}_p \)-algebra whose Frobenius endomorphism \( \Phi_R \) is a finite map, \( k_R \) the residue field of \( R \), and \( \Sigma \subset R \) any subset. Set \( R_0 := R/\Sigma R \), and let \((g_1, \ldots, g_n)\) be a finite sequence of elements of \( R \) such that \( dg_1, \ldots, dg_n \) is a system of generators for the \( k_R \)-vector space \( \Omega_{R_0/Z}^1 \otimes_R k_R \). Then \( R = R^p[\Sigma, g_1, \ldots, g_n] \).

**Proof of the claim.** Set \( S := R^p[\Sigma, g_1, \ldots, g_n] \). The inclusion map \( S \to R \) is clearly radicial, and it is finite, since \( \Phi_R \) is finite; hence claim [17.2.12] reduces to checking that \( \Omega_{S/R}^1 \) vanishes. By Nakayama’s lemma, it then suffices to show that \( \Omega_{S/R}^1 \otimes_R k_R = 0 \). However, let \( M \) (resp. \( N \)) be the \( R \)-submodule of \( \Omega := \Omega_{R/Z}^1 \) generated by \( \{ da \mid a \in \Sigma \} \) (resp. \( \{ dg_1, \ldots, dg_n \} \)); then \( \Omega_{R/S}^1 = \Omega/(M + N) \) (43 Ch.0, Th.20.5.7(i)) and on the other hand, the induced map \( (\Omega/M) \otimes_R R_0 \to \Omega_{R_0/Z}^1 \) is an isomorphism (43 Ch.0, Th.20.5.12(i)). We deduce a right exact sequence of \( R \)-modules
\[
N \to \Omega_{R_0/Z}^1 \otimes_R k_R \to \Omega_{R/S}^1 \otimes_R k_R \to 0.
\]
But our choice of the sequence \((g_1, \ldots, g_n)\) implies that \( j \) is surjective, whence the contention.

Finally, notice that the image of \( \Psi_{B_{n+1}} \) is the subring \((B_n/pB_n)^p[\beta_n(P(n)), f_1^{1/p^n}, \ldots, f_r^{1/p^n}]\). For every \( n > 0 \), consider the exact sequence
\[
\Omega_{A/Z}^1 \otimes_A \kappa(x_n) \to \Omega_{A_{n+1}/Z}^1 \otimes_{A_n} \kappa(x_n) \to \Omega_{A_{n+1}/A}^1 \otimes_{A_n} \kappa(x_n) \to 0
\]
(43 Ch.0, Th.20.5.7(i)); the image of \( j \) is generated by the image of the generating system \( df_i := (df_1, \ldots, df_r) \) of the \( \kappa(x_0) \)-vector space \( \Omega_{A/Z}^1 \otimes \kappa(x_0) \). However, since \( f_i \) admits a \( p \)-th root in \( A_n \) for every \( i = 1, \ldots, r \), it is easily seen that the image of \( df_i \) vanishes in \( \Omega_{A/Z}^1 \). Hence \( \Omega_{A_{n+1}/Z}^1 \otimes A_n \kappa(x_n) = \Omega_{A_{n+1}/Z}^1 \otimes A_n \kappa(x_n) \) is generated by the image of the system \((df_1^{1/p^n}, \ldots, df_r^{1/p^n})\). Therefore, to prove the lemma, it suffices to apply claim 17.2.13 to \( R := B_n/pB_n \), \( \Sigma := \beta_n(m_{P(n)}) \) and the sequence \((f_1^{1/p^n}, \ldots, f_r^{1/p^n})\).

**Theorem 17.2.14.** With the notation of (17.2.5), we have:

(i) If \( B_0 \) is an \( \mathbb{F}_p \)-algebra, \( \Psi_{B_n} \) is an isomorphism for every \( n \in \mathbb{N} \).
(ii) If $B_0$ is not an $\mathbb{F}_p$-algebra, then there exist $\pi \in B_1$ and $u \in B_1^\times$ such that $\pi^p = pu$.

(iii) For every $\pi \in B_1$ as in (ii) and every integer $n > 0$, we have $\operatorname{Ker} \Psi_{B_n} = \pi B_n/pB_n$.

(iv) Let $\mathcal{I}_{p,B}$ be the $p$-adic topology of $B$. Then $(B, \mathcal{I}_{p,B})$ is a formal perfectoid ring.

**Proof.** (i) is immediate from lemma [17.2.11] since in that case $\Phi_{B_n}$ is the Frobenius endomorphism of $B_n$, so it is injective, since the latter is a domain.

(iii): Suppose we have found $\pi$ as in (ii), and let $x \in B_n$ whose image in $B_n/pB_n$ lies in $\operatorname{Ker} \Psi_{B_n}$; this means that $x^p = py$ holds in $B_n$ for some $y \in B_n$; hence $(x/\pi)^p \in B_n$, and since $B_n$ is a normal ring (corollary [12.5.13]), we deduce that $x/\pi \in B_n$, i.e. $x \in \pi B_n$.

(ii): Assume first that $p \in m_A^2$. Then we may write

$$p = \sum_{i=1}^t b_i b_i' + \sum_{j=1}^s b_j'' \beta_0(x_j)$$

for certain $b_1, b_1', \ldots, b_t, b_t' \in m_{B_0}, b_1', \ldots, b_t' \in B_0,$ and $x_1, \ldots, x_s \in m_P$. In light of lemma [17.2.11] we may then write

$$b_i = c_i^p + pd_i \quad b_i' = c_i^p + pd_i' \quad \text{where } c_i, c_i', d_i, d_i' \in m_{B_1} \text{ for every } i = 1, \ldots, t$$

and likewise, $b_j'' = c_j'' + pd_j''$ where $c_j'' \in B_1$ for $j = 1, \ldots, s$. Moreover, by construction, $\beta_0$ extends to a morphism of monoids $\beta_1 : P^{(1)} \to B_1$, and we may write $x_j = y_j^p$ with $y_j \in m_{P^{(1)}}$ for $j = 1, \ldots, s$. A simple computation then yields

$$(17.2.15) \quad p \cdot (1 + e) = \sum_{i=1}^t c_i^p c_i^p + \sum_{j=1}^s c_j''' \beta_1(y_j)^p \quad \text{for some } e \in m_{B_1}.$$ 

However, the right-hand side of $(17.2.15)$ can be written in the form $g^p + ph$ for some $g, h \in m_{B_1}$ (details left to the reader); clearly $1 + e - h \in B_1^\times$, whence the contention, in this case.

Next, suppose that $p \notin m_A^2$. In this case, recall that

$$\dim_{\kappa(x_0)^{1/p}} \Omega_A = 1 + \dim_{\kappa(x_0)} \Omega_A^1 \otimes_A \kappa(x_0).$$

Therefore, after reordering the sequence $(f_1, \ldots, f_r)$, we may assume that $df_1, \ldots, df_{r-1}$ is a basis of the $\kappa(x_0)$-vector space $\Omega_A^1 \otimes_A \kappa(x_0)$. Set

$$B' := (P^{(1)} \otimes P B_0)[T_1, \ldots, T_{r-1}]/(T_1^p - f_1, \ldots, T_{r-1}^p - f_{r-1}).$$

Clearly $B_1$ is a faithfully flat $B'$-algebra, hence $B'/pB'$ is a $B_0/pB_0$-subalgebra of $B_1/pB_1$, so the natural map $B_0/pB_0 \to B'/pB'$ is injective (lemma [17.2.4]), and just as in (17.2.5), we deduce that the Frobenius endomorphism of $B'/pB'$ factors through a ring homomorphism $\Psi_{B'} : B'/pB' \to B_0/pB_0$, and arguing as in the foregoing, we also see that $B'$ is a local ring. Moreover, by applying claim [17.2.13] with $R := B'/pB'$, $\Sigma := \beta_0(m_P)$ and the sequence $(f_1, \ldots, f_{r-1})$ we conclude – as in the proof of lemma [17.2.11] – that $\Psi_{B'}$ is surjective. Hence, denote by $m_{B'}$ the maximal ideal of $B'$; it follows that there exist $g \in m_{B'}$ and $h \in B'$ such that $f_r = g^p + ph$ in $B'$. Set

$$A' := B'/m_{p^{(1)}} B' = A[T_1, \ldots, T_{r-1}]/(T_1^p - f_1, \ldots, T_{r-1}^p - f_{r-1}).$$

Then $A'$ is a regular local ring, by corollary [9.6.34], applied to the sequence $(\overline{f}_1, \ldots, \overline{f}_{r-1})$ consisting of the images of the elements $f_i$ in $A$. By the same criterion – applied to the similar sequence $(\overline{f}_1, \ldots, \overline{f}_r)$ – we see that $A'[T]/(T^p - f_r)$ is regular as well. So once again the same corollary – applied to the element $\overline{f}_r$ of $A'$ – says that the element $d(f_r) \in \Omega_{A'}$ does not vanish. However

$$d(f_r) = d(g^p) + d(ph) = pg^{p-1}d(g) + h d(p) + pd(h) = hd(p) \quad \text{in } \Omega_{A'}$$

where
(see (9.6.16)). We conclude that \(h \in B^{*k}\). Lastly, notice that \(f_r\) admits a \(p\)-th root \(f_r^{1/p}\) in \(B_1\), hence \(ph = f_r - g^n = (f_r^{1/p} - g^p + pe)\) in \(B_1\) for some \(e \in \mathfrak{m}_{B_1}\) (details left to the reader). Since \(h - e \in B_1^*\), we are done.

(iv): If \(B_0\) is an \(\mathbb{F}_p\)-algebra, then \(\mathcal{T}_{p,B}\) is the discrete topology, and \(B\) is a perfect \(\mathbb{F}_p\)-algebra, whence the assertion in this case. Suppose then that \(B_0\) is not an \(\mathbb{F}_p\)-algebra, in which case the topology of the completion \(B^\wedge\) of \((B, \mathcal{T}_{p,B})\) is still \(p\)-adic (remark 8.3.3(iv)). Pick \(\pi \in B_1\) as in (ii), set \(I := \pi B^\wedge\), and notice that \(\pi\) is a regular element of \(B^\wedge\), by proposition 8.2.13): the details shall be left to the reader. In light of (iii), it is easily seen that \(B^\wedge\) is a \(\mathbb{P}\)-ring, \(I\) is a special ideal of definition, and the Frobenius endomorphism of \(B^\wedge\) : \(pB^\wedge = B/pB\) induces an isomorphism \(B^\wedge/I \xrightarrow{\sim} B^\wedge/I^{(p)}\). The assertion then follows from theorem 16.4.1.

17.2.16. Let \(\beta : P^{(\infty)} \to B\) be the chart of the log structure \(\mathcal{M}\) on \(X\) from (17.2.3), and notice that the inclusion map \(P^{(n)} \to P^{(\infty)}\) induces bijections \(\text{Spec } P^{(n)} \xrightarrow{\sim} \text{Spec } P^{(\infty)}\) for every \(n \in \mathbb{N}\) (lemma 6.4.57(i)); especially, \(\text{Spec } P^{(\infty)}\) is a finite set. Let \(I \subset B\) be any non-zero ideal; we say that \(I\) is a branch ideal, if there exist radical ideals \(J \subset B\) and \(r \subset P^{(\infty)}\) such that

\[
p \in J \quad \text{and} \quad I = J \cap rB.
\]

**Remark 17.2.18.** (i) Notice that, in case \(B_0\) is an \(\mathbb{F}_p\)-algebra, a branch ideal is just any non-zero radical ideal of \(B\).

(ii) Let \(I \subset B\) be a branch ideal, and pick radical ideals \(J \subset B\) and \(r \subset P^{(\infty)}\) such that (17.2.17) holds. Set \(r^{(n)} := r \cap P^{(n)}\) for every \(n \in \mathbb{N}\); from corollary 12.5.20(ii) we know that \(r^{(n)}B_0\) is a radical ideal of \(B_0\), hence \(rB\) is a radical ideal of \(B\), and then the same holds for \(I\).

(iii) In the situation of (ii), let \(\mathfrak{J} \subset \text{Spec } P^{(\infty)}\) be a subset such that \(r = \bigcap_{p \in \mathfrak{J}} p\) (lemma 6.1.16), and set \(p^{(n)} := p \cap P^{(n)}\) for every \(p \in \mathfrak{J}\) and every \(n \in \mathbb{N}\), so \(r^{(n)} = \bigcap_{p \in \mathfrak{J}} p^{(n)}\) for every \(n \in \mathbb{N}\). In view of proposition 12.5.16 and lemmata 12.5.1 and 6.1.38 we see that

\[
r^{(n)}B = \bigcap_{p \in \mathfrak{J}} p^{(n)}B_0,
\]

and therefore

\[
rB = \bigcap_{p \in \mathfrak{J}} pB.
\]

(iv) Furthermore, any branch ideal \(I \subset B\) is the radical of \(I_0B\), for some ideal \(I_0 \subset B_0\). Indeed, pick \(J\) and \(r\) such that (17.2.17) holds; since the projection \(\text{Spec } B/pB \to (X_0)/p\) is radical and surjective, it is clear that \(J\) is the radical of \(J_0B\) for some ideal \(J_0 \subset B_0\), and on the other hand, \(rB\) is the radical of \(r^{(0)}B\).

**Proposition 17.2.20.** With the notation of (17.2.16), let \(I \subset B\) be any branch ideal. We have :

(i) \(I^2 = I\), and \(I\) fulfills condition (B) of [59 §2.1.6].

(ii) Let \(I_1, I_2 \subset B\) be any two branch ideals. Then \(I_1 \cap I_2\) and \(I_1 + I_2\) are also branch ideals, and \(I_1I_2 = I_1 \cap I_2\).

**Proof.** (i): By assumption, \(I = J \cap rB\) for radical ideals \(J \subset B\) and \(r \subset P^{(\infty)}\) with \(p \in J\).

**Claim 17.2.21.** \((\tau B)^2 = \tau B\) and \(J^2 = J\), and the ideals \(\tau B\) and \(J\) fulfill condition (B).

**Proof of the claim.** Since the \(p\)-Frobenius endomorphism of \(P^{(\infty)}\) is an automorphism, the first stated identity is clear. Next, set \(\tilde{J} := J/pB\). By lemma 17.2.11 the Frobenius endomorphism of \(B/pB\) is surjective; since \(\tilde{J}\) is a radical ideal, we deduce that \(\tilde{J}^2 = \tilde{J}\). On the other hand, from theorem 17.2.14(ii) we see that \(p \in J^2\), from which also the second identity follows easily.

Next, it is clear that \(\tau B\) fulfills condition (B), and for \(J\) we apply [59 Claim 2.1.9] which reduces checking that \(J/pJ\) is generated by the \(p\)-th powers of its elements. However, the foregoing already shows that \(J/pB\) is generated by the \(p\)-th powers of its elements; combining with theorem 17.2.14(ii), the contention follows easily. \(\Diamond\)
Taking into account remark \[17.2.18\](i), we see that claim \[17.2.21\] already implies the assertion, in case \(B_0\) is an \(\mathbb{F}_p\)-algebra. Thus, we may assume that \(B_0\) is not an \(\mathbb{F}_p\)-algebra, in which case – again by claim \[17.2.21\] – it suffices to show that \(J \cap \pi B = \pi \cdot J\), or equivalently, that:

\[ \text{Tor}^C_1(B/\pi B, B/J) = 0. \]

Now, the chart \(\beta\) yields a ring homomorphism \(C := \mathbb{Z}[P^{(\infty)}] \to B\), and we have a base change spectral sequence for Tor-functors (see [125 Th.5.6.6]):

\[ E^n_{pq} := \text{Tor}^B_p(\text{Tor}^C_q(C/\pi C, B), B/J) \Rightarrow \text{Tor}^C_{p+q}(C/\pi C, B/J). \]

\textbf{Claim 17.2.22.} \(\text{Tor}^C_q(C/\pi C, B) = 0\) for every \(q > 0\).

\textbf{Proof of the claim.} Set \(\pi(n) := \pi \cap P^{(n)}\) and \(C_n := \mathbb{Z}[P^{(n)}]\) for every \(n \in \mathbb{N}\). We have natural isomorphisms:

\[ \text{Tor}^C_q(C/\pi C, B) \cong \text{colim}_{n \in \mathbb{N}} \text{Tor}^C_{q,n}(C_n/\pi_n C, B_n) \quad \text{for every } q, n \in \mathbb{N} \]

so we are reduced to showing that \(\text{Tor}^C_{q,n}(C_n/\pi_n C, B_n) = 0\) for every \(q, n \in \mathbb{N}\) with \(q > 0\). The latter follows from propositions \[17.5.16\] and \[6.1.41\].

From claim \[17.2.22\] we see that \(E^2_{pq} = 0\) for every \(q > 0\) and every \(p \in \mathbb{N}\). Thus, we deduce a natural isomorphism:

\[ \text{Tor}^B_p(B/\pi B, B/J) \cong \text{Tor}^C_p(C/\pi C, B/J) \quad \text{for every } p \in \mathbb{N}. \]

By the same token, the projection \(C \to \overline{C} := C/pC\) induces a base change spectral sequence:

\[ F^n_{ij} := \text{Tor}^\overline{C}_i(\text{Tor}^C_j(C/\pi C, \overline{C}), B/J) \Rightarrow \text{Tor}^C_{i+j}(C/\pi C, B/J) \]

(notice that \(B/J\) is a \(\overline{C}\)-algebra, since \(p \in J\) and \(\text{Tor}^C_j(C/\pi C, \overline{C}) = 0\) for every \(j > 0\), since \(C/\pi C\) has no \(p\)-torsion. Hence \(F^n_{ij} = 0\) whenever \(j > 0\), and we get an isomorphism:

\[ \text{Tor}^\overline{C}_i(C/\pi \overline{C}, B/J) \cong \text{Tor}^C_i(C/\pi C, B/J) \quad \text{for every } i \in \mathbb{N}. \]

Notice now that \(\overline{C}\) is a perfect \(\mathbb{F}_p\)-algebra, since \(P^{(\infty)}\) is \(p\)-divisible, and with \(I_{\overline{C}} := \pi \overline{C}\) we have \(\overline{C}/\pi \overline{C} = \overline{C}/I_{\overline{C}}^0 \overline{C}\). Then \(\text{Tor}^\overline{C}_i(C/\pi \overline{C}, B/J) = 0\) for every \(i > 0\), by proposition \[16.4.7\] whence the contention.

(ii): It is clear that \(I_1 \cap I_2\) is a branch ideal; we have inclusions

\[ (I_1 \cap I_2)^2 \subset I_1 I_2 \subset I_1 \cap I_2 \]

and from (i) we know that the first ideal in this chain coincides with the third, so \(I_1 I_2 = I_1 \cap I_2\).

Next, for \(k = 1, 2\) let us write \(I_k = J_k \cap r_k B\), where \(J_k \subset B\) and \(r_k \subset P^{(\infty)}\) are radical ideals and \(p \in J_k\). Set \(Z_k := \text{Spec} B/J_k, Z'_k := \text{Spec} B/r_k B\) for \(k = 1, 2\); clearly

\[ Z := \text{Spec} B/(I_1 + I_2) \cong (Z_1 \cup Z_1') \cap (Z_2 \cup Z_2'). \]

Now let \(J \subset B\) be the largest ideal such that \(\text{Spec} B/J = (Z_1 \cap Z_2) \cup (Z_1 \cap Z_2') \cup (Z_1' \cap Z_2)\). It follows easily that

\[ Z = (\text{Spec} B/J) \cup (\text{Spec} B/(r_1 \cup r_2) B). \]

Now, \(J \) and \(r_1 \cup r_2\) are radical ideals, and \(p \in J\) so we deduce that the radical of \(I_1 + I_2\) is a branch ideal, and it remains only to show that \(I_1 + I_2\) is a radical ideal. However, notice the inclusions

\[ (r_1 J_1 + r_2 J_2)^2 \subset I := (J_1 + J_2)(J_1 + r_2 B)(r_1 B + J_2)(r_1 r_2 B) \subset (r_1 J_1 + r_2 J_2). \]

Especially, \(r_1 J_1 + r_2 J_2\) is contained in the radical \(I'\) of \(I\), Since we already know that \(r_k J_k = I_k\) for \(k = 1, 2\), it suffices to check that each of the four factors of the middle term in this chain of
inclusions is a branch ideal: indeed, in this case the same holds for $I$, and therefore $I = I'$, so finally $I = I_1 + I_2$.

- First, set $J := J_1 + J_2$, and let $J \subset B/pB$ be the image of $J$; since $p \in J$, in order to see that $J$ is a branch ideal, it suffices to check that $J$ is a radical ideal; then it suffices to prove that the same holds for $J$, and the latter assertion will follow, if we show that $\Phi_B^{-1}J = J$, where $\Phi_B : B/pB \to B/pB$ is the Frobenius endomorphism. Now, say that $x \in B/pB$ and $x^p \in J$; then $x^p = x_1 + x_2$ for some $x_i \in J_i := J_i/pB (i = 1, 2)$, and since $\Phi_B$ is surjective and $J$, is a radical ideal, we can write $x_i = y_i^p$ for some $y_i \in J_i$. Consequently, $x^p = (y_1 + y_2)^p$, so $x - y_1 - y_2$ is nilpotent; but clearly $J$ contains the nideal of $B/pB$, whence the claim.

- Next we consider $J' := J_1 + \tau_2B$; as in the previous case, since $p \in J$, we see that $J'$ is a branch ideal, provided $J'/pB$ is a radical ideal of $B/pB$. However, say that $x \in B/pB$ and $x^p = y + z$, for some $y \in J_1$ and $z \in \tau_2B/pB$; arguing as in the foregoing case, we may write $y = u^p$ for some $u \in J_1$. Likewise, since both $\Phi_B$ and the Frobenius endomorphism of $B/pB$ are surjective, we see that $z = w^p$ for some $w \in \tau_2B/pB$, so $x = u + w$ is nilpotent, and especially, it lies in $J_1$, whence the claim. The same argument applies as well to the factor $\tau_1B + J_2$.

- Lastly, since $\tau_1$ and $\tau_2$ are both radical ideals of $P(\infty)$, the same holds for $\tau_1 \tau_2B$; so $\tau_1 \tau_2B$ is a branch ideal.

Proposition 17.2.20(i) says that the pair $(B, I)$ is a basic setup, in the sense of [59, (2.1.1)], so we may consider the associated categories of almost modules and almost algebras.

17.2.23. Henceforth we shall restrict to the case where $B_0$ is not an $\mathbb{F}_p$-algebra, so $B_0$ is a local integral domain whose field of fractions has characteristic zero, and whose residue field has characteristic $p$. For every $n \in \mathbb{N}$, set

$$(X_n)_p := \text{Spec} B_n/pB_n \quad V_n := X_n \setminus (X_n)_p \quad V_{n, tr} := (X_n, M)^{\text{tr}}_{\text{n, fr}} \cap V_n.$$  

We consider now a finite morphism $\varphi_0 : Y_0 \to X_0$ with $Y_0$ a normal scheme, such that $\varphi_0$ maps each connected component of $Y_0$ onto $X_0$, and such that the restriction $\varphi_0^{-1}V_{0, tr} \to V_{0, tr}$ is a finite étale covering. For every $n \in \mathbb{N}$, we let $Y_n$ be the normalization of $X_n$ in $\varphi^{-1}V_{0, tr} \times_{X_0} X_n$, and denote by $\varphi_n : Y_n \to X_n$ the resulting finite morphism ([100, Lemma 1, p.262]), by

$$\varphi : Y \to X$$

the limit of the system $(\varphi_n | n \in \mathbb{N})$, and by $W_n \subset X_n$ the étale locus of $\varphi_n$, i.e. the largest open subset such that the restriction $\varphi_n^{-1}W_n \to W_n$ of $\varphi_n$ is an étale covering (lemma 13.1.7(iii) and claim 13.1.8). Let also $(X_{n, p} | p \in \text{Spec } P(n))$ be the logarithmic stratification of $(X_n, M_n)$ (see (12.5.35)) and set $V_{n, p} := X_{n, p} \cap V_n$ for every $n \in \mathbb{N}$ and every $p \in \text{Spec } P(n)$. We call $(V_{n, p} | p \in \text{Spec } P(n))$ the logarithmic stratification of $V_n$.

Lemma 17.2.24. With the notation of (17.2.23), the following holds:

(i) $V_n \setminus W_n$ is a union of strata of the logarithmic stratification of $V_n$, for every $n \in \mathbb{N}$.
(ii) $X_n \times_{X_m} W_m = W_n$ for every sufficiently large $m \in \mathbb{N}$ and every $n \geq m$.
(iii) For $m$ as in (ii), set $W := X \times_{X_m} W_m$, and let $I \subset B$ be the largest ideal such that $\text{Spec } B/I = X \setminus W$. Then $I$ is a branch ideal of $B$.

Proof. (i): Since every $X_{n, p}$ is irreducible (corollary 12.5.37(iii)), the same holds for each $V_{n, p}$. Hence, suppose that $V_{n, p} \setminus W_n$ contains a point $z$ of $V_{n, p}$, for some $p \in \text{Spec } P(n)$; we have to show that in this case $V_{n, p} \cap W_n = \emptyset$, and since $W_n$ is an open subset of $X_n$, it suffices to check that the generic point $\eta_n$ of $V_{n, p}$ does not lie in $W_n$. However, let $\eta$ be any geometric point localized at $\eta$; then $\eta$ lies in $W_n$ if and only if the induced morphism $\varphi_n \times_{X_n} X_n(\eta)$ is étale (claim 13.1.9). Let also $\overline{z}$ be a geometric point localized at $z$, and denote by $M_{n, z}$ (resp. $M_{n, \eta}$) the stalk at $\overline{z}$ (resp. $\overline{\eta}$) of the logarithmic structure of $(X_n(\overline{z}), M_n(\overline{z}))$ (resp. of $(X_n(\overline{\eta}), M_n(\overline{\eta}))$). Any
choice of a strict specialization morphism \( s : X_n(\eta) \to X_n(\zeta) \) induces a strict specialization map \( \sigma : M_{n,\pi} \to M_{n,\pi} \) (see (4.9.23)) that extends the specialization map \( \sigma : M_{n,\eta} \to M_{n,\eta} \). Since the natural maps \( M_{b,\pi} \to M_{b,\pi} \) and \( M_{b,\eta} \to M_{b,\eta} \) are isomorphisms (see (12.1.9)), and \( \sigma^{\text{str}} \) is an isomorphism (since \( z \) and \( \eta \) lie in the same stratum), the same holds for \( \sigma^{\text{str}} \), and therefore the induced map \( M_{b,\pi}^{\text{str}} \to M_{b,\pi}^{\text{str}} \) is bijective. Pick any geometric point \( \xi \) of \( X_n(\zeta) \) localized at the maximal point, and lift \( \xi \) to a geometric point \( \eta \) of \( X_n(\eta) \); in light of (13.3.52), we conclude that \( s \) induces an isomorphism

\[
\pi_1((X_n(\eta), M_{n}(\eta))_{\text{et}}, \xi) \cong \pi_1((X_n(\zeta), M_{n}(\zeta))_{\text{et}}, \xi).
\]

Therefore, \( \phi_n \times X_n X_n(\eta) \) is étale if and only if it is a trivial covering, if and only if the same holds for \( \phi_n \times X_n X_n(\zeta) \), if and only if \( z \in W_n \), whence the assertion.

(ii): For every \( n \in \mathbb{N} \), set

\[
\mathbf{3}_n := \{ p \in \text{Spec } P(n) \mid V_{n,p} \neq \emptyset \quad \text{and} \quad V_{n,p} \cap W_n = \emptyset \}.
\]

The continuous map \( \omega_n : \text{Spec } P((n+1)) \to \text{Spec } P(n) \) induced by the inclusion \( P(n) \to P(n+1) \) sends \( \mathbf{3}_{n+1} \) into \( \mathbf{3}_n \), for every \( n \in \mathbb{N} \). On the other hand, \( \omega_n \) is also a bijection of finite sets (lemmata 6.1.21(iii) and 6.4.57(i)); we conclude that \( \omega_n \) restricts to a bijection \( \mathbf{3}_{n+1} \to \mathbf{3}_n \) for every sufficiently large integer \( n \in \mathbb{N} \). For every \( n, m \in \mathbb{N} \) with \( n \geq m \), let \( g_{n,m} : X_n \to X_m \) be the transition morphism in the maximal tower (17.2.6), in light of (i), it follows that

\[
g^{-1}_{n,m}(V_m \cap W_m) = V_n \cap W_n \quad \text{for every sufficiently large } m \in \mathbb{N} \text{ and every } n \geq m.
\]

On the other hand, the restriction \( (X_n)/p \to (X_m)/p \) of \( g_{n,m} \) is radicial and surjective for every such \( n, m \in \mathbb{N} \), so the underlying continuous map is a homeomorphism; since the underlying topological spaces are noetherian, we see as well that

\[
g^{-1}_{n,m}(X_m)/p \cap W_n = (X_n)/p \cap W_n \quad \text{for every sufficiently large } m \in \mathbb{N} \text{ and every } n \geq m.
\]

Summing up, the assertion follows.

(iii): The assertion follows easily from (i) and (17.2.19). \( \square \)

17.2.26. Let \( I \subset B \) be a fixed branch ideal, and consider a pair \( (X, Z) \) with \( Z \subset \text{Spec } B/I \) and such that \( Z \) is constructible in \( X \). Clearly such a pair is normal (see definition [14.4.1](ii)), and we aim to show that \( (X, Z) \) is almost pure for the almost structure given by the basic setup \( (B, I) \) supplied by proposition [17.2.20]. This will be achieved in several steps.

To begin with, set \( U := X \setminus Z \), and let \( \mathcal{A} \) be any étale almost finitely presented \( O_\mathbf{X}^{\text{str}} \)-algebra. Set also \( U_I := X \setminus \text{Spec } B/I \); then \( \mathcal{A}_{U_I} \) is a finite étale \( O_{U_I} \)-algebra, \( U_I = X \times_{X_0} U_{I,0} \) for some open subset \( U_{I,0} \subset X_0 \) (remark [17.2.18](iv)), and a simple inspection shows that

\[
V_{0,\text{tr}} \subset U_{I,0}.
\]

Let \( \psi : U_I \to U_{I,0} \) be the natural projection; by [51] Ch.IV, Prop.17.7.8(ii)] and [50] Ch.IV, Th.8.8.2(ii)], and by virtue of remark [17.2.7], we may assume – after replacing \( (X_0, M_0) \) by \( (X_n, M_n) \) for some sufficiently large \( n \in \mathbb{N} \) – that there exists a coherent étale \( O_{U_{I,0}} \)-algebra \( \mathcal{A}_0 \) with an isomorphism \( \psi^* \mathcal{A}_0 \cong \mathcal{A}_{U_I} \) of \( O_{U_I} \)-algebras. Denote by \( Y_0 \) the normalization of \( X_0 \) in \( \text{Spec } \mathcal{A}_0(U_{I,0}) \); the resulting morphism \( \varphi_0 : Y_0 \to X_0 \) is finite (lemma 9.7.4(i)) and induces an isomorphism \( (\varphi_0, O_{Y_0})_{U_{I,0}} \cong \mathcal{A}_0 \). Especially, \( \varphi_0 \) is a morphism of the type contemplated in (17.2.23), and the resulting morphism \( \varphi : Y \to X \) induces an isomorphism \( (\varphi_0, O_{Y_0})_{U_I} \cong O_{U_I} \). However, we have as well \( \mathcal{A} = (\mathcal{A}_{U_I})^\nu \) (lemma [14.4.5](i)), and since \( Y \) is normal, there follows an isomorphism of \( O_{U_I}^{\text{str}} \)-algebras \( (\varphi_0, O_{Y_0})_{U_I} \cong \mathcal{A} \). Then proposition [14.4.8] and [59] Lemma 8.2.28 show that \( (X, Z) \) is almost pure if and only if the resulting \( O_{X_0}^{\text{str}} \)-algebra \( \varphi_0 O_{Y_0} \) is weakly unramified, for every such \( \varphi_0 \).
17.2.27. Keep the notation of \([17.2.26]\), and suppose now that \(B_0\) is strictly henselian; especially, the \(N\)-torsion subgroup \(\mu_N\) of \(B_0^\circ\) has cardinality equal to \(N\), for every \(N > 0\) such that \((N, p) = 1\). Let \(k > 0\) be any integer and write \(k = p^s \cdot q\), with \(s, q \in \mathbb{N}\) and \((q, p) = 1\); set \(Q := P\), let \(\nu : P \to Q\) be the \(k\)-Frobenius map, define
\[
C'_0 := Q \otimes_P B_0^\circ \quad C_0 := C'_0 \otimes_{B_0^\circ} B''_s
\]
and endow \(X'_0 := \text{Spec } C_0\) with the log structure \(M'_0\) deduced from the natural map \(Q \to C_0\). Notice that \(C_0\) is strictly henselian and the Frobenius endomorphism of \(C_0/pC_0\) is still a finite map (claim [9.7.21(i)]); also, since the induced map \(A \to C_0'/mQC_0'\) is an isomorphism, the image of the sequence \((f_1, \ldots, f_r)\) in \(C_0\) is still maximal, in the sense of \((17.2.26)\), and therefore \(C_0'/mQC_0'\) is still a regular local ring, by corollary [9.6.34]. Arguing as in \([17.2.25]\), we deduce that \((X'_0, M'_0)\) is a regular log scheme, and we may consider the maximal tower
\[
((X'_n, M'_n) \mid n \in \mathbb{N})
\]
associated with the chart \(Q \to C_0\) and the maximal sequence \((f_{1/p^s}, \ldots, f_{1/p^r})\) (see remark [9.6.35](iii)). So, \(X'_n = \text{Spec } C_n\) for a finite \(C_0\)-algebra \(C_n\), and \(M'_n\) is given by a chart \(Q'(n) \to C_n\), where \(Q'(n)\) is a submonoid of \(Q_0\) containing \(Q\), for every \(n \in \mathbb{N}\). For every \(n \in \mathbb{N}\), we set \(V_{n, tr} := V_{0, tr} \times_{X_0} X'_n\), we let \(Y'_n\) be the normalization of \(X'_n\) in \(Y_0 \times_{X_0} V_{n, tr}\), we denote by
\[
\varphi'_n : Y'_n \to X'_n \quad \text{and} \quad h_n : (X'_n, M'_n) \to (X_n, M_n)
\]
the resulting finite morphisms, and by \(\varphi' : Y' \to X'\) (resp. \(h : (X', M') \to (X, M)\)) the limit of the system of morphisms \((\varphi'_n \mid n \in \mathbb{N})\) (resp. the limit of the system \((h_n \mid n \in \mathbb{N})\)). Recall also that the induced morphism \(V'_{0, tr} \to V_{0, tr}\) is a torsor for the finite abelian group
\[
G := \text{Hom}_\mathbb{Z}(Q^{(\infty)}, \mu_k)
\]
(see [13.3.30]). Set
\[
C := \bigcup_{n \in \mathbb{N}} C_n \quad Q^{(\infty)} := \bigcup_{n \in \mathbb{N}} Q'(n).
\]
With this notation, we have
\[
Q^{(\infty)} = Q \otimes_P P^{(\infty)} \quad \text{and} \quad C = Q^{(\infty)} \otimes_P B''.
\]
Let also write \(Y = \text{Spec } D\) (resp. \(Y' = \text{Spec } D'\)) for a \(B\)-algebra \(D\) (resp. for a \(C\)-algebra \(D'\)). The morphism \(h : (X', M') \to (X, M)\) shall be called the standard covering of \((X, M)\) of degree \(k\).

**Lemma 17.2.28.** In the situation of \([17.2.27]\), set \(U' := X' \setminus h^{-1} Z\). The induced diagram
\[
\begin{array}{ccc}
\mathcal{O}_X^{\circ} \cdot \acute{\text{E}}t_{fr} & \xrightarrow{\rho} & \mathcal{O}_{X'}^{\circ} \cdot \acute{\text{E}}t_{fr} \\
\downarrow & & \downarrow \\
\mathcal{O}_X^{\circ} \cdot \acute{\text{E}}t_{fr} & \xrightarrow{\rho'} & \mathcal{O}_{X'}^{\circ} \cdot \acute{\text{E}}t_{fr}
\end{array}
\]
is 2-cartesian (notation of definition [14.4.2]).

**Proof.** A simple inspection shows that \(h_0\) factors through a morphism \((X'_0, M'_0) \to (X_s, M_s)\), and indeed we have natural isomorphisms of \((X', M')\)-schemes
\[
(X'_n, M'_n) \xrightarrow{\sim} (X'_0, M'_0) \times_{(X_s, M_s)} (X_{n+s}, M_{n+s}) \quad \text{for every } n \in \mathbb{N}
\]
that identify the transition morphisms \((X'_{n+1}, M'_{n+1}) \to (X'_n, M'_n)\) with the base change of the corresponding morphisms for the tower \(((X_{n+s}, M_{n+s}) \mid n \in \mathbb{N})\). In view of remark [17.2.7] we may then replace \((X_0, M_0)\) by \((X_s, M_s)\), and \(P\) by \(P^{(s)}\), and assume that \((k, p) = 1\), so also \((o(G), p) = 1\).
Suppose now that \((\varphi'_n, \theta'^n)_{\mathcal{U}_n}\) is in the essential image of the restriction functor \(\rho';\) by proposition 14.4.8, this means that \(D'\) is an étale almost finitely presented \((C, IC)^\alpha\)-algebra. Then, taking into account the discussion of (17.2.26) and recalling that \(\rho'\) and \(\rho\) are fully faithful (lemma 14.4.5(ii)), we are reduced to checking that \(D'\) is an étale almost finitely presented \((B, I)^\alpha\)-algebra.

However, the action of \(G\) on \(V'_{\mathcal{U}_n}\) is inherited by \(C\) and \(D'\), and clearly \(C^G = B\) and \(D'^G = D;\) by corollary 14.6.28(ii), it suffices therefore to show that the action of \(G\) on \(D'\) is horizontal. Denote

\[ G \to \text{Aut}(C) : \chi \mapsto \rho_\chi \]

the action of \(G\), let \(\chi \in G\) be any element, and \(J_\chi \subset C\) the ideal generated by all elements of the form \(\rho_\chi(c) - c\), for \(c\) ranging over all elements of \(C\). By the discussion in (13.3.30) we get

\[ \rho_\chi((q \otimes y) \otimes b) = \chi(q) \cdot (q \otimes y) \otimes b \quad \text{for every } q \in Q, y \in P^{(\infty)} \text{ and } b \in B''\]

Hence, \(J_\chi\) is the ideal generated by all elements of the form \((1 - \chi(q)) \cdot q \otimes y \otimes 1\), for all \(q \otimes y \in Q^{(\infty)}\). However, since \(\chi(q) \in \mu_k\) and \((k, p) = 1\), it is easily seen that \(1 - \chi(q)\) either vanishes, or else it is invertible in \(B_0;\) thus, denote by \(q_\chi \subset Q^{(\infty)}\) the ideal generated by all elements of the form \(q \otimes y\), with \(\chi(q) \neq 1\); it follows that

\[ J_\chi = q_\chi \cdot C.\]

**Claim 17.2.29.** \(q_\chi\) is a radical ideal.

**Proof of the claim.** Indeed, say that \((q \otimes y)^n \in q_\chi\), so there exist elements \(q_1 \otimes y_1\) and \(x_1\) of \(Q^{(\infty)}\) such that \((q \otimes y)^n = (q_1 \otimes y_1) \cdot x_1\) and \(\chi(q_1) \neq 1\). We may assume that \(n = p^t\) for some integer \(t \in \mathbb{N}\), and since \(Q^{(\infty)}\) is uniquely \(p\)-divisible, we may write \(q_1 \otimes y_1 = (q_2 \otimes y_2)^n\) and \(x_1 = x_2^n\) for some elements \(q_2 \otimes y_2\) and \(x_2\) of \(Q^{(\infty)}\), and then \(q \otimes y = (q_2 \otimes y_2) \cdot x_2\); however, clearly \(\chi(q_2) \neq 1\), whence the claim.

In view of claim 17.2.29, we may write \(q_\chi = q_1 \cap \cdots \cap q_s\), for certain \(q_1, \ldots, q_s \in \text{Spec } Q^{(\infty)}\) (lemma 6.1.16). Set \(\Omega := \{q_1, \ldots, q_s\};\) we also know that \((q \cap Q^{(\infty)}) \cdot C_n\) is a prime ideal of \(C_n\), for every \(q \in \Omega\) and every \(n \in \mathbb{N}\) (corollary 12.5.20(i)), therefore \(qC\) is a prime ideal of \(C\), for every \(q \in \Omega\). Especially, the induced map

\[(17.2.30) \quad C/\bigcap_{q \in \Omega} C/qC \to \prod_{q \in \Omega} C/C_q\]

is injective. Since, by assumption, \(D'\) is a flat \(C\)-algebra, it follows that the map of almost modules \(D' \otimes_C C/qC\) is a monomorphism. Summing up, we are reduced to checking that \(\chi\) acts trivially on \((D'/qD')^\alpha\), for every \(q \in \Omega\). However, set

\[ X'_q := \text{Spec } C/qC \quad \text{and } U'_q := X'_q \times_X U_q \quad \text{for every } q \in \Omega.\]

Suppose first that \(U'_q = \emptyset;\) in that case, set \(p := q \cap P^{(\infty)}\), and notice that \(q\) is the radical of the ideal \(p \cdot Q^{(\infty)}\), so \(qC\) is the radical of \(pC\), and therefore \(\text{Spec } (C/pC) \times_X U_I = \emptyset.\) However, the induced morphism \(\text{Spec } C/pC \to \text{Spec } B/pB\) is surjective, so \(\text{Spec } (B/pB) \cap U_I = \emptyset;\) since \(pB\) is a prime ideal of \(B,\) the latter means that \(I \subset pB,\) whence \((B/pB)^\alpha = 0,\) so \((D'/qD')^\alpha\) vanishes as well, and the assertion is trivial. If \(U'_q \neq \emptyset;\) set \(Y'_q := Y' \times_X X'_q;\) let \(\varphi'_q : Y'_q \to X'_q\) be the induced morphism, and define

\[ B := \varphi_* \mathcal{O}_Y \quad B' := \varphi'_* \mathcal{O}_{Y'} \quad B'_q := \varphi'_* \mathcal{O}_{Y'_q}.\]

On the one hand, by assumption \(B'/qB'\) is a flat \(\mathcal{O}_{X'_q}\)-algebra; on the other hand, \(X'_q\) is reduced and irreducible, hence the restriction map \(\Gamma(X'_q, \mathcal{O}_{X'_q}) \to \Gamma(U'_q, \mathcal{O}_{X'_q})\) is injective. Consequently, the restriction map

\[ (D'/qD')^\alpha = \Gamma(X'_q, \mathcal{O}_{X'_q}) \to \Gamma(U'_q, \mathcal{O}_{X'_q})\]
is a monomorphism; so, we are reduced to checking that \( \chi \) acts trivially on \( \Gamma(U'_P, \mathcal{D}^n_P) \). To this aim, we remark that the open subset \( U'_P := X' \times_X U'_P \) is stable under the action of \( G \), and the restriction \( \mathcal{D}'_{|U'_P} \) of \( \mathcal{D}' \) to the open subset \( U'_P \) is isomorphic to \( (h^* \mathcal{D})_{|U'_P} \) ([51] Ch.IV, Prop.17.5.8(iii)), so the action of \( G \) on \( \mathcal{D}'_{|U'_P} \) is horizontal, and the assertion follows easily. □

17.2.31. In the situation of (17.2.27), define \( Z_n \) as in (17.2.25), for every \( n \in \mathbb{N} \). As already remarked, in view of lemma (17.2.24(i,ii)) we may assume that the map \( \text{Spec} \ P(n+1) \to \text{Spec} \ P(n) \) sends \( Z_{n+1} \) bijectively onto \( Z_n \), for every \( n \in \mathbb{N} \). Set \( V'_0 := V_0 \times_{X_0} X'_0 \), and let
\[
(V'_0 \mid \mathfrak{p} \in \text{Spec} \ P) \quad \text{and} \quad (V_0 \mid \mathfrak{p} \in \text{Spec} \ P)
\]
be the logarithmic stratifications of \( V'_0 \) and respectively \( V_0 \), defined as in (17.2.23); notice that the map \( \nu^* : \text{Spec} \ Q \to \text{Spec} \ P \) induced by \( \nu \) is bijective (lemma (6.4.57(i))), and clearly
\[
V'_0|\mathfrak{p} = h^{-1}_0(V_0|\nu^*(-\mathfrak{p})) \quad \text{for every} \quad \mathfrak{p} \in \text{Spec} \ P.
\]
Let \( Z'_0 := \nu^{-1}Z_0 \), and for every \( \mathfrak{p} \in Z'_0 \), let \( \eta'_\mathfrak{p} \) (resp. \( \eta^\nu \)) denote the generic point of \( V'_0|\mathfrak{p} \) (resp. of \( V_0|\nu^*(-\mathfrak{p}) \)), pick geometric points \( \eta'_\mathfrak{p} \) and \( \xi'_\mathfrak{p} \) localized respectively at \( \eta'_\mathfrak{p} \) and at a point of \( V'_{0,\text{tr}}(\eta'_\mathfrak{p}) := V'_{0,\text{tr}} \times_{X'_0} X'_0(\eta'_\mathfrak{p}) \). Denote by \( \eta^\nu \) the image of \( \eta'_\mathfrak{p} \) in \( V_0|\nu^*(-\mathfrak{p}) \), and by \( \xi^\nu \) the image of \( \xi'_\mathfrak{p} \) in \( V'_{0,\text{tr}}(\eta^\nu) \). According to (13.3.29) there follows, for every integer \( N > 0 \), a commutative diagram of groups
\[
\begin{align*}
\pi_1(V'_0|\mathfrak{p})(\eta^\nu, \xi^\nu) & \longrightarrow \pi_1(V'_{0,\text{tr}}(\eta^\nu), \xi^\nu) \\
M_{0,\mathfrak{p}}^{\mathbb{R}_{\text{gp}}} \otimes_{\mathbb{Z}} \mu_N & \longrightarrow M_{0,\mathfrak{p}}^{\mathbb{R}_{\text{gp}}} \otimes_{\mathbb{Z}} \mu_N
\end{align*}
\]
(where \( \mu_N \) is the \( N \)-torsion subgroup of \( \kappa(\xi^\nu)^x \) whose top arrow is induced by the natural morphism \( V'_{0,\text{tr}}(\eta^\nu) \to V'_{0,\text{tr}}(\eta^\nu) \), and whose bottom arrow is induced by \( \nu^{\text{gp}} : Q^{\text{gp}} \to P^{\text{gp}} \), i.e. by the \( k \)-Frobenius map of \( P^{\text{gp}} \), for every \( \mathfrak{p} \in Z'_0 \). Now, the restriction
\[
\varphi^\mathfrak{p} : Y_0(\eta^\nu) := Y_0 \times_{X_0} X_0(\eta^\nu) \to X_0(\eta^\nu)
\]
of \( \varphi \) is a tamely ramified covering, hence the action of \( \pi_1(V'_{0,\text{tr}}(\eta^\nu), \xi^\nu) \) on \( F^\mathfrak{p} := \varphi^{-1}(\xi^\nu) \) factors through a group homomorphism
\[
\rho^\mathfrak{p} : M_{0,\mathfrak{p}}^{\mathbb{R}_{\text{gp}}} \otimes_{\mathbb{Z}} \mu_N \to \text{Aut}(F^\mathfrak{p})
\]
for some sufficiently large \( N \in \mathbb{N} \) (theorem (13.3.43)). We may then find \( k \in \mathbb{N} \) such that the image of \( k \cdot \rho^\mathfrak{p} \) in \( M_{0,\mathfrak{p}}^{\mathbb{R}_{\text{gp}}} \) lies in the kernel of \( \rho^\mathfrak{p} \), for every \( \mathfrak{p} \in Z'_0 \). Especially, for this choice of \( k \), the image of \( M_{0,\mathfrak{p}}^{\mathbb{R}_{\text{gp}}} \otimes_{\mathbb{Z}} \mu_N \) acts trivially on \( \text{Aut}(F^\mathfrak{p}) \) via \( \rho^\mathfrak{p} \), for every such \( \mathfrak{p} \). Consequently, \( \pi_1(V'_0|\mathfrak{p})(\eta^\nu, \xi^\nu) \) acts trivially on the fibres \( \varphi_0^{-1}(\xi^\nu) \) (by virtue of (3.5.22)); after applying lemma (17.2.24(i)) to the morphism \( \varphi^\mathfrak{p} \), we conclude that the étale locus of \( \varphi^\mathfrak{p} \) contains the whole of \( V'_0 \).

**Theorem 17.2.32.** In the situation of (17.2.26), the pair \( (X, Z) \) is almost pure, relative to the basic setup \( (B, I) \).

**Proof.** Fix a geometric point \( \pi \) of \( X \) localized at the closed point \( x \) of \( X \), and let \( B^\text{sh} \) denote the strict henselization of \( B \) at \( x \). In view of proposition (14.4.10), in order to prove that \( (X, Z) \) is almost pure, it suffices to show that the pair \( (X(\pi), Z(\pi)) \) is almost pure relative to the basic setup \( (B, I) \), or – equivalently – relative to the basic setup \( (B^\text{sh}, IB^\text{sh}) \). However, it is easily seen that \( IB^\text{sh} \) is also a branch ideal of \( B^\text{sh} \), if the latter is endowed with the chart \( P(\infty) \to B^\text{sh} \) deduced from the given chart of \( M \). Taking into account remark (17.2.9(i)), we may then replace \( B \) by \( B^\text{sh} \), and assume that \( X_0 \) and \( X \) are strictly local.
Now, consider a finite morphism $\varphi_0 : Y_0 \to X_0$ and the resulting morphism $\varphi : Y \to X$ as in (17.2.23). The discussion of (17.2.26) shows that $(X, Z)$ is almost pure if and only if $\varphi_* \mathcal{O}_Y$ is an étale $\mathcal{O}_X$-algebra, for every such $\varphi_0$. Set $V := \text{Spec } B[1/p]$; in view of (17.2.31) and lemma (17.2.28), we may then assume that $V_0 \subset U_0$, and therefore $(\varphi_* \mathcal{O}_Y)|_V$ is a finite étale $\mathcal{O}_X$-algebra. On the other hand, let $I' \subset B$ be the radical of the ideal $I + pB$, and set $Z' := Z \setminus V$; clearly, $I'$ is a branch ideal. It then suffices to show that $\varphi_* \mathcal{O}_Y$ is an étale $\mathcal{O}_X$-algebra, for the almost structure given by the new setup $(B, I')$. Thus, we may assume that $p \in I$, in which case the assertion follows from theorems (17.2.14)(iii) and 16.8.43.

**Theorem 17.2.33.** In the situation of (17.2.5), the ring $B$ is ind-measurable.

**Proof.** (See remark 14.5.69(i) for the definition of ind-measurable ring.) One argues as in the proof of theorem 17.1.43 with some simplifications. We have to exhibit a sequence $(d_n \mid n \in \mathbb{N})$ of normalizing factors fulfilling conditions (a) and (b) of definition 14.5.64, where the $\lambda_n$ occurring in loc. cit. meant to be the usual length function for finitely generated $B_n$-modules supported at the closed point $x_n$ of $X_n$. Now, fix $n \in \mathbb{N}$, set

$$T_n := \frac{P_{\mathbb{R}}^{gp}}{P^{(n)gp}}$$

and endow $T_n$ with its invariant measure $d\mu_n$ of total volume equal to 1. For every $\gamma \in P_{\mathbb{R}}^{gp}$, let $[\gamma] \in T_n$ be the equivalence class of $\gamma$; notice that the $P^{(n)gp}$-module

$$S_{[\gamma]} := \gamma P^{(n)gp} \cap P_{\mathbb{Q}}$$

is finitely generated (proposition 6.3.22(ii)) and depends only on the class $[\gamma]$, and for any given finitely generated $B_n$-module $M$ supported at $x_n$, consider the function

$$l_M : T_n \to \mathbb{N} \quad [\gamma] \mapsto \lambda_n(S_{[\gamma]} \cap P^{(n)gp} M).$$

Let $e_1, \ldots, e_r$ be a basis of the free $\mathbb{Z}$-module $P_{\mathbb{R}}^{gp}$, and define $\Omega_n \subset P_{\mathbb{R}}^{gp}$ as in the proof of theorem 17.1.43 so that $\Omega_n$ is a fundamental domain for the lattice $P^{(n)gp}$, and 0 lies in the interior of $\Omega_n$. Denote also by $\Sigma \subset T_n$ the image of $P_{\mathbb{R}} \cap \Omega_n$.

**Claim 17.2.35.** There is a partition of $T_n$ into finitely many measurable subsets $\Theta_1, \ldots, \Theta_t$, independent of $\mathbb{M}$, such that:

(i) For every $\gamma, \lambda \in \Omega_n$, the classes $[\gamma], [\lambda] \in T_n$ lie in the same $\Theta_i$ if and only if $\gamma^{-1} S_{[\gamma]} = \lambda^{-1} S_{[\lambda]}$.

(ii) Especially, $l_M$ restricts to a constant function on each $\Theta_i$.

(iii) Let $\Theta = \{\Theta_1, \ldots, \Theta_t\}$ be the subset containing $[0] \in T_n$; then $\Theta \cap \Sigma$ has measure $> 0$.

**Proof of the claim.** According to proposition 6.3.35(i,iii), the set $\mathcal{S} := \{\gamma^{-1} S_{[\gamma]} \mid \gamma \in \Omega_n\}$ is finite, and for every non-empty $S \in \mathcal{S}$, the set $\{\gamma \in \Omega_n \mid \gamma^{-1} S_{[\gamma]} = S\}$ is the intersection of $\Omega_n$ with a $\mathbb{Q}$-linearly constructible subset. It follows that the same must hold also in case $S = \emptyset$. The image in $T_n$ of any such $\mathcal{S}$-linearly constructible subset is obviously measurable, whence (i). Moreover, in view of our choice of $\Omega$, assertion (ii) follows easily from claim 6.3.40. \hfill \Box

Let $m \geq n$ be any integer; since $B^n_m$ is a free $B^n_n$-module of rank $p^{(m-n)}$ (notation of (17.2.3)), we may compute:

$$\lambda_m(B_m \otimes_{B_n} M) = \frac{p^{(m-n)}}{\kappa(x_m) : \kappa(x_n)} \cdot \sum_{[\gamma] \in P^{(m)gp} / P^{(n)gp}} l_M([\gamma]).$$

However, lemma (17.2.11) easily implies that $\kappa(x_{n+1})^p = \kappa(x_n)$ for every $n \in \mathbb{N}$, whence

$$[\kappa(x_{n+1}) : \kappa(x_n)] = p^{e_n} \quad \text{where } e_n := \Omega_{\kappa(x_n)/\mathbb{Z}}^{1}.$$
by virtue of [48, Ch.IV, Th.21.4.5]. But by the same token, the field \( \kappa(x_n) \) is isomorphic to 
\( \kappa(x_m) \) for every \( m \geq n \), so \( e_n \) is actually independent of \( n \), and we get 
\[
[k(x_m) : k(x_n)] = p^{\omega_0(m-n)} \quad \text{for every } m \geq n.
\]

Therefore, set 
\[
d_n := p^{n\dim B_0} \quad \text{for every } n \in \mathbb{N}.
\]

We claim that \( (d_n \mid n \in \mathbb{N}) \) is a suitable sequence of normalizing factors for \( B \). Indeed, claim \(17.2.35\) ii) says that \( l_M \) is a measurable function on \( T_\mathbb{R} \), and the foregoing, together with the discussion of \( (17.2.8) \) implies that:
\[
\lambda(B \otimes_{B_n} M) := \lim_{m \to +\infty} d_m^{-1} \cdot \lambda_m(B_m \otimes_{B_n} M) = d_n^{-1} \int_{T_\mathbb{R}} l_M d\mu_n
\]
(recall that \( \dim P = \text{rk}_P \mathcal{P}^{\text{gp}} \), by corollary \( 6.4.10 \) i)), so condition (a) holds for this choice of factors. Next, fix \( \varepsilon > 0 \), let \( N \to N' \) be a surjection of finitely generated \( B_n \)-modules supported at \( x_n \), and suppose that \( d_n^{-1}(\lambda_n(N) - \lambda_n(N')) \geq \varepsilon \). Since \( \lambda_n(N) = l_N(0) \) (and likewise for \( N' \)), we deduce that
\[
\lambda(B \otimes_{B_n} N) - \lambda(B \otimes_{B_n} N') \geq \varepsilon \cdot \int_{\Theta} d\mu_n
\]
where \( \Theta \in \{\Theta_1, \ldots, \Theta_l\} \) is the unique subset of \( T_\mathbb{R} \) such that \( [0] \in \Theta \), so the volume of \( \Theta \) is \( > 0 \), by claim \(17.2.35\) iii). This shows that condition (b) holds as well, and concludes the proof of the theorem. \( \square \)

17.3. **The direct summand conjecture.** In the following paragraphs we prove a generalization of the direct summand conjecture for finite injective extensions of log-regular rings.

To begin with, let \( A \) be a ring, and consider a short exact sequence of \( A \)-modules

\[
\Sigma : \quad 0 \to M' \xrightarrow{f} M \xrightarrow{g} M'' \to 0.
\]

We say that \( \Sigma \) is **universally exact** if the sequence \( X \otimes_A \Sigma \) is short exact for every \( A \)-module \( X \).

**Lemma 17.3.1.** (i) In the situation of (17.3), the following conditions are equivalent:
(a) The sequence \( \Sigma \) is universally exact.
(b) The sequence \( X \otimes_A \Sigma \) is short exact for every finitely presented \( A \)-module \( X \).
(c) The sequence \( \Sigma' := \text{Hom}_\mathbb{Z}(\Sigma, \mathbb{Q}/\mathbb{Z}) \) splits.
(d) \( \Sigma' \) is universally exact.
(e) The sequence \( \text{Hom}_A(X, \Sigma) \) is exact for every finitely presented \( A \)-module \( X \).
(f) \( \Sigma \) is the colimit of a filtered system of split short exact sequences of \( A \)-modules.
(ii) If moreover \( M'' \) is finitely presented, then conditions (a)–(f) are also equivalent to:
(g) \( \Sigma \) is a split short exact sequence of \( A \)-modules.
(h) If furthermore, \( A \) is local and noetherian, and \( M, M', M'' \) are finitely generated, then conditions (a)–(g) are also equivalent to:
(i) The sequence \( X \otimes_A \Sigma \) is short exact for every \( A \)-module \( X \) of finite length.

**Proof.** Obviously (f)⇒(a)⇒(b). To see that (b)⇒(a), write any given \( A \)-module \( X \) as the filtered colimit of a system \( (X_\lambda \mid \lambda \in \Lambda) \) of finitely presented \( A \)-modules; then \( H^i(X \otimes_A \Sigma) \) is the colimit of the induced filtered system of \( A \)-modules \( (H^i(X_\lambda \otimes_A \Sigma) \mid \lambda \in \Lambda) \), for every \( i \in \mathbb{Z} \). But (b) says that each \( X_\lambda \otimes_A \Sigma \) is exact, whence (a).

(a)⇒(c): Clearly \( \Sigma' \) is short exact, since \( \mathbb{Q}/\mathbb{Z} \) is an injective \( \mathbb{Z} \)-module. For every \( A \)-module \( X \), recall that \( X' := \text{Hom}_\mathbb{Z}(X, \mathbb{Q}/\mathbb{Z}) \) is naturally an \( A \)-module (see (14.2.26)); notice that for every pair of \( A \)-modules \( X, Y \) we have a natural isomorphism of \( A \)-modules:
\[
\omega_{X,Y} : \text{Hom}_A(X', Y') \xrightarrow{\sim} (X' \otimes_A Y')' \quad \varphi \mapsto (h \otimes y \mapsto \varphi(h)(y)).
\]
There follows a commutative diagram:

\[
\begin{array}{ccc}
\text{Hom}_A(M^\vee, M^\vee) & \xrightarrow{\omega_{M^\vee, M}} & \text{Hom}_A(M^\vee, M^\vee) \\
\downarrow{\omega_{M^\vee, M}} & & \downarrow{\omega_{M^\vee, M}} \\
(M^\vee \otimes_A M)^\vee & \xrightarrow{(M^\vee \otimes_A f)^\vee} & (M^\vee \otimes_A M')^\vee.
\end{array}
\]

By assumption, $M^\vee \otimes_A f$ is injective, hence $(M^\vee \otimes_A f)^\vee$ is surjective, so the same holds for \(\text{Hom}_A(M^\vee, f^\vee)\), and (c) follows easily.

Obviously (c)⇒(d). In order to show that (d)⇒(e), let $X$ be any finitely presented $A$-module; by assumption, $X \otimes_A g^\vee$ is an injection. On the other hand, for every pair of $A$-modules $X, Y$ we have a natural $A$-linear map

\[
\sigma_{X,Y} : X \otimes_A Y^\vee \to \text{Hom}_A(X, Y)^\vee \quad x \otimes t \mapsto (h \mapsto t \circ h(x))
\]

and it is easily seen that $\sigma_{X,Y}$ is an isomorphism if $X$ is finitely presented (details left to the reader). By naturality of $\sigma_{X,Y}$, it follows that $\text{Hom}_A(X, g^\vee)$ is injective, hence $\text{Hom}_A(X, g^\vee)$ is surjective, whence (e).

(e)⇒(f): Write $M''$ as the colimit of a filtered system $(M''_\lambda | \lambda \in \Lambda)$ of finitely presented $A$-modules, and let $(j_\lambda : M \to M | \lambda \in \Lambda)$ be the universal co-cone; for every $\lambda$, set $\Sigma_\lambda := j_\lambda^* \Sigma$. Then $\Sigma$ is the colimit of the resulting system of short exact sequences $(\Sigma_\lambda | \lambda \in \Lambda)$, and we are reduced to checking that each $\Sigma_\lambda$ is split. However, (e) implies that for every $\lambda$ there exists an $A$-linear map $h_\lambda : M''_\lambda \to M$ such that $g \circ h_\lambda = j_\lambda$; the assertion follows straightforwardly.

Next, if $M''$ is finitely presented, (e) implies that $\text{Hom}_A(M'', g)$ is surjective, whence (g).

(iii): Let $(A, m)$ be a local and noetherian ring, and let $X$ be any finitely presented $A$-module; if (h) holds, then for every $n \in \mathbb{N}$ the map $f_n := X/m^n X \otimes_A f$ is injective. Let $t \in \text{Ker } (X \otimes_A f) \setminus \{0\}$; since the $m$-adic topology of $X \otimes_A M'$ is separated ([100, Th.8.10(i)]), there exists $n \in \mathbb{N}$ such that the image $\overline{t}$ of $t$ in $X/m^n X \otimes_A M'$ does not vanish, so $f_n(\overline{t}) \neq 0$ by assumption, and therefore $f(t) \neq 0$, a contradiction. So $X \otimes_A f$ is injective for every such $X$, whence (b).

\[17.3.2.\] Let $\mathcal{A}$ be a regular log-structure on either the Zariski or the étale site of a noetherian and affine scheme $X$; say that $X = \text{Spec } A$ for a noetherian ring $A$. Let also $f : A \to B$ be a finite injective ring homomorphism; we want to show that there exists an $A$-linear map $g : B \to A$ such that $g \circ f = 1_A$, or equivalently, that the short exact sequence of $A$-modules

\[
\Sigma_f : 0 \to A \xrightarrow{f} B \to Q := \text{Coker } f \to 0
\]

splits. The latter holds if and only if the class $[\Sigma_f] \in \text{Ext}_A^1(Q, A)$ of $\Sigma_f$ vanishes. Let us recall:

**Lemma 17.3.3.** (i) Let $A$ be a noetherian ring, and $M, N$ two $A$-modules, with $M$ of finite type; then every flat $A$-algebra $A'$ induces an isomorphism:

\[
A' \otimes_A \text{Ext}_A^1(M, N) \xrightarrow{\sim} \text{Ext}_{A'}^1(A' \otimes_A M, A' \otimes_A N).
\]

(ii) In the situation of (17.3.3), suppose that $A$ is noetherian and $M''$ is of finite type. Then the following conditions are equivalent :

(a) $\Sigma$ is a split short exact sequence of $A$-modules.

(b) For every $p \in \text{Spec } A$ there exists a faithfully flat $A_p$-algebra $A'$ such that $A' \otimes_A \Sigma$ is a split short exact sequence of $A'$-modules.

**Proof.** (i): Pick a resolution $P^\bullet \to M$ by projective $A$-modules of finite type; then $\text{Ext}_A^1(M, N)$ is computed by $H^1 \text{Hom}_A(P^\bullet, N)$, and likewise $\text{Ext}_{A'}^1(A' \otimes_A M, A' \otimes_A N)$ is computed by
foundations for almost ring theory

\[ H^1 \text{Hom}_A(A' \otimes_A P^*, A' \otimes_A N) \]. But since \( A \) is noetherian and \( P^i \) is an \( A \)-module of finite type for every \( i \), the induced morphism of complexes

\[ A' \otimes_A \text{Hom}_A(P^*, N) \to \text{Hom}_A(A' \otimes_A P^*, A' \otimes_A N) \]

is an isomorphism, whence the assertion.

(ii): It is easily seen that the class \( [A' \otimes_A \Sigma] \in \text{Ext}_A^1(A' \otimes_A Q, A') \) corresponds – under the isomorphism of (i) – to \( 1 \otimes [\Sigma] \in A' \otimes_A \text{Ext}_A^1(A', Q, A') \). The assertion follows immediately. \( \square \)

In view of lemma 17.3.3(ii) we are reduced to checking that \( f_p : A_p \to B_p \) admits an \( A_p \)-linear section for every \( p \in \text{Spec} \ A \); hence we may assume that \( (A, m) \) is a local noetherian ring. Likewise, let \( A^{\text{sh}} \) be a strict henselization of \( A \) (at the closed point \( m \)); since the structure map \( A \to A^{\text{sh}} \) is faithfully flat, lemma 17.3.3(ii) implies that \( [\Sigma_p] = 0 \) if and only if \( [A^{\text{sh}} \otimes_A \Sigma_p] = 0 \) in \( \text{Ext}_A^1(A^{\text{sh}} \otimes_A Q, A^{\text{sh}}) \); also, \( A^{\text{sh}} \) is noetherian, by [51, Ch.IV, Prop.18.8.8(iv)]. Thus, it suffices to check that \( A^{\text{sh}} \otimes_A f \) admits an \( A^{\text{sh}} \)-linear section, and therefore we may assume that \( \mathfrak{M} \) admits a chart \( \beta : P \to A \) that is sharp at the point \( m \).

17.3.4. Arguing likewise, we may replace \( A \) by its m-adic completion, and suppose therefore that \( A \) is a complete local noetherian ring. Moreover, \( A \) is normal and Cohen-Macaulay, by corollary 12.5.13. Furthermore, the proof of theorem 12.5.10 show that there exists \( r \in \mathbb{N} \) and a surjective ring homomorphism

\[ \varphi : V[[Q]] \to A \quad \text{where } Q := P \times \mathbb{N}^\oplus r \]

and where:

- \((V, m_V)\) is a coefficient ring of \( A \), i.e. either a field, or a complete discrete valuation
- ring with \( A = \varphi(V) + m \) and such that \( m_V = pV \) for a prime integer \( p \)

- The kernel of \( \varphi \) is trivial if \( V \) is a field, and otherwise it is principal, generated by a power series \( \sum_{q \in Q} a_q \cdot q \) with \( a_0 \in m_V \setminus m_V^2 \)

- The chart \( \beta \) is the composition of \( \varphi \) with the obvious inclusion map \( P \to Q \to V[[Q]] \).

Let \( k' \) be an algebraically closed field extension of the residue field \( k \) of \( A \); by [100, Th.29.1] there exists a flat ring homomorphism \( \psi : V \to V' \), where \( V' = k' \) if \( V = k \), and otherwise \( V' \) is a complete discrete valuation ring with maximal ideal \( pV' \) and residue field \( k' \). The induced ring extension \( \psi[[Q]] : V[[Q]] \to V'[[Q]] \) is again faithfully flat, hence it induces a faithfully flat ring homomorphism \( V[[Q]] \to V'[[Q]] \). Set \( A' := V'[[Q]] \otimes_V[[Q]] A \); the induced map \( A \to A' \) is faithfully flat, and \( A' \) is the quotient of \( V'[[Q]] \) by the principal ideal generated by the image of \( \text{Ker} \varphi \). Hence, \( A' \) is a complete local noetherian ring, and by theorems 12.5.10 and 12.5.31, the induced map of monoids \( Q \to A' \) is a chart for a regular log structure on \( \text{Spec} A' \). By lemma 17.3.3(ii), we may then replace \( A, B, P \) by respectively \( A', A' \otimes_A B, Q \), and assume that \( k \) is algebraically closed and \( m = m_P A \) (recall that \( m_P = P \setminus \{0\} \); see (6.1.10)).

17.3.5. Let \( p_1, \ldots, p_k \) be the finitely many minimal prime ideals of \( B \); since \( A \) is reduced, \( f(A) \cap p_1 \cap \cdots \cap p_k = 0 \), hence the composition of \( f \) with the natural map \( B \to B/p_1 \times \cdots \times B/p_k \) is still finite and injective, and its kernel contains the ideal \( \prod_{i=1}^k f^{-1}p_i \). Then there exists \( i \in \{1, \ldots, k\} \) such that \( f^{-1}p_i = 0 \), so that the composition \( \beta_i : A \to B/p_i \) of \( f \) with the projection \( B \to B/p_i \) is still injective; clearly it suffices to check that \( \beta_i \) admits an \( A \)-linear section, so we may assume that \( B \) is a domain.

Let \( K \) be the field of fractions of \( A \), set \( B_K := K \otimes_A B \), let \( d := \dim_K B_K \), and denote by \( \text{Tr}_{B_K/K} : B_K \to K \) the trace form; since \( A \) is integrally closed in \( K \), the composition of \( \text{Tr}_{B_K/K} \) with the localization \( B \to B_K \) factors through an \( A \)-linear map (lemma 14.3.15(i))

\[ \text{Tr}_{B/A} : B \to A. \]
Then \( \text{Tr}_{B/A} \circ f = d \cdot 1_A \). In particular, if \( A \) is a \( \mathbb{Q} \)-algebra, the map \( d^{-1} \cdot \text{Tr}_{B/A} \) is a section of \( f \) as sought. Thus, we may assume that \( k \) has characteristic \( p > 0 \). Let us set
\[
P^{(n)} := \{ \gamma \in P_{\mathbb{Q}} \mid \gamma^p \in P \} \quad P^{(\infty)} := \bigcup_{n \in \mathbb{N}} P^{(n)} \quad \text{and} \quad \Gamma := (P^{(\infty)}/P)^{\text{gp}}.
\]
Then \( P^{(\infty)} \) is naturally a \( \Gamma \)-graded monoid. More precisely, for every \( \gamma \in (P^{(\infty)})^{\text{gp}} \), denote by \( [\gamma] \in \Gamma \) the class of \( \gamma \); then we have:
\[
\text{gr}_{[\gamma]} P^{(\infty)} = P^{(\infty)} \cap \gamma P^{\text{gp}} \quad \text{for every } \gamma \in (P^{(\infty)})^{\text{gp}}.
\]

**Theorem 17.3.6.** In the situation of (17.3.2), suppose that \( A \) is an \( \mathbb{F}_p \)-algebra. Then \( f \) admits an \( A \)-linear section.

**Proof.** After the foregoing reductions, we may assume that \( A = k[[P]] \) for a sharp, fine and saturated monoid \( P \), and that \( B \) is a domain. For every \( n \in \mathbb{N} \), set
\[
A_n := k[[P^{(n)}]] \quad B_n := A_n \otimes_A B \quad \text{and} \quad A_\infty := \bigcup_{n \in \mathbb{N}} A_n.
\]
Notice that \( A_0 \) is a direct summand of the \( A_0 \)-module \( A_n \), hence the inclusion map \( i_n : A \to A_n \) has a section \( \sigma_n : A_n \to A \) for every \( n \in \mathbb{N} \); we are then reduced to checking that the induced map \( f_n : A_n \to B_n \) has an \( A_n \)-linear section \( s_n : B_n \to A_n \), for some \( n \in \mathbb{N} \): indeed, in this case let \( j_n : B \to B_n \) be the induced inclusion map, and set \( s := \sigma_n \circ s_n \circ j_n : B \to A \). We get:
\[
s \circ f = \sigma_n \circ s_n \circ j_n \circ f = \sigma_n \circ s_n \circ f_n \circ i_n = \sigma_n \circ i_n = 1_A
\]
as required. On the other hand, let \( K_n \) be the field of fractions of \( A_n \), and denote by \( B'_n \) the maximal reduced quotient of \( B_n \), for every \( n \in \mathbb{N} \); since \( A_n \) is reduced, the induced map \( f'_n : A_n \to B'_n \) is still injective, so it suffices to exhibit a section for \( f'_n \). Moreover, \( E_n := K_n \otimes_A B'_n \) is a finite field extension of \( K_n \) (since \( K_n \) is a purely inseparable field extension of \( K \)), and the inclusion map \( K_n \to K_{n+1} \) induces a field extension \( E_n \to E_{n+1} \) for every such \( n \). Notice also that \( K_\infty := \bigcup_{n \in \mathbb{N}} K_n \) is a perfect field; hence \( E_\infty := \bigcup_{n \in \mathbb{N}} E_n \) is the maximal reduced quotient of \( K_\infty \otimes_A B \), and is a finite separable field extensions of \( K_\infty \). It follows easily that for \( n \in \mathbb{N} \) sufficiently large, \( E_n \) is already a separable and finite field extension of \( K_n \). Summing up, we may replace \( A \) and \( B \) by \( A_n \) and \( B'_n \) for \( n \) large enough, and assume that \( f \) is generically étale, i.e. there exists \( g \in A \setminus \{0\} \) such that \( A[1/g] \otimes_A f \) is a finite, injective and étale map. Then, notice that \( A_\infty \) is a perfect \( \mathbb{F}_p \)-algebra, and let \( n \subset A_\infty \) be the radical of the ideal \( A_\infty g ; \); let also \( C_\infty \) be the integral closure of \( A_\infty \) in \( A_\infty [1/g] \otimes_A B \). By theorems [16.8.2 and 16.8.43 ii], and proposition [14.4.8], the \( (A_\infty, n)^a \)-algebra \( C_\infty ^a \) is étale, faithfully flat and of almost finite rank. Now, let \( X \) be any \( A \)-module of finite length; by virtue of lemma [17.3.1 ii,iii], it suffices to check that the map \( X \otimes_A f : X \to X \otimes_A B \) is injective. However, since \( A \) is a direct summand of the \( A \)-module \( A_\infty \), the induced map \( h : X \to X \otimes_A A_\infty \) is injective, and since \( C_\infty ^a \) is a faithfully flat \( (A_\infty, n)^a \)-algebra, the kernel of the induced map \( l : X \otimes_A A_\infty \to X \otimes_A C_\infty \) is annihilated by \( n \). Clearly \( l \circ h \) factors through \( X \otimes_A f \); hence:
\[
n \cdot \text{Ker}(X \otimes_A f) = 0
\]
(we regard \( \text{Ker}(X \otimes_A f) \) as a subset of \( \text{Ker} l \), via \( h \)). Now, as \( P^{(\infty)} \) is \( \Gamma \)-graded, \( A_\infty \) is naturally a \( \Gamma \)-graded \( A \)-algebra, and \( X \otimes_A A_\infty \) is a \( \Gamma \)-graded \( (A_\infty, \text{gr}_{[\gamma]} A_\infty) \)-module (see definition [7.6.9 ii]); by definition:
\[
\text{gr}_{[\gamma]} A_\infty := A \otimes \mathbb{Z}[P] \mathbb{Z}[\text{gr}_{[\gamma]} P^{(\infty)}] \quad \text{for every } \gamma \in P^{(\infty)}.
\]
According to proposition [6.4.12 ii], there exist \( \lambda_1, \ldots, \lambda_k \in P^\vee := \text{Hom}_{\text{Mnd}}(P, \mathbb{N}) \) such that \( \mathbb{R} \lambda_1, \ldots, \mathbb{R} \lambda_k \) are the extremal rays of \( P^{(\infty)}_{\mathbb{R}} \) (see [6.3.15]).

**Claim 17.3.7.** If \( \gamma \in P^{(\infty)} \), and \( 0 \leq \lambda_i(\gamma) < 1 \) for every \( i = 1, \ldots, k \), then \( \text{gr}_{[\gamma]} P^{(\infty)} = \gamma P \).
Proof of the claim. By proposition 6.4.12(iv), we have

\[ P^{(\infty)} = \{ \gamma \in (P^{(\infty)})^{\geq 0} \mid \lambda_i(\gamma) \geq 0 \text{ for every } i = 1, \ldots, k \} \]

Hence \( \text{gr}_{[\gamma]} P^{(\infty)} \) is the subset of all \( \gamma \cdot \beta \), with \( \beta \in P^{\geq 0} \) and \( \lambda_i(\gamma \cdot \beta) \geq 0 \) for \( i = 1, \ldots, k \). But \( \lambda_i(\beta) \in \mathbb{Z} \) for every such \( i \) and \( \beta \); our assumption on \( \lambda_i(\gamma) \) then implies that \( \lambda_i(\beta) \in \mathbb{N} \) for every such \( i \) and \( \beta \), whence \( \beta \in P \) (again, by proposition 6.4.12(iv)), and the claim follows. \( \Diamond \)

We have \( g = \sum_{\gamma \in P} g_{[\gamma]} \cdot \gamma \) for a system \( (g_{[\gamma]} \mid \gamma \in P) \) of elements of \( k \). Pick \( \beta \in P \) with \( g_{[\beta]} \neq 0 \), and \( N \in \mathbb{N} \) large enough, so that \( \lambda_i(\beta^{1/p^N}) = p^{-N}\lambda_i(\beta) < 1 \) for \( i = 1, \ldots, k \); by claim 17.3.7 we then have \( \text{gr}_{[\beta^{1/p^N}]} P^{(\infty)} = \beta^{1/p^N} P \). Clearly \( g_{[\beta^{1/p^N}]} = \sum_{[\gamma] \in \Gamma} g_{[\gamma]} A_{\gamma} \) for every \( [\gamma] \in \Gamma \). It follows that \( g_{[\beta^{1/p^N}]} = g_{[\beta^{1/p^N}]} \cdot \beta^{1/p^N} \cdot (1 + a) \) for some \( a \in \mathbb{m} \). Let now \( x \in \ker X \otimes_A f \); we have \( x \in \text{gr}_0(X \otimes_A A_{\infty}) \), and \( g^{1/p^N} x = 0 \), then \( g_{[\gamma]} x = 0 \) for every \( [\gamma] \in \Gamma \), and especially:

\[ x \otimes g_{[\beta^{1/p^N}]} = 0 \quad \text{in} \quad \text{gr}_{[\beta^{1/p^N}]}(X \otimes_A A_{\infty}) = X \otimes_A A_{[\beta^{1/p^N}]} = X \otimes \mathbb{Z}[p] \mathbb{Z}[\beta^{1/p^N}] P \]

and since \( g_{[\beta]} \neq 0 \), we have \( x \otimes \beta^{1/p^N} = 0 \) in \( X \otimes \mathbb{Z}[p] \mathbb{Z}[\beta^{1/p^N}] P \), so finally \( x = 0 \), as required. \( \Box \)

17.3.8. By theorem 17.3.6 and the foregoing reductions, we may assume that

\[ A = V[[P]]/(\partial) \]

for a fine, sharp and saturated monoid \( P \neq 0 \), a complete discrete valuation ring \( (V, m_V) \) with \( m_V = pV \), whose residue field \( k := V/pV \) is algebraically closed, and a power series \( \partial := \sum_{\gamma \in P} a_{[\gamma]} \cdot \gamma \) with \( a_{[\gamma]} \in pV \setminus p^2V \). Then \( m_P A = m \), the maximal ideal of \( A \). We set

\[ A_n := A \otimes \mathbb{Z}[P/P^{(n)}] \quad \text{and} \quad B_n := A_n \otimes_A B \quad \text{for every} \quad n \in \mathbb{N} \]

Notice that the induced map \( A_n \to A_{n+1} \) is injective for every \( n \in \mathbb{N} \), since \( \mathbb{Z}[P^{(n)}] \) is a direct summand of the \( \mathbb{Z}[P^{(n)}] \)-module \( \mathbb{Z}[P^{(n+1)}] \); hence, let as well \( A_{\infty} := \bigcup_{n \in \mathbb{N}} A_n \). Moreover, notice that \( A/m_P A = V/a_0 V = k \), and \( \Omega^1_{V/k} = 0 \), since \( k \) is perfect; then, the integer \( r \) of (17.2.3) vanishes in the current situation, hence theorem 17.2.14(iv) tells us that \( A_{\infty} \) is a formal perfectoid ring, for its \( p \)-adic topology, and clearly it is also naturally \( \Gamma \)-graded.

Let \( \lambda_1, \ldots, \lambda_k \in P^V := \text{Hom}_{\text{fin}}(P, \mathbb{N}) \) such that \( \mathbb{R} \lambda_1, \ldots, \mathbb{R} \lambda_k \) are the extremal rays of \( P_{\mathbb{R}} \) (see the proof of theorem 17.3.6), and \( \beta_1, \ldots, \beta_i \in P \) a finite system of generators of the \( \mathbb{Q}_+ \)-module \( \mathbb{Q}_+ \otimes_{\mathbb{N}} P \) (see (3.6.17)); set

\[ \lambda := \lambda_1 + \cdots + \lambda_k \quad \beta := \beta_1 \cdots \beta_i \quad \text{and} \quad L := \max(\lambda(\beta_1), \ldots, \lambda(\beta_i)). \]

Lemma 17.3.9. In the situation of (17.3.8), let \( J \subset A_{\infty} \) be a \( \Gamma \)-graded ideal, \( g \in A_{\infty} \), and let \( e, n \in \mathbb{N} \) such that

\[ g \in m^e A_{\infty} \setminus m^{e+1} A_{\infty} \quad g \in J^{p^n} \quad \text{and} \quad 1 \geq \varepsilon(e, n) := (e L + \lambda(\beta))/p^n. \]

Then there exists \( \gamma \in P^{(\infty)} \) such that:

\[ \text{gr}_{[\gamma]} J = \text{gr}_{[\gamma]} A_{\infty} \quad \text{and} \quad \lambda(\gamma) < \varepsilon(e, n). \]

Proof. We may write \( g = g_1 + \cdots + g_r \) for a finite sequence \( g_1, \ldots, g_r \in J^{p^n} \) such that each \( g_i \) is in turn of the form \( g_i = \prod_{j=1}^n a_{ij} \otimes \gamma_{ij} \) with:

\[ a_{i1}, \ldots, a_{ir} \in A \quad \gamma_{i1}, \ldots, \gamma_{ir} \in P^{(\infty)} \quad a_{ij} \otimes \gamma_{ij} \in \text{gr}_{[\gamma_{ij}]} J \quad \text{for every} \quad j = 1, \ldots, p^n. \]

It is clear that there exists \( e' \leq e \) and \( i \in \{1, \ldots, r\} \) such that \( g_i \in m^{e'} A_{\infty} \setminus m^{e'+1} A_{\infty} \). Up to reordering the \( p^n \) factors of \( g_i \), we may then assume that there exists \( c \in \{0, \ldots, p^n\} \) such that

\[ g_{i1} \otimes \gamma_{i1} \in \cdots \otimes \gamma_{ip} \otimes \gamma_{ip} \in J^{p^n} \quad \text{for every} \quad j = 1, \ldots, p^n. \]
\[ \lambda(\gamma_{ij}) < \varepsilon(e, n) \] for \( j = 1, \ldots, c \), and \( \lambda(\gamma_{ij}) \geq \varepsilon(e, n) \) for \( j = c + 1, \ldots, p^n \). Suppose now that the lemma fails; then we must have \( a_{ij} \in m \) for every \( i = 1, \ldots, c \), and therefore

\[
(17.3.10) \quad \prod_{j=c+1}^{p^n} a_{ij} \otimes \gamma_{ij} \notin m^{e-c+1}A_\infty.
\]

For every \( j = c + 1, \ldots, p^n \), write \( \gamma_{ij} = \prod_{s=1}^{l} d_{js} \) for certain \( d_{ij1}, \ldots, d_{ijl} \in \mathbb{Q}_+ \); then there exist unique \( d'_{is} \in \mathbb{N} \) and \( d''_{is} \in \{0, 1\} \) with

\[
\sum_{j=c+1}^{p^n} d_{js} = d'_{is} + d''_{is} \quad \text{for every } s = 1, \ldots, l
\]

and (17.3.10) then implies that \( \sum_{s=1}^{l} d'_{is} \leq e' - c \), whence:

\[
\sum_{j=c+1}^{p^n} \lambda(\gamma_{ij}) < (e' - c) \cdot L + \lambda(\beta') \leq p^n \cdot \varepsilon(e, n) - cL.
\]

However, \( \sum_{j=c+1}^{p^n} \lambda(\gamma_{ij}) \geq (p^n - c) \cdot \varepsilon(e, n) \), and since \( \varepsilon(e, n) \leq 1 \leq L \), this is absurd. \( \square \)

**Theorem 17.3.11.** In the situation of (17.3.2), the map \( f \) admits an \( A \)-linear section.

**Proof.** In view of the foregoing reductions, we may assume that \( A \) and \( A_\infty \) are as in (17.3.8) and \( B \) is a domain; recall also that \( B[1/g] \) is an étale and faithfully flat \( A[1/g] \)-algebra. Let:

\[ A_n' := A_\infty X^{1/p^n}/(X - g) \quad \text{for every } n \in \mathbb{N} \quad \text{and} \quad A'_\infty := \bigcup_{n \in \mathbb{N}} A'_n. \]

Let also \( D \) be the \( p \)-integral closure of \( A'_\infty \) in \( A'_\infty[1/p] \), and endow \( D \) with its \( p \)-adic topology; by theorem [16.9.17] we know that \( D \) is a faithfully flat \( A_\infty \)-algebra, and that \( D \) is a formal perfection ring. Denote by \( D^\wedge \) the \( p \)-adic completion of \( D \), and set \( B' := D^\wedge \otimes_A B[1/g] \). Hence, \( B' \) is a finite étale \( D^\wedge[1/g] \)-algebra. Let now \( n \in D^\wedge \) be the ideal generated by \( \langle g^{1/p^n} \mid n \in \mathbb{N} \rangle \); then \( (D^\wedge, n) \) is a basic setup, and we set \( D'_n := (D^\wedge, n)^n \subset D^\wedge[1/g] \) (see lemma [16.9.33]; lastly, let \( B'_n \) be the integral closure of \( D'_n \) in \( B' \). By theorem [16.9.34]i,iii), for every \( n \in \mathbb{N} \), the \( (D/p^nD)^\wedge \)-algebra \( (B'_n/p^nB'_n)^\wedge \) is faithfully flat and étale of finite rank, for the almost structure given by the basic setup \( (D'_n, n) \). After these preliminaries, let \( X \) be any \( A \)-module of finite length; by lemma [17.3.1]ii,iii), it suffices to show that the map \( X \otimes_A f \) is injective. However, let \( x \in Ker(X \otimes_A f) \), and pick \( m \in \mathbb{N} \) large enough, so that \( p^n X = 0 \). Since \( A_\infty \) is a \( \Gamma \)-graded \( A \)-algebra with \( \text{gr}_0A_\infty = A \), the induced map \( \varphi : X \to X_\infty := X \otimes_A A_\infty/p^nA_\infty \) is injective, and \( X_\infty \) is naturally a \( \Gamma \)-graded \( (A_\infty, \text{gr}_\bullet) \)-module, with \( \text{gr}_0X_\infty = X \). Especially, the annihilator \( J \) of \( \varphi(x) = x \otimes 1 \in gr_0X_\infty \) is a \( \Gamma \)-graded ideal of \( A_\infty \). Next, since \( D \) is a faithfully flat \( A_\infty \)-algebra, the induced map \( \varphi' : X_\infty \to X_\infty \otimes_A \infty D/p^nD \) is again injective, and \( \text{Ann}_D(\varphi'(x \otimes 1)) = JD \). Lastly, since \( (B'_n/p^nB'_n)^\wedge \) is a faithfully flat \( (D/p^nD)^\wedge \)-algebra, the kernel of the induced map \( \varphi'' : X_\infty \otimes_A \infty D/p^nD \to X_\infty \otimes_A \infty B'_n/p^nB'_n \otimes_A \infty D/p^nD \) is annihilated by \( n \). Clearly \( \varphi'' \circ \varphi' \circ \varphi \) factors through \( X \otimes_A f \), hence \( \varphi''(x \otimes 1) \in Ker \varphi'' \), and consequently:

\[ n \subseteq JD. \]

Thus, \( g^{1/p^n} \in JD \cap A_\infty = J \) for every \( n \in \mathbb{N} \) (100 Th.7.5(ii)), i.e. \( g \in J^p \) for every \( n \in \mathbb{N} \). Notice that the \( m \)-adic topology is separated on \( A_\infty \); hence, let \( e \in \mathbb{N} \) such that \( g \in m^eA_\infty \setminus m^{e+1}A_\infty \); by lemma [17.3.9] for every \( n \in \mathbb{N} \) there exists \( \gamma_n \in P^{(n)} \) such that \( \lambda(\gamma_n) < \varepsilon(e, n) \) and \( \text{gr}_{\gamma_n}J = \text{gr}_{\gamma_n}A_\infty \). By claim [17.3.7] it follows that for every sufficiently large \( n \in \mathbb{N} \), we have \( \text{gr}_{\gamma_n}J = A \otimes \mathbb{Z}[P] \mathbb{Z}[\gamma_n + P] \), a free \( A \)-module of rank one, with generator \( 1 \otimes \gamma_n \). Finally, we get \( x \otimes \gamma_n = 0 \) in \( \text{gr}_{\gamma_n}X_\infty = X \otimes \mathbb{Z}[P] \mathbb{Z}[\gamma_n + P] \) for every such \( n \); thus, \( x = 0 \), and the proof is concluded. \( \square \)
17.4. **Diagonal idempotents of generically étale maps.** Let \( f : A \to B \) be a finite and injective ring homomorphism of noetherian rings; set \( X := \text{Spec } A \), denote by \( B \) the quasi-coherent \( \mathcal{O}_X \)-algebra associated with \( B \), and by \( \mu : B \otimes_{\mathcal{O}_X} B \to B \) the multiplication morphism. For every affine open subset \( U \subset X \) such that \( B|_U \) is an étale \( \mathcal{O}_U \)-algebra, we have a unique diagonal idempotent \( e_{f,U} \in B(U) \otimes_{e_X(U)} B(U) \) such that:

\[
\mu_U(e_{f,U}) = 1 \quad \text{and} \quad x \cdot e_{f,U} = 0 \quad \text{for every } x \in \text{Ker } (B(U) \otimes_{e_X(U)} B(U) \xrightarrow{\mu_U} B(U)).
\]

We suppose moreover that \( f \) is generically étale, i.e. that the union \( U_f \subset X \) of all such affine open subsets is dense in \( X \); the uniqueness property of the diagonal idempotents then implies that there exists a unique section

\[
e_f \in \Gamma(U_f, B \otimes_{e_X} B)
\]

such that \( e_{f,U} = e_{f,U} \) for every affine open subset \( U \subset U_f \). Moreover, \( B|_{U_f} \) is a locally free \( \mathcal{O}_{U_f} \)-module of finite rank, hence we have a well defined \( \mathcal{O}_{U_f} \)-linear trace map

\[
\text{tr}_{\mathcal{O}_X} : B|_{U_f} \to \mathcal{O}_{U_f}
\]

that assigns to every affine open subset \( U \subset U_f \) and every \( b \in B(U) \) the trace of the \( \mathcal{O}_X(U) \)-linear endomorphism \( b \cdot 1_{B(U)} \). The corresponding trace form

\[
t_{\mathcal{O}_X} := \text{tr}_{\mathcal{O}_X} \circ \mu : (B \otimes_{\mathcal{O}_X} B)|_{U_f} \to \mathcal{O}_{U_f}
\]

is a perfect pairing (\cite[Th.4.1.14]{fondements}), hence it induces an \( \mathcal{O}_{U_f} \)-linear isomorphism

\[
\omega_{\mathcal{O}_X} : B|_{U_f} \cong (B^\vee)|_{U_f} \quad \text{where} \quad B^\vee := \text{Hom}_{\mathcal{O}_X}(B, \mathcal{O}_X).
\]

**Remark 17.4.1.** Let \( f : A \to B \) be as in \((17.4)\), \( p \in \mathbb{N} \) a prime integer, and suppose that \( A \) is an \( \mathbb{F}_p \)-algebra. Let also \( h \in A \) such that the localization \( f_h : A_h \to B_h \) of \( f \) is étale. It is easily seen that the natural map (notation of \((9.8.11)\))

\[
B^\text{perf} \otimes_{A^\text{perf}} B^\text{perf} \to (B \otimes_A B)^\text{perf}
\]

is bijective. By assumption, \( h^n e_f \) is in the image of the localization \( B \otimes_A B \to B_h \otimes_{A_h} B_h \), for some \( n \in \mathbb{N} \). The image \( e_f^\text{perf} \) of \( e_f \) in \((B \otimes_A B)^\text{perf} \) is the diagonal idempotent of the étale map \( A_h^\text{perf} \otimes_A f : A_h^\text{perf} \to B_h^\text{perf} = A_h^\text{perf} \otimes_A B \). Since \((e_f^\text{perf})^p = e_f^\text{perf} \), we conclude that \( h^n/p^e f \) lies in the image of the localization \((B \otimes_A B)^\text{perf} \to (B \otimes_A B)^\text{perf} \), for every \( k \in \mathbb{N} \).

**Definition 17.4.2.** (i) A log ring \((A, P, \beta)\) is the datum of a ring \( A \), an integral saturated monoid \( P \) whose associated abelian group \( P^\text{gp} \) is torsion-free, and a morphism of monoids \( \beta : P \to A \) from \( P \) to the multiplicative monoid \((A, \cdot)\), furnishing a chart for a log structure \( \mathcal{P} \) on the Zariski site of \( \text{Spec } A \) (see definition \((12.1.17)\)), which we call the log structure of \((A, P, \beta)\).

(ii) We say that the log ring \((A, P, \beta)\) is regular if \( A \) is noetherian, \( P \) is fine and saturated, and the log structure of \((A, P, \beta)\) is regular. In this case, \( P^\text{gp} \) is a free abelian group of finite rank, and \( A \) is a product of finitely many normal domains (corollary \((12.5.13)\)).

17.4.3. Let \((A, P, \beta)\) be any log ring, \( f : A \to B \) a ring homomorphism as in \((17.4)\), and set \( X := \text{Spec } A \). We consider the monoid \( P^{(\infty)} \) associated with \( P \) as in \((17.3.5)\), and the abelian group \( \Gamma := (P^{(\infty)}/P)^\text{gp} \). We will likewise use the monoid \( P_Q := Q_+ \otimes_{\mathbb{N}} P \), and the abelian group \( \Gamma_Q := (P_Q/P)^\text{gp} \), and for every \( \gamma \in P_Q \), we let \([\gamma]\) \in \Gamma_Q \) be the class of \( \gamma \). Then the ring

\[
A_\infty := A \otimes_{\mathbb{Z}[P]} \mathbb{Z}[P_Q]
\]

is naturally a \( \Gamma_Q \)-graded \( A \)-algebra, with graded summands:

\[
A_{[\gamma]} := A \otimes_{\mathbb{Z}[P]} \mathbb{Z}[\text{gr}_{[\gamma]} P_Q] \quad \text{for every } \gamma \in P_Q.
\]
Likewise, set $B_{\infty} := A_{\infty} \otimes_A B$; both $B_{\infty}$ and its dual $A_{\infty}$-module $B_{\infty}' := \text{Hom}_{A_{\infty}}(B_{\infty}, A_{\infty})$ inherit natural $\Gamma_{Q}$-graded structures whose graded summands are respectively

\[B_{[\gamma]} := A_{[\gamma]} \otimes_A B \quad \text{and} \quad B_{[\gamma]}' := \text{Hom}_A(B, A_{[\gamma]}) \quad \text{for every } \gamma \in P_Q.

Let $\mathcal{O}_{X, \infty}$ and $\mathcal{B}_{\infty}$ be the quasi-coherent $\mathcal{O}_X$-algebras associated with $A_{\infty}$ and $B_{\infty}$. Hence, $\mathcal{B}_{\infty}|_{U_f}$ is an étale $\mathcal{O}_{X, \infty}|_{U_f}$-algebra, whose trace morphism induces the isomorphism

\[\omega_{\mathcal{B}_{\infty}/\mathcal{O}_{X, \infty}} := \mathcal{O}_{X, \infty}|_{U_f} \otimes_{\mathcal{O}_{X}} \mathcal{B}_{\infty} \otimes_{\mathcal{O}_{X}} \mathcal{B}_{\infty} \rightarrow \mathcal{B}_{\infty} \otimes_{\mathcal{O}_{X, \infty}} \mathcal{B}_{\infty}.

Also, the corresponding diagonal idempotent $e_{f, \infty} \in \Gamma(U_f, \mathcal{B}_{\infty} \otimes_{\mathcal{O}_{X, \infty}} \mathcal{B}_{\infty})$ is the image of $e_f$, under the natural morphism

\[\mathcal{B} \otimes_{\mathcal{O}_{X}} \mathcal{B} \rightarrow \mathcal{O}_{X, \infty} \otimes_{\mathcal{O}_{X}} \mathcal{B} \otimes_{\mathcal{O}_{X}} \mathcal{B} \rightarrow \mathcal{B}_{\infty} \otimes_{\mathcal{O}_{X, \infty}} \mathcal{B}_{\infty}.

More precisely, since $U_f$ is quasi-compact, the $A_{\infty}$-module $\Gamma(U_f, \mathcal{B}_{\infty} \otimes_{\mathcal{O}_{X, \infty}} \mathcal{B}_{\infty})$ is also $\Gamma_{Q}$-graded, and on the other hand, $\text{gr}_{Q} P_Q = P$, since $P$ is saturated; then $\text{gr}_{Q} B_{\infty} = B$, and the map (17.4.4) identifies $\Gamma(U_f, \mathcal{B}_{\infty} \otimes_{\mathcal{O}_{X, \infty}} \mathcal{B}_{\infty})$ with $\text{gr}_{Q} \Gamma(U_f, \mathcal{B}_{\infty} \otimes_{\mathcal{O}_{X, \infty}} \mathcal{B}_{\infty})$.

17.4.5. Let $f := (f, P, \beta)$ be the datum of a log ring $(A, P, \beta)$ and a ring homomorphism $f : A \rightarrow B$ as in (17.4); with the notation of (17.4.3), we attach to $f$ the composition

\[B_{\infty}' \otimes A_{\infty} B_{\infty} \xrightarrow{\rho} \Gamma(U_f, \mathcal{B}_{\infty} \otimes_{\mathcal{O}_{X, \infty}} \mathcal{B}_{\infty}') \xrightarrow{\alpha} \Gamma(U_f, \mathcal{B}_{\infty} \otimes_{\mathcal{O}_{X, \infty}} \mathcal{B}_{\infty}')

where $\rho$ is the restriction map of the quasi-coherent $\mathcal{O}_X$-module $\mathcal{B}_{\infty}' \otimes_{\mathcal{O}_{X, \infty}} \mathcal{B}_{\infty}'$, and $\alpha$ is induced by the isomorphism $\omega_{\mathcal{B}_{\infty}'/\mathcal{O}_{X, \infty}}^{-1} \otimes_{\mathcal{O}_{X, \infty}|_{U_f}} \omega_{\mathcal{B}_{\infty}'/\mathcal{O}_{X, \infty}}^{-1}$. Set as well:

\[R(B, \Delta) := \bigoplus_{[\gamma] \in \Delta} B_{[\gamma]} \otimes_A B_{[\gamma/\gamma]} \quad \text{for every subset } \Delta \subset P_Q.

Since (17.4.6) is a morphism of graded $A_{\infty}$-modules, it restricts to an $A$-linear map

\[\partial_{L} : R(B, \Gamma_Q) \rightarrow \text{gr}_{Q} \Gamma(U_f, \mathcal{B}_{\infty} \otimes_{\mathcal{O}_{X, \infty}} \mathcal{B}_{\infty}) \rightarrow \Gamma(U_f, \mathcal{B} \otimes_{\mathcal{O}_{X}} \mathcal{B}).

Remark 17.4.7. (i) In the situation of (17.4.5), let $g : A \rightarrow A'$ be a ring homomorphism; set $B' := A' \otimes_A B$, let $f' : A' \rightarrow B'$ be the induced map, and suppose that $f' := (f', P, g \circ \beta)$ is also a datum as in (17.4.5). Set $X' := \text{Spec} A'$, and let $h : X' \rightarrow X$ be the morphism of schemes induced by $g$; also, let $\mathcal{B}'$ be the quasi-coherent $\mathcal{O}_{X'}$-algebra arising from $B'$. For every $[\gamma] \in P_Q$ we get a natural $A$-linear map

\[B_{[\gamma]}' \rightarrow \text{Hom}_A(B, A_{[\gamma]}) \xrightarrow{\sim} B_{[\gamma]}'^{\ell} := \text{Hom}_{A'}(B', A_{[\gamma]})

and a direct inspection of the definitions yields a commutative diagram:

\[
\begin{array}{ccc}
R(B, \Gamma_Q) & \xrightarrow{\partial_{L}} & \Gamma(U_f, \mathcal{B} \otimes_{\mathcal{O}_{X}} \mathcal{B}) \\
\downarrow & & \downarrow \\
R(B', \Gamma_Q) & \xrightarrow{\partial_{L}'} & \Gamma(U_{f'}, \mathcal{B}' \otimes_{\mathcal{O}_{X}} \mathcal{B}')
\end{array}
\]

whose left (resp. right) vertical arrow is induced by the maps (17.4.8) (resp. by the natural morphisms of quasi-coherent $\mathcal{O}_X$-algebras $\mathcal{B} \rightarrow h_* \mathcal{O}_X$, and $\mathcal{B}' \rightarrow h_* \mathcal{B}'$, and where $\rho$ is the restriction map. Also, it is clear that the right vertical arrow maps $e_f$ to $\rho(e_f)$.

(ii) Let $R$ be any ring, $S$ and $S'$ two finite $R$-algebras whose underlying $R$-modules are projective (of finite rank). Then all the trace maps $\text{tr}_{S/R}, \text{tr}_{S'/R}$ and $\text{tr}_{S \otimes_R S'/R}$ are well defined, and [59] Lemma 4.1.3] implies that:

\[\text{tr}_{S \otimes_R S'/R} = \text{tr}_{S/R} \otimes_R \text{tr}_{S'/R} : S \otimes_R S' \rightarrow R.

We deduce the following alternative description of $\vartheta_L$. First, we have a natural $A_\infty$-linear map
\[(17.4.9) \quad B^\vee_\omega \otimes_{A_\infty} B^\vee_\omega \to (B_\infty \otimes_{A_\infty} B_\infty)^\vee := \text{Hom}_A(B_\otimes A B, A_\infty)\]
given by the rule: $\varphi \otimes \varphi' \mapsto (b \otimes b' \mapsto \varphi(b) \cdot \varphi'(b'))$ for every $\varphi, \varphi' \in B^\vee_\omega$ and every $b, b' \in B$. Next, the trace map of the $\mathcal{O}_X$-algebra $B_\infty \otimes_{\mathcal{O}_X} B_\infty$ induces an $\mathcal{O}_X$-linear map
\[\omega_B : B_\infty \otimes_{\mathcal{O}_X} B_\infty \otimes_{\mathcal{O}_X} B_\infty \to (B_\infty \otimes_{\mathcal{O}_X} B_\infty)^\vee\]
whose restriction to the open subset $U_f$ is an isomorphism. Then it is easily seen that $(17.4.6)$ equals the composition of $(17.4.9)$ with the map
\[(B_\infty \otimes_{A_\infty} B_\infty)^\vee \xrightarrow{\rho'} \Gamma(U_f, (B_\infty \otimes_{A_\infty} B_\infty)^\vee) \xrightarrow{\alpha'} \Gamma(U_f, B_\infty \otimes_{A_\infty} B_\infty)\]
where $\rho'$ is the restriction map of the quasi-coherent $\mathcal{O}_X$-module $(B_\infty \otimes_{A_\infty} B_\infty)^\vee$, and $\alpha'$ is induced by the isomorphism $\omega_B : B_\infty \otimes_{A_\infty} B_\infty \xrightarrow{\sim} B_\otimes A B$. Moreover, $(B_\infty \otimes_{A_\infty} B_\infty)^\vee$ is naturally a $\mathcal{O}_X$-graded $A_\infty$-module, with a natural identification:
\[\text{gr}_0 (B_\infty \otimes_{A_\infty} B_\infty)^\vee \xrightarrow{\sim} (B_\otimes A B)^\vee := \text{Hom}_A(B_\otimes A B, A)\]
and $(17.4.9)$ is a morphism of $\mathcal{O}_X$-graded modules. It follows that $\vartheta_L$ is the composition
\[R(B, \mathcal{O}_X) \xrightarrow{\xi_L} (B_\otimes A B)^\vee \xrightarrow{\xi_L^\prime} \Gamma(U_f, B_\otimes_{A_\infty} B_\infty)\]
where $\xi_L$ is induced by the restriction of $(17.4.9)$, and $\xi_L^\prime$ is the restriction of $\alpha' \circ \rho'$. In turn, $\xi_L^\prime$ can be described as the composition of the restriction map $(B_\otimes A B)^\vee \to \Gamma(U_f, (B_\otimes_{A_\infty} B_\infty)^\vee)$ of the quasi-coherent $\mathcal{O}_X$-module $(B_\otimes_{A_\infty} B_\infty)^\vee$ arising from $(B_\otimes A B)^\vee$, and the isomorphism $\Gamma(U_f, (B_\otimes_{A_\infty} B_\infty)^\vee) \xrightarrow{\sim} \Gamma(U_f, B_\otimes_{A_\infty} B_\infty)$ induced by the isomorphism $(B_\otimes_{A_\infty} B_\infty)\mid_{U_f} \xrightarrow{\sim} (B_\otimes_{A_\infty} B_\infty)\mid_{U_f}$ as usual from the trace map of $B_\otimes_{A_\infty} B_\infty$.

(iii) With the notation of (ii), notice as well that $\xi_L^\prime$ is injective if $A$ is reduced. Indeed, if $\varphi : B_\otimes A B \to A$ restricts to $U_f$ to the zero section of $B_\otimes_{A_\infty} B_\infty$, then for every $b, b' \in B$ the element $\varphi(b \otimes b') \in A$ restricts to $U_f$ to the zero section of $\mathcal{O}_X$; since $A$ is reduced and $U_f$ is dense in $X$, this means that $\varphi(b \otimes b') = 0$ for every such $b, b'$, whence the contention.

**Lemma 17.4.10.** (i) In the situation of $(17.4.5)$, let $\Delta \subset \Gamma_Q$ be any subset. Then there exists a finite subset $\Sigma \subset \Delta$ such that $\xi_L(R(B, \Delta)) = \xi_L(R(B, \Sigma))$ (where $\xi_L$ is defined as in remark 17.4.7(ii)). Moreover, $\Sigma$ depends only on $P$ and $\Delta$ (and neither on $\beta$ nor $f$).

(ii) Suppose that $P = P_1 \times P_2$, where $P_s = N^{\geq r} \times \mathbb{Z}_{\geq s}^\geq$, for some $r, s \in \mathbb{N}$. For $i = 1, 2$, let $\Delta_i \subset \Gamma_{i,Q} := (P_{i,Q}/P_{i,Q})^{\text{gp}}$ be any subset, so that $\Delta_1 \times \Delta_2 \subset \Gamma_Q = \Gamma_{1,Q} \oplus \Gamma_{2,Q}$. Then
\[\xi_L(R(B, \Delta_1 \times \Delta_2)) = \xi_L(R(B, \Delta_1 \times \{0\}))\]

**Proof.** (i): On the one hand, the multiplication law of $A_\infty$ induces by restriction $A$-linear maps
\[\mu : A_{[\gamma]} \otimes A_{[\gamma]} \to \text{gr}_0 A_\infty = A \quad (a \otimes \gamma \lambda) \otimes (a' \otimes \lambda' \gamma) \mapsto a a' \cdot \beta(\lambda \lambda')\]
(notice that if $\gamma, \lambda, \lambda' \in P_{Q,\gamma}^{\text{gp}}$ and we have both $\gamma \lambda \in \text{gr}_{[\gamma]} P_Q$ and $\lambda' \gamma \in \text{gr}_{[\gamma]} P_Q$, then $\lambda \lambda' \in \text{gr}_{[\gamma]} P_Q$). On the other hand, we have an obvious isomorphism of $P$-modules:
\[Q_{\gamma} := P_{Q,\gamma}^{\text{gp}} \cap \gamma^{-1} P_Q \xrightarrow{\text{gr}_{[\gamma]} P_Q} \lambda \mapsto \gamma \lambda \quad \text{for every } \gamma \in P_{Q,\gamma}^{\text{gp}}\]
Especially, if $Q_{\gamma} = Q_{\delta}$ for some $\gamma, \delta \in P_{Q,\gamma}^{\text{gp}}$, we deduce an $A$-linear isomorphism
\[\omega_{\gamma,\delta} : A_{[\gamma]} \xrightarrow{\sim} A_{[\delta]} \quad a \otimes \gamma \lambda \mapsto a \otimes \delta \lambda \quad \text{for every } a \in A \text{ and } \gamma \lambda \in \text{gr}_{[\gamma]} P_Q\]
which induces an $A$-linear isomorphism
\[\omega_{\gamma,\delta} : B_{[\gamma]}^\vee \xrightarrow{\sim} B_{[\delta]}^\vee \quad (\varphi : B \to A_{[\gamma]}) \mapsto (\omega_{\gamma,\delta} \circ \varphi : B \to A_{[\delta]}).\]
Furthermore, if we have both $Q_{\gamma} = Q_{\delta}$ and $Q_{1/\gamma} = Q_{1/\delta}$ for some $\gamma, \delta \in P_{\gamma}^{sp}$, a direct inspection yields a commutative diagram:

$$A_{[\gamma]} \otimes_A A_{[1/\gamma]} \xrightarrow{\omega_{\gamma,\delta} \otimes_A \omega_{1/\gamma,1/\delta}} A_{[\delta]} \otimes_A A_{[1/\delta]}$$

(17.4.11)

For such $\gamma$ and $\delta$, there follows a commutative diagram:

$$B^\vee_{[\gamma]} \otimes_A B^\vee_{[1/\gamma]} \xrightarrow{\omega_{\gamma,\delta} \otimes_A \omega_{1/\gamma,1/\delta}} B^\vee_{[\delta]} \otimes_A B^\vee_{[1/\delta]}$$

(17.4.12)

whose downward arrows are the restrictions of $\xi_I^r :$ the details shall be left to the reader. Pick a section of the projection $P^\text{sp}_Q \to \Gamma_Q$:

$$\Gamma_Q \to P^\text{sp}_Q \subset P^\text{sp}_R \quad [\gamma] \mapsto [\gamma]^*$$

whose image is contained in a bounded subset of the finite dimensional $\mathbb{R}$-vector space $P^\text{sp}_R$. Summing up, we see that if $Q_{[\gamma]}^* = Q_{[\delta]}^*$ and $Q_{[1/\gamma]}^* = Q_{[1/\delta]}^*$, then $\xi_I(B^\vee_{[\gamma]} \otimes B^\vee_{[1/\gamma]}) = \xi_I(B^\vee_{[\delta]} \otimes B^\vee_{[1/\delta]})$. To conclude, it suffices now to invoke proposition 6.3.35(i).

(ii): For every $(\gamma_1, \gamma_2) \in P^\text{sp}_Q$, let $[\gamma_i] \in \Gamma_i,Q$ be the class of $\gamma_i$ for $i = 1, 2$, and $[\gamma_1, \gamma_2] \in \Gamma_Q$ the class of $(\gamma_1, \gamma_2)$; also, for each $x \in \mathbb{Q}$, denote by $x^\dagger$ the smallest element of $(x + \mathbb{Z}) \cap \mathbb{Q}_+$. It is easily seen that

$$\text{gr}_{[\gamma_1, \gamma_2]} P_Q = (\text{gr}_{[\gamma_1]} P_{1,Q}) \times (\gamma_2^\dagger P_2)$$

whence a natural identification:

$$B^\vee_{[\gamma_1,0]} \otimes_{Z[P]} Z[\gamma_2^\dagger P_2] \xrightarrow[\sim]{} B^\vee_{[\gamma_1,\gamma_2]}.$$ 

(17.4.12)

Notice that for every $x \in \mathbb{Q}$ the rational number $x^\dagger + (-x)^\dagger$ equals 0 if $x \in \mathbb{Z}$, and otherwise it equals 1. Especially:

$$\gamma_2^\dagger + (-\gamma_2)^\dagger \in P_2 \quad \text{for every } \gamma_2 \in P^\text{sp}_{2,Q}.$$ 

Therefore the multiplication law of $Z[P_{2,Q}]$ induces by restriction an $A$-linear map:

$$\mu_{\gamma_2} : Z[\gamma_2^\dagger P_2] \otimes_{Z[P]} Z[(-\gamma_2)^\dagger P_2] \to Z[P_2].$$

We then get a commutative diagram

$$
\begin{array}{ccc}
(B^\vee_{[\gamma_1,0]} \otimes_{Z[P]} Z[\gamma_2^\dagger P_2]) \otimes_A (B^\vee_{[1/\gamma_1,0]} \otimes_{Z[P]} Z[(-\gamma_2)^\dagger P_2]) & \longrightarrow & B^\vee_{[\gamma_1,\gamma_2]} \otimes_A B^\vee_{[1/\gamma_1,-1/\gamma_2]} \\
\xi_{L([\gamma_1,0]) \otimes_{Z[P]} Z[\gamma_2^\dagger P_2] \otimes_{Z[P]} Z[(-\gamma_2)^\dagger P_2]} & \downarrow & \xi_{L([\gamma_1,\gamma_2])} \\
(B \otimes_A B)^\vee \otimes_{Z[P]} Z[\gamma_2^\dagger P_2] \otimes_{Z[P]} Z[(-\gamma_2)^\dagger P_2] & \longrightarrow & (B \otimes_A B)^\vee
\end{array}
$$

where $\xi_{L([\gamma_1,0])} : B^\vee_{[\gamma_1,0]} \otimes_A B^\vee_{[1/\gamma_1,0]} \to (B \otimes_A B)^\vee$ is the restriction of $\xi_I$, and likewise for $\xi_{L([\gamma_1,\gamma_2])}$. Also, the top horizontal arrow is the isomorphism induced by (17.4.12), and the bottom horizontal arrow is $(B \otimes_A B)^\vee \otimes_{Z[P]} \mu_{\gamma_2}$. Summing up, we conclude that:

$$\xi_{L(B^\vee_{[\gamma_1,\gamma_2]} \otimes_A B^\vee_{[1/\gamma_1,-1/\gamma_2]})} \subset \xi_{L(B^\vee_{[\gamma_1,0]} \otimes_A B^\vee_{[1/\gamma_1,0]})}$$

for every $[\gamma_1, \gamma_2] \in P^\text{sp}_Q$

whence the assertion. \qed
Example 17.4.13. Let \( V \) be a noetherian regular ring, \( P \) a fine and saturated monoid such that \( P^{gp} \) is torsion-free, \( \psi : V[P] \to A \) a smooth ring homomorphism, and \( \beta : P \to A \) the composition of \( \psi \) with the natural inclusion map \( \alpha : P \to V[P] \). Set \( S := \text{Spec} V \), \( X_0 := \text{Spec} V[P] \) and \( X := \text{Spec} A \); then \( \alpha \) is a chart for a log structure \( \mathcal{P}_0 \) on the Zariski site of \( X_0 \), and the induced morphism of log schemes \((X_0, \mathcal{P}_0) \to (S, \mathcal{O}^*_S)\) is smooth, by virtue of proposition 12.3.34. Since \((S, \mathcal{O}^*_S)\) is trivially a regular log scheme, it follows that the same holds for \((X_0, \mathcal{P}_0)\), by theorem 12.5.28, then, again by theorem 12.5.28 and corollary 12.3.27, the log scheme \((X, \mathcal{P}) \equiv X \times_{X_0} (X_0, \mathcal{P}_0) \) is regular, and \( \beta \) is a chart for \( \mathcal{P} \). Summing up, this shows that the datum \((A, P, \beta)\) is a regular log ring.

Lemma 17.4.14. Let \( A \) be a domain, \( B \) an \( A \)-algebra of finite type, \( C \) a \( B \)-algebra of finite type, \( M \) a \( B \)-module of finite type, and \( N \) a \( C \)-module of finite type. Set also \( K \equiv \text{Frac}(A) \).

(i) There exists \( f \in A \setminus \{0\} \) such that the following holds for every \( A \)-algebra \( A' \). Set \( B' \equiv A' \otimes_A B \), \( C' \equiv A' \otimes_A C \), \( M' \equiv B' \otimes_B M \) and \( N' \equiv C' \otimes_C N \); then the natural map
\[
A' \otimes_A \text{Hom}_B(M, N)_f \to \text{Hom}_{B'}(M', N')_f
\]
is an isomorphism.

(ii) For every \( B \)-linear map \( \varphi : M \to N \) there exists \( f \in A \setminus \{0\} \) such that \((\text{Coker} \varphi)_f \) is a free \( A \)-module.

(iii) In the situation of (ii), let \( x \in N \). Then \( x \in \text{Im}(K \otimes_A \varphi) \) if and only if there exists a dense subset \( U \subset \text{Spec} A \) such that \( 1 \otimes x \in \text{Im}(\kappa(p) \otimes_A \varphi) \) for every \( p \in U \).

Proof. (i): Pick \( n \in \mathbb{N} \) and a \( B \)-linear surjection \( \psi : B^{\otimes n} \to M \); let also \( M' \subset B^{\otimes n} \) be a finitely generated \( B \)-submodule such that \( K \otimes_A M' = \text{Ker}(K \otimes_A \psi) \). Set \( M'' := B^{\otimes n}/M' \), and denote by \( \tilde{\psi} : M'' \to M \) the \( B \)-linear surjection induced by \( \psi \). By [50 Ch.IV, Lemma 8.9.4.1], there exists \( f \in A \setminus \{0\} \) such that the \( A_f \)-module \( M''_f \) is flat, and by construction \( \text{Ker}(\psi_f : M''_f \to M_f) \) is a torsion \( A \)-module; then \( \text{Ker} \psi_f = 0 \), hence \( M_f \) is a finitely presented \( B_f \)-module. We may thus replace \( A, B, C, M, N \) by \( A_f, B_f, C_f, M_f, N_f \), and assume that \( M \) is a \( B \)-module of finite presentation. Now, let
\[
B^{\otimes n} \xrightarrow{\varphi} B^{\otimes n} \to M
\]
be a finite presentation of \( M \); there follow short exact sequences of \( B \)-modules:
\[
\Sigma : 0 \to \text{Hom}_B(M, N) \to N^{\otimes n} \to T := \text{Im}(\varphi^\vee \otimes_B N) \to 0
\]
\[
\Sigma' : 0 \to T \to T' \to C :\xrightarrow{C} T' := \text{Coker}(\varphi^\vee \otimes_B N) \to 0
\]
where \( \varphi^\vee : B^{\otimes n} \to B^{\otimes m} \) is the transpose of \( \varphi \). Notice that \( T \) and \( T' \) are \( C \)-modules of finite type. By invoking again [50 Ch.IV, Lemma 8.9.4.1], we find \( f \in A \setminus \{0\} \) such that \( T_f \) and \( T'_f \) are flat \( A_f \)-modules; after replacing again \( A, B, C, M, N \) and \( \varphi \) by their respective localizations, we may therefore assume that \( T \) and \( T' \) are flat \( A \)-modules. In this case, the induced sequences \( A' \otimes A \Sigma \) and \( A' \otimes A \Sigma' \) are again short exact, for every \( A \)-algebra \( A' \), whence a left exact sequence
\[
0 \to A' \otimes_A \text{Hom}_B(M, N) \to N^{\otimes n} \xrightarrow{\varphi^\vee \otimes_B N'} N^{\otimes m} \quad \text{with} \quad \varphi' := \varphi \otimes_B B'.
\]
But we have a natural identification \( \text{Ker}(\varphi^\vee \otimes_B N') \cong \text{Hom}_B(M', N') \), and the resulting isomorphism \( A' \otimes_A \text{Hom}_B(M, N) \cong \text{Hom}_B(M', N') \) is the natural map of (i).

(ii): Arguing as in the proof of (i), we reduce easily to the case where \( B \) and \( C \) are finitely presented \( A \)-algebras, and \( M \) (resp. \( N \)) is a finitely presented \( B \)-module (resp. \( C \)-module). Then we may find a \( \mathbb{Z} \)-subalgebra of finite type \( A_0 \subset A \), an \( A_0 \)-algebra of finite type \( B_0 \), a \( B_0 \)-algebra of finite type \( C_0 \), a \( B_0 \)-module \( M_0 \) of finite type, a \( C_0 \)-module of finite type \( N_0 \), and a \( B_0 \)-linear map \( \varphi_0 : M_0 \to N_0 \) with isomorphisms
\[
A \otimes_{A_0} B_0 \xrightarrow{\sim} B \quad A \otimes_{A_0} C_0 \xrightarrow{\sim} C \quad B \otimes_{B_0} M_0 \xrightarrow{\sim} M \quad C \otimes_{C_0} N_0 \xrightarrow{\sim} N.
\]
which identify $B \otimes_{B_0} \varphi_0$ with $\varphi$. It suffices then to exhibit $f \in A_0$ such that $(\text{Coker } \varphi_0)_f$ is a free $A_0$-$f$-module; the latter follows easily from \cite[Th.24.1]{100}.

(iii): If $x \in \text{Im}(K \otimes_A \varphi)$, we have $x \in \text{Im} \varphi_f$ for some $f \in A \setminus \{0\}$, and then $x \otimes 1 \in \text{Im}(\kappa(p) \otimes_A \varphi)$ for every $p \in \text{Spec } A_f$. Conversely, suppose that $U \subset \text{Spec } A$ is a dense subset such that $x \otimes 1 \in \text{Im}(\kappa(p) \otimes_A \varphi)$ for every $p \in U$. We pick $f \in A \setminus \{0\}$ as in (ii), so that $(\text{Coker } \varphi)_f$ is a free $A$-module. Clearly $U \cap \text{Spec } A_f$ is still dense in $\text{Spec } A_f$, hence we may replace $A, B, C, M, N$ and $\varphi$ by $A_f, B_f, C_f, M_f, N_f$ and $\varphi_f$, and assume that $\text{Coker } \varphi$ is a free $A$-module, say with basis $(e_i \mid i \in I)$. Suppose now that $x \notin \text{Im}(K \otimes_A \varphi)$, so that the image $\pi \in \text{Coker } \varphi$ of $x$ does not vanish. Then there exists a finite subset $I_0 \subset I$ and a system $(f_i \mid i \in I_0)$ of non-zero elements of $A$, with $\pi = \sum_{i \in I_0} f_i e_i$. Pick $j \in I_0$, and any $p \in U \cap \text{Spec } A_{f_j}$; then $\text{Coker } (\kappa(p) \otimes_A \varphi)$ is a free $\kappa(p)$-vector space with basis $(1 \otimes e_i \mid i \in I)$, and $1 \otimes x = \sum_{i \in I_0} \overline{f_i} \otimes e_i$, where $\overline{f_i} \in \kappa(p)$ denotes the image of $f_i$, for every $i \in I$. Especially, $\overline{f_j} \neq 0$, whence $1 \otimes x \neq 0$, a contradiction. \hfill $\square$

17.4.15. Let $(P, +, 0)$ be a fine and saturated monoid such that $P^{gp}$ is torsion-free, and fix a Banach norm $\| \cdot \|$ on the finite dimensional $\mathbb{R}$-vector space $P^{\text{gp}} := \mathbb{R} \otimes_{\mathbb{Z}} P^{\text{gp}}$. Let also $P^{\text{gp}}(\rho) := \{ \gamma \in P^{\text{gp}} \mid \| \gamma \| \leq \rho \}$ for all $\rho \in \mathbb{R}_+$. Define also $P^{(\infty)}$ and $P_0$ as in \cite[(17.4.5)]{17.4.5}, as well as the polyhedral cone $P_\rho := \mathbb{R}_+ \otimes_{\mathbb{Z}} P \subset P^{\text{gp}}$. Moreover, for every $m \in \mathbb{N} \setminus \{0\}$, let $P_{(m)} := \{ \gamma \in P_\rho \mid m \gamma \in P^{(\infty)} \}$.

Lemma 17.4.16. With the notation of (17.4.15), there exists an integer $m > 0$ with $(p, m) = 1$ such that the following holds. For every $\delta > 0$ there exists a real number $\varepsilon > 0$ such that for every $\beta_1, \beta_2 \in P^{\text{gp}}$ with $\| \beta_1 + \beta_2 \| < \varepsilon$ we may find $\beta'_1, \beta'_2 \in P^{\text{gp}}_{(m)}$ with:

(i) $\beta'_1 + \beta'_2 = 0$

(ii) $\| \beta'_i - \beta_i \| < \delta$ for $i = 1, 2$

(iii) $(P_\rho - \beta_i) \cap P^{\text{gp}} \subset (P_\rho - \beta'_i) \cap P^{\text{gp}}$ for $i = 1, 2$.

Proof. Since $P^{(\infty)}$ is $p$-divisible, $P^{\text{gp}}_{(m)} = P^{\text{gp}}_{(m)}$ for every integer $m > 0$, so we may always arrange that $(p, m) = 1$, if all the other conditions are already fulfilled. Moreover, let $\rho > 0$ such that every class of $P^{\text{gp}}_\rho / P^{\text{gp}}$ admits a representative $\beta \in P^{\text{gp}}_\rho$ with $\| \beta \| \leq \rho$. Then it is easily seen that, after replacing $\beta_i$ by $\beta_i + (-1)^i \gamma$ for $i = 1, 2$, with a suitable $\gamma \in P^{\text{gp}}$, we may assume that $\beta_i \in P^{\text{gp}}_\rho(\rho)$. Now, for every $\gamma \in P^{\text{gp}}_\rho$, let $\overline{\Omega}(\gamma)$ be the topological closure of the subset $\Omega(P_\rho, P^{\text{gp}} \cap (P_\rho - \gamma))$ in $P^{\text{gp}}_\rho$ (notation of \cite[(6.3.34)]{6.3.34}); in view of condition (i) and of proposition \cite[(6.3.35)]{6.3.35}v), condition (iii) is implied by:

\begin{equation}
(17.4.17) \quad \beta'_i \in \overline{\Omega}(\beta_i) \cap (\overline{-\Omega}(\beta_2)).
\end{equation}

Moreover, suppose that

\begin{equation}
(17.4.18) \quad \| \beta'_1 - \beta_1 \| \leq \delta/2.
\end{equation}

Then

\begin{equation}
\| \beta'_2 - \beta_2 \| = \| \beta'_2 + \beta_1 - \beta_1 - \beta_2 \| \leq \| - \beta'_1 + \beta_1 \| + \| \beta_1 + \beta_2 \| < \delta/2 + \varepsilon.
\end{equation}

Hence condition (ii) will hold, provided $\varepsilon \leq \delta/2$. Thus, we have to exhibit $m > 0$ and $\varepsilon > 0$ such that, for every $\beta_1, \beta_2 \in P^{\text{gp}}_\rho$ with $\| \beta_i \| \leq \rho$ and $\| \beta_1 + \beta_2 \| < \varepsilon$, there exists $\beta'_i \in P^{\text{gp}}_{(m)}$ fulfilling \cite[(17.4.17)]{17.4.17} and \cite[(17.4.18)]{17.4.18}. Then, by proposition \cite[(6.3.35)]{6.3.35}i) and lemma \cite[(6.3.42)]{6.3.42} it suffices to find $\beta'_i \in P^{\text{gp}}_\rho$ fulfilling these two latter conditions. By way of contradiction, suppose that such $\beta'_i$ cannot always be found: this means that there exists a sequence $\beta := ((\beta_{1,k}, \beta_{2,k}) \mid k \in \mathbb{N})$ of pairs of elements in $P^{\text{gp}}_\rho$, with $\beta_{1,k} \in P^{\text{gp}}_\rho(\rho)$ for every $k \in \mathbb{N}$, and such that

(a) $\| \beta_{1,k} + \beta_{2,k} \| < 2^{-k}$ for every $k \in \mathbb{N}$
(b) $\Omega(\beta_{1,k}) \cap (\Omega(\beta_{2,k})) \cap (P_{\mathbb{R}}^{\text{gp}}(\delta/2) + \beta_{1,k}) = \emptyset$ for every $k \in \mathbb{N}$.

However, by proposition 6.3.35(i), after replacing $\beta$ by a subsequence we may assume that both $\Omega(\beta_{1,k})$ and $\Omega(\beta_{2,k})$ are independent of $k$. Since $P_{\mathbb{R}}^{\text{gp}}(\rho)$ is a compact subset, we may also assume that the sequence $(\beta_{1,k} | k \in \mathbb{N})$ converges to an element $\beta' \in P_{\mathbb{R}}^{\text{gp}}(\rho)$; then clearly $(\beta_{2,k} | k \in \mathbb{N})$ converges to $\beta'' = -\beta'$. Since $\beta_{i,k} \in \Omega(\beta_{i,k})$ for $i = 1, 2$ and every $k \in \mathbb{N}$, we also have $\beta'_i \in \Omega(\beta_{i,k})$ for $i = 1, 2$. Lastly, we have $\|\beta'_1 - \beta_{1,k}\| < \delta/2$ for every sufficiently large $k \in \mathbb{N}$; this contradicts (b), and the claim follows. \hfill \square

**Theorem 17.4.19.** In the situation of (17.4.5), suppose that $(A, P, \beta)$ is regular. We have:

(i) $\epsilon_d \in \partial_d(R(B, \Gamma_\varnothing)).$

(ii) Let $J \subset A$ be the real ideal such that Spec $A/J = X \setminus U_f$. Then $\partial_d \subset \partial_d(R(B, \Gamma))$.

Proof. For every datum $f := (\beta', \rho, P)$ as in (17.4.5), let $X(f) := \Gamma(U_f, \mathcal{B} \otimes_{\mathcal{B}_X} \mathcal{B})$; denote also by $Y(f) \subset X(f)$ the image of $\partial_d$, and set $Z(f) := A \epsilon_d \subset X(f)$. We notice:

**Claim 17.4.20.** Let $A'$ be a noetherian ring, $g : A \to A'$ a flat ring homomorphism; set $X' := \text{Spec } A', f' := A' \otimes_A f$ and $f'' := (f', P, g \circ \beta)$. Then $U_{f'} = X' \times_X U_f$, and we have a natural isomorphism

$$A' \otimes_A X(f) \sim X(f')$$

that identifies $Y(f')$ and $Z(f')$ respectively with $A' \otimes_A Y(f)$ and $A' \otimes_A Z(f)$.

**Proof of the claim.** The first assertion follows from [51] Ch.IV, Prop.17.7.1]. Next, set $B' := A' \otimes_A B$; since $B$ is an $A$-module of finite type, $B'$ is an $A'$-module of finite presentation. Hence, the natural map $A' \otimes_A B' \to B' := \text{Hom}_{A'}(B', A')$ is an isomorphism (details left to the reader). Then the second assertion follows by a direct inspection of the constructions. \hfill \diamond

Now, assertion (i) comes down to the inclusion $Z(f) \subset Y(f)$, and it suffices to check that $Z(f) \subset Y(f)$ in $X(f)$, for every $p \in \text{Spec } A$. Let $(p, \rho, P)$ be the localization map, set $f_p := A_p \otimes_A f : A_p \to B_p$, and $f_p := (f_p, P, \rho \circ j(p))$; by claim 17.4.20, we are then reduced to checking that $Z(f_p) \subset Y(f_p)$ in $X(f_p)$, for every such $p$. Thus, in order to show (i), we may assume that $(A, m)$ is a local noetherian ring. Likewise we may reduce assertion (ii) to the case where $(A, m)$ is local. Next, let $A^\wedge$ be the $m$-adic completion of $A$; since the completion map $j : A \to A^\wedge$ is faithfully flat, we are reduced to checking that $A^\wedge \otimes_A Y(f) \subset A^\wedge \otimes_A X(f)$ in $A^\wedge \otimes_A X(f)$. Moreover, the log structure attached to the chart $j \otimes \beta : P \to A^\wedge$ is still regular (theorems 12.5.10 and 12.5.31); after invoking again claim 17.4.20, we may thus assume that $(A, m)$ is a complete noetherian local ring. In order to prove (i), and a similar argument reduces the proof of (ii) as well to the complete case.

Next, let $p := \beta^{-1}(A^\wedge)$; then $\beta$ extends uniquely to a morphism of monoids $\beta' : A_p \to A$ (notion of remark 6.1.11); moreover, the log structures on the Zariski site of $X$ induced by $\beta$ and by $\beta'$ are naturally isomorphic, so the datum $f' := (f, P, \beta')$ still fulfills the conditions of (17.4.5) and $(A, P, \beta')$ is regular. Moreover, $(A_p)^{gp} = P_{\mathbb{R}}$ and $(A_p)^{gp} = P_{\mathbb{R}}$, hence $(A_p)^{gp}$ is still naturally $\Gamma$-graded. Furthermore, for every $\gamma \subset (P_{\mathbb{R}})^{gp}$, we have

$$\text{gr}_{\gamma}((P_{\mathbb{R}})^{gp}) = (\text{gr}_{\gamma}(P_{\mathbb{R}}))$$

whence: $A \otimes_{(P_{\mathbb{R}})^{gp}} Z[\text{gr}_{\gamma}((P_{\mathbb{R}})^{gp})] = A_{\gamma}$.

Hence, the $A$-modules $X(f')$, $Y(f')$, $Z(f')$ are naturally identified with $X(f), Y(f), Z(f)$. Thus, in order to prove (i), it suffices to show that $Z(f') \subset Y(f')$; after replacing $f$ by $f'$, we may therefore assume that the chart $\beta$ is local at the closed point of $X$ (see definition 12.1.17(vi)). Arguing likewise we reduce as well the proof of (ii) to the case where $\beta$ is local.

Recall now that $P$ admits a decomposition $P \sim Q \times P^\times$, where $Q$ is a fine, sharp and saturated monoid, and $P^\times \subset P$ is the abelian group of invertible elements of $P$ (lemma 6.2.10). Let $\alpha : Q \to A$ be the restriction of $\beta$; by direct inspection, we see that the inclusion $Q \to P$
induces an isomorphism between the log structures on \( \text{Spec} A \) associated with the charts \((P, \beta)\) and \((Q, \alpha)\); see \((12.1.6)\). Hence, the datum \( f'' := (f, Q, \alpha) \) fulfills again the conditions of \((17.4)\), and \((A, Q, \alpha)\) is regular. In light of lemma \((17.4.10)\), we may then replace \( f \) by \( f'' \), and thus assume that \( \beta \) is a sharp chart at the closed point of \( X \) (see definition \((12.1.17)\).

After these preliminaries, we may then assume, as in \((17.3.4)\), that there exists \( r \in \mathbb{N} \), a coefficient ring \((V, m_V)\) of \( A \), and a surjective ring homomorphism

\[ \varphi : V[[P \times \mathbb{N}^r]] \to A \]

and \( \beta \) is the composition of \( \varphi \) with the natural inclusion map \( P \to V[[P \times \mathbb{N}^r]] \).

**Claim 17.4.21.** The theorem holds if \( A \) contains a field of positive characteristic.

**Proof of the claim.** In this case, \( V \) is the residue field of \( A \), and \( \varphi \) is an isomorphism. The induced morphism of monoids \( \beta' : P \times \mathbb{N}^r \to V[[P \times \mathbb{N}^r]] \to A \) is the chart for another regular log structure on the Zariski site of \( X \) (theorems \((12.5.10)\) and \((12.5.31)\)); in view of lemma \((17.4.10)\), we may then replace \( \beta \) by \( \beta' \), and assume that \( A = V[[P]] \) and \( \Gamma = m_P \cdot A \) (with \( m_P := P \setminus \{1\} \)). Next, let \( k \) be an algebraic closure of \( V \); the induced map \( V[P] \to k[P] \) is faithfully flat, so the same holds for its completion \( A \to k[[P]] \) \(([[100]\text{ Th.22.4})]; moreover, the inclusion map \( P \to k[[P]] \) is again a chart for a regular log structure on the Zariski site of \( \text{Spec} k[[P]] \). In view of claim \((17.4.20)\), we may then replace \( V \) by \( k \) and \( B \) by \( k[[P]] \otimes_A B \), and assume that \( A = k[[P]] \). In this case, notice that, with the notation of \((9.8.11)\), we have:

\[ A_{\text{perf}} = \Gamma \times_{\Gamma_Q} A_{\infty} \]

Let now \( h \in J \). The isomorphism \((9.8.12)\) yields a natural identification of \( A_{\text{perf}} \)-algebras:

\[ \Gamma \times_{\Gamma_Q} B_{\infty}[h^{-1}] \cong B_{\text{perf}}[h^{-1}] \]

and then remark \((17.4.1)\) shows that \( h^{1/p^n} e_f \) lies in the image of the induced map

\[ B_{\text{perf}} \otimes_{A_{\text{perf}}} B_{\text{perf}} = (B \otimes_A B)_{\text{perf}} \to B_{\infty} \otimes_{A_{\infty}} B_{\infty}[h^{-1}] \to \Gamma(U_f, \mathcal{B}_{\infty} \otimes_{\mathcal{O}_{X_{\infty}}} \mathcal{B}_{\infty}) \]

for every \( n \in \mathbb{N} \). On the other hand, \( B_{\text{perf}} \) is an integral \( A_{\text{perf}} \)-algebra, and \( A_{\text{perf}} \) is a normal domain, hence the trace map of the finite étale map \( A_{\text{perf}}[h^{-1}] \to B_{\text{perf}}[h^{-1}] \) restricts to an \( A_{\text{perf}} \)-linear map \( B_{\text{perf}} \to A_{\text{perf}} \) (lemma \((14.3.15)\)) which in turns induces an \( A_{\text{perf}} \)-linear map

\[ \omega_{B_{\text{perf}}/A_{\text{perf}} : B_{\text{perf}} \to \text{Hom}_{A_{\text{perf}}}(B_{\text{perf}}, A_{\text{perf}})} : B_{\text{perf}} \to B_{\infty}^\vee \]

such that

\[ A_{\infty}[h^{-1}] \otimes_{A_{\text{perf}}} \omega_{B_{\text{perf}}/A_{\text{perf}}} = \Gamma(\text{Spec} A[h^{-1}], \omega_{\mathcal{B}_{\infty}/\mathcal{O}_{X_{\infty}}} \mathcal{B}_{\infty}). \]

A simple inspection then shows that \((17.4.22)\) is the composition of \( \omega_{B_{\text{perf}}/A_{\text{perf}} \otimes_{A_{\text{perf}}} \omega_{B_{\text{perf}}/A_{\text{perf}}}} \) with \((17.4.6)\). Summing up, this proves that \( h^{1/p^n} e_f \) lies in the image of the map \((17.4.6)\) for every \( n \in \mathbb{N} \), and especially, \( h e_f \in \partial_f(R(B, \Gamma)) \), whence assertion (ii).

In order to show (i), let \( \delta = \sum_{\gamma \in P, h_\gamma \cdot \gamma} \) for a system \((h_\gamma | \gamma \in P)\) of elements of \( k \), and pick \( \gamma_0 \in P \) with \( h_\gamma \neq 0 \). According to claim \((17.3.7)\), there exists \( n \in \mathbb{N} \) such that

\[ \text{gr}_{\gamma_0} h^{1/p^n} P_Q = h^{1/p^n} P \text{ } \text{ for } n \in \mathbb{N} ; \text{ then we have an } A_{\text{perf}} \text{-linear isomorphism:} \]

\[ (17.4.23) \quad \chi(f) \cong \text{gr}_{\gamma_0} h^{1/p^n} \Gamma(U_f, \mathcal{B}_{\infty} \otimes_{\mathcal{O}_{X_{\infty}}} \mathcal{B}_{\infty}) = \chi(f) \otimes_A A_{\text{perf}}[h^{1/p^n}] \]

We have already remarked that \( h^{1/p^n} e_f \) lies in the image of \((17.4.6)\); let us write \( h^{1/p^n} = \sum_{[\gamma] \in \Gamma} h_{[\gamma]} \), with \( h_{[\gamma]} \in A_{[\gamma]} \) for every \( [\gamma] \in \Gamma \); then \( h^{1/p^n} = \sum_{\gamma \in P} h_{\gamma}^{1/p^n} \cdot \gamma^{1/p^n} \), and \( h^{1/p^n} = h_{\gamma_0}^{1/p^n} \cdot \gamma^{1/p^n} \cdot a \) for some \( a \in 1 + m \). Hence, \( h^{1/p^n} e_f \) is in the image of \( \text{gr}_{\gamma_0} h^{1/p^n} (B_{\infty}^\vee \otimes A_{\infty} B_{\infty}^\vee) \), and so the same holds for \( e_f \otimes \gamma^{1/p^n} \). Thus, there exists a finite subset \( \Sigma \subset \Gamma \) and an element of
Suppose next that $A$ is a $\mathbb{Q}$-algebra, so that $V$ is a field of characteristic zero, and $\varphi$ is an isomorphism. We pick a complete discrete valuation ring $W$ with residue field $V$, and a surjective map of monoids $\pi : \mathbb{N}^{\oplus r} \to P$; for $s := r + r'$ we get a surjective map of $\mathcal{W}$-algebras $W[\mathbb{N}^{\oplus s}] \to A_s := V[P \times \mathbb{N}^{\oplus r}]$ whose completion is a surjective map $W[[\mathbb{N}^{\oplus s}]] \to A$. According to [26, §3.6, Th.12], the completion map $W[[\mathbb{N}^{\oplus s}]] \to W[[\mathbb{N}^{\oplus r}]]$ is the colimit of a filtered system $(R_\lambda | \lambda \in \Lambda)$ of smooth $W[[\mathbb{N}^{\oplus r}]]$-algebras; set $A_\lambda := R_\lambda \otimes_{W[[\mathbb{N}^{\oplus r}]}} A_0$ for every $\lambda \in \Lambda$. Then $A$ is the colimit of the filtered system of smooth $A_0$-algebras $A_{\bullet} := (A_\lambda | \lambda \in \Lambda)$. For every $\lambda \in \Lambda$, let $X_{\lambda}$ be the connected component of $\text{Spec} A_{\lambda}$ containing the image of $X$, and let $A_\lambda$ be the quotient of $A_{\lambda}$ with $\text{Spec} A_{\lambda} = X_{\lambda}$. It is easily seen that the colimit of the induced system $A'_{\bullet} := (A'_{\lambda} | \lambda \in \Lambda)$ is still $A$; after replacing $A_{\lambda}$ by $A'_{\lambda}$, we may then assume that $A_{\lambda}$ is a domain for every $\lambda \in \Lambda$. Now, after replacing $A$ by a cofinal submonoid, we may assume that for every $\lambda \in \Lambda$ there exists an open subset $U_{\lambda} \subset X_{\lambda}$ such that $\varphi_f = X \times_{X_{\lambda}} U_\lambda$, and $U_{\mu} = X_\mu \times_{X_{\lambda}} U_{\lambda}$ for every $\mu \in \Lambda$ with $\mu \geq \lambda$. We may then find $\lambda \in \Lambda$ and a finite morphism of schemes $\varphi_{\lambda} : Y_{\lambda} \to X_{\lambda}$ with $\varphi_{\lambda}$ an isomorphism of $\mathcal{X}$-schemes $X \times_{X_{\lambda}} Y_{\lambda} \to \text{Spec} B$. Then there exists $\mu \in \Lambda$ with $\mu \geq \lambda$ such that $U_{\mu} \times_{X_{\lambda}} Y_{\lambda}$ is a finite étale $U_{\mu}$-scheme; set $Y_{\mu} := X_\mu \times_{X_{\lambda}} Y_{\lambda}$, and $B_{\mu} := \varphi_{Y_{\mu}}(Y_{\mu})$. By construction, the morphism $Y_{\mu} \to X_{\lambda}$ is surjective; since $A_{\mu}$ is a domain, it follows easily that the induced ring homomorphism $f_{\mu} : A_{\mu} \to B_{\mu}$ is injective. Let $\beta_{\mu} : P \to A_{\mu}$ be the natural map; by example 17.4.13, the datum $(A_{\mu}, P, \beta_{\mu})$ is a regular log ring, and $f_{\mu} : (f_{\mu}, P, \beta_{\mu})$ is a datum as in 17.4.3. In light of remark 17.4.7(ii), it then suffices to prove assertions (i) and (ii) for the map $\varphi_{Y_{\mu}}$; the latter is covered by the following:

**Claim 17.4.24.** The theorem holds if there exists a field $K$ of characteristic zero and a smooth ring homomorphism $\psi : K[P] \to A$, such that $\beta$ is the composition of $\psi$ and the inclusion map $P \to K[P]$ (see example 17.4.13).

**Proof of the claim.** The field $K$ is the colimit of the filtered system of its smooth $\mathbb{Z}$-subalgebras $(V_{\lambda} | \lambda \in \Lambda)$. Then we may find $\lambda \in \Lambda$, a smooth $V_{\lambda}[P]$-algebra $A_{\lambda}$, and a finite, injective and generically finite ring homomorphism $f_{\lambda} : A_{\lambda} \to B_{\lambda}$ with isomorphisms

$$K \otimes_{V_{\lambda}} A_{\lambda} \xrightarrow{\sim} A \quad A \otimes A_{\lambda} B_{\lambda} \xrightarrow{\sim} B$$

(details left to the reader). Let $\alpha : P \to V_{\lambda}[P] \to A_{\lambda}$ be the natural map; since $V_{\lambda}$ is a regular noetherian ring, the datum $(A_{\lambda}, P, \alpha)$ is a regular log ring, by example 17.4.13 and in light of remark 17.4.7(i), it suffices to show assertions (i) and (ii) for the map $\varphi_{f_{\lambda}}$ corresponding to the datum $f_{\lambda} := (f_{\lambda}, P, \alpha)$. Now, for every $p \in \text{Spec} V_{\lambda}$, every $V_{\lambda}$-module $M$, let $M(p) := \kappa(p) \otimes_{A_{\lambda}} M$; also, for every homomorphism of $V_{\lambda}$-modules $h : M \to N$ let likewise $h(p) := \kappa(p) \otimes_{V_{\lambda}} h : M(p) \to N(p)$; moreover, let $\alpha(p) : P \to A_{\lambda}(p)$ be the composition of $\alpha$ with the natural map $A_{\lambda} \to A_{\lambda}(p)$. Let also $a \in A_{\lambda} \setminus \{0\}$ such that $\text{Spec} A_{\lambda}[a^{-1}] \subset U_{f_{\lambda}}$. According to [50] Ch.IV, Prop.9.5.3, the set $Z := \{p \in \text{Spec} V_{\lambda} | \text{Spec} A_{\lambda}[a^{-1}](p)$ is dense in $\text{Spec} A_{\lambda}(p)\}$
is constructible in Spec $V_\lambda$; furthermore, $Z$ contains the generic point of Spec $V_\lambda$, so it is dense in Spec $V_\lambda$. For every $p \in Z$, the datum $f_{\lambda(p)} := (f_{\lambda(p)}, P, \alpha(p))$ fulfills therefore the conditions of (17.4.4), and moreover $(A_\lambda(p), P, \alpha(p))$ is still a regular log ring. Set $X_\lambda := \text{Spec } A_\lambda$, and denote by $\mathscr{R}_\lambda$ the quasi-coherent $\mathcal{O}_{X_\lambda}$-algebra arising from $B_\lambda$. By remark [17.4.7](i), for $\Delta$ either equal to $\Gamma_Q$ or to $\Gamma$ we have a commutative diagram:

\[
\begin{array}{ccc}
R(B_\lambda(\Gamma), \Delta) & \xrightarrow{\vartheta_\Delta} & B_\lambda \otimes_{A_\lambda} B_\lambda[a^{-1}] \\
\downarrow & & \downarrow \\
R(B_\lambda(p, \Delta)) & \xrightarrow{\vartheta(p)} & B_\lambda \otimes_{A_\lambda} B_\lambda(p)[a^{-1}]
\end{array}
\]

whose right vertical arrow maps $e_{f_{\lambda(p)}}$ to $e_{f_{\lambda(p)}}$, and where $\vartheta(p)$ is the composition of the restriction of $\vartheta_\Delta$ to $R(B, \Delta)$ with the restriction map $\Gamma(U_{f_{\lambda(p)}} \mathcal{R}_\lambda \otimes_{\mathcal{O}_{X_\lambda}} \mathcal{R}_\lambda) \rightarrow B_\lambda \otimes_{A_\lambda} B_\lambda[a^{-1}]$, and likewise $\vartheta(p)$ is deduced from $\vartheta(p)$. Lemma [17.4.10](i) yields a finite subset $\Sigma \subset \Delta$ such that

\[
\vartheta(p)(R(B(p), \Sigma)) = \vartheta(p)(R(B(p), \Delta)) \quad \text{for every } p \in Z.
\]

On the other hand, in view of lemma [17.4.14](i), after replacing $V_\lambda$ by a suitable localization $V_\lambda[t^{-1}]$ (with $t \neq 0$), and $Z$ by $Z \cap \text{Spec } V[t^{-1}]$, we may assume that the natural maps

\[
(B^\vee_{\Gamma}(p))[\gamma] \rightarrow (B_\lambda(p))[\gamma] \quad \text{and} \quad (B^\vee_{\Gamma}(p))[\gamma][1] \rightarrow (B_\lambda(p))[\gamma][1]
\]

are isomorphisms, for every $p \in Z$ and every $[\gamma] \in \Sigma$. Summing up, we may assume that the image of $\vartheta(p)$ equals the image of $\vartheta(p)$, for every $p \in Z$. Lastly, recall that the set $Z'$ of all $p \in \text{Spec } V_\lambda$ such that $\kappa(p)$ is a finite field is dense in the constructible topology of Spec $V_\lambda$, since $V_\lambda$ is a $Z$-algebra of finite type ([50, Ch.IV, Cor.10.4.6]). Hence, $Z \cap Z'$ is a dense subset of Spec $V_\lambda$, and by claim [17.4.21], the image of $\vartheta(p)$ (resp. of $\vartheta(p)$) contains $e_{f_{\lambda(p)}} = 1 \otimes e_{f_{\lambda(p)}}$ (resp. $b_{e_{f_{\lambda(p)}}} = 1 \otimes b_{e_{f_{\lambda(p)}}}$) for every $p \in Z \cap Z'$ (resp. and every $b \in J$). By lemma [17.4.14](iii) it follows that the image of $\vartheta(p)$ contains $e_f$ (resp. that the image of $\vartheta(p)$ contains $b_{e_f}$ for every $b \in J$). The claim is an immediate consequence.

It remains to deal with the case where $A$ does not contain a field, hence $A = V[[P]]/(h)$, for a discrete valuation ring $(V, m_V)$ whose residue field $k$ has positive characteristic, such that $m_V = pV$, and with some $h := \sum_{\gamma \in \Gamma} h_\gamma \cdot \gamma$ such that $h_0 \in pV \setminus p^2V$. Arguing as in (17.3.4), and taking into account claim [17.4.20], we may then further reduce to the case where $k$ is algebraically closed. In this situation, let $g \in J \setminus \{0\}$, and set

\[
A_{\Gamma} := \Gamma \times_{\Gamma_Q} A_{\infty} \quad \text{and} \quad A' := A_{\Gamma}[X^{1/p^\infty}]/(X - g) = A_{\Gamma}[g^{1/p^\infty}].
\]

We get a basic setup $(A_{\Gamma}, n)$, where $n \subset A_{\Gamma}$ is the ideal generated by $(g^\delta | \delta \in N[\{1/p\} \setminus \{0\})$. Moreover, let $D$ be the $p$-integral closure of $A_{\Gamma}$ in $A_{\Gamma}[1/p]$, and $D^h$ the $p$-adic completion of $D$; also, set $D^h := (D^h)^a$, the ring of almost elements of the $(A_{\Gamma}, n)$-algebra $(D^h)^a$, and denote by $B_1^a$ the integral closure of $D^h$ in $B' := D^h \otimes_A B_{\Gamma}[1/g]$. Pick $N \in \mathbb{N}$ and $e \in B \otimes_A B$ whose image in $B \otimes_{A} B_{\Gamma}[1/g]$ equals $g^N e_f$, and let $e' \in B'^a \otimes_{D^h} B'_1$ be the image of $e$.

Claim 17.4.25. For every $\delta \in N[\{1/p\} \setminus \{0\}$ we have $g^\delta e' \in g^N (B'_1 \otimes_{D^h} B'_1)$.

Proof of the claim. For every $n \in \mathbb{N}$, the $(D/p^nD)^a$-algebra $(B'_1/p^nB'_1)^a$ is étale of finite rank, and we let $\varepsilon_n \in (B'_1/p^nB'_1 \otimes_{D^h} B'_1/p^nB'_1)^a$ be the corresponding diagonal idempotent. The system $(\varepsilon_n | n \in \mathbb{N})$ corresponds to a unique element

\[
\varepsilon \in (B'_1 \otimes_{D^h} B'_1)^a
\]
where $B'_1 \otimes_{D^\wedge} B'_1$ denotes the $p$-adic completion of $B'_1 \otimes_{D^\wedge} B'_1$. Let $\mu : B'_1 \otimes_{D^\wedge} B'_1 \to B'_1$ be the multiplication law of $B'_1$, and $\widehat{\mu}$ the $p$-adic completion of $\mu$; by construction, we see that:

(17.4.26) \[ \widehat{\mu}(\varepsilon) = 1 \] \[ \varepsilon \cdot (1 \otimes x - x \otimes 1) = 0 \] for every $x \in B'_1 = (B'_1)^\wedge$.

By corollary [16.9.44(ii)], the completion map $B'_1 \otimes_{D^\wedge} B'_1 \to B'_1 \otimes_{D^\wedge} B'_1$ induces an isomorphism

\[ B \otimes_A B \otimes_A D^\wedge[1/g] \cong B'_1 \otimes_{D^\wedge} B'_1[1/g] \cong B'_1 \otimes_{D^\wedge} B'_1[1/g] \]

and it follows easily from (17.4.26) that the image of $e_I \otimes 1$ in $B'_1 \otimes_{D^\wedge} B'_1[1/g]$ agrees with the image of $\varepsilon$. But $g$ is a regular element of $(B'_1 \otimes_{D^\wedge} B'_1)^\wedge$, due to corollary [16.9.44(ii)], hence the image of $e$ in $(B'_1 \otimes_{D^\wedge} B'_1)^\wedge$ agrees with $g^\wedge \varepsilon$, whence the claim.

Recall that $D^\wedge_1$ is integrally closed in $D^\wedge[1/g]$ (theorem [16.9.34(iv)], and A is a normal domain; then the trace maps for the étale ring homomorphisms $D^\wedge[1/g] \to B'$ and $A[1/g] \to B'[1/g]$ restrict to a $D^\wedge_1$-linear map and respectively an $A$-linear map

\[ \text{tr}_{B'/D^\wedge_1} : B'_1 \to D^\wedge_1 \quad \text{tr}_{B/A} : B \to A \]

(lemma [14.3.15]) whence an $A$-linear map and a $D^\wedge_1$-linear map

\[ \tau : B \to B^\vee := \text{Hom}_A(B, A) \quad b \mapsto (b' \mapsto \text{tr}_{B/A}(bb')) \]

\[ \tau' : B'_1 \to \text{Hom}_A(B, D^\wedge_1) \quad b \mapsto (b' \mapsto \text{tr}_{B'/D^\wedge_1}(bb')). \]

Let also $i : A \to A_r$ and $i_D : D^\wedge \to D^\wedge_1$ be the natural maps; since $i_D^\wedge$ is an isomorphism of $A_r$-modules, we get by adjunction a unique $A_r$-linear map $j_D : \bar{n} \otimes_{A_r} D^\wedge_1 \to D^\wedge$ such that $i_D \circ j_D = \mu \otimes_{A_r} D^\wedge_1$, where as usual $\bar{n} := n \otimes_{A_r} n$, and $\mu : n \to A$ is the multiplication map : $a \otimes a' \mapsto aa'$. Then, for every $\delta, \delta' \in \mathbb{N}[1/p] \setminus \{0\}$ we let $j_{\delta, \delta'} : D^\wedge_1 \to D^\wedge$ be the $A_r$-linear map such that $j_{\delta, \delta'}(d) := j_D(g^\delta \otimes g^{\delta'} \otimes d)$ for every $d \in D^\wedge_1$; it is easily seen that this map depends only on the sum $\delta + \delta'$. Hence:

\[ i_D \circ j_\delta = g^\delta \cdot 1_{D^\wedge_1} \quad \text{and} \quad j_{\delta, \delta'} = g^\delta \cdot j_{\delta'} \quad \text{for every} \ \delta, \delta' \in \mathbb{N}[1/p] \setminus \{0\} \]

and moreover for every such $\delta$ we get a commutative diagram of $A_r$-modules:

\[
\begin{array}{ccc}
A_r & \xrightarrow{g^\delta \cdot 1_{A_r}} & A_r \\
\downarrow & & \downarrow \\
D^\wedge_1 & \xrightarrow{j_\delta} & D^\wedge
\end{array}
\]

whose vertical arrows are the structure maps of the $A_r$-algebras $D^\wedge_1$ and $D^\wedge$. Set

\[ B^\vee_1 := \text{Hom}_A(B, A_r) \quad B^\vee : = \text{Hom}_A(B, D^\wedge_1) \quad C := \text{Hom}_A(B, D^\wedge) \]

and let $i : B^\vee \to B^\vee_1$ (resp. $j_\delta : B^\vee \to C$) be the $A$-linear (resp. $A_r$-linear) map such that $i_\delta(\varphi) := i \circ \varphi$ for every $A$-linear map $\varphi : B \to A$ (resp. $j_\delta(\varphi) := j_\delta \circ \varphi$ for every $A_r$-linear map $\varphi : B \to D^\wedge_1$). To ease notation, set as well

\[ B^\vee_{1,r} := \text{Hom}_A(B, A_r/p^i A_r) \quad \text{and} \quad C_i := \text{Hom}_A(B, D/p^i D) \quad \text{for every} \ \delta \in \mathbb{N}. \]

We then obtain a commutative diagram for every $\delta \in \mathbb{N}[1/p] \setminus \{0\}$ and every $\delta \in \mathbb{N}$:

\[
\begin{array}{cccccccc}
B \otimes_A B & \xrightarrow{\tau \otimes A} & B^\vee \otimes_A B^\vee & \xrightarrow{g^\delta \cdot i \otimes A g^\delta \cdot i} & B^\vee_1 \otimes_{A_r} B^\vee_1 & \xrightarrow{B^\vee_{1,r} \otimes_A B^\vee_{1,r}} & B^\vee_{1,r} \otimes_{A_r} B^\vee_{1,r} \\
\downarrow & & \downarrow & & \downarrow & & \downarrow \\
B'_1 \otimes_{D^\wedge} B'_1 & \xrightarrow{\tau' \otimes_{D^\wedge} \tau'} & B^\vee \otimes_{D^\wedge} B^\vee & \xrightarrow{g^\delta \cdot j_\delta \otimes_{D^\wedge} g^\delta \cdot j_\delta} & C \otimes_{D^\wedge} C & \xrightarrow{C_i \otimes_{D^\wedge} C_i} & C_i \otimes_{D^\wedge} C_i
\end{array}
\]

For given $\delta$, pick $\delta' \in \mathbb{N}[1/p] \setminus \{0\}$ with $\delta = \delta' + \delta''$; then

\[ (j_{\delta, \delta'} \circ \tau')(j_{\delta, \delta'} \circ \tau')(\varepsilon') = (j_{\delta, \delta'} \circ \tau')(j_{\delta, \delta'} \circ \tau')(g^{2\delta''} \varepsilon'). \]
By claim 17.4.25 we deduce that the image of \((j_{\delta*} \circ \tau') \otimes_D (j_{\delta*} \circ \tau')(e')\) in \(C_i \otimes_D C_i\) is divisible by \(g^{n_i}\). Recall now that \(D\) is a faithfully flat \(A\Gamma\)-algebra (theorem 16.9.17); since \(A\) is noetherian, and \(B\) is a finite \(A\)-algebra, we deduce a natural isomorphism
\[
B_{\Gamma,i} \otimes_{A\Gamma} D \xrightarrow{\sim} C_i \quad \text{for every } i \in \mathbb{N}.
\]
Set \(e'' := (i_* \circ \tau) \otimes_A (i_* \circ \tau)(e)\); it follows that the image of \(ge''\) in \(B_{\Gamma,i} \otimes_{A\Gamma} B_{\Gamma,i}^\prime\) is divisible by \(g^N\), for every \(i \in \mathbb{N}\). Next, for every \(i \in \mathbb{N}\) and every subset \(\Delta \subset \Gamma_Q\), let :
\[
R(B, \Delta, i) := \bigoplus_{[\gamma] \in \Delta} B_{\gamma,i}^\vee \otimes_A B_{\gamma,i}^\prime \quad \text{with } B_{\gamma,i}^\vee := \text{Hom}_A(B, A_{[\gamma]}/p^iA_{[\gamma]}) \text{ for every } [\gamma] \in \Gamma_Q
\]
and notice that we have an \(A\)-linear surjection \(R(B, \Gamma, i) \to \text{gr}_0(B_{\Gamma,i}^\vee \otimes_{A\Gamma} B_{\Gamma,i}^\prime)\), for the natural \(\Gamma\)-grading on \(B_{\Gamma,i}^\vee \otimes_{A\Gamma} B_{\Gamma,i}^\prime\). Summing up, for every \(i \in \mathbb{N}\) there exists \(e_i \in R(B, \Gamma, i)\) such that the image of \(ge''\) in \(\text{gr}_0(B_{\Gamma,i}^\vee \otimes_{A\Gamma} B_{\Gamma,i}^\prime)\) equals the image of \(g^N e_i\). On the other hand, as in remark 17.4.7(ii) we obtain for every \(i \in \mathbb{N}\) a commutative diagram of \(A\)-linear maps
\[
\begin{array}{ccc}
A/p^iA \otimes_A R(B, \Gamma) & \longrightarrow & A/p^iA \otimes_A \text{gr}_0(B_{\Gamma,i}^\vee \otimes_{A\Gamma} B_{\Gamma,i}^\prime) \\
\downarrow & & \downarrow \\
R(B, \Gamma, i) & \longrightarrow & \text{gr}_0(B_{\Gamma,i}^\vee \otimes_{A\Gamma} B_{\Gamma,i}^\prime) \longrightarrow \text{Hom}_A(B \otimes_A B, A/p^iA)
\end{array}
\]
whose left vertical arrow is induced by the projections \(A_{[\gamma]} \to A_{[\gamma]}/p^iA_{[\gamma]}\) for every \([\gamma] \in \Gamma_Q\), and such that the composition of the top horizontal arrows is \(A/p^iA \otimes_A \xi_{\Gamma,i}\). Denote by \(\xi_{\Gamma,i}\) the composition of the bottom horizontal arrows; arguing as in the proof of lemma 17.4.10(i) we find a finite subset \(\Sigma \subset \Gamma\) such that \(\xi_{\Gamma,i}(R(B, \Gamma)) = \xi_{\Gamma,i}(R(B, \Sigma))\) and \(\xi_{\Gamma,i}(R(B, \Gamma, i)) = \xi_{\Gamma,i}(R(B, \Sigma, i))\) for every \(i \in \mathbb{N}\). We notice:

Claim 17.4.27. Let \(R\) be a noetherian ring, \(M, N\) two \(R\)-modules of finite type, and \(I \subset R\) an ideal. Set \(H^i := \text{Hom}_R(M, N/I \cdot N)\) for every \(i \in \mathbb{N}\). Then there exists \(c \in \mathbb{N}\) such that
\[
\text{Im}(H^{i+c} \to H^i) = \text{Im}(\text{Hom}_R(M, N) \to H^i) \quad \text{for every } i \in \mathbb{N}.
\]

Proof of the claim. Pick a finite presentation \(R^{op} \xrightarrow{\nu} R^{op} \to M\) of the \(R\)-module \(M\); let \(\nu^\vee : R^{op} \to R^{op}\) be the transpose of \(\nu\), set \(\nu^\vee := \nu^\vee \otimes_A N : N^{op} \to N^{op}\) and \(N^i := \text{Im} \nu^\vee_i\); by the Artin-Rees lemma ([100, Th.8.5]) there exists \(c \in \mathbb{N}\) such that \(N^i \cap I^i+c N^{op} = I^i(N^i \cap I^c N^{op})\) for every \(i \in \mathbb{N}\). We consider then the induced commutative diagram :
\[
\begin{array}{cccc}
0 & \longrightarrow & \text{Hom}_R(M, N) & \longrightarrow & N^{op} \\
0 & \longrightarrow & H^{i+c} & \longrightarrow & N^{op} / I^{i+c} N^{op} \\
0 & \longrightarrow & H^i & \longrightarrow & N^{op} / I^i N^{op}
\end{array}
\]
whose horizontal rows are left exact sequences. Let then \(\overline{h} \in \text{Ker} \nu^\vee_{N/I^i N^{op}}\), and pick a representative \(h \in N^{op}\) for the class \(\overline{h}\). Then \(\nu^\vee_h(h) \in N^i \cap I^{i+c} N^{op}\), so there exists \(k \in \mathbb{N}\) such that \(\nu^\vee_h(h) = \sum_{j=1}^k a_j \nu^\vee_h(x_j)\) for certain \(a_1, \ldots, a_k \in I^i\) and \(x_1, \ldots, x_k \in N^{op}\). Set \(h' := h - \sum_{j=1}^k a_j x_j\). Then \(h' \in \text{Ker} \nu^\vee\), and the image of \(h'\) in \(N^{op} / I^i N^{op}\) agrees with the image of \(\overline{h}\), whence the claim.

By claim 17.4.27 for every \(i \in \mathbb{N}\) there exists \(e'_i \in R(B, \Sigma, i)\) such that \(\xi_{\Gamma,i}(e'_i)\) agrees with the image of \(1 \otimes \xi_{\Gamma,i}(e'_i) \in A/p^iA \otimes_A (B \otimes_A B)^\vee\). Now, let \(M \subset (B \otimes_A B)^\vee\) be the \(A\)-submodule
generated by the system \((\xi_{\ell}(e'_i) \mid i \in \mathbb{N})\); we conclude that the image of \(ge''\) in \((B \otimes_A B)^\gamma\) lies in the submodule \(g^N M + p^s(B \otimes_A B)^\gamma\), for every \(i \in \mathbb{N}\); but then it lies already in \(g^N M\), since \(g^N M\) is a closed subset for the \(p\)-adic topology of the finitely generated \(A\)-module \((B \otimes_A B)^\gamma\) (Th.8.10(i)). Lastly, this shows that the image of \(ge''\) in \(X(f)\) lies in \(g^N \cdot \delta_f(R(B, \Gamma))\); but this image equals \(g^{N+1}e_f\), whence \(ge_f \in \delta_f(R(B, \Gamma))\), which achieves the proof of (ii).

To show (i), let \(e''_i\) be the image of \(e''\) in \(B_{\Gamma,i}^\gamma \otimes_A B_{\Gamma,i}^\gamma\) for every \(i \in \mathbb{N}\), and set
\[
I_i := \{a \in A \mid ac_{\gamma}'' \in g^N(B_{\Gamma,i}^\gamma \otimes_A B_{\Gamma,i}^\gamma)\} \quad \text{and} \quad I_{D,i} := \{d \in D \mid dc_{\gamma}'' \in g^N(C_i \otimes_D C_i)\}.
\]
As already observed in the foregoing, \(g^s \in I_{D,i}\) for every \(s \in \mathbb{N}\), then, since \(D\) is a flat \(A\)-algebra, we have \(I_{D,i} = I_i D\) for every \(i \in \mathbb{N}\) (details left to the reader), so that \(I_{D,i} = I_i D\) for every \(i, k \in \mathbb{N}\). Since \(D\) is faithfully flat \(A\)-algebra, it follows that \(I_i^k = I_{D,i} \cap A = I_{D,i}\), and by claim 17.3.7 we may assume that \(g_{[\gamma]}P^{(\infty)} = \gamma_n P\) for every \(n \in \mathbb{N}\), so that \(A_{[\gamma]} = A \cdot (1 \otimes \gamma_n)\), and therefore
\[
(1 \otimes \gamma_n) \cdot e''_i \in g^N \cdot g_{[\gamma]}(B_{\Gamma,i}^\gamma \otimes_A B_{\Gamma,i}^\gamma).
\]
On the other hand, lemma 17.4.16 yields for every \([\gamma] \in \Gamma\) an element \([\gamma'] \in \Sigma_Q\) such that:
\[
\gamma^{-1}P_Q \cap P^{SP} \subset \gamma^{-1}P_Q \cap P^{SP} \quad \text{and} \quad (\gamma/\gamma_n)P_Q \cap P^{SP} \subset \gamma/\gamma_n P_Q \cap P^{SP}.
\]
We then get a commutative diagram of \(A\)-modules:
\[
R(B, \Gamma_Q, i) \longrightarrow g_{0}(B_{\infty,i}^\gamma \otimes_A B_{\infty,i}^\gamma) \longrightarrow \text{Hom}_A(B \otimes_A B, A/p^i A)
\]
\[
\bigoplus_{[\gamma] \in \Gamma} B_{[\gamma],i}^\gamma \otimes_A B_{[\gamma],i}^\gamma \longrightarrow g_{[\gamma]}(B_{\infty,i}^\gamma \otimes_A B_{\infty,i}^\gamma) \longrightarrow \text{Hom}_A(B \otimes_A B, A_{[\gamma]}/p^i A_{[\gamma]})
\]
whose right vertical arrow is an isomorphism induced by scalar multiplication by \(1 \otimes \gamma_n\). Moreover, the composition of the top horizontal arrows is \(\xi_{\Gamma,i}\). With this notation, we have \(e''_i \in g_{0}(B_{\infty,i}^\gamma \otimes_A B_{\infty,i}^\gamma)\), and it follows easily that the image of \(e''_i\) lies in \(g^N \cdot \xi_{\Gamma,i}(R(B, \Gamma_Q, i))\), for every \(i \in \mathbb{N}\). Arguing as in the proof of lemma 17.4.10(i), we then find a finite subset \(\Delta \subset \Gamma_Q\) such that the image of \(e''_i\) in \(\text{Hom}_A(B \otimes_A B, A/p^i A)\) lies in the \(A\)-submodule \(g^N \cdot \xi_{\Gamma,i}(R(B, \Delta, i))\), for every \(i \in \mathbb{N}\). By invoking again claim 17.4.27 we deduce that for every \(i \in \mathbb{N}\), the image of \(e''\) in \((B \otimes_A B)^\gamma\) lies in the \(A\)-submodule \(g^N \cdot \xi_{\Gamma}(R(B, \Delta)) + p^i \cdot (B \otimes_A B)^\gamma\).

Arguing as in the foregoing proof of (ii), we conclude that the image of \(e''\) in \((B \otimes_A B)^\gamma\) lies already in \(g^N \cdot \xi_{\Gamma}(R(B, \Delta))\), and finally \(e_f \in \delta_{\Gamma}(R(B, \Gamma_Q))\), as stated. □

17.4.28. Keep the notation of (17.4.5), and for every \(m \in \mathbb{N}\), let \(\Gamma_m := \{\gamma \in \Gamma_Q \mid m\gamma = 0\}\). By theorem 17.4.19 if \((A, P, \beta)\) is regular, there exists \(m \in \mathbb{N}\) such that \(e_f \in \delta_{\Gamma}(R(B, \Gamma_m))\).

It turns out that a suitable integer \(m\) with this property can be exhibited purely in terms of the combinatorics of the monoid \(P\). Indeed, let \(P^\gamma\) be the dual of \(P\) (see (6.4.11)); since \(P\) is fine, \(P^\gamma\) is fine, sharp and saturated (proposition 6.4.12(ii)), and we let \(F_1, \ldots, F_k\) be the one-dimensional faces of \(P^\gamma\). Then \(F_i \simeq \mathbb{N}\) (theorem 6.4.16(ii)), and we denote by \(\lambda_i\) the unique generator of \(F_i\), for every \(i = 1, \ldots, k\). Set \(\Lambda := \{\lambda_1, \ldots, \lambda_k\}\), and denote by \(\mathcal{E}\) the set of all subsets \(\Sigma \subset \Lambda\) such that \(\{\lambda \in \mathcal{E} \mid \lambda \in \Sigma\}\) is a basis of \((P^{SP})^\gamma\). For every \(\Sigma \in \mathcal{E}\), let \(L_{\Sigma} \subset P^{SP}\) be the subgroup generated by \(\{\lambda \in \mathcal{E} \mid \lambda \in \Sigma\}\), and denote by \(m_{SP}\) the exponent of the finite abelian group \(P^{SP}/L_{\Sigma}\). Lastly, denote by \(m_P\) the least common multiple of the finite system of integers \((m_{SP} \mid \Sigma \in \mathcal{E})\). We may then state:
Corollary 17.4.29. In the situation of theorem 17.4.19 we have $e_f \in \partial_L(R(B, \Gamma_{m_p}))$.

Proof. For every $\Sigma \in \mathscr{E}$, let $\lambda_\Sigma : P_{Q, \Sigma} \rightarrow \mathbb{Q}^{\mathbb{Z}^\Sigma}$ be the $\mathbb{Q}$-linear isomorphism given by the rule:

$$\gamma \mapsto (\lambda_{Q, \Sigma}^\Sigma(\gamma) | \lambda \in \Sigma)$$

for every $\gamma \in P_{Q, \Sigma}$.

Notice that $P_{Q, \Sigma} \subset \lambda_{Q, \Sigma}^{-1}(\mathbb{Z}^\Sigma)$ for every such $B$, and $m_\Sigma$ equals the exponent of the finite abelian group $\lambda_{Q, \Sigma}^{-1}(\mathbb{Z}^\Sigma)/P_{Q, \Sigma}$. With this notation, we have:

Claim 17.4.30. For every $\beta \in P_{Q, \Sigma}$ there exist $\Sigma \in \mathscr{E}$ and an element $\beta^\dagger \in \lambda_{Q, \Sigma}^{-1}(\mathbb{Z}^\Sigma)$ such that

$$\beta P_{Q, \Sigma} \subset \beta^\dagger P_{Q, \Sigma} \subset P_{Q, \Sigma} \quad \text{and} \quad \beta^{-1} P_{Q, \Sigma} \subset \beta^{-1} P_{Q, \Sigma} \subset P_{Q, \Sigma}.$$ 

Proof of the claim. Notice that, for every $\beta \in P_{R, \Sigma}$, we have

$$\beta P_{R, \Sigma} \subset P_{Q, \Sigma} = \{ x \in P_{Q, \Sigma} | \lambda_{R, \Sigma}(x) \geq \lambda_{R, \Sigma}(\beta) \text{ for every } \lambda \in \Sigma \}.$$ 

For every such $\beta$ and every $\lambda \in \Sigma$, denote by $N_{\beta, \lambda}$ (resp. $N_{\beta, \lambda}'$) the largest (resp. smallest) integer which is smaller than (resp. larger than) or equal to $\lambda_{R, \Sigma}^{-1}(\beta)$. Recalling that $\lambda_{R, \Sigma}(P_{Q, \Sigma}) \subset \mathbb{Z}$ for every $\lambda \in \Sigma$, it is easily seen that (17.4.31) holds if and only if

$$\lambda_{Q, \Sigma}^\Sigma(\beta^\dagger) \in [N_{\beta, \lambda}, N_{\beta, \lambda}'] \quad \text{for every } \lambda \in \Lambda.$$ 

Set $\Sigma_\beta := \{ \lambda \in \Sigma | \lambda_{Q, \Sigma}(\beta) \in \mathbb{Z} \}$. Now, if $\beta \in P_{Q, \Sigma}$ and $\Sigma_\beta$ spans $(P_{Q, \Sigma})^\vee$, obviously the claim holds with $\beta^\dagger := \beta$. Thus, a simple induction argument reduces to showing that, if $\beta \in P_{Q, \Sigma}$ and $\Sigma_\beta$ does not span $(P_{Q, \Sigma})^\vee$, there exists $\gamma \in P_{Q, \Sigma}$ such that (17.4.32) holds, and such that $\Sigma_\gamma$ strictly contains $\Sigma_\beta$. To this aim, let $l : P_{R, \Sigma} \rightarrow \mathbb{R}^{\mathbb{A}}$ be the $\mathbb{R}$-linear map such that

$$l(\gamma) := (\lambda_{R, \Sigma}(\gamma) | \lambda \in \Lambda)$$

for every $\gamma \in P_{Q, \Sigma}$ and set

$$K := \prod_{\lambda \in \Lambda} [N_{\beta, \lambda}, N_{\beta, \lambda}'] \subset \mathbb{R}^{\mathbb{A}} \quad \text{and} \quad M := \bigcap_{\lambda \in \Sigma_\beta} \ker \lambda_{R, \Sigma} \subset P_{Q, \Sigma}.$$ 

Notice that $l$ is a closed immersion, $K$ is a compact subset of $\mathbb{R}^{\mathbb{A}}$, and by assumption, $M \neq 0$. Clearly $\beta \in l^{-1}K$, and we pick any non-zero $\mu \in M$. It follows that the subset

$$\{ a \in \mathbb{R} | \beta + a \mu \in l^{-1}K \}$$

is non-empty and compact, so it admits a largest element $a_0$. Set $\gamma := \beta + a_0 \mu$; by construction, $\Sigma_\gamma \subset \Sigma_\beta$, and it is easily seen that there must exist some $\lambda \in \Lambda \setminus \Sigma_\beta$ such that $\lambda_{R, \Sigma}(\gamma) \in \{ N_{\beta, \lambda}, N_{\beta, \lambda}' \}$, since otherwise we could find a real number $a > a_0$ with $\beta + a \mu \in l^{-1}K$. Thus $\Sigma_\gamma$ strictly contains $\Sigma_\beta$. Lastly, since both $\beta$ and $\mu$ lie in $P_{Q, \Sigma}$ and $\lambda_{R, \Sigma}(\beta) \notin \mathbb{Z}$, we must have $\lambda_{R, \Sigma}(a_0 \mu) \in \mathbb{Q} \setminus \mathbb{Z}$, and since $\lambda_{R, \Sigma}(\mu) \in \mathbb{Q}$, we conclude that $a_0 \in \mathbb{Q}$, hence $\gamma \in P_{Q, \Sigma}$, whence the claim. \(\Diamond\)

Now, for every $[\beta] \in \Gamma_{Q, \Sigma}$ pick $\beta^\dagger \in P_{Q, \Sigma}$ fulfilling the condition of claim 17.4.30, and set $\Delta := \{ [\beta^\dagger] | [\beta] \in \Gamma_{Q, \Sigma} \}$. Notice that $\Delta \subset \Gamma_{m_p}$. Arguing as in the proof of lemma 17.4.10(ii) we easily deduce that $\partial_L(R(B, \Delta)) = \partial_L(R(B, \Gamma_Q))$, whence the corollary. \(\square\)

Example 17.4.33. (i) Suppose that $\dim P = 2$. Then we may find a basis $(f_1, f_2)$ of $P_{Q, \Sigma}$ and integers $a, b \in \mathbb{N}$ such that $b > a$, $(a, b) = 1$ and $P$ is the submonoid of $P_{Q, \Sigma}$ generated by $f_1$ and $af_1 + bf_2$ (example 6.4.17(ii)). With this notation, a simple calculation shows that $m_{q, \beta} = b$ (details left to the reader).

(ii) In the situation of theorem 17.4.19, suppose that $P = \mathbb{N}^{p_r} \times \mathbb{Z}^{n_s}$ for some $r, s \in \mathbb{N}$; by corollary 17.4.19, the latter holds if and only if $A$ is a regular ring. In this case, the integer $m_{q, \beta}$ of (17.4.28) equals 1, and therefore corollary 17.4.29 says that $e_f \in \partial_L((B^\vee \otimes_A B^\vee))$. However, the latter follows also more directly from lemma 17.4.10(ii). Moreover, in case $A$ is regular, the submodule $\partial_L((B^\vee \otimes_A B^\vee))$ can be interpreted in terms of the different ideal of the finite ring.
extension $f : A \to B$. We conclude this section with a review of different ideals in the more
general context of quasi-coherent algebras on schemes; especially, remark [17.4.44] explains the
connection with theorem [17.4.19].

17.4.34. Let $X$ be a reduced scheme, $\mathcal{A}$ a quasi-coherent and finite $\mathcal{O}_X$-algebra and $j : U \to X$ a quasi-compact open immersion with dense image, such that $j^*\mathcal{A}$ is a locally free $\mathcal{O}_U$-
module. Denote by

$$\text{Max } X$$

the set of maximal points of $X$, and notice that Max $X \subset U$, by proposition [8.1.44]i). In this
situation, there is a trace form as in remark [14.3.10]iii):

$$t_{j^*\mathcal{A}} : j^*\mathcal{A} \otimes_{\mathcal{O}_U} j^*\mathcal{A} \to \mathcal{O}_U$$

whence a pairing

$$t_{\mathcal{A},U} : \mathcal{A} \otimes_{\mathcal{O}_X} j_*j^*\mathcal{A} \to j_*(j^*\mathcal{A} \otimes_{\mathcal{O}_U} j^*\mathcal{A}) \to j_*\mathcal{O}_U$$

which in turns yields a morphism of $\mathcal{O}_X$-modules

$$\tau_{\mathcal{A},U} : j_*j^*\mathcal{A} \to \text{Hom}_{\mathcal{O}_X}(\mathcal{A}, j_*\mathcal{O}_U).$$

Since $X$ is reduced, the natural morphism $\mathcal{O}_X \to j_*\mathcal{O}_U$ is injective, and therefore the same holds
for the induced $\mathcal{O}_X$-linear morphism

$$\mathcal{A}^\vee \to \text{Hom}_{\mathcal{O}_X}(\mathcal{A}, j_*\mathcal{O}_U)$$

so we may define

$$\mathcal{D}_{\mathcal{A},U}^{-1} := \tau_{\mathcal{A},U}^{-1}(\mathcal{A}^\vee).$$

We call $\mathcal{D}_{\mathcal{A},U}^{-1} \subset j_*j^*\mathcal{A}$ the inverse different of $\mathcal{A}$ relative to the open subset $U$.

**Remark 17.4.35.**

(i) In the situation of (17.4.34), notice that the natural isomorphism

$$\text{Hom}_{\mathcal{O}_X}(\mathcal{A}, j_*\mathcal{O}_U) \cong j_*(j^*\mathcal{A})^\vee$$

(see [10.1.19]) identifies $\tau_{\mathcal{A},U}$ with $j_*\tau_{\mathcal{A},U}$, where $\tau_{\mathcal{A},U} : j_*j^*\mathcal{A} \to j^*\mathcal{A}^\vee$ is the $\mathcal{O}_U$-
linear morphism deduced from the trace pairing $t_{j^*\mathcal{A}}$.

(ii) Moreover, set $\mathcal{B} := \text{Im}(\mathcal{A} \to j_*j^*\mathcal{A})$. Since the natural map $\mathcal{O}_X \to j_*\mathcal{O}_U$ is a
monomorphism, it is easily seen that the the epimorphism $\mathcal{A} \to \mathcal{B}$ induces an isomorphism $\mathcal{B}^\vee \cong \mathcal{A}^\vee$, and taking (i) into account, we deduce that the latter induces an isomorphism

$$\mathcal{D}_{\mathcal{A},U}^{-1} \cong \mathcal{D}_{\mathcal{B},U}^{-1}.$$

(iii) Suppose next that $U' \subset U$ is another open subset, such that the open immersion $j' : U' \to X$ is also quasi-compact with dense image. A direct inspection of the definitions yields a commutative diagram

$$
\begin{array}{ccc}
     j_*j^*\mathcal{A} & \xrightarrow{\tau_{\mathcal{A},U}} & \text{Hom}_{\mathcal{O}_X}(\mathcal{A}, j_*\mathcal{O}_U) \\
     \downarrow & & \downarrow \\
     j'_*j'^*\mathcal{A} & \xrightarrow{\tau_{\mathcal{A},U'}} & \text{Hom}_{\mathcal{O}_X}(\mathcal{A}, j'_*\mathcal{O}_U)
\end{array}
$$

whose vertical arrows are monomorphisms, under the current assumptions. It follows easily
that

$$\mathcal{D}_{\mathcal{A},U}^{-1} = \mathcal{D}_{\mathcal{A},U'}^{-1} \cap j_*j^*\mathcal{A}.$$

(iv) In the situation of (iii), suppose that $\mathcal{A}$ is generically étale, and let $U' \subset U$ be the
largest open subset such that $\mathcal{A}_{U'}$ is an étale $\mathcal{O}_{U'}$-algebra. Then the inclusion $U' \to U$ is a
dense and quasi-compact open immersion. For the proof, we may assume that $U$ is affine, say
$U = \text{Spec } R$, and that $j^*\mathcal{A}$ is the quasi-coherent $\mathcal{O}_U$-algebra associated with an $R$-algebra $A$
which is a projective $R$-module of finite rank; then we easily reduce to the case where $A$ is a free $R$-module of finite rank. In this case, let $(e_i \mid i = 1, \ldots, r)$ be a basis of the $R$-module $A$; consider the matrix $D := (t_{j,i}(e_i, e_j) \mid i, j = 1, \ldots, r)$, and set $d := \det(D)$. We have $U' = \text{Spec } R[d^{-1}]$, a quasi-compact dense open subset of $U$ ([59, Th.4.1.14]), as required.

(v) In the situation of (iii), suppose additionally that $j^* \mathcal{A}$ is an étale $\mathcal{O}_U$-algebra. Then $t^*_{j,\mathcal{A}}$ and $t^*_{j',\mathcal{A}}$ are perfect pairings ([59, Th.4.1.14]). Taking (i) into account, we conclude that $\tau_{\mathcal{A},U}$ is an isomorphism, and the same applies to $\tau_{\mathcal{A}',U}$, so the inclusion map $j^*_{\mathcal{A}} j^*_{\mathcal{A}} \to j^*_{\mathcal{A}} j^*_{\mathcal{A}}$ restricts to a natural isomorphism

$$\mathcal{D}_{\mathcal{A},U}^{-1} \sim \mathcal{D}_{\mathcal{A}',U}^{-1}.$$  

More generally, if $j : U \to X$ and $j' : U' \to X$ are any two quasi-compact dense open immersions such that $j^* \mathcal{A}$ and $j'^* \mathcal{A}$ are respectively an étale $\mathcal{O}_U$-algebra and an étale $\mathcal{O}_U$-algebra, then both $\mathcal{D}_{\mathcal{A},U}$ and $\mathcal{D}_{\mathcal{A}',U}$ are naturally identified with $\mathcal{D}_{\mathcal{A},U \cap U'}$, and in this sense we may say that the inverse different of a finite and generically étale $\mathcal{O}_X$-algebra is independent of the open subset $U$. We shall therefore henceforth denote just by $\mathcal{D}_{\mathcal{A}}^{-1}$ the inverse different of $\mathcal{A}$.

**Lemma 17.4.36.** In the situation of ([17.4.34], denote by $\mathcal{A}'$ the normalization of $j^* \mathcal{A}$ over $X$ (see remark [14.4.3(ii)])). The following holds:

(i) If $X$ is normal, $\mathcal{A}' \subset \mathcal{D}_{\mathcal{A},U}^{-1}$.

(ii) Suppose that $\mathcal{A}'$ is a generically étale $\mathcal{O}_X$-algebra. Then:

(a) There exists a dense quasi-compact open subset $U' \subset U$ such that the map $\tau_{\mathcal{A},U'}$ restricts to an $\mathcal{O}_X$-linear isomorphism $\mathcal{D}_{\mathcal{A},U}^{-1} \sim \mathcal{A}'$.

(b) If $X$ is locally coherent, $\mathcal{D}_{\mathcal{A},U}^{-1}$ is a reflexive $\mathcal{O}_X$-module of finite type.

(c) If $X$ is normal, $\mathcal{A}' \subset \mathcal{D}_{\mathcal{A}}^{-1}$.

(iii) Suppose that $X$ is normal, and $j^* \mathcal{A}$ is an étale $\mathcal{O}_U$-algebra. Let also $j' : U' \to X$ be a quasi-compact open immersion with dense image, with $U' \subset U$, and $\mathcal{A}'$ the integral closure of $\mathcal{O}_{X_U}$ in $j^* \mathcal{A}_U$. Then the natural map $\mathcal{A}' \to \mathcal{A}'$ is an isomorphism.

**Proof.** (i) follows immediately from lemma [14.3.15].

(ii.a) follows immediately from the discussion of remark [17.4.35(iv,v)], and (ii.b) follows from (ii.a) and lemma [11.3.3].

(ii.c): Taking into account remark [17.4.35(ii)], we may assume without loss of generality that $\mathcal{A} = \text{Im } (\mathcal{A} \to j^* \mathcal{A})$, in which case the natural map $\mathcal{A} \to \mathcal{A}'$ is a monomorphism. Moreover, the assertion is clearly local on $X$, hence we may assume that $X$ is affine, in which case $\mathcal{A}'$ is the union of the filtered family of its $\mathcal{A}$-subalgebras $\mathcal{B}$ that are quasi-coherent and finite $\mathcal{O}_X$-algebras. For any such $\mathcal{B}$, the $\mathcal{O}_X$-module $\mathcal{B}/\mathcal{A}$ is supported on $X \setminus U$. It follows that $(\mathcal{B}/\mathcal{A})^{\mathcal{A}} = 0$, so the transpose map $\mathcal{B}^{\mathcal{A}} \to \mathcal{B}'^{\mathcal{A}}$ is a monomorphism as well; by the same token, we see that $\tau_{\mathcal{A},U} = \tau_{\mathcal{A}',U}$ (notation of ([17.4.34])), so $\mathcal{D}_{\mathcal{A}}^{-1} \subset \mathcal{D}_{\mathcal{A}}^{-1}$, whence $\mathcal{B} \subset \mathcal{D}_{\mathcal{A}}^{-1}$, by virtue of (i). Since $\mathcal{B}$ is arbitrary, the assertion follows.

(iii): We may assume that $X$ is local, say $X = \text{Spec } R$ for a local and normal domain $R$, and let $K$ be the field of fractions of $R$; then $A' := \mathcal{A}'(X)$ (resp. $A''$) is the integral closure of $R$ in $\mathcal{A}(U)$ (resp. in $\mathcal{A}'(U)$); but under the stated assumptions, both $A'$ and $A''$ are also the integral closure of $R$ in $K \otimes_R \mathcal{A}(X)$, whence the assertion. \hfill \Box

**Remark 17.4.37.** Let $X$ be a reduced and quasi-separated scheme, such that $\text{Max } X$ is finite.

(i) Let also $\mathcal{F}$ be a quasi-coherent $\mathcal{O}_X$-module of finite type. Then we claim that there exists a dense and quasi-compact open immersion $j : U \to X$ such that $j^* \mathcal{F}$ is a locally free $\mathcal{O}_U$-module. Indeed, for any maximal point $\eta \in X$, pick an affine open subset $V_\eta \subset X$ such that $\eta$ is the unique maximal point of $V_\eta$; hence $V_\eta = \text{Spec } A$ for an integral domain $A$ and $\mathcal{F}|_{V} = M$ for an $A$-module $M$ of finite type. Set $K := \text{Frac } A$; then $P := M \otimes_A K$ is a finite dimensional $K$-vector space, and we may find a element $f \in A \setminus \{0\}$, a free $A_f$-module $Q$ of finite rank and an $A_f$-linear map $\varphi : Q \to M \otimes_A A_f$ such that $\text{Ker } \varphi \otimes_A K = 0 = \text{Coker } \varphi \otimes_A K$. However,
the natural map $Q \to Q \otimes_A \mathcal{O}_X$ is injective, so we see that $\text{Ker} \varphi = 0$, and on the other hand $\text{Coker} \varphi$ is an $A_f$-module of finite type, so we may find $g \in A \setminus \{0\}$ such that $\varphi_g$ is surjective. Set $U_\eta := \text{Spec} \ A_{fg}$; by construction $\mathcal{F}_{U_\eta}$ is a locally free $\mathcal{O}_{U_\eta}$-module, and since $\eta$ is arbitrary, the assertion follows easily.

(ii) Let $\mathcal{A}$ be a quasi-coherent and finite $\mathcal{O}_X$-algebra, and suppose that $\mathcal{A}_\eta$ is an étale $\mathcal{O}_{X,\eta}$-algebra, for every maximal point $\eta$ of $X$. Then we claim that there exists an dense quasi-compact open immersion $j : U \to X$ such that $j^* \mathcal{A}$ is an étale $\mathcal{O}_U$-algebra. Indeed, by (i), we may already assume that $\mathcal{A}$ is a locally free $\mathcal{O}_X$-module, and then we may argue as in remark 17.4.35(iv).

17.4.38. Keep the situation of (17.4.34), let $X'$ be another reduced scheme, and $g : X' \to X$ a quasi-compact and quasi-separated morphism of schemes which restricts to a map $\text{Max} X' \to \text{Max} X$.

Set

$$U' := g^{-1}U$$

and denote by $j' : U' \to X'$ the resulting open immersion. It is easily seen that $j'$ is quasi-compact and has dense image, and clearly $j'^* \mathcal{A}'$ is a locally free $\mathcal{O}_{U'}$-module, so there is a well defined inverse different $\mathcal{D}^{-1}_{\mathcal{A}',U'}$ relative to $U'$. Moreover, we have a commutative diagram

$$
\begin{array}{ccc}
\mathcal{A} & \xrightarrow{\mathcal{D}^{-1}_{\mathcal{A},U}} & \mathcal{A}' \\
\mathcal{H}(\mathcal{A}, \mathcal{O}_U) & \xrightarrow{\mathcal{H}(\mathcal{A}', \mathcal{O}_U)} & \mathcal{H}(\mathcal{A}', \mathcal{O}_U)
\end{array}
$$

(17.4.39)

(59 Lemma 4.1.13(iii)). It follows that the left vertical arrow restricts to an $\mathcal{O}_{X'}$-linear map

$$
\mathcal{D}^{-1}_{\mathcal{A},U} \to \mathcal{D}^{-1}_{\mathcal{A}',U}.
$$

Lemma 17.4.41. The map (17.4.40) is an isomorphism in the following cases :

(a) if $\mathcal{A}$ is a locally free $\mathcal{O}_X$-module of finite type and $j^* \mathcal{A}$ is an étale $\mathcal{O}_U$-algebra

(b) or if $g$ is a flat morphism.

Proof. For case (a), notice that when $\mathcal{A}$ is locally free, the map $c$ is an isomorphism, and if $j^* \mathcal{A}$ is an étale $\mathcal{O}_U$-algebra, the discussion of remark 17.4.35(v) identifies (17.4.40) with the map $c$.

If $g$ is flat, the map $a$ in (17.4.39) is an isomorphism (corollary 10.3.8). The isomorphism of remark 17.4.35(i) identifies $b$ with the composition

$$
\mathcal{H}(\mathcal{A}, \mathcal{O}_U) \xrightarrow{d} \mathcal{H}(\mathcal{A}', \mathcal{O}_U) \xrightarrow{e} \mathcal{H}(\mathcal{A}', \mathcal{O}_U)
$$

where $d$ is an isomorphism, since $g$ is flat (corollary 10.3.8), and the same holds for $e$, since $j^* \mathcal{A}$ is locally free of finite type (proposition 10.3.3(ii)). To conclude, it then suffices to show that $c$ is an isomorphism as well. The assertion is local on $X$, hence we may assume that $X$ is affine; in this case, we may find a finitely presented $\mathcal{O}_X$-module $\mathcal{G}$ and an $\mathcal{O}_X$-linear epimorphism $\varphi : \mathcal{G} \to \mathcal{A}$ such that $j^* \varphi$ is an isomorphism. Set $\mathcal{G}' := g^* \mathcal{G}$; there follows a commutative diagram

$$
\begin{array}{ccc}
\mathcal{G} & \xrightarrow{g^*} & \mathcal{G}' \\
\mathcal{G}' & \xrightarrow{(\varphi g)^*} & \mathcal{G}'
\end{array}
$$

whose right vertical arrows is an isomorphism, by virtue of [59 Lemma 2.4.29(i)]. Moreover $\text{Ker} (\varphi^*) = 0$ and $\text{Coker} (\varphi^*) \subset (\text{Ker} \varphi)^*$, and since $\text{Max} X \subset U$, we see that $\text{Ker} \varphi_\eta = 0$ for every $\eta \in \text{Max} X$, whence $(\text{Ker} \varphi)^* = 0$, since $X$ is reduced. Thus, the top horizontal arrow of
the foregoing diagram is also an isomorphism; the same argument applies as well to the bottom horizontal arrow, and the assertion follows.

17.4.42. In the situation of (17.4.38), suppose now that \( X \) and \( X' \) are locally coherent and \( \mathcal{A} \) is generically étale. Taking into account lemma [17.4.36](ii.b), we see that (17.4.40) factors as a composition

\[
g^* \mathcal{D}_{\mathcal{A}}^{-1} \xrightarrow{\beta} (g^* \mathcal{D}_{\mathcal{A}}^{-1})^{\vee} \xrightarrow{\gamma} \mathcal{D}_{\mathcal{B}}^{-1},
\]

where \( \beta \) is the natural map as in (11.3).

**Proposition 17.4.43.** With the notation of (17.4.42), suppose moreover that:

(a) both \( X \) and \( X' \) are locally noetherian normal schemes

(b) \( g \) maps the points of codimension one of \( X' \) to points of codimension \( \leq 1 \) of \( X \).

Then \( \gamma \) is an isomorphism.

*Proof.* Set \( \mathcal{B} := \text{Im}(\mathcal{A} \to j_* j^* \mathcal{A}) \) and \( \mathcal{B}' := g^* \mathcal{B} \). It is easily seen that the image of \( \mathcal{B}' \) in \( j'_* j'^* \mathcal{B}' \) agrees with the image of \( \mathcal{A}' \); in view of remark [17.4.35](ii) we deduce that the natural maps \( \mathcal{A} \to \mathcal{B} \) and \( \mathcal{A}' \to \mathcal{B}' \) induce isomorphisms

\[
\mathcal{D}_{\mathcal{A}}^{-1} \xrightarrow{\sim} \mathcal{D}_{\mathcal{B}}^{-1}, \quad \mathcal{D}_{\mathcal{A}}'^{-1} \xrightarrow{\sim} \mathcal{D}_{\mathcal{B}'}^{-1}.
\]

We may then replace \( \mathcal{A} \) by \( \mathcal{B} \), and assume that the natural map \( \mathcal{A} \to j_* j^* \mathcal{A} \) is a monomorphism. By lemmata [11.3.3] and [17.4.36](ii.b), both the source and target of \( \gamma \) are reflexive \( \mathcal{O}_{X,-} \)-modules. Thus, denote by \( V \subset X' \) the subset of all points such that \( \gamma_x \) is an isomorphism; then \( V \) is a open subset of \( X' \) ([100, Th.4.10]) and the inclusion map \( V \to X' \) is quasi-compact, since \( X' \) is locally noetherian. In view of proposition [11.3.8](ii), it suffices to check that \( V \) contains all the points of codimension one of \( X' \). Thus, let \( x' \) be such a point, and set \( x := g(x') \); by assumption (b), the point \( x \) has codimension \( \leq 1 \) in \( X \), so \( \mathcal{O}_{X,x} \) is either a field or a discrete valuation ring and \( (j_* j^* \mathcal{A})_x \) is a torsion-free \( \mathcal{O}_{X,x,-} \)-module of finite type. Then the same holds for \( \mathcal{A}_x \), so the latter is a free \( \mathcal{O}_{X,x,-} \)-module of finite rank. By lemma [17.4.41] it follows that \( (17.4.40)_{x'} \) is an isomorphism. It is also clear that \( \beta_{x'} \) is an isomorphism, and since \( \gamma_{x'} = (17.4.40)_{x'} \circ \beta_{x'}^{-1} \), the contention follows. \( \square \)

**Remark 17.4.44.** (i) Let us now consider a domain \( A \), and a finite, injective, and generically étale ring homomorphism \( f : A \to B \). As in (17.4), we let \( X := \text{Spec} A \), and denote by \( \mathcal{B} \) the quasi-coherent \( \mathcal{O}_X \)-algebra arising from \( B \). Let also \( K \) be the field of fractions of \( A \); set \( B_K := K \otimes_A B \), and let \( \mathcal{B} \) be the image of \( B \) in \( B_K \). We may then regard the diagonal idempotent \( e_f \) of the map \( f \) as an element in \( B_K \otimes_K B_K \), and the associated trace form as a \( K \)-bilinear map \( B_K \otimes_K B_K \to K \), inducing an isomorphism \( \omega_f : B_K \xrightarrow{\sim} B'_K \). With this notation, the inverse different \( \mathcal{D}_{\mathcal{B}}^{-1} \) corresponds to \( \omega_f^{-1}(\mathcal{B}') \subset B_K \), and the subset

\[
\mathcal{D}_\mathcal{B} := \{ b \in B \mid b \mathcal{D}_{\mathcal{B}}^{-1} \subset B \}
\]

is an ideal of \( B \) called the *different* of \( f \). (If \( A \) and \( B \) are noetherian normal domains, then \( \mathcal{D}_\mathcal{B}^{-1} \) is the inverse of \( \mathcal{D}_\mathcal{B} \) in the group of reflexive fractional ideals of \( B \); see example [6.4.36].)

(ii) Suppose moreover that \( B \) is a projective \( A \)-module. Then we have a natural isomorphism \( B \otimes_A B' \xrightarrow{\sim} \text{Hom}_A(B, B) \), and we denote by \( \zeta_f \) the unique element of \( B \otimes_A B' \) corresponding to \( 1_B : B \to B \) under this isomorphism. According to [59, Rem.4.1.17], we have the identity:

\[
(B_K \otimes_K \omega_f)(e_f) = \zeta_f
\]

and it follows easily that:

\[
(B \otimes_A \mathcal{D}_\mathcal{B}) \cdot e_f \subset \text{Im}(B \otimes_A B \to B_K \otimes_K B_K).
\]
(iii) If $B$ is not a projective $A$-module, the inclusion of (ii) can fail; however, if $A$ is a regular and noetherian domain, theorem [17.4.19] tells us that we have at least:

\[ \text{Ker}(i): \quad \text{Im}(B \otimes_A B) \subset \text{Im}(B \otimes_A B) \to B_K \otimes_K B_K. \]

### 17.5. Big Cohen-Macaulay algebras

We shall use the following auxiliary construction. For every abelian group $(G, 0, +)$, set

\[ G^\circ := G^N / G^{(N)}. \]

Hence, the elements of $G^\circ$ are represented by sequences $(g_n \mid n \in \mathbb{N})$ of elements of $G$, and such a sequence represents the zero element of the quotient group $G^\circ$ if and only if the set \( \{ n \in \mathbb{N} \mid g_n \neq 0 \} \) is finite. Especially, $G = 0 \iff G^\circ = 0$. Moreover, for every group homomorphism $\varphi : G \to H$, we have $\varphi^N(G^\circ) \subset H^{(N)}$, hence $\varphi$ induces a group homomorphism

\[ \varphi^\circ : G^\circ \to H^\circ \]

and the rules $G \mapsto G^\circ$ and $\varphi \mapsto \varphi^\circ$ define an endofunctor of the category of abelian groups. Notice as well that $(\varphi + \psi)^\circ = \varphi^\circ + \psi^\circ$ for every pair of group homomorphisms $\varphi, \psi : G \to H$. Lastly, we have an injective natural transformation that maps $G$ diagonally into $G^\circ$

\[ \Delta_G : G \to G^\circ : \quad g \mapsto (g, g, \ldots). \]

- If $(R, +, \cdot, 0, 1)$ is a ring, then $R^{(N)}$ is an ideal of the $R$-algebra $R^N$ (the product in the category of rings of rings of copies of $R$ indexed by $\mathbb{N}$), hence $R^\circ$ is naturally an $R$-algebra via the map $\Delta_R$, and for every ring homomorphism $\varphi : R \to S$, the map $\varphi^\circ : R^\circ \to S^\circ$ is a ring homomorphism such that

\[ \Delta_S \circ \varphi = \varphi^\circ \circ \Delta_R. \]

- Moreover, if $M$ is any $R$-module, then $M^{(N)}$ is obviously an $R^{(N)}$-module, and since $R^{(N)}$ is a module, it follows that $M^\circ$ is naturally an $R^\circ$-module, and for every $R$-linear map $f : M \to N$, the map $f^\circ : M^\circ \to N^\circ$ is $R^\circ$-linear.

**Lemma 17.5.1.**

(i) The functor $(\_)^\circ : R\text{-Mod} \to R^\circ\text{-Mod}$ is exact and faithful.

(ii) We have $(IM)^\circ = IM^\circ$ for every ideal $I \subset R$ of finite type, and every $R$-module $M$.

**Proof.** (i): Since we have $M = 0 \iff M^\circ = 0$, it is clear that $(\_)^\circ$ is faithful. Next, let $f : M \to N$ be an $R$-linear map, and $g_* := (g_n \mid n \in \mathbb{N}) \in M^{(N)}$; denote by $\overline{g_*} \in M^\circ$ the class of $g_*$, and suppose that $f^\circ(\overline{g_*}) = 0$. This means that there exists $k \in \mathbb{N}$ such that $f(g_n) = 0$ for every $n \geq k$; then clearly $\overline{g_*}$ is in the image of the natural map $(\text{Ker} f)^\circ \to M^\circ$. In particular, if $\varphi$ is injective, the same holds for $\varphi^\circ$, and it is also clear that if $\varphi$ is surjective, the same holds for $\varphi^\circ$. It follows that the natural surjection $N \to \text{Coker} f$ induces a surjection $N^\circ \to (\text{Coker} f)^\circ$, whose kernel is $(\text{Im} f)^\circ$, and it is easily seen that $(\text{Im} f)^\circ = \text{Im}(f^\circ)$; hence $(\text{Coker} f)^\circ$ represents Coker$(f^\circ)$, whence the exactness of $(\_)^\circ$.

(ii): Let $a_1, \ldots, a_k$ a finite system of generators of $I$; there follows an $R$-linear surjection $f : M^{\oplus k} \to IM$ whose composition with the inclusion map $j : IM \to M$ is given by the rule: $(m_1, \ldots, m_k) \mapsto a_1m_1 + \cdots + a_km_k$. Hence $j^\circ \circ f = (j \circ f)^\circ : (M^\circ)^{\oplus k} \to M^\circ$ is given by the same rule, and by the foregoing $f^\circ : (M^\circ)^{\oplus k} \to (IM)^\circ$ is a surjection, whence the claim.

**17.5.2.** Let now $(V, m)$ be a basic setup (in the sense of [59 §2.1.1]), such that $m$ is the filtered union of a countable system of principal subideals. We consider the subset

\[ S \subset V^N \]

of all $(a_n \mid n \in \mathbb{N})$ such that $Va_n \subset Va_{n+1}$ for every $n \in \mathbb{N}$, and $m = \bigcup_{n \in \mathbb{N}} Va_n$.

**Remark 17.5.3.**

(i) Since $m = m^2$, it is easily seen that $S$ is a multiplicative system.

(ii) Also, for every $V$-module $M$ we have

\[ \text{Ker}(j_M : M^\circ \to S^{-1}M^\circ) = \{ x \in M^\circ \mid mx = 0 \} \quad \text{and} \quad m \cdot \text{Coker}(j_M) = 0. \]
Especially, \( j_M^\bullet : (M^\circ)^a \to (S^{-1}M^\circ)^a \) is an isomorphism of \((V, m)^a\)-modules.

(iii) Notice that \(S\) contains the multiplicative subset \(T := (e_{k,} \mid k \in \mathbb{N})\), where \(e_{k,} := (e_{k,n} \mid n \in \mathbb{N})\), with \(e_{k,n} = 0\) for every \(n = 0, \ldots, k - 1\) and \(e_{k,n} = 1\) for every \(n \geq k\). Notice moreover that \(e_{k,}\) is invertible in \(V^\circ\) for every \(k \in \mathbb{N}\), and for every \(V\)-module \(M\) the projection \(M^\mathbb{N} \to M^\circ\) factors through the localization \(M^\mathbb{N} \to T^{-1}M^\mathbb{N}\) and an isomorphism

\[ T^{-1}M^\mathbb{N} \cong M^\circ. \]

Hence, we also get an isomorphism of \(V^\circ\)-modules

\[ S^{-1}M^\circ \cong S^{-1}M^\mathbb{N} \quad \text{for every } V\text{-module } M. \]

**Lemma 17.5.4.** In the situation of \((17.5.2)\), let \(A \to V\) be a ring homomorphism. We have:

(i) \(M^a = 0\) if and only if \(S^{-1}M^\circ = 0.\)

(ii) The functor \(V^{-}\text{-Mod} \to V^\circ^{-}\text{-Mod} : M \mapsto S^{-1}M^\circ\) factors via an exact faithful functor

\[ S^{-1}(-)^\circ : V^\circ^{-}\text{-Mod} \to V^{-}\text{-Mod} \]

(iii) The unit of adjunction \(S^{-1}M^\circ \to (S^{-1}M^\circ)^a\) is an isomorphism of \(V\)-modules.

(iv) If \(A\) is a coherent ring, then \(S^{-1}M^\circ\) is a flat \(A\)-module if and only if \(M^a\) is flat over \(A\) in the sense of definition \(14.2.40\).

(v) If \(A\) is noetherian, then \(S^{-1}M^\circ\) is a faithfully flat \(A\)-module if and only if \(M^a\) is faithfully flat over \(A\) in the sense of definition \(14.2.40\).

**Proof.** The proof of (i) shall be left to the reader.

(ii) is an immediate consequence of (i) and the Lemma 17.5.1.(ii).

(iii): Let \(x \in S^{-1}M^\circ\) be an element such that \(m \cdot x = 0\), and write \(x = s_m 1\). For some \(s_m := (s_m \mid n \in \mathbb{N}) \in S\) and \(m := (m_n \mid n \in \mathbb{N}) \in M^\circ\). Let us also write \(m = \bigcup_{i \in \mathbb{N}} V_{a_i}\) for a sequence \((a_i \mid i \in \mathbb{N})\) of elements of \(V\) such that \(V_{a_i} \subset m \cdot a_{i+1}\) for every \(i \in \mathbb{N}\). Then, for every \(i \in \mathbb{N}\) there exist \(\rho(i) \in \mathbb{N}, c_i \in m,\) and \(t_i := (t_{i,n} \mid n \in \mathbb{N}) \in S\) such that

\[ a_i = c_i a_{i+1} \quad \text{and} \quad a_i a_{i,n} = 0 \quad \text{for every } n \geq \rho(i). \]

and we may assume that \(\rho(i + 1) > \rho(i)\) for every \(i \in \mathbb{N}\). Moreover, since \(m \subset \bigcup_{i \in \mathbb{N}} V_{t_{i,n}}\), we may also assume that \(a_i \in V_{t_{i,n}}\) for every \(n \geq \rho(i),\) in which case we get:

\[ a_i^2 a_{i,n} = 0 \quad \text{for every } i \in \mathbb{N} \text{ and } n \geq \rho(i). \]

Hence, let \(b := (b_n \mid n \in \mathbb{N}) \in V^\mathbb{N}\) be the element such that \(b_n := 0\) for every \(n \leq \rho(0)\), and \(b_i := a_i^2\) for every \(i \in \mathbb{N}\) and every \(n = \rho(i), \ldots, \rho(i + 1) - 1\). It follows easily that \(b_\bullet \in S\) and \(b \cdot m_\bullet = 0\) in \(M^\circ\), so finally \(x = 0\). This shows that the unit of adjunction \(\gamma_S^{-1}M^\circ : S^{-1}M^\circ \to (S^{-1}M^\circ)^a\) is injective. Next, let \(y \in (S^{-1}M^\circ)^a\). By remark \(16.9.24\)(ii), the \(V\)-module \(\overline{m}\) is the inductive limit of a system \((L_n \mid n \in \mathbb{N})\) with \(L := V\) for every \(n \in \mathbb{N}\), and with \(V\)-linear transition maps \(\varphi_n : L_n \to L_{n+1}\) such that \(\varphi_n(1) = c_n\) for every \(n \in \mathbb{N}\); hence \(y\) is represented by a system \((y^{(n)} \mid n \in \mathbb{N})\) of elements of \(S^{-1}M^\circ\) such that

\[ c_n y^{(n+1)} = y^{(n)} \quad \text{for every } n \in \mathbb{N}. \]

**Claim 17.5.6.** Let \(\Sigma \subset S\) be any countable subset. Then \(\bigcap_{s \in \Sigma} V^\circ s_\bullet \neq \emptyset.\)

**Proof of the claim.** Say that \(\Sigma = \{s_{n,} \mid n \in \mathbb{N}\}\). Let the sequence \((a_n \mid n \in \mathbb{N})\) of generators of \(m\) be as in the foregoing; then, for every \(n, k \in \mathbb{N}\) there exists \(\rho(n, k) \in \mathbb{N}\) such that

\[ a_k \in V s_{n,j} \quad \text{for every } j \geq \rho(n, k). \]

Hence, for every \(k \in \mathbb{N}\), we can find \(\rho(k) \in \mathbb{N}\) such that

\[ a_k \in V s_{n,j} \quad \text{for every } n = 0, \ldots, k \text{ and every } j \geq \rho(k) \]

and moreover we may assume that \(\rho(k + 1) > \rho(k)\) for every \(k \in \mathbb{N}\). Then, let \(x_k := (x_{n} \mid n \in \mathbb{N}) \in V^\mathbb{N}\) be the sequence such that \(x_n := 0\) for every \(n = 0, \ldots, \rho(0) - 1\), and \(x_n := a_k\)
whenever \( \rho'(k) \leq n < \rho'(k+1) \), for every \( k \in \mathbb{N} \). It is easily seen that \( x_\bullet \in S \cap V^oc_n \) for every \( n \in \mathbb{N} \), whence the claim.

Now, say that \( y^{(n)} = s_{n,\bullet}^{-1}m_{n,\bullet} \) with \( s_{n,\bullet} \in S \) and \( m_{n,\bullet} \in M^o \) for every \( n \in \mathbb{N} \); by claim [17.5.6] we may assume that all the elements \( s_{n,\bullet} \) are equal, in which case (17.5.5) amounts to the identities:

\[
m_{n,\bullet} = c_nm_{n+1,\bullet} \quad \text{in } S^{-1}M^o \text{ for every } n \in \mathbb{N}.
\]

The latter in turns means that for every \( n \in \mathbb{N} \) there exists \( t_{n,\bullet} \in S \) such that \( t_{n,\bullet}m_{n,\bullet} = c_nm_{n+1,\bullet} \) in \( M^o \). By invoking again claim [17.5.6] we may also assume that all the \( t_{n,\bullet} \) are equal; then set \( m'_{n,\bullet} := t_{0,\bullet}m_{n,\bullet} \) for every \( n \in \mathbb{N} \), so that \( m'_{n,\bullet} = c_nm'_{n+1,\bullet} \) in \( M^o \) for every \( n \in \mathbb{N} \). The latter means that for every \( n \in \mathbb{N} \) there exists \( \rho(n) \in \mathbb{N} \) such that

\[
m_{n,j} = c_nm_{n+1,j} \quad \text{for every } j \geq \rho(n)
\]

and we may assume that \( \rho(n+1) > \rho(n) \) for every \( n \in \mathbb{N} \). Then, let \( t_\bullet := (t_n \mid n \in \mathbb{N}) \in V^N \) (resp. \( l_\bullet := (l_n \mid n \in \mathbb{N}) \in M^N \)) be the element with \( t_j := 0 \) (resp. \( l_j := 0 \)) for \( j = 0, \ldots, \rho(0) - 1 \) and \( t_j := a_n \) (resp. \( l_j := m_{n,j} \)) whenever \( \rho(n) \leq j < \rho(n+1) \), for every \( n \in \mathbb{N} \).

**Claim 17.5.7.** \( t_\bullet m_\bullet = a_n l_\bullet \) in \( M^o \) for every \( n \in \mathbb{N} \).

**Proof of the claim.** It suffices to show that for every \( k \geq n \) and every \( j = \rho(k), \ldots, \rho(k+1) - 1 \) we have \( a_k m_{n,j} = a_m k_{n,j} \). The latter follows by a simple inspection.

Set \( z := t_\bullet l_\bullet \); claim [17.5.7] implies that \( m_{n,\bullet} = a_n y \) in \( S^{-1}M^o \) for every \( n \in \mathbb{N} \); hence \( \eta_{S^{-1}M^o}(z) = y \), whence the assertion.

(iv): Suppose that \( M^o \) is flat over \( A \), and let \( I \subset A \) be an ideal of finite type; in light of lemma [17.5.1(ii)], it suffices to check that the natural map

\[
f : I \otimes_A S^{-1}M^o \to S^{-1}(IM)^o
\]

is an isomorphism. Now, it is easily seen that for every \( A \)-module \( N \) of finite type, the natural map \( N \otimes_A S^{-1}M^o \to S^{-1}(N \otimes_A M)^o \) is surjective; on the other hand, since \( A \) is coherent, there exists \( k \in \mathbb{N} \) and a surjective \( A \)-linear map \( A^{\oplus k} \to I \), whose kernel is an \( A \)-module \( N \) of finite type. Thus, we have the following commutative diagram

\[
\begin{array}{ccccccccc}
0 & \longrightarrow & N \otimes_A S^{-1}M^o & \longrightarrow & A^{\oplus k} \otimes_A S^{-1}M^o & \longrightarrow & I \otimes_A S^{-1}M^o & \longrightarrow & 0 \\
\downarrow & & \downarrow & & \downarrow & & \downarrow & & \\
0 & \longrightarrow & S^{-1}(N \otimes_A M)^o & \longrightarrow & S^{-1}(M^{\oplus k})^o & \longrightarrow & S^{-1}(IM)^o & \longrightarrow & 0 \\
\end{array}
\]

whose first and third vertical arrows are surjections, and whose central vertical arrow is an isomorphism. Moreover, the top horizontal sequence is right exact, and since \( M^o \) is flat over \( A \), combining (i) and lemma [17.5.1(i)] it is easily seen that the bottom horizontal arrow is a short exact sequence. Then, by the snake lemma, \( \text{Ker } f = 0 \), whence the contention.

Conversely, suppose that \( S^{-1}M^o \) is a flat \( A \)-module, and consider any short exact sequence \( \Sigma := (0 \to N' \to N \to N'' \to 0) \) of \( A \)-modules; we need to show that the induced sequence \( M^o \otimes_A \Sigma \) is still exact. To this aim, notice that \( \Sigma \) is the filtered colimit of a system of short exact sequences \( (0 \to N_{\lambda} \to N_{\lambda} \to N_{\lambda} \to 0) \mid \lambda \in \Lambda \) such that \( N_{\lambda} \) and \( N_{\lambda}'' \) are finitely presented \( A \)-modules, for every \( \lambda \in \Lambda \). Thus, we may assume that \( N \) and \( N'' \) are finitely presented, in which case the same holds for \( N' \), since \( A \) is coherent, and we consider the diagram:

\[
\begin{array}{ccccccccc}
\Sigma \otimes_A S^{-1}M^o & \longrightarrow & N' \otimes_A S^{-1}M^o & \longrightarrow & N \otimes_A S^{-1}M^o & \longrightarrow & N'' \otimes_A S^{-1}M^o & \longrightarrow & 0 \\
\downarrow & & \downarrow & & \downarrow & & \downarrow & & \\
S^{-1}(\Sigma \otimes_A M)^o & \longrightarrow & S^{-1}(N' \otimes_A M)^o & \longrightarrow & S^{-1}(N \otimes_A M)^o & \longrightarrow & S^{-1}(N'' \otimes_A M)^o & \longrightarrow & 0.
\end{array}
\]
Since $N$, $N'$ and $N''$ are finitely presented, lemma \ref{17.5.1}(i) easily implies that all the vertical arrows are isomorphisms. By assumption, the top horizontal row is short exact, hence the same holds for the bottom one, and therefore the sequence of $(V, m)^o$-modules $((\Sigma \otimes_A M)^o)^n$ is short exact; then we conclude by invoking again lemma \ref{17.5.1}(i).

(v): Suppose that $M^o$ is faithfully flat over $A$; in view of (iv), it suffices to show that for every $A$-module $N \neq 0$ of finite type, we have $S^{-1}M^o \otimes_A N \neq 0$. But then $N$ is finitely presented, since $A$ is noetherian, hence the natural map $S^{-1}M^o \otimes_A N \rightarrow S^{-1}(M \otimes_A N)^o$ is an isomorphism, and by assumption $M^o \otimes_A N \neq 0$; then the assertion follows from (i). One argues similarly for the converse: details left to the reader. \hfill \qed

**Proposition 17.5.8.** In the situation of \ref{17.5.2}, let $I \subset V$ be any ideal of finite type; then both $M^o$ and $S^{-1}M^o$ are $I$-adically complete $V$-modules.

**Proof.** Let $x_{i*} := (x_{k,i} \mid k \in \mathbb{N})$ be a Cauchy sequence for the $I$-adic topology in $M^o$. Hence, $x_{k,i}$ is the class of a sequence $(x_{k,i} \mid i \in \mathbb{N})$, for every $i \in \mathbb{N}$, and after replacing $x_{i*}$ by a subsequence, we may assume that $x_{k,i} - x_{k+1,i} \in I^kM^o$ for every $k \in \mathbb{N}$. In light of lemma \ref{17.5.1}(ii), the latter means that for every $k \in \mathbb{N}$ there exists $n(k) \in \mathbb{N}$ such that $x_{k,i} - x_{k+1,i} \in I^kM$ for every $i \geq n(k)$, and clearly we may assume that $n(k+1) > n(k)$ for every $k \in \mathbb{N}$. Now, let $y_{i*} := (y_i \mid i \in \mathbb{N})$ be the following element of $M^o$. For every $i \leq n(0)$ we let $y_i := x_{0,i}$; then, for every $k \in \mathbb{N}$ and $n(k) < i \leq n(k + 1)$ we let $y_i := x_{k+1,i}$. For every $k \geq j$ and $n(k) < i \leq n(k + 1)$, we get:

$$y_i - x_{j,i} = (x_{k+1,i} - x_{k,i}) + \ldots + (x_{j+1,i} - x_{j,i}) \in I^kM + \ldots + I^jM = I^jM.$$ 

Hence, $y_{i*} \in I^jM^o$ for every $j \in \mathbb{N}$, so $y_{i*}$ is a limit of $x_{i*}$.

Next, let $x_{k*} := (x_{k,i} \mid k \in \mathbb{N})$ be a Cauchy sequence for the $I$-adic topology in $S^{-1}M^o$; again, we may assume that $x_{k,i} - x_{k+1,i} \in I^kS^{-1}M^o$ for every $k \in \mathbb{N}$, and then there exist $s_{k,i} \in S$ and $z_{k,i} \in I^kM^o$ with $y_{k*} = s_{k,i}^{-1}z_{k,i}$ for every $k \in \mathbb{N}$. Also, we may assume:

$$s_{k+1,i} \in V^Ns_{k,i} \quad \text{for every } k \in \mathbb{N}.$$

Now, by assumption there exists a sequence $(a_n \mid n \in \mathbb{N})$ of elements of $V$ such that $V a_n \subset V a_{n+1}$ for every $n \in \mathbb{N}$, and $\bigcup_{n \in \mathbb{N}} V a_n = m$. For every $k \in \mathbb{N}$ we define inductively a sequence of integers $(n(k, i) \mid i \in \mathbb{N})$ as follows. For $i = 0$, let $n(k, i)$ be the smallest of the integers $n \in \mathbb{N}$ such that $a_0 \in V s_{k,n}$; then, for every $i > 0$ let $n(k, i) \in \mathbb{N}$ be the smallest of the integers $n > n(k, i - 1)$ such that $a_i \in V s_{k,n}$. Notice that \ref{17.5.9} implies

$$n(k + 1, i) \geq n(k, i) \quad \text{for every } k \in \mathbb{N}.$$ 

Lastly, let $t_*$ be the sequence such that $t_* := 0$ for every $n < n(0, 0)$, and $t_* := a_i$ for every $n, i \in \mathbb{N}$ with $n(i, i) \leq n < n(i + 1, i + 1)$. We have $t_* \in S$, and $t_* \in V s_{k,i}$ for every $k \in \mathbb{N}$ and every $i \geq n(k, k)$; thus, the class of $s_{k,i}$ in $V^o$ divides the class of $t_*$, and we may replace $s_{k,i}$ by $t_*$ for every $k \in \mathbb{N}$. By the foregoing case, the series $\sum_{k \in \mathbb{N}} z_{k,i}$ converges in $M^o$, and let $z_*$ be a limit; then $t_*^{-1}z_*$ is a limit for $x_{i*}$ in $S^{-1}M^o$. \hfill \qed

**Lemma 17.5.10.** In the situation of \ref{16.9.26}, let us endow $S^{-1}A_0^o$ with its $b$-adic topology, and let $A_0^\wedge$ be the $b$-adic completion of $A_0$; then the basic setup $(A_0^\wedge, m A_0^\wedge)$ is almost perfectoid if and only if the maximal separated quotient $(S^{-1}A_0^o)^{\text{sep}}$ of $S^{-1}A_0^o$ is perfectoid.

**Proof.** Clearly $S^{-1}\overline{\Phi}_{A_0} : S^{-1}(A_0/bA_0)^o \rightarrow S^{-1}(A_0/b^pA_0)^o$ is the ring endomorphism induced by Frobenius endomorphism of $S^{-1}(A_0/b^pA_0)^o$. On the other hand, by lemma \ref{17.5.4}(ii), $\overline{\Phi}_{A_0}$ is an isomorphism if and only if the same holds for $S^{-1}\overline{\Phi}_{A_0}$. Notice also that $C := (S^{-1}A_0^o)^{\text{sep}}$ is $b$-adically complete and separated, by virtue of propositions \ref{17.5.8} and \ref{8.2.13}(v). Then let $\overline{\Phi}_C : C/bC \rightarrow C/b^pC$ be the ring homomorphism induced by the Frobenius endomorphism of $C/b^pC$; in view of theorem \ref{16.4.1}, we are reduced to showing:
Claim 17.5.11. $\Phi_C$ is an isomorphism if and only if the same holds for $S^{-1}\Phi_{A_0}$.

Proof of the claim. By lemma 17.5.1(ii), the projection $A_0 \to A_0/bA_0$ induces a ring isomorphism $S^{-1}A_0^0/(b) \to S^{-1}(A_0/bA_0)^0$, and likewise $S^{-1}A_0^0/(b^p) \to S^{-1}(A_0/b^pA_0)^0$. Therefore, the projections $S^{-1}A_0^0 \to C/bC$ and $S^{-1}A_0^0 \to C/b^pC$ factor through ring isomorphisms

$$S^{-1}(A_0/bA_0)^0 \to C/bC \quad S^{-1}(A_0/b^pA_0)^0 \to C/b^pC$$

whence the claim. □

17.5.12. Let $A$ be a Tate ring, $A_0 \subset A$ a subring of definition, and $p \in \mathbb{N}$ a prime integer; suppose that there exists $b \in A_0^0 \cap A^x$ with $pA_0 \subset b^pA_0$, and let $A_0^0$ be the $b$-adic completion of $A_0$. Let also $g_\bullet := (g_n | n \in \mathbb{N}) \in E(A_0)$, and set $g := g_0 \in A_0$, so that $g^\gamma$ is well defined in $A_0$ for every $\gamma \in \mathbb{N}[1/p]$. We let $m := \bigcup_{\gamma \in \mathbb{N}[1/p]} A_0g^\gamma$, and we suppose that the basic setup $(A_0^0, mA_0^0)$ is almost perfectoid (see definition 16.9.27).

Proposition 17.5.13. In the situation of (17.5.12), suppose moreover that $A_0$ is complete and separated, and let $A_0^\bullet$ be the integral closure of the image of $A_0$ in $A_0[1/g]$. Then we have:

(i) The induced morphism $A_0^0 \to (A_0^0)^\circ$ is an isomorphism of $(A_0, m)^\circ$-algebras.

(ii) If moreover, the unit of adjunction $A_0 \to A_0^\bullet$ is an isomorphism, the same holds for the natural map $A_0 \to A_0^\bullet$.

Proof. (i): Let us check first that the kernel of the localization $A_0 \to A_0[1/g]$ is annihilated by $m$. Hence, let $x \in A_0$ such that $g^n(x) = 0$ for some $n \in \mathbb{N}$, and denote by $\tau_\bullet \in B := (S^{-1}A_0^0)^{sep}$ the image of the constant sequence $(x, x, x, \ldots) \in A_0^\mathbb{N}$ (notation of lemma 17.5.10). Since $B$ is reduced (corollary [16.3.61]), we have $g^\gamma \cdot \tau = 0$ in $B$ for every $\gamma \in \mathbb{N}[1/p] \setminus \{0\}$. The latter means that for all $i \in \mathbb{N}$ and $\gamma \in \mathbb{N}[1/p] \setminus \{0\}$ there exists $s_\bullet := (s_n | n \in \mathbb{N}) \in S$ such that $s_\bullet \cdot g^\gamma \cdot \tau \in b^i A_0^0$. In turn, this means that for every $i$ and $\gamma$ there exists $s_\bullet$ and $n \in \mathbb{N}$ such that $s_n g^\gamma x \in b^n A_0$ for every $m \geq n$; equivalently, for every $i \in \mathbb{N}$ and $\gamma \in \mathbb{N}[1/p] \setminus \{0\}$ we have $g^\gamma \cdot b^i A_0$, and then $g^\gamma x = 0$ in $A_0$ for every such $\gamma$, as required.

Next, we show that the cokernel of the map $A_0 \to A_0^\bullet$ is annihilated by $m$. Indeed, let $a/g^n \in A_0^0$ for some $a \in A_0$ and $n \in \mathbb{N}$, and denote by $\pi_\bullet \in B$ the image of the constant sequence $(a, a, a, \ldots) \in A_0^\mathbb{N}$. Hence $\pi_\bullet \cdot g^n \in B[g^{-1}]$ lies in the integral closure $C$ of the image $\overline{B}$ of $B$ in $B[1/g]$. Since $B$ is perfectoid, the induced map $B^n \to C^n$ is an isomorphism of $(A_0, m)^\circ$-algebras (theorem 16.9.34(iv)), hence $g^\gamma \cdot (\pi_\bullet \cdot g^n) \in \overline{B}$ for every $\gamma \in \mathbb{N}[1/p] \setminus \{0\}$; then there exists $y_\bullet := (y_n | n \in \mathbb{N}) \in B$ such that

$$g^\gamma \cdot \pi_\bullet = g^{n+\gamma} \cdot y_\bullet \quad \text{for every } \gamma \in \mathbb{N}[1/p].$$

Hence, for every $i \in \mathbb{N}$ there exists $s_\bullet \in S$ such that $s_\bullet (g^{\gamma+i} \cdot \pi_\bullet - g^{n+\gamma} \cdot y_\bullet) \in b^i A_0^0$. The latter implies that for every $i \in \mathbb{N}$ and $\gamma \in \mathbb{N}[1/p] \setminus \{0\}$ the image $\pi_{\gamma+i}$ of $a/g^n$ in $A_0/b^i A_0$ lies in $J_i := g^n(A_0/b^i A_0)$. For every $i \in \mathbb{N}$, let $K_i := \text{Ker } g^n1_{A_0/b^i A_0}$; we get an exact sequence

$$K := \varinjlim_{i \in \mathbb{N}} K_i \to A_0 = \varinjlim_{i \in \mathbb{N}} A_0/b^i A_0 \xrightarrow{a} J := \varinjlim_{i \in \mathbb{N}} J_i \to \varinjlim_{n \in \mathbb{N}} K_i$$

and notice that $K = \text{Ker } g^n1_{A_0}$ lies in the kernel of the localization $A_0 \to A_0[1/g]$, hence $K^n = 0$, by the foregoing. Moreover, the system of inclusions $(J_i \to A_0/b^i A_0 | i \in \mathbb{N})$ induces a map $\beta : J \to A_0$ such that $\beta \circ a = g^n1_{A_0}$.

Claim 17.5.14. The inverse system $(K_i | i \in \mathbb{N})$ is almost essentially zero.

Proof of the claim. Since $A_0$ is almost perfectoid, the Frobenius endomorphism of $A_0/b^p A_0$ induces a map $A_0/b A_0 \to A_0/b^p A_0$ whose kernel is almost zero. By a simple induction on $j$, it follows that for every $j \in \mathbb{N}$ and every $x \in A_0$ such that $x^p \in b^{jp} A_0$, we have $g^j x \in b^{jp} A_0$.
for every $\gamma \in \mathbb{N}[1/p] \setminus \{0\}$. Now, fix $i, k \in \mathbb{N}$ and let $x \in A_0$ whose class in $A_0/b^kA_0$ lies in $K_{p^k}$, i.e. $g^x \in b^{p^k}A_0$. Then $(g^{n/p^k}x)^{p^k} \in b^{p^k}A_0$, and an easy induction on $j$ yields

$$(g^{(j+1)n/p^k}x)^{p^{k-j}} \in b^{p^{k-j}}A_0$$

for every $j = 0, \ldots, k$.

For $j = k$, it follows that $g^{(k+1)n/p^k}x \in b^kA_0$. This shows that for every $i \in \mathbb{N}$ and every $\beta \in \mathbb{N}[1/p] \setminus \{0\}$ there exists $k \in \mathbb{N}$ such that the image of $K_{p^k}$ in $K_i$ is annihilated by $g^\beta$, whence the contention.

From proposition 14.2.25(iii) and claim 17.5.14 we get $\lim_{i \in \mathbb{N}} K_i^\alpha = 0$, hence $\alpha$ is almost surjective. By construction, $z_{\gamma,i} := (z_{\gamma,i} \mid i \in \mathbb{N}) \in \lim_{i \in \mathbb{N}} J_i$; so we find for every $\gamma \in \mathbb{N}[1/p] \setminus \{0\}$ an element $a' \in A$ such that $a(a') = g^\gamma z_{\gamma,i}$, whence $g^\gamma a' = \beta \circ (a') = g^\gamma \beta(z_{\gamma,i}) = g^\gamma a$. The image of $a' \in A_0^\alpha$ therefore equals $g^\gamma(a/g^\gamma)$, and the proof of (i) is complete.

(ii): We have already seen that $m$ annihilates the kernel of the localization $\phi : A_0 \to A_0[1/g]$; on the other hand, $A_0^\alpha$ has no $m$-torsion elements, so $\phi$ is injective under the assumptions of (ii). By (i), the inclusion map $A_0 \to A_0^\alpha$ induces an isomorphism $A_0 \cong \gamma (A_0^\alpha)$, and notice that $(A_0^\alpha)^\alpha$ is a subring of $A_0[1/g]$ containing $A_0^\alpha$; the assertion follows immediately.

---

**Proposition 17.5.15.** In the situation of (17.5.12), let $h \in A_0$, and set $B := A_0[h^{1/p^\infty}] = A_0[X^{1/p^\infty}] / (X - h)$. Let moreover $C$ be the $p$-integral closure of $B$ in $B[1/b]$, and $C^\wedge$ the $b$-adic completion of $C$. Then $C^\alpha$ is a faithfully flat $(A_0, m)$-algebra, and the basic setup $(C^\wedge, mC^\wedge)$ is almost perfectoid for the $b$-adic topology of $C^\wedge$.

**Proof.** For every $A_0$-module $M$, let $\Delta_M : M \to M^N$ be the diagonal map, and for every $n \in \mathbb{N}$, let $\pi_{M,n} : M^N \to M$ be the projection on the $n$-th factor. Let us regard $A_0^\alpha$ as an $A_0$-algebra via $\Delta_A_0 : A_0 \to A_0^N$, and denote by $C'$ the $p$-integral closure of $B' := B \otimes_{A_0} A_0^\alpha$ in $B'[1/b]$. By remark 9.8.25(iii), the induced map $\Delta_{B[1/b]} : B[1/b] \to B'[1/b]$ restricts to a ring homomorphism $\phi_C : C \to C'$. By the same token, $B[1/p] \otimes_{A_0} \pi_{A_0, n} : B'[1/b] \to B[1/b]$ restricts to a map $\varphi_{C,n} : C' \to C$ such that $\varphi_{C,n} \circ j_C = 1_C$, for every $n \in \mathbb{N}$. For every such $M$ and every $n \in \mathbb{N}$ we then get maps of $A_0$-modules,

$$T_0 := \text{Tor}_1^A(M, C) \xrightarrow{\alpha} T := \text{Tor}_1^{A_0^\alpha}(M^N, C') \xrightarrow{\beta} T_0$$

where $\alpha$ is induced by $(\Delta_{A_0}, \Delta_M, j_C)$, and $\beta_n$ is induced by $(\pi_{A_0, n}, \pi_{M,n}, \varphi_{C,n})$. On the other hand, $S^{-1}A_0^N$ is a formal perfectoid ring for its $b$-adic topology, by lemma 17.5.10 and remark 17.5.3(iii), hence $S^{-1}C'$ is a faithfully flat $S^{-1}A_0^N$-algebra, by theorem 16.9.17(i) and lemma 9.8.26(iv). Hence, $S^{-1}T = 0$. Now, let $x \in T_0$; then there exist $s_n := (s_n \mid n \in \mathbb{N}) \in S$ with $s_n \cdot \alpha(x) = 0$ in $T$, whence $s_n \cdot \beta_n \circ \alpha(x) = s_n x = 0$ in $T_0$ for every $n \in \mathbb{N}$, so $T_0 = 0$. This shows that $C^\alpha$ is a flat $A_0^\alpha$-algebra. Next, consider, for every $n \in \mathbb{N}$, the commutative diagram:

$$\begin{array}{ccc}
M & \xrightarrow{\Delta_M} & M^N \\
\gamma \downarrow & & \downarrow \delta \\
C \otimes_{A_0} M & \xrightarrow{j_C \otimes_{A_0} \Delta_M} & C' \otimes_{A_0^\alpha} M^N
\end{array}$$

and let $y \in \text{Ker } \gamma$; then $\Delta_M(y) \in \text{Ker } \delta$, and since $S^{-1}C'$ is a faithfully flat $S^{-1}A_0^N$-algebra, it follows that there exists $s_{\bullet} \in S$ with $s_{\bullet} \cdot \Delta_M(y) = 0$, i.e. $s_n y = 0$ for every $n \in \mathbb{N}$, so that $(\text{Ker } \gamma)^\wedge = 0$, which proves that $C^\alpha$ is a faithfully flat $A_0^\alpha$-algebra.

Next, since $b$ is a regular element of $C$, it is also regular in $C^\wedge$; also, we already know that the Frobenius endomorphism of $C^\wedge$ induces an injection $\Phi_C : C/bC \to C/b^pC$ (lemma 9.8.26(i));
on the other hand, for any \( n \in \mathbb{N} \), consider the commutative diagram:

\[
\begin{array}{ccc}
C/bC & \xrightarrow{A_0/bA_0 \otimes_{A_0} j_C} & C'/bC' \\
\Phi_C & \downarrow & \Phi_{C'} \\
C/bpC & \xrightarrow{A_0/bpA_0 \otimes_{A_0} j_C} & C'/bpC'.
\end{array}
\]

By theorem \([16.9.17] (ii)\), the map \( S^{-1}\Phi_{C'} \) is an isomorphism. Now, let \( x \in C/bpC \), and pick \( s_* := (s_n \mid n \in \mathbb{N}) \in S \) and \( y_* \in C'/bC' \) such that \( \Phi_{C'}(y_*) = s_* \cdot (A_0/bpA_0 \otimes_{A_0} j_C)(x) \). Set \( z_n := (A_0/bA_0 \otimes_{A_0} \varphi_C, n)(y_*) \) for every \( n \in \mathbb{N} \); then \( \Phi_{C}(z_n) = s_nx \) for every \( n \in \mathbb{N} \). This shows that \( \Phi_C \) is an almost isomorphism, so \( (C^\wedge, mC^\wedge) \) is an almost perfectoid basic setup. \( \square \)

**Remark 17.5.16.** (i) In the situation of \([17.5.12]\), suppose moreover that there exists a perfectoid Tate ring \( R \), with a perfectoid subring of definition \( R_0 \), and an adic ring homomorphism \( R_0 \to A_0 \), such that \( g_* \) is the image of an element \( g'_* := (g'_n \mid n \in \mathbb{N}) \) of \( E(R_0) \). Then we get a basic setup \((R_0, m_R)\) with \( m_R := \bigcup_{n \in \mathbb{N}} \mathbb{N}_{1/p} \setminus \{0\} \to R_0 \), and we can form as in \([16.9.51]\) the topological \( R \)-algebra \( A_0^\wedge \) := \( R \otimes_{E(R_0)} W(E(A_0/pA_0)) \), which is perfectoid and admits a natural adic map \( A_0^\wedge \to A_0 \); the latter is an almost isomorphism relative to the basic setup \((R_0, m_R)\), by theorem \([16.9.55]\) (iii.a). Let \( A_0^\wedge (\text{resp. } (A_0^\wedge)^{\gamma}) \) be the integral closure of \( A_0 \) in \( A_0[1/g] \) (resp. of \( A_0^\wedge \) in \( A_0^\wedge[1/g'_*] \)). Then, on the one hand, the induced morphism \((A_0^\wedge)^{\gamma} \to (A_0^\wedge)^{\gamma}\) is an isomorphism of \((R_0, m_R)^{\gamma}\)-algebras \([59] \text{ Lemma 8.2.28}\); on the other hand, the same holds for the morphism \((A_0^\wedge)^{\gamma} \to ((A_0^\wedge)^{\gamma})^\wedge\), due to theorem \([16.9.34]\) (iv). In this way we thus obtain a shorter proof of proposition \([17.5.15]\) under the stated further assumptions.

(ii) We can also give an alternative proof of the first assertion of proposition \([17.5.15]\) along the same lines, under the assumptions of (i). Indeed, first let us remark that, since the map \( A_0^\wedge \to A_0 \) is an almost isomorphism, there exists an almost element \( l \in (A_0^\wedge)_0 \) whose image in \((A_0)_0^\wedge\) agrees with \( h \); by definition, \( l : m_R \otimes_R m_R \to A_0^\wedge \) is an \( R \)-linear map, and we set \( l_{\gamma, \delta} := l(g^{\gamma}_n \otimes g^{\delta}_n) \) for every \( \gamma, \delta \in \mathbb{N}_{[1/p]} \setminus \{0\} \). It is easily seen that \( l_{\gamma, \delta} \) depends only on the sum \( \gamma + \delta \), hence we get a compatible system \((l_{\gamma} \mid \gamma \in \mathbb{N}_{[1/p]} \setminus \{0\})\) of elements of \( A_0^\wedge \) such that \( g^{\gamma}_n \otimes l_{\gamma} = l_{\gamma, \delta} \) for every such \( \gamma, \delta \). Let \( D_{\gamma} \) (resp. \( E_{\gamma} \)) be the \( p \)-integral closure of \( A^\wedge_{0, \gamma} := A_0^\wedge[[t^{\gamma}_{\gamma}]_{\wedge} \in A_{0, \gamma}[[1/b]] \) (resp. of \( A_0^\wedge := A_0^\wedge[[g^{\gamma}h^{1/p\wedge}] \in A_{0, \gamma}[1/b]] \) for every \( \gamma \in \mathbb{N}_{[1/p]} \setminus \{0\} \); by theorem \([16.9.17]\) (i), \( D_{\gamma} \) is a faithfully flat \( A^\wedge_{0, \gamma} \)-algebra; moreover, for every \( \gamma, \delta \in \mathbb{N}_{[1/p]} \setminus \{0\}, \) the natural map \( A^\wedge_{0, \gamma + \delta} \to A^\wedge_{0, \gamma} \) induces a map of \( A^\wedge_{0, \gamma} \)-algebras \( D_{\gamma + \delta} \to D_{\gamma} \) (remark \([9.8.25]\)) (ii). Furthermore, for every such \( \gamma \) we have a natural map \( i_{\gamma} : A_{0, \gamma} \to A_{0, \gamma}, \) whence an induced map \( j_{\gamma} : D_{\gamma} \to E_{\gamma} \). Since \( p \not\in bA_0 \), the localization \( A_0^\wedge \to A_{0, \gamma}[1/b] \) induces an isomorphism \( A_{0, \gamma}[1/p] \cong A_{0, \gamma}[1/b, 1/p] \), and therefore \( E_{\gamma} \) is also the weak normalization of \( A_{0, \gamma} \) in \( A_{0, \gamma}[1/b] \) (proposition \([9.8.28]\)); likewise we see that \( D_{\gamma} \) is the weak normalization of \( A^\wedge_{0, \gamma} \) in \( A_{0, \gamma}[1/b] \). On the other hand, clearly \( i^\wedge_{\gamma} \) is an isomorphism; taking into account \([14.3.12]\) (ii), we conclude that the same holds for \( j^\wedge_{\gamma} \). Lastly, the compatible system of ring homomorphisms \((A_0^\wedge[[g^{\gamma}h^{1/p\wedge}] \to A_0[1/h^{1/p\wedge}] \mid \gamma \in \mathbb{N}_{[1/p]} \setminus \{0\}) \) yields a compatible system of maps \((E_{\gamma} \to B \mid \gamma \in \mathbb{N}_{[1/p]} \setminus \{0\})\), and it is easily seen that the induced co-cone of \( A^\wedge_{0, \gamma} \)-algebras \((E_{\gamma} \to B_{\gamma} \mid \gamma \in \mathbb{N}_{[1/p]} \setminus \{0\})\) is universal. Summing up, \( B^\wedge_{\gamma} \) is the colimit of the filtered system of faithfully flat \( A^\wedge_{0, \gamma} \)-algebras \((D_{\gamma} \mid \gamma \in \mathbb{N}_{[1/p]} \setminus \{0\})\), so it is a faithfully flat \( A^\wedge_{0, \gamma} \)-algebra (lemma \([14.3.7]\)).

(iii) Likewise, by applying the functor \((-)^\wedge\) in a similar fashion, one may show that the basic setup \((C^\wedge, mC^\wedge)\) is almost perfectoid: we leave the details as an exercise for the reader.

**17.5.17.** Let \((A, n)\) be a noetherian local ring. The aim of this section is to exhibit an \( A \)-algebra \( B \) such that \( \text{depth}_A B = \dim A \) (notation of remark \([10.4.29]\)). Quite generally, we say that an
A-module $M$ is \textit{big Cohen-Macaulay} (or briefly, that $M$ is \textit{big CM}) if $\text{depth}_AM = \dim A$; hence our sought $B$ is a \textit{big CM} $A$-module.

\textbf{Remark 17.5.18.} Set $d := \dim A$, and let $f := (f_1, \ldots, f_d)$ a \textit{system of parameters} for $A$, i.e. a system of generators for an $n$-primary ideal of $A$. Let also $M$ be an $A$-module.

(i) By proposition 10.4.32, $M$ is a big CM $A$-module if and only if $H^i(f, M) = 0$ for every $i = 0, \ldots, d - 1$, and $H^d(f, M) \neq 0$, or equivalently, if and only if $f$ is completely secant on $M$ (see definition 7.8.6), and $H_0(f, M) = M/fM \neq 0$ (lemma 7.8.2(v)). It follows easily that $M$ is a big CM $A$-module if and only if $H^i(f, M) = 0$ for $i = 0, \ldots, d - 1$, and $M/\mathfrak{n}M \neq 0$.

(ii) Notice also that a big CM $A$-module is the same as a Cohen-Macaulay module whose support has dimension $d$ (see definition 11.3.60(ii)). The additional \textit{big} adjective can then be somewhat justified, by remarking that the condition on the support often forces $M$ to be an $A$-module of non-finite type (and likewise for $A$-algebras); the question is discussed in B.Bhatt’s article [177], which exhibits a non-trivial cohomological obstruction to the existence of \textit{finite} $CM$ $A$-algebras, when $A$ has positive characteristic. However, sometimes a big CM-algebra can be of finite type. This is for instance the case for a Nagata universally catenary local domain $(A, \mathfrak{n})$ of dimension 2. Indeed, the normalization $B$ of $A$ in its field of fractions is a finite $A$-algebra, hence noetherian, catenary and of dimension 2; so it is a Cohen-Macaulay ring, by Serre’s criterion for normality ([100, Th.23.8]), and the support of $B$ is Spec $A$.

(iii) Let $f : (A', \mathfrak{n}') \to (A, \mathfrak{n})$ be a local ring homomorphism of local noetherian rings with $\dim A' = \dim A$, and such that $\mathfrak{n}$ is the radical of $\mathfrak{n}'A$ (this holds e.g. if $f$ is faithfully flat ([100, Th.15.1(ii)]), or if $f$ is quasi-finite). Let $B$ be an $A$-algebra, and $B'$ an $A'$-algebra. We have :

- (a) $B$ is a big CM $A$-algebra if and only if, by restriction of scalars, $B$ is a big CM $A'$-algebra (lemma 10.4.17(ii)).
- (b) If $f$ is faithfully flat, then $B'$ is a big CM $A'$-algebra if and only if $A \otimes_{A'} B'$ is a big CM $A$-algebra (corollary 10.4.37).

\textbf{Lemma 17.5.19.} Let $(A, \mathfrak{m}_A)$ and $(B, \mathfrak{m}_B)$ be local noetherian rings, $f : A \to B$ a local ring homomorphism of complete intersection (see definition 9.7.30(ii)), and $M$ a big CM $A$-module. Then the $\mathfrak{m}_B$-adic completion $B \widehat{\otimes}_A M$ of $B \otimes_A M$ is a big CM $B$-module.

\textit{Proof.} We establish first the following special cases :

\textbf{Claim 17.5.20.} (i) The $\mathfrak{m}_A$-adic completion $M^{\wedge}$ of $M$ is a big CM $A$-module.

(ii) If $f$ is surjective, with kernel generated by a regular sequence $g := (g_1, \ldots, g_r)$ of $A$, and $M$ is $\mathfrak{m}_A$-adically complete and separated, then $B \otimes_A M$ is a big CM $B$-module.

\textit{Proof of the claim.} (i): Let $f$ be any system of parameters for $A$. Clearly the sequence $f$ is $M$-quasi-regular if and only if it is $M^{\wedge}$-quasi-regular (see definition 7.8.13). Then the assertion follows from proposition 7.8.15 and remark 17.5.18(i).

(ii): By [48] Ch.0, Prop.16.4.1 we may find a sequence $g' := (g_{r+1}, \ldots, g_d)$ such that $g' := (g_1, \ldots, g_d)$ is a system of parameters for $A$, and then $H_i(g', M) = 0$ for every $i > 0$, by remark 17.5.18(i). Consequently, $g''$ is a regular sequence on $M$ (proposition 7.8.15), so that $g'$ is regular on $M/\mathfrak{m}M$, and thus $H_i(g', B \otimes_A M) = 0$ for every $i > 0$, again by proposition 7.8.15 in view of remark 17.5.18(i). We are then reduced to checking that $g'$ is a system of parameters for $B$. But the latter follows immediately from [100, Th.14.1].

Now, let us pick a Cohen factorization $A \xrightarrow{\pi} (C, \mathfrak{m}_C) \xrightarrow{h} B^{\wedge}$ of $f$, such that $\text{Ker} \ h$ is generated by a regular sequence of $\mathfrak{m}_C$. Since $g$ is flat, and $\overline{C} := C/\mathfrak{m}_AC$ is regular, we have :

$$\dim C = \dim A + \dim \overline{C} = \text{depth}_AM + \text{depth}_{\overline{C}} \overline{C} = \text{depth}_C(C \otimes_A M)$$

by [100, Th.15.1] and theorem 10.4.38. Combining with claim 17.5.20(i), we see that the $\mathfrak{m}_C$-adic completion $C \widehat{\otimes}_A M$ of $C \otimes_A M$ is a CM $C$-module. Then, claim 17.5.20(ii) says that
The following conditions are equivalent:

Proof of the claim.

(a) 17.5.23 Claim defined, and the lemma will follow from the more general: $V$ $(\text{Here, } A \subset V)$ that the latter is a big $CM$ $A$-algebra. Proposition 17.5.24 and theorem 17.5.27 below illustrate the method in the easier case where $A$ is an $F_p$-algebra, for some prime integer $p$. 

To explain how we shall produce big CM-algebras, let us make the following:

Definition 17.5.21. Let $(A, \mathfrak{m})$ be a noetherian local ring, $V$ an $A$-algebra, $\mathfrak{m} \subset V$ an ideal such that $\mathfrak{m} = \mathfrak{m}^2$, so that $(V, \mathfrak{m})$ is a basic setup, in the sense of [59, §2.1.1], and suppose moreover that $\tilde{m} := \mathfrak{m} \otimes_V \mathfrak{m}$ is a flat $V$-module. Let also $M$ be a $V$-module; we say that $M$ is big almost $CM$ over $A$ if $M^\circ$ is a big Cohen-Macaulay $A$-module.

With this terminology, our strategy relies on the following observation:

Lemma 17.5.22. In the situation of definition 17.5.21 set $d := \dim A$, and suppose that the basic setup $(V, m)$ fulfills the condition of (17.5.2). The following conditions are equivalent:

(a) $M$ is big almost $CM$ over $A$.
(b) $(R^i\Gamma_{(n)} M)^a = 0$ for every $i = 0, \ldots, d - 1$, and $(R^d\Gamma_{(n)} M)^a \neq 0$.
(c) $M^\circ$ is big almost $CM$ over $A$.
(d) $S^{-1} M^\circ$ is a big Cohen-Macaulay $A$-module.

Proof. (Here, $S \subset V^N$ is the multiplicative subset associated with $m$, as in (17.5.2).) Let $Z := \text{Spec } V/\mathfrak{m} V$; in view of lemma 10.4.13(v), we have a natural identification $R^i\Gamma_{(n)} M \sim R^i\Gamma_{Z} M$ for every $i \in \mathbb{N}$ whence a natural $V$-module structure on $R^i\Gamma_{(n)} M$, so the $(V, m)^a$-module $(R^i\Gamma_{(n)} M)^a$ is well defined, and the lemma will follow from the more general:

Claim 17.5.23. Let $I \subset V$ be a finitely generated ideal, $d \in \mathbb{N}$, and $Z := \text{Spec } V/I \subset \text{Spec } V$. The following conditions are equivalent:

(a) $\text{depth}_I(M^\circ) = d$ (notation of (10.4.29)).
(b) $(R^i\Gamma_{Z} M)^a = 0$ for every $i < d$ and $(R^d\Gamma_{Z} M)^a \neq 0$.
(c) $\text{depth}_I((M^\circ)^a) = d$.
(d) $\text{depth}_I(S^{-1} M^\circ) = d$.

Proof of the claim. (a)$\iff$(b): Since $\tilde{m}$ is a flat $V$-module, we have natural identifications:

$$(R^i\Gamma_{Z} M)^a \sim \tilde{m} \otimes_V R^i\Gamma_{Z} M \sim R^i\Gamma_{Z}(\tilde{m} \otimes_V M) \sim R^i\Gamma_{Z}(M^\circ)$$

for every $i \in \mathbb{N}$ provided by lemma 10.4.17(iv), whence the contention.

(a)$\iff$(c)$\iff$(d): Let $f$ be a finite system of generators of $I$, and $K^\bullet(f, M)$ the Koszul complex of $M$ relative to the sequence $f$. Let $S^{-1}K^\bullet(f, M)^\circ$ be the complex obtained by applying the functor $S^{-1}(-)^\circ$ termwise to $K^\bullet(f, M)$, and define likewise $K^\bullet(M)^\circ$ and $K^\bullet(f, M)^\circ$. By direct inspection (and since $\tilde{m}$ is a flat $V$-module), we easily obtain natural identifications:

$$K^\bullet(f, M)^\circ \sim K^\bullet(f, M^\circ) \quad K^\bullet(f, M)^\circ \sim K^\bullet(f, M^\circ) \quad S^{-1}K^\bullet(f, M)^\circ \sim K^\bullet(f, S^{-1}M^\circ).$$

In view of lemmata [17.5.1(i)] and [17.5.4(ii)], we deduce for every $i \in \mathbb{N}$ natural isomorphisms:

$$H^i(f, M)^\circ \sim H^i(f, M^\circ) \quad H^i(f, M)^\circ \sim H^i(f, M^\circ) \quad S^{-1}H^i(f, M)^\circ \sim H^i(f, S^{-1}M^\circ)$$

and moreover, $H^i(f, M)^\circ = 0$ if and only if $S^{-1}H^i(f, M)^\circ = 0$. Combining with proposition 10.4.32(i), the assertion follows.

Hence, we shall seek a suitable basic setup $(V, m)$ as in definition 17.5.21 fulfilling the additional condition of (17.5.2), together with a $V$-algebra $C$ whose underlying $V$-module is big almost $CM$ over $A$; in this situation, lemma 17.5.22 will ensure that $S^{-1}C^\circ$ is a big $CM$ $A$-algebra. Proposition 17.5.24 and theorem 17.5.27 below illustrate the method in the easier case where $A$ is an $F_p$-algebra, for some prime integer $p$. 

$N := B^h \otimes_C (C \otimes_A M)$ is a CM $B^h$-module, so also a CM $B$-module, by remark 17.5.18(iii.a). Lastly, it is easily seen that the $B^h$-adic completion of $N$ is naturally isomorphic to $B \otimes_A M$, so the latter is a big CM $B$-module, again by claim 17.5.20(i).
**Proposition 17.5.24.** Let $p$ be a prime integer, $(A, n)$ a noetherian local $\mathbb{F}_p$-algebra, and $a \in A$ a non-nilpotent element. Let also $A^{\text{perf}}$ be the perfection of $A$, defined as in (9.8.11), and $J \subset A^{\text{perf}}$ the ideal generated by $(a^{1/p^n} \mid n \in \mathbb{N})$. We have:

(i) $J(A^{\text{perf}}/nA^{\text{perf}}) \neq 0$.

(ii) If $A$ is excellent and equidimensional, and $A[a^{-1}]$ is a Cohen-Macaulay ring, then:

$$J \cdot R^i\Gamma_{(n)} A^{\text{perf}} = 0 \quad \text{for } i = 0, \ldots, \dim A - 1.$$

**Proof.** (i): Let $q \subset A$ be a minimal prime ideal that does not contain $a$, and set $B := A/q$; clearly $B^{\text{perf}}$ is a quotient of $A^{\text{perf}}$, hence it suffices to check that $J(B^{\text{perf}}/nB^{\text{perf}}) \neq 0$. Thus, we may replace $A$ by $B$, and assume that $A$ is a domain. If $a \in A^\times$, the assertion is trivial; suppose then that $a \notin A^\times$, in which case $a$ lies in a prime ideal $p \subset A$ of height one (100 Th.13.5). Set $C := A_p$; clearly $C^{\text{perf}}$ is a localization of $A^{\text{perf}}$, hence it suffices to check that $J(C^{\text{perf}}/nC^{\text{perf}}) \neq 0$. Thus, we may replace $A$ by $C$, and assume that $A$ is a one-dimensional domain, in which case there exists a one-dimensional valuation ring $V$ of $\text{Frac} A$ that dominates $A$ (claim 15.3.27). It is easily seen that $V^{\text{perf}}$ is a one-dimensional valuation ring of $\text{Frac} (A^{\text{perf}})$ dominating $A^{\text{perf}}$ (the details shall be left to the reader). We have to show that $J A^{\text{perf}} \nsubseteq nA^{\text{perf}}$, and it suffices to check that $JV^{\text{perf}} \nsubseteq nV^{\text{perf}}$. However, since $n$ is an ideal of finite type, $V^{\text{perf}}$ is a principal ideal lying in the maximal ideal $m_V^{\text{perf}}$ of $V^{\text{perf}}$, on the other hand, the value group of $V^{\text{perf}}$ is of rank one and $p$-divisible, and $a \in m_V^{\text{perf}}$, so $JV^{\text{perf}} = m_V^{\text{perf}}$, whence the assertion.

(ii): Let us first notice:

**Claim 17.5.25.** Let $i \in \mathbb{N}$ such that $a^n R^i \Gamma_{(n)} A = 0$ for some $n \in \mathbb{N}$; then $J \cdot R^i\Gamma_{(n)} A^{\text{perf}} = 0$.

**Proof of the claim.** Let $\Phi_A : A \to A$ be the Frobenius endomorphism, and for every $k \in \mathbb{N}$ and every $A$-module $M$, let $M(k)$ be the $A$-module obtained from $M$ by restriction of scalars along the map $\Phi_A^k : A \to A$. Clearly $n$ is the radical of the ideal $\Phi_A^k (n)$, for every $k \in \mathbb{N}$, hence we have a natural identification of $A$-modules:

$$H^i_k := R^i \Gamma_{(n)} (A(k)) = (R^i \Gamma_{(n)} A)(k) \quad \text{for every } i, k \in \mathbb{N}$$

(lemma 10.4.13(v)). It follows that $a^{n/k} H^i_k = 0$ for every $k \in \mathbb{N}$. But by definition, $A^{\text{perf}}$ is the direct limit of the system of $A$-algebras $(A(k) \mid k \in \mathbb{N})$, hence $R^i \Gamma_{(n)} A^{\text{perf}}$ is the direct limit of the system of $A$-modules $(H^i_k \mid k \in \mathbb{N})$ (proposition 10.4.9), whence the claim. \hfill \Box

In light of claim [17.5.25], it suffices to check that for every $i = 0, \ldots, \dim A - 1$ we have $a^n R^i \Gamma_{(n)} A = 0$ for some $n \in \mathbb{N}$. Let $(A^n, n^\wedge)$ be the completion of $A$; by assumption, the induced morphism of schemes $\text{Spec} A^n \to \text{Spec} A$ is faithfully flat and regular, hence $A^n[a^{-1}]$ is again a Cohen-Macaulay ring ([100 Th.32.2(i)]), and $\dim A^n = \dim A$; moreover, $A^n$ is equidimensional, by [100 Th.31.7]. Furthermore, since $n^\wedge = n A^n$, we have a natural identification

$$R^i \Gamma_{(n^\wedge)} A^n = A^n \otimes_A R^i \Gamma_{(n)} A \quad \text{for every } i \in \mathbb{N}$$

(lemma 10.4.17(iii)). Thus, it suffices to check that for every $i = 0, \ldots, \dim A^n - 1$ there exists $n \in \mathbb{N}$ such that $a^n R^i \Gamma_{(n^\wedge)} A^n = 0$; i.e. we may replace $A$ by $A^n$, and assume from start that $A$ is complete, and especially, $A$ admits a dualizing complex $\omega^\bullet$ (remark 11.3.45(iv)). Set $X := \text{Spec} A$, and define the map $c_X : |X| \to \mathbb{Z}$ as in (11.3.49); since $A$ is equidimensional, we have $c_X(n) - c_X(p) = \dim A$ for every minimal prime ideal $p \subset A$ (lemma 11.3.50). Thus, after replacing $\omega^\bullet$ by a suitable shift $\omega^\bullet[c]$, we may assume that $c_X(p) = 0$ for every minimal prime ideal $p \subset A$, and consequently $c_X(x) = \dim \mathcal{O}_{X,x}$ for every $x \in X$.

**Claim 17.5.26.** $H^i(\omega^\bullet) = 0$ for every $i < 0$, and $A[a^{-1}] \otimes_A H^i(\omega^\bullet) = 0$ for every $i > 0$.

**Proof of the claim.** Let $x \in X$ be any point; by proposition 11.3.37 the complex $\omega^\bullet(x)$ is dualizing on $X(x)$, and denote by $\mathcal{D}_x$ the corresponding dualizing functor. Recall that
\[D_x(\mathcal{O}_{X,x}) = \omega_x^*,\] and that the natural map

\[\mathcal{O}_{X,x} \to D_x \circ D_x(\mathcal{O}_{X,x}) = D_x(\omega^*(x))\]

is an isomorphism. Let also \(A^\wedge\) be the completion of the local ring \(A_x := \mathcal{O}_{X,x};\) by corollary [11.5.17](iii) there follow natural isomorphisms:

\[D(H^c_{\{x\}} \mathcal{O}_{X,x}) \cong D(H^c_{\{x\}} D_x(\omega^*(x))) \cong A^\wedge_n \otimes_A H^i(\omega^*(x)) \quad \text{for every } i \in \mathbb{Z}\]

where the functor \(D\) is defined as in ([11.5.16]). By assumption, if \(x \in \text{Spec } A[a^{-1}],\) we have \(H^c_{\{x\}} \mathcal{O}_{X,x} = 0\) for every \(i > 0,\) so that \(H^c_{\{x\}} \mathcal{O}_{X,x} = 0\) for every such \(i\) and every such \(x,\) since \(A^\wedge\) is a faithfully flat \(A_x\)-algebra. Lastly, we have \(H^c_{\{x\}} \mathcal{O}_{X,x} = 0\) for every \(i < 0\) and every \(x \in X,\) by proposition [10.4.7](ii), hence \(H^i(\omega^*(x)) = 0\) for every such \(i\) and \(x.\)

By corollary [11.5.17] we have a natural isomorphism:

\[H^i_{\{a\}}(A) \cong H^i_{\{a\}}(\mathcal{D}(\omega^*)) \cong D(H^c_{\{a\}}(\omega^*)) \quad \text{for every } i \in \mathbb{Z}\]

and \(e(n) = \dim A.\) Since \(H^j(\omega^*)\) is a finitely generated \(A\)-module for every \(j \in \mathbb{Z},\) claim [17.5.26] implies that there exists \(n \in \mathbb{N}\) such that \(a^n \cdot H^j(\omega^*) = 0\) for every \(j > 0.\) Since \(D\) is an \(A\)-linear functor, it follows that \(a^n \cdot H^j_{\{a\}}(A) = 0\) for every \(i < \dim A,\) as required.

**Theorem 17.5.27.** Let \(p\) be a prime integer, and \((A, n)\) a local noetherian \(\mathbb{F}_p\)-algebra. Then there exists a big CM \(A\)-algebra.

**Proof.** We first notice:

**Claim 17.5.28.** We may assume that \(A\) is an excellent and equidimensional local ring.

**Proof of the claim.** Let \(p\) be a minimal prime ideal of the completion \(A^\wedge\) of \(A,\) such that \(A' := A^\wedge/p\) has dimension equal to \(\dim A;\) then the natural map \(A \to A'\) fulfills the conditions of remark [17.5.18](ii); thus it suffices to exhibit a big CM \(A'\)-algebra, and \(A'\) is an excellent local domain ([49], Ch.IV, Sch.7.8.3(iii))).

Thus, we assume now that \(A\) is as in claim [17.5.28]. Then, by ([49], Ch.IV, Sch.7.8.3(iv)), the subset \(U\) of points \(p \in X := \text{Spec } A\) such that \(A_p\) is Cohen-Macaulay, is open in \(X,\) and trivially contains all the maximal points of \(X,\) hence it is dense in \(X.\) We may therefore find \(a \in A\) such that \(0 \neq \text{Spec } A[a^{-1}] \subseteq U,\) so that \(a\) is not nilpotent, and \(A[a^{-1}]\) is a Cohen-Macaulay ring. Define \(A_{\text{perf}}\) and \(J\) as in proposition [17.5.24]. Clearly \(J^2 = J,\) and the basic setup \((A_{\text{perf}}, J)\) fulfills the condition of [17.5.2]. By proposition [17.5.24](ii), we then have

\[(A_{\text{perf}}/n A_{\text{perf}})^{a} \neq 0 \quad \text{and} \quad (R^i \text{Hom}_{\{a\}} A_{\text{perf}})^{a} = 0 \quad \text{for every } i = 0, \ldots, \dim A - 1.\]

It follows that \((A_{\text{perf}}/n A_{\text{perf}})^a \neq 0.\) Recall that \(J^{\sim} := J \otimes_{A_{\text{perf}}} J\) is a flat \(A_{\text{perf}}\)-module ([59], Prop.2.1.7(ii)), and let \(S_n \subseteq (A_{\text{perf}})^{\mathbb{N}}\) be the multiplicative subset associated with \(J,\) as in [17.5.23]; then by lemmata [17.5.22] and [17.5.4](i,ii) we conclude that \(S_n^{-1}(A_{\text{perf}})^{\mathbb{N}}\) is a big CM \(A\)-algebra.

It is useful to generalize theorem [17.5.27] to non-local noetherian \(\mathbb{F}_p\)-algebras. To this aim, let us make the following:

**Definition 17.5.29.** Let \(A\) be a noetherian ring, \(M\) an \(A\)-module, and \(B\) an \(A\)-algebra.

(i) We say that \(A\) is **locally equidimensional** if \(A_p\) is equidimensional for every \(p \in \text{Spec } A.\)

(ii) We say that \(M\) is a **big locally CM \(A\)-module**, if \(M_p\) is a big CM \(A_p\)-module for every \(p \in \text{Spec } A.\) Likewise, \(B\) is a **big locally CM \(A\)-algebra**, if it is big locally CM as an \(A\)-module.

(iii) Let \(f : X \to Y\) be a morphism of schemes. We say that \(f\) is **maximizing**, if for every maximal point \(x\) of \(X\) (for the partial order given by specialization of points), the point \(f(x)\) is maximal in \(Y.\) We say that a ring homomorphism \(f : A \to B\) is **maximizing**, if \(\text{Spec } f\) is a maximizing morphism of schemes.
Lemma 17.5.30. Let $A$ be a catenarian noetherian ring (see definition 9.7.3(iii)). The following conditions are equivalent:

(a) $A$ is locally equidimensional.
(b) $A_m$ is equidimensional for every maximal ideal $m \subset A$.
(c) For every two irreducible components $Z$ and $Z'$ of $\text{Spec } A$, and every maximal point $p$ of the topological space $Z \cap Z'$, the ring $A_p$ is equidimensional.

Proof. Trivially (a)$\Rightarrow$(b), and (a)$\Rightarrow$(c).

(b)$\Rightarrow$(a): Indeed, say that $p \in \text{Spec } A$, and let $q$ and $q'$ be two minimal prime ideal contained in $p$; we need to check that two every saturated chain of prime ideals

\begin{equation}
q \subset \cdots \subset p \quad \text{and} \quad q' \subset \cdots \subset p
\end{equation}

have the same length. To this aim, pick any maximal ideal $m$ of $A$ containing $p$, and complete the two chains with the same saturated chain $p \subset \cdots \subset m$; the resulting chains $q \subset \cdots \subset m$ and $q' \subset \cdots \subset m$ are saturated, so by assumption they both have length equal to $\dim A_m$, whence the assertion.

(c)$\Rightarrow$(b): Let $m \subset A$ be a maximal ideal, and $q$, $q'$ two minimal prime ideals of $A$ contained in $m$; set $Z := \text{Spec } A/q$ and $Z' := \text{Spec } A/q'$. Then, $m \in Z \cap Z'$, so let $p$ be any maximal generization of $m$ in $Z \cap Z'$; pick any two saturated chains as in (17.5.31), and complete them again with the same saturated chain $p \subset \cdots \subset m$, say of length $l_0$. Since $A_p$ is equidimensional, the chains (17.5.31) have the same length $l_1$; now, let $q \subset \cdots \subset m$ and $q' \subset \cdots \subset m$ be any other pair of saturated chains, of lengths $l$ and respectively $l'$; since $A$ is catenary, we must have $l = l_0 + l_1 = l'$, so $A_m$ is equidimensional. \qed

Corollary 17.5.32. Let $A$ be an excellent and locally equidimensional $F_p$-algebra. Then there exists a big locally CM $A$-algebra $B$.

Proof. The subset $U$ of points $p \in X := \text{Spec } A$ such that $A_p$ is Cohen-Macaulay is open ([49 Ch.IV, Sch.7.8.3(iv)]), and trivially contains the subset $\text{Min}(A)$ of all minimal prime ideals of $A$, hence it is dense in $X$. Say that $X \setminus U = \text{Spec } A/I$ for some ideal $I \subset A$; then $I$ is not contained in any minimal ideal of $A$, and so there exists $a \in I \setminus \bigcup_{p \in \text{Min}(A)} p$ ([10 Prop.1.11(i)]). Let $A_{\text{perf}}$ be the perfection of $A$ (see (9.8.11)), and $J \subset A_{\text{perf}}$ the ideal generated by $(a^{1/n^n} \mid n \in \mathbb{N})$. Let moreover $S_a \subset (A_{\text{perf}})^{\mathbb{N}}$ be the multiplicative subset associated with $J$, as in (17.5.2). We claim that $B := S_a^{-1}(A_{\text{perf}})^{\mathbb{N}}$ will do. Indeed, let $p \subset A$ be any prime ideal, $k(p)$ its residue field, $j : A \to A_p$ the localization, and $S_{j(a)} \subset (A_{\text{perf}})^{\mathbb{N}}$ the corresponding multiplicative subset, associated with the ideal $J_a$.

Claim 17.5.33. $S_a^{-1}(A_{\text{perf}})^{\mathbb{N}}$ is a big CM $A_p$-algebra; especially, $S_a^{-1}(A_{\text{perf}})^{\mathbb{N}} \otimes_A k(p) \neq 0$.

Proof of the claim. By [49 Ch.IV, Sch.7.8.3(ii)], $A_p$ is excellent and equidimensional. Then the assertion follows from the proof of theorem 17.5.27 \qed

The map $j$ induces a ring homomorphism $B \to S_a^{-1}(A_{\text{perf}})^{\mathbb{N}}$; with claim 17.5.33 we then get $B \otimes_A k(p) \neq 0$ for every $p \in \text{Spec } A$. In view of (10.4.30), we are then reducing to showing:

Claim 17.5.34. $\text{depth}_p B = \dim A_p$ for every $p \in \text{Spec } A$.

Proof of the claim. Set $I := pA_{\text{perf}}$, $Z := \text{Spec } A/p$ and $Z' := \text{Spec } A_{\text{perf}}/I$; by lemma 10.4.13(v), we have a natural identification:

$$R^i \Gamma Z B \sim R^i \Gamma Z'I B \quad \text{for every } i \in \mathbb{N}.$$ 

In view of claim 17.5.23, we are then reduced to checking that:

$$\text{depth}_I((A_{\text{perf}})^{\mathbb{N}}_I) = \dim A_p$$
for the almost structure attached to the basic setup \((A^\perf, J)\). However, recall that \((A^\perf)_q = (A^\perf)_q^a\) for every \(q \in \Spec A\) (see (9.8.11)); also, \(((A^\perf)_q^a)^a\) agrees with \((A^\perf)_q^a\), for every such \(q\), where now \((A^\perf)_q^a\) is regarded as an \((A^\perf)_q, J A^\perf)_q^a\)-module, and \((-)\); refers to the left adjoint of the localization \(A^\perf_{\mathcal{M}} \Mod \to (A^\perf_q, J A^\perf)_q^a\-\Mod\). It follows that:
\[
\text{depth}_{A_q}(A^\perf)_q^a = \dim A_q \quad \text{for every } q \in \Spec A
\]
by virtue of lemma 17.5.22 and claim 17.5.33. We conclude by invoking again (10.4.30). □

Remark 17.5.35. (i) Theorem 17.5.27 was first proved by Hochster and Huneke in [7]; more precisely, they showed that for every excellent local domain \(A\) of equicharacteristic \(p \neq 0\), the integral closure of \(A\) in the algebraic closure of \(\text{Frac}(A)\) is a big CM \(A\)-algebra. Our construction yields a different big CM \(A\)-algebra.

(ii) Our construction can be easily upgraded to a functor on the category
\[\mathcal{B}_p\]
whose objects are all the excellent and locally equidimensional \(\mathbb{F}_p\)-algebras, and whose morphisms are the maximizing ring homomorphisms (see definition 17.5.29(iii)). Namely, for every \(A \in \Ob(\mathcal{B}_p)\), let \(\text{Min}(A)\) be the set of minimal primes of \(A\), and endow \(\text{Min}(A)\) as with the partial ordering such that \(a \leq b\) if and only if \(b A \subseteq a A\), and for every \(a \in \text{Min}(A)\), define the multiplicative subset \(S_a \subseteq (A^\perf)^a\) in the proof of theorem 17.5.27. Clearly \((A^\ast, \leq)\) is a filtered partially ordered set, and we have \(S_a \subseteq S_b\) for every \(a, b \in A^\ast\) with \(a \leq b\). Then, denote by \(E_p(A)\) the colimit of the induced filtered system of \(A\)-algebras \((S_a^{-1}(A^\perf)^a \mid a \in \text{Min}(A))\). The proof of corollary 17.5.32 shows that \(A^\ast\) admits a cofinal subset \(\Sigma \subseteq \text{Min}(A)\) such that \(S_a^{-1}(A^\perf)^a\) is a big locally CM \(A\)-algebra for every \(a \in \Sigma\); it follows easily that the same holds for \(E_p(A)\) (the details shall be left to the reader). Now, let \(f : A \to B\) be a morphism of \(\mathcal{B}_p\), clearly \(f\) extends uniquely to a ring homomorphism \(f^\perf : A^\perf \to B^\perf\), and restricts to a map \(f^* : A^\ast \to B^\ast\), as \(f\) is maximizing. Moreover, we have \((f^\perf)^a(S_a) \subseteq S_{f(a)}\) for every \(a \in \text{Min}(A)\). Hence, we obtain an induced map \(S_a^{-1}(A^\perf)^a \to S_{f(a)}^{-1}(B^\perf)^a\) for every such \(a\), and the colimit of these maps is a ring homomorphism \(E_p(f) : E_p(A) \to E_p(B)\). It is then easily seen that the rules \(A \mapsto E_p(A)\) and \(f \mapsto E_p(f)\) yield the sought functor \(E_p : \mathcal{B}_p \to \mathbb{F}_p\-\text{Alg}\).

(iii) Moreover, consider the functor
\[
(-)^{\ast} : \mathcal{B}_p \to \mathcal{B}_p \quad A \mapsto A^\ast := \prod_{p \in \text{Min}(A)} (A/p)^{\nu(p)}
\]
where, for every \(p \in \text{Min}(A)\), we denote by \((A/p)^{\nu}\) the integral closure of \(A/p\) in its field of fractions. Clearly, the natural map \(j_A : A \to A^\ast\) is a morphism of \(\mathcal{B}_0\). It is easily seen that every morphism \(f : A \to B\) in \(\mathcal{B}_p\) induces a well defined morphism \(f^\ast : A^\ast \to B^\ast\), such that \(f^\ast \circ j_A = j_B \circ f\); this completes the construction of the functor \((-)^{\ast}\), and shows that the rule : \(A \mapsto j_A\) yields a natural transformation \(j_* : 1_{\mathcal{B}_p} \to (-)^{\ast}\). With this notation, we have:

Proposition 17.5.36. (i) The functor \(E_p\) factors through the functor \((-)^{\ast}\).

(ii) The functor \(E_p\) commutes with finite products.

Proof. (i): We need to check that \(E_p(j_A)\) is an isomorphism for every \(A \in \Ob(\mathcal{B}_p)\); to this aim, let \(A_{\text{red}}\) be the maximal reduced quotient of \(A\), and notice that \(j_A\) factors through the quotient map \(j'_A : A \to A_{\text{red}}\) and a unique map \(j''_A : A_{\text{red}} \to A^\ast\), and both maps are morphisms in \(\mathcal{B}_p\). Now, clearly \(j'_A\) induces an isomorphism \((j'_A)^{\perf} : A_{\text{red}}^\perf \cong (A_{\text{red}})^{\perf}\) that identifies \(S_a\) with \(S_{j'_A(a)}\) for every \(a \in A^\ast\) (notation of remark 17.5.35(ii)). Then, under these identifications, \(E_p(A_{\text{red}})\) is the colimit of the functor
\[
F : ((A_{\text{red}})^{\ast}, \leq) \to \mathbb{F}_p\-\text{Alg} \quad a \mapsto S_a^{-1}(A^\perf)^a
\]
and $E_p(A)$ is the colimit of the functor $F \circ (j_A^!): (A^*, \leq) \to \mathbb{P}_p$-Alg. But notice that the map $(j_A^!): A^* \to (A^*_{\text{red}})$ is surjective, so it is a cofinal functor of filtered categories (lemma 1.5.7(ii)), and thus $E_p(j_A^!)$ is an isomorphism (proposition 1.5.2). Next, we remark :

**Claim 17.5.37.** (i) There exists $c \in A^*_{\text{red}}$ such that $j_A^*(c) \cdot A^\nu \subset j_A^*(A_{\text{red}})$.

(ii) For every $c$ as in (i), and every $n \in \mathbb{N}$, we have $c^{1/p^n}(A^\nu)^{\text{perf}} \subset A^{\text{perf}}$.

**Proof of the claim.** (i): We further write $j_A^*(c)$ as the composition of injective maps

$$A_{\text{red}} \ni i_1 B := \prod_{p \in \text{Min} A} A/p \ni \to A^\nu.$$

It then suffices to find $c_1 \in A^*_{\text{red}}$ and $c_2 \in B^*$ such that $c_1 B \subset i_1(A_{\text{red}})$ and $c_2 A^\nu \subset i_2(B)$, since in that case $c_3 := i_1(c_1)c_2 \in i_1(A_{\text{red}}) \cap B^* = i_1(A^*_{\text{red}})$, and $i_2(c_3)A^\nu \subset j_A^*(A_{\text{red}})$. Now, let $Z_1, \ldots, Z_k$ be the irreducible components of $\text{Spec} A_{\text{red}}$, and set $Z := \bigcup_{1 \leq i < j \leq k} Z_i \cap Z_j$; pick any ideal $J \subset A_{\text{red}}$ such that $Z = \text{Spec} A/J$. Hence, $J$ does not lie in any minimal prime ideal of $A_{\text{red}}$, so $J \cap A^*_{\text{red}} \neq \emptyset$ (10. Prop. 1.11(ii)); let then $d \in J \cap A^*_{\text{red}}$. We have $Z \cap \text{Spec} A_{\text{red}}[d^{-1}] = \emptyset$, so $i_1$ induces an isomorphism $A_{\text{red}}[d^{-1}] \cong B[d^{-1}]$. Since $B$ is a finite $A_{\text{red}}$-algebra, it follows that $d^nB \subset i_1(A_{\text{red}})$, for some $n \in \mathbb{N}$, so $c_1 := d^n$ will do. Next, notice that $B^* = \prod_{p \in \text{Min} A}(A/p)^*$ and $(A^\nu)^* = \prod_{p \in \text{Min} A}(A/p)^{\nu}$, so in order to exhibit $c_2$ it suffices to find for every $p \in \text{Min} A$ some $c_{p} \in (A/p)^* = (A/p) \setminus \{0\}$ with $c_{p}(A/p)^{\nu} \subset A/p$. To this aim, it suffices to notice that, as $A$ is excellent, $(A/p)^{\nu}$ is a finite $A/p$-subalgebra of $\text{Frac}(A/p)$.

(ii) shall be left to the reader.

Pick $c \in A^*_{\text{red}}$ as in claim (17.5.37(i)); set $\Sigma := \{ca \in A^*_{\text{red}} \mid a \in A^*_{\text{red}} \}$, and let $\bullet := (17.5.37(i))$ states that the image of $\Sigma$ is cofinal in the partially ordered set $((A^\nu)^*)$. Moreover, $j_A^*$ induces an injection $A_{\text{perf}} \to (A^\nu)^{\text{perf}}$; combining with claim (17.5.37(ii)) we deduce that $j_A^*$ induces an isomorphism

$$(A^\nu)^{\text{perf}}[c^{-1}] \cong ((A^\nu)^{\text{perf}})[c^{-1}]$$

and on the other hand, $\bullet \in S_b$ for every $b \in \Sigma$. Summing up, we conclude that $E_p(j_A^*)$ is naturally identified with the colimit of the system of maps

$$(17.5.38) \quad S_b^{-1}((A^\nu)^{\text{perf}})^{\circ} \to S^{-1}_{(A_{\text{red}})}((A^\nu)^{\text{perf}})^{\circ}$$

for every $b \in \Sigma$ induced by the inclusion $S_b \subset S_{(A_{\text{red}})}$, for every such $b$ (here, $S_b$ lies in $(A^\nu)^{\text{perf}}$), whereas $S_{(A_{\text{red}})}$ lies in $((A^\nu)^{\text{perf}})^{\circ}$.

In order to check that $E_p(j_A^*)$ is an isomorphism, it then suffices to prove that the same holds for the maps (17.5.38); the latter follows at once from :

**Claim 17.5.39.** $\bullet \in S_b$, for every $s \in S_{(A_{\text{red}})}$.

**Proof of the claim.** Say that $s_n := (s_n \mid n \in \mathbb{N}) \in ((A^\nu)^{\text{perf}})^{\circ}$ and $b = ac$ for some $a \in (A_{\text{perf}})^*$; we need to check that $b^{1/p^n} \in \bigcup_{n \in \mathbb{N}} c^{1/p^n}s_n A^{\text{perf}}$ for every $k \in \mathbb{N}$. However, by assumption $j_A^*(b^{1/p^n}) \in \bigcup_{n \in \mathbb{N}} s_n (A^\nu)^{\text{perf}}$, so say that $j_A^*(b^{1/p^n}) = s_n x$ for some $n \in \mathbb{N}$ and $x \in (A^\nu)^{\text{perf}}$; also, we may assume that $n > k$. By claim (17.5.37(ii)), we get $x = b^{1/p^n} \in A^{\text{perf}}$, and it follows easily that $(ac^2)^{1/p^n} = (bc)^{1/p^n} \in c^{1/p^n}s_n A^{\text{perf}}$. Then we get $b^{2/p^n} = (ac)^{2/p^n} \in \bigcup_{n \in \mathbb{N}} c^{1/p^n}s_n A^{\text{perf}}$ for every $k \in \mathbb{N}$, whence the claim.

(ii): First, it is easily seen that the finite products in $\mathcal{B}_p$ are represented by the usual (categorical) products of rings (details left to the reader). Hence, say that $A = A_1 \times \cdots \times A_n$, for some $A_1, \ldots, A_n \in \text{Ob}(\mathcal{B}_p)$. It is easily seen that $A^* = A_1^* \times \cdots \times A_n^*$. It is also clear that

$$(A^{\text{perf}})^{\circ} = \prod_{i=1}^n (A_i^{\text{perf}})^{\circ}$$

(lemma 17.5.1(i)). Moreover, for each $a_{\bullet} := (a_1, \ldots, a_n) \in A^*$, we have $s_{a_{\bullet}} = s_{a_1} \times \cdots \times s_{a_n}$, and thus $S_{a_{\bullet}}^{-1} = \prod_{i=1}^n S_{a_i}^{-1}(A_i^{\text{perf}})^{\circ}$. Since finite products commute with filtered colimits in the category of rings, the assertion follows.}

\[\square\]
17.5.40. It turns out that the construction of big CM algebras over \( \mathbb{Q} \)-algebras can be reduced to the case of algebras of positive characteristic. Indeed, consider first a locally equidimensional \( \mathbb{Q} \)-algebra \( A \) of finite type. Let \( \Delta(A) \) be the set of all \( \mathbb{Z} \)-subalgebras \( B \subset A \) of finite type with \( \mathbb{Q} \otimes_{\mathbb{Z}} B = A \). Let also \( \text{Max} \mathbb{Z} \) be the maximal spectrum of \( \mathbb{Z} \), i.e. the set of prime integers.

**Lemma 17.5.41.** With the notation of [17.5.40], the following holds:

- (i) Every connected component of \( \text{Spec} \ A \) is equidimensional.
- (ii) For every \( B \in \Delta(A) \) there exists a finite subset \( S_B \subset \text{Max} \mathbb{Z} \) such that \( B/pB \) is excellent and locally equidimensional, for every \( p \in \text{Max} \mathbb{Z} \setminus S_B \).

**Proof.** (i): It suffices to check that if \( Z \) and \( Z' \) are two irreducible components of \( \text{Spec} \ A \) with \( Z \cap Z' \neq \emptyset \), then \( \dim Z = \dim Z' \). Hence, pick any maximal ideal \( m \) of \( A \) that lies in \( Z \cap Z' \); by assumption, \( A_m \) is equidimensional, and \( Z(m), Z'(m) \) are two irreducible components of \( \text{Spec} A_m \) (notation of definition [8.1.42(iii)]), so \( \dim Z(m) = \dim Z'(m) \). On the other hand, \( \dim Z = \dim Z(m) \), and likewise for \( Z' \) ([49] Ch.IV, Prop.5.2.1), whence the assertion.

(ii): Since the localization \( B \to \mathbb{Q} \otimes_{\mathbb{Z}} B \) is injective, the unique morphism of schemes \( \varphi : \text{Spec} \ B \to \text{Spec} \mathbb{Z} \) is flat. Let \( T_1, \ldots, T_l \) be the connected components of \( \text{Spec} A \), and for \( i = 1, \ldots, l \), denote by \( \overline{T_i} \) the topological closure of \( T_i \) in \( \text{Spec} B \); since \( \varphi \) is generizing, it follows easily that \( \text{Spec} B = \overline{T_1} \cup \cdots \cup \overline{T_l} \). On the other hand, for every \( i = 1, \ldots, l \), we have also \( \overline{T_i} = \text{Spec} A/e_i A \), for a unique idempotent element \( e_i \in A \); we may then find \( d \in \mathbb{Z} \setminus \{0\} \) such that \( e_1, \ldots, e_l \in B[d^{-1}] \). Set \( U := \text{Spec} B[d^{-1}] \); it follows easily that the connected components of \( U \) are \( \overline{T_1} \cap U, \ldots, \overline{T_l} \cap U \). After replacing \( B \) by \( B[d^{-1}] \), we may then assume that \( B = B_1 \times \cdots \times B_l \), and \( \text{Spec} \mathbb{Q} \otimes_{\mathbb{Z}} B_i \) is connected for every \( i = 1, \ldots, l \). Thus, it suffices to prove the assertion for \( A \) replaced by \( \mathbb{Q} \otimes_{\mathbb{Z}} B_i \) for every \( i = 1, \ldots, l \), and we may therefore assume from start that \( \text{Spec} A \) is connected, so \( A \) is equidimensional, by (i).

Let \( Z_1, \ldots, Z_k \) be the irreducible components of \( \text{Spec} A \), and denote by \( \overline{Z_i} \) the topological closure of \( Z_i \) in \( \text{Spec} B \), for every \( i = 1, \ldots, k \); it follows easily that \( Z_1, \ldots, Z_k \) are the irreducible components of \( \text{Spec} B \), and we endow them with their reduced closed subscheme structures. Then the restriction \( \varphi_i : \overline{Z_i} \to \text{Spec} \mathbb{Z} \) of \( \varphi \) is a flat morphism of schemes, for every \( i = 1, \ldots, k \). According to [50] Ch.IV, Lemme 14.3.10], for every \( p \in \text{Max} \mathbb{Z} \) and every \( i = 1, \ldots, k \), every irreducible component of \( \varphi_i^{-1}(p) \) has dimension equal to \( \dim Z_i \), and we know already that the latter equals \( d := \dim A \). Summing up, for every \( p \in \text{Max} \mathbb{Z} \), every irreducible component of \( \text{Spec} B/pB \) has dimension \( d \); combining with [49] Ch.IV, Prop.5.2.1], we deduce that for every maximal ideal \( m \subset B/pB \), the localization \( (B/pB)_m \) is equidimensional of dimension \( d \). Lastly, \( B/pB \) is an excellent ring, by [49] Ch.IV, Sch.7.8.3(ii)], so we may invoke lemma [17.5.30] to conclude.

For every \( B \in \Delta(A) \), pick a finite subset \( S_B \subset \text{Max} \mathbb{Z} \) fulfilling the condition of lemma [17.5.41](ii), and set

\[
F_0(A, B) := \prod_{p \in \text{Max}(\mathbb{Z}) \setminus S_B} E_p(B/pB) \text{ and } I_0(A, B) := \bigoplus_{p \in \text{Max}(\mathbb{Z}) \setminus S_B} E_p(B/pB)
\]

where \( E_p \) is the functor exhibited in remark [17.5.35](ii). Notice then that \( F_0(A, B) \) is naturally a \( B \)-algebra, and \( I_0(A, B) \) is an ideal of \( F_0(A, B) \); then the quotient

\[
E_0(A, B) := F_0(A, B)/I_0(A, B)
\]

is again endowed with a natural \( B \)-algebra structure. Moreover, if \( B, B' \in \Delta(A) \), we may find \( d \in \mathbb{Z} \setminus \{0\} \) such that \( B[d^{-1}] = B'[d^{-1}] \), and hence \( B/pB = B'/pB' \) for every \( p \in \text{Max}(\mathbb{Z}) \setminus \text{Spec} \mathbb{Z}/d\mathbb{Z} \). There follows a natural identification

\[
E_0(A, B) \xrightarrow{\sim} E_0(A, B')
\]
in which of which, we shall denote this ring simply by $E_0(A)$. Since $A = \bigcup_{B \in \Delta(A)} B$, we conclude that $E_0(A)$ carries a natural $A$-algebra structure.

17.5.42. Next, let $f : A \to A'$ be a maximizing ring homomorphism of locally equidimensional $\mathbb{Q}$-algebras of finite type. Clearly, we may find $B \in \Delta(A)$ and $B' \in \Delta(A')$ such that $f$ restricts to a ring homomorphism $g : B \to B'$. If $h : C \to C'$ is another such restriction with $C \in \Delta(A)$ and $C' \in \Delta'$, then for any $d \in \mathbb{Z} \setminus \{0\}$ such that $B[d^{-1}] = C[d^{-1}]$ and $B'[d^{-1}] = C'[d^{-1}]$ we have $\mathbb{Z}[d^{-1}] \otimes g = \mathbb{Z}[d^{-1}] \otimes h$, so the induced maps $\mathbb{F}_p \otimes g : B/pB \to B'/pB'$ and $\mathbb{F}_p \otimes h : C/pC \to C'/pC'$ are naturally identified for every $p \in \text{Max}(\mathbb{Z}) \setminus \text{Spec } \mathbb{Z}/d\mathbb{Z}$.

Moreover, we have:

**Lemma 17.5.43.** With the notation of (17.5.42), there exists a finite subset $S_g \subset \text{Max } \mathbb{Z}$ such that $\mathbb{F}_p \otimes g$ is maximizing for every $p \in \text{Max}(\mathbb{Z}) \setminus S_g$.

*Proof.* Notice first that $B$ and $B'$ are flat $\mathbb{Z}$-algebra, so all the maximal points of $X := \text{Spec } B$ and $X' := \text{Spec } B'$ lie in $\text{Spec } A$ and respectively $\text{Spec } A'$, so $\varphi := \text{Spec } g$ is maximizing. Let $Z_1, \ldots, Z_h$ (resp. $Z_1', \ldots, Z_l'$) be the irreducible components of $X$ (resp. of $X'$), which we endow with their reduced closed subscheme structures; it follows that for every $i = 1, \ldots, l$ there exists a unique $t(i) \in \{1, \ldots, k\}$ such that $\varphi$ restricts to a dominant morphism of schemes $\varphi_i : Z_i \to Z_{t(i)}$. By [49] Ch.IV, Lemme 6.9.2, we may then find $h \in B \setminus \{0\}$ such that, with $U := \text{Spec } B[h^{-1}]$, the morphism $\varphi_i$ restricts to a flat morphism

$$\varphi_i|U : \varphi_i^{-1}(U \cap Z_{t(i)}) \to U \cap Z_{t(i)}$$

for every $i = 1, \ldots, l$.

Endow likewise the irreducible components $T_1, \ldots, T_n$ of $\text{Spec } B/hB$ with their reduced closed subscheme structures; by the same token, we may find $d \in \mathbb{Z} \setminus \{0\}$ such that, with $W := \text{Spec } \mathbb{Z}[d^{-1}]$, the unique morphism of schemes $\psi_i : T_i \to \text{Spec } \mathbb{Z}$ restricts to a flat morphism

$$\psi_i^{-1}(W) \to W$$

for every $i = 1, \ldots, n$.

Let $\eta \in \text{Spec } \mathbb{Z}$ be the generic point; on the one hand, we have

$$\dim \psi_i^{-1}(\eta) < \dim A$$

for every $i = 1, \ldots, n$ and on the other hand, [50] Ch.IV, Lemme 14.3.10] says that for every $p \in W$ we have:

$$\dim \psi_i^{-1}(p) = \dim \psi_i^{-1}(\eta)$$

for every $i = 1, \ldots, n$ and $\dim B/pB = \dim A$.

Summing up, we conclude that for every $p \in W \setminus \text{Max}(\mathbb{Z})$, all the maximal points of $\text{Spec } B/pB$ lie in $U$. Arguing likewise with the irreducible components of $\text{Spec } B'/hB'$, we get an open subset $W' \subset \text{Spec } \mathbb{Z}$ such that, for every $p \in W \cap \text{Max}(\mathbb{Z})$, all the maximal points of $\text{Spec } B'/pB'$ lie in $\varphi^{-1}U$. But since each $\varphi_i|U$ is flat, for every $p \in \text{Max}(\mathbb{Z})$ the restriction of $\varphi$:

$$\varphi^{-1}(U) \cap \text{Spec } B'/pB' \to U \cap \text{Spec } B/pB$$

is maximizing, so the lemma holds with $S_g := \text{Max}(\mathbb{Z}) \setminus (W \cap W')$. $\square$

Using lemma [17.5.43] we may attach to any $f : A \to A'$ as in (17.5.42) a well defined map

$$E_0(f) : E_0(A) \to E_0(A').$$

Namely, pick $B$, $B'$ and $g : B \to B'$ as in (17.5.42), and finite subsets $S_B, S_B', S_g \subset \text{Max } \mathbb{Z}$ as in lemmata [17.5.41] and [17.5.43] set $M := \text{Max}(\mathbb{Z}) \setminus (S_B \cup S_B' \cup S_g)$ and

$$F_0(f, g) := \prod_{p \in M} E_p(\mathbb{F}_p \otimes g) \otimes \prod_{p \in M} E_p(B/pB) \to \prod_{p \in M} E_p(B'/pB').$$

Clearly $F_0(f, g)$ maps the ideal $\bigoplus_{p \in M} E_p(B/pB)$ into $\bigoplus_{p \in M} E_p(B'/pB')$, so it induces a unique map $E_0(f)$ as sought. It is also easily seen that if $A''$ is any other locally equidimensional $\mathbb{Q}$-algebra of finite type, and $f' : A' \to A''$ is any maximizing ring homomorphism, then
$E_0(f' \circ f) = E_0(f') \circ E_0(f)$: details left to the reader. Summing up, we have a well defined functor

$$E_0 : \mathcal{B}_0 \to \mathbb{Z}\text{-}Alg$$

where $\mathcal{B}_0$ is the category whose objects are the locally equidimensional $\mathbb{Q}$-algebras of finite type, and whose morphisms are the maximizing ring homomorphisms. Furthermore, just as in remark 17.5.35(iii), we have a normalization functor

$$(-)^\nu : \mathcal{B}_0 \to \mathcal{B}_0 \quad A \mapsto \prod_{p \in \text{Min} A} (A/p)^\nu$$

(where $(A/p)^\nu$ denotes the integral closure of $A/p$ in $\text{Frac}(A/p)$, for every $p \in \text{Min} A$), as well as a natural transformation $j_\bullet : 1_{\mathcal{B}_0} \Rightarrow (-)^\nu$. With this notation, we may now state:

**Theorem 17.5.44.** (i) $E_0(A)$ is a big locally CM $A$-algebra, for every $A \in \text{Ob}(\mathcal{B}_0)$.

(ii) The functor $E_0$ commutes with finite products.

(iii) The functor $E_0$ factors through the functor $(-)^\nu$.

**Proof.** (i): It is easily seen that the products in $\mathcal{B}_0$ are represented by the usual (cartesian) products of rings; then, say that $A = A_1 \times \cdots \times A_k$ for some $A_1, \ldots, A_k \in \text{Ob}(\mathcal{B}_0)$, and pick $B_i \in \Delta(A_i)$ for $i = 1, \ldots, k$. Clearly $B := B_1 \times \cdots \times B_k \in \Delta(A)$, and in light of proposition 17.5.36(ii), we easily deduce that $E_0(A, B) = \prod_{i=1}^k E_0(A_i, B_i)$, whence the assertion.

(i): In view of (ii) and lemma 17.5.41, we may assume that $A$ is equidimensional. Then, let $p \subset A$ be any prime ideal; set $Z := \text{Spec} A/p$, and $c := \text{dim} A_p$. We show:

**Claim 17.5.45.** $\text{depth}_p(E_0(A)) = c$.

**Proof of the claim.** Pick any $B \in \Delta(A)$, and let $\overline{Z}$ be the topological closure of $Z$ in $\text{Spec} B$, which we endow with its reduced closed subscheme structure. Hence, $\overline{Z} = \text{Spec} B/q$, with $q = B \cap p$, and let $f := (f_1, \ldots, f_r)$ be any finite system of generators of $q$. In view of (10.4.30) and proposition 10.4.32(ii), it suffices to check that $H^i(f, E_0(A, B)) = 0$ for every $i < c$ and $H^c(f, E_0(A, B)) \neq 0$. However, pick also a finite subset $S_B \subset \text{Max} Z$ as in lemma 17.5.41(ii); moreover, notice that the image of $\overline{Z}$ in $\text{Spec} Z$ is constructible and dense ([48, Ch.IV, Th.1.8.4]), so its complement $S_Z$ is a finite set of closed points. Set $S := S_B \cup S_Z$; a direct inspection yields a natural short exact sequence of complexes of $B$-modules:

$$0 \to \bigoplus_{p \in \text{Max}(Z) \setminus S} K^*(f, E_p(B/pB)) \to \prod_{p \in \text{Max}(Z) \setminus S} K^*(f, E_p(B/pB)) \to K^*(f, E_0(A, B)) \to 0$$

so we are reduced to checking that for every $p \in \text{Max}(Z) \setminus S$ we have:

$$H^i(f, E_p(B/pB)) = 0 \quad \text{for every } i < c, \quad \text{and} \quad H^c(f, E_p(B/pB)) \neq 0.$$  

But since $E_p(B/pB)$ is a big locally CM $B/pB$-algebra, invoking again (10.4.30) and proposition 10.4.32(i), we are further reduced to showing that $\overline{Z} \cap \text{Spec} B/pB$ has codimension $c$ in $\text{Spec} B/pB$, for every $p \in \text{Max}(Z) \setminus S$. But the unique morphisms of schemes $\varphi : \text{Spec} B \to \text{Spec} Z$ and $\psi : \overline{Z} \to \text{Spec} Z$ are flat, and the generic fibre of $\varphi$ (resp. $\psi$) is the equidimensional scheme $\text{Spec} A$ (resp. $Z$), so $\varphi^{-1}(p)$ is as well equidimensional of dimension $\text{dim} A$, for every $p \in \text{Max}(Z) \setminus S$, by [50, Ch.IV, Lemme 14.3.10]. By the same token, $\psi^{-1}(p)$ is equidimensional of dimension $\text{dim} Z$, for every such $p$, whence the assertion.  

From claim 17.5.45 and (10.4.30), we already see that $\text{depth}_p E_0(A)_p \geq \text{dim} A_p$ for every prime ideal $p \subset A$. By the same token, if $p \subset q$ are two such prime ideals, we have $\text{depth}_p E_0(A)_q > \text{dim} A_p$, so, again by virtue of claim 17.5.45 and (10.4.30), we must have $\text{depth}_p E_0(A)_p = \text{dim} A_p$ for every $p \in \text{Spec} A$, as required.

(iii): Arguing as in the proof of proposition 17.5.36(i), for every $A \in \text{Ob}(\mathcal{B}_0)$ we write $j_A : A \to A^\nu$ as the composition of the projection $j'_A : A \to A_{\text{red}}$ onto the maximal reduced
quotient, and the natural injective map $j_A' : A_{\text{red}} \to A^\nu$. It is easily seen that both maps are morphisms of $\mathcal{B}_0$, and we then need to check that $E_0(j_A')$ and $E_0(j_A'_{\text{red}})$ are isomorphisms. However, clearly $B_{\text{red}} \in \Delta(A_{\text{red}})$, for every $B \in \Delta(A)$; for such $B$, pick a finite subset $S_B \subset \text{Max}Z$ as in lemma [17.5.41](ii). In order to prove that $E_0(j_A')$ is an isomorphism, it suffices to check that the induced map $j_{B,p}' : B/pB \to B_{\text{red}}/pB_{\text{red}}$ induces an isomorphism $E_p(j_{B,p}') : E_p(B/pB) \to E_{p}(B_{\text{red}}/pB_{\text{red}})$ for every $p \in \text{Max}(Z) \setminus S_B$; but $j_{B,p}'$ induces an isomorphism

$$(B/pB)_{\text{red}} \cong (B_{\text{red}}/pB_{\text{red}})_{\text{red}}$$

so the assertion follows from proposition [17.5.36](i). Next, set $B^\nu := \prod_{p \in \text{Max}B}(B/p)^\nu$, and consider the commutative diagram of schemes:

$$\begin{align*}
\text{Spec } B^\nu & \xrightarrow{\pi} \text{Spec } B_{\text{red}} \\
\psi & \downarrow \\
\text{Spec } Z & \xrightarrow{\varphi} \text{Spec } Z.
\end{align*}$$

We have a maximal open subset $U \subset \text{Spec } B_{\text{red}}$ such that $\pi$ restricts to an isomorphism $\pi^{-1}U \cong U$, and since $B_{\text{red}}$ is reduced, $U$ is dense in $\text{Spec } B_{\text{red}}$. Let $\eta \in \text{Spec } Z$ be the generic point; it follows that $U \cap \varphi^{-1}(\eta)$ is a dense open subset of $\varphi^{-1}(\eta)$, and then there exists an open subset $V \subset \text{Spec } Z$ such that $U \cap \varphi^{-1}(x)$ is dense in $\varphi^{-1}(x)$ for every $x \in V$ ([50, Ch.IV, Prop.9.5.3]). Therefore, for every $x \in V$, the subset $\pi^{-1}U \cap \psi^{-1}(x)$ is open and dense in $\psi^{-1}(x)$, and $\pi$ induces an isomorphism

$$\pi^{-1}U \cap \psi^{-1}(x) \cong U \cap \varphi^{-1}(x) \quad \text{for every } x \in V.$$

On the other hand, since the $\mathbb{Q}$-schemes $\varphi^{-1}(\eta)$ and $\psi^{-1}(\eta)$ are respectively geometrically reduced and geometrically normal, there exists a dense open subset $W \subset \text{Spec } Z$ such that $\varphi^{-1}(x)$ and $\psi^{-1}(x)$ are respectively a geometrically reduced and a geometrically normal $\kappa(x)$-scheme, for every $x \in W$ ([50, Ch.IV, Prop.9.9.4]). Summing up, we conclude that, for every $x \in V \cap W$, the fibre $\psi^{-1}(x)$ is the normalization of the affine reduced scheme $\varphi^{-1}(x)$. By proposition [17.5.36](ii), we conclude that the natural map $j_{B,p}'' : B_{\text{red}}/pB_{\text{red}} \to B^\nu/pB^\nu$ induces an isomorphism $E_p(j_{B,p}'')$ for every $p \in \text{Max}(Z) \cap V \cap W$. Therefore, $j_A''$ induces an isomorphism $E_0(A_{\text{red}}, B_{\text{red}}) \cong E_0(A^\nu, B^\nu)$, as required. \hfill $\square$

17.5.46. The functor $E_0$ can be extended naturally to the category

$\mathcal{B}_0$

whose objects are all locally equidimensional $\mathbb{Q}$-algebras of essentially finite type, and whose morphisms are again the maximizing ring homomorphisms. Indeed, for $A \in \text{Ob}(\mathcal{B}_0)$, let $\Delta'(A)$ be the set of $\mathbb{Q}$-subalgebras of finite type $B \subset A$, such that $A$ is a localization of $B$. Notice that $\Delta'(A)$ is a filtered set, for the partial order given by inclusion of $\mathbb{Q}$-subalgebras; moreover, $A = \bigcup_{B \in \Delta'(A)} B$. Let also $\Delta''(A) := \{B \in \Delta'(A) \mid B \text{ is locally equidimensional}\}$. We notice:

**Lemma 17.5.47.** With the notation of (17.5.46), we have:

(i) For every $B \in \Delta'(A)$, the natural map $\text{Spec } A \to \text{Spec } B$ restricts to a bijection $\text{Min } A \overset{\sim}{\to} \text{Min } B$ on the respective sets of minimal prime ideals.

(ii) $\Delta''(A)$ is a cofinal subset of $\Delta'(A)$.

**Proof.** (i): This is clear, since the natural morphism of schemes $\text{Spec } A \to \text{Spec } B$ is flat, injective on the underlying topological spaces, and with dense image.

(ii): Let $B \in \Delta'(A)$, so that $A = S^{-1}B$ for some multiplicative subset $S \subset B$, and say that $\text{Min } A = \{p_1, \ldots, p_n\}$. Set $q_i := B \cap p_i$ for every $i = 1, \ldots, n$. Also, for $1 \leq i < j \leq n$, set $B_{ij} := B/(q_i + q_j)$ and $A_{ij} := A/(p_i + p_j) = S^{-1}B_{ij}$. For every such $i, j$ and
every $s \in S$, the induced map $\text{Spec } A_{ij} \to \text{Spec } B_{ij}[s^{-1}]$ restricts to an injective map of finite sets $\text{Min } A_{ij} \to \text{Min } B_{ij}[s^{-1}]$, and the system of such maps yields a natural identification: $\text{Min } A_{ij} \sim \lim_{s \in S} \text{Min } B_{ij}[s^{-1}]$. Hence, for a suitable $s \in S$ we get bijections

\begin{equation}
\text{Min } A_{ij} \sim \text{Min } B_{ij}[s^{-1}] \quad \text{for every } 1 \leq i < j \leq n.
\end{equation}

Now, both $A$ and $B$ are excellent rings ([49, Ch.IV, Sch.7.8.3(ii)]), and $A$ fulfills condition (c) of lemma 17.5.30 since it is locally equidimensional; but in light of (17.5.48), we see that $B[s^{-1}]$ fulfills the same condition as well, so $B[s^{-1}] \in \Delta''(A)$, by lemma 17.5.30.

In view of lemma 17.5.47(i), for every pair $B_1 \subset B_2$ of elements of $\Delta'(A)$, the inclusion map $B_1 \to B_2$ is trivially maximizing; with lemma 17.5.47(ii), we then get a well defined ring $E'_0(A) := \text{colim}_{B \in \Delta''(A)} E_0(B)$ and the $B$-algebra structures on each $E_0(B)$ assemble into a natural $A$-algebra structure for $E'_0(A)$. Then, with theorem 17.5.44, we see that $E'_0(A)$ is a big locally CM $A$-algebra. If $A \in \text{Ob}(\mathcal{R}_0)$, clearly $A$ is a final object of $\Delta''(A)$, so $E'_0(A) = E_0(A)$ in this case. Furthermore, let $f : A \to A'$ be any morphism of $\mathcal{R}_0$; for every $B \in \Delta''(A)$, we may pick $B' \in \Delta''(A')$ such that $f$ restricts to a map of $\mathbb{Q}$-algebras $g : B \to B'$. Since $f$ is maximizing, from lemma 17.5.47(i) it follows easily that the same holds for $g$. We may therefore compose $E_0(g) : E_0(B) \to E_0(B')$ with the natural map $E_0(B') \to E_0(A')$, to get a ring homomorphism $h_B : E_0(B) \to E_0(A')$, and it is easily seen that $h_B$ depends only on the restriction $B \to A'$ of $f$ (and is independent of the choice of $B'$: details left to the reader). The colimit of the system of maps $(h_B \mid B \in \Delta''(A))$ is a well defined ring homomorphism

\[
E'_0(f) : E'_0(A) \to E'_0(A')
\]

and the rules: $A \mapsto E'_0(A)$ and $f \mapsto E'_0(f)$ yield the sought functor $E' : \mathcal{R}_0 \to \mathbb{Z}\text{-Alg}$. Lastly, from theorem 17.5.44 we easily deduce that $E'_0$ commutes with finite products, and factors through the corresponding normalization functor $(-)^{\text{\tiny{nor}}} : \mathcal{R}_0 \to \mathcal{R}_0'$: details left to the reader.

17.5.49. We turn now to consider the case of a noetherian local ring $(A, n)$ with residue field $k := A/n$ of characteristic $p > 0$. Arguing as in the proof of theorem 17.5.27, we can assume that $A$ is a complete domain, with field of fractions of zero characteristic. By [100, Th.29.4], there exists a complete discrete valuation ring $R \subset A$ whose maximal ideal is $pR$, and such that the induced map $R/pR \to k$ is an isomorphism; moreover, if $p, x_1, \ldots, x_n$ is any system of parameters of $A$, then the inclusion of $R$ into $A$ extends to a finite injective map:

\[
R[[X_1, \ldots, X_n]] \to A \quad X_i \mapsto x_i \quad \text{for } i = 1, \ldots, n
\]

whose image we call $A_0$. Let $n_0 \subset A_0$ be the maximal ideal; clearly the natural map $A_0/n_0 \to k$ is an isomorphism. Pick also $g \in A_0 \setminus \{0\}$ such that $A[g^{-1}]$ is faithfully flat étale over $A_0[g^{-1}]$.

- We consider first the case where $[k : k^p] < +\infty$, and we pick $x_{n+1}, \ldots, x_m \in A_0$ whose classes in $k$ form a $p$-basis (i.e. a basis of the $k^p$-vector space $k$). Set $x_0 := p$, and

\[
A_\infty := A_0[T_0^{1/p}, \ldots, T_m^{1/p}] / (x_0 - T_0, \ldots, x_m - T_m)
\]

(notation as in example 4.8.55(iii)). Notice that the sequence $(p, x_{n+1}, \ldots, x_m)$ is maximal in the sense of remark 9.6.35(iii); hence $A_\infty$ is formal perfectoid for its $p$-adic topology, according to theorem 17.2.14(iv). Next, if $g \in \{p, x_1, \ldots, x_m\}$, set $B_\infty := A_\infty$, and otherwise, let

\[
B_\infty := A_\infty[T_{m+1}^{1/p}] / (g - T_{m+1}).
\]

In either case, let $C$ be the $p$-integral closure of $B_\infty$ in $B_\infty[1/p]$, and $C^\wedge$ the $p$-adic completion of $C$; then $C^\wedge$ is perfectoid for its $p$-adic topology, and $C$ is a faithfully flat $A_\infty$-algebra (theorem 16.9.17). Let $D$ be the integral closure of $C^\wedge$ in $C^\wedge \otimes_{A_0} A[1/g]$. Denote also by $m \subset C$ the
ideal generated by \((g^{1/p^n} \mid n \in \mathbb{N})\); clearly \((C, m)\) is a basic setup (in the sense of \([59, \S 2.1.1]\)), and we let \((C^n)^m\) and \(D^n\) be the \((C, m)^a\)-algebras arising from \(C^n\) and respectively \(D\).

**Lemma 17.5.50.** \(D^n\) is faithfully flat over \(A_0\), in the sense of definition \([14.2.40]\).

**Proof.** Denote as usual by \((C^n)^m\) the ring of almost elements of \((C^n)^m\), and let \(D_1^n\) be the integral closure of \((C^n)^m\) in \(C^n \otimes_{A_0} A[1/g]\). Recall that the natural morphism \(D^n \rightarrow D_1^n\) of \((C^n, m)^a\)-algebras is an isomorphism \([59, \text{Lemma 8.2.28}]\); taking into account theorem \([16.9.34](i, iii)\), it follows that \(D^n\) is a \(p\)-adically complete \(C^n\)-algebra, and \((D/p^nD)^a\) is a faithfully flat \((C/p^nC)^m\)-algebra, for every \(n \in \mathbb{N}\). By virtue of proposition \([14.2.43]\) in order to prove that \(D^n\) is flat over \(A_0\), it then suffices to check that \((D/p^nD)^a\) is flat over \(A_0/p^nA_0\), for every \(n \in \mathbb{N}\). But it is easily seen that \(A_\infty\) is a flat \(A_0\)-algebra, whence the assertion. By lemma \([14.2.41](ii)\), we then come down to checking that \((D/n_0D)^a\) \(\neq 0\). Since we already know that \((D/pD)^a\) is a faithfully flat \((C/pC)^m\)-algebra, and since \(p \in n_0\), we are further reduced to checking that \((C/n_0C)^a\) \(\neq 0\). In turn, this amounts to showing that \(g^{1/p^n} \notin n_0C\) for some \(m \in \mathbb{N}\). If the latter fails, we get:

\[(17.5.51) \quad g \in n_0^nC \quad \text{for every } n \in \mathbb{N}.

Now, recall that \(C\) is a faithfully flat \(A_0^n\)-algebra, and \(A_\infty\) is a faithfully flat \(A_0^n\)-algebra, so \(C\) is a faithfully flat \(A_0^n\)-algebra. Then, from \((17.5.51)\) we deduce that \(g \in \bigcap_{n \in \mathbb{N}} n_0^n\). But the \(n_0\)-adic topology of \(A_0\) is separated \([100, \text{Th.8.10}(i)]\), hence \(g = 0\), a contradiction. \(\square\)

Denote by \(S \subset C^n\) the multiplicative subset associated with \(m\), as in \((17.5.2)\); we endow \(E := S^{-1}D^n\) with its \(p\)-adic topology, and denote by \(E^{\text{sep}}\) the maximal separated quotient of \(E\). Notice that \(D\) contains the integral closure of \(A_0\) in \(A[1/g]\), which contains \(A\), hence \(D\) is naturally an \(A\)-algebra, and therefore the same holds for \(E\) and \(E^{\text{sep}}\). We may then state:

**Theorem 17.5.52.** \(E\) and \(E^{\text{sep}}\) are big CM \(A\)-algebras.

**Proof.** In light of remark \([17.5.18](iii)\), it suffices to show that \(E\) and \(E^{\text{sep}}\) are big CM \(A_0^n\)-algebras. By lemmas \([17.5.50]\) and \([17.5.41]\), \(E\) is a faithfully flat \(A_0^n\)-algebra; then, by proposition \([14.2.43](i)\), the same holds for the \(A_0^n\)-algebra \(E^{\text{sep}}\), since the latter is the \(p\)-adic completion of \(E\) (proposition \([17.5.8]\)). Especially, \(E/n_0E \cong E^{\text{sep}}/n_0E^{\text{sep}} \neq 0\). Now the theorem follows from lemma \([10.4.20]\) proposition \([10.4.32](i)\), and remark \([17.5.18]\) \(i)\). \(\square\)

- **Next, we consider the case where \([k : k^p]\) can be infinite.** Define the regular local ring \((A_0, n_0)\), and pick \(g \in A_0\) as in the foregoing case; choose also a family \((b_\lambda \mid \lambda \in \Lambda)\) of elements of \(A_\infty^n\) whose image \((\tilde{b}_\lambda \mid \lambda \in \Lambda)\) in \(k\) is a \(p\)-basis. Again, we set \(x_0 := p\), and

\[A_\infty := A_0[T_0^{1/p^n}, \ldots, T_n^{1/p^n}] [T_\lambda^{1/p^n} \mid \lambda \in \Lambda]/(x_0 - T_0, \ldots, x_n - T_n, b_\lambda - T_\lambda \mid \lambda \in \Lambda).

We endow \(A_\infty\) with its \(n_0\)-adic topology, and let \(A_\infty^n\) be the completion of \(A_\infty^n\).

**Lemma 17.5.53.** \(A_\infty^n\) is perfectoid for its \(p\)-adic topology.

**Proof.** With the notation of \([9.8.11]\), set

\[B_0 := k[T_0, \ldots, T_n] \otimes_k k^{\text{perf}} \quad B_\infty := k[T_0^{1/p^n}, \ldots, T_n^{1/p^n}] \otimes_k k^{\text{perf}}

and let \(\bar{n}_0 \subset B_0\) be the ideal generated by \(T_0, \ldots, T_n\). Endow \(B_\infty\) with its \(\bar{n}_\infty^n\)-adic topology, and let \(B_\infty^n\) be the completion of \(B_\infty^n\). Then \(B_\infty^n\) is naturally an \(A_\infty^n\)-algebra, via the projection \(A_0 \rightarrow k\), and by simple inspection we get an isomorphism of topological \(A_\infty^n\)-algebras

\[A_\infty^n/pA_\infty^n \cong B_\infty^n/T_0B_\infty^n \quad T_i^{1/p^k} \mapsto T_i^{1/p^k} \quad (i = 0, \ldots, n) \quad T_\lambda^{1/p^k} \mapsto 1 \otimes \bar{b}_\lambda^{1/p^k} \quad \text{for every } \lambda \in \Lambda\]

for the respective quotient topologies. Notice that the sequence \((p, x_1, \ldots, x_n)\) is \(A_0^n\)-regular, hence also \(A_\infty^n\)-regular, since \(A_\infty^n\) is a faithfully flat \(A_0^n\)-algebra; by proposition \([7.8.15]\) we deduce that the \(n_0\)-topology of \(A_\infty^n\) induces the \(n_0\)-topology on the ideal \(pA_\infty^n\), and therefore the
natural map $A^n_\infty/pA^n_\infty \to (A/\langle pA_\infty \rangle)^\wedge$ is an isomorphism of topological rings (proposition 8.2.13(i,v)). Likewise, the sequence $(T_0, \ldots, T_n)$ is $B_0$-regular, hence also $B_\infty$-regular, since $B_\infty$ is a faithfully flat $B_0$-algebra; arguing as in the foregoing, we deduce that the natural map $B_\infty^\wedge/T_0B_\infty^\wedge \to (B_\infty/\langle T_0B_\infty \rangle)^\wedge$ is as well an isomorphism of topological rings. However, by direct inspection we see that $B_0^\text{perf}$ is a dense subring of $B_\infty^\wedge$ (here it is important to work with the $\pi_0$-adic topology), and the $\pi_0$-adic topology of $B_\infty^\wedge$ induces the $\pi_0$-adic topology on $B_0^\text{perf}$, hence $B_\infty^\wedge$ is also the completion $C$ of $B_0^\text{perf}$ (theorem 8.2.8(iii)), and therefore it is a perfect topological $\mathbb{F}_p$-algebra (remark 9.4.9(v) and corollary 9.4.14). Summing up, we see that $A^\wedge_\infty/pA^\wedge_\infty$ is isomorphic to $C/\langle T_0C \rangle$, and clearly the Frobenius endomorphism of $C$ induces a bijection $C/T_0^1C \cong C/\langle T_0C \rangle$; therefore the Frobenius endomorphism of $A^\wedge_\infty$ induces a bijection $A^\wedge_\infty/pA^\wedge_\infty \cong A^\wedge_\infty/pA^\wedge_\infty$. Moreover, $A^\wedge_\infty$ is complete and separated for its $p$-adic topology (lemma 8.3.12); then the lemma follows from corollary 16.3.73. \[\square\]

17.5.54. We may now proceed as in the previous case: if $g \in \{x_0, \ldots, x_n\} \cup \{b_\lambda \mid \lambda \in \Lambda\}$, set $B_\infty := A_\infty$, and otherwise set $B_\infty := A^\wedge_\infty[X^{1/p^n}]/(g - X)$. Let also $C$ be the $p$-integral closure of $B_\infty$ in $B_\infty[1/p]$, and $C^\wedge$ the $p$-adic completion of $C$. Then, again by theorem 16.9.17 $C^\wedge$ is perfectoid and $C$ is a faithfully flat $A^\wedge_\infty$-algebra. Denote by $m \subseteq C^\wedge$ the ideal generated by $(g^{1/p^n}) \mid n \in \mathbb{N}$, and let $D$ be the integral closure of $C^\wedge$ in $C^\wedge \otimes_{A_0} A[1/g]$. Arguing as in 17.5.49 we see that $(D/p^nD)^a$ is a faithfully flat $(C/p^nC)^a$-algebra for every $n \in \mathbb{N}$ (relative to the basic setup $(C^a, m)$). Moreover, $A^\wedge_\infty$ is the $\pi_0$-adic completion of a faithfully flat $A_0$-algebra, hence it is a faithfully flat $A_0$-algebra (proposition 14.2.43(i)). Thus, $C$ is a faithfully flat $A_0$-algebra. After these observations, the proof of lemma 17.5.50 can be repeated in our current situation, so that $D^a$ is still faithfully flat over $A_0$ (in the sense of definition 14.2.40). Lastly, we define again $E := S^{-1}D^a$, and let $E^{\text{sep}}$ be the maximal $p$-adically separated quotient of $E$; now the proof of theorem 17.5.52 applies again verbatim, and we finally conclude that $E$ and $E^{\text{sep}}$ are big CM $A$-algebras.

17.5.55. Next, we would like to upgrade the constructions of the previous paragraphs to a functor on a suitable category of local noetherian domains. Hence, let $(A, n)$ be a local noetherian domain, complete for its $n$-adic topology, with field of fractions of zero characteristic, and residue field $k$ of characteristic $p > 0$, and suppose first that $|k : k^p| < +\infty$. Let $\Sigma \subseteq A \setminus \{0\}$ be a finite subset with $p \in \Sigma$, and $\Sigma' \subseteq \Sigma$ a non-empty subset; we consider the category $\mathcal{C}^A_{\Sigma, \Sigma'}$ whose objects are all pairs $(f, \Delta)$, where $f : A \to B$ is a ring homomorphism, and $\Delta := (\beta_{a, \bullet} \mid a \in \Sigma)$ is a family of elements of $E(B)$ (notation of remark 9.4.12(ii)), fulfilling the following conditions:

(a) the projection $\beta_{a, 0} \in B$ of $\beta_{a, \bullet}$ equals $f(a)$, for every $a \in \Sigma$ (especially, $\beta_{p, 1}^p = p$)

(b) let $m \subseteq B$ be the ideal generated by the system $(\delta_n := \prod_{a \in \Sigma} \beta_{a,n} \mid n \in \mathbb{N})$; we call $(B, m)$ the basic setup attached to $(f, \Delta)$, and denote by $(B, m)^a$ the $(B, m)^a$-algebra arising from $B$; then the unit of adjunction $B \to (B, m)^a$ is an isomorphism

(c) $B$ is $p$-torson free, and complete and separated for its $p$-adic topology

(d) $B$ is $\delta_0$-torson free, integrally closed in $B[\delta_0^{-1}]$, and $p$-integrally closed in $B[p^{-1}]$.

For two such pairs $(f : A \to B, \Delta)$ and $(f' : A \to B', \Delta' := (\beta'_{a, \bullet} \mid a \in \Sigma))$, the morphisms $(f, \Delta) \to (f', \Delta')$ in $\mathcal{C}^A_{\Sigma, \Sigma'}$ are the ring homomorphisms $h : B \to B'$ with:

$$f' = h \circ f \quad \text{and} \quad E(h)(\beta_{a, \bullet}) = \beta'_{a, \bullet} \quad \text{for every } a \in \Sigma.$$ We shall say that the object $(f : A \to B, \Delta)$ of $\mathcal{C}^A_{\Sigma, \Sigma'}$ is almost perfectoid, if the basic setup $(B, m)$ attached to $(f, \Delta)$ is almost perfectoid for the $p$-adic topology of $B$. 

Remark 17.5.56. Let $\Sigma_1 \subset \Sigma_2$ be two finite subsets of $A \setminus \{0\}$ with $p \in \Sigma_1$, and $\Sigma'_1 \subset \Sigma_1$, $\Sigma'_2 \subset \Sigma_2$ two subsets, with $\emptyset \neq \Sigma'_1 \subset \Sigma'_2$. For every object $(f : A \to B, \Delta := (\beta_{x,\bullet} \mid a \in \Sigma_2))$ of $\mathcal{E}_{A_{\Sigma_2,\Sigma_2}}^A$ set $\Delta_{|\Sigma_1} := (\beta_{a,\bullet} \mid a \in \Sigma_2)$. By remark (4.2.7)(ii), we get a well defined functor:

$$
\mathcal{E}_{A_{\Sigma_2,\Sigma_2}}^A \to \mathcal{E}_{A_{\Sigma'_1,\Sigma'_1}}^A \quad (f, \Delta) \mapsto (f, \Delta)_{|\Sigma_1,\Sigma_1} := (f, \Delta_{|\Sigma_1}).
$$

Proposition 17.5.57. Let $\Sigma_1 \subset \Sigma_2$ be an inclusion of finite subsets of $A \setminus \{0\}$ with $p \in \Sigma_1$, and $\Sigma'_1 \subset \Sigma_1$, $\Sigma'_2 \subset \Sigma_2$ two non-empty subsets, with $\Sigma'_1 \subset \Sigma'_2$. If the category $\mathcal{E}_{A_{\Sigma_1,\Sigma_2}}^A$ admits an almost perfectoid initial object, the latter induces a map of $\Sigma$-sets $x$.

Proof. Let $(f_1 : A \to D_1, \Delta_1)$ be a given almost perfectoid initial object of $\mathcal{E}_{A_{\Sigma_1,\Sigma_2}}^A$, with $\Delta_1 := (\beta_{x,\bullet} \mid x \in \Sigma_1)$, and let $m_1 \subset D_1$ be the ideal generated by $(\delta_n := \prod_{x \in \Sigma_1} \beta_{x,n} \mid n \in \mathbb{N})$.

We suppose first that $\Sigma' := \Sigma'_2 = \Sigma_1$, and we are easily reduced to the case where $\Sigma_2 = \Sigma_1 \cup \{a\}$ for some $a \in A$. We set

$$
D'_2 := D_1[T^{1/p^n}]/(a - T).
$$

Let $D'_2$ be the $p$-integral closure of $D'_2$ in $D'_2[1/p]$, and $D''_2$ the $p$-adic completion of $D''_2$. For every $x \in \Sigma_1$, denote by $\beta'_{x,\bullet} \in \mathbb{E}(D'_2)$ the image of $\beta_{x,\bullet}$, and let likewise

$$
\beta'_{a,\bullet} := (T^{1/p^n} \mid n \in \mathbb{N}) \in \mathbb{E}(D'_2)
$$

where $T^{1/p^n} \in D'_2$, for every $n \in \mathbb{N}$. Set $D_2 := (D''_2, m_1 D''_2)_{\Sigma_1}$, and let $f_2 : A \to D_2$ be the structure map of the $A$-algebra $D_2$. Lastly, let $\beta''_{x,\bullet} \in \mathbb{E}(D_2)$ be the image of $\beta'_{x,\bullet}$, for every $x \in \Sigma_2$, and set $\Delta_2 := (\beta''_{x,\bullet} \mid x \in \Sigma_2)$. We show more precisely:

Claim 17.5.58. $(f_2, \Delta_2)$ is an almost perfectoid initial object of the category $\mathcal{E}_{A_{\Sigma_2,\Sigma_2}}^A$.

Proof of the claim. By proposition (17.5.15) the basic setup $(D''_2, m_1 D''_2)$ is almost perfectoid, hence the same holds for $(D_2, m_1 D_2)$, by proposition (16.9.29)(iii); then $D_2$ is $p$-integrally closed in $D_2[1/p]$, by proposition (16.9.29)(iv), and is integrally closed in $D_2[1/\delta_0]$, by virtue of proposition (17.5.13)(ii). This shows that $(f_2, \Delta_2)$ is an almost perfectoid object of $\mathcal{E}_{A_{\Sigma_2,\Sigma_2}}^A$.

Next, let $(f : A \to D, \Delta := (\delta_{x,\bullet} \mid x \in \Sigma_2))$ be any other object of $\mathcal{E}_{A_{\Sigma_2,\Sigma_2}}^A$; by assumption, there exists a unique morphism $h_0 : (f_1, \Delta_1) \to (f, \Delta)_{|\Sigma_2,\Sigma_2}$ in $\mathcal{E}_{A_{\Sigma_1,\Sigma_2}}^A$ (notation of remark (17.5.56)). Clearly $h_0$ extends to a unique map $h_1 : D'_2 \to D$ such that $\mathbb{E}(h_1)(\beta'_{x,\bullet}) = \delta_{x,\bullet}$, for every $x \in \Sigma_2$, and as argued in the proof of proposition (17.5.60) we see that $A_0[1/p] \otimes_{h_0} h_1 : D'_2[1/p] \to D[1/p]$ restricts to a map of $A$-algebras $h_2 : D''_2 \to D$. Since $D$ is $p$-adically complete and separated, the completion of $h_2$ is a map $h' : D''^\wedge_2 \to D$, and since $D = D'\wedge$, the latter induces a map of $A$-algebras $h := (h'_2)^\wedge_A : D'_2 \to D'$; it is then easily seen that $h$ is the unique morphism $(f_2, \Delta_2) \to (f, \Delta)$ in $\mathcal{E}_{A_{\Sigma_2,\Sigma_2}}^A$.

It remains to consider the case where $\Sigma := \Sigma_2 = \Sigma_1$. Then, let $m_2 \subset D_1$ be the ideal generated by $(\gamma_n := \prod_{x \in \Sigma_2} \beta_{x,n} \mid n \in \mathbb{N})$; endow $D_2 := (D_1, m_2)^\wedge$ with its $p$-adic topology, and let $\eta : D_1 \to D_2$ be the unit of adjunction. Since the basic setup $(D_1, m_1)$ is almost perfectoid, and since $m_2 \subset m_1$, it is clear that the basic setup $(D_1, m_2)$ is almost perfectoid. Then the same holds for the basic setup $(D_2, m_2 D_2)$, according to proposition (16.9.29)(iii). By proposition (17.5.13)(ii), it follows that $D_2$ is $\gamma_0$-torsion free and integrally closed in $D_2[\gamma_0]^{-1}$. For every $x \in \Sigma$, let $\beta''_{x,\bullet} \in \mathbb{E}(D_2)$ be the image of $\beta_{x,\bullet}$; set $\Delta_2 := (\beta''_{x,\bullet} \mid x \in \Sigma)$ and $f_2 := \eta \circ f_1$. The foregoing already shows that $(f_2, \Delta_2)$ is an object of $\mathcal{E}_{A_{\Sigma_1,\Sigma_2}}^A$. Lastly, let $(f' : A \to D', \Delta')$ be any object of $\mathcal{E}_{A_{\Sigma_2,\Sigma_2}}^A$; by assumption, there exists a unique morphism $h : (f_1, \Delta_1) \to (f', \Delta')_{|\Sigma_2,\Sigma_2}$ in $\mathcal{E}_{A_{\Sigma_1,\Sigma_2}}^A$, and since $D' = (D', m_2)^\wedge$, it follows easily that $(h, m_2)^\wedge_A : D_2 \to D'$ is the unique morphism $(f_2, \Delta_2) \to (f', \Delta')$ in $\mathcal{E}_{A_{\Sigma_2,\Sigma_2}}^A$. 

Let $f_0 : A \to D^a_0 := (D, mD)^a_0$ be the structure map of the $A$-algebra $D^a_0$, and for $i = 0, \ldots, t$, set $\beta_{ai} := \mathbb{I}_{i/p^n} | a \in \mathbb{N} \in \mathcal{E}(D^a_0)$, where $\mathbb{I}_{i/p^n}$ denotes the image of $T_i^a/p^n$. For every such $i$ and every $n \in \mathbb{N}$. Set $\Delta_0 := (\beta_{ai} | a \in \Sigma_0)$. Lastly, let $\Sigma'_1 \subset \Sigma_1 \subset A \setminus \{0\}$ be two finite subsets with $\Sigma_0 \subset \Sigma_1$ and $\Sigma'_0 \subset \Sigma_1$.

**Proposition 17.5.60.** In the situation of Proposition 17.5.59, we have:

(i) The pair $(f_0, \Delta_0)$ is an almost perfectoid initial object of the category $\mathcal{C}_{\Sigma_0, \Sigma'_0}^A$.

(ii) Let $(f_1 : A \to D_1, \Delta_1)$ be an initial object of $\mathcal{C}_{\Sigma_1, \Sigma'_1}^A$, and $(D_1, m_1)$ the basic setup attached to $(f_1, \Delta_1)$. Then $(D_1, m_1)^a$ is faithfully flat over $A_0$, in the sense of definition 14.2.40.

**Proof.** (i): From theorem 16.9.34(i,v) and lemma 16.9.33 we see that $(f_0, \Delta_0)$ is an almost perfectoid object of $\mathcal{C}_{\Sigma_0, \Sigma'_0}^A$. Now, define $B_\infty, C$ and $C^\infty$ as in (17.5.49), and let

$$(f' : A \to D', \Delta' := (\beta'_{ai} | a \in \Sigma_0))$$

be any other object of $\mathcal{C}_{\Sigma_0, \Sigma'_0}^A$; clearly there exists a unique homomorphism $h_0 : B_\infty \to D'$ of $A_0$-algebras such that $E(h_0)(\beta_{ai}) = \beta'_{ai}$ for every $a \in \Sigma_0$. Since $D'$ is $p$-integrally closed in $D'[1/p]$, by proposition 9.8.28(i,ii) and remark 9.8.16(i), the map

$$A_0[1/p] \otimes A_0 h_0 : B_\infty[1/p] \to D'[1/p]$$

restricts to a map of $A_0$-algebras $h_1 : C \to D'$, and clearly $h_1$ is the unique map of $A_0$-algebras extending $h_0$. Next, $h_1$ extends uniquely to a map of $A_0$-algebras $h_1^\infty : C^\infty \to D'$, since by assumption $D'$ is $p$-adically complete and separated. Set $h_2 := A[1/g] \otimes A_0 h_1^\infty : A[1/g] \otimes A_0 C^\infty \to D'[1/g]$; by assumption, the localization $D' \to D'[1/g]$ is injective, and $D'$ is integrally closed in $D'[1/g]$, so $h_2$ restricts to a map of $A$-algebras $h_3 : D \to D'$. Lastly, since $D' = (D')^a$, we get an induced map of $A$-algebras $h := h_3^a : D^a_0 \to D'$, and by construction it is easily seen that $h$ is the unique morphism $(f_0, \Delta_0) \to (f', \Delta')$ in $\mathcal{C}_{\Sigma_0, \Sigma'_0}^A$.

(ii): Suppose first that $\Sigma'_1 = \Sigma'_0$. Recall that $D_1$ is $p$-adically complete and separated; taking into account proposition 14.2.43, we know that $(D_1, m_1)^a$ is flat over $A_0$, so it suffices to check that $(D_1/p^nD_1)^a$ is flat over $A_0/p^nA_0$ for every $n \in \mathbb{N}$. But lemma 17.5.50 implies that $(D/p^nD)^a$ is flat over $A_0/p^nA_0$ for every such $n$; hence we come down to the following:

**Claim 17.5.61.** In the situation of proposition 17.5.57, suppose that $\Sigma' := \Sigma'_1 = \Sigma'_2$, and let $(f_1 : A \to D_1, \Delta_1)$ (resp. $(f_2 : A \to D_2, \Delta_2)$) be an initial object of $\mathcal{C}_{\Sigma_1, \Sigma'_2}^A$ (resp. of $\mathcal{C}_{\Sigma_2, \sigma'}^A$). Let also $(D_1, m_1)$ be the basic setup attached to $(f_1, \Delta_1)$. Then the unique morphism $(f_1, \Delta_1) \to (f_2, \Delta_2)\Sigma_1, \Sigma'_2$ in $\mathcal{C}_{\Sigma_2, \sigma'}^A$ induces a faithfully flat morphism of $(D_1, m_1)^a$-algebras

$$(D_1/p^nD_1)^a \to (D_2/p^nD_2)^a$$

for every $n \in \mathbb{N}$.

**Proof of the claim.** We are easily reduced to the case where $\Sigma_2 = \Sigma_1 \cup \{a\}$ for some $a \in A \setminus \{0\}$, and then the assertion follows from proposition 17.5.15 after inspecting the proof of proposition 17.5.57.

By lemma 14.2.41(ii), there remains only to show that $(D_1/n_0D_1)^a \neq 0$. Since $p \in n_0$, it suffices to check that $(D_1/pD_1)^a$ is faithfully flat over $A_0/pA_0$; since the morphism $(D/pD_1)^a \to (D_1/pD_1)^a$ is faithfully flat (claim 17.5.61), lemma 14.2.41(iii) further reduces to checking that $(D/pD)^a$ is faithfully flat over $A_0/pA_0$, which follows from lemma 17.5.50.

To deal with the general case, let $(f'_1 : A \to D'_1, \Delta'_1 := (\beta'_{ai} | a \in \Sigma_1))$ be an initial object of $\mathcal{C}_{\Sigma_1, \Sigma'_0}^A$, and $m'_1 \subset D'_1$ the ideal generated by $(\beta'_a := \prod_{a \in \Sigma_1} \beta'_{an} | n \in \mathbb{N})$. By the foregoing, the
$\text{(C, m)}^a$-algebra $(D'_1, mD'_1)^a$ is faithfully flat over $A_0$, and by inspecting the proof of proposition \[17.5.57\] we see that the $A$-algebra $D_1$ is isomorphic to $(D'_1, m'_1)^a$. Hence, the two functors

$$A_0\text{-Mod} \to (D_1, m)_a\text{-Mod} \quad N \mapsto (D_1, m_1)^a \otimes_{A_0} N \quad N \mapsto (D'_1, m'_1)^a \otimes_{A_0} N$$

are isomorphic (notation of definition \[14.2.40\]). However, the functor $(D'_1, m'_1)^a \otimes_{A_0}$ is the composition of the exact functor

$$A_0\text{-Mod} \to (D'_1, mD'_1)^a\text{-Mod} \quad N \mapsto (D'_1, mD'_1)^a \otimes_{A_0} N$$

and the natural functor $(D'_1, mD'_1)^a\text{-Mod} \to (D'_1, m'_1)^a\text{-Mod} \cong (D_1, m_1)^a\text{-Mod}$, which is obviously exact, so the same holds for the functor $(D'_1, m'_1)^a \otimes_{A_0}$, and hence also for $(D_1, m_1)^a \otimes_{A_0}$, i.e., $(D_1, m_1)^a$ is flat over $A_0$. Again, there remains to show that the $(D_1, m_1)^a$-module $(D_1/n_0D_1)^a$ is not zero, or equivalently, that the same holds for the $(D'_1, m'_1)^a$-module $(D'_1/n_0D'_1)^a$. Suppose that the latter fails: then we have $\beta_n^a \in n_0D'_1$ for every $n \in \mathbb{N}$. Set $b := \prod_{a \in \Sigma'_1} a \in A \setminus \{0\}$; it follows that $f'_1(b) \in n_0^kD'_1$ for every $k \in \mathbb{N}$.

**Claim 17.5.62.** (i) There exists $c \in A \setminus \{0\}$ such that $bc \in A_0$.

(ii) $f'_1$ induces an injective map $A_0/n_0^k \to D'_1/n_0^kD'_1$ for every $k \in \mathbb{N}$.

**Proof of the claim.** (i): Since $A$ is a finite $A_0$-algebra, we may find a monic polynomial $P \in A_0[X]$ such that $P(b) = 0$, and since $A$ is a domain, we may assume that $P(0) \neq 0$. Then it is easily seen that $P(0) = bc$ for some $c \in A \setminus \{0\}$.

(ii): We know already that $(D'_1, m'_1)^a$ is faithfully flat over $A_0$, hence $(D'_1/n_0^kD'_1)^a$ is faithfully flat over $A_0/n_0^k$ for every $k \in \mathbb{N}$. Then the assertion follows from lemma \[14.2.41\]).

Let $c$ be as in claim \[17.5.62\]; hence $bc \in A_0 \setminus \{0\}$, and $f'_1(bc) \in n_0^kD'_1$ for every $k \in \mathbb{N}$. By claim \[17.5.62\], (ii), it follows that $bc \in \bigcap_{k \in \mathbb{N}} n_0^k$, but the $n_0$-adic topology of $A_0$ is separated (([100], Th.8.10(ii))), so $bc = 0$, a contradiction. \(\square\)

17.5.63. Next, let $(A, n)$ be any local noetherian domain, complete for its $n$-adic topology, with $\text{Fr}_A$ of $A$ zero characteristic, and residue field of characteristic $p > 0$. Let $\Sigma' \subset \Sigma$ be two subsets of $A \setminus \{0\}$ such that $\Sigma'$ is finite and non-empty, and $p \in \Sigma$; we consider the category

$$\mathcal{D}_n^{A, \Sigma'}$$

whose objects are all pairs $(f, \Delta)$, where $f : A \to B$ is a ring homomorphism, and $\Delta := (\beta_{n, a} \mid a \in \Sigma)$ is a family of elements of $E(B)$, fulfilling conditions (a)–(d) of \[17.5.55\], as well as the following:

(e) $B$ is complete and separated for its $n$-adic topology.

If $\Sigma_1 \subset \Sigma_2$ is an inclusion of subsets of $A \setminus \{0\}$, and $\Sigma'_1 \subset \Sigma_1$, $\Sigma'_2 \subset \Sigma_2$ are two non-empty finite subsets with $\Sigma'_1 \subset \Sigma'_2$, then clearly, remark \[17.5.56\] holds verbatim in the present situation, i.e. we get a well defined restriction functor:

$$\mathcal{D}_n^{A, \Sigma'} \to \mathcal{D}_n^{A, \Sigma_1' \Sigma_2} \quad (f, \Delta) \mapsto (f, \Delta)_{|\Sigma_1, \Sigma_1'} := (f, \Delta_{|\Sigma_1}).$$

Let moreover the subring $A_0 \subset A$ be as in \[17.5.49\]; we shall say that an object $(f : A \to B, \Delta)$ of $\mathcal{D}_n^{A, \Sigma'}$ is almost flat (resp. almost faithfully flat) over $A_0$, if $B^n$ is flat (resp. faithfully flat) over $A_0$ (as usual, we refer here to the almost structure associated with the basic setup $(B, m)$ attached to $(f, \Delta)$). We have the following variant of proposition \[17.5.57\].

**Proposition 17.5.64.** Let $\Sigma_1 \subset \Sigma_2$ be two subsets of $A \setminus \{0\}$ with $p \in \Sigma_1$, and $\Sigma'_1 \subset \Sigma_1$, $\Sigma'_2 \subset \Sigma_2$ two finite subsets, with $\emptyset \neq \Sigma'_1 \subset \Sigma'_2$. If the category $\mathcal{D}_n^{A, \Sigma'_1}$ admits an almost perfectoid initial object that is almost flat (resp. almost faithfully flat) over $A_0$, the same holds for $\mathcal{D}_n^{A, \Sigma'_1 \Sigma'_2}$. 
Proof. Let \((f_1 : A \rightarrow D_1, \Delta_1 := (\beta_a \bullet | a \in \Sigma_1))\) be an almost perfectoid initial object of \(\mathcal{P}_{\Sigma_1, \Sigma_1} A\). Consider first the case where \(\Sigma' := \Sigma_2 = \Sigma_1'\). Say that \(\Sigma_2 \setminus \Sigma_1 = (\alpha_\lambda | \lambda \in \Lambda)\); we set:

\[
D_2' := D_1[T_\lambda^{1/p\infty} | \lambda \in \Lambda]/(a_\lambda - T_\lambda | \lambda \in \Lambda).
\]

Let \(D_2''\) be the p-integral closure of \(D_2'\) in \(D_2'[1/p]\); endow \(D_2''\) with its p-adic topology, and let \(D_2''^n\) be the completion of \(D_2''\). Let moreover \((D_1, m_1)\) be the basic setup attached to \((f_1, \Delta_1)\).

Claim 17.5.65. (i) The basic setup \((D_2'^n, m_1 D_2'^n)\) is almost perfectoid.

(ii) \((D_2'^n)^a\) is a faithfully flat \(D_1\)-algebra.

Proof of the claim. Let \(\mathcal{P}\) be the set of all finite subsets of \(\Lambda\), and for every \(\Omega \in \mathcal{P}\), set

\[
D_2^\Omega := D_1[T_\lambda^{1/p\infty} | \lambda \in \Omega]/(a_\lambda - T_\lambda | \lambda \in \Omega)
\]

and let \(D_2^\Omega\) be the p-integral closure of \(D_2^\Omega\) in \(D_2'^\Omega[1/p]\); endow \(D_2^\Omega\) with its p-adic topology, and denote by \(D_2''^\Omega\) the completion of \(D_2^\Omega\). Clearly, every inclusion \(\Omega \subset \Omega'\) of elements of \(\mathcal{P}\) induces an injective map of \(D_1\)-algebras \(D_2^\Omega \rightarrow D_2^\Omega'\), which induces in turn a map of \(D_1\)-algebras \(D_2^\Omega \rightarrow D_2''^\Omega\) (remark 9.8.16(i) and proposition 9.8.28). Clearly \(D_2'\) is the colimit of the filtered system of \(D_1\)-algebras \((D_2^\Omega | \Omega \in \mathcal{P})\), and by lemma 9.8.17, \(D_2''\) is the colimit of the filtered system \((D_2''^\Omega | \Omega \in \mathcal{P})\). Recall that, by construction, \(p\) admits a \(p\)-th root \(p^{1/p}\) in \(D_1\). Let \(\Phi\) be the Frobenius endomorphism of \(D_1/pD_1\), and suppose now that the Frobenius endomorphism of \(D_2''^\Omega\) induces an isomorphism \((D_2''^\Omega/p^{1/p}D_2''^\Omega)^a \cong (D_2''^\Omega/pD_2''^\Omega)^a\), for every \(\Omega \in \mathcal{P}\) (notation as in definition 16.9.27); then the Frobenius endomorphism of \(D_2''\) induces an isomorphism \((D_2''/p^{1/p}D_2'')^a \cong (D_2''/pD_2'')^a\). We are thus reduced to checking that the basic setup \((D_2'^n, m_1 D_2'^n)\) is almost perfectoid, and that \((D_2'^n)^a\) is a faithfully flat \(D_2\)-algebra, for every \(\Omega \in \mathcal{P}\). The latter follows from proposition 17.5.15 by an easy induction on the cardinality of \(\Omega\); the details shall be left to the reader.

Set \(D_2 := (D_2'^n, m_1 D_2'^n)^a\); the basic setup \((D_2, m_1 D_2)\) is almost perfectoid for the \(p\)-adic topology of \(D_2\), by claim 17.5.65(i) and proposition 16.9.29(iii). Moreover, if \(D_2^a\) is flat (resp. faithfully flat) over \(A_m\), the same holds for \((D_2'^n)^a\), by claim 17.5.65(ii) and lemma 14.2.41(iii); consequently, the same holds as well for both \((D_2'^n)^a\) and \(D_2''^a\), by proposition 14.2.43(i).

Endow \(D_2\) with its \(n\)-adic topology, let \(D_2''\) be the completion of \(D_2\), and \(E_2 := (D_2''^n, m_1 D_2''^n)^a\). Notice that the \(n\)-adic topology agrees with the \(n\)-adic topology, on every \(A\)-module \(M\).

Claim 17.5.66. (i) \(E_2\) has no \(p\)-torsion and is \(n\)-adically complete and separated.

(ii) Let \(\mathcal{R}\) be any \(D_1/pD_1\)-algebra, and denote by \(\mathcal{R}^\wedge\) and \((\mathcal{R}(\Phi))^\wedge\) the \(n\)-adic completions of \(\mathcal{R}\) and of \(R(\Phi)\). Then \((\mathcal{R}(\Phi))^\wedge = (\mathcal{R}(\Phi))^\wedge\).

(iii) The basic setup \((E_2, m_1 E_2)\) is almost perfectoid for the \(p\)-adic topology of \(E_2\).

Proof of the claim. (i): For the first assertion, it suffices to check that the endomorphism \(p \cdot 1(D_2^a)^e\) is a monomorphism, since the functor \(\cdot\), is left exact. The latter will follow from lemma 14.2.45 after we check that the \(n\)-adic topology of \(D_2^a\) induces the \(n\)-adic topology on the ideal \(pD_2^a\) (see 59, §5.3 for generalities on topological almost algebras and modules). However, by the Artin-Rees lemma, there exists \(c \in \mathbb{N}\) such that \(n_0^{c+1}A_0 \cap pA_0 \subset n_0^c pA_0\) for every \(n \in \mathbb{N}\). But we have already noticed that \(D_2^a\) is flat over \(A_0\), hence \(n_0^{c+1}D_2^a \cap pD_2^a \subset n_0^c pD_2^a\) for every \(n \in \mathbb{N}\), as required. The second assertion follows from claim 16.9.31.

(ii): By definition, \(n \cdot R(\Phi) = J \cdot R\), where \(J \subset A\) is the ideal generated by \((a^p | a \in \mathcal{R})\); since \(n\) is finitely generated, there exists \(N \in \mathbb{N}\) such that \(n^N \subset J \subset n\), so the \(J\)-adic topology agrees with the \(n\)-adic topology on \(R\), whence the assertion.

(iii): First, \(E_2\) is \(p\)-adically complete and separated, by (i) and lemma 8.3.12. Next, pick \(c \in \mathbb{N}\) as in the proof of (i); for every \(n \in \mathbb{N}\) and every \(x \in n_0^{c+1}D_2^a \cap pD_2^a\) we have \(p^{(p-1)/p} \in n_0^{c+1}D_2^a \cap pD_2^a\), whence \(m_1 \cdot p^{(p-1)/p} \subset n_0^c pD_2^a\), and therefore \(m_1 \cdot x \subset n_0^c pD_2^a\).
This shows that $n_0^{p^c} D^a_2 \cap p^{1/p} D_2^a \subseteq n_0^{p^c} p^{1/p} D_2^a$ for every $n \in \mathbb{N}$, so the $n_0$-adic topology of $D_2$ induces the $n_0$-adic topology on the ideal $p^{1/p} D_2^a$. By assumption, the Frobenius endomorphism of $D_2/pD_2$ induces an isomorphism $D_2^a/p^{1/p} D_2^a \sim (D_2^a/pD_2^a)(\phi)$; the latter persists after taking $n_0$-adic completions, and in view of (ii) and lemma 14.2.45 we conclude that the Frobenius endomorphism of $E_2/pE_2$ induces an isomorphism $E_2^a/p^{1/p} E_2^a \sim (E_2^a/pE_2^a)(\phi)$, as needed.

For every $a \in \Sigma_1$, let $\beta_{a^*} \in E(D_2)$ be the image of $\beta_a$, and set likewise

$$\beta_{a^*} := (T^1/p^n | n \in \mathbb{N}) \in E(D_2) \quad \text{for every } \lambda \in \Lambda$$

where $T^1/p^n \in D_2$ denotes the image of $T^1/p^n$, for every such $\lambda$ and every $n \in \mathbb{N}$. Moreover, for every $a \in \Sigma_2$, let $\beta_{a^*} \in E(E_2)$ be the image of $\beta_{a^*}$, and set $\Delta_2 := (\beta_{a^*} | a \in \Sigma_2)$. Let also $f_2 : A \to E_2$ be the structure map of the $A$-algebra $E_2$; by claim 17.5.66(ii) the pair $(f_2 : A \to E_2, \Delta_2)$ fulfills conditions (a),(b),(c) of (17.5.55) and condition (e) of (17.5.63). Combining with propositions 16.9.29(iv) and 17.5.13(ii) we deduce that also condition (d) of (17.5.55) holds for this pair, i.e. $(f_2, \Delta_2)$ is an almost perfectoid object of $\mathcal{D}_A^{\Sigma_2, \Sigma_2'}$, moreover, if $D_2^a$ is flat (resp. faithfully flat) over $A_0$, the same holds for $E_2^a$, by virtue of proposition 14.2.43.

Lastly, let $(g : A \to F, \Delta := (\delta_{a^*} | a \in \Sigma_2))$ be any other object of $\mathcal{D}_A^{\Sigma_2, \Sigma_2'}$; arguing as in the proof of claim 17.5.58 we see that there exists a unique map $h : D_2 \to F$ of $A$-algebras such that $E(h')(\beta_{a^*}) = \delta_{a^*}$ for every $a \in \Sigma_2$. Let $h^* : D_2^a \to F$ be the $n_0$-adic completion of $h^*$; it follows easily that $h := (h^* \delta) : E_2 \to F$ is the unique morphism $(f_2, \Delta_2) \to (g, \Delta)$ in $\mathcal{D}_A^{\Sigma_2, \Sigma_2'}$.

It remains consider the case where $\Sigma_2' = \Sigma_2$. Then, let $m_2 \subset D_1$ be the ideal generated by $(\prod_{a \in \Sigma_2} \beta_{a, a^*} | n \in \mathbb{N})$; let $D_2^a$ be the $n_0$-adic completion of $D_2 := (D_2, m_2)$. Arguing as in the proof of proposition 17.5.57 we see that the basic setup $(D_2, m_2)$ is almost perfectoid for the $p$-adic topology of $D_2$. Moreover, arguing as in the proof of proposition 17.5.60(ii), we see that if $(D_1, m_1)$ is flat over $A_0$, the same holds for $(D_2, m_2)\rho$, so also for $(D_2, m_2 D_2)$, and then also for $(D_2, m_2 D_2)$, by proposition 16.9.29. Furthermore, if $(D_1, m_1)^a$ is faithfully flat over $A_0$, then arguing again as in the proof of proposition 17.5.60(ii), we check that the same holds for $(D_2, m_2 D_2)^a$, and thus, also for $(D_2, m_2 D_2)^a$. Summing up, we conclude that if $(D_1, m_1)^a$ is flat (resp. faithfully flat) over $A_0$, the same holds for $(E_2, m_2 E_2)^a$. Then, arguing as in the proof of claim 17.5.66 we see that $E_2$ has no $p$-torsion and is $n_0$-adically complete and separated, and the basic setup $(E_2, m_1 E_2)$ is almost perfectoid for the $p$-adic topology of $E_2$. For every $a \in \Sigma_2$, let $\beta_{a^*} \in E(E_2)$ be the image of $\beta_{a^*}$, and set $\Delta_2 := (\beta_{a^*} | a \in \Sigma_2)$; let also $f_2 : A \to E_2$ be the structure map of the $A$-algebra $E_2$; as in the previous case, we conclude that $(f_2, \Delta_2)$ is an almost perfectoid object of $\mathcal{D}_A^{\Sigma_2, \Sigma_2'}$, and it is easily seen that it is the sought initial object: details left to the reader.

17.5.67. Resume the notation of (17.5.54), and let $D^a$ be the $n_0$-adic completion of $D$, and $D' := (D^a, m D^a)^a$. Set also $x_0 := p$, and let either $t := n$ if $g \in \{x_0, \ldots, x_n\} \cup \{b_\lambda | \lambda \in \Lambda\}$, or else $t := n + 1$ and $x_1 := g$; we take

$$\Sigma_0 := \{x_0\} \quad \Sigma_0 := \{x_0, \ldots, x_t\} \cup \{b_\lambda | \lambda \in \Lambda\}.$$ 

For $i = 0, \ldots, t$ and for every $\lambda \in \Lambda$, let $\beta_{x_i, \lambda} := (T^1/p^k \mathbb{Z}/p) \in E(D')$ and $\beta_{b_\lambda, \lambda} := (T^1/p^k \mathbb{Z}/p^k) \in E(D')$, where as usual $T^1/p^k, T^1/p^k \in D'$ denote the image of $T^1/p^k$ and $T^1/p^k$, for every such $i$, every $\lambda$, and every $k \in \mathbb{N}$. Lastly, set $\Delta_0 := (\beta_{a^*} | a \in \Sigma_0)$, and let $f_0 : A \to D'$ be the structure map of the $A$-algebra $D'$.

**Proposition 17.5.68.** The pair $(f_0, \Delta_0)$ is an almost perfectoid initial object of $\mathcal{D}_A^{\Sigma_0, \Sigma_0}$, and is almost faithfully flat over $A_0$.

**Proof.** Let $D_1$ be the integral closure of $(C^a, m C^a)^a$ in $C^a \otimes_{A_0} A_1$; and recall that the inclusion map $j : D \to D_1$ induces an isomorphism $D^a \sim D_1^a$ of $(C, m)^a$-algebras (59).
Lemma 8.2.28), so its \(n\)-adic completion \(j^! : D^! \to D_1^!\) induces an isomorphism of \(C\)-algebras \((j^!)^a : D^! \cong (D_1^!)^a\). By theorem 16.9.34(i,iii), \((D_1, mD_1)\) is an almost perfectoid basic setup, for the \(p\)-adic topology of \(D_1\), and \(D_1^a/p^aD_1^a\) is a faithfully flat \(C^a/p^aC^a\)-algebra, for every \(n \in \mathbb{N}\); hence \(D_1^a/p^aD_1^a\) is faithfully flat over \(A_0/p^aA_0\), for every \(n \in \mathbb{N}\), and therefore \(D_1^a\) is faithfully flat over \(A_0\) (proposition 14.2.43(i)). We may now argue as in the proof of claim 17.5.60(iii), to conclude that \((D_1^a)^a, m(D_1^a)^a)\) is an almost perfectoid basic setup, for the \(p\)-adic topology of \(D_1\), so the same holds for \((D', mD')\). This already shows that the pair \((f_0, \Delta_0)\) fulfills conditions (a),(b),(c) of (17.5.55) and condition (e) of (17.5.63). Combining with propositions 16.9.29(iv) and 17.5.13(ii) we deduce that also condition (d) of (17.5.55) holds for this pair, i.e. \((f_0, \Delta_0)\) is an almost perfectoid setup. Moreover, since \(D_1^a\) is faithfully flat over \(A_0\), the same holds for \((D_1)^a\), again by proposition 14.2.43(i), so also for \(D'^a\). Lastly, one verifies as in the proof of proposition 17.5.60(i) that \((f_0, \Delta_0)\) is an initial object of \(\mathcal{D}^A_{\Sigma_0, \Sigma_0}\). DETAILS LEFT TO THE READER.

17.5.69. Consider now the category \(\mathscr{A}\) whose objects are all local noetherian domains \((A, \mathfrak{n})\), complete for their \(n\)-adic topology, with \(\text{Frac} A\) of zero characteristic, residue field \(k\) of characteristic \(p > 0\) and with \([k : k^p] < +\infty\). The morphisms \((A, \mathfrak{n}) \to (A', \mathfrak{n}')\) of \(\mathscr{A}\) are all the injective ring homomorphisms \(A \to A'\).

For every object \((A, \mathfrak{n})\) of \(\mathscr{A}\), let \(\Omega(A)\) be the set of all pairs \((\Sigma, \Sigma')\) of finite non-empty subsets of \(A \setminus \{0\}\) with \(\Sigma' \subseteq \Sigma\) and \(p \in \Sigma\), such that the corresponding category \(\mathcal{C}^{A}_{\Sigma, \Sigma'}\) admits an initial object (notation of (17.5.55)), and for every \((\Sigma, \Sigma') \in \Omega(A)\), fix such an initial object \(f_{\Sigma, \Sigma'} : A \to D_{\Sigma, \Sigma}, \Delta_{\Sigma, \Sigma}\).

We let \(\leq\) be the partial ordering on \(\Omega(A)\) such that \((\Sigma_1, \Sigma'_1) \leq (\Sigma_2, \Sigma'_2)\) if and only if \(\Sigma_1 \subseteq \Sigma_2\) and \(\Sigma'_1 \subseteq \Sigma'_2\). Clearly, \((\Omega(A), \leq)\) is a filtered partially ordered set, and with the notation of remark 17.5.56, we have a unique morphism

\[
(f_{\Sigma_1, \Sigma'_1}, \Delta_{\Sigma_1, \Sigma'_1}) \to (f_{\Sigma_2, \Sigma'_2}, \Delta_{\Sigma_2, \Sigma'_2})|_{\Sigma_1, \Sigma'_1} \quad \text{in } \mathcal{C}^{A}_{\Sigma_1, \Sigma'_1}, \text{ whenever } (\Sigma_1, \Sigma'_1) \leq (\Sigma_2, \Sigma'_2).
\]

In other words, we get a well defined filtered system of \(A\)-algebras \(D_{\Sigma, \Sigma} = \bigcup_{(\Sigma, \Sigma') \in \Omega(A)} D_{\Sigma, \Sigma'}\).

For every \((\Sigma, \Sigma') \in \Omega(A)\), let \((D_{\Sigma, \Sigma}, m_{\Sigma, \Sigma})\) be the basic setup attached to \((f_{\Sigma, \Sigma'}, \Delta_{\Sigma, \Sigma'})\), and consider the subset \(\mathcal{S}_{\Sigma, \Sigma'} \subset D_{\Sigma, \Sigma}^{\mathbb{N}}\) of all \((a_n | n \in \mathbb{N})\) such that \(a_n \in D_{\Sigma, \Sigma'} a_{n+1}\) for every \(n \in \mathbb{N}\), and \(m_{\Sigma, \Sigma} \subset \bigcup_{n \in \mathbb{N}} D_{\Sigma, \Sigma'} a_n\). We let \(\Theta(A) \subset \Omega(A)\) be the subset of all \((\Sigma, \Sigma')\) such that

\[
E_{\Sigma, \Sigma'} := \mathcal{S}_{\Sigma, \Sigma'} D_{\Sigma, \Sigma}^{\mathbb{N}}\]

is a big CM \(A\)-algebra (see 17.5.2).

**Lemma 17.5.70.** \(\Theta(A)\) is a cofinal subset of \(\Omega(A)\), for every \((A, \mathfrak{n}) \in \text{Ob} (\mathscr{A})\).

**Proof.** Choose a subring \((A_0, \mathfrak{n}_0) \subset (A, \mathfrak{n})\) as in (17.5.49), then propositions 17.5.57 and 17.5.60 show that there exists \((\Sigma_0, \Sigma'_0) \in \Omega(A)\) such that \((D_{\Sigma, \Sigma}, m_{\Sigma, \Sigma})^a\) is faithfully flat over \(A_0\), for every \((\Sigma, \Sigma') \geq (\Sigma_0, \Sigma'_0)\). Then, arguing as in the proof of theorem 17.5.52 we see that \(E_{\Sigma, \Sigma'}\) is a big CM \(A\)-algebra for every such \((\Sigma, \Sigma')\). □

Notice that whenever \((\Sigma_1, \Sigma'_1) \leq (\Sigma_2, \Sigma'_2)\), the induced map \(D_{\Sigma_1, \Sigma'_1}^{\mathbb{N}} \to D_{\Sigma_2, \Sigma'_2}^{\mathbb{N}}\) sends \(\mathcal{S}_{\Sigma_1, \Sigma_2}\) into \(\mathcal{S}_{\Sigma_2, \Sigma'_2}\). Let then \(E(A)\) be the colimit of the induced filtered system \((E_{\Sigma, \Sigma'} | (\Sigma, \Sigma') \in \Omega(A))\). In light of lemma 17.5.70, it is easily seen that \(E(A)\) is a big CM \(A\)-algebra. Next, let \(g : (A, \mathfrak{n}) \to (A', \mathfrak{n}')\) be any morphism of \(\mathscr{A}\), and \((\Sigma_1, \Sigma'_1) \in \Omega(A), (\Sigma_2, \Sigma'_2) \in \Omega(A')\) with

\[
g(\Sigma_1) \subset \Sigma_2\]

and \(g(\Sigma'_1) \subset \Sigma'_2\).

For every object \((f, \Delta := (\beta_{a, a} | a \in \Sigma_2))\) of \(\mathcal{C}^{A'}_{\Sigma_2, \Sigma'_2}\), set \(\Delta_{\Sigma_1} := (\beta g(a), a \in \Sigma_1)\); since \(g\) is injective, the pair \((f \circ g, \Delta_{\Sigma_1})\) fulfills conditions (a),(c) and (d) of (17.5.55), defining the
objects of $\mathcal{C}^A_{\Sigma_1, \Sigma'_1}$, and with remark 14.2.7(ii), we easily check that also condition (b) holds for this pair. We get therefore a well defined functor:

$$\mathcal{C}^A_{\Sigma_2, \Sigma'_2} \to \mathcal{C}^A_{\Sigma_1, \Sigma'_1} \quad (f, \Delta) \mapsto (f, \Delta)|_{\Sigma_1, \Sigma'_1} := (f \circ g, \Delta|_{\Sigma_1}).$$

Especially, notice that for every $(\Sigma, \Sigma') \in \text{Ob}(A)$ we have $(g\Sigma, g\Sigma') \in \text{Ob}(A')$, whence a natural morphism in $\mathcal{C}^A_{\Sigma, \Sigma'}$:

$$(f_{\Sigma, \Sigma'}, \Delta_{\Sigma, \Sigma'}) \to (f_{g\Sigma, g\Sigma'}, \Delta_{g\Sigma, g\Sigma'})|_{\Sigma, \Sigma'}.$$ 

Moreover, the induced map $D^N_{\Sigma, \Sigma'} \to D^N_{g\Sigma, g\Sigma'}$ sends $S_{\Sigma, \Sigma'}$ into $S_{g\Sigma, g\Sigma'}$, so we get a map of $A$-algebras:

$$E_{\Sigma, \Sigma'} \to E_{g\Sigma, g\Sigma'}$$

for every $(\Sigma, \Sigma') \in \Omega(A)$. Finally, the colimit of this system of maps yields a well defined map $E(g) : E(A) \to E(A')$, and a simple inspection shows that the rules : $(A, n) \mapsto E(A)$ and $g \mapsto E(g)$ define a functor

$$E : \mathcal{A} \to \mathcal{Z}\text{-Alg}.$$ 

17.5.71. Using the categories $\mathcal{D}^A_{\Sigma, \Sigma'}$ of (17.5.63) we may obtain the following variant of the functor $E$. Consider the category

$$\mathcal{A}'$$

whose objects are all local noetherian domains $(A, n)$, complete for their $n$-adic topology, with Frac $A$ of zero characteristic, and residue field $k$ of characteristic $p > 0$. The morphisms $(A, n) \to (A', n')$ of $\mathcal{A}'$ are all the injective and local ring homomorphisms $A \to A'$.

For every object $(A, n)$ of $\mathcal{A}$, let $\Omega'(A)$ be the set of all pairs $(\Sigma, \Sigma')$ of non-empty subsets of $A \setminus \{0\}$ where $\Sigma'$ is finite, and $\Sigma' \cup \{p\} \subseteq \Sigma$, and such that the corresponding category $\mathcal{D}^A_{\Sigma, \Sigma'}$ admits an initial object. For every $(\Sigma, \Sigma') \in \Omega(A)$, fix such an initial object

$$(f_{\Sigma, \Sigma'}, \Delta_{\Sigma, \Sigma'}) : A \to D_{\Sigma, \Sigma'}, \Delta_{\Sigma, \Sigma'}).$$

We define a partial ordering $\leq$ on $\Omega'(A)$ just as for $\Omega(A)$ in (17.5.69). Clearly, $(\Omega'(A), \leq)$ is a filtered partially ordered set, and with the notation of (17.5.63), we have a unique morphism

$$(f_{\Sigma_1, \Sigma_1'}, \Delta_{\Sigma_1, \Sigma_1'}) \to (f_{\Sigma_2, \Sigma_2'}, \Delta_{\Sigma_2, \Sigma_2'})|_{\Sigma_1, \Sigma_1'}$$

in $\mathcal{D}^A_{\Sigma_1, \Sigma_1'}$, whenever $(\Sigma_1, \Sigma_1') \leq (\Sigma_2, \Sigma_2')$.

In other words, we get a well defined filtered system of $A$-algebras $(D_{\Sigma, \Sigma'} | (\Sigma, \Sigma') \in \Omega'(A))$.

For every $(\Sigma, \Sigma') \in \Omega'(A)$, let $(D_{\Sigma, \Sigma'}, m_{\Sigma, \Sigma'})$ be the basic setup attached to $(f_{\Sigma, \Sigma'}, \Delta_{\Sigma, \Sigma'})$, and define the multiplicative subset $S_{\Sigma, \Sigma'} \subseteq D_{\Sigma, \Sigma'}$ as in (17.5.69). We let $\Theta'(A) \subset \Omega'(A)$ be the subset of all $(\Sigma, \Sigma')$ such that $E'_{\Sigma, \Sigma'} := S_{\Sigma, \Sigma'}^{-1}D_{\Sigma, \Sigma'}$ is a big CM $A$-algebra. Using propositions 17.5.64 and 17.5.68 and arguing as in the proof of lemma 17.5.70 we see that $\Theta'(A)$ is a cofinal subset of $\Omega'(A)$, for every $(A, n) \in \text{Ob}(\mathcal{A}')$. Then, the colimit $E'(A)$ of the induced filtered system $(E'_{\Sigma, \Sigma'} | (\Sigma, \Sigma') \in \Omega'(A))$ is a big CM $A$-algebra. Next, let $g : (A, n) \to (A', n')$ be any morphism of $\mathcal{A}'$, and $(\Sigma_1, \Sigma_1') \in \Omega'(A)$, $(\Sigma_2, \Sigma_2') \in \Omega'(A')$ with

$$g(\Sigma_1) \subset \Sigma_2 \quad \text{and} \quad g(\Sigma_1') \subset \Sigma_2'.$$

For every object $(f, \Delta := (\beta_{a, n} | a \in \Sigma_2))$ of $\mathcal{D}^A_{\Sigma_2, \Sigma_2'}$, set again $\Delta|_{\Sigma_1} := (\beta_{g(a), n} | a \in \Sigma_1)$; since $g$ is injective, arguing as in the foregoing we see that the pair $(f \circ g, \Delta|_{\Sigma_2})$ fulfills conditions (a),(b), (c),(d) of (17.5.55). Moreover, since $g$ is local, lemma 8.3.12 implies that also condition (e) of (17.5.63) is fulfilled. We get therefore a well defined functor:

$$\mathcal{D}^A_{\Sigma_2, \Sigma_2'} \to \mathcal{D}^A_{\Sigma_1, \Sigma_1'} \quad (f, \Delta) \mapsto (f, \Delta)|_{\Sigma_1, \Sigma_1'} := (f \circ g, \Delta|_{\Sigma_1}).$$

From this, arguing as in the foregoing case, we obtain a natural map of $A$-algebras $E'(g) : E'(A) \to E'(A')$, whence a well defined functor:

$$E' : \mathcal{A}' \to \mathcal{Z}\text{-Alg}.$$
17.5.72. Next, we wish to establish a weak funtoriality property of big CM algebras, for not necessarily injective maps of local rings. The first step is the following:

**Proposition 17.5.73.** Let $A$ be noetherian ring, $I \subset A$ an ideal, $f_1, \ldots, f_r \in I$ a finite sequence such that the following holds for every $p \in \Sigma := \text{Ass}_A(A/I)$ (see definition [10.5.1](iii)):

(a) $I_p$ is generated by the image of the sequence $f_\bullet$.

(b) The image of the sequence $f_\bullet$ is regular in $I_p$.

Then we have:

(i) There exists $g \in A \setminus \bigcup_{p \in \Sigma} p$ such that $gI \subset J := \sum_{i=1}^r f_i A$.

(ii) For every $g$ as in (i), the sequence $f_\bullet' := (f_1/g, \ldots, f_r/g)$ is quasi-regular in the subring $A' := A[f_1/g, \ldots, f_r/g] \subset A[1/g]$.

(iii) With the notation of (ii), let $J' \subset A'$ be the ideal generated by $f_\bullet'$. The natural map

$$A \rightarrow A'$$

induces an isomorphism $A/I \sim A'/J'$.

**Proof.** (i): Let $L := \{x \in A \mid xI \subset J\}$; since $I$ is finitely generated, it is easily seen that $L_p = \{x \in A_p \mid xI_p \subset J_p\}$ for every $p \in \text{Spec} \ A$. Especially, $L_p = A_p$ for every $p \in \Sigma$, by assumption (a), i.e. $L \not\subset p$ for every such $p$; then the assertion follows from [10, Prop.1.11(i)].

(ii): Clearly the natural map $A \rightarrow A'$ induces a surjection $\varphi : A \rightarrow A'/J'$, and we need to check that $\ker \varphi = I$. However, if $x \in I$, then $gx = \sum_{i=1}^r a_if_i$ for some $a_1, \ldots, a_r \in A$, whence $x = \sum_{i=1}^r a_i f_i/g \in J'$ in $A'$, so $I \subset \ker \varphi$. Let then $\varphi : A/I \rightarrow A'/J'$ be the map induced by $\varphi$; notice that $A[1/g] = A'[1/g]$, and $IA[1/g] = J' A'[1/g]$, so that the localization $\varphi_g$ of $\varphi$ is an isomorphism. Especially, $\varphi_g$ is an isomorphism for every $p \in \Sigma$, and it suffices then to invoke the following:

**Claim 17.5.74.** Let $M$ and $N$ be two $A$-modules, and $h : M \rightarrow N$ an $A$-linear map. Then $h$ is injective if and only if $h_p : M_p \rightarrow N_p$ is injective for every $p \in \text{Ass}_A(M)$.

**Proof of the claim.** To ease notation, set $\Omega := \text{Ass}_A(M)$, and consider the commutative diagram

$$
\begin{array}{ccc}
M & \xrightarrow{h} & N \\
\Pi_{p \in \Omega} M_p & \xrightarrow{\Pi_{p \in \Omega} h_p} & \Pi_{p \in \Omega} N_p
\end{array}
$$

whose left vertical arrow is injective, by lemma [10.5.3](iii), and whose bottom horizontal arrow is injective if and only if $h_p$ is injective for every $p \in \Omega$. The assertion is an immediate consequence.

(ii): Set $A_r := A/I[T_1, \ldots, T_r]$, let $I_r \subset A_r$ be the ideal generated by $T_1, \ldots, T_r$, and denote by $\text{gr}_rA_r$ the graded $A/I$-algebra associated with the $I_r$-adic filtration of $A_r$. Also, for every $i = 1, \ldots, r$, let $T_i \in \text{gr}_1A_r$ (resp. $x_i \in J'/J'^2$) be the image of $T_i$ (resp. of $f_i/g$); we consider the map of graded $A/I$-algebras

$$
\psi_\bullet : \text{gr}_rA_r \rightarrow \bigoplus_{n \in \mathbb{N}} J^n/J^{n+1} \quad T_1 \mapsto x_1, \ldots, T_r \mapsto x_r.
$$

In view of (iii), we need to check that $\psi$ is an isomorphism, and since $\psi$ is surjective, it suffices to show that its restriction $\psi_n : \text{gr}_nA_r \rightarrow J^n/J^{n+1}$ is injective for every $n \in \mathbb{N}$. However, by assumption (b), the image of the sequence $f_\bullet$ is regular in $I_p$, for every $p \in \Sigma$, hence $\psi_{n,p}$ is an isomorphism for every $n \in \mathbb{N}$ and every $p \in \Sigma$ (proposition [7.8.15]). Then the assertion follows from claim[17.5.74].

**Remark 17.5.75.** Let $A$ be a noetherian ring, and $p \subset A$ a prime ideal such that $A_p$ is a regular local ring. Then $\text{Ass}_A(A/p) = \{p\}$, and we may find $g_1, \ldots, g_r \in p$ whose images in $A_p$ are a
regular system of parameters (just take any regular system of parameters for $A_p$, and multiply by a suitable element of $A \setminus p$ to clear denominators: details left to the reader). Hence, assumptions (a) and (b) of proposition 17.5.73 hold for $I := p$ and $f_* := g_*$. 

17.5.76. Consider now a sequence of local ring homomorphisms
\[ A_0 \xrightarrow{f_0} A_1 \xrightarrow{f_1} \cdots \xrightarrow{f_{n-1}} A_n \]
of some finite length $n$, where $A_0, \ldots, A_n$ are complete, local noetherian domains.

**Proposition 17.5.77.** In the situation of (17.5.76), there exists a commutative diagram of complete local noetherian domains, and local ring homomorphisms :
\[
\begin{array}{ccc}
A_0 & \xrightarrow{f_0} & A_1 \\
| & | & | \\
\downarrow{j_1} & \downarrow{\pi_1} & \downarrow{j_n} \\
B_1 & \xrightarrow{g_1} & B_n \\
| & | & | \\
\downarrow{h_0} & \downarrow{\pi_n} & \downarrow{h_{n-1}} \\
C_1 & \xrightarrow{h_1} & C_n \\
\end{array}
\]
(17.5.78)
such that $h_0, \ldots, h_{n-1}$ are injective maps, and the following holds for every $i = 1, \ldots, n$ :

(i) the map $j_i$ is finite and injective.

(ii) the map $\pi_i$ is surjective, and $\text{Ker} \, \pi_i$ is generated by a regular sequence of $C_i$.

**Proof.** Let us show first how to reduce to the case where $n = 1$. Indeed, suppose that $n > 1$, and $B_1$ and $C_1$ are given as required, with local ring homomorphisms $h_0 : A_0 \to C_0$, $j_1 : A_1 \to B_1$ and $\pi_1 : C_1 \to B_1$ such that $h_0$ is injective, and conditions (i) and (ii) hold for $i = 1$. By induction on $n$, we further suppose that the proposition is already known for every sequence $A_0 \to \cdots \to A_{n-1}$ of local ring homomorphisms of complete local noetherian domains.

- We construct by induction on $i = 1, \ldots, n$, a commutative diagram :
\[
\begin{array}{ccc}
A_1 & \xrightarrow{f_1} & \cdots \xrightarrow{f_{n-1}} & A_n \\
| & | & | & | \\
\downarrow{j'_1} & \downarrow{\pi_1} & \downarrow{j'_{n-1}} & \downarrow{j_n} \\
A'_1 & \xrightarrow{f'_1} & \cdots \xrightarrow{f'_{n-1}} & A'_n \\
\end{array}
\]
(17.5.79)
where $A'_1, \ldots, A'_n$ are complete local noetherian domains, $j'_1, \ldots, j'_n$ are local, finite and injective ring homomorphisms, and $f'_1, \ldots, f'_{n-1}$ are local ring homomorphisms. For $i = 1$, we take $A'_1 := B_1$ and $j'_1 := j_1$; suppose next that $i > 1$, and $A'_i$ has already been given for every $j < i$, together with the required commutative diagram of maps $j'_1, \ldots, j'_{i-1}$ and $f'_1, \ldots, f'_{i-2}$. Since $j'_{i-1}$ is finite and injective, the induced map $\text{Spec} \, A'_1 \to \text{Spec} \, A_{i-1}$ is surjective, so the same holds for its base change $\text{Spec} (A_i \otimes_{A_{i-1}} A'_1) \to \text{Spec} \, A_i$, and hence we may pick $p \in \text{Spec} (A_i \otimes_{A_{i-1}} A'_1)$ whose image in $\text{Spec} \, A_i$ is the generic point; we set $A'_i := (A_i \otimes_{A_{i-1}} A'_1)/p$, and let $j_i : A_i \to A'_i$ be the induced map. By construction, $\text{Spec}(j_i)$ is dominant with closed image, hence it is surjective, so $\text{Ker} \, j_i = 0$, since $A_i$ is a domain. Moreover, since $A_i$ is complete and separated, $j_i$ is local, and $A'_i$ is a finite $A_i$-algebra, so it is a complete local noetherian domain, as required. Lastly, let $k_{i-1}, k_i$ and $k'_{i-1}$ be the residue fields of $A_{i-1}, A_i$ and $A'_{i-1}$; to see that the natural map $f'_i : A'_{i-1} \to A'_i$ is local, it suffices to remark that the residue field of $A'_i$ is a quotient of $k_i \otimes_{k_{i-1}} k'_{i-1}$.

- Next, we apply the inductive assumption to the sequence of local ring homomorphisms
\[
C_1 \xrightarrow{f'_1 \otimes 1} A'_2 \xrightarrow{f'_2} \cdots \xrightarrow{f'_{n-1}} A'_n.
\]
(17.5.80)
Thus, we find a commutative diagram of complete local noetherian domains and local ring homomorphisms:

\[
\begin{array}{cccc}
C_1 & f'_0 \circ \pi_1 & A'_2 & f'_1 & \cdots & f'_{n-1} & A'_n \\
\downarrow h_1 & & \downarrow & & \downarrow & & \downarrow \\
B_2 & g_2 & \cdots & g_{n-1} & B_n & & \\
\downarrow \pi_2 & & & & \downarrow \pi_n & & \\
C_2 & h_2 & \cdots & h_{n-1} & C_n & &
\end{array}
\]

where \(h_1, \ldots, h_{n-1}\) are injective, and the map \(j''_i\) (resp. \(\pi_i\)) fulfills the corresponding condition (i) (resp. (ii)) of the proposition, for every \(i = 2, \ldots, n\). Then we obtain the sought diagram with \(g_1 := j''_0 \circ f'_1\) and \(j_i := j''_i \circ f'_i\) for every \(i = 2, \ldots, n\).

- We consider now the case \(n = 1\), so we are given a single local ring homomorphism \(f_0 : A_0 \to A_1\) of complete local noetherian domains. We notice:

**Claim 17.5.81.** There exist a complete local noetherian domain \(D_0\), and local ring homomorphisms \(\varphi_0 : A_0 \to D_0\), \(\psi_0 : D_0 \to A_1\) such that \(\varphi_0\) is injective, \(\psi_0\) is surjective, and \(\psi_0 \circ \varphi_0 = f_0\).

**Proof of the claim.** By proposition 9.7.31(i) there exists a complete local noetherian ring \(D_0\), a faithfully flat ring homomorphism \(\varphi_0 : A_0 \to D_0\), and a surjective map \(\psi_0 : D_0 \to A_1\) with \(\psi_0 \circ \varphi_0 = f_0\). Then, let \(p\) be any minimal prime ideal of \(D_0\) contained in \(\ker \psi_0\), and set \(D_0 := D_0/p\); since \(\varphi_0\) is flat, we have \(\varphi_0^{-1} p = 0\), so the induced map \(\varphi_0 : A_0 \to D_0\) is still injective, and \(\psi_0\) factors through a surjection \(\psi_0 : D_0 \to A_1\), whence the claim.

Let \(\varphi_0 : A_0 \to D_0\) and \(\psi_0 : D_0 \to A_1\) be as in claim [17.5.81] and set \(p := \ker \psi_0\); lemma 9.7.4(v) says that \(D_0\) is excellent, so \(D_0/p\) is quasi-excellent, by lemma 9.7.4(ii,iv). Especially, \(D_0/p\) is a Nagata ring, and the regular locus of \(\text{Spec} D_0/p\) is an open subset ([51 Ch.IV, Th.6.12.4]); by corollary [9.6.56] we may then find a regular local domain \((D_1, m_1)\), and an injective local ring homomorphism \(D_0/p \to D_1\) of essentially finite type, inducing an isomorphism \(\text{Frac}(D_0) \xrightarrow{\sim} \text{Frac}(D_1)\) and a finite field extension \(\text{Frac}(D_0/p) \to D_1/m_1\). Pick \(y_1, \ldots, y_n \in D_1\) and a prime ideal \(q \subset D_2 := D_0[y_1, \ldots, y_n]\) such that \(D_1 = D_2/q\); we remark:

**Claim 17.5.82.** We can assume that the induced injective map \(A_1 \xrightarrow{\sim} D_0/p \to D_2/q\) is finite.

**Proof of the claim.** The image \(\overline{y}_i \in D_1/m_1 = \text{Frac}(D_2/q)\) of \(y_i\) is algebraic over \(\text{Frac}(D_0/p)\) for every \(i = 1, \ldots, n\), so we may find \(x \in D_0 \setminus p\) such that the images of \(x y_1, \ldots, x y_n\) in \(\text{Frac}(D_2/q)\) are integral over \(D_0/p\). Set \(D'_2 := D_0[x y_1, \ldots, x y_n]\) and \(q' := q \cap D'_2\); then clearly \(D'_2/q' \to D_1\), so we may replace \(y_i\) by \(x y_i\) for \(i = 1, \ldots, n\), and assume that \(\overline{y}_i\) is integral over \(D_0/p\), for every \(i = 1, \ldots, n\), whence the claim.

- Now we apply proposition 17.5.73 and remark 17.5.75 to \(A := D_2\), \(I := q\), and to a finite sequence \(x_1, \ldots, x_d\) of elements of \(q\) whose images in the regular local ring \(D_1\) are a regular system of parameters: we obtain \(g \in D_2\setminus q\) with \(g \cdot q \subset \sum_{i=1}^d x_i D_2\), and such that the sequence \(t_1 := x_1/g, \ldots, t_d := x_d/g\) is quasi-regular in the subring \(D'_2 := D_2[t_1, \ldots, t_d] \subset D_2[1/g]\); moreover, if \(q' \subset D'_2\) denotes the ideal generated by \(t_1, \ldots, t_d\), the inclusion map \(D_2 \to D'_2\) induces an isomorphism

\[
D_2/q \xrightarrow{\sim} B_1 := D'_2/q'.
\]

Since \(A_1\) is complete, claim 17.5.82 implies that \(D_2/q\) is a complete local noetherian domain, so the same holds for \(B_1\), and the resulting map \(g_1 : A_1 \to B_1\) is injective and finite; then, let \(m \subset B_1\) be the maximal ideal, \(m' \subset D'_2\) its preimage, and \(C_1\) the \(m'\)-adic completion of \(D'_2\). Since \(C_1\) is a flat \(D'_2\)-algebras, the image \(t\) in \(C_1\) of the sequence \(t_1, \ldots, t_d\) is still quasi-regular, hence it is regular, by proposition 7.8.15 and [100 Th.8.10]. Also, the localization \(D'_2 \to D'_{2,m'}\)
is injective, since $D_2$ is a domain, and the same holds for the completion map $D_2'[m'] \to C_1$, since the latter is faithfully flat; summing up, we deduce that the structure map $h_0 : A_0 \to C_1$ of the resulting $A_0$-algebra $C_1$ is injective. To conclude the proof, it now suffices to remark:

**Claim 17.5.83.** $C_1$ is a domain, and $h_0$ is a local ring homomorphism.

**Proof of the claim.** In order to show that $h_0$ is local, it suffices to check that the same holds for the natural map $A_0 \to D_2'[m']$. The latter comes down to verifying that the preimage of $m'$ under the natural map $A_0 \to D_2'$ is the maximal ideal of $A_0$. But in turns, this is the same as the preimage of $m$ under the composition $A_0 \to A_1 \to D_2/\mathfrak{q} \to B_1$, which is local, whence the assertion. Next, let $\text{gr}_C 1$ be the graded ring associated with the $\mathfrak{q}'$-adic filtration on $C_1$; hence $\text{gr}_0 C_1$ is the $\mathfrak{q}'$-adic completion of $B_1$. But $B_1$ is $\mathfrak{m}'$-adically complete and separated, so $\text{gr}_0 C_1 = B_1$ and since $t$ is quasi-regular, the natural map of graded $B_1$-algebras

$$B_1[T_1, \ldots, T_d] \to \text{gr}_C 1 \quad T_1 \mapsto t_1, \ldots, T_d \mapsto t_d$$

is an isomorphism. Since the $\mathfrak{q}'$-adic filtration is separated on $C_1$, the assertion follows. \hfill \Box

**17.5.84.** We will also need the following variant of the situation contemplated in (17.5.76): we consider a sequence, of some finite length $n$, of ring homomorphisms

$$A_0 \xrightarrow{f_0} A_1 \xrightarrow{f_1} \cdots \xrightarrow{f_{n-1}} A_n$$

where $A_0, \ldots, A_n$ are quasi-excellent domains, and $f_0, \ldots, f_{n-1}$ are of finite type.

**Proposition 17.5.85.** In the situation of (17.5.84), there exists a commutative diagram (17.5.78) of quasi-excellent domains, such that $h_0, \ldots, h_{n-1}$ are injective maps of finite type, and for every $i = 1, \ldots, n$ the following holds:

(i) the map $j_i$ is finite and injective

(ii) the map $\pi_i$ is surjective, and $\text{Ker} \, \pi_i$ is generated by a quasi-regular sequence of $C_i$.

**Proof.** We argue as in the proof of proposition 17.5.77: first, we show how to reduce to the case where $n = 1$. Hence, suppose that $n > 1$, and $B_1$ and $C_1$ are given as required, with local ring homomorphisms $h_0 : A_0 \to C_0$, $j_1 : A_1 \to B_1$ and $\pi_1 : C_1 \to B_1$ such that $h_0$ is injective, and conditions (i) and (ii) of proposition 17.5.77 hold for $i = 1$. By induction on $n$, we further suppose that the proposition is already known for every sequence $A_0 \to \cdots \to A_{n-1}$ consisting of maps of finite type, and quasi-excellent domains $A_0, \ldots, A_{n-1}$.

- We construct by induction on $i = 1, \ldots, n$, a commutative diagram (17.5.79), where $A'_1, \ldots, A'_n$ are quasi-excellent domains, $j'_1, \ldots, j'_n$ are injective and finite ring homomorphisms, and $f'_1, \ldots, f'_{n-1}$ are of finite type. For $i = 1$, we take $A'_1 := B_1$ and $j'_1 := j_1$; suppose next that $i > 1$, and $A'_j$ has already been given for every $j < i$, together with the required commutative diagram of maps $j'_1, \ldots, j'_i$ and $f'_1, \ldots, f'_{i-2}$. Just as in the proof of proposition 17.5.77, we may then find $\mathfrak{p} \in \text{Spec}(A_i \otimes_{A_{i-1}} A'_{i-1})$ whose image in $\text{Spec} \, A_i$ is the generic point; we set $A'_i := (A_i \otimes_{A_{i-1}} A'_{i-1})/\mathfrak{p}$, and let $j_i : A_i \to A'_i$ and $f'_i : A'_{i-1} \to A'_i$ be the induced maps.

- Next, we apply the inductive assumption to the sequence (17.5.80), to construct the sought commutative diagram, as in the proof of proposition 17.5.77.

- We consider now the case $n = 1$, so we are given a single map of finite type $f_0 : A_0 \to A_1$ of quasi-excellent domains. Then we pick a polynomial $A_0$-algebra $D_0 := A_0[T_1, \ldots, T_k]$ with a surjection of $A_0$-algebras $\psi_0 : D_0 \to A_1$. Set $\mathfrak{p} := \text{Ker} \, \psi_0$; then $D_0/\mathfrak{p}$ is quasi-excellent, by lemma 9.7.4(ii,iv). Especially, $D_0/\mathfrak{p}$ is a Nagata ring, and the regular locus of $\text{Spec} \, D_0/\mathfrak{p}$ is an open subset (51, Ch.IV, Th.6.12.4); by corollary 9.6.56 we may then find a regular local domain $(D_1, m_1)$, and an injective local ring homomorphism $D_0/\mathfrak{p} \to D_1$ of essentially finite type, inducing an isomorphism $\text{Frac}(D_0) \cong \text{Frac}(D_1)$ and a finite field extension $\text{Frac}(D_0/\mathfrak{p}) \to D_1/m_1$. Pick $y_1, \ldots, y_n \in D_1$ and a prime ideal $\mathfrak{q} \subset D_2 := D_0[y_1, \ldots, y_n]$
such that $D_1 = D_{2,q}$. Arguing as in the proof of claim 17.5.82, we can assume that the induced injective map $A_1 \xrightarrow{\sim} D_0/p \rightarrow D_2/q$ is finite.

- Now we apply proposition 17.5.73 and remark 17.5.75 to $A := D_2$, $I := q$, and to a finite sequence $x_1, \ldots, x_d$ of elements of $q$ whose images in the regular local ring $D_1$ are a regular system of parameters: we obtain $g \in D_2 \setminus q$ with $q \cdot g \subseteq \sum_{i=1}^d x_i D_2$, and such that the sequence $t_1 := x_1 / g, \ldots, t_d := x_d / g$ is quasi-regular in the subring $C_1 := D_2[t_1, \ldots, t_d] \subset D_2[1/g]$; moreover, if $q' \subset C_1$ denotes the ideal generated by $t_1, \ldots, t_d$, the inclusion map $D_2 \hookrightarrow C_1$ induces an isomorphism

$$D_2/q \xrightarrow{\sim} B_1 := C_1/q'.$$

By construction, the resulting map $g_1 : A_1 \rightarrow B_1$ is injective and finite, and the natural map $A_0 \rightarrow C_1$ is injective of finite type, as required.$\square$

We are now ready to state:

**Theorem 17.5.86.** In the situation of (17.5.76), suppose that the residue field of $A_i$ is of characteristic $p > 0$ for every $i = 0, \ldots, n$. Then there exists a commutative diagram of ring homomorphisms:

$$
\begin{array}{ccc}
A_0 & \xrightarrow{f_0} & A_1 & \xrightarrow{f_1} & \cdots & \xrightarrow{f_{n-1}} & A_n \\
\downarrow & & \downarrow & & \downarrow & & \downarrow \\
D_0 & \rightarrow & D_1 & \rightarrow & \cdots & \rightarrow & D_n
\end{array}
$$

such that $D_i$ is a big CM $A_i$-algebra for every $i = 0, \ldots, n$.

**Proof.** We pick a commutative diagram as in proposition 17.5.77. Especially, $h_0, \ldots, h_{n-1}$ are injective and local maps, so if $\text{Frac} \ A_0$ has characteristic zero, the same holds for $\text{Frac} \ C_i$, for every $i = 1, \ldots, n$, in which case the discussion of (17.5.71) yields a commutative diagram

$$
\begin{array}{ccc}
A_0 & \xrightarrow{h_0} & C_1 & \xrightarrow{h_1} & \cdots & \xrightarrow{h_{n-1}} & C_n \\
\downarrow & & \downarrow & & \downarrow & & \downarrow \\
D'_0 & \rightarrow & D'_1 & \rightarrow & \cdots & \rightarrow & D'_n
\end{array}
$$

such that $D'_0$ is a big CM $A_0$-algebra, and $D'_i$ is a big CM $C_i$-algebra for every $i = 1, \ldots, n$. Let $m_0, m_1, \ldots, m_n$ be the maximal ideals of $A_0, C_1, \ldots, C_n$; by claim 17.5.20(i), the $m_0$-adic completion $D_0$ of $D'_0$ (resp. the $m_i$-adic completion $D'_i$ of $D'_i$, for $i = 1, \ldots, n$) is still a CM $D_0$-algebra (resp. a CM $C_i$-algebra). After setting $D_i := B_i \otimes_{C_i} D'_i$ for $i = 1, \ldots, n$, we get a commutative diagram as sought, such that $D_i$ is a big CM $B_i$-algebra for every $i = 1, \ldots, n$, by claim 17.5.20(ii). Next, by restriction of scalars along the finite injective map $j_i$, the ring $D_i$ is a big CM $A_i$-algebra for $i = 1, \ldots, n$ (remark 17.5.18(iii)), whence the theorem, in this case.

Lastly, if $A_0$ is an $\mathbb{F}_p$-algebra, the same holds for $C_1, \ldots, C_n$, and then we may argue likewise, using the functor $E_p$ from remark 17.5.35(ii) (recall that all complete noetherian local rings are excellent: see lemma 9.7.4(v)).$\square$
