10.5.26. Let $A$ be a ring, $M$ an $A$-module, $I \subset A$ an ideal. We shall show how to characterize the finite subsets $\Sigma \subset \text{Spec} A$ such that the $\Sigma$-symbolic topology on $M$ agrees with the $I$-preadic topology (see theorem [10.5.35]). Hereafter, we begin with a few preliminary observations. First, suppose that $A$ is noetherian; then it is easily seen that, for every prime ideal $p \subset A$, and every $p$-primary ideal $I \subset A_p$, there exists $n \in \mathbb{N}$ such that $p^n A_p \subset I$. From lemma [10.5.24] we deduce that every $p$-primary ideal of $A$ contains a symbolic power of $p$; i.e., every $p$-primary ideal is open in the $p$-symbolic topology of $A$. More generally, let $\Sigma \subset \text{Spec} A$ be any subset, $M$ a finitely generated $A$-module, and $N \subset M$ a submodule; from the existence of a primary decomposition for $N$ ([100, Th.6.8]), we see that $N$ is open in the $\Sigma$-symbolic topology of $M$, whenever $\text{Ass} M/N \subset \Sigma$. Especially, if $\text{Ass} M/I^n M \subset \Sigma$ for every $n \in \mathbb{N}$, then the $\Sigma$-symbolic topology is finer than the $I$-preadic topology on $M$. On the other hand, clearly $I^n M \subset \text{Fil}_p^{(n)} M$ for every $p \in \text{Supp} M/I M$ and every $n \in \mathbb{N}$, so the $I$-preadic topology on $M$ is finer than the $\text{Supp} M/I M$-symbolic topology. Summing up, if we have:

$$\Sigma_0(M) := \bigcup_{n \in \mathbb{N}} \text{Ass} M/I^n M \subset \Sigma \subset \text{Supp} M/I M$$

then the $\Sigma$-symbolic topology on $M$ agrees with the $I$-preadic topology. Notice that the above expression for $\Sigma_0(M)$ is a union of finite subsets ([100, Th.6.5(i)]), hence $\Sigma_0(M)$ is a priori – at most countable; in fact, we shall show that $\Sigma_0(M)$ is finite. Indeed, for every $n \in \mathbb{N}$, set:

$$\text{gr}_I^n A := I^n/I^{n+1} \quad \text{gr}_I^n M := I^n M/I^{n+1} M.$$  

Then $\text{gr}_I^* A := \bigoplus_{n \in \mathbb{N}} \text{gr}_I^n A$ is naturally a graded $A/I$-algebra, and $\text{gr}_I^* M := \bigoplus_{n \in \mathbb{N}} \text{gr}_I^n M$ is a graded $\text{gr}_I^* A$-module. Let $\psi : \text{Spec} \text{gr}_I^* A \to \text{Spec} A/I$ be the natural morphism, and set:

$$\Sigma(M) := \psi(\text{Ass}_{\text{gr}_I^* A}(\text{gr}_I^* M)).$$

Lemma 10.5.27. With the notation of [10.5.26], we have:

$$\text{Ass}_{A/I}(\text{gr}_I^* M) \subset \Sigma(M) \quad \text{for every } n \in \mathbb{N}.$$  

**Proof.** To ease notation, set $A_0 := A/I$ and $B := \text{gr}_I^* A$. Suppose that $p \in \text{Ass}_{A_0}(\text{gr}_I^* M)$; by lemma [10.5.3(i)], there exists $m \in \text{gr}_I^* M$ such that $p$ is the preimage of a minimal prime ideal of $A_0/\text{Ann}_{A_0}(m)$. However, if we regard $m$ as a homogeneous element of the $B$-module $\text{gr}_I^* M$, we have the obvious identity:

$$\text{Ann}_{A_0}(m) = A_0 \cap \text{Ann}_B(m) \subset B$$

from which we see that the induced map

$$A_0/\text{Ann}_{A_0}(m) \to B/\text{Ann}_B(m)$$

is injective, hence $\psi$ restricts to a dominant morphism $V(\text{Ann}_B(m)) \to V(\text{Ann}_{A_0}(m))$. Especially, there exists $q \in V(\text{Ann}_B(m))$ with $\psi(q) = p$; up to replacing $q$ by a generization, we may assume that $q$ is a maximal point of $V(\text{Ann}_B(m))$, hence $q$ is an associated prime for $\text{gr}_I^* M$, again by lemma [10.5.3(i)].  

$\square$
An easy induction, starting from lemma 10.5.27, shows that $\text{Ass}_A M/I^n M \subseteq \Sigma(M)$, for every $n \in \mathbb{N}$, therefore $\Sigma(M) \subseteq \Sigma(M)$. However, if $A$ is noetherian, the same holds for $gr^*_I A$ (since the latter is a quotient of an $A/I$-algebra of finite type), hence $\Sigma(M)$ is finite, provided $M$ is finitely generated ([100] Th.6.5(i)), and a fortiori, the same holds for $\Sigma_0(M)$.

Remark 10.5.29. Another proof of the finiteness of $\Sigma_0(M)$ can be found in [35].

10.5.30. Next, we wish to show that actually there exists a smallest subset $\Sigma_{\min}(M) \subseteq \text{Spec} A$ such that $\Sigma_{\min}(M)$-symbolic topology on $M$ agrees with both the $\Sigma \\setminus \{p\}$-symbolic topology and the $\Sigma \\setminus \{p'\}$-symbolic topology; then these topologies agree as well with the $\Sigma \\setminus \{p, p'\}$-symbolic topology. Indeed, given any subset $\Sigma' \subseteq \text{Spec} A$ with $p \in \Sigma'$, for the $\Sigma'$-symbolic and the $\Sigma' \\setminus \{p\}$-symbolic topologies to agree, it is necessary and sufficient that, for every $n \in \mathbb{N}$ there exists $m \in \mathbb{N}$ such that:

$$F_i^{(m)} \subseteq F_i^{(n)} M \quad \text{or, what is the same} \quad F_i^{(m)} \subseteq F_i^{(n)} M_p.$$

In the latter inclusion, we may then replace $\Sigma' \setminus \{p\}$ by the smaller subset $\Sigma' \cap \text{Spec} A_p \setminus \{p\}$, without changing the two terms. Suppose now that $p' \notin \text{Spec} A_p$; then if we apply the above, first with $\Sigma' := \Sigma$, and then with $\Sigma' := \Sigma \setminus \{p'\}$, we see that the $\Sigma$-symbolic topology agrees with the $\Sigma \setminus \{p\}$-symbolic topology, and if only if the $\Sigma \setminus \{p'\}$-symbolic topology agrees with the $\Sigma \setminus \{p, p'\}$-symbolic topology, whence the contention. In case $p' \in \text{Spec} A_p$, we may assume that $p \neq p'$, otherwise there is nothing to prove; then we shall have $p \notin \text{Spec} A_p'$, so the foregoing argument still goes through, after reversing the roles of $p$ and $p'$.

10.5.31. Finally, theorem 10.5.35 will characterize the subset $\Sigma_{\min}(M)$ as in (10.5.28). To this aim, for every prime ideal $p \subseteq A$, let $A_p$ denote the $p$-adic completion of $A$; we set:

$$\text{Ass}_A(I, M) := \{p \in \text{Spec} A \mid \text{there exists } q \in \text{Ass}_{A_p} M \otimes_A A_p \text{ such that } q + IA_p = pA_p\}$$

(where, for any ideal $J \subseteq A_p$, we denote by $\sqrt{J} \subseteq A_p$ the radical of $J$, so the above condition selects the points $q \in \text{Spec} A_p$, such that $\{q\} \cap V(IA_p) = \{pA_p\}$).

Lemma 10.5.32. Let $A$ be a noetherian ring, $M$ an $A$-module. Then we have:

(i) $\text{depth}_{A_p} M \otimes_A A_p = \text{depth}_{A_p} M \otimes_A A_p$ for every $p \in \text{Spec} A$.

(ii) $\text{Ass}_A(0, M) = \text{Ass}_A M$.

(iii) $\text{Ass}_A(I, M) \subseteq V(I) \cap \text{Supp} M$.

(iv) Suppose that $M$ is the union of a filtered family $(M_{\lambda} \mid \lambda \in \Lambda)$ of $A$-submodules. Then:

$$\text{Ass}_A(I, M) = \bigcup_{\lambda \in \Lambda} \text{Ass}_A(I, M_{\lambda}).$$

(v) $\text{Ass}_A(I, M)$ contains the maximal points of $V(I) \cap \text{Supp} M$.

Proof. (iii) is immediate, and in view of [100] Th.8.8, (i) is a special case of corollary 10.4.37.

(ii): By definition, $\text{Ass}_A(0, M)$ consists of all the prime ideals $p \subseteq A$ such that $p A_p$ is an associated prime ideal of $M \otimes_A A_p$; in light of proposition 10.5.6(i), the latter condition holds if and only if $\text{depth}_{A_p} M \otimes_A A_p = 0$, hence if and only if $\text{depth}_{A_p} M \otimes_A A_p = 0$, by (i); to conclude, one appeals again to proposition 10.5.6(i).

(iv): In view of proposition 10.5.6(v), we have $\text{Ass}_{A_p} M \otimes_A A_p = \bigcup_{\lambda \in \Lambda} \text{Ass}_{A_p} M_{\lambda} \otimes_A A_p$; the contention is an immediate consequence.

(v): In view of (iv), we are easily reduced to the case where $M$ is a finitely generated $A$-module, in which case $\text{Supp} M = V(J)$ for some ideal $J \subseteq A$. Hence, suppose that $p \subseteq A$ is a maximal point of $\text{Spec} A/(I + J)$, in other words, the preimage of a minimal prime ideal of
A/(I + J); notice that \(\text{Supp } M \otimes_A A_p^\wedge = V(JA_p^\wedge)\). Hence we have \((J + I)A_p^\wedge \subset q + IA_p^\wedge\) for every \(q \in \text{Supp } M \otimes_A A_p^\wedge\), so the radical of \(q + IA_p^\wedge\) equals \(pA_p^\wedge\), as required. \(\square\)

**Lemma 10.5.33** (Chevalley’s theorem). Let \((A, m)\) be an \(m\)-adically complete local noetherian ring, \(M\) a finitely generated \(A\)-module, and \((\text{Fil}^n M \mid n \in \mathbb{N})\) a descending filtration consisting of \(A\)-submodules of \(M\). Then the following conditions are equivalent:

(a) \(\bigcap_{n \in \mathbb{N}} \text{Fil}^n M = 0\).

(b) For every \(i \in \mathbb{N}\) there exists \(n \in \mathbb{N}\) such that \(\text{Fil}^n M \subset m^n M\).

**Proof.** Clearly (b) \(\Rightarrow\) (a), hence suppose that (a) holds. For every \(i, n \in \mathbb{N}\), set 
\(J_{i,n} := \text{Im}(\text{Fil}^n M \to M/m^n M)\).

For given \(i \in \mathbb{N}\), the \(A\)-module \(M/m^n M\) is artinian, hence there exists \(n \in \mathbb{N}\) such that \(J_i := J_{i,n} = J_{i,n'}\) for every \(n' \geq n\). Assertion (b) then follows from the following:

**Claim 10.5.34.** If (a) holds, \(J_i = 0\) for every \(i \in \mathbb{N}\).

**Proof of the claim.** By inspecting the definition, it is easily seen that the natural \(A/m^{i+1}\)-linear map \(J_{i+1} \to J_i\) is surjective for every \(i \in \mathbb{N}\), hence we are reduced to showing that \(J := \lim_{i \in \mathbb{N}} J_i\) vanishes. However, \(J\) is naturally a submodule of \(\lim_{i \in \mathbb{N}} M/m^n M \simeq M\), and if \(x \in M\) lies in \(J\), then we have \(x \in \text{Fil}^n M + m^n M\) for every \(i, n \in \mathbb{N}\). Since \(\text{Fil}^n M\) is a closed subset for the \(m\)-adic topology of \(M\) (100 Th.8.10(i)), we have \(\bigcap_{n \in \mathbb{N}} (\text{Fil}^n M + m^n M) = \text{Fil}^n M\), for every \(n \in \mathbb{N}\), hence \(x \in \bigcap_{n \in \mathbb{N}} \text{Fil}^n M\), which vanishes, if (a) holds. \(\square\)

The following theorem generalizes [113, Ch.VIII, §5, Cor.5] and [71, Prop.7.1], and is closely related to [115, Th.3.2]; see also [41, Th.3.6].

**Theorem 10.5.35.** Let \(A\) be a noetherian ring, \(I \subset A\) an ideal, \(M\) a finitely generated \(A\)-module, and \(\Sigma \subset \text{Spec } A/I\) a finite subset. Then the \(\Sigma\)-symbolic topology on \(M\) agrees with the \(I\)-preadic topology if and only if \(\text{Ass}_A(I, M) \subset \Sigma\).

**Proof.** Let \(p \in \text{Ass}_A(I, M) \setminus \Sigma\), and suppose, by way of contradiction, that the \(\Sigma\)-symbolic topology agrees with the \(I\)-adic topology, i.e. for every \(n \in \mathbb{N}\) there exists \(m \in \mathbb{N}\) such that:

\[\text{Fil}^m_{\Sigma} M \subset I^n M.\]

Let \(X := \text{Spec } A_p\) and \(U := X \setminus \{p\}\); after localizing at the prime \(p\), we deduce the inclusion:

\[(10.5.36) \quad \text{Fil}^m_{\Sigma U} M_p \subset I^n M_p\]

(\text{ep. the discussion in (10.5.28)}). Let also \(\mathcal{M} := M^\wedge\), the quasi-coherent \(\mathcal{O}_X\)-module associated to \(M\); clearly we have \(I^n M \subset \text{Fil}^n_{\mathcal{M}} M\) for every \(q \in \text{Spec } A/I\), hence (10.5.36) implies the inclusion:

\[\{ x \in M_p \mid x|_U \in I^n \mathcal{M}(U) \} \subset I^n M_p.\]

Let \(A_p^\wedge\) (resp. \(M_p^\wedge\)) be the \(p\)-adic completion of \(A\) (resp. of \(M\)), \(f : X^\wedge := \text{Spec } A_p^\wedge \to X\) the natural morphism, and set \(U^\wedge := f^{-1} U = X^\wedge \setminus \{pA_p^\wedge\}\). Since \(f\) is faithfully flat, and \(U\) is quasi-compact, we deduce that:

\[(10.5.37) \quad \{ x \in M_p^\wedge \mid x|_U \in I^n f^* \mathcal{M}(U^\wedge) \} \subset I^n M_p^\wedge.\]

On the other hand, by assumption there exists \(q \in \text{Ass}_{A_p^\wedge} M_p^\wedge\) such that \(\overline{\{q\}} \cap V(IA_p^\wedge) = \{pA_p^\wedge\}\), hence we may find \(x \in M_p^\wedge\) whose support is \(\overline{\{q\}}\) (lemma 10.5.3(ii)). It follows easily that the image of \(x\) vanishes in \(f^* \mathcal{M}/I^n f^* \mathcal{M}(U)\) for all \(m \in \mathbb{N}\), i.e. \(x|_U \in I^n f^* \mathcal{M}(U)\) for every \(m \in \mathbb{N}\), hence \(x \in I^n M_p^\wedge\) for every \(n \in \mathbb{N}\), in view of (10.5.37). However, \(M_p^\wedge\) is separated for the \(p\)-adic topology, a fortiori also for the \(I\)-preadic topology, so \(x = 0\), a contradiction.
Next, let \( p \in \Sigma \setminus \text{Ass}_A(I, M) \), set \( \Sigma' := \Sigma \setminus \{ p \} \), and suppose that the \( \Sigma \)-symbolic topology agrees with the \( I \)-adic topology; we have to prove that the latter agrees as well with the \( \Sigma' \)-symbolic topology. This amounts to showing that, for every \( n \in \mathbb{N} \) there exists \( m \in \mathbb{N} \) such that:

\[
\text{Fil}^m_{\Sigma'} M \subset \text{Fil}^n M \quad \text{or, what is the same:} \quad \text{Fil}^m_{\Sigma'} M_p \subset p^n M_p.
\]

We may write:

\[
\text{Fil}^m_{\Sigma'} M_p = \{ x \in M_p \mid x|_U \in (\text{Fil}^m_{\Sigma'} M_p)^\sim(U) \} = \{ x \in M_p \mid x|_U \in (\text{Fil}^m_{\Sigma'} M_p)^\sim(U) \}
\]

from which it is clear that the contention holds if and only if, for every \( n \in \mathbb{N} \) there exists \( m \in \mathbb{N} \) such that:

\[
\{ x \in M_p \mid x|_U \in I^m M_p \} \subset p^n M_p.
\]

Arguing as in the foregoing, we see that the latter condition holds if and only if:

\[
\text{Fil}^m M_p := \{ x \in M_p \mid x|_U \in I^m f^\ast \mathcal{M}(U^\sim) \} \subset p^n M_p.
\]

In view of lemma 10.5.33, we are then reduced to showing the following:

**Claim 10.5.38.** \( \bigcap_{m \in \mathbb{N}} \text{Fil}^m M_p = 0 \).

**Proof of the claim.** Let \( x \) be an element in this intersection; for any \( q \in U^\sim \cap V(I A_p^\wedge) \), we have \( x_q \in \bigcap_{m \in \mathbb{N}} q^m (M^\wedge)_q \), hence \( x_q = 0 \), by 100 Th.8.10(i). In other words, \( \text{Supp}(x) \cap U \cap V(I) = \emptyset \). Suppose that \( x \neq 0 \), and let \( q \) be any maximal point of \( \text{Supp}(x) \); by lemma 10.5.33(i), \( q \) is an associated prime, and the foregoing implies that \( \{ q \} \cap V(I A_p^\wedge) = \{ p A_p^\wedge \} \), which contradicts the assumption that \( p \notin \text{Ass}_A(I, M) \).

**Corollary 10.5.39.** In the situation of theorem 10.5.35 \( \text{Ass}_A(I, M) \) is a finite set.

**Proof.** We have already found a finite subset \( \Sigma \subset \text{Spec} A/I \) such that the \( \Sigma \)-symbolic topology on \( M \) agrees with the \( I \)-preadic topology (see 10.5.28). The contention then follows straightforwardly from theorem 10.5.35.

**Example 10.5.40.** Let \( k \) be a field with \( \text{char} k \neq 2 \), and let \( C \subset A_2^\wedge := \text{Spec} k[X, Y] \) be the nodal curve cut by the equation \( Y^2 = X^2 + X^3 \), so that the only singularity of \( C \) is the node at the origin \( p := (0, 0) \in C \). Let \( R := k[X, Y, Z], A := R/(Y^2 - X^2 - X^3); \) denote by \( \pi : A_2^\wedge := \text{Spec} R \to A_2^\wedge \) the linear projection which is dual to the inclusion \( k[X, Y] \to R \), so that \( D := \pi^{-1} C = \text{Spec} A \). We define a morphism \( \varphi : A_2^\wedge := \text{Spec} k[T] \to D \) by the rule: \( T \mapsto (T^2 - 1, T(T^2 - 1), T) \) (i.e. \( \varphi \) is dual to the homomorphism of \( k \)-algebras such that \( X \mapsto T^2 - 1, Y \mapsto T(T^2 - 1) \) and \( Z \mapsto T \)). Let \( C' \subset D \) be the image of \( \varphi \), with its reduced subscheme structure. It is easy to check that the restriction of \( \pi \) maps \( C' \) birationally onto \( C \), so there are precisely two points \( p_0, p_1 \in C' \) lying over \( p \). Let \( n := I(C') \subset A \), the prime ideal which is the generic point of the (irreducible) curve \( C' \). We claim that the \( n \)-preadic topology on \( A \) does not agree with the \( n \)-symbolic topology. To this aim – in view of theorem 10.5.35 – it suffices to show that \( \{ p_0, p_1 \} \subset \text{Ass}_A(n, A) \). However, for any closed point \( p \in \pi^{-1}(p) \), the \( p \)-adic completion \( A_p^\wedge \) admits two distinct minimal primes, corresponding to the two branches of the nodal conic \( C \) at the node \( p \), and the corresponding irreducible components of \( B := \text{Spec} A_p^\wedge \) meet along the affine line \( V(Z) \). To see this, we may suppose that \( p = (X, Y, Z) \), hence \( A_p^\wedge \simeq k[[X, Y, Z]]/(Y^2 - X^2(1 + X)) \), and notice that the latter is isomorphic to \( k[[S, Y, Z]]/(Y^2 - S^2) \), via the isomorphism that sends \( Y \mapsto Y, Z \mapsto Z \) and \( S \mapsto X(1 + X)^{1/2} \) (the assumption on the characteristic of \( k \) ensures that \( 1 + X \) admits a square root in \( k[[X]] \)). Now, say that \( p = p_0 \); then \( C'_p := C' \cap B \) is contained in only one of the two irreducible components of \( B \). Let \( q \in B \) be the minimal prime ideal whose closure does not contain \( C'_p \); then \( q \in \text{Ass}_A(n, A) \) and \( \{ q \} \cap C'_p = \{ p A_p^\wedge \} \), therefore \( p_0 \notin \text{Ass}_A(n, A) \), as stated.
Example 10.5.41. Let $A$ be an excellent normal ring, $I \subset A$ any ideal, and set $Z := V(I)$. Then $\text{Ass}_A(I, A)$ is the set $\text{Max}(Z)$ of all maximal points of $Z$. Indeed, $\text{Max}(Z) \subset \text{Ass}_A(I, A)$ by Lemma 10.5.32(v). Conversely, suppose $p \in \text{Ass}_A(I, A)$; the completion $A_p^\wedge$ is still normal ([100] Th.32.2(i)), and therefore its only associated prime is $0$, so the assumption means that the radical of $IA_p^\wedge$ is $pA_p^\wedge$. Equivalently, $\dim A_p^\wedge/IA_p^\wedge = 0$, so $\dim A_p/IA_p = 0$, which is the contention.

Definition 10.5.42. Let $X$ be a noetherian scheme, $Y \subset X$ a closed subset, $\mathcal{X}$ the formal completion of $X$ along $Y$ ([44] Ch.I, §10.8), and $f : \mathcal{X} \to X$ the natural morphism of locally ringed spaces. We say that the pair $(X, Y)$ satisfies the Lefschetz condition, if for every open subset $U \subset X$ with $Y \subset U$, and every locally free $\mathcal{O}_U$-module $\mathcal{E}$ of finite type, the natural map

$$\Gamma(U, \mathcal{E}) \to \Gamma(\mathcal{X}, f^*\mathcal{E})$$

is an isomorphism. In this case, we also say that $\text{Lef}(X, Y)$ holds. (Cp. [68] Exp.X, §2.)

Lemma 10.5.43. In the situation of definition 10.5.42, suppose that $\text{Lef}(X, Y)$ holds, and let $U \subset X$ be any open subset such that $Y \subset U$. Then:

(i) The functor:

$$\mathcal{O}_U^\text{-Mod}_{\text{lift}} \to \mathcal{O}_X^\text{-Mod}_{\text{lift}} : \mathcal{E} \mapsto f^*\mathcal{E}$$

is fully faithful (notation of (10.3)).

(ii) Denote by $\mathcal{O}_U^\text{-Alg}_{\text{lift}}$ the category of $\mathcal{O}_U$-algebras, whose underlying $\mathcal{O}_U$-module is locally free of finite type, and define likewise $\mathcal{O}_X^\text{-Alg}_{\text{lift}}$. Then the functor:

$$\mathcal{O}_U^\text{-Alg}_{\text{lift}} \to \mathcal{O}_X^\text{-Alg}_{\text{lift}} : \mathcal{A} \mapsto f^*\mathcal{A}$$

is fully faithful.

Proof. (i): Let $\mathcal{E}$ and $\mathcal{F}$ be any two locally free $\mathcal{O}_U$-modules of finite type. We have:

$$\text{Hom}_{\mathcal{O}_U}(\mathcal{E}, \mathcal{F}) = \Gamma(U, \text{Hom}_{\mathcal{O}_U}(\mathcal{E}, \mathcal{F}))$$

and likewise we may compute $\text{Hom}_{\mathcal{O}_U}(f^*\mathcal{E}, f^*\mathcal{F})$. However, the natural map:

$$f^*\text{Hom}_{\mathcal{O}_U}(\mathcal{E}, \mathcal{F}) \to \text{Hom}_{\mathcal{O}_X}(f^*\mathcal{E}, f^*\mathcal{F})$$

is an isomorphism of $\mathcal{O}_X$-modules. The assertion follows.

(ii): An object of $\mathcal{O}_U^\text{-Alg}_{\text{lift}}$ is a locally free $\mathcal{O}_U$-module $\mathcal{A}$ of finite type, together with morphisms $\mathcal{A} \otimes_{\mathcal{O}_U} \mathcal{A} \to \mathcal{A}$ and $1_{\mathcal{A}} : \mathcal{O}_U \to \mathcal{A}$ of $\mathcal{O}_U$-modules, fulfilling the usual unitarity, commutativity and associativity conditions. An analogous description holds for the objects of $\mathcal{O}_X^\text{-Alg}_{\text{lift}}$, and for the morphisms of either category. Since $\mathcal{A} \otimes_{\mathcal{O}_U} \mathcal{A}$ is again locally free of finite type, the assertion follows easily from (i): the details are left to the reader.

Lemma 10.5.44. Let $A$ be a noetherian ring, $I \subset A$ an ideal, $U \subset \text{Spec } A$ an open subset, $\mathfrak{U}$ the formal completion of $U$ along $U \cap V(I)$. Consider the following conditions:

(a) $\text{Lef}(U, U \cap V(I))$ holds.

(b) The natural map $\rho_U : \Gamma(U, \mathcal{O}_U) \to \Gamma(\mathfrak{U}, \mathcal{O}_\mathfrak{U})$ is an isomorphism.

(c) The natural map $\rho : A \to \Gamma(\mathfrak{U}, \mathcal{O}_\mathfrak{U})$ is an isomorphism.

Then (c)$\Rightarrow$(b)$\Leftrightarrow$(a), and (c) implies that $A$ is $I$-adically complete.

Proof. Clearly (a)$\Rightarrow$(b), hence we assume that (b) holds, and we show (a). Let $V \subset U$ be an open subset with $U \cap V(I) \subset V$ and $\mathcal{E}$ a coherent locally free $\mathcal{O}_V$-module. As $A$ is noetherian, $V$ is quasi-compact, so we may find a left exact sequence $\mathcal{P}_* := (0 \to \mathcal{E} \to \mathcal{O}_V^{\oplus m} \to \mathcal{O}_V^{\oplus m})$ of $\mathcal{O}_V$-modules (corollary 10.3.26). Since the natural map of locally ringed spaces $f : \mathfrak{U} \to U$ is
flat, the sequence \( f^* \mathcal{P} \) is still left exact. Since the global section functors are left exact, there follows a ladder of left exact sequences:

\[
\Gamma(V, \mathcal{P}_*) \to \Gamma(U, f^* \mathcal{P}_*)
\]

which reduces the assertion to the case where \( \mathcal{E}' = \mathcal{O}_V \); the latter is covered by the following:

**Claim 10.5.45.** The natural map \( \rho_V : \Gamma(V, \mathcal{O}_V) \to \Gamma(U, \mathcal{O}_U) \) is an isomorphism.

**Proof of the claim.** The isomorphism \( \rho_V \) factors through \( \rho_V \), hence the latter is a surjection. Suppose that \( s \in \text{Ker} \rho_V \), and \( s \neq 0 \); then we may find \( x \in V \) such that the image \( s_x \) of \( s \) in \( \mathcal{O}_{V,x} \) does not vanish. Moreover, we may find \( a \in A \) whose image \( a(x) \) in \( \kappa(x) \) does not vanish, and such that \( as \) is the restriction of an element of \( A \); especially, \( as \in \Gamma(U, \mathcal{O}_U) \), and clearly the image of \( as \) in \( \Gamma(V, \mathcal{O}_V) \) lies in \( \text{Ker} \rho_V \). Therefore, \( as = 0 = \Gamma(U, \mathcal{O}_U) \); however the image \( as_x \) of \( as \) in \( \mathcal{O}_{U,x} \) is non-zero by construction, a contradiction. This shows that \( \rho_V \) is injective, whence the claim. \( \blacklozenge \)

Finally, suppose that (c) holds; arguing as in the proof of claim [10.5.45], one sees that \( \rho_U \) is an isomorphism. Moreover, since \( \Gamma(U, \mathcal{O}_U) \simeq \varprojlim_{n \in \mathbb{N}} \Gamma(U, \mathcal{O}_U/I^n \mathcal{O}_U) \), the morphism \( \rho \) factors through the natural \( A \)-linear map \( \iota : A \to A^\wedge \) to the \( I \)-adic completion of \( A \). The composition with \( \rho_i \) yields an \( A \)-linear left inverse \( s : A^\wedge \to A \) to \( i \). Set \( N := \ker s \); clearly \( s \) is surjective, hence \( A^\wedge \simeq A \oplus N \). It follows easily that \( N/I^n N = 0 \) for every \( n \in \mathbb{N} \), especially \( N \subset \bigcap_{n \in \mathbb{N}} I^n A^\wedge \). Therefore \( N = 0 \), since \( A^\wedge \) is separated for the \( I \)-adic topology. \( \square \)

**Proposition 10.5.46.** Let \( \varphi : A \to B \) be a flat homomorphism of noetherian rings, \( I \subset A \) an ideal, \( U \subset \text{Spec} B \) an open subset. Set \( f := \text{Spec} \varphi : \text{Spec} B \to \text{Spec} A \), and assume that:

(a) \( B \) is complete for the \( IB \)-adic topology.
(b) For every \( x \in V(I) \), we have : \( \{ y \in f^{-1}(x) \mid \delta(y, \mathcal{O}_{f^{-1}(x)}) = 0 \} \subset U \).
(c) For every \( x \in \text{Ass}_A(I, A) \), we have : \( \{ y \in f^{-1}(x) \mid \delta(y, \mathcal{O}_{f^{-1}(x)}) \leq 1 \} \subset U \).

Then \( \text{Lef}(U, U \cap V(IB)) \) holds.

**Proof.** Set \( \Sigma := \text{Ass}_A(I, A) \), and let \( U \) be the formal completion of \( U \) along \( V(IB) \); by theorem [10.5.35], the \( I \)-adic topology on \( A \) agrees with the \( \Sigma \)-symbolic topology. Let also \( \mathcal{J} \) be the family consisting of all ideals \( J \subset A \) such that \( \text{Ass} A/J \subset \Sigma \); it follows that the natural maps:

\[
B \to \varprojlim_{j \in \mathcal{J}} B/IB, \quad \Gamma(U, \mathcal{O}_U) \to \varprojlim_{j \in \mathcal{J}} \Gamma(U, \mathcal{O}_U/J \mathcal{O}_U)
\]

are isomorphisms (see the discussion in [10.5.26]). In view of lemma [10.5.44] we are then reduced to showing:

**Claim 10.5.47.** The natural map \( B/IB \to \Gamma(U, \mathcal{O}_U/J \mathcal{O}_U) \) is an isomorphism for every \( J \in \mathcal{J} \).

**Proof of the claim.** Let \( f : Y := \text{Spec} B/IB \to X := \text{Spec} A/J \) be the induced morphism; in view of corollary [10.4.23], it suffices to prove that \( \delta(y, \mathcal{O}_Y) \geq 2 \) whenever \( y \in Y \setminus U \). Thus, set \( x := f(y) \); by corollary [10.4.47] we have:

\[
\delta(y, \mathcal{O}_Y) = \delta(y, \mathcal{O}_{f^{-1}(x)}) + \delta(x, \mathcal{O}_X).
\]

Now, if \( \delta(x, \mathcal{O}_X) = 1 \), notice that \( f(Y) \subset V(J) \subset V(I) \), by lemmata [10.5.3(i)] and [10.5.32(iii)]; hence (b) implies the contention in this case. Lastly, if \( \delta(x, \mathcal{O}_X) = 0 \), then \( x \in \text{Ass} A/J \) by proposition [10.5.6], hence we use assumption (c) to conclude. \( \square \)

10.6. **Cohomology of projective schemes.** We begin by recalling a few generalities on graded algebras and their homogeneous prime spectra; next we define the blow up of a scheme along a quasi-coherent sheaf of ideals, and we prove some basic results on the higher direct images of quasi-coherent modules under blow up morphisms.
10.6.1. Let \( A := \oplus_{n \in \mathbb{N}} A_n \) be a \( \mathbb{N} \)-graded ring, and set \( A_+ := \oplus_{n \geq 0} A_n \), which is an ideal of \( A \). Following \cite{45} Ch.II, (2.3.1), one denotes by \( \text{Proj} A \) the set consisting of all graded prime ideals of \( A \) that do not contain \( A_+ \), and one endows \( \text{Proj} A \) with the topology induced from the Zariski topology of \( \text{Spec} A \). For every homogeneous element \( f \in A_+ \), set:

\[
D_+(f) := D(f) \cap \text{Proj} A
\]

where as usual, \( D(f) := \text{Spec} A_f \subset \text{Spec} A \). Clearly:

\[
D_+(fg) = D_+(f) \cap D_+(g) \quad \text{for every homogeneous } f, g \in A_+.
\]

The system of open subsets \( D_+(f) \), for \( f \) ranging over the homogeneous elements of \( A_+ \), is a basis of the topology of \( \text{Proj} A \) \((\cite{45} \text{Ch.II, Prop.2.3.4})\), and obviously any system of homogeneous generators \( \{f_\lambda \mid \lambda \in \Lambda\} \) for the ideal \( A_+ \) yields an open covering

\[
\text{Proj} A = \bigcup_{\lambda \in \Lambda} D_+(f_\lambda).
\]

For any homogeneous element \( f \in A_+ \), let also \( A(f) \subset A_f \) be the subring consisting of all elements of degree zero (for the natural \( \mathbb{Z} \)-grading of \( A_f \)); in other words:

\[
A(f) := \sum_{k \in \mathbb{N}} A_k \cdot f^{-k} \subset A_f.
\]

The topological space \( \text{Proj} A \) carries a sheaf of rings \( \mathcal{O} \), with isomorphisms of ringed spaces:

\[
\omega_f : (D_+(f), \mathcal{O}_{D_+(f)}) \xrightarrow{\sim} \text{Spec} A_f \quad \text{for every homogeneous } f \in A_+.
\]

and the system of isomorphisms \( \omega_f \) is compatible, in an obvious way, with the inclusions:

\[
j_{fg} : D_+(fg) \subset D_+(f)
\]

as in \((10.6.2)\), and with the natural homomorphisms \( A_f \to A(f_g) \). Especially, the locally ringed space \((\text{Proj} A, \mathcal{O})\) is a separated scheme.

**Example 10.6.3.** For any \( d \in \mathbb{N} \), and any ring \( R \), take \( A := R[T_0, \ldots, T_d] \), endowed with its standard \( \mathbb{N} \)-grading such that \( \text{gr}_n A \) is the \( R \)-module generated by the monomials of total degree \( n \), for every \( n \in \mathbb{N} \). The scheme \( \text{Proj} A \) is the projective \( d \)-dimensional space over \( \text{Spec} R \), denoted

\[
\mathbb{P}^d_R.
\]

According to \((10.6.1)\), it admits the standard covering \( \mathbb{P}_R^d = \bigcup_{i=0}^d D_+(T_i) \). Set as well

\[
\tau_{ij} := T_j/T_i \quad \text{for every } i, j = 0, \ldots, n.
\]

Then clearly \( A_i := A(\tau_{ij}) = R[\tau_{ij} \mid j = 0, \ldots, d] \) is a free polynomial \( R \)-algebra in \( d \) variables, so that \( U_i := D_+(T_i) \) is isomorphic to the \( d \)-dimensional affine space \( \mathbb{A}^d_R \) over \( \text{Spec} R \), for every \( i = 0, \ldots, d \). For \( i \neq j \), the intersection \( U_{ij} := D_+(T_iT_j) = U_i \cap U_j \) corresponds, under these identifications, to the open subsets

\[
\text{Spec} A_i[\tau_{ij}^{-1}] \subset U_i \quad \text{and} \quad \text{Spec} A_j[\tau_{ji}^{-1}] \subset U_j
\]

so we get a commutative diagram of isomorphisms of \( R \)-algebras

\[
\mathcal{O}_{\mathbb{P}^d_R}(U_{ij}) \quad \xrightarrow{A_i[\tau_{ij}^{-1}]} \quad A_j[\tau_{ji}^{-1}]
\]

whose downward arrows are induced by the maps \( \omega_{T_i} \) and \( \omega_{T_j} \) of \((10.6.1)\), and where the horizontal arrow is given by the rule:

\[
\tau_{ik} \mapsto \tau_{jk} \cdot \tau_{ij}^{-1} \quad \text{for every } k = 0, \ldots, d.
\]
10.6.5. Let \( A' := \oplus_{n \in \mathbb{N}} A'_n \) be another \( \mathbb{N} \)-graded ring, and \( \varphi : A \to A' \) a homomorphism of graded rings (i.e. \( \varphi(A_n) \subseteq A'_n \) for every \( n \in \mathbb{N} \)). Following \([45]\) Ch.II, (2.8.1)), we let:

\[
G(\varphi) := \text{Proj} A' \setminus \text{V}(\varphi(A_+)).
\]

This open subset of \( \text{Proj} A' \) is also the same as the union of all the open subsets of the form \( D_+(\varphi(f)) \), where \( f \) ranges over the homogeneous elements of \( A_+ \). The restriction to \( G(\varphi) \) of \( \text{Spec} \varphi : \text{Spec} A' \to \text{Spec} A \), is a continuous map \( a\varphi : G(\varphi) \to \text{Proj} A \). Moreover, we have the identity:

\[
a\varphi^{-1}(D_+(f)) = D_+(\varphi(f)) \quad \text{for every homogeneous } f \in A_+.
\]

Furthermore, the homomorphism \( \varphi \) induces a homomorphism \( \varphi(f) : A(f) \to A'(\varphi(f)) \), whence a morphism of schemes:

\[
\Phi_f : D_+(\varphi(f)) \to D_+(f).
\]

Let \( g \in A_+ \) be another homogeneous element; it is easily seen that:

\[
j_{f,g} \circ \Phi_{fg} = (\Phi_f)|_{D_+(\varphi(f))}.
\]

It follows that the locally defined morphisms \( \Phi_f \) glue to a unique morphism of schemes:

\[
\text{Proj} \varphi : G(\varphi) \to \text{Proj} A
\]

such that the diagram of schemes:

\[
\begin{array}{ccc}
\text{Spec} A'(\varphi(f)) & \xrightarrow{\omega_{\varphi(f)}} & \text{Spec} A(f) \\
\downarrow & & \downarrow \varphi_f \\
D_+(\varphi(f)) & \xrightarrow{(\text{Proj} \varphi)|_{D_+(\varphi(f))}} & D_+(f)
\end{array}
\]

commutes for every homogeneous \( f \in A_+ \) (\([45]\) Ch.II, Prop.2.8.2)). Lastly, we remark that, for every homogeneous element \( f'' \in A'_+ \), the open subset \( D_+(f'') \) lies in \( G(\varphi) \) if and only if \( f'' \) lies in the radical of the ideal of \( A' \) generated by \( \varphi(A_+) \) (\([45]\) Ch.II, Cor.2.3.15)). Especially, \( G(\varphi) = \text{Proj} A' \) whenever \( \varphi(A_+) \) generates the ideal \( A'_+ \).

10.6.7. To ease notation, set \( Y := \text{Proj} A \). Let \( M := \oplus_{n \in \mathbb{Z}} M_n \) be a \( \mathbb{Z} \)-graded \( A \)-module (i.e. \( A_k \cdot M_n \subseteq M_{k+n} \) for every \( k \in \mathbb{N} \) and \( n \in \mathbb{Z} \); for every homogeneous \( f \in A_+ \), denote by \( M_f \subseteq M \) the submodule consisting of all elements of degree zero (for the natural \( \mathbb{Z} \)-grading of \( M_f \)). Clearly \( M_f \) is an \( A_f \)-module in a natural way, whence a quasi-coherent \( \mathcal{O}_{D_+(f)} \)-module \( M_f \); these modules glue to a unique quasi-coherent \( \mathcal{O}_Y \)-module \( M^\sim \) (\([45]\) Ch.II, Prop.2.5.2)). Especially, for every \( n \in \mathbb{Z} \), let \( A(n) \) be the \( \mathbb{Z} \)-graded \( A \)-module such that \( A(n)_k := A_{n+k} \) for every \( k \in \mathbb{Z} \) (with the convention that \( A_k = 0 \) if \( k < 0 \)). We set:

\[
\mathcal{O}_Y(n) := A(n)^\sim.
\]

Any element \( f \in A_n \) induces a natural isomorphism of \( D_+(f) \)-modules:

\[
\mathcal{O}_Y(n)|_{D_+(f)} \xrightarrow{\sim} \mathcal{O}_{D_+(f)}
\]

(\([45]\) Ch.II, Prop.2.5.7)). Hence, on the open subset

\[
U_n(A) := \bigcup_{f \in A_n} D_+(f)
\]

the sheaf \( \mathcal{O}_Y(n) \) restricts to an invertible \( \mathcal{O}_{U_n(A)} \)-module. Especially, if \( A_1 \) generates the ideal \( A_+ \), the \( \mathcal{O}_Y \)-modules \( \mathcal{O}_Y(n) \) are invertible, for every \( n \in \mathbb{Z} \).
Example 10.6.8. Resume the notation of example [10.6.3] A direct inspection of the definitions shows that $A(n)_{(T_i)}$ is the $A_i$-module generated by all fractions of the form $T_0^{r_0} T_1^{r_1} \cdots T_d^{r_d} T_i^{-k}$, for every $k \in \mathbb{N}$ and every $(r_0, \ldots, r_d) \in \mathbb{N}^{d+1}$ such that $r_0 + r_1 + \cdots + r_d = n + k$. In other words, $A(n)_{(T_i)}$ is the $A_i$-submodule of $A(n)_{T_i}$ generated by $T_i^n$. We see then directly that this is a free $A_i$-module of rank one. Moreover, we get a commutative diagram of isomorphisms

$$\begin{align*}
\mathcal{O}_{P^d_R}(n)(U_{ij}) & \to T_i^n A_i[\tau_{ij}^{-1}] \\
& \to T_j^n A_j[\tau_{ji}^{-1}]
\end{align*}$$

whose downward arrows are induced by the restriction maps of the sheaf $\mathcal{O}_{P^d_R}(n)$, and where the horizontal map is the $A_i[\tau_{ij}^{-1}]$-linear map given by the rule

$$T_i^n \to T_j^n \cdot \tau_{ji}^n$$

and where the $A_i[\tau_{ij}^{-1}]$-module structure of $T_j^n A_j[\tau_{ji}^{-1}]$ is defined by restriction of scalars along the isomorphism $A_i[\tau_{ij}^{-1}] \xrightarrow{\sim} A_j[\tau_{ji}^{-1}]$ as in (10.6.4).

10.6.9. In the situation of (10.6.5), let $M := \bigoplus_{n \in \mathbb{Z}} M_n$ be a $\mathbb{Z}$-graded $A$-module. Then $M' := M \otimes A A'$ is a $\mathbb{Z}$-graded $A'$-module, with the grading defined by the rule:

$$M'_n := \sum_{j+k=n} \text{Im}(M_j \otimes \mathbb{Z} A_k' \to M') \quad \text{for every } n \in \mathbb{Z}$$

([45, Ch.II, (2.1.2)]). Then [45, Ch.II, Prop.2.8.8] yields a natural morphism of $\mathcal{O}_{G(\varphi)}$-modules:

$$\nu_M : (\text{Proj } \varphi)^* M^\sim \to (M')_{\sim G(\varphi)}.$$

Moreover, set:

$$G_1(\varphi) := \bigcup_{f \in A_1} D_+(\varphi(f))$$

and notice that $G_1(\varphi) \subset U_1(A') \cap G(\varphi)$; by inspecting the proof of loc.cit. we see that the restriction $\nu_M|_{G_1(\varphi)}$ is an isomorphism. Especially, $\nu_M$ is an isomorphism whenever $A_1$ generates the ideal $A_+$. It is also easily seen that $G_1(\varphi) = U_1(A')$ if $\varphi(A_+)$ generates $A_+'$.

For any $f \in A_1$, the restriction $(\nu_M)|_{D_+(\varphi(f))}$ can be described explicitly: namely, we have natural identifications

$$\omega_f^*(M|_{D_+(\varphi(f))}) \xrightarrow{\sim} M_{\sim f} \quad \omega_{\varphi(f)}^*(M'|_{D_+(\varphi(f))}) \xrightarrow{\sim} (M'|_{\sim \varphi(f)})$$

and in view of (10.6.6), the morphism $(\nu_M)|_{D_+(\varphi(f))}$ is induced by the $A'_+(\varphi(f))$-linear map:

$$M(f) \otimes_{A(f)} A'_+(\varphi(f)) \to M'_{\sim \varphi(f)}$$

given by the rule:

$$(m_k \cdot f^{-k}) \otimes (a_j' \cdot \varphi(f)^{-j}) \mapsto (m_k \otimes a_j') \cdot \varphi(f)^{-j-k} \quad \text{for all } k, j \in \mathbb{Z}, m_k \in M_k, a_j' \in A_j'.$$

10.6.10. The foregoing results can be improved somewhat, in the following special situation. Let $R \to R'$ be a ring homomorphism, $A$ a $\mathbb{N}$-graded $R$-algebra (hence the structure morphism $R \to A$ is a ring homomorphism $R \to A_0$); the ring $A' := R' \otimes_R A$ is naturally a $\mathbb{N}$-graded $R'$-algebra, and the induced map $\varphi : A \to A'$ is a homomorphism of graded rings. In this case, obviously $\varphi(A_+)$ generates the ideal $A'_+$, hence $G(\varphi) = \text{Proj } A'$, and indeed, $\text{Proj } \varphi$ induces an isomorphism of $\text{Spec } R'$-schemes:

$$Y' \xrightarrow{\sim} \text{Spec } R' \times_{\text{Spec } R} Y.$$
where again $Y := \text{Proj} A$ and $Y' := \text{Proj} A'$. Moreover, for every $\mathbb{Z}$-graded $A$-module $M$, the corresponding morphism $\nu_M$ is an isomorphism, regardless of whether or not $A_1$ generates $A_+$ ([45, Ch.II, Prop.2.8.10]). Especially, $\nu_{A(n)}$ is a natural identification ([45, Ch.II, Cor.2.8.11]):

$$\nu_{A(n)} = \text{Proj} \varphi^* \mathcal{O}_Y(n) \sim \mathcal{O}_{Y'}(n) \quad \text{for every } n \in \mathbb{Z}.$$

10.6.11. Keep the notation of (10.6.1), and for every integer $d > 0$, set

$$A_n^{(d)} := A_{nd} \quad \text{for every } n \in \mathbb{N}, \quad A^{(d)} := \bigoplus_{n \in \mathbb{N}} A_n^{(d)}.$$

Clearly $A^{(d)}$ is an $\mathbb{N}$-graded ring, and a subring of $A$, but the inclusion map $j : A^{(n)} \to A$ is not a homomorphism of $\mathbb{N}$-graded rings. However, for every homogeneous element $f \in A_+$, the map $j$ induces a natural identification of $A$-algebras:

$$j^{(d)}(f) : A^{(d)} \to \text{Proj} A \sim \text{Proj} A^{(d)} \quad \text{for every } d > 0.$$

To ease notation, we shall let $Y := \text{Proj} A$ and $Y^{(d)} := \text{Proj} A^{(d)}$ for every integer $d > 0$. Likewise, if $M$ is any $\mathbb{Z}$-graded $A$-module, we may consider that $\mathbb{Z}$-graded $A^{(d)}$-module $M^{(d)}$ whose homogeneous direct summand of degree $n$ equals $M_{nd}$, for every $n \in \mathbb{Z}$. Then the inclusion map $M^{(d)} \to M$ induces natural identifications

$$M^{(d)} \to M \quad \text{for every homogeneous element } f \in A.$$

Indeed, it is easily seen that this map is surjective, and it is injective, since it is the restriction of the injective map $M^{(d)}_{f^d} \to M_{f^d}$. Moreover, if we endow $M_{f^d}$ with the $A^{(d)}_{f^d}$-module structure induced by (10.6.12), it is easily seen that (10.6.13) is an isomorphism of $A^{(d)}_{f^d}$-modules. Thus, we obtain a natural isomorphism of quasi-coherent $\mathcal{O}_{Y^{(d)}}$-modules

$$M^{(d)} \sim \Omega^{(d)} M \sim \Omega^{(d)} M^{(d)}.$$

Next, for every $n \in \mathbb{Z}$, let $M(n)$ be the $\mathbb{Z}$-graded $A$-module such that $M(n)_k := M_{n+k}$ for every $k \in \mathbb{Z}$ (with $A$-module structure deduced from that of $M$, in the obvious way). Clearly

$$M^{(d)}(n) = M^{(d)}(n) \quad \text{for every } n \in \mathbb{Z} \text{ and every } d > 0$$

whence an induced isomorphism of quasi-coherent $\mathcal{O}_{Y^{(d)}}$-modules

$$M^{(d)}(n) \sim \Omega^{(d)} M^{(d)}(n) \sim \Omega^{(d)} M^{(d)} \sim \Omega^{(d)} M^{(d)}.$$

Especially, we have a natural identification

$$\nu_{Y^{(d)}}(n) \sim \Omega^{(d)} \mathcal{O}_Y(n) \quad \text{for every } n \in \mathbb{Z} \text{ and every } d > 0.$$

10.6.15. Let $X$ be a scheme, $\mathcal{A} := \bigoplus_{n \in \mathbb{N}} \mathcal{A}_n$ a $\mathbb{N}$-graded quasi-coherent $\mathcal{O}_X$-algebra on the Zariski site of $X$; we let $\mathcal{A}_+ := \bigoplus_{n > 0} \mathcal{A}_n$. According to [45, Ch.II, Prop.3.1.2], there exists an $X$-scheme $\pi : \text{Proj} \mathcal{A} \to X$, with natural isomorphisms of $U$-schemes:

$$\psi_U : U \times_X \text{Proj} \mathcal{A} \sim \text{Proj} \mathcal{A}(U)$$

for every affine open subset $U \subset X$, and the system of isomorphisms $\psi_U$ is compatible, in an obvious way, with inclusions $U' \subset U$ of affine open subsets. Especially, $\pi$ is a separated morphism. For any integer $d > 0$, every $f \in \Gamma(X, \mathcal{A}_d)$ defines an open subset $D_+(f) \subset \text{Proj} \mathcal{A}$, such that:

$$D_+(f) \cap \pi^{-1} U = D_+(f|_U) \subset \text{Proj} \mathcal{A}(U) \quad \text{for every affine open subset } U \subset X.$$
10.6.16. To ease notation, set $Y := \text{Proj} \mathcal{A}$, and let again $\pi : Y \to X$ be the natural morphism. Let $\mathcal{M} := \bigoplus_{n \in \mathbb{Z}} \mathcal{M}_n$ be a $\mathbb{Z}$-graded $\mathcal{A}$-module, quasi-coherent as a $O_X$-module; for every affine open subset $U \subset X$, the graded $\mathcal{A}(U)$-module $\mathcal{M}(U)$ yields a quasi-coherent $O_{\pi^{-1}(U)}$-module $\mathcal{M}_U$, and every inclusion of affine open subsets $U' \subset U$ induces a natural isomorphism of $O_{\pi^{-1}(U')}$-modules: $\mathcal{M}_{U'} \simto \mathcal{M}_U$. Therefore the locally defined modules $\mathcal{M}_U$ glue to a well defined quasi-coherent $O_Y$-module $\mathcal{M}^\sim$.

Especially, for every $n \in \mathbb{Z}$, denote by $\mathcal{A}(n)$ the $\mathbb{Z}$-graded $\mathcal{A}$-module such that $\mathcal{A}(n)_k := \mathcal{A}_{n+k}$ for every $k \in \mathbb{Z}$, with the convention that $\mathcal{A}_n = 0$ whenever $n < 0$. We set:

$$\mathcal{O}_Y(n) := \mathcal{A}(n)^\sim \quad \text{and} \quad \mathcal{M}(n)^\sim := \mathcal{M}^\sim \otimes_{O_Y} \mathcal{O}_Y(n).$$

Denote by $U_n(\mathcal{A}) \subset Y$ the union of the open subsets $U_n(\mathcal{A}(U))$, for $U$ ranging over the affine open subsets of $X$: from the discussion in (10.6.7), it clear that the restriction $\mathcal{O}_Y(n)|_{U_n(\mathcal{A})}$ is an invertible $\mathcal{O}_{U_n(\mathcal{A})}$-module. This open subset can be described as follows. For every $x \in X$, let:

$$\mathcal{A}_n(x) := \mathcal{A}_{n,x} \otimes \kappa(x) \quad \text{and set} \quad \mathcal{A}(x) := \bigoplus_{n \in \mathbb{Z}} \mathcal{A}_n(x)$$

which is a $\mathbb{N}$-graded $\kappa(x)$-algebra; then:

$$U_n(\mathcal{A}) = \{ y \in Y \mid \mathcal{A}_n(\pi(y)) \nsubseteq \mathfrak{p}(y) \}$$

where $\mathfrak{p}(y) \subset \mathcal{A}(\pi(y))$ denotes the prime ideal corresponding to the point $y$.

10.6.19. Moreover, for every $\mathbb{Z}$-graded $\mathcal{A}$-module $\mathcal{M}$, and every $n \in \mathbb{Z}$, there exists a natural morphism of $\mathcal{O}_Y$-modules:

$$\mathcal{M}(n)^\sim : \to \mathcal{M}(n)^\sim$$

where $\mathcal{M}(n)$ is the $\mathbb{Z}$-graded $\mathcal{A}$-module given by the rule: $\mathcal{M}(n)_k := \mathcal{M}_{n+k}$ for every $k \in \mathbb{N}$ ([45, Prop.3.2.16]). The restriction of (10.6.20) to the open subset $U_1(\mathcal{A})$ is an isomorphism ([45, Ch.II, Cor.3.2.8]). Especially, we have natural morphisms of $\mathcal{O}_Y$-modules:

$$\mathcal{O}_Y(n) \otimes_{\mathcal{O}_Y} \mathcal{O}_Y(m) \to \mathcal{O}_Y(n + m) \quad \text{for every} \ n, m \in \mathbb{Z}$$

([45, Ch.II, Prop.3.2.6]) whose restrictions to $U_1(\mathcal{A})$ are isomorphisms. Furthermore, we have a natural morphism $\mathcal{M}_0 \to \mathcal{M}^\sim$ of $\mathcal{O}_X$-modules ([45, Ch.II, (3.3.2.1)]), whence, by adjunction, a morphism of $\mathcal{O}_Y$-modules:

$$\pi^* \mathcal{M}_0 \to \mathcal{M}^\sim.$$

Applying (10.6.22) to the modules $\mathcal{M}_n = \mathcal{M}(n)_0$, and taking into account the isomorphism (10.6.20), we deduce a natural morphism of $\mathcal{O}_{U_1(\mathcal{A})}$-modules:

$$(\pi^* \mathcal{M}_n)_{|U_1(\mathcal{A})} \to \mathcal{M}^\sim(n)_{|U_1(\mathcal{A})}$$

which can be described as follows. Let $U \subset X$ be any affine open subset; for every $f \in \mathcal{A}_1(U)$, the restriction of (10.6.23) to $D_+(f) \subset \pi^{-1}U$ is given by the morphisms

$$\mathcal{M}_n(U) \otimes_{\mathcal{O}_X(U)} \mathcal{A}(f) \to \mathcal{M}(n)(U)(f) := \sum_{k \in \mathbb{Z}} \mathcal{M}_{k+n}(U) \cdot f^{-k} \subset \mathcal{M}(U)$$

induced by the scalar multiplication $\mathcal{M}_n \otimes_{\mathcal{O}_X} \mathcal{A}_k \to \mathcal{M}_{n+k}$. Especially, we have natural morphisms of $\mathcal{O}_Y$-modules:

$$\pi^* \mathcal{A}_n \to \mathcal{O}_Y(n) \quad \text{for every} \ n \in \mathbb{N}$$
whose restrictions to $U_1(\mathcal{A})$ are epimorphisms. An inspection of the definition also shows that the diagram of $\mathcal{O}_Y$-modules:

$$
\begin{array}{ccc}
\pi^* \mathcal{A}_n \otimes_{\mathcal{O}_Y} \pi^* \mathcal{A}_m & \longrightarrow & \pi^* \mathcal{A}_{n+m} \\
\downarrow & & \downarrow \\
\mathcal{O}_Y(n) \otimes_{\mathcal{O}_Y} \mathcal{O}_Y(m) & \longrightarrow & \mathcal{O}_Y(n + m)
\end{array}
$$

(10.6.25)

commutes for every $n, m \in \mathbb{N}$, where the top horizontal arrow is induced by the graded multiplication $\mathcal{A}_n \otimes_{\mathcal{O}_X} \mathcal{A}_m \to \mathcal{A}_{n+m}$, the vertical arrows are the maps (10.6.24), and the bottom horizontal arrow is the map (10.6.21).

10.6.26. Next, let $\mathcal{A}' := \bigoplus_{n \in \mathbb{N}} \mathcal{A}'_n$ be another $\mathbb{N}$-graded quasi-coherent $\mathcal{O}_X$-algebra on the Zariski site of $X$, and $\varphi : \mathcal{A} \to \mathcal{A}'$ a morphism of graded $\mathcal{O}_X$-algebras; for every affine open subset $U \subset X$, we deduce a morphism $\varphi_U : \mathcal{A}(U) \to \mathcal{A}'(U)$ of graded $\mathcal{O}_X(U)$-algebras, whence an open subset $G(\varphi_U) \subset \text{Proj} \mathcal{A}'(U)$ as in (10.6.5). If $V \subset U$ is a smaller affine open subset, the natural isomorphism

$$V \times_U \text{Proj} \mathcal{A}'(U) \xrightarrow{\sim} \text{Proj} \mathcal{A}'(V)$$

induces an identification $V \times_U G(\varphi_U) \xrightarrow{\sim} G(\varphi_V)$, hence there exists a well defined open subset $G(\varphi) \subset \text{Proj} \mathcal{A}'$ such that the morphisms $\text{Proj} \varphi_U$ glue to a unique morphism of $X$-schemes:

$$\text{Proj} \varphi : G(\varphi) \to \text{Proj} \mathcal{A}.$$

If $\mathcal{A}'$ is generated locally on $X$ by $\varphi(\mathcal{A}_+)$, we have $G(\varphi) = \text{Proj} \mathcal{A}'$.

Moreover, if $\mathcal{M}$ is a $\mathbb{Z}$-graded quasi-coherent $\mathcal{A}$-module, the morphisms $\nu_{\mathcal{M}}(U)$ assemble into a well defined morphism of $\mathcal{O}_{G(\varphi)}$-modules:

$$\nu_{\mathcal{M}} : (\text{Proj} \varphi)^* \mathcal{M} \sim \to (\mathcal{M}')_{|G(\varphi)}$$

where the grading of $\mathcal{M}' := \mathcal{M} \otimes_{\mathcal{A}} \mathcal{A}'$ is defined as in (10.6.9). Likewise, the union of the subsets $G_1(\varphi_U)$, for $U$ ranging over the affine open subsets of $X$, is an open subset:

$$G_1(\varphi) \subset U_1(\mathcal{A}') \cap G(\varphi)$$

(10.6.27)

such that the restriction $\nu_{\mathcal{M}}|_{G_1(\varphi)}$ is an isomorphism. Especially, set $Y' := \text{Proj} \mathcal{A}'$; we have a natural morphism:

$$\nu_{\mathcal{M}}(n) : (\text{Proj} \varphi)^* \mathcal{O}_Y(n) \to \mathcal{O}_{Y'}(n)|_{G(\varphi)}$$

(10.6.28)

which is an isomorphism, if $\mathcal{A}$ generates $\mathcal{A}'$ locally on $X$. Again, we have $G_1(\varphi) = U_1(\mathcal{A}')$ whenever $\varphi(\mathcal{A}_+)$ generates $\mathcal{A}_+$ locally on $X$.

10.6.29. The discussion in (10.6.10) implies that any morphism of schemes $f : X' \to X$ induces a natural isomorphism of $X'$-schemes ([45 Ch.II, Prop.3.5.3]):

$$\text{Proj} f^* \mathcal{A} \xrightarrow{\sim} X' \times_X \text{Proj} \mathcal{A}$$

(10.6.30)

and the description (10.6.18) implies that (10.6.30) restricts to an isomorphism:

$$U_n(f^* \mathcal{A}) \xrightarrow{\sim} X' \times_X U_n(\mathcal{A}) \quad \text{for every } n \in \mathbb{N}.$$

Furthermore, set $Y' := \text{Proj} f^* \mathcal{A}$, and let $\pi_Y : Y' \to Y$ be the morphism deduced from (10.6.30); the discussion in (10.6.10) implies as well that, for any $\mathbb{Z}$-graded quasi-coherent $\mathcal{A}$-module $\mathcal{M}$, there is a natural isomorphism:

$$(f^* \mathcal{M})^\sim \xrightarrow{\sim} \pi_Y^* \mathcal{M}^\sim$$

([45 Ch.II, Prop.3.5.3]). Especially, $f$ induces a natural identification ([45 Ch.II, Cor.3.5.4]):

$$\mathcal{O}_{Y'}(n) \xrightarrow{\sim} \pi_Y^* \mathcal{O}_Y(n) \quad \text{for every } n \in \mathbb{Z}.$$
10.6.32. Keep the notation of (10.6.16), and let $\mathcal{C}_X$ be the category whose objects are all the pairs $(\psi : Z \to X, \mathcal{L})$, where $\psi$ is a morphism of schemes and $\mathcal{L}$ is an invertible $\mathcal{O}_Z$-module on the Zariski site of $Z$; the morphisms $(\psi : Z \to X, \mathcal{L}) \to (\psi' : Z' \to X, \mathcal{L}')$ are the pairs $(\beta, h)$, where $\beta : Z \to Z'$ is a morphism of $X$-schemes, and $h : \beta^* \mathcal{L}' \sim \mathcal{L}$ is an isomorphism of $\mathcal{O}_Z$-modules (with composition of morphisms defined in the obvious way). Consider the functor:

$$F_{\mathcal{A}} : \mathcal{C}_X \to \text{Set}$$

which assigns to any object $(\psi, \mathcal{L})$ of $\mathcal{C}_X$, the set consisting of all homomorphisms of graded $\mathcal{O}_Z$-algebras:

$$g : \psi^* \mathcal{A} \to \text{Sym}_{\mathcal{O}_Z}^* \mathcal{L}$$

which are epimorphisms on the underlying $\mathcal{O}_Z$-modules (here $\text{Sym}_{\mathcal{O}_Z}^* \mathcal{L}$ denotes the symmetric $\mathcal{O}_Z$-algebra on the $\mathcal{O}_Z$-module $\mathcal{L}$); on a morphism $(\beta, h)$ as in the foregoing, and an element $g' \in F_{\mathcal{A}}(\psi', \mathcal{L}')$, the functor acts by the rule:

$$F_{\mathcal{A}}(\beta, h)(g') := (\text{Sym}_{\mathcal{O}_Z}^* h) \circ \beta^* g'.$$

**Lemma 10.6.33.** The object $(\pi : U_1(\mathcal{A}) \to X, \mathcal{O}_Y(1)|_{U_1(\mathcal{A})})$ of $\mathcal{C}_X$ represents the functor $F_{\mathcal{A}}$.

**Proof.** Given an object $(\psi : Z \to X, \mathcal{L})$ of $\mathcal{C}_X$, and $g \in F_{\mathcal{A}}(\psi, \mathcal{L})$, set:

$$\mathcal{P}(\mathcal{L}) := \text{Proj}(\text{Sym}_{\mathcal{O}_Z}^* \mathcal{L}).$$

According to [45, Ch.II, Cor.3.1.7, Prop.3.1.8(iii)], the natural morphism $\pi_Z : \mathcal{P}(\mathcal{L}) \to Z$ is an isomorphism, and among the natural maps (10.6.24) are isomorphisms:

$$(10.6.34) \quad \pi_Z^* \mathcal{L} \otimes_{\mathcal{O}(Z)} \mathcal{O}(\mathcal{P}(\mathcal{L})) \sim \mathcal{O}(\mathcal{P}(\mathcal{L}))(n) \quad \text{for every } n \in \mathbb{N}.$$  

On the other hand, since $g$ is an epimorphism, we have $G(g) = \mathcal{P}(\mathcal{L})$; taking (10.6.30) into account, we deduce a morphism of $Z$-schemes:

$$\text{Proj } g : \mathcal{P}(\mathcal{L}) \to Y' := Z \times_X \text{Proj } \mathcal{A}$$

which is the same as a morphism of $X$-schemes:

$$\mathcal{P}(g) : Z \to \text{Proj } \mathcal{A}.$$  

We need to show that the image of $\mathcal{P}(g)$ lies in the open subset $U_1(\mathcal{A})$; to this aim, we may assume that both $X$ and $Z$ are affine, say $X = \text{Spec } R$, $Z = \text{Spec } S$, in which case $\mathcal{A}$ is the quasi-coherent algebra associated to a $\mathbb{N}$-graded $R$-algebra $A$, $\mathcal{L}$ is the invertible module associated to a projective rank one $S$-module $L$, and $g : S \otimes_R A \to \text{Sym}_S^* L$ is a surjective homomorphism of $R$-algebras. Then locally on $Z$, $\mathcal{L}$ is generated by elements of the form $g(1 \otimes t)$, for some local sections $t$ of $\mathcal{A}$, and up to replacing $Z$ by an affine open subset, we may assume that $t \in A_1$ is an element such that $t' := g(1 \otimes t)$ generates the free $S$-module $L$. In this situation, we have $\mathcal{P}(\mathcal{L}) = D_+(t')$, and $\mathcal{P}(g)$ is the same as the morphism $\Phi_t : D_+(t') \to D_+(t)$ (notation of (10.6.35)); especially the image of $\mathcal{P}(g)$ lies in $U_1(\mathcal{A})$, as required.

Moreover, the isomorphism $\pi_Z : \mathcal{P}(\mathcal{L}) \sim Z$ is induced by the natural identification:

$$(10.6.35) \quad S = S[t']_{(t')},$$  

From this description, we also can extract an explicit expression for $\Phi_t$; namely, it is induced by the map of $R$-algebras:

$$A(t) \to S \quad \text{such that } \quad a_k \cdot t^{-k} \mapsto g(1 \otimes a_k) \cdot t'^{-k}$$  

for every $k \in \mathbb{N}$, and every $a_k \in A_k$. Next, letting $n := 1$ in (10.6.28) and (10.6.31), we obtain a natural isomorphism of $\mathcal{O}_{\mathcal{P}(\mathcal{L})}$-modules:

$$\mathcal{O}_{\mathcal{P}(\mathcal{L})}(1) \sim (\text{Proj } g)^* \mathcal{O}_Y(1) \sim (\text{Proj } g)^* \mathcal{O}_Y(1) \sim \pi_Z^* \mathcal{O}(g)^* \mathcal{O}_Y(1)$$
(notice that, since by assumption \( g \) is an epimorphism, we have \( G_{1}(g) = U_{1}(\text{Sym}^{*}_{s\mathfrak{g}}) = \mathbb{P}(\mathcal{L}) \), hence \( \psi^*\mathfrak{g}(1) \) is an isomorphism). Composition with (10.6.34) yields an isomorphism:

\[ h(g) : \mathbb{P}(g)^*\mathfrak{O}_{Y}(1) \rightarrow \mathcal{L} \]

of \( \mathfrak{O}_{Z} \)-modules, whence a morphism in \( \mathcal{C}_{X} \)

\[ (\mathbb{P}(g), h(g)) : (\psi, \mathcal{L}) \rightarrow (\mathbb{P}(1), \mathfrak{O}_{Y}(1)) \]

In case \( X \) and \( Z \) are affine, and \( \mathcal{L} \) is associated to a free module \( L \), generated by an element of the form \( t' := g(1 \otimes t) \) as in the foregoing, we can describe explicitly \( h(g) \); namely, a direct inspection of the construction shows that in this case \( h(g) \) is induced by the map of \( S \)-modules

\[ S \otimes_{A(t)} A(1)_{(t)} \rightarrow L : s \otimes a_{k} \cdot t^{1-k} \mapsto s \cdot g(1 \otimes a_{k}) \cdot (t')^{1-k} \quad \text{for every} \ s \in S, a_{k} \in A_{k}. \]

Conversely, let \( \beta : Z \rightarrow U_{1}(\mathfrak{a}) \) be a morphism of \( X \)-schemes, and \( h : \beta^*\mathfrak{O}_{Y}(1)|_{U_{1}(\mathfrak{a})} \rightarrow \mathcal{L} \) an isomorphism of \( \mathfrak{O}_{Z} \)-modules. In view of the natural isomorphisms (10.6.21), we deduce, for every \( n \in \mathbb{N} \), an isomorphism:

\[ h^\otimes n : \beta^*\mathfrak{O}_{Y}(n)|_{U_{1}(\mathfrak{a})} \rightarrow \mathcal{L}^\otimes n. \]

Combining with the epimorphisms (10.6.24):

\[ \omega_{n} : (\pi^*\mathfrak{a})|_{U_{1}(\mathfrak{a})} \rightarrow \mathfrak{O}_{Y}(n)|_{U_{1}(\mathfrak{a})} \]

we may define the epimorphism of \( \mathfrak{O}_{Z} \)-modules:

\[
(10.6.36) \quad g(\beta, h) := \bigoplus_{n \in \mathbb{N}} h^\otimes n \circ \beta^* (\omega_{n}) : \pi^*\mathfrak{a} \rightarrow \text{Sym}^{*}_{s\mathfrak{g}} \mathcal{L}
\]

which, in view of (10.6.25), is a homomorphism of graded \( \mathfrak{O}_{Z} \)-algebras, i.e. \( g(\beta, h) \in F(\psi, \mathcal{L}) \).

This homomorphism can be described explicitly, locally on \( Z \) : namely, say again that \( X = \text{Spec} \mathfrak{R}, Z = \text{Spec} \mathfrak{S}, \mathcal{L} = L^\mathfrak{S} \) for a free \( S \)-module of rank one, and \( \mathfrak{a} = \mathfrak{A}^\mathfrak{S} \) for some \( \mathbb{N} \)-graded \( R \)-algebra \( \mathfrak{A} \); suppose moreover that the image of \( \beta \) lies in an open subset \( D_{+}(t) \subset U_{1}(\mathfrak{a}) \), for some \( t \in A_{1} \). Then \( \beta \) comes from a ring homomorphism \( \beta^\mathfrak{S} : A(t) \rightarrow S, h \) an \( S \)-linear isomorphism \( S \otimes_{A(t)} A(1)_{(t)} \rightarrow L, t' := h(1 \otimes t) \) is a generator of \( L \); moreover, \( \omega_{n} \) is the epimorphism deduced from the map:

\[ A_{n} \otimes_{R} A(t) \rightarrow A(n)_{(t)} : a_{n} \otimes b_{k} \cdot t^{-k} \mapsto a_{n}b_{k} \cdot t^{-k} \quad \text{for every} \ a_{n} \in A_{n}, b_{k} \in A_{k} \]

By inspecting the construction, we see therefore that \( g \) is the direct sum of the morphisms:

\[ g_{n} : S \otimes_{A} A_{n} \rightarrow L^\otimes n : s \otimes a_{n} \mapsto s \cdot \beta^\mathfrak{S}(a_{n} \cdot t^{-n}) \cdot t'^\otimes n \quad \text{for every} \ s \in S, a_{n} \in A_{n}. \]

Finally, it is easily seen that the natural transformations:

\[
(10.6.37) \quad g \mapsto (\mathbb{P}(g), h(g)) \quad \text{and} \quad (\beta, h) \mapsto g(\beta, h)
\]

are inverse to each other: indeed, the verification can be made locally on \( Z \), hence we may assume that \( X \) and \( Z \) are affine, and \( \mathcal{L} \) is free, in which case one may use the explicit formulae provided above.

**Definition 10.6.38.** Let \( X \) be a scheme, \( \mathcal{I} \) a quasi-coherent sheaf of ideals of \( \mathfrak{O}_{X} \).

(i) The **Rees algebra** of \( \mathcal{I} \) is the quasi-coherent \( \mathbb{N} \)-graded \( \mathfrak{O}_{X} \)-algebra

\[ R(\mathcal{I})_{\cdot} := \bigoplus_{n \in \mathbb{N}} \mathcal{I}^{n} \]

with multiplication law deduced in the obvious way from that of \( \mathfrak{O}_{X} \).

(ii) The **blowing up** of \( \mathcal{I} \) is the \( X \)-scheme

\[ \text{Proj} R(\mathcal{I})_{\cdot} \rightarrow X. \]
Remark 10.6.39. (i) With the notation of definition 10.6.38 let \( \pi : Y \to X \) be the blowing up of \( \mathcal{I} \). Notice that \( \mathcal{I} \) is an invertible \( \mathcal{O}_X \)-module if and only if it is generated, locally on \( X \), by a regular section of \( \mathcal{O}_X \), and then the natural map

\[
\text{Sym}^n_{\mathcal{O}_X} \mathcal{I} \to \mathcal{I}^n
\]

is an isomorphism, for every \( n \in \mathbb{N} \). Taking into account [45, Ch.II, Cor.3.1.7, Prop.3.1.8(iii)], it follows that if \( \mathcal{I} \) is an invertible ideal, then the blowing up of \( \mathcal{I} \) is an isomorphism.

(ii) Let \( X' \to X \) be any flat morphism of schemes; in light of (10.6.29), we get a natural isomorphism from \( X' \times_X Y \to X' \) to the blowing up of the quasi-coherent ideal \( \mathcal{I} \mathcal{O}_{X'} \) of \( \mathcal{O}_{X'} \).

(iii) Especially, let \( U \subset X \) be the complement in \( X \) of the closed subscheme \( \text{Spec} \mathcal{O}_X / \mathcal{I} \).

From (i) and (ii) we deduce that the restriction \( \pi^{-1}U \to U \) of \( \pi \) is an isomorphism.

(iv) Notice that \( R(\mathcal{I}) \) is generated, locally on \( X \), by its degree one direct summand \( \mathcal{I} \), hence \( \mathcal{O}_Y(1) \) is an invertible \( \mathcal{O}_Y \)-module. On the other hand, a simple inspection shows that

\[
R(\mathcal{I}) \ni (n) = \mathcal{I}^n \cdot R(\mathcal{I}) \quad \text{for every } n \in \mathbb{N}
\]

whence a natural identification

\[
\mathcal{O}_Y(n) \xrightarrow{\sim} \mathcal{I}^n \cdot \mathcal{O}_Y \quad \text{for every } n \in \mathbb{N}.
\]

Proposition 10.6.40. With the notation of definition 10.6.38, the blowing up \( Y \to X \) of \( \mathcal{I} \) is characterized, up to unique isomorphism of \( X \)-schemes, by the following two conditions:

(i) The sheaf of ideals \( \mathcal{I} \cdot \mathcal{O}_Y \) is an invertible \( \mathcal{O}_Y \)-module.

(ii) For every \( X \)-scheme \( Z \) such that \( \mathcal{I} \cdot \mathcal{O}_Z \) is an invertible \( \mathcal{O}_Z \)-module, there exists a unique morphism \( Z \to Y \) of \( X \)-schemes.

Proof. The uniqueness up to unique isomorphism of an \( X \)-scheme \( \pi : Y \to X \) fulfilling conditions (i) and (ii) is clear. It remains to check that these conditions hold for \( Y := \text{Proj} R(\mathcal{I}) \).

However, condition (i) follows immediately from remark 10.6.39(iv). Next, let \( f : Z \to X \) be as in (ii), and set \( \mathcal{L} := \mathcal{I} \cdot \mathcal{O}_Z \); the induced map \( f^* \mathcal{O}_X \to \mathcal{O}_Z \) induces an epimorphism of \( \mathcal{O}_Z \)-modules

\[
\varphi_n : f^* \mathcal{I}^n \to \mathcal{I}^n \cdot \mathcal{O}_Z \xrightarrow{\sim} \text{Sym}^n_{\mathcal{O}_Z} \mathcal{L} \quad \text{for every } n \in \mathbb{N}
\]

and it is clear that the system \( (\varphi_n : n \in \mathbb{N}) \) amounts to a morphism of \( \mathbb{N} \)-graded \( \mathcal{O}_Z \)-algebras

\[
\varphi_\bullet : f^* R(\mathcal{I}) \ni (n) \to \text{Sym}^\bullet_{\mathcal{O}_Z} \mathcal{L}
\]

which in turn corresponds to a morphism \( g : Z \to Y \) of \( X \)-schemes, by virtue of lemma 10.6.33. Lastly, let \( g' : Z \to Y \) be any other morphism of \( X \)-schemes, and denote by \( U \subset X \) (resp. \( U' \subset Z \)) the complement in \( X \) (resp. in \( Z \)) of the closed subset \( \text{Spec} \mathcal{O}_X / \mathcal{I} \) (resp. \( \text{Spec} \mathcal{O}_Z / \mathcal{I} \mathcal{O}_Z \)); clearly \( f(U') \subset U \), hence \( g \) and \( g' \) both restrict to morphisms \( U' \to \pi^{-1}U \) of \( X \)-schemes. Then remark 10.6.39(iii) implies that

\[
g|_{U'} = g'|_{U'}.
\]

Next, since \( \mathcal{I} \mathcal{O}_Z \) is generated, locally on \( Z \), by a regular section of \( \mathcal{O}_Z \), the open subset \( U' \) is schematically dense in \( Z \) ([50, Ch.IV, Déf.11.10.2]), and on the other hand, we know that \( \pi \) is a separated morphism (see [10.6.15]); in view of [50, Ch.IV, Prop.11.10.1] we deduce that \( g = g' \), which concludes the verification of (ii).}

10.6.41. We may generalize as follows remark 10.6.39(ii). Let \( X \to X_0 \) be a morphism of schemes, \( \mathcal{I}_0 \subset \mathcal{O}_{X_0} \) a quasi-coherent ideal, and set \( \mathcal{I} := \mathcal{I}_0 \mathcal{O}_X \); let also \( \pi_0 : Y_0 \to X_0 \) and
\( \psi : Y \to X \) be the blowing up morphisms of \( \mathcal{O}_0 \) and respectively \( \mathcal{I} \). By proposition 10.6.40 there exists a unique morphism of schemes \( \psi : Y \to Y_0 \) that makes commute the diagram

\[
\begin{array}{ccc}
Y & \xrightarrow{\psi} & Y_0 \\
\downarrow{\pi} & & \downarrow{\pi_0} \\
X & \longrightarrow & X_0.
\end{array}
\]

(10.6.42)

Then we have:

**Lemma 10.6.43.** The morphism of \( X \)-schemes \( \bar{\psi} : Y \to Y' := Y_0 \times_{X_0} X \) induced by \( \psi \) is a closed immersion, and identifies \( Y \) with \( \text{Spec} \mathcal{O}_{Y'} / \mathcal{I} \), where

\( \mathcal{I} := \bigcup_{n \in \mathbb{N}} \text{Ann}_{\mathcal{O}_{Y'}}(\mathcal{I}^n). \)

**Proof.** Let \( Z \to X \) be any morphism of schemes such that \( \mathcal{I} \mathcal{O}_Z \) is an invertible \( \mathcal{O}_Z \)-module; since \( \mathcal{I} = \mathcal{O}_0 \mathcal{O}_X \), proposition 10.6.40 yields a unique morphism of \( X_0 \)-schemes \( Z \to Y_0 \), so there exists a unique morphism of \( X \)-schemes \( g : Z \to Y' \) as well. Next, since \( \mathcal{I} \mathcal{O}_Z \) is invertible, it is easily seen that the induced morphism \( \mathcal{O}_{Y'} \to g_* \mathcal{O}_Z \) factors through \( \mathcal{O}_{Y'} / \mathcal{I} \), whence a unique morphism of \( X \)-schemes \( Z \to Y'' := \text{Spec} \mathcal{O}_{Y'}/\mathcal{I} \). Lastly, by construction \( \mathcal{I} \mathcal{O}_{Y'} \) is a locally principal ideal of \( \mathcal{O}_{Y'} \), and then it is clear that \( \mathcal{I} \mathcal{O}_{Y''} \) is an invertible \( \mathcal{O}_{Y''} \)-module. Summing up, we see that the morphism \( Y'' \to X \) enjoys the universal property that characterizes the blowing up of \( \mathcal{I} \), whence the lemma. \( \square \)

10.6.44. Let \( A \) be a ring, \( r \geq 1 \) an integer, \( f := (f_1, \ldots, f_r) \) a sequence of elements of \( A \), and \( I \subset A \) the ideal generated by \( f \). We view \( A \) as an algebra over the ring \( A_0 := \mathbb{Z}[T_1, \ldots, T_r] \), via the ring homomorphism

\( g : A_0 \to A \quad T_i \mapsto f_i \quad i = 1, \ldots, r \)

and denote by \( I_0 \subset A_0 \) the ideal generated by \( (T_1, \ldots, T_r) \). Set also \( X := \text{Spec} A, X_0 := \text{Spec} A_0 \), let \( \mathcal{I} \subset \mathcal{O}_X \) (resp. \( \mathcal{I}_0 \subset \mathcal{O}_{X_0} \)) be the quasi-coherent sheaf of ideals arising from \( I \) (resp. from \( I_0 \)), and \( \pi : Y \to X \) (resp. \( \pi_0 : Y_0 \to X_0 \)) the blowing up of \( \mathcal{I} \) (resp. of \( \mathcal{I}_0 \)). Clearly \( \mathcal{I}_0 \mathcal{O}_Y = \mathcal{I} \), whence a commutative diagram (10.6.42), with bottom horizontal arrow given by \( \text{Spec} g : X \to X_0 \). Furthermore, notice that we have systems of monomorphisms of invertible \( \mathcal{O}_{Y'} \)-modules :

\[
\mathcal{O}_{Y_0}(n+1) \to \mathcal{O}_{Y_0}(n) \quad \mathcal{O}_{Y}(n+1) \to \mathcal{O}_{Y}(n) \quad \text{for every } n \in \mathbb{N}
\]

(10.6.45)

and corresponding to the inclusion maps \( \mathcal{I}^{n+1} \mathcal{O}_{Y_0} \to \mathcal{I}^{n} \mathcal{O}_{Y_0} \) and \( \mathcal{I}^{n+1} \mathcal{O}_{Y} \to \mathcal{I}^{n} \mathcal{O}_{Y} \) under the natural identifications of remark 10.6.39(iv).

**Proposition 10.6.46.** With the notation of (10.6.44), suppose moreover that the sequence \( f \) is completely secant. Then, for every \( n \in \mathbb{N} \) we have :

(i) The natural map \( I^n \to H^0(Y, \mathcal{O}_{Y}(n)) \) is an isomorphism.

(ii) \( H^p(Y, \mathcal{O}_{Y}(n)) = 0 \) for every \( p > 0 \).

**Proof.** We consider first the ring \( A_0 \) and the sequence \( f_0 := (T_1, \ldots, T_r) \); we endow \( A_0 \) with its standard \( \mathbb{N} \)-grading, such that \( \text{gr}_n A_0 \) is the \( \mathbb{Z} \)-module generated by the monomials of total degree \( n \), for every \( n \in \mathbb{N} \). Let also \( R_0 \subset A_0[V] \) be the Rees algebra associated with the \( I_0 \)-adic filtration of \( A_0 \), so that \( Y_0 = \text{Proj} R_0 \) (see definition 7.9.1(iii)); but since here we have a descending filtration on \( A_0 \), we let \( V := U^{-1} \), so \( \text{gr}_n R_0 := V^n T_0^n \) for every \( n \in \mathbb{N} \). We consider the morphism of \( \mathbb{N} \)-graded \( \mathbb{Z} \)-algebras

\( h : A_0 \to R_0 \quad T_i \mapsto VT_i \quad i = 1, \ldots, r. \)
Notice that $\varphi(A_{0+})$ generates the ideal $R_{0+}$ of $R_0$, hence $\varphi := \text{Proj} \, h$ is well defined on the whole of $Y_0$ (see (10.6.5)), and we get a commutative diagram of morphisms of schemes

\[
\begin{array}{ccc}
Y_0 & \xrightarrow{\varphi} & \mathbb{P}^{r-1}_Z \\
\downarrow{\pi_0} & & \downarrow \\
X_0 & \xrightarrow{\varphi} & \text{Spec} \, Z.
\end{array}
\]

For every $i = 1, \ldots, r$, set $U_i := D_+(T_i) \subset \mathbb{P}^{r-1}_Z$, and $U'_i := \varphi^{-1}U_i$. Recall that there are natural isomorphisms $\omega_i : \mathcal{O}_{\mathbb{P}^{r-1}_Z}(U_i) \xrightarrow{\sim} A_i := \mathbb{Z}[\tau_{ij} \mid j = 1, \ldots, r]$ (notation of example 10.6.3); we wish to give a corresponding description of the $A_i$-algebra $B_i := \mathcal{O}_{Y_0}(U'_i)$. To this aim, notice that, by definition, every element of $B_i \subset \mathbb{Z}[T_1, \ldots, T_r, V, (VT_i)^{-1}]$ is a finite sum of terms of the form

\[
(VT_i)^{\alpha_1} \cdots (VT_r)^{\alpha_r} \cdot (VT_i)^{-k} \cdot P(T_1, \ldots, T_r) = \tau_{i1}^{\alpha_1} \cdots \tau_{ir}^{\alpha_r} \cdot P(T_i \tau_{i1}, \ldots, T_r \tau_{ir})
\]

where $k \in \mathbb{N}$ is any integer, $P \in A$ any polynomial, and $\alpha_1 + \cdots + \alpha_r = k$; i.e.

\[
B_i = A_i[T_i] \quad \text{for every } i = 1, \ldots, r.
\]

Likewise, for every $n \in \mathbb{N}$, the elements of $R_0(n)(T_i)$ are the finite sums of terms (10.6.47) where $k \in \mathbb{N}$ is any integer, $P \in A$ any polynomial, and $\alpha_1 + \cdots + \alpha_r = n + k$; i.e.

\[
R_0(n)(T_i) = (VT_i)^n B_i \quad \text{for every } i = 1, \ldots, r.
\]

For every $i \neq j$, set also $U_{ij} := U_i \cap U_j$ and $U'_{ij} := \varphi^{-1}U_{ij}$, and recall that the isomorphisms $\omega_i$ induce isomorphisms $\omega_{ij} : \mathcal{O}_{\mathbb{P}^{r-1}_Z}(U_{ij}) \xrightarrow{\sim} A_i[\tau_{ij}^{-1}]$, such that the composition

\[
\psi_{ij} := \omega_{ji} \circ \omega_{ij} : A_i[\tau_{ij}^{-1}] \xrightarrow{\sim} A_j[\tau_{ij}^{-1}]
\]

is given by the rule (10.6.4). There follow natural identifications $\mathcal{O}_{Y_0}(U'_{ij}) \xrightarrow{\sim} B_i[\tau_{ij}^{-1}]$, whence a commutative diagram

\[
\begin{array}{ccc}
A_i[\tau_{ij}^{-1}] & \xrightarrow{\psi_{ij}} & A_j[\tau_{ij}^{-1}] \\
\downarrow & & \downarrow \\
B_i[\tau_{ij}^{-1}] & \xrightarrow{\psi'_{ij}} & B_j[\tau_{ij}^{-1}]
\end{array}
\]

whose vertical arrows are induced by the map $\mathcal{O}_{\mathbb{P}^{r-1}_Z} \xrightarrow{\varphi_*} \mathcal{O}_{Y_0}$ associated with $\varphi$, and where $\psi'_{ij}$ is the isomorphism given by the rule:

\[
T_i \mapsto T_j \cdot \tau_{ji}.
\]

Likewise, we get a commutative diagram

\[
\begin{array}{ccc}
\mathcal{O}_{Y_0}(U'_{ij}) & \xrightarrow{} & (VT_i)^n B_i[\tau_{ij}^{-1}] \\
(VT_j)^n B_i[\tau_{ij}^{-1}] & \xrightarrow{} & (VT_j)^n B_j[\tau_{ij}^{-1}]
\end{array}
\]

whose downward arrows are induced by the restriction maps of the sheaf $\mathcal{O}_{Y_0}(n)$, and where the horizontal map is the $B_i[\tau_{ij}^{-1}]$-linear map given by the rule

\[
(VT_i)^n \mapsto (VT_j)^n \cdot \tau_{ji}^{-n}
\]
and where the $B_i[τ_{ij}^{-1}]$-module structure of $(VT_i)^n B_i[τ_{ij}^{-1}]$ is defined by restriction of scalars along the isomorphism $ψ_{ij}'$. Comparing with example [10.6.8] we deduce a natural isomorphism of $𝒪_{ℙ^n}^{-1}$-modules:

$$φ_*𝒪_Y(n) \sim \bigoplus_{k ∈ ℤ} 𝒪_{ℙ^n}^{-1}(n + k) \quad \text{for every } n ∈ ℤ.$$

On the other hand, from [46, Ch.III, Prop.2.1.12] we get isomorphisms of $ℤ$-modules:

$$H^p \left( ℙ^n, \bigoplus_{k ∈ ℤ} 𝒪_{ℙ^n}^{-1}(k) \right) = \begin{cases} 0 & \text{for every } p > 0 \\ A & \text{for } p = 0 \end{cases}$$

Now, since $φ$ is affine, we have

$$H^p(Y_0, 𝒪_{Y_0}(n)) = H^p(ℙ^n, φ_*𝒪_{Y_0}(n)) \quad \text{for every } n ∈ ℤ$$

and assertion (ii) already follows. We also deduce an isomorphism of $ℤ$-modules

$$H^0(Y_0, 𝒪_{Y_0}(n)) \sim H^0(ℙ^n, φ_*𝒪_{Y_0}(n)) = I^n_0$$

where $gr_k I^n_0 := gr_k A$, for every $k ∈ ℤ$. To conclude the proof in this case, it remains only to check that this identification is the inverse of the natural map of (i). To this aim, we consider the induced commutative diagram

$$
\begin{array}{ccc}
H^n(U_0, 𝒪_{Y_0}(n)) & \longrightarrow & H^0(ℙ^n, φ_*𝒪_{Y_0}(n)) \\
\downarrow & & \downarrow \\
H^n(U'_0, 𝒪_{Y_0}(n)) & \longrightarrow & H^0(U_i, φ_*𝒪_{Y_0}(n)).
\end{array}
$$

Now, let $T^a := T_1^{α_1} \cdots T_r^{α_r} ∈ gr_k I^n$ be any monomial (for any $k ∈ ℤ$); by inspecting the foregoing notation, we see that the image of $T^a$ in $H^0(U'_0, 𝒪_{Y_0}(n))$ equals $(VT_i)^n T_1^{k_1 α_1} \cdots T_r^{k_r α_r}$, which maps to the section $T_i^{n+k} T_1^{k_1 α_1} \cdots T_r^{k_r α_r}$ of $H^0(U_i, φ_*𝒪_{Y_0}(n))$. But the latter is also the image of $T^a$ under the restriction map $H^0(ℙ^n, φ_*𝒪_{ℙ^n}^{-1}(n + k)) → H^0(U_i, φ_*𝒪_{ℙ^n}^{-1}(n + k))$, whence the contention.

Next, let $A, f$ and $I$ as in (10.6.44), and we define likewise $R ⊂ A[V]$ as the Rees algebra associated with the $I$-adic filtration of $A$; we consider the homomorphism of graded $ℤ$-algebras

$$G : R_0 → R \quad V^n x → V^n g(x) \quad \text{for every } n ∈ ℤ \text{ and every } x ∈ I^n_0.$$

Notice that $G$ is even a morphism of $ℤ$-graded $A_0$-algebras, for the $A_0$-algebra structure on $A$ and $R$ induced by $g$. There follows a morphism of $ℤ$-graded $A$-algebras

$$h' : A ⊗_{A_0} R_0 → R$$

whose restriction $gr_n h'$ is induced by the natural map $A ⊗_{A_0} I^n_0 → I^n$, for every $n ∈ ℤ$. The latter is an isomorphism for every $n ∈ ℤ$, by virtue of lemma [7.8.23] and it is clear that the morphism $ψ$ of (10.6.44) equals $Prj h'$; in view of (10.6.10), we deduce that the diagram (10.6.42) is cartesian under the current assumptions, and moreover $h'$ induces natural isomorphisms of $𝒪_Y$-modules

$$ψ^*𝒪_Y(n) \sim 𝒪_Y(n) \quad \text{for every } n ∈ ℤ.$$

Denote by $𝒰'$ the affine open covering $(U'_i \mid i = 1, \ldots, r)$ of $Y_0$, and set $ψ^{-1}𝒰' := (ψ^{-1}U'_i \mid i = 1, \ldots, r)$. there follows a natural isomorphism of alternating Čech complexes

$$(10.6.48) \quad \overline{C}^•_{alt}(𝒰', 𝒪_{Y_0}(n)) ⊗_{A_0} A \sim \overline{C}^•_{alt}(ψ^{-1}𝒰', 𝒪_Y(n)) \quad \text{for every } n ∈ ℤ.$$

Claim 10.6.49. The natural map $\overline{C}^•_{alt}(𝒰', 𝒪_{Y_0}(n)) ⊗_{A_0} A → \overline{C}^•_{alt}(𝒰', 𝒪_{Y_0}(n)) ⊗_{A_0} A$ is an isomorphism in $D(A-\text{Mod})$, for every $n ∈ ℤ$. 
Proof of the claim. We consider the standard spectral sequence
\[ E_1^{pq} := \text{Tor}_{R_0}^q(\mathcal{C}_{\text{alt}}^i(\mathcal{U}', \mathcal{O}_{Y_0}(n)), A) \Rightarrow H^{p+q}(\mathcal{C}_{\text{alt}}^i(\mathcal{U}', \mathcal{O}_{Y_0}(n)) \otimes_{A_0} A) \]
and notice that it suffices to check that \( E_1^{pq} = 0 \) for every \( p \neq 0 \), since in that case the abutment is naturally isomorphic to the cohomology of the complex \( (E_1^i, d_1^i) \), which is the same as \( \mathcal{C}_{\text{alt}}^i(\mathcal{U}', \mathcal{O}_{Y_0}(n)) \otimes_{A_0} A \). However, with the foregoing notation, we see that \( \mathcal{C}_{\text{alt}}^i(\mathcal{U}', \mathcal{O}_{Y_0}(n)) \) is a direct sum of finitely many \( A_0 \)-modules, each of which is a localization of \( B_s \), for some \( i \leq r \), so we are reduced to checking that \( \text{Tor}_{R_0}^i(B_s, A) = 0 \) for \( i = 1, \ldots, r \) and every \( p \). But in turn, \( B_s \) is the degree 0 summand of a \( \mathbb{Z} \)-graded \( A_0 \)-module, which is a localization of \( R_0 \), so we are further reduced to checking that \( \text{Tor}_{R_0}^i(R_0, A) = 0 \) for every \( p > 0 \), or equivalently, that \( \text{Tor}_{R_0}^i(I_0, A) = 0 \) for every \( p > 0 \) and every \( n \in \mathbb{N} \). The latter follows from lemma 7.8.23.

Combining (10.6.48), claim 10.6.49 and theorem 10.2.28(ii), we get a natural isomorphism:
\[ \mathcal{C}_{\text{alt}}^i(\mathcal{U}', \mathcal{O}_{Y_0}(n)) \otimes_{A_0} A \cong \text{RG}(Y, \mathcal{O}_Y(n)) \quad \text{in D}(A\text{-Mod}), \quad \text{for every } n \in \mathbb{N}. \]

By the same token, we have a natural isomorphism \( \mathcal{C}_{\text{alt}}^i(\mathcal{U}', \mathcal{O}_{Y_0}(n)) \cong \text{RG}(Y_0, \mathcal{O}_{Y_0}(n)) \) in \( D(A_0\text{-Mod}) \), whence a standard spectral sequence for every \( n \in \mathbb{N} \)
\[ E(n)^{pq}_2 := \text{Tor}_{R_0}^i(H^q(Y_0, \mathcal{O}_{Y_0}(n)), A) \Rightarrow H^{p+q}(\mathcal{C}_{\text{alt}}^i(\mathcal{U}', \mathcal{O}_{Y_0}(n)) \otimes_{A_0} A) \]
and the previous case tells us that \( E(n)^{pq}_2 = 0 \) for every \( q > 0 \) and every \( n \in \mathbb{N} \), and moreover \( E(n)^{q0}_2 = \text{Tor}_{R_0}^i(I_0, A) \) for every \( p \in \mathbb{Z} \) and every \( n \in \mathbb{N} \). Lastly, by invoking again lemma 7.8.23 we see that \( E(n)^{q0}_2 = 0 \) whenever \( p \neq 0 \), and \( E(n)^{q0}_2 = I_0 A = I^n_0 \) for every \( n \in \mathbb{N} \), which concludes the proof of the proposition.

**Theorem 10.6.50.** With the notation of (10.6.44), the following conditions are equivalent:

(a) The ring \( A \) satisfies condition (a)\( I^n \).

(b) The inverse system \( (H^n(Y, \mathcal{O}_Y(n)) \mid n \in \mathbb{N}) \) deduced from the system of maps (10.6.45) is uniformly essentially zero for every \( p > 0 \), and the same holds for the kernel and cokernel of the natural morphism of inverse systems \( (I^n \to H^n(Y, \mathcal{O}_Y(n)) \mid n \in \mathbb{N}). \)

(c) There exists \( n \in \mathbb{N} \) such that \( I^n \cdot H^n(Y, \mathcal{O}_Y) = 0 \) for every \( p > 0 \), and \( I^n \) annihilates the kernel and cokernel of the natural morphism \( A \to H^n(Y, \mathcal{O}_Y) \).

**Proof.** Define \( I_0 \subset A \), the Rees algebras \( R_0 \), \( R \), and the morphism \( \pi_0 : Y_0 \to X_0 := \text{Spec } A_0 \) as in the proof of proposition 10.6.46. We set \( Y' := Y_0 \times_X X \), and define \( \mathcal{F} \subset \mathcal{O}_{Y'}, \psi : Y \to Y \) and \( \overline{\psi} : Y \to Y' \) as in lemma 10.6.43, so that \( \mathcal{F} \) is the kernel of the induced map \( \overline{\psi}^* : \mathcal{O}_{Y'} \to \overline{\psi}_* \mathcal{O}_Y \). We shall consider as well the condition:

(d) There exists \( k \in \mathbb{N} \) such that \( I^k \mathcal{F} = I^k \cdot \mathcal{F} \cdot \text{Tor}_{R_0}^X(\mathcal{O}_{Y_0}, \mathcal{O}_X) = 0 \) for every \( i > 0 \).

**Claim 10.6.51.** If condition (a) holds, then there exists \( k \in \mathbb{N} \) such that
\[ I^k : \text{Tor}_{R_0}^i(I_0^n, A) = I^k : \text{Ker}(I_0^n \otimes_{A_0} A \to I^n_0) = 0 \quad \text{for every } n \in \mathbb{N} \text{ and every } i > 0. \]

**Proof of the claim.** For every integer \( p > 0 \), let \( k(p) \) be the step of the uniformly essentially zero system \( (\text{Tor}_{R_0}^i(A_0/I_0^n, A) \mid n \in \mathbb{N}). \) For \( p > 1 \) (resp. \( p = 1 \)), the integer \( k(p) \) is also the step of the uniformly essentially zero system \( (T_{n-1}^p := \text{Tor}_{R_0}^i(I_0^n, A) \mid n \in \mathbb{N}) \) (resp. the uniformly essentially zero system \( (K^n := \text{Ker}(I_0^n \otimes_{A_0} A \to I^n_0) \mid n \in \mathbb{N}). \)) Now, for every \( a \in I_0^{k(p)} \), scalar multiplication by \( a \) on \( I_0^n \) factors through the inclusion map \( I_0^{n+k(p)} \to I_0^n \), so it induces the zero map on \( T_{n-1}^p \) (resp. on \( K^n \)) for every \( n \in \mathbb{N} \). Lastly, recall that the homological dimension of \( A_0 \) equals \( r + 1 \), so \( T_{n-1}^p = 0 \) for every \( p > r + 1 \). We may therefore choose \( k := \max(k(1), \ldots, k(r+1)). \) \( \Diamond \)
(a)⇒(d): Indeed, recall that we have a natural $\mathcal{O}_Y(U \times X_n, X)$-linear isomorphism

$$\Gamma(U \times X_n, \mathcal{O}_Y(U, \mathcal{O}_X)) \cong T_i(U) := \text{Tor}^A_0(H^0(\mathcal{O}_Y(U), A))$$

for every affine open subsets $U \subset Y$. Since $Y'$ is quasi-compact, and taking into account lemma [10.6.43] it will then suffice to find $k \in \mathbb{N}$ and a finite open covering $U := (U_\lambda \mid \lambda \in \Lambda)$ of $Y_0$ such that

- $I^k \cdot T_\lambda(U_\lambda) = 0$ for every $i > 0$ and every $\lambda \in \Lambda$
- $I^k \cdot \text{Ker}(\psi^{(i)}_{U_\lambda}) : \mathcal{O}_Y(U_\lambda) \otimes A \to \mathcal{O}_Y(\psi^{-1}U_\lambda)) = 0$ for every $\lambda \in \Lambda$.

However, we may choose $U_\lambda$ such $\mathcal{O}_Y(U_\lambda)$ is a direct summand of a localization of $R_0$, for every $\lambda \in \Lambda$; then $T_\lambda(U_\lambda)$ is a direct summand of a localization of $\text{Tor}^A_0(R_0, A)$, and $\psi^{(i)}_{U_\lambda}$ is a direct summand of a localization of the natural map $R_0 \otimes A \to R$. Thus, the assertion follows from claim [10.6.51].

(b)⇒(c): The natural identification $\mathcal{I}^n \mathcal{O}_Y \cong \mathcal{O}_Y(n)$ of remark [10.6.39] yields exact cohomology sequences

$$H^n(Y, \mathcal{O}_Y(n)) \xrightarrow{\alpha^n_p} H^n(Y, \mathcal{O}_Y) \to H^n(Y, \mathcal{O}_Y/\mathcal{I}^n \mathcal{O}_Y)$$

for every $p, n \in \mathbb{N}$.

However, assumption (b) implies that for every $p > 0$ there exists $k \in \mathbb{N}$ such that $\alpha^n_p$ is the zero map, for every $n \geq k$; hence, for such $k$ the term $H^n(Y, \mathcal{O}_Y)$ is a submodule of $H^n(Y, \mathcal{O}_Y/\mathcal{I}^k \mathcal{O}_Y)$, which is obviously annihilated by $I^k$. By the same token we get a commutative lattice with exact rows for every $n \in \mathbb{N}$:

$$
\begin{array}{cccc}
0 & \xrightarrow{\beta_n} & I^n & \xrightarrow{\gamma_n} & A/\mathcal{I}^n & \xrightarrow{\delta_n} & 0 \\
\end{array}
$$

whence an exact sequence

$$0 \to \text{Ker} \beta_n \xrightarrow{\tau_n} \text{Ker} \gamma_n \to \text{Ker} \delta_n \to \text{Coker} \beta_n \xrightarrow{\sigma^n_n} \text{Coker} \gamma_n \to \text{Coker} \delta_n.
$$

However, assumption (b) implies that there exists $n \in \mathbb{N}$ such that $\tau_n$ and $\sigma^n_n$ both vanish; since $\text{Ker} \delta_n$ and $\text{Coker} \delta_n$ are both annihilated by $I^n$, we conclude that (c) holds.

Next, we show that (d) implies both (a) and (b). To this aim, we remark:

Claim 10.6.52. Suppose that condition (d) holds; then we have:

(i) The inverse system $\{\mathcal{I}^n \mathcal{O}_Y(n) \mid n \in \mathbb{N}\}$ induced by the system of morphisms [10.6.45] is uniformly essentially zero, for every $i > 0$.

(ii) Likewise, the inverse system $\{\mathcal{I}^n \mathcal{O}_Y(n) \mid n \in \mathbb{N}\}$ is uniformly essentially zero.

Proof of the claim. (i): There exists an affine open covering $(U_1, \ldots, U_r)$ of $Y_0$ such that

$$(\mathcal{I}^n \mathcal{O}_Y)|_{U_i} = f_i \mathcal{O}_Y \quad \text{for every } i = 1, \ldots, r$$

and $f_i$ is a regular element of $\mathcal{O}_Y(U_i)$, whence an identification

$$(\mathcal{I}^n \mathcal{O}_Y)|_{U_i} = f_i^n \mathcal{O}_U \xrightarrow{\gamma_i} \mathcal{O}_U \quad \text{for every } i = 1, \ldots, r.$$

Under this identification, the restriction $\mathcal{O}_Y(n+1)|_{U_i} \to \mathcal{O}_Y(n)|_{U_i}$ of the morphism [10.6.45] corresponds to the scalar multiplication by $f_i$. Hence, the inverse system $\{\mathcal{I}^n | n \in \mathbb{N}\}$ is naturally identified with the inverse system $\{\mathcal{I}^n \mid n \in \mathbb{N}\}$ with $\mathcal{I}^n := \text{Tor}^A_0(\mathcal{O}_U, \mathcal{O}_X)$ for every $i, n \in \mathbb{N}$, with transition maps given by scalar multiplication by $f_i$, whence (i).

For the proof of (ii) one argues in the same way, using the fact that $I^k \mathcal{I} = 0$ for some $k \in \mathbb{N}$ whose existence is ensured by condition (d) : the details shall be left to the reader.
We consider now the inverse systems of spectral sequences provided by proposition 10.2.30

\[ (10.6.53) \quad E(n)_{2}^{pq} := H^{p}(Y_{0} \times_{X_{0}} X, Tor^{\infty}_{q}(O_{Y_{0}}(n), O_{X}) \Rightarrow H^{p+q}(A \otimes_{A_{0}} R \Gamma O_{Y_{0}}(n)) \]

where, as usual, the transition maps \( E(n+1)_{2}^{pq} \rightarrow E(n)_{2}^{pq} \) are induced by the morphisms \( (10.6.45) \). Clearly \( E_{2}^{pq} = 0 \) if either \( p < 0 \) or \( q > 0 \), and claim \( 10.6.52 \) implies that the inverse system \( (E(n)_{2}^{pq} \mid n \in \mathbb{N}) \) is uniformly essentially zero whenever \( q < 0 \). It follows already that the inverse system \( (E(n)_{2}^{pq} \mid n \in \mathbb{N}) \) is uniformly essentially zero whenever \( p + q < 0 \). On the other hand, proposition \( 10.6.46 \) shows that

\[ H^{-i}(A \otimes_{A_{0}} R \Gamma O_{Y_{0}}(n)) = Tor_{i}^{A_{0}}(A, I_{0}^{n}) \quad \text{for every } i \in \mathbb{Z}. \]

Summing up, and taking into account lemma 7.8.19, a simple induction shows that the system \( (Tor_{i}^{A_{0}}(A, I_{0}^{n}) \mid n \in \mathbb{N}) \) is uniformly essentially zero for every \( i > 0 \). Notice also that \( E(n)_{2}^{00} = H^{p}(Y', O_{Y}(n)) \) for every \( n, p \in \mathbb{N} \).

**Claim 10.6.54.** (i) The inverse system \( (E(n)_{s}^{00} \mid n \in \mathbb{N}) \) is uniformly essentially zero, for every \( p > 0 \) and every \( s \geq 2 \).

(ii) The kernel and cokernel of the natural morphism of inverse systems

\[ h_{\bullet} : (A \otimes_{A_{0}} I_{0}^{n} \mid n \in \mathbb{N}) \rightarrow (E(n)_{2}^{00} \mid n \in \mathbb{N}) \]

are both uniformly essentially zero.

**Proof of the claim.** (i): We argue by descending induction on \( p \): if \( p \geq r \), we have \( E(n)_{2}^{pq} = 0 \) for every \( n \in \mathbb{N} \), by theorem \( 10.2.28 \)(iii), hence the claim trivially holds in this case. Thus, suppose that \( q < r \), and that the claim is already known for every \( p > q \) and every \( s \geq 2 \). We show, by descending induction on \( s \geq 2 \), that \( (E(n)_{s}^{00} \mid n \in \mathbb{N}) \) is uniformly essentially zero. Since \( E(n)_{2}^{q-s,s-1} = 0 \) for every \( s \geq 2 \), we have \( E(n)_{s}^{q-s,s-1} = E(n)_{s}^{q+s,1-s} = 0 \) as well, whenever \( q + s \geq r \), and therefore \( E(n)_{s}^{00} = E(n)_{2}^{00} = 0 \) for every \( p > 0 \) and every \( s \geq r \). Thus, suppose that \( 2 \leq t < r \), and that the assertion is known for every \( s > t \); we consider the exact sequence of inverse systems

\[ 0 \rightarrow (E(n)_{t+1}^{0} \mid n \in \mathbb{N}) \rightarrow (E(n)_{t}^{00} \mid n \in \mathbb{N}) \rightarrow (E(n)_{t}^{q+t,1-t} \mid n \in \mathbb{N}). \]

Since \( 1 - t < 0 \), the third term is uniformly essentially zero, and the same holds for the first term, by inductive assumption; by lemma 7.8.19, we deduce that the same holds for the middle term, as required.

(ii): The map \( h_{n} \) is the composition of the projection \( h_{n}' : A \otimes_{A_{0}} I_{0}^{n} \rightarrow E(n)_{0}^{00} \) with the injective map \( h_{n}'' : E(n)_{0}^{00} \rightarrow E(n)_{2}^{00} \) deduced from the spectral sequences \( (10.6.53) \). But since the inverse system \( (E(n)_{2}^{pq} \mid n \in \mathbb{N}) \) is uniformly essentially zero for every \( p > 0 \), and vanishes for \( p \geq r \), the same holds for the inverse systems \( (E(n)_{\infty}^{pq} \mid n \in \mathbb{N}) \), and consequently the kernel of \( h_{n}' \) is uniformly essentially zero. Likewise, it is easily seen that the cokernel of \( h_{n}' \) is uniformly essentially zero.\[ \square \]

Define \( \mathcal{J}(n) \) as in claim 10.6.52(ii), and set \( J(n)^{p} := H^{p}(Y', \mathcal{J}(n)) \) for every \( n, p \in \mathbb{N} \); we get an exact sequence of inverse systems

\[ (J(n)^{p} \mid n \in \mathbb{N}) \rightarrow (E(n)_{2}^{00} \mid n \in \mathbb{N}) \rightarrow (H^{p}(Y, O_{Y}(n)) \mid n \in \mathbb{N}) \rightarrow (J(n)^{p+1} \mid n \in \mathbb{N}) \]

for every \( p \in \mathbb{N} \), and claims 10.6.52(ii) and 10.6.54(i) imply that the first and third terms are uniformly essentially zero, whenever \( p > 0 \). Therefore, the same holds for the middle term.
Lastly, we consider the commutative diagram

\[(A \otimes_{A_0} I_n^0 \mid n \in \mathbb{N}) \xrightarrow{m_*} (I_n^0 \mid n \in \mathbb{N}) \]

\[h_* \downarrow \quad \downarrow h_* \]

\[(E(n)_2^{0\circ} \mid n \in \mathbb{N}) \xrightarrow{k_0^\circ} (H^0(Y, \mathcal{O}_Y(n)) \mid n \in \mathbb{N}) \]

where \(m_*\) is given by the natural surjections, and \(h_*\) is defined as in claim [10.6.54]. Since the inverse system \((J(n)^p \mid n \in \mathbb{N})\) is uniformly essentially zero for \(p = 0, 1\), we see that the kernel and cokernel of \(k_0^\circ\) are both uniformly essentially zero. In view of claim [10.6.54](ii), it follows immediately that the kernel of \(m_*\) is uniformly essentially zero, and the same holds for the kernel and cokernel of \(h_*\), which concludes the verification of both (a) and (b).

Lastly, we check that (c) implies both (a) and (b). To this aim we consider, for every \(n \in \mathbb{N}\), the spectral sequences provided by proposition [10.2.30](ii)

\[E(n)_2^{pq} := \text{Tor}_p^{A_0}(I_0^0, H^q(Y, \mathcal{O}_Y)) \Rightarrow H^{p+q}(I_0^0 \otimes_{A_0} R \Gamma \mathcal{O}_Y)\]

\[F(n)_2^{pq} := H^p(Y, \mathcal{F} \text{or}_{-q}^0(\mathcal{I}_0^n, \mathcal{O}_Y)) \Rightarrow H^{p+q}(I_0^0 \otimes_{A_0} R \Gamma \mathcal{O}_Y).\]

Moreover, for every \(n \in \mathbb{N}\) denote by

\[\varphi_n : \mathcal{F} \text{or}_{-0}^0(\mathcal{O}_Y(n), \mathcal{I}_0^n) = \pi_0^* \mathcal{I}_0^n \rightarrow \mathcal{I}_0^n \mathcal{O}_Y = \mathcal{O}_Y(n)\]

the natural morphism, and notice that \(\psi_0^* \mathcal{I}_0^n = \mathcal{F} \text{or}_{-0}^0(\mathcal{I}_0^n, \mathcal{O}_Y)\).

**Claim 10.6.55.** (i) The inverse system \((\ker \varphi_n \mid n \in \mathbb{N})\) is uniformly essentially zero, and the same holds for the inverse system \((\mathcal{F} \text{or}_{-0}^0(\mathcal{I}_0^n, \mathcal{O}_Y) \mid n \in \mathbb{N})\), for every \(q > 0\).

(ii) The spectral inverse systems \((E(n)_2^{pq} \mid n \in \mathbb{N})\) is uniformly essentially zero for \(i \neq 0\).

(iii) The spectral sequences \((E(n)_2^{pq} \mid n \in \mathbb{N})\) induce, for every \(p \in \mathbb{Z}\), an epimorphism of inverse systems \((E(n)_2^{pq} \mid n \in \mathbb{N}) \rightarrow (E(n)_2^{pq} \mid n \in \mathbb{N})\) whose kernel is uniformly essentially zero.

(iv) The spectral sequences \((F(n)_2^{pq} \mid n \in \mathbb{N})\) induce, for every \(p \in \mathbb{Z}\), a monomorphism of inverse systems \((F(n)_2^{pq} \mid n \in \mathbb{N}) \rightarrow (F(n)_2^{pq} \mid n \in \mathbb{N})\) whose cokernel is uniformly essentially zero.

(v) The inverse systems \((E(n)_2^{-pq} \mid n \in \mathbb{N})\) and \((F(n)_2^{pq} \mid n \in \mathbb{N})\) are uniformly essentially zero for \(p < 0\), and vanish identically for \(p > 0\).

**Proof of the claim.** (i): We look at the spectral sequence

\[G(n)_2^{pq} := \mathcal{F} \text{or}_{-0}^0(\mathcal{O}_Y(n), \mathcal{F} \text{or}_{-0}^0(\mathcal{I}_0^n, \mathcal{O}_Y)) \Rightarrow \mathcal{F} \text{or}_{-0}^0(\mathcal{I}_0^n, \mathcal{O}_Y)\]

of proposition [10.2.30](i). Since \(Y_0\) is a noetherian scheme, corollary [7.9.20](iii) implies that the inverse system \((\mathcal{F} \text{or}_{-0}^0(\mathcal{O}_Y(n), \mathcal{I}_0^n) \mid n \in \mathbb{N})\) is uniformly essentially zero for every \(q > 0\), so the same holds for the inverse system \((G(n)_2^{pq} \mid n \in \mathbb{N})\), for every \(p \in \mathbb{N}\) and every \(q > 0\). By the same token, the inverse system \((\mathcal{F} \text{or}_{-0}^0(\mathcal{O}_Y(n), \mathcal{I}_0^n) \mid n \in \mathbb{N})\) is uniformly essentially zero; since the functor \(\mathcal{F} \text{or}_p^0(\mathcal{O}_Y, -) : \mathcal{D}^- (\mathcal{O}_Y_{-\text{Mod}_{\text{qcoh}}}) \rightarrow \mathcal{D}^- (\mathcal{O}_Y_{-\text{Mod}_{\text{qcoh}}})\)

is triangulated for every \(p \in \mathbb{Z}\), we get a short exact sequence

\[0 \rightarrow \mathcal{F} \text{or}_p^0(\mathcal{O}_Y, \ker \varphi_0) \rightarrow G(n)_2^{p0} \rightarrow \mathcal{F} \text{or}_p^0(\mathcal{O}_Y, \mathcal{O}_Y(n)) \rightarrow 0 \quad \text{for every} \ p, n \in \mathbb{N}\]

which shows that the inverse system \((G(n)_2^{p0} \mid n \in \mathbb{N})\) is uniformly essentially zero for every \(p > 0\). The assertion now follows by a simple induction, using lemma [7.8.19](ii).

(ii): Condition (c) implies that the inverse system \((E(n)_2^{pq} \mid n \in \mathbb{N})\) is uniformly essentially zero for \(q > 0\), and clearly it vanishes identically when either \(q < 0\) or \(p > 0\). It also vanishes identically for \(q \geq r\), due to theorem [10.2.28](iii). Summing up, we see that the filtration induced by the spectral sequence \(E(n)_2^{pq}\) on its abutment \(H^i := H^i(I_0^0 \otimes_{A_0} R \Gamma \mathcal{O}_Y)\) is finite for
every $i \in \mathbb{Z}$, and the inverse systems of its graded subquotients $(E(n)_{2}^{\mathbb{Z}} \mid n \in \mathbb{N})$ are uniformly essentially zero whenever $p + q > 0$, whence the assertion in case $i > 0$, after invoking as usual lemma 7.8.19. For $i < 0$, we argue likewise, using the spectral sequences $F(n)_{2}^{\mathbb{Z}}$: indeed, we see again easily that the filtration induced on the abutment $H^j$ is finite for every $i \in \mathbb{Z}$; moreover, if $p < 0$ the inverse system $(F(n)_{2})_{p}^{\mathbb{Z}} \mid n \in \mathbb{N}$ is identically zero, and it is uniformly essentially zero if $q < 0$, by virtue of (i), whence the assertion.

(iii): For $p > 0$ we have $E(n)_{2}^{p0} = 0$ for every $n \in \mathbb{N}$, so the assertion is trivial in this case. For $p \leq 0$, notice that $E(n)_{s}^{p+s+1-s} = 0$ for every $s \geq 2$, hence $E(n)_{s}^{p0}$ is a quotient of $E(n)_{2}^{p0}$ for every $s \geq 2$, whence a surjection $E(n)_{2}^{p0} \to E(n)_{s}^{p0}$ as sought. Moreover, notice that the inverse system $(E(n)_{s}^{p+s-s-1} \mid n \in \mathbb{N})$ is uniformly essentially zero for every $s \geq 2$, due to condition (c) and lemma 7.8.24, and it vanishes identically for $s \geq r$. Then the same holds for the inverse system $(E(n)_{s}^{p-s,s-1} \mid n \in \mathbb{N})$, for every $s \geq 2$, and the assertion follows easily.

(iv): For $p < 0$ we have $F(n)_{2}^{p0} = 0$ for every $n \in \mathbb{N}$, so the assertion is trivial in this case. For $p \geq 0$, notice that $F(n)_{s}^{p-s,s-1} = 0$ for every $s \geq 2$, hence $F(n)_{s}^{p0}$ is a submodule of $F(n)_{2}^{p0}$ for every $s \geq 2$, whence a injection $F(n)_{2}^{p0} \to F(n)_{s}^{p0}$ as sought. Moreover, notice that the inverse system $(F(n)_{2}^{p+s+1-s} \mid n \in \mathbb{N})$ is uniformly essentially zero for every $s \geq 2$, due to (i), and it vanishes identically for $s \geq r$. Then the same holds for the inverse system $(F(n)_{s}^{p+s-s-1} \mid n \in \mathbb{N})$, for every $s \geq 2$, and the assertion follows easily.

(v): The assertion for $p > 0$ is obvious, and the case $p < 0$ for $(E(n)_{2}^{p} \mid n \in \mathbb{N})$ follows from condition (c) and lemma 7.8.24 and for $(F(n)_{2}^{p} \mid n \in \mathbb{N})$ follows from (i).

Assumption (c) implies that the natural map $A \to H^{0}(Y, \mathcal{O}_{Y})$ induces a morphism of inverse systems $$(\text{Tor}^{A}_{0}(I_{n}^{0}, A) \mid n \in \mathbb{N}) \to (E(n)_{2}^{0} \mid n \in \mathbb{N}) \quad \text{for every } p \in \mathbb{Z}$$ whose kernel and cokernel are uniformly essentially zero. Combining with claim 10.6.55(ii,iii), it follows already that the inverse system $(\text{Tor}^{A}_{p}(A/I_{n}^{0}, A) \mid n \in \mathbb{N})$ is uniformly essentially zero for every $p > 1$. Next, since $\mathcal{O}_{Y_0}(n)$ is a flat $\mathcal{O}_{Y_0}$-module for every $n \in \mathbb{N}$, we have an exact sequence of $\mathcal{O}_{Y}$-modules $0 \to \psi^{*}\text{Ker } \varphi_{n} \to \mathcal{I}_{Y_{0}}^{X_{0}}(\mathcal{I}_{0}^{n}, \mathcal{O}_{Y}) \to \psi^{*}\mathcal{O}_{Y_0}(n) = \mathcal{O}_{Y}(n) \to 0$ whence exact sequences $$H^{p}(Y, \psi^{*}\text{Ker } \varphi_{n}) \to F(n)_{2}^{p0} \to H^{p}(Y, \mathcal{O}_{Y}(n)) \to H^{p+1}(Y, \psi^{*}\text{Ker } \varphi_{n})$$ for every $p \in \mathbb{Z}$ and every $n \in \mathbb{N}$. Combining with claim 10.6.55(ii,iv), we deduce that the inverse system $(H^{p}(Y, \mathcal{O}_{Y}(n)) \mid n \in \mathbb{N})$ is uniformly essentially zero for every $p > 0$.

Lastly, claim 10.6.55(v) implies that $(E(n)_{p}^{p-p} \mid n \in \mathbb{N})$ and $(F(n)_{p}^{p} \mid n \in \mathbb{N})$ vanish identically for every $p > 0$, and are uniformly essentially zero inverse systems for $p < 0$. It follows that the spectral sequences $E(n)_{2}^{\mathbb{Z}}$ and $F(n)_{2}^{\mathbb{Z}}$ induce respectively a monomorphism and an epimorphism $$(E(n)_{2}^{00} \mid n \in \mathbb{N}) \to (H^{0}(I_{n}^{0} \otimes_{A_{0}} R \mathcal{O}_{Y}) \mid n \in \mathbb{N}) \to (F(n)_{2}^{00} \mid n \in \mathbb{N})$$ and the kernel and cokernel of the composition of these morphisms is uniformly essentially zero inverse systems. Taking into account claim 10.6.55(iv) we get therefore a commutative diagram of inverse systems $$\begin{align*} (E(n)_{2}^{00} \mid n \in \mathbb{N}) & \to (E(n)_{2}^{00} \mid n \in \mathbb{N}) \to (F(n)_{2}^{00} \mid n \in \mathbb{N}) \\
(I_{n}^{0} \otimes_{A_{0}} H^{0}(Y, \mathcal{O}_{Y}) \mid n \in \mathbb{N}) & \xrightarrow{\delta} (H^{0}(Y, \mathcal{O}_{Y}(n)) \mid n \in \mathbb{N}) \leftarrow (F(n)_{2}^{00} \mid n \in \mathbb{N}) \end{align*}$$
all whose arrows, except possibly \( \beta_* \), have uniformly essentially zero kernels and cokernels, but then also \( \beta_* \) does.

**Claim 10.6.56.** \( \beta_* \) is the map induced by the identification \( \omega_n : \mathcal{S}^n \mathcal{O}_Y \cong \mathcal{O}_Y(n) \) of remark 10.6.39(iv) and the natural map \( \psi^* \pi_0^s \mathcal{S}_0^n \to \mathcal{S}^n \mathcal{O}_Y \).

**Proof of the claim.** Indeed, by construction, the map \( F(n)_2^0 \rightarrow H^0(Y, \mathcal{O}_Y(n)) \) is obtained from the identification \( \omega_n \) and the natural isomorphism \( \mathcal{S}^n \mathcal{O}_{Y_0} \cong \psi^* \pi_0^s \mathcal{S}_0^n \), so we are reduced to checking that the map

\[
E(n)_2^0 = I^n_0 \otimes A_0 H^0(Y, \mathcal{O}_Y) \rightarrow F(n)_2^0 = H^0(Y, \psi^* \pi_0^s \mathcal{S}_0^n)
\]

deduced from the foregoing commutative diagram, agrees with the standard one that assigns to any element \( x \otimes s \) its class in \( H^0(Y, \psi^* \pi_0^s \mathcal{S}_0^n) \). To this aim, set \( U_i := D_+(f_i) \subset Y \) for \( i = 1, \ldots, r \), and let \( Y' := \amalg_{i=1}^r U_i \), the affine \( X \)-scheme given by the disjoint union of the affine open subsets \( U_1, \ldots, U_r \). We have an obvious morphism \( \nu : Y' \rightarrow Y \) of schemes, that restricts to the inclusion map on each open subset \( U_i \) of \( Y' \), and let also \( \psi' := \psi \circ \nu : Y' \rightarrow Y_0 \).

We have as well two systems of spectral sequences \( E''(n)_2^0 \) and \( F''(n)_2^0 \), obtained as in the foregoing, after replacing \( Y \) by \( Y' \) and \( \mathcal{O}_Y \) by \( \mathcal{O}_{Y'} \). By functoriality of the spectral sequences, there follows a commutative diagram

\[
\begin{array}{ccc}
E(n)_2^0 = I^n_0 \otimes A_0 H^0(Y, \mathcal{O}_Y) & \longrightarrow & F(n)_2^0 = H^0(Y, \psi^* \pi_0^s \mathcal{S}_0^n) \\
\downarrow & & \downarrow \\
E''(n)_2^0 = I^n_0 \otimes A_0 H^0(Y', \mathcal{O}_{Y'}) & \longrightarrow & F''(n)_2^0 = H^0(Y', \psi'^* \pi_0^s \mathcal{S}_0^n)
\end{array}
\]

and notice that the right vertical arrow is injective. Thus, it suffices to check that the bottom horizontal arrow is the expected map. However, we have \( E''(n)_2^0 = E''(n)_\infty^0 = E''(n)_\infty^0 = F''(n)_\infty^0 = F''(n)_\infty^0 = F''(n)_2^0 \) for every \( n \in \mathbb{N} \), and a direct inspection shows that the bottom horizontal map is the identity map, whence the claim.

From claim 10.6.56 and condition (c), it follows already that the natural morphism of inverse systems \( \left( I^n_0 \otimes A_0 \mid n \in \mathbb{N} \right) \rightarrow \left( H^0(Y, \mathcal{O}_{Y'}(n)) \mid n \in \mathbb{N} \right) \) has uniformly essentially zero kernel and cokernel. But the latter factors as the composition of the epimorphism of inverse systems \( \left( I^n_0 \otimes A_0 \mid n \in \mathbb{N} \right) \rightarrow \left( I^n \mid n \in \mathbb{N} \right) \) and the natural morphism \( \left( I^n \mid n \in \mathbb{N} \rightarrow \left( H^0(Y, \mathcal{O}_{Y'}(n)) \mid n \in \mathbb{N} \right) \right) \). It follows that the kernels and cokernels of both of the latter morphisms are uniformly essentially zero, and the proof of the theorem is concluded.

**Remark 10.6.57.** By direct inspection of the proof, we obtain the following refinement of theorem 10.6.50. For every \( r \in \mathbb{N} \) there exists an integer \( \nu(r) \) such that, if the ring \( A \) satisfies condition (a)\( _4^n \) with step \( \leq r \), then the inverse system \( \left( H^0(Y, \mathcal{O}_{Y'}(n)) \mid n \in \mathbb{N} \right) \) is uniformly essentially zero with step \( \leq \nu(r) \), and the same holds for the kernel and cokernel of the inverse system \( \left( I^n \rightarrow H^0(Y, \mathcal{O}_{Y'}(n)) \mid n \in \mathbb{N} \right) \). The detailed verification shall be left to the reader.

### 11. Duality theory

#### 11.1. Duality for quasi-coherent modules

Let \( f : X \rightarrow Y \) be a morphism of schemes; theorem 10.1.18 falls short of proving that \( Lf^* \) is a left adjoint to \( Rf_* \), since the former functor is defined on bounded above complexes, while the latter is defined on complexes that are bounded below. This deficiency has been overcome by N.Spaltenstein’s paper [118], where he shows how to extend the usual constructions of derived functors to unbounded complexes. On the other hand, in many cases one can also construct a right adjoint to \( Rf_* \). This is the subject of Grothendieck’s duality theory. We shall collect the statements that we need from that theory, and refer to the original source [70] for the rather elaborate proofs.
11.1.1. For any morphism of schemes \( f : X \to Y \), let \( \overline{f} : (X, \mathcal{O}_X) \to (Y, f_*\mathcal{O}_X) \) be the corresponding morphism of ringed spaces. The functor
\[
\overline{f}_*: \mathcal{O}_X\text{-Mod} \to f_*\mathcal{O}_X\text{-Mod}
\]
admits a left adjoint \( \overline{f}^* \) defined as usual ([44 Ch.0, §4.3.1]). In case \( f \) is affine, \( \overline{f} \) is flat and the unit and counit of the adjunction restrict to isomorphisms of functors:
\[
1 \to \overline{f}_* \circ \overline{f}^*: f_*\mathcal{O}_X\text{-Mod}_{qcoh} \to f_*\mathcal{O}_X\text{-Mod}_{qcoh}
\]
\[
\overline{f}^* \circ \overline{f}_* \to 1 : \mathcal{O}_X\text{-Mod}_{qcoh} \to \mathcal{O}_X\text{-Mod}_{qcoh}
\]
on the corresponding subcategories of quasi-coherent modules ([45 Ch.II, Prop.1.4.3]). It follows easily that, on these subcategories, \( \overline{f}^* \) is also a right adjoint to \( \overline{f}_* \).

**Lemma 11.1.2.** Keep the notation of ([11.1.1]), and suppose that \( f \) is affine. Then the functor:
\[
\overline{f}^*: \mathbf{D}^+(f_*\mathcal{O}_X\text{-Mod})_{qcoh} \to \mathbf{D}^+(\mathcal{O}_X\text{-Mod})_{qcoh}
\]
is right adjoint to the functor \( R\overline{f}_*: \mathbf{D}^+(\mathcal{O}_X\text{-Mod})_{qcoh} \to \mathbf{D}^+(f_*\mathcal{O}_X\text{-Mod})_{qcoh} \). Moreover, the unit and counit of the resulting adjunction are isomorphisms of functors.

**Proof.** By trivial duality (theorem [10.1.18]), \( \overline{f}^* \) is left adjoint to \( R\overline{f}_* \) on \( \mathbf{D}^+(\mathcal{O}_X\text{-Mod}) \); it suffices to show that the unit (resp. and counit) of this latter adjunction are isomorphisms for every object \( K^* \) of \( \mathbf{D}^+(\mathcal{O}_X\text{-Mod})_{qcoh} \) (resp. \( L^* \) of \( \mathbf{D}^+(f_*\mathcal{O}_X\text{-Mod})_{qcoh} \)). Concerning the unit, we can use a Cartan-Eilenberg injective resolution of \( \overline{f}^*K^* \), and a standard spectral sequence, to reduce to the case where \( K^* = \mathcal{F}[0] \) for a quasi-coherent \( f_*\mathcal{O}_X \)-module \( \mathcal{F} \); however, the natural map \( \overline{f}_* \circ \overline{f}^*\mathcal{F} \to R\overline{f}_* \circ \overline{f}^*\mathcal{F} \) is an isomorphism, so the assertion follows from ([11.1.1]). \( \square \)

**Remark 11.1.3.** (i) Even when both \( X \) and \( Y \) are affine, neither the unit nor the counit of adjunction in ([11.1.1]) is an isomorphism on the categories of all modules. For a counterexample concerning the unit, consider the case of a finite injection of domains \( A \to B \), where \( A \) is local and \( B \) is semi-local (but not local); let \( f : X := \text{Spec } B \to \text{Spec } A \) be the corresponding morphism, and denote by \( \mathcal{F} \) the \( f_*\mathcal{O}_X \)-module supported on the closed point, with stalk equal to \( B \). Then one verifies easily that \( \overline{f}_* \circ \overline{f}^*\mathcal{F} \) is a direct product of finitely many copies of \( \mathcal{F} \), indexed by the closed points of \( X \). Concerning the counit, keep the same morphism \( f \), let \( U := X \setminus \{x\} \), where \( x \) is a closed point and set \( \mathcal{F} := j_!\mathcal{O}_U \); then it is clear that \( \overline{f}^* \circ \overline{f}_*\mathcal{F} \) is supported on the complement of the closed fibre of \( f \).

(ii) Similarly, one sees easily that \( \overline{f}^* \) is not a right adjoint to \( \overline{f}_* \) on the category of all \( f_*\mathcal{O}_X \)-modules.

(iii) Incidentally, the analogous functor \( \overline{f}^*_{\text{ét}} \) defined on the étale (rather than Zariski) site is a right adjoint to \( \overline{f}_{\text{ét}*} : \mathcal{O}_{X,\text{ét}}\text{-Mod} \to f_*\mathcal{O}_{X,\text{ét}}\text{-Mod} \), and on these sites the unit and counit of the adjunctions are isomorphisms for all modules.

11.1.4. For the construction of the right adjoint \( f^! \) to \( Rf_* \), one considers first the case where \( f \) factors as a composition of a finite morphism followed by a smooth one, in which case \( f^! \) admits a corresponding decomposition. Namely:

- In case \( f \) is smooth, we shall consider the functor:
\[
f^! : \mathbf{D}(\mathcal{O}_Y\text{-Mod}) \to \mathbf{D}(\mathcal{O}_X\text{-Mod}) \quad K^* \mapsto f^*K^* \otimes_{\mathcal{O}_X} \Omega^1_{X/Y}[n]
\]
where \( n \) is the locally constant relative dimension function of \( f \).
- In case \( f \) is finite, we shall consider the functor:
\[
f^! : \mathbf{D}^+(\mathcal{O}_Y\text{-Mod}) \to \mathbf{D}^+(\mathcal{O}_X\text{-Mod}) \quad K^* \mapsto R\mathcal{H}om^\bullet_{\mathcal{O}_Y}(f_*,\mathcal{O}_X,K^*).
\]
If $f$ is any quasi-projective morphism, such factorization can always be found locally on $X$, and one is left with the problem of patching a family of locally defined functors $((f_U)^i | i \in I)$, corresponding to an open covering $X = \bigcup_{i \in I} U_i$. Since such patching must be carried out in the derived category, one has to take care of many cumbersome complications.

11.1.5. Recall that a finite morphism $f : X \to Y$ is said to be pseudo-coherent if $f_* \mathcal{O}_X$ is a pseudo-coherent $\mathcal{O}_Y$-module. This condition is equivalent to the pseudo-coherence of $f$ in the sense of [16, Exp.III, Def.1.2].

**Lemma 11.1.6.** Let $f : X \to Y$ be a finite morphism of schemes. Then:

(i) If $f$ is finitely presented, the functor
\[ \mathcal{F} \mapsto \mathcal{T}^* \mathcal{H}om_{\mathcal{O}_Y}(f_* \mathcal{O}_X, \mathcal{F}) \]
is right adjoint to $f_* : \mathcal{O}_X^{\text{Mod}_{\text{qcoh}}} \to \mathcal{O}_Y^{\text{Mod}_{\text{qcoh}}}$.

(ii) If $f$ is pseudo-coherent, the functor
\[ K^* \mapsto \mathcal{T}^* R \mathcal{H}om_{\mathcal{O}_Y}(f_* \mathcal{O}_X, K^*) : D^+ (\mathcal{O}_Y^{\text{Mod}}) \to D^+ (\mathcal{O}_X^{\text{Mod}}) \]
is right adjoint to
\[ Rf_* : D^+ (\mathcal{O}_X^{\text{Mod}}) \to D^+ (\mathcal{O}_Y^{\text{Mod}}) \]
(notation of (10.3)).

**Proof.** (i): Under the stated assumptions, $f_* \mathcal{O}_X$ is a finitely presented $\mathcal{O}_Y$-module (by claim 9.1.33), hence the functor
\[ \mathcal{F} \mapsto \mathcal{H}om_{\mathcal{O}_Y}(f_* \mathcal{O}_X, \mathcal{F}) : \mathcal{O}_Y^{\text{Mod}} \to f_* \mathcal{O}_X^{\text{Mod}} \]
preserves the subcategories of quasi-coherent modules, hence it restricts to a right adjoint for the forgetful functor $f_* \mathcal{O}_X^{\text{Mod}_{\text{qcoh}}} \to \mathcal{O}_Y^{\text{Mod}_{\text{qcoh}}}$ (claim 10.1.17). Then the assertion follows from (11.1.1).

(ii) is analogous: since $f_* \mathcal{O}_X$ is pseudo-coherent, the functor
\[ K^* \mapsto R \mathcal{H}om_{\mathcal{O}_Y}(f_* \mathcal{O}_X, K^*) : D^+ (\mathcal{O}_Y^{\text{Mod}}) \to D^+ (f_* \mathcal{O}_X^{\text{Mod}}) \]
preserves the subcategories of complexes with quasi-coherent homology, hence it restricts to a right adjoint for the forgetful functor $D^+ (f_* \mathcal{O}_X^{\text{Mod}_{\text{qcoh}}}) \to D^+ (\mathcal{O}_Y^{\text{Mod}_{\text{qcoh}}})$, by lemma 10.1.16(iii). To conclude, it then suffices to apply lemma 11.1.2. \hfill $\square$

**Proposition 11.1.7.** Suppose that $X \xrightarrow{f} Y \xrightarrow{g} Z \xrightarrow{h} W$ are morphisms of schemes. Then:

(i) If $f$ and $g$ are finite and $f$ is pseudo-coherent, there is a natural isomorphism of functors on $D^+ (\mathcal{O}_Z^{\text{Mod}})$:
\[ \xi_{f,g} : (g \circ f)^\flat \xrightarrow{\sim} f^\flat \circ g^\flat. \]

(ii) If $f$ and $g \circ f$ are finite and pseudo-coherent, and $g$ is smooth of bounded fibre dimension, there is a natural isomorphism of functors on $D^+ (\mathcal{O}_Z^{\text{Mod}})$:
\[ \xi_{f,g} : (g \circ f)^\flat \xrightarrow{\sim} f^\flat \circ g^\flat. \]

(iii) If $f$, $g$ and $h \circ g$ are finite and pseudo-coherent, and $h$ is smooth of bounded fibre dimension, then the diagram of functors on $D^+ (\mathcal{O}_W^{\text{Mod}})$:
\[ \begin{array}{ccc}
(h \circ g \circ f)^\flat & \xrightarrow{\xi_{g \circ f,h}} & (g \circ f)^\flat \circ h^\flat \\
\xi_{f,h \circ g} \downarrow & & \downarrow \xi_{f,g \circ h} \\
(f^\flat \circ (h \circ g)^\flat) & \xrightarrow{f^\flat (\xi_{g \circ f,h})} & f^\flat \circ g^\flat \circ h^\flat
\end{array} \]
commutes.
(iv) If, moreover

\[
\begin{array}{ccc}
Y & \xrightarrow{g} & Z \\
\downarrow{h'} & & \downarrow{h} \\
W' & \xrightarrow{j} & W
\end{array}
\]

is a cartesian diagram of schemes, such that \(h\) is smooth of bounded fibre dimension and \(j\) is finite and pseudo-coherent, then there is a natural isomorphism of functors:

\[\vartheta_{j,h} : g^\flat \circ h^\# \sim h'^{\sharp} \circ j^{\flat}.\]

**Proof.** This is [70, Ch.III, Prop.6.2, 8.2, 8.6]. We check only (i). There is a natural commutative diagram of ringed spaces:

\[
\begin{array}{ccc}
(X, \mathcal{O}_X) & \xrightarrow{f} & (Y, \mathcal{O}_Y) \\
\downarrow{\alpha} & & \downarrow{\gamma} \\
(Y, f_*\mathcal{O}_X) & \xrightarrow{\varphi} & (Z, g_*\mathcal{O}_Y) \\
\downarrow{\beta} & & \downarrow{\beta} \\
(Z, (g \circ f)_*\mathcal{O}_X)
\end{array}
\]

where:

\[(11.1.8) \quad \varphi \circ f = \overline{g} \circ \overline{f}.
\]

By claim [10.1.17] the (forgetful) functors \(\alpha_*\), \(\beta_*\) and \(\gamma_*\) admit right adjoints:

\[\begin{array}{ccc}
\alpha^b : \mathcal{O}_Y\text{-Mod} & \rightarrow & f_*\mathcal{O}_X\text{-Mod} \\
\beta^b : g_*\mathcal{O}_Y\text{-Mod} & \rightarrow & (g \circ f)_*\mathcal{O}_X\text{-Mod} \\
\gamma^b : \mathcal{O}_Z\text{-Mod} & \rightarrow & g_*\mathcal{O}_Y\text{-Mod}
\end{array}\]

\[\begin{array}{c}
\mathcal{F} \rightarrow \mathcal{H}om_{\mathcal{O}_X}(f_*\mathcal{O}_X, \mathcal{F}) \\
\mathcal{F} \rightarrow \mathcal{H}om_{g_*\mathcal{O}_Y}((g \circ f)_*\mathcal{O}_X, \mathcal{F}) \\
\mathcal{F} \rightarrow \mathcal{H}om_{g_*\mathcal{O}_Y}(g_*\mathcal{O}_Y, \mathcal{F})
\end{array}\]

Likewise, \((\gamma \circ \beta)_*\) admits a right adjoint \((\gamma \circ \beta)^b\) and the natural identification

\[\gamma_* \circ \beta_* \sim (\gamma \circ \beta)_*\]

induces a natural isomorphisms of functors:

\[(11.1.9) \quad (\gamma \circ \beta)^b := \mathcal{H}om_{\mathcal{O}_Z}((g \circ f)_*\mathcal{O}_X, -) \sim \beta^b \circ \gamma^b.
\]

(Notice that, in general, there might be several choices of such natural transformations \((11.1.9)\), but for the proof of (iii) – as well as for the construction of \(f'!\) for more general morphisms \(f\) – it is essential to make an explicit and canonical choice.)

**Claim 11.1.10.** (i) \(\alpha_* \circ \varphi^* = \overline{g}^k \circ \beta_*\).

(ii) The natural commutative diagram of sheaves:

\[
\begin{array}{ccc}
\overline{g}^{-1}g_*\mathcal{O}_Y & \rightarrow & \mathcal{O}_Y \\
\downarrow & & \downarrow \\
\overline{g}^{-1}(g \circ f)_*\mathcal{O}_X & \rightarrow & f_*\mathcal{O}_X
\end{array}
\]

is cocartesian.

**Proof of the claim.** (i) is an easy consequence of (ii). Assertion (ii) can be checked on the stalks, hence we may assume that \(Z = \text{Spec} \, A\), \(Y = \text{Spec} \, B\) and \(X = \text{Spec} \, C\) are affine schemes. Let \(p \in Y\) be any prime ideal, and set \(q := g(p) \in Z\); then \((\overline{g}^{-1}g_*\mathcal{O}_Y)_p = B_q\) (the \(A_q\)-module
obtained by localizing the $A$-module $B$ at the prime $q)$. Likewise, $(\overline{g}^{-1}(g \circ f)_* \mathcal{O}_X)_p = C_q$ and $(f_* \mathcal{O}_X)_p = C_p$. Hence the claim boils down to the standard isomorphism : $C_q \otimes_{B_q} B_p \cong C_p$. \end{proof}

Let $I^*$ be a bounded below complex of injective $\mathcal{O}_Z$-modules; by lemma [10.1.16 (i)], $\overline{g} I^*$ is a complex of injective $g_* \mathcal{O}_Y$-modules; taking into account (11.1.9) we deduce a natural isomorphism of functors on $\text{D}^+(\mathcal{O}_Z^{-\text{Mod}})$:

$$R(\gamma \circ \beta^\circ) \sim R(\beta^\circ \circ \gamma^\circ) = R\beta^\circ \circ R\gamma^\circ.$$  

Furthermore, (11.1.8) implies that $g \circ f^* = \overline{f}^* \circ \varphi^*$. Combining with (11.1.11), we see that the sought $\xi_{f,g}$ is a natural transformation:

$$\overline{f}^* \circ \varphi^* \circ R\beta^\circ \circ R\gamma^\circ \rightarrow \overline{f}^* \circ R\alpha^\circ \circ \overline{g}^\circ \circ R\gamma^\circ$$

of functors on $\text{D}^+(\mathcal{O}_Z^{-\text{Mod}})$. Hence (i) will follow from:

**Claim 11.1.12.** (i) There exists a natural isomorphism of functors : $g_* \mathcal{O}_Y^{-\text{Mod}} \rightarrow f_* \mathcal{O}_X^{-\text{Mod}}$ : $\varphi^* \circ \beta^\circ \sim \alpha^\circ \circ \overline{g}^\circ$.

(ii) The natural transformation:

$$R(\alpha^\circ \circ \overline{g}^\circ) \rightarrow R\alpha^\circ \circ \overline{g}^\circ$$

is an isomorphism of functors : $\text{D}^+(g_* \mathcal{O}_Y^{-\text{Mod}}) \rightarrow \text{D}^+(f_* \mathcal{O}_X^{-\text{Mod}})$.

**Proof of the claim.** First we show how to construct a natural transformation as in (i); this is the same as exhibiting a map of functors : $\alpha \circ \varphi \circ \beta \rightarrow \overline{g}^\circ$. In view of claim [11.1.10 (i)], the latter can be defined as the composition of $\overline{g}^\circ$ and the counit of adjunction $\beta \circ \beta \rightarrow 1_{g_* \mathcal{O}_Y^{-\text{Mod}}}$.

Next, recall the natural transformation :

$$\overline{g}^\circ \mathcal{H}om_{g_* \mathcal{O}_Y}(\mathcal{F}, \mathcal{G}) \rightarrow \mathcal{H}om_{\mathcal{O}_Y}(\overline{g}^\circ \mathcal{F}, \overline{g}^\circ \mathcal{G})$$

for every $g_* \mathcal{O}_Y$-modules $\mathcal{F}$ and $\mathcal{G}$ (defined so as to induce the pull-back map on global $\mathcal{H}om$ functors). Notice that the natural map $\overline{g}^\circ \mathcal{F} \rightarrow \mathcal{F}$ (counit of adjunction) is an isomorphism for every quasi-coherent $\mathcal{O}_Y$-module $\mathcal{F}$. Especifially, if $\mathcal{F} = g_* \mathcal{A}$ for a quasi-coherent $\mathcal{O}_Y$-module $\mathcal{A}$, then (11.1.13) takes the form :

$$\overline{g}^\circ \mathcal{H}om_{g_* \mathcal{O}_Y}(\overline{g}^\circ \mathcal{A}, \mathcal{G}) \rightarrow \mathcal{H}om_{\mathcal{O}_Y}(\mathcal{A}, \overline{g}^\circ \mathcal{G})$$

Furthermore, by inspecting the definitions (and the proof of claim [10.1.17]), one verifies easily that the map $\varphi \circ \beta \rightarrow \alpha \circ \overline{g}^\circ$ constructed above is the same as the map (11.1.14), taken with $\mathcal{A} = f_* \mathcal{O}_X$. Notice that, since $f$ is pseudo-coherent, $f_* \mathcal{O}_X$ is even a finitely presented $\mathcal{O}_Y$-module; thus, in order to conclude the proof of (i), it suffices to show that (11.1.14) is an isomorphism for every finitely presented $\mathcal{O}_Y$-module $\mathcal{A}$ and every $g_* \mathcal{O}_Y$-module $\mathcal{G}$. To this aim, we may assume that $Z$ and $Y$ are affine; then we may find a presentation $\mathcal{E} : = ( \mathcal{O}_Y^{\oplus} \rightarrow \mathcal{O}_Y^{\oplus} \rightarrow \mathcal{A} \rightarrow 0)$. We apply the natural transformation (11.1.14) to $\mathcal{E}$, thereby obtaining a commutative ladder with left exact rows; then the five-lemma reduces the assertion to the case where $\mathcal{A} = \mathcal{O}_Y$, which is obvious. To prove assertion (ii) we may again assume that $Y$ and $Z$ are affine, in which case we can find a resolution $L_* \rightarrow f_* \mathcal{O}_X$ consisting of free $\mathcal{O}_Y$-modules of finite rank. For a given bounded below complex $I^*$ of injective $g_* \mathcal{O}_Y$-modules, we deduce a commutative ladder :

$$\overline{g}^\circ \mathcal{H}om_{\mathcal{O}_Y}^\circ (g_* f_* \mathcal{O}_X, I^*) \xrightarrow{\mu_1} \mathcal{H}om_{\mathcal{O}_Y}^\circ (f_* \mathcal{O}_X, \overline{g}^\circ I^*) \xrightarrow{\mu_3} \mathcal{H}om_{\mathcal{O}_Y}^\circ (f_* \mathcal{O}_X, J^*)$$

$$\overline{g}^\circ \mathcal{H}om_{\mathcal{O}_Y}^\circ (g_* L_*, I^*) \xrightarrow{\mu_2} \mathcal{H}om_{\mathcal{O}_Y}^\circ (L_*, \overline{g}^\circ I^*) \xrightarrow{\mu_4} \mathcal{H}om_{\mathcal{O}_Y}^\circ (L_*, J^*)$$

Since $\overline{g}$ is flat, $\lambda_1$ is a quasi-isomorphism, and the same holds for $\lambda_2$. The maps $\mu_1$ and $\mu_2$ are of the form (11.1.14), hence they are quasi-isomorphisms, by the foregoing proof of (i). Finally,
it is clear that \( \mu_4 \) is a quasi-isomorphism as well, hence the same holds for \( \mu_3 \circ \mu_1 \), and (ii) follows.

11.1.15. Let now \( f : X \to Y \) be an embeddable morphism, i.e. such that it can be factored as a composition \( f = g \circ h \) where \( h : X \to Z \) is a finite pseudo-coherent morphism, \( g : Z \to Y \) is smooth and separated, and the fibres of \( g \) have bounded dimension. One defines:

\[ f^! := h^! \circ g^! \]

**Lemma 11.1.16.** Let \( X \xrightarrow{f} Y \xrightarrow{g} Z \xrightarrow{h} W \) be three embeddable morphisms of schemes, such that the compositions \( g \circ f \), \( h \circ g \) and \( h \circ g \circ f \) are also embeddable. Then we have:

(i) There exists a natural isomorphism of functors

\[ \psi_{g,f} : (g \circ f)^! \cong f^! \circ g^! . \]

Especially, \( f^! \) is independent – up to a natural isomorphism of functors – of the choice of factorization as a finite morphism followed by a smooth morphism.

(ii) The diagram of functors:

\[
\begin{array}{ccc}
(h \circ g \circ f)^! & \xrightarrow{\psi_{h,g} \circ f} & f^! \circ h^! \\
\psi_{h,g,f} & & \psi_{g,f} \circ h^!
\end{array}
\]

commutes.

**Proof.** The proof is a complicated verification, starting from proposition 11.1.7. See [70, Ch.III, Th.8.7] for details.

11.1.17. Let \( X \xrightarrow{f} Y \xrightarrow{g} Z \) be two finite and pseudo-coherent morphisms of schemes. The map

\[ f^! : \mathcal{O}_Y \to f_* \mathcal{O}_X \]

induces a natural transformation:

\[ Rf_* \circ g \circ f^* \overset{1}{\longrightarrow} \alpha_* \circ Rf_* \circ f^* \overset{2}{\longrightarrow} \alpha_* \circ \varphi^* \overset{3}{\longrightarrow} g^* \circ \beta_* \]

(11.1.18)

\[ \mathcal{H}om_{\mathcal{O}_X}(g_*(f^!), -) : \beta_* \circ (\gamma \circ \beta)^! \to \gamma^! \]

(11.1.19)

where:

1. is deduced from (11.1.8) and the decomposition \( f = \alpha \circ \overline{f} \).
2. is induced from the counit of adjunction \( \overline{\varepsilon} : Rf_* \circ \overline{f}^* \to 1 \) provided by lemma 11.1.2.
3. is the identification of claim 11.1.10.

We define a morphism of functors as a composition:

\[ Rf_* \circ (g \circ f)^! = Rf_* \circ g \circ \overline{f}^* \circ R(\gamma \circ \beta)^! \overset{4}{\longrightarrow} g^* \circ \beta_* \circ R(\gamma \circ \beta)^! \overset{5}{\longrightarrow} g^! \]

(11.1.20)

where:

4. is the isomorphism (11.1.19) \( \circ R(\gamma \circ \beta)^! \).
5. is the composition of \( g^* \) and the morphism \( \beta_* \circ R(\gamma \circ \beta)^! \to R\gamma^! \) deduced from (11.1.18).
We have a natural diagram of functors on $\mathbf{D}^+(\mathcal{O}_Z\text{-Mod})_{qcoh}$:

$$
\begin{array}{cccc}
R(g \circ f)_* \circ (g \circ f)^b & \xrightarrow{\delta} & Rg_* \circ Rf_* \circ (g \circ f)^b & \xrightarrow{\gamma} & Rg_* \circ g^b \\
\downarrow_{R(g \circ f)_*(\xi_{f,g})} & & \downarrow_{Rg_* \circ Rf_*(\xi_{f,g})} & & \downarrow_{Rg_* \circ Rf_* (f^b \circ g^b)}
\end{array}
\tag{11.1.21}
$$

where:

- $\delta$ and $\gamma$ are induced by the natural isomorphism $R(g \circ f)_* \sim Rg_* \circ Rf_*$. 
- $\epsilon$ is induced by the counit of the adjunction $\varepsilon : Rf_* \circ f^b \to 1$. 
- $\eta$ is $Rg_* \circ (11.1.20)$. 

**Lemma 11.1.22.** *In the situation of (11.1.17), diagram (11.1.21) commutes.*

**Proof.** The diagram splits into left and right subdiagrams, and clearly the left subdiagram commutes, hence it remains to show that the right one does too; to this aim, it suffices to consider the simpler diagram:

$$
\begin{array}{c}
Rf_* \circ (g \circ f)^b \\
\downarrow_{Rf_* (\xi_{f,g})}
\end{array} \xrightarrow{\alpha} \begin{array}{c}
g^b \\
\downarrow_{Rf_* (\xi_{f,g})}
\end{array}
$$

whose horizontal arrow is (11.1.20), and whose upward arrow is deduced from the counit $\varepsilon$. However, the counit $\varepsilon$, used in $\epsilon$, can be expressed in terms of the counit $\varepsilon : Rf_* \circ f^b \to 1$, used in $\delta$, therefore we are reduced to considering the diagram of functors on $\mathbf{D}^+(\mathcal{O}_Z\text{-Mod})_{qcoh}$:

$$
\begin{array}{cccc}
\alpha_* \circ Rf_* \circ \overline{f}^* \circ \varphi^* \circ R(\gamma \circ \beta)^b & \xrightarrow{\alpha} & \alpha_* \circ \varphi^* \circ R(\gamma \circ \beta)^b & \xrightarrow{\gamma} & \overline{g}^* \circ \beta_* \circ R(\gamma \circ \beta)^b \\
\downarrow_{Rf_*(\xi_{f,g})} & & \downarrow_{\alpha_* \circ \varphi^* \circ R(\beta^b \circ R\gamma^b)} & & \downarrow_{\overline{g}^* \circ \beta_* \circ R(\gamma \circ \beta)^b} \\
\alpha_* \circ Rf_* \circ \overline{f}^* \circ R(\alpha^b \circ g^b) & \xrightarrow{\beta} & \alpha_* \circ R\alpha^b \circ \overline{g}^* \circ R\gamma^b & \xrightarrow{f} & g^b = \overline{g}^* \circ R\gamma^b
\end{array}
$$

where:

- $\alpha$ and $\beta$ are induced from $\varepsilon$. 
- $\delta$ is induced by the isomorphism (11.1.11). 
- $\delta$ is induced by the isomorphism of claim 11.1.12(i). 
- $\delta$ is induced by the identity of claim 11.1.10. 
- $\delta$ is induced by the counit $\alpha_* \circ R\alpha^b \to 1$.

Now, by inspecting the construction of $\xi_{f,g}$ one checks that the left subdiagram of the latter diagram commutes; moreover, from claim 11.1.12(ii) (and from lemma 10.1.16(i)), one sees that the right subdiagram is obtained by evaluating on complexes of injective modules the analogous
Furthermore, by inspecting the proof of claim [11.1.12(i), one verifies that $f \circ d$ is the same as the composition
\[
\beta \circ (\gamma \circ \beta) \xrightarrow{(j)} g^* \circ \beta \circ \beta \circ \gamma \xrightarrow{(k)} g^* \circ \gamma.
\]
where $(j)$ is deduced from the counit $\beta \circ \beta \to 1$, and $(i)$ is deduced from the identity of claim [11.1.10]. Hence we come down to showing that the diagram:
\[
\beta \circ (\gamma \circ \beta) \xrightarrow{(11.1.18)} \gamma \xrightarrow{(11.1.19)} \beta \circ \beta \circ \gamma
\]
commutes in $g_* \mathcal{O}_Y$-$\text{Mod}$, where $(k)$ is deduced from the counit $\beta \circ \beta \to 1$. This is an easy verification, that shall be left to the reader. □

11.2. Cousin complexes. In this section we study a special type of complexes of abelian sheaves, called Cousin complexes, defined on a large class of topological spaces. These complexes play an important role in the further development of duality theory for locally coherent schemes: in many cases the techniques explained in this section will allow to exhibit canonical representatives for the dualizing complexes that shall be investigated at length in section 11.3.

11.2.1. We resume the notation of (10.1.30), so $(X, \mathcal{A})$ is a ringed topological space, $\varphi : V \to X$ a locally closed immersion, we denote by $\overline{V}$ the topological closure of $V$ in $X$, and we set $\partial V := \overline{V} \setminus V$. In (10.4.1) we have introduced the functor $\Gamma_\mathcal{F}$ of sections with support in $V$, and its sheaf-valued variant $\Gamma_\mathcal{F}$. We now extend these definitions to the case of a general locally closed immersion, by setting
\[
\Gamma_V := \varphi_* \circ \varphi^* \circ \Gamma_\mathcal{F} : \mathcal{A}$-$\text{Mod} \to \mathcal{A}$-$\text{Mod} \quad \Gamma_V := \Gamma \circ \Gamma_V : \mathcal{A}$-$\text{Mod} \to \mathcal{A}(X)$-$\text{Mod}.
\]
The functor $\Gamma_V$ admits a derived functor
\[
\mathcal{R}_\Gamma : D^+(\mathcal{A}$-$\text{Mod}) \to D^+(\mathcal{A}$-$\text{Mod})
\]
obtained as usual by evaluating on injective resolutions of given bounded below complexes.

Remark 11.2.2. (i) We have the following explicit description of $\Gamma_V$. Let $k : V \to X \setminus \partial V$ and $l : X \setminus \partial V \to X$ be respectively the closed and open immersions. Since $\varphi = l \circ k$, there exist natural isomorphisms
\[
\Gamma_V \xrightarrow{\sim} \varphi_* \circ k^* \circ l^* \circ \Gamma_\mathcal{F} \xrightarrow{\sim} l_* \circ k_* \circ k^* \circ \Gamma_\mathcal{F} \circ l^* \xrightarrow{\sim} l_* \circ \Gamma_V \circ l^*
\]
where the last map is induced by the natural identification $k_* \circ k^* \circ \Gamma_V \xrightarrow{\sim} \Gamma_V$ provided by lemma [10.1.32]. There follows a natural isomorphism
\[
\Gamma_V \mathcal{F}(S) \xrightarrow{\sim} \Gamma_\mathcal{F}(S \setminus \partial V) \quad \text{for every open subset } S \text{ of } X.
(ii) Notice that $\partial V = \emptyset$ if $\varphi$ is a closed immersion; in this case, (i) says that the functor defined in (11.2.1) is naturally isomorphic to its namesake introduced in (10.4.1), so the current notation is consistent with that of section 10.4.

(iii) For a general locally closed subset $V$ and any $\mathcal{A}$-module $\mathcal{F}$, the natural monomorphism $t_{\mathcal{F}} : \Gamma_{V} \mathcal{F} \to \mathcal{F}$ induces a natural transformation

$$\Gamma_{V} \mathcal{F} \to \varphi_{*} \varphi^{*} \mathcal{F} \tag{11.2.3}$$

which is a monomorphism for every such $\mathcal{F}$, since the functor $\varphi_{*} \varphi^{*}$ is left exact. Notice that if $V$ is open in $X$, the map $\varphi^{*} t_{\mathcal{F}}$ is an isomorphism, so the same holds for (11.2.3).

**Proposition 11.2.4.** In the situation of (11.2.1), the functor $\Gamma_{V}$ is right adjoint to $t_{\mathcal{F}}$.

**Proof.** For $\varphi$ a closed immersion, remark 11.2.2(ii) reduces the assertion to lemma 10.4.13(i), since in this case $\varphi_{1} = \varphi_{*}$. The assertion is also clear in case $\varphi$ is an open immersion, since in this case $\Gamma_{V}$ is naturally isomorphic to the functor $\varphi_{*} \circ \varphi^{*}$, by remark 11.2.2(iii). Notice that $V = V \cap (X \setminus \partial V)$. By proposition 10.1.33(i) (and by remark 1.1.17(i)) we are reduced to exhibiting a natural isomorphism of functors

$$\Gamma_{V} \cong \Gamma_{X \setminus \partial V} \circ \Gamma_{\mathcal{F}}.$$

But the existence of such an isomorphism is asserted already in remark 11.2.2(i). \qed

11.2.5. For our discussion, it will be important to know that in fact there exists a canonical adjunction for the pair $(t_{\mathcal{F}}, \Gamma_{V})$. In view of the proof of proposition 11.2.4 (and of remark 11.2.2(i)), it suffices to exhibit a canonical pair $(\eta^{V}, \varepsilon^{V})$ of units and counits for this adjunction, in case $\varphi$ is either an open or a closed immersion.

- Suppose first that $\varphi$ is a closed immersion. Then we want natural transformations

$$\eta^{V}_{\mathcal{F}} : \mathcal{F} \to \Gamma_{V} \circ \varphi_{*} \circ \varphi^{*} \mathcal{F} \quad \varepsilon^{V}_{\mathcal{F}} : \varphi_{*} \circ \varphi^{*} \circ \Gamma_{V} \mathcal{F} \to \mathcal{F}$$

related by the triangular identities of (11.1.13). However, remark 11.2.2(ii) yields a natural isomorphism $\eta_{1} : \Gamma_{V} \varphi_{*} \varphi^{*} \mathcal{F} \cong \varphi_{*} \varphi^{*} \mathcal{F}$, and on the other hand, we have a canonical unit $\eta_{2} : \mathcal{F} \to \varphi_{*} \varphi^{*} \mathcal{F}$ for the adjunction $(\varphi^{*}, \varphi_{*})$, so we take $\eta^{V}_{\mathcal{F}} := \eta_{1}^{-1} \circ \eta_{2}$. Likewise, let $\varepsilon_{1} : \Gamma_{V} \mathcal{F} \to \mathcal{F}$ be the natural monomorphism; we take $\varepsilon^{V}_{\mathcal{F}} := \varepsilon_{1} \circ f_{\mathcal{F}}$, where $f_{\mathcal{F}} : t_{\mathcal{F}} \circ \Gamma_{V} \mathcal{F} \cong \Gamma_{V} \mathcal{F}$ is the isomorphism provided by lemma 10.1.32. The triangular identities may then be checked on the stalks: we leave the details to the reader.

- Next, if $\varphi$ is an open immersion, we need to find natural transformations

$$\eta^{V}_{\mathcal{F}} : \mathcal{F} \to \varphi_{*} \circ \varphi^{*} \circ \varphi_{1} \circ \varphi^{*} \mathcal{F} \quad \varepsilon^{V}_{\mathcal{F}} : \varphi_{1} \circ \varphi^{*} \circ \varphi_{*} \circ \varphi^{*} \mathcal{F} \to \mathcal{F}$$

again related by the same triangular identities. We take for $\eta^{V}_{\mathcal{F}}$ (resp. $\varepsilon^{V}_{\mathcal{F}}$) the composition of the natural unit $\mathcal{F} \to \varphi_{*} \varphi^{*} \mathcal{F}$ of the adjunction $(\varphi^{*}, \varphi_{*})$ (resp. the counit $\varphi_{1} \circ \varphi^{*} \mathcal{F} \to \mathcal{F}$ of the adjunction $(\varphi_{1}, \varphi^{*})$), with the isomorphism

$$\varphi_{*} \varphi^{*} \mathcal{F} \cong \varphi_{*} \varphi^{*} \varphi_{1} \varphi^{*} \mathcal{F} \quad (\text{resp. } \varphi_{1} \varphi^{*} \varphi_{*} \varphi^{*} \mathcal{F} \cong \varphi_{1} \varphi^{*} \mathcal{F})$$

deduced from the natural identification of $\varphi^{*} \circ \varphi_{1}$ (resp. of $\varphi_{*} \circ \varphi_{*}$) with the identity functor of $\varphi^{*} \mathcal{A} \text{-Mod}$. The triangular identities are as usual checked on the stalks.

11.2.6. Due to proposition 11.2.4 and the subsequent observations in (11.2.5), all the constructions of proposition 10.1.33 have natural counterparts for the functors $\Gamma_{V}$. Namely:

- If $V$ and $V'$ are any two locally closed subsets of $X$, there is a natural isomorphism

$$\beta_{V,V'} : \Gamma_{V} \circ \Gamma_{V'} \cong \Gamma_{V \cap V'}$$
and if $V'' \subset X$ is any other locally closed subset, the diagram of functors

\[
\begin{array}{ccc}
\Gamma_V \circ \Gamma_{V'} \circ \Gamma_{V''} & \xrightarrow{\beta_{V,V',V''}} & \Gamma_V \circ \Gamma_{V' \cap V''} \\
\downarrow \beta_{V',V''} & & \downarrow \beta_{V',V''} \\
\Gamma_{V \cap V'} \circ \Gamma_{V''} & \xrightarrow{\gamma_{V',V''}} & \Gamma_{V' \cap V'' \cap V''} \\
\end{array}
\]

(11.2.7)

commutes.

- Moreover, suppose that the pair $(V, V')$ satisfies either of the conditions (a), (b) of proposition 10.1.33(iii); then there exists a natural morphism

$$\gamma_{V,V'} : \Gamma_V \to \Gamma_{V'}.$$  

which corresponds to $e^{V,V'}$ under the natural adjunction described in (11.2.3), and if $V''$ is any third locally closed subset of $X$, we get a commutative diagram

\[
\begin{array}{ccc}
\Gamma_{V''} \circ \Gamma_V & \xrightarrow{\beta_{V',V''}} & \Gamma_{V''} \circ \Gamma_{V'} \\
\downarrow \beta_{V',V''} & & \downarrow \beta_{V',V''} \\
\Gamma_V \cap V' & \xrightarrow{\gamma_{V',V''}} & \Gamma_{V',V''} \\
\end{array}
\]

- Lastly, in the situation of proposition 10.1.33(v) we have the identity:

$$\gamma_{V',V''} \circ \gamma_{V,V'} = \gamma_{V,V''} : \Gamma_V \to \Gamma_{V''}.$$  

**Remark 11.2.8.** Let $X$ be a topological space, $j : U \to X$ an open immersion, $\varphi : V \to X$ and $\varphi' : V' \to X$ two locally closed immersions fulfilling either of conditions (a),(b) of proposition 10.1.33(iii). The transformations $\gamma_{V,V'}$ can also be described explicitly, thanks to the following considerations.

(i) First, notice that the functors $t_\bullet$ on $\mathcal{A}$-modules, the unit $\eta^*$ and the counit $e^*$ are all compatible with restriction to $U$, i.e. we have identities of functors on $j^* \mathcal{A}$-modules and of morphisms between such functors:

$$j^* t_V = t_{U \cap V} \quad j^* \eta^* = e^{V \cap U} \quad j^* e^* = \eta^{V \cap U}$$

for every locally closed subset $V \subset X$.

This is obvious for the truncation functors, and for the units and counits it follows by a simple inspection of the definition. Then, the uniqueness properties of the transformations $\tau^{**}$ and $e^{**}$ imply that the same compatibility with restriction to $U$ holds for the latter.

(ii) It follows formally from (i) that the isomorphisms $\beta_{\bullet}$ and the transformations $\gamma_{\bullet}$ are likewise compatible with restriction to $U$. On the other hand, notice that the restriction map

$$\text{Hom}_{\mathcal{A}\text{-Mod}}(t_{V'}, \mathcal{F}, \mathcal{G}) \to \text{Hom}_{j^* \mathcal{A}\text{-Mod}}((t_{V'}, \mathcal{F})_{|U}, \mathcal{G}_{|U})$$

is a bijection for every $\mathcal{F}, \mathcal{G} \in \text{Ob}(\mathcal{A}\text{-Mod})$, whenever $V' \subset U$. We conclude that the restriction map

$$\text{Hom}_{\mathcal{A}\text{-Mod}}(\mathcal{F}, \Gamma_{V'} \mathcal{G}) \to \text{Hom}_{j^* \mathcal{A}\text{-Mod}}((\mathcal{F}|_U, \Gamma_{V' \cap U} \mathcal{G}_{|U})$$

is also bijective when $V' \subset U$. Letting $\mathcal{F} := \Gamma_{V'} \mathcal{G}$, we deduce that $\gamma_{V,V'}$ is determined by its restriction to $U$, which is just $\gamma_{V' \cap U, V' \cap U}$.

(iii) Now, suppose first that $\psi : V \to V'$ is a closed immersion, and denote by $\nabla$ and $\nabla'$ the topological closures in $X$ of $V$ and respectively $V'$; notice that the unit of the adjunction $(\psi^*, \psi_*)$ induces an isomorphism

\[
\varphi'^* \circ \Gamma_{\nabla'} \sim \psi_\ast \circ \psi^* \circ \varphi'^* \circ \Gamma_{\nabla'}
\]

(11.2.9)
since \((\varphi^* \circ \Gamma_{\mathcal{F}})|_{V \setminus V} = 0\) for every \(\mathcal{A}\)-module \(\mathcal{F}\) (lemma 10.1.32). We claim that \(\gamma_{V,V'}\) is the composition

\[
\varphi_\ast \circ \varphi^* \circ \Gamma_{\mathcal{F}} \cong \varphi_\ast \circ \psi_\ast \circ \psi^* \circ \varphi' \circ \varphi'^* \circ \Gamma_{\mathcal{F}} \cong \varphi_\ast \circ \varphi' \circ \varphi'^* \circ \Gamma_{\mathcal{F}}.
\]

where the second map is the inverse of (11.2.9) and the third is deduced from \(\gamma_{\mathcal{F}} : \Gamma_{\mathcal{F}} \to \Gamma_{\mathcal{F}}\). Indeed, notice that the foregoing construction is compatible with restriction to \(U\); taking into account (iii), we may then replace \(X\) by its open subset \(X \setminus \partial V\), and assume that both \(\varphi\) and \(\varphi'\) are closed immersions. In this case, the assertion follows by direct inspection of the definition of the unit and counit of the adjunction \((t_\ast, \Gamma_\ast)\), and of the definition of \(t_\ast\), in the case of closed immersions.

(iv) Likewise, if \(V'\) is an open subset of \(V\), pick a factorization of \(\varphi : V \to X\) as the composition of a closed immersion \(i : V \to U\) and an open immersion \(j : U \to X\). There is a unique open subset \(U' \subset U\) such that \(V' = U' \cap V\); denote by \(j' : U' \to X\) the open immersion, and for any given \(\mathcal{A}\)-module \(\mathcal{F}\), let \(\eta_{\mathcal{F}} : \mathcal{F} \to j'_* j'^* \mathcal{F}\) be the unit of adjunction; according to remark 11.2.2, we may regard \(\eta_{\mathcal{F}}\) as a natural transformation

\[
\eta_{\mathcal{F}} : \mathcal{F} \to \Gamma_{U'} \mathcal{F}
\]

and we claim that \(\gamma_{V,V'}\) is the composition

\[
\Gamma_V \xrightarrow{\Gamma_V \eta_{\mathcal{F}}} \Gamma_V \circ \Gamma_{U'} \xrightarrow{\beta_{U',V}} \Gamma_{U'}.
\]

For the proof, we may argue as in (iii) to see that \(\gamma_{V,V'}\) is determined by its restriction to \(U'\), and since the proposed construction is compatible with restriction to \(U'\), we are then reduced to the case where \(U' = U = X\) and therefore \(V = V'\). However, clearly \(\gamma_{V,V'}\) is the identity endomorphism of \(t_U\), so it remains only to prove that the proposed map is the identity of \(\Gamma_{U'}\), if \(V = V'\). The latter can be checked easily, whence the claim. We could have used the above construction as a definition for \(\gamma_{V,V'}\) in the case of open immersions, but the method we followed has the advantage of dispensing us from verifying that the resulting transformation is independent of the chosen factorization of \(\varphi\).

11.2.10. Let \(V \subset V'\) be a closed immersion of locally closed subsets of a topological space \(X\); from remark 11.2.8(iii), it is clear that \(\gamma_{V,V'}\) is a monomorphism. Moreover, we have:

**Lemma 11.2.11.** In the situation of (11.2.10), the sequence

\[
\Sigma_{V,V'} : 0 \to \Gamma_{V'} \mathcal{F} \xrightarrow{\gamma_{V,V'}} \Gamma_{V'} \mathcal{F} \xrightarrow{\gamma_{V',V' \setminus V}} \Gamma_{V' \setminus V} \mathcal{F}
\]

is left exact for every \(\mathcal{A}\)-module \(\mathcal{F}\).

**Proof.** Indeed, say that \(V' = U \cap Z\) for some closed subset \(Z\) and open subset \(U\); then \(V = V' \cap U\), with \(V\) the topological closure of \(V\) in \(X\), and in light of (11.2.6) we see that there is a natural isomorphism \(\Sigma_{V,V'} \cong \Gamma_U(\Sigma_{T,Z})\). However, \(\Gamma_U\) is a left exact functor (since it admits a left adjoint), so it suffices to check that \(\Sigma_{T,Z}\) is left exact. Thus, we may assume from start that \(V\) and \(V'\) are closed in \(X\). By the same token, we see that \(\Sigma_{V,V'} \cong \Gamma_{V'}(\Sigma_{V,X})\), so we may further assume that \(V' = X\), in which case the sequence reduces to the initial segment of (10.4.2). \(\square\)

**Proposition 11.2.12.** With the notation of (11.2.1), the following holds:

(i) If \(\mathcal{F}\) is a flabby \(\mathcal{A}\)-module, the same holds for \(\Gamma_{V'} \mathcal{F}\).

(ii) Every flabby \(\mathcal{A}\)-module is \(\Gamma_{V'}\)-acyclic.

(iii) If \(\mathcal{B} \to \mathcal{A}\) is any morphism of sheaves of rings on \(X\), the functor \(R\Gamma_{V'}\) commutes with the forgetful functor \(D^+(\mathcal{A}\text{-Mod}) \to D^+(\mathcal{B}\text{-Mod})\).
(iv) If \( \varphi' : V' \to X \) is any other locally closed immersion, there exists a natural isomorphism of functors:

\[
R_U \Gamma_{V \cap V'} \cong R_U \Gamma_V \circ R_U \Gamma_{V'}, \quad \mathcal{D}^+(\mathcal{A}\text{-Mod}) \to \mathcal{D}^+(\mathcal{A}\text{-Mod}).
\]

(v) Suppose that \( X \) is locally spectral and quasi-separated, and \( V \) is a constructible locally closed subset of \( X \), then we have:

(a) Every qc-flabby \( \mathcal{A} \)-module is \( \Gamma_V \)-acyclic.

(b) For every \( i \in \mathbb{N} \), the functor \( R^i \Gamma_V \) commutes with filtered colimits of \( \mathcal{A} \)-modules.

(c) For every \( x \in V \), denote by \( j_x : (x) \to X \) the inclusion map (notation of definition 8.1.42(iii)). Then there exists a natural isomorphism

\[
j_x^* R\Gamma_V \cong R\Gamma_{V(x)} \quad \text{in} \ \mathcal{D}^+(j_x^* \mathcal{A}\text{-Mod}).
\]

Proof. (i): By lemmata [10.4.13(ii) and 10.4.4(i)] , we know already that both assertions (i) and (ii) hold in case \( \varphi \) is a closed immersion; for the general case, we may then assume that \( \varphi \) is an open immersion. However, in this case both \( \varphi_\ast \) and \( \varphi^* \) take flabby sheaves to flabby sheaves (lemmata [10.1.2 and 10.1.5(ii)]), and flabby sheaves are acyclic for both of these functors (lemma [10.1.5(ii)]), so the assertion follows from remark [11.2.2(iii)].

(iii) is clear from (ii), as every injective \( \mathcal{A} \)-module is a flabby \( \mathcal{B} \)-module (lemma [10.1.5(v)]).

(iv) follows formally from (i), (ii) and (11.2.6) : details left to the reader.

(v.a): Since the assertion is local on \( X \), we may assume that \( X \) is spectral, in which case \( V \) is the intersection of a closed constructible subset and an open constructible subset. By (iv) and lemma [10.1.5(iii)], it then suffices to consider separately the cases where \( V \) is either open or closed in \( X \). By lemma [10.4.4(iii.b)] we know already the assertions in case \( \varphi_\ast \) and \( \varphi^\ast \) take flabby sheaves to flabby sheaves (lemmata [10.1.2 and 10.1.5(ii)]), and flabby sheaves are acyclic for both of these functors (lemma [10.1.5(ii)]), so the assertion follows from remark [11.2.2(iii)].

(v.b): We reduce again to the case where \( V \) is the intersection of a closed constructible subset \( Z \) and an open constructible subset \( U \). Since – by (ii) – the functor \( \Gamma_Z \) transforms injective \( \mathcal{A} \)-modules into \( \Gamma_U \)-acyclic \( \mathcal{A} \)-modules, we have a convergent spectral sequence

\[
R^i \Gamma_U \circ R^j \Gamma_Z \Rightarrow R^{i+j} \Gamma_V, \mathcal{F}.
\]

It then suffices to consider separately the case where \( V \) is either open or closed. These cases follow respectively from lemma [10.4.4(iii.b)] and claim [10.4.5]

(v.c): Arguing as in the proof of (v.b), we reduce to consider separately the cases where \( V \) is either open or closed. For \( V \) closed, the assertion is corollary [10.4.10]. For \( V \) open, the assertion follows from proposition [10.1.10(ii)] and remark [11.2.2(iii)], by arguing as in the proof of corollary [10.4.10]: details left to the reader. \( \square \)

Remark 11.2.13. (i) Using proposition [11.2.12] the various compatibilities that have been found so far between the functors \( \Gamma_V \) extend straightforwardly to their derived extensions. Especially, diagram (11.2.7) still commutes, after replacing the functors \( \Gamma_\ast \) by their derived extensions everywhere, and the natural transformations \( \beta_\ast \) by their derived versions, provided by proposition [11.2.12(iii)].

(ii) Likewise, if \( V \subset V' \) (resp. \( V' \subset V \)) is any closed (resp. open) immersion of locally closed subsets of \( X \), by deriving the morphisms \( \gamma_{V,V'} \) of (11.2.6) we get a natural transformation

\[
R_{\Gamma_V} \rightarrow R_{\Gamma_{V'}}, \quad \text{in} \ \mathcal{D}^+(\mathcal{A}\text{-Mod})
\]

and the compatibilities between the functors \( \gamma_\ast \) and \( \beta_\ast \) explicited in (11.2.6) hold, mutatis mutandis, also for the functors \( R_{\Gamma_\ast} \).

Lemma 11.2.14. In the situation of (11.2.10), let \( \mathcal{F} \) be any flabby \( \mathcal{A} \)-module. Then, for every open subset \( U \subset X \), the sequence

\[
0 \to \Gamma_V \mathcal{F}(U) \to \Gamma_{V'} \mathcal{F}(U) \to \Gamma_{V \cap V'} \mathcal{F}(U) \to 0
\]
induced by the sequence $\Sigma_{V, V'}$ of lemma [11.2.11] is short exact.

Proof. We may assume that $U = X$, and it suffices to show that the map $g : \Gamma_V, \mathcal{F} \to \Gamma_{V \setminus V}, \mathcal{F}$
deduced from $\gamma_{V, V \setminus V}$ is surjective, whenever $\mathcal{F}$ is flabby. To this aim, write $V' \setminus V = U' \cap V'$
for some open subset $U' \subset X$; then $g$ is naturally identified with the map

$$\Gamma_X \circ \Gamma_{V, \mathcal{F}} \to \Gamma_U \circ \Gamma_{V, \mathcal{F}}$$
deduced from $\gamma_{X, U'}$. But $\Gamma_{V, \mathcal{F}}$ is still flabby (proposition [11.2.12](i)) so we are reduced to the
case where $V' = X$, in which case $g$ is naturally identified with the restriction map $\mathcal{F}(X) \to \mathcal{F}(X \setminus V)$, whence the contention. \qed

11.2.15. Let $(X, \mathcal{A})$ be a ringed topological space. A family of supports on $X$ is a set $\Phi$
consisting of closed subsets of $X$, such that:

- $\emptyset \in \Phi$.
- If $Z \in \Phi$ and $Z' \subset Z$ is any closed subset, then $Z' \in \Phi$ as well.
- If $Z_1, Z_2 \in \Phi$, then $Z_1 \cup Z_2 \in \Phi$ as well.

Now, let $\Phi$ and $\Phi'$ be any two families of supports on $X$; we let $\Phi|\Phi'$ be the set whose elements
are all the pairs $Z := (Z, Z')$, where $Z$ and $Z'$ are arbitrary elements of $\Phi$ and respectively $\Phi'$,
such that $Z' \subset Z$. We endow $\Phi|\Phi'$ with a partial ordering, by declaring that, for given pairs
$Z_1 := (Z_1, Z_1'), Z_2 := (Z_2, Z_2')$ of $\Phi|\Phi'$, we have $Z_1 \leq Z_2$ if $Z_1 \subset Z_2$ and $Z_1' \subset Z_2'$.
It is easily seen that $\Phi|\Phi'$ is filtered. To every object $Z \in \Phi|\Phi'$ we assign the functor $\Gamma_{Z, \mathcal{F}}$,
and to any pair $(Z_1, Z_2)$ of elements of $\Phi|\Phi'$ with $Z_1 \leq Z_2$, we attach the composition

$$\Gamma_{Z_1, Z_1'} \rightarrow \Gamma_{Z_2, Z_1'} \rightarrow \Gamma_{Z_2, Z_2'}$$

(notation of [11.2.6]). We then define the functor

$$\Gamma_{\Phi|\Phi'} := \text{colim}_{(Z, Z') \in \Phi|\Phi'} \Gamma_{Z, \mathcal{F}} : \mathcal{A}\text{-Mod} \to \mathcal{A}\text{-Mod}$$

where the transition maps in the colimit are the maps [11.2.16], whence a derived functor

$$R\Gamma_{\Phi|\Phi'} : D^+ (\mathcal{A}\text{-Mod}) \to D^+ (\mathcal{A}\text{-Mod})$$

and we have a natural isomorphism of functors on $\mathcal{A}\text{-Mod}$:

$$R\Gamma_{\Phi|\Phi'} \cong \text{colim}_{(Z, Z') \in \Phi|\Phi'} R\Gamma_{Z, \mathcal{F}}$$

for every $i \in \mathbb{N}$.

11.2.17. Keep the notation of [11.2.15]. As a special case, we may take $\Phi' := \{\emptyset\}$, and we let

$$\Gamma_{\emptyset} := \Gamma_{\Phi|\{\emptyset\}} : \mathcal{A}\text{-Mod} \to \mathcal{A}\text{-Mod}.$$ 

If $\Phi$ and $\Phi'$ are arbitrary family of supports, we have maps of partially ordered sets

$$\Phi \leftarrow \Phi|\Phi' : Z \leftarrow (Z, Z') \mapsto Z'.$$

Suppose moreover that $\Phi' \subset \Phi$; then both of these maps are cofinal, by lemma [11.5.7](i), and with lemma [11.2.10] and proposition [11.2.12](ii), we deduce a short exact sequence of complexes

$$0 \rightarrow \Gamma_{\Phi|\mathcal{F}} \rightarrow \Gamma_{\Phi, \mathcal{F}} \rightarrow \Gamma_{\Phi|\Phi', \mathcal{F}} \rightarrow 0$$

for every flabby $\mathcal{A}\text{-module}$ $\mathcal{F}$, whence a distinguished triangle of functors on $D^+ (\mathcal{A}\text{-Mod})$:

$$R\Gamma_{\Phi|\mathcal{F}} \rightarrow R\Gamma_{\Phi} \rightarrow R\Gamma_{\Phi|\Phi'} \rightarrow R\Gamma_{\Phi}[1].$$
Keep the notation of (11.2.15). Suppose now that $X$ is sober and locally noetherian, and moreover that we are given a weak codimension function on $X$, i.e. a map
$$c : X \to \mathbb{Z}$$
such that $c(x) > c(y)$ whenever $x \neq y$ and $x$ is a specialization of $y$ in $X$. To the weak codimension function $c$ we attach a system $(\Phi^p | p \in \mathbb{N})$ of families of supports, by the rule:
$$\Phi^p := \{ Z \subset X | Z \text{ is closed in } X, \text{ and } c(z) \geq p \text{ for every } z \in Z \} \quad \text{for every } p \in \mathbb{N}.$$ 
For every $x \in X$, let also $j_x : X(x) \to X$ and $i_x : \{x\} \to X$ be the inclusion maps (notation of definition 8.1.42(iii)). Moreover, let us set $\Phi^p(x) := \{ Z \cap X(x) | Z \in \Phi^p \}$, for every $p \in \mathbb{Z}$.

**Lemma 11.2.20.** In the situation of (11.2.19), the following holds for every $x \in X$:

(i) The topological space $X(x)$ is spectral, noetherian and finite dimensional, and the function $c$ is bounded on $X(x)$.

(ii) There exists a natural isomorphism of functors on $D^+(j^*_x \mathcal{O} \text{-Mod})$:
$$j^*_x R\Gamma_{\Phi^p} \overset{\sim}{\rightarrow} R\Gamma_{\Phi^p(x)} \quad \text{for every } p \in \mathbb{Z}.$$

(iii) $(\Phi^p(x) | p \in \mathbb{Z})$ is the system of families of supports on $X(x)$ attached to the weak codimension function $c(X(x))$.

**Proof.** (i): Since the topology of $X(x)$ is induced from that of $X$, it is clear that $X(x)$ is noetherian, and we have already seen that it is spectral (remark 8.1.43(ii)). Especially, $X(x)$ admits finitely many maximal points (remark 8.1.43(iii)); if $\eta_1, \ldots, \eta_k$ are these maximal points, set $C := \max(c(\eta_1), \ldots, c(\eta_k))$. Then it is clear that the restriction to $X(x)$ of the function $c$ takes its values in the range $C, C + 1, \ldots, c(x)$, and it follows easily that the length of any descending sequence of points in $(X(x), \preceq)$ is bounded by $c(x) - C$.

(ii) follows easily from proposition 11.2.12(v,c), since every closed subset of a locally noetherian topological space is constructible.

(iii): If $Z$ is any closed subset of $X(x)$, denote by $\overline{Z}$ the topological closure of $Z$ in $X$; since $X(x)$ is a pro-constructible subset of $X$, the same holds for $Z, Z = X(x) \cap \overline{Z}$. Then $\overline{Z}$ is the set of specializations in $X$ of the points of $Z$ (proposition 8.1.44(ii)). Especially, if $c(z) \geq p$ for every $z \in Z$, then $c(z) \geq p$ for every $z \in \overline{Z}$, and then clearly $\overline{Z} \in \Phi^p(x)$. The assertion follows immediately. 

**Proposition 11.2.21.** In the situation of (11.2.19), we have a natural isomorphism of functors
$$R^i\Gamma_{\Phi^p | \Phi^{p+1}} \overset{\sim}{\rightarrow} \bigoplus_{c(x) = p} j^*_x \circ R^i\Gamma_{\{x\}} \circ j^*_x \quad \text{for every } p \in \mathbb{Z} \text{ and } i \in \mathbb{N}.$$

**Proof.** Since the assertion is local on $X$, we may assume that $X$ is noetherian. We consider first the case where $i = 0$, and we fix $p \in \mathbb{Z}$. Let $Z \in \Phi^p$ be any element; recall that $Z$ has a finite number of irreducible components $Z_1, \ldots, Z_k$ (proposition 8.1.4). Let $\eta_i$ be the generic point of $Z_i$, so that $c(\eta_i) \geq p$ for every $i = 1, \ldots, k$. For every $i, j = 1, \ldots, k$ with $i \neq j$, set $Z_{ij} := Z_i \cap Z_j$; then, for every such $i, j$, every irreducible component of $T$ of $Z_{ij}$ and every $t \in T$, we must have $c(t) \geq c(\eta_T) > c(\eta_i)$, if $\eta_T$ denotes the generic point of $T$. We conclude that $Z_{ij} \in \Phi^{p+1}$ for every $i, j = 1, \ldots, k$ with $i \neq j$. Set also
$$Z^{>p} := \bigcup_{c(\eta_i) > p} Z_i \bigcup_{i \neq j} Z_{ij} \quad \text{and} \quad \Psi^{p+1} := \{(Z, Z') \in \Phi^p | \Phi^{p+1} | Z^{>p} \subset Z' \subset Z \}.$$ 
Since the subset $\Psi^p$ is clearly cofinal in $\Phi^p | \Phi^{p+1}$, we deduce a natural isomorphism
$$\Gamma_{\Phi^p | \Phi^{p+1}} \overset{\sim}{\rightarrow} \colim_{(Z, Z') \in \Psi^p} \Gamma_{\{Z \setminus Z' \}}.$$
However, say that \((Z, Z') \in \Psi^p\); we notice that the closed subset \(V := Z \setminus Z'\) of \(X \setminus Z'\) is the disjoint union of its irreducible components \(V_1, \ldots, V_t\), hence the topology induced by \(X\) on \(V\) is the coproduct (i.e. disjoint union) of the topologies induced by \(X\) on \(V_1, \ldots, V_t\), and there follows a natural isomorphism

\[
(11.2.22) \quad \Gamma_V \cong \bigoplus_{i=1}^{t} \Gamma_{V_i}.
\]

Moreover, say that \(Z_1, Z_2 \in \Psi^p\) and \(Z_1 \leq Z_2\), and denote by \(V_1, \ldots, V_s\) (resp. \(W_1, \ldots, W_t\)) the irreducible components of \(V := Z_1 \setminus Z_2\) (resp. of \(W := Z_2 \setminus Z'_2\)). A simple inspection of the definitions reveals that \(s \leq t\) and – after reordering of the \(W_i\) – the subset \(W_i\) is open in \(V_i\) for every \(i = 1, \ldots, s\). Moreover, under the isomorphism \((11.2.22)\), the transition map \(\Gamma_V \to \Gamma_W\) is identified with the composition

\[
\bigoplus_{i=1}^{s} \Gamma_{V_i} \xrightarrow{\bigoplus_{i=1}^{s} \gamma_{V_i,W_i}} \bigoplus_{i=1}^{s} \Gamma_{W_i} \to \bigoplus_{i=1}^{t} \Gamma_{W_i}
\]

(where the second map is the natural monomorphism). Hence, let \(\Delta^p\) be the set of all locally closed subsets \(V\) of \(X\) fulfilling the following condition. There exists \(x \in X\) with \(c(x) = p\), and \(V\) is a non-empty open subset of the topological closure \(\overline{\{x\}}\) of \(\{x\}\) in \(X\). We endow \(\Delta^p\) with a partial ordering, by declaring that, for any \(V, V' \in \Delta^p\) we have \(V \leq V'\) if \(V' \subset V\) (notice that \(\Delta^p\) is usually not a filtered partially ordered set); from the foregoing, we get a natural isomorphism

\[
\Gamma_{\phi|\phi} \cong \lim_{V \in \Delta^p} \Gamma_V
\]

where, for every \(V, V' \in \Delta^p\) such that \(V \leq V'\), the transition map \(\Gamma_V \to \Gamma_{V'}\) is again given by the transformation \(\gamma_{V,V'}\) corresponding to the open immersion \(V' \to V\).

Next, for every \(x \in X\) such that \(c(x) = p\), set \(\Delta_x := \{ V \in \Delta^p \mid x \in V \}\), and notice that the partially ordered set \(\Delta^p\) is the coproduct (i.e. the disjoint union) of its partially ordered subsets \(\Delta_x\). We deduce a natural isomorphism

\[
\Gamma_{\phi|\phi} \cong \bigoplus_{c(x) = p} \lim_{V \in \Delta_x} \Gamma_V.
\]

Thus, we come down to checking the following:

**Claim 11.2.23.** For every \(p \in \mathbb{Z}\) and every \(x \in X\) such that \(c(x) = p\), there exists a natural isomorphism of functors

\[
\lim_{V \in \Delta^p} \Gamma_V \cong j_{x*} \circ \Gamma(x) \circ j_{x*}.
\]

**Proof of the claim.** Let \(\Sigma_x\) be the set of all quasi-compact open neighborhoods of \(x\) in \(X\), and endow \(\Sigma_x\) with the partial ordering such that, for every \(U, U' \in \Sigma_x\) we have \(U \leq U'\) if \(U' \subset U\); then \(\Sigma_x\) is filtered, and there follows a morphism of partially ordered sets

\[
\Sigma_x \to \Delta_x \quad U \mapsto U \cap \{x\}
\]

and using lemma [1.5.7](i), it is easily seen that this map is cofinal. Now, for every \(U \in \Sigma_x\), let \(j_U : U \to X\) be the open immersion; we have a natural identification

\[
\Gamma_{U \cap \{x\}} \cong j_{U*} \circ j_{U*} \circ \Gamma(x)
\]

whence a natural isomorphism

\[
\lim_{V \in \Delta_x} \Gamma_V = \lim_{U \in \Sigma_x} \Gamma_U \circ j_{U*} \circ \Gamma(x).
\]

However, \(X(x)\) is the limit of the filtered system of spectral spaces \(\Sigma_x\), so the claim follows easily from proposition [10.1.10](ii) (details left to the reader). \(\diamond\)
Next, let \( i \in \mathbb{N} \) be arbitrary, let \( \mathcal{F} \) be any \( \mathcal{A} \)-module, and pick any resolution \( \mathcal{F} \to \mathcal{J}^\bullet \) consisting of injective \( \mathcal{A} \)-modules; by the foregoing case, we get a natural isomorphism of \( \mathcal{A} \)-modules

\[
R^i \Gamma_{\{x\}|\Phi \to 0+1} \mathcal{F} \xrightarrow{\sim} \bigoplus_{c(x)=p} H^i(j_{x*} \circ \Gamma_{\{x\}} \circ j_{x}^* \mathcal{J}^\bullet).
\]

However, on the one hand, \( j_{x}^* \mathcal{J}^\bullet \) is a complex of qc-flabby \( j_{x}^* \mathcal{A} \)-modules (claim \(10.1.11\)); on the other hand, qc-flabby abelian sheaves are acyclic for the functor \( \Gamma_{\{x\}} \) (lemmata \(10.4.4\)(iii.b) and \(8.1.2\)(vi)), so we get a natural isomorphism

\[
H^i(j_{x*} \circ \Gamma_{\{x\}} \circ j_{x}^* \mathcal{J}^\bullet) \xrightarrow{\sim} H^i(j_{x*} \circ R\Gamma_{\{x\}} \circ j_{x}^* \mathcal{F}) \quad \text{for every } i \in \mathbb{N} \text{ and every } x \in X.
\]

Lastly, notice that \( R\Gamma_{\{x\}} \circ j_{x}^* \mathcal{F} \) is a complex of \( j_{x}^* \mathcal{A} \)-modules supported on \( \{x\} \), and the functor \( j_{x*} \) is exact on the full subcategory of \( j_{x}^* \mathcal{A} \)-Mod consisting of such sheaves; thus, we have a natural isomorphism

\[
H^i(j_{x*} \circ R\Gamma_{\{x\}} \circ j_{x}^* \mathcal{F}) \xrightarrow{\sim} j_{x*} \circ R^i \Gamma_{\{x\}} \circ j_{x}^* \mathcal{F} \quad \text{for every } i \in \mathbb{N} \text{ and every } x \in X.
\]

Summing up, we obtain the proposition. \( \square \)

**Definition 11.2.24.** Let \((X, \mathcal{A})\) be a ringed topological space, with \( X \) sober and locally noetherian, and \( c \) a weak codimension function on \( X \).

(i) We say that an object \( K^\bullet \) of \( D^+ (\mathcal{A} \text{-Mod}) \) is a \( c \)-Cohen-Macaulay complex, if we have

\[
R^i \Gamma_{\{x\}} K^\bullet_{|X(x)} = 0 \quad \text{for every } x \in X \text{ and every integer } i \neq c(x).
\]

We denote by

\( \mathcal{A} \text{-CM}^c \)

the full subcategory of \( D^+ (\mathcal{A} \text{-Mod}) \) whose objects are the \( c \)-Cohen-Macaulay complexes.

(ii) We say that an object \( C^\bullet \) of \( C^+ (\mathcal{A} \text{-Mod}) \) is a Cousin complex, if there exists a family \((M_x \mid x \in X)\) where \( M_x \) is an \( i_x^* \mathcal{A} \)-module for every \( x \in X \) (notation of \((11.2.19)\)), such that

\[
C^p = \bigoplus_{c(x)=p} i_x M_x \quad \text{for every } p \in \mathbb{Z}.
\]

The full subcategory of \( C^+ (\mathcal{A} \text{-Mod}) \) whose objects are the Cousin complexes is denoted \( \mathcal{A} \text{-Cousin} \).

**Lemma 11.2.25.** In the situation of definition \(11.2.24\) we have:

(i) \( R^i \Gamma_{\{x\}} \circ j_{x*} \circ i_{y*} = 0 \) for every \( x, y \in X \) such that \( x \neq y \).

(ii) If \( C^\bullet \) is a Cousin complex of \( \mathcal{A} \text{-modules}, then \( C^p \) is qc-flabby, for every \( p \in \mathbb{Z} \).

**Proof.** (i): Notice that any \( i_y^* \mathcal{A} \)-module \( M \) is trivially qc-flabby, so the same holds for \( i_{y*} M \) (lemma \(10.1.5\)(iv)), and therefore also for \( j_{x*} j_{y*} M \) (claim \(10.1.11\)). Since \( j_{x*} \mathcal{A} \)-modules are acyclic for \( \Gamma_{\{x\}} \) (lemma \(10.4.4\)(iii.a)), we conclude that \( R^i \Gamma_{\{x\}} j_{y*} \) is the derived functor of \( \Gamma_{\{x\}} j_{y*} \), but it is easily seen that the latter vanishes, whence the assertion.

(ii): We have just seen that \( i_x^* \mathcal{A} \)-module \( M \) is qc-flabby, for every \( i_x^* \mathcal{A} \)-module \( M \); on the other hand, all direct sums of qc-flabby \( \mathcal{A} \)-modules are qc-flabby (claim \(10.1.11\)), whence the contention. \( \square \)

**11.2.26.** As \( j_{x}^* \) and \( R^i \Gamma_{\{x\}} \) commute with all direct sums (proposition \(11.2.12\)(v.b)), lemma \(11.2.25\)(i) implies that the localization \( C^+ (\mathcal{A} \text{-Mod}) \to D^+ (\mathcal{A} \text{-Mod}) \) restricts to a functor

\[
F : \mathcal{A} \text{-Cousin} \to \mathcal{A} \text{-CM}^c.
\]

**Theorem 11.2.27.** The functor \( F \) of \((11.2.26)\) is an equivalence of categories.
Proof. We construct a quasi-inverse to $F$, as follows. First, we endow every object $C^\bullet$ of $C(\mathcal{A}\text{-Mod})$, with a descending filtration $\text{Fil}^p_q C^\bullet$, by the rule

$$\text{Fil}^p_q C^\bullet := \bigcap_{p < q} C^\bullet$$

where $(\Phi^p | p \in \mathbb{Z})$ is the system of families of supports associated with the weak codimension function $c$, as in (11.2.19). We also denote by $\text{gr}_{q}^p C^\bullet$ the resulting associated graded object of $C(\mathcal{A}\text{-Mod})$. Next, for every object $K^\bullet$ of $D^+(\mathcal{A}\text{-Mod})$ we choose a quasi-isomorphism $\beta^\bullet_K : K^\bullet \to \mathcal{J}_K^\bullet$, with $\mathcal{J}_K^\bullet$ a bounded below complex of injective $\mathcal{A}$-modules. Following (7.2.14), we denote $E(\mathcal{J}_K^\bullet)$ the spectral sequence arising from the filtered complex $(\mathcal{J}_K^\bullet, \text{Fil}^p_q \mathcal{J}_K^\bullet)$. In light of (11.2.18) we have a natural identification

$$\text{gr}_{q}^p \mathcal{J}_K^\bullet \cong \bigcap_{p \leq q} \mathcal{J}_K^\bullet$$

and combining with remark 7.2.16(ii), we get a natural isomorphism

$$E(\mathcal{J}_K^\bullet)_{p-q} \cong R^{p-q} \bigcap_{p \leq q} K^\bullet.$$ 

Taking into account proposition 11.2.21 we deduce that

$$G(K^\bullet) := (E(\mathcal{J}_K^\bullet))_{p-q}, d(\mathcal{J}_K^\bullet)_{p-q}$$

is a Cousin complex, for every $q \in \mathbb{Z}$. Moreover, every morphism $\varphi^\bullet : K^\bullet \to L^\bullet$ in the category $D^+(\mathcal{A}\text{-Mod})$ can be represented by a unique morphism $\mathcal{J}_\varphi^\bullet : \mathcal{J}_K^\bullet \to \mathcal{J}_L^\bullet$ in $\text{Hot}(\mathcal{A}\text{-Mod})$ (notation of definition 7.1.4(ii)), and notice that $\mathcal{J}_\varphi^\bullet$ is a morphism of filtered complexes; in light of (7.2.23) we deduce a well defined morphism $G(\varphi^\bullet) : G(K^\bullet) \to G(L^\bullet)$. In this way, we obtain a functor

$$G : D^+(\mathcal{A}\text{-Mod}) \to \mathcal{A}\text{-Cousin}$$

and we claim that the restriction of $G$ to the subcategory $\mathcal{A}\text{-CM}^c$ is the sought quasi-inverse.

We check first that $G \circ F$ is naturally isomorphic to the identity endofunctor of $\mathcal{A}\text{-Cousin}$. To this aim, let us remark:

**Claim** 11.2.28. Let $K^\bullet$ be any $c$-Cohen-Macaulay complex. We have:

(i) $E(\mathcal{J}_K^\bullet)_{p-q} = 0$ for every $p, q \in \mathbb{Z}$ with $q \neq 0$.

(ii) If $K^\bullet = FC^\bullet$ for a Cousin complex $C^\bullet$, the map $\beta^\bullet_K$ induces a natural isomorphism

$$\text{gr}_{q}^p C^\bullet \cong E(\mathcal{J}_K^\bullet)_{p-q} \cong C^\bullet_{p-q} \quad \text{for every } p \in \mathbb{Z}.$$

**Proof of the claim.** (i): Indeed, from proposition 11.2.21 we get a natural isomorphism

$$(11.2.29) \quad H^{p+q}(\text{gr}_{q}^p \mathcal{J}_C^\bullet) \cong \bigoplus_{c(x) = p} j_{x *} \circ R^{p+q} \prod_{\{x\}} K^\bullet_{|X(x)},$$

which vanishes for $q \neq 0$, since $K^\bullet$ is $c$-Cohen-Macaulay.

(ii): Let $C^\bullet$ and $(M_x \mid x \in X)$ be as in definition 11.2.24(ii); from (11.2.18) and lemma 11.2.25(ii), it follows that the natural map

$$\text{gr}_{q}^p C^\bullet \to \prod_{p \leq q} C^\bullet$$

is an isomorphism in $C^+(\mathcal{A}\text{-Mod})$. Also, combining with claim 10.1.11 we see that $C^\bullet_{|X(x)}$ is a complex of $qc$-flabby $j_{x *}$-modules. By lemma 10.4.4(iii.a) we deduce that the natural map $\prod_{\{x\}} C^\bullet_{|X(x)} \to R\Gamma_{\{x\}} C^\bullet_{|X(x)}$ is an isomorphism in $D^+(\mathcal{A}\text{-Mod})$, for every $x \in X$. Moreover, since the functor $\prod_{\{x\}}$ commutes with arbitrary direct sums (lemma 10.4.4(iii.b)), lemma 11.2.25(i) says that

$$\prod_{\{x\}} C^\bullet_{|X(x)} = j_{x *} i_{x *} M_x [-c(x)] \quad \text{for every } x \in X.$$ 

Taking into account (11.2.29) (and again, proposition 11.2.21), the assertion follows. \(\diamondsuit\)
Now, let $C^\bullet$ be a cousin complex, and set $D^\bullet := GF(C)^\bullet$. From claim [11.2.28] we obtain a natural isomorphism

$$\text{gr}^p_C C^\bullet \sim C^p[-p] \quad \text{for every } p \in \mathbb{Z}.$$  

We need to show that, under this identification, the differential $d^p_D$ of $D^\bullet := H^p(\text{gr}^p_C C^\bullet)$ corresponds to the differential $d^p_C$ of $C^\bullet$. However, on the one hand we have a commutative ladder

$$
\begin{array}{cccccc}
0 & \rightarrow & \text{gr}^{p+1}_C C^\bullet & \rightarrow & \text{Fil}^p_C C^\bullet / \text{Fil}^{p+2}_C C^\bullet & \rightarrow & \text{gr}^p_C C^\bullet & \rightarrow & 0 \\
& & \downarrow & & \downarrow & & \downarrow & & \\
0 & \rightarrow & \text{gr}^{p+1}_C C^\bullet & \rightarrow & \text{Fil}^p_C C^\bullet / \text{Fil}^{p+2}_C C^\bullet & \rightarrow & \text{gr}^p_C C^\bullet & \rightarrow & 0
\end{array}
$$

and claim [11.2.28(ii)] says that both the first and third vertical arrows are isomorphisms, so the top row of is isomorphic to the bottom row. Moreover, we see that the top row is the natural short exact sequence

$$0 \rightarrow C^{p+1}[-p - 1] \rightarrow t^{\leq p+1} t^{\geq p} C^\bullet \rightarrow C^{p}[-p] \rightarrow 0$$

where $t^{\leq p+1}$ and $t^{\geq p}$ are the brutal truncation functors of (7.1.1). Then it is clear that the boundary map $H^p(C^{p}[-p]) \rightarrow H^{p+1}(C^{p+1}[-p - 1])$ in degree $p$ associated with this short exact sequence, is none else than the differential $d^p_C$. Now the contention follows from the naturality of the boundary map, together with remark [7.2.16(ii)].

Next, let $K^\bullet$ be any $c$-Cohen-Macaulay complex, and set

$$(\mathcal{K}_K, \text{Fil}^\bullet \mathcal{K}_K) := \text{Déc} (\mathcal{K}_K, \text{Fil}^\bullet \mathcal{K}_K)$$

(note of (7.2.24)). By proposition [7.2.26(i,ii)] and claim [11.2.28(i)], we have a natural epimorphism

$$u^\bullet : E(\mathcal{K}_K)^0 \rightarrow E(\mathcal{K}_K)^0 \quad \text{in } C^+ (\mathcal{A}\text{-Mod})$$

which induces an isomorphism in $D^+(\mathcal{A}\text{-Mod})$. Moreover, from claim [11.2.28(i)] we see that the subcomplex $(E(\mathcal{K}_K)_n^{p,n-p} \mid n \in \mathbb{Z})$ lies in $\text{Ker } u^\bullet$, for every $p \neq 0$, so $u^\bullet$ restricts to an isomorphism

$$E(\mathcal{K}_K)_0^\bullet = \text{gr}^0 \mathcal{K}_K^\bullet \sim G(K)^\bullet \quad \text{in } D^+(\mathcal{A}\text{-Mod})$$

(see remark [7.2.16(i)]). We point out:

**Claim 11.2.31.** $\text{Fil}^1 \mathcal{K}_K^\bullet$ and $\mathcal{K}_K^\bullet / \text{Fil}^0 \mathcal{K}_K^\bullet$ are acyclic.

**Proof of the claim.** The assertion can be checked on the stalks over the points of $X$; taking into account lemma [11.2.20(ii,iii)], we may then replace $X$ by $X(x)$, for any point $x \in X$, and assume from start that $e$ is bounded on $X$ (lemma [11.2.20(i)]). In this case, it is clear that the filtration $\text{Fil}^p_C C^\bullet$ is finite, for every complex $K^\bullet$ of $\mathcal{A}$-modules, and then the same holds for the filtration $\text{Fil}^p_C C^\bullet$ (see (7.2.24)). In this situation, a simple induction argument reduces to checking that the associated subquotients $\text{gr}^p K^\bullet$ are acyclic, for every $p \neq 0$. However, combining remarks [7.2.9(i)] and [7.2.16(ii)], proposition [7.2.26(ii)] and claim [11.2.28(i)] we may compute

$$H^q \text{gr}^p K^\bullet \sim E(\mathcal{K}_K)_1^{p,q-p} \sim E(\mathcal{K}_K)_2^{p+q-p} = 0 \quad \text{for every } p, q \in \mathbb{Z} \text{ with } p \neq 0$$

whence the claim. \hfill \Box

Claim [11.2.31] yields a natural isomorphism

$$\text{gr}^0 \mathcal{K}_K^\bullet \sim \mathcal{K}_K^\bullet = \mathcal{K}_K^\bullet \quad \text{in } D^+(\mathcal{A}\text{-Mod})$$

and combining with (11.2.30), we finally get an isomorphism

$$K^\bullet \sim FG(K)^\bullet \quad \text{in } D^+(\mathcal{A}\text{-Mod}).$$

Now the theorem follows from proposition [1.1.20(i)]. \hfill \Box
11.3. **Duality over coherent schemes.** If \( X \) is a locally coherent scheme (definition \[8.1.55\](i)) and \( \mathcal{F} \) is an \( \mathcal{O}_X \)-module, we define the **dual \( \mathcal{O}_X \)-module**

\[
\mathcal{F}^\vee := \text{Hom}_{\mathcal{O}_X}(\mathcal{F}, \mathcal{O}_X).
\]

Moreover, for every morphism of \( \mathcal{O}_X \)-modules \( \varphi : \mathcal{F} \to \mathcal{G} \), we denote by \( \varphi^\vee : \mathcal{G}^\vee \to \mathcal{F}^\vee \) the induced (transpose) morphism. As usual, there is a natural morphism of \( \mathcal{O}_X \)-modules:

\[
\beta_\varphi : \mathcal{F} \to \mathcal{G}^\vee.
\]

**Definition 11.3.1.** Let \( X \) be a locally coherent scheme, and \( \mathcal{F} \) an \( \mathcal{O}_X \)-module.

(i) We say that \( \mathcal{F} \) is reflexive at a point \( x \in X \) if there exists an open neighborhood \( U \subset X \) of \( x \) such that \( \mathcal{F}|_U \) is a coherent \( \mathcal{O}_U \)-module, and \( \beta_{\mathcal{F}|U} \) is an isomorphism.

(ii) We say that \( \mathcal{F} \) is reflexive if it is reflexive at all points of \( X \).

(iii) We denote by \( \mathcal{O}_X\text{-Rflx} \) the full subcategory of the category \( \mathcal{O}_X\text{-Mod} \), consisting of all the reflexive \( \mathcal{O}_X \)-modules. It contains \( \mathcal{O}_X\text{-Mod}_{\text{fin}} \) as a full subcategory (see \([10.3]\)).

(iv) Suppose that \( X = \text{Spec} R \) for a coherent ring \( R \), and \( \mathcal{F} = M^\sim \) for an \( R \)-module \( M \).

Then we say that \( M \) is a reflexive \( R \)-module if \( \mathcal{F} \) is a reflexive \( \mathcal{O}_X \)-module.

**Lemma 11.3.2.** Let \( X \) be a locally coherent scheme, \( x \in X \) any point, and \( \mathcal{F} \) a coherent \( \mathcal{O}_X \)-module. We have :

(i) \( \mathcal{F}^\vee \) is a coherent \( \mathcal{O}_X \)-module.

(ii) The following conditions are equivalent:
   (a) \( \mathcal{F} \) is reflexive at the point \( x \).
   (b) \( \mathcal{F}|_x \) is a reflexive \( \mathcal{O}_{X,x} \)-module.
   (c) The map \( \beta_{\mathcal{F}|x} : \mathcal{F}|_x \to (\mathcal{F}^\vee)|_x \) is an isomorphism.

**Proof.** (i): The assertion is local on \( X \), hence we may assume that there exists a presentation

\[
\mathcal{O}_X^\oplus \to \mathcal{O}_X^\oplus \to \mathcal{F} \to 0,
\]

whence – after taking duals – a left exact sequence \( 0 \to \mathcal{F}^\vee \to \mathcal{O}_X^\oplus \to \mathcal{O}_X^\oplus \). Since \( \mathcal{O}_X \) is coherent, the assertion follows.

(ii) shall be left to the reader. 

**Lemma 11.3.3.** Let \( X \) be a reduced locally coherent scheme, and \( \mathcal{F} \) a quasi-coherent \( \mathcal{O}_X \)-module of finite type. Endow the set \( \text{Max} X \) of maximal points of \( X \) with the topology induced by \( X \), and consider the following conditions :

(a) There exists a quasi-compact open immersion \( j : U \to X \) with dense image, such that \( j^* \mathcal{F} \) is a locally free \( \mathcal{O}_U \)-module.

(b) There exists a quasi-compact open immersion \( j : U \to X \) with dense image, such that \( j^* \mathcal{F} \) is a coherent \( \mathcal{O}_U \)-module.

(c) The rank function of \( \mathcal{F} \):

\[
\dim_{\kappa(x)} \kappa(x) \otimes_{\mathcal{O}_{X,x}} \mathcal{F}|_x
\]

restricts to a locally constant function on \( \text{Max} X \).

(d) \( \mathcal{F}^\vee \) is a reflexive \( \mathcal{O}_X \)-module and \( \beta_{\mathcal{F}|x}^\vee \circ \beta_{\mathcal{F}^\vee}|_x = 1_{\mathcal{F}^\vee} \).

Then (a)\( \Rightarrow \) (b) \( \Rightarrow \) (c) \( \Rightarrow \) (d) and if \( X \) is coherent we have (c) \( \Rightarrow \) (a) as well.

**Proof.** Let us check first that (c) \( \Rightarrow \) (a) in case \( X \) is coherent. Indeed, notice that \( j \) is quasi-compact if and only if \( U \) is retro-compact in \( X \), and the latter holds if and only if \( U \) is open and constructible in \( X \) (lemma \([8.1.25]\)(iv, v), c)). It follows that the existence of \( j \) with the sought properties can be checked locally on \( X \), hence we may assume that \( X \) is affine. By proposition \([10.3.32]\)(i) we may find a coherent \( \mathcal{O}_X \)-module \( \mathcal{G} \) and an \( \mathcal{O}_X \)-linear epimorphism \( \varphi : \mathcal{G} \to \mathcal{F} \). Now, fix any \( \eta \in \text{Max} X \) and write \( \mathcal{K} := \text{Ker} \varphi \) as the filtered union of the system \( \{ \mathcal{K}_i | i \in I \} \) of its quasi-coherent \( \mathcal{O}_X \)-submodules of finite type; since \( \mathcal{O}_{X,\eta} \) is a field, there exists \( i \in I \) such that \( \mathcal{K}_{i,\eta} = \mathcal{K}_\eta \). Thus, after replacing \( \mathcal{G} \) by \( \mathcal{G}/\mathcal{K}_i \), we may assume that \( \varphi_\eta \) is an isomorphism.
Moreover, by [100, Th.4.10] we may find an affine open neighborhood $U_\eta$ of $\eta$ in $X$, an integer $r \in \mathbb{N}$ and an isomorphism $\mathcal{G}_{U_\eta} \xrightarrow{\sim} \mathcal{O}_{U_\eta}^{\oplus r}$, and by assumption (c) we may also assume that the rank function of $\mathcal{F}$ is constant on $\text{Max} U_\eta$. In this case, $\varphi_\tau$ is an isomorphism for every $\tau \in \text{Max} U_\eta$, so $\mathcal{K}_\tau = 0$ for every such point $\tau$. Since $X$ is reduced and $\mathcal{G}_{U_\eta}$ is a locally free $\mathcal{O}_{U_\eta}$-module, it follows that $\mathcal{K}_{U_\eta} = 0$. By proposition [8.1.56] we may then find a finite subset $\Sigma \subset \text{Max} X$ such that $\bigcup_{\eta \in \Sigma} \text{Max} U_\eta = \text{Max} X$, and it is easily seen that the open subset $U := \bigcup_{\eta \in \Sigma} U_\eta$ fulfills condition (a).

(a)⇒(b) is obvious.

(b)⇒(c): Notice first that any $U$ as in (b) contains $\text{Max} X$, by proposition [8.1.44(iii)]. Then, since $X$ is reduced, [100, Th.4.10] implies that, for every $\eta \in \text{Max} X$, we may find an affine open neighborhood $U_\eta$ of $\eta$ in $X$ such that $\mathcal{F}_{U_\eta}$ is a locally free $\mathcal{O}_{U_\eta}$-module, whence (c).

(c)⇒(d): Let us show first that $\mathcal{F}^\vee$ is coherent, under condition (c). The assertion is local on $X$, hence we may assume that $X$ is affine, in which case, as we have already seen, (c) implies that there exists a quasi-compact open immersion $j : U \to X$ fulfilling condition (a), and we also know that any such $U$ contains $\text{Max} X$. By proposition [10.3.32(i)], we may then find a coherent $\mathcal{O}_X$-module $\mathcal{G}$ and an $\mathcal{O}_X$-linear epimorphism $\varphi : \mathcal{G} \to \mathcal{F}$ such that $j^* \varphi$ is an isomorphism. There follows a left exact sequence $0 \to \mathcal{F}^\vee \to \mathcal{G}^\vee \to (\ker \varphi)^\vee$, and $\mathcal{F}^\vee$ is coherent, by lemma [11.3.21(i)]. Since $\text{Max} X \subset U$, we have $(\ker \varphi)_\eta = 0$ for every $\eta \in \text{Max} X$, and since $\mathcal{O}_X$ is reduced, it follows easily that $(\ker \varphi)^\vee = 0$, and the claim follows. Now, since $X$ is reduced, the only associated points of $\mathcal{O}_X$ are the maximal points of $X$ (i.e. $\mathcal{O}_X$ has no imbedded points). It follows easily that, for every quasi-coherent $\mathcal{O}_X$-module $\mathcal{G}$, the dual $\mathcal{G}^\vee$ satisfies condition $S_1$ (see definition [10.5.1(ii)]). Next, rather generally, let $\mathcal{M}$ be any $\mathcal{O}_X$-module; directly from the definitions one derives the identity:

\[(11.3.4) \quad \beta^\vee_{\mathcal{M}} \circ \beta_{\mathcal{M}} = 1_{\mathcal{M}^\vee}.
\]

It remains therefore only to show that $\beta^\vee_{\mathcal{G}}$ is a right inverse for $\beta_{\mathcal{G}^\vee}$ when $\mathcal{F}^\vee$ is coherent. Since $\mathcal{G}^\vee$ satisfies condition $S_1$, it suffices to check that, for every maximal point $\xi$, the induced map on stalks

\[
\beta^\vee_{\mathcal{G},\xi} : \mathcal{G}^\vee_{\xi} \xrightarrow{\sim} \mathcal{F}^\vee_{\xi}
\]

is a right inverse for $\beta_{\mathcal{G},\xi}$. However, since $\mathcal{O}_{X,\xi}$ is a field, $\beta^\vee_{\mathcal{G},\xi}$ is a linear map of $\mathcal{O}_{X,\xi}$-vector spaces of the same finite dimension, hence it is an isomorphism, in view of (11.3.4).

\[\square\]

**Remark 11.3.5.** The following observation is often useful. Suppose that $X$ is a locally coherent scheme, $\mathcal{F}$ an $\mathcal{O}_X$-module, reflexive at a given point $x \in X$. We can then choose a presentation $\mathcal{O}_{X,x} \to \mathcal{O}_{X,x}^{\oplus m} \to \mathcal{F}_x \to 0$, and after dualizing we deduce a left exact sequence

\[(11.3.6) \quad 0 \to \mathcal{F}_x^\vee \to \mathcal{O}_{X,x}^{\oplus n} \xrightarrow{u} \mathcal{O}_{X,x}^{\oplus n}.
\]

Especially, if $\mathcal{O}_{X,x}$ satisfies condition $S_1$ (in the sense of definition [10.5.1(iii)]), then the same holds for $\mathcal{F}_x$. For the converse, suppose additionally that $X$ is reduced, and let $x \in X$ be a point for which there exists a left exact sequence such as (11.3.6); then lemma [11.3.3] says that $\mathcal{F}$ is reflexive at $x$ : indeed, $\mathcal{F}_x \simeq (\text{Coker } u^\vee)^\vee$.

**Lemma 11.3.7.** (i) Let $f : X \to Y$ be a flat morphism of locally coherent schemes. The induced functor $\mathcal{O}_Y$-$\text{Mod} \to \mathcal{O}_X$-$\text{Mod}$ restricts to a functor

\[f^* : \mathcal{O}_Y$-Rflx $\to \mathcal{O}_X$-Rflx.\]

(ii) Let $X_0$ be a quasi-compact and quasi-separated scheme, $(X_\lambda \mid \lambda \in \Lambda)$ a cofiltered family of coherent $X_0$-schemes with flat transition morphisms $\psi_{\lambda\mu} : X_\lambda \to X_\mu$ such that the structure morphisms $X_\lambda \to X_0$ are affine, and set $X := \lim_{\lambda \in \Lambda} X_\lambda$. Then:

(a) $X$ is coherent.

(b) the natural functor: $2$-colim $\mathcal{O}_{X_\lambda}$-$\text{Rflx} \to \mathcal{O}_X$-$\text{Rflx}$ is an equivalence.
(iii) Suppose that $f$ is surjective, and let $\mathcal{F}$ be any coherent $O_Y$-module. Then $\mathcal{F}$ is reflexive if and only if $f^* \mathcal{F}$ is a reflexive $O_X$-module.

Proof. (i) follows easily from \cite{99}, Lemma 2.4.29(i.a)].

(ii) For every $\lambda \in \Lambda$, denote by $\psi_\lambda : X \to X_\lambda$ the natural morphism. Let $U \subset X$ be a quasi-compact open subset, $u : O_{U, \lambda} \to O_U$ any morphism of $O_{U}$-modules; by corollary \cite{81.3.8} ii.a there exist $\lambda \in \Lambda$ and a quasi-compact open subset $U_\lambda \subset X_\lambda$ such that $U = \psi_\lambda^{-1}(U_\lambda)$. By \cite{50} Ch.IV, Th.8.5.2(ii)] we may then suppose that $u$ descends to a homomorphism $u_\lambda : O_{U_\lambda} \to O_{U_\lambda}$ whose kernel is of finite type, since $X_\lambda$ is coherent. Since the transition morphisms are flat, we have $\text{Ker} u = \psi_\lambda^*(\text{Ker} u_\lambda)$, whence (ii.a). Next, using \cite{50} Ch.IV, Th.8.5.2] one sees easily that the functor of (ii.b) is fully faithful and moreover, every reflexive $O_X$-module $\mathcal{F}$ descends to a coherent $O_{X_\lambda}$-module $\mathcal{F}_\lambda$ for some $\lambda \in \Lambda$. For every $\mu \geq \lambda$ let $\mathcal{F}_\mu := \psi_\mu^* \mathcal{F}_\lambda$; since $\beta_\mathcal{F}$ is an isomorphism, loc.cit. shows that $\beta_{\mathcal{F}_\mu}$ is already an isomorphism for some $\mu \geq \lambda$, whence (ii.b).

(iii): By virtue of (i), we may assume that $f^* \mathcal{F}$ is reflexive, and we need to show that the same holds for $\mathcal{F}$. However, the natural map $f^*(\mathcal{F}^\vee^\vee) \to (f^* \mathcal{F})^\vee^\vee$ is an isomorphism (proposition \cite{10.3.3} ii)), hence $f^* \beta_\mathcal{F} = \beta_{f^* \mathcal{F}}$ is an isomorphism. Since $f$ is faithfully flat, we deduce that $\beta_\mathcal{F}$ is an isomorphism, as stated.

Proposition 11.3.8. Let $X$ be a coherent scheme, $U \subset X$ a quasi-compact open subset. Then:

(i) If $X$ is reduced, the restriction functor

$$O_X - \text{Rflx} \to O_U - \text{Rflx}$$

is essentially surjective.

(ii) Let $\mathcal{F}$ be a reflexive $O_X$-module. If $\delta(x, O_X) \geq 2$ for all $x \in X \setminus U$, the natural map

$$\mathcal{F} \to j_* j^* \mathcal{F}$$

is an isomorphism. Especially, the restriction functor of (i) is an equivalence.

Proof. (i): Given a reflexive $O_U$-module $\mathcal{F}$, lemma \cite{10.3.25} ii) says that we can find a finitely presented quasi-coherent $O_X$-module $\mathcal{G}$ extending $\mathcal{F}^\vee$; since $X$ is coherent, $\mathcal{G}$ is a coherent $O_X$-module, hence the same holds for $\mathcal{G}^\vee$, which extends $\mathcal{F}$ and is reflexive in light of lemma \cite{11.3.3}.

(ii): Notice that the first assertion easily implies that the restriction functor of (i) is fully faithful, so the second assertion follows from the first together with (i).

Next, since the first assertion is local on $X$, we can suppose that there exists a left exact sequence $0 \to \mathcal{F} \to \mathcal{O}_X^{\oplus m} \to \mathcal{O}_X^{\oplus n}$ (see remark \cite{11.3.5}). Since the functor $j_*$ is left exact, it then suffices to prove the contention for the sheaves $\mathcal{O}_X^{\oplus m}$ and $\mathcal{O}_X^{\oplus n}$, and thus we may assume from start that $\mathcal{F} = \mathcal{O}_X$. Then, since $X \setminus U$ is constructible, corollary \cite{10.4.23} applies and yields the assertion.

Corollary 11.3.9. Let $X$ be a locally coherent scheme, $f : X \to S$ a flat, locally finitely presented morphism, $j : U \to X$ a quasi-compact open immersion, $\mathcal{F}$ a reflexive $O_X$-module. Suppose that

(a) $\text{depth}_{f}(x) \geq 1$ for every point $x \in X \setminus U$, and

(b) $\text{depth}_{f}(x) \geq 2$ for every maximal point $\eta$ of $S$ and every $x \in (X \setminus U) \cap f^{-1}(\eta)$.

(c) $\delta'(s, \mathcal{O}_S) > 0$ for every non-maximal point $s \in S$.

Then the natural morphism $\mathcal{F} \to j_* j^* \mathcal{F}$ is an isomorphism.

Proof. Since $f$ is flat, corollary \cite{10.4.47} and our assumptions imply that $\delta'(x, O_X) \geq 2$ for every $x \in X \setminus U$, so the assertion follows from proposition \cite{11.3.8} ii).
11.3.10. Let $X$ be any scheme. Recall that the rank of an $\mathcal{O}_X$-module $\mathcal{F}$ of finite type, is the upper semicontinuous function:
$$\text{rk} \, \mathcal{F} : X \to \mathbb{N} \quad x \mapsto \dim_{\kappa(x)} \mathcal{F}_x \otimes_{\mathcal{O}_{X,x}} \kappa(x).$$
Clearly, if $\mathcal{F}$ is a locally free $\mathcal{O}_X$-module of finite type, $\text{rk} \, \mathcal{F}$ is a continuous function on $X$. The converse holds, provided $X$ is a reduced scheme. Moreover, if $\mathcal{F}$ is of finite presentation, $\text{rk} \, \mathcal{F}$ is a constructible function and there exists a dense open subset $U \subset X$ such that $\text{rk} \, \mathcal{F}$ restricts to a continuous function on $U$. We denote by $\text{Pic} \, X$ the full subcategory of $\mathcal{O}_X$-$\text{Mod}_{\text{fin}}$ consisting of all the objects whose rank is constant equal to one (i.e. the invertible $\mathcal{O}_X$-modules). In case $X$ is locally coherent, we shall also consider the category $\text{Div} \, X$ of generically invertible $\mathcal{O}_X$-modules, defined as the full subcategory of $\mathcal{O}_X$-$\text{Rflx}$ consisting of all objects which are locally free of rank one on a dense open subset of $X$. If $X$ is locally coherent, $\text{Pic} \, X$ is a full subcategory of $\text{Div} \, X$.

**Remark 11.3.11.** (i) Let $A$ be any integral domain, and set $X = \text{Spec} \, A$. Classically, one has a notion of reflexive fractional ideal of $A$ (see [100, p.80] or example [6.4.36]). Suppose now that $A$ is also coherent, in which case we have the notion of reflexive $A$-module of definition [11.3.1(iv)]. We claim that these two notions overlap on the subclass of reflexive fractional ideals of finite type: more precisely, let $\text{Div} \, (A)$ be the full subcategory of $A$-$\text{Mod}$ whose objects are the finitely generated reflexive fractional ideals of $A$. Then the essential image of the functor

$$\text{Div}(A) \to \mathcal{O}_X$-$\text{Mod} \quad M \mapsto M^\sim$$

is the category $\text{Div} \, X$, and ([11.3.12]) yields an equivalence of $\text{Div}(A)$ with the latter category. Indeed, let $\mathcal{F}$ be any generically invertible $\mathcal{O}_X$-module, and set $I := \mathcal{F}(X)$; if $K$ denotes the field of fractions of $A$, then $\dim_K I \otimes_A K = 1$. Let us then fix a $K$-linear isomorphism $I \otimes_A K \cong K$, and notice that the induced $A$-linear map $I \to K$ is injective, since $\mathcal{F}$ is $S_1$ (remark [11.3.5]). We may then view $I$ as a finitely generated $A$-submodule of $K$, and then it is clear that $I$ is a fractional ideal of $A$. Moreover, on the one hand $\mathcal{F}^\vee$ is the coherent $\mathcal{O}_X$-module $\text{Hom}_A(I, A)^\sim$; on the other hand, the natural map $\text{Hom}_A(I, A) \to \text{Hom}_K(I \otimes_A K, K) = K$ is injective, and its image is the fractional ideal $I^{-1}$ (see [6.4.33]). We easily deduce that $I$ is a reflexive fractional ideal, and conversely it is easily seen that every $\mathcal{O}_X$-module in the essential image of ([11.3.12]) is generically invertible; since this functor is also obviously fully faithful, the assertion follows.

(ii) Let $A$ be a coherent integral domain, and denote by $\text{coh} \, \text{Div}(A)$ the set of all coherent reflexive fractional ideals of $A$. It is easily seen that $\text{coh} \, \text{Div}(A)$ is a submonoid of $\text{Div}(A)$, for the natural monoid structure introduced in example [6.4.36]. More generally, if $X$ is a coherent integral scheme, we may define a sheaf of monoids $\mathcal{D}iv_X$ on $X$, as follows. First, to any affine open subset $U \subset X$, we assign the monoid $\mathcal{D}iv_X(U) := \text{coh} \, \text{Div}(\mathcal{O}_X(U))$. For each inclusion $j : U' \subset U$ of affine open subset, notice that the restriction map $\mathcal{O}_X(U) \to \mathcal{O}_X(U')$ is a flat ring homomorphism, hence it gives a flat morphism of monoids $\mathcal{O}_X(U) \setminus \{0\} \to \mathcal{O}_X(U') \setminus \{0\}$. We then have an induced map of monoids $\mathcal{D}iv_X(j) : \mathcal{D}iv_X(U) \to \mathcal{D}iv_X(U')$, by virtue of lemma [6.4.43(iv)]. It is easily seen that the resulting presheaf $\mathcal{D}iv_X$ is a sheaf on the site of all affine open subsets of $X$. By [44, Ch.0, §3.2.2], the latter extends uniquely to a sheaf of monoids on $X$, which we denote again $\mathcal{D}iv_X$. We set

$$\text{Div}(X) := \mathcal{D}iv_X(X).$$

If $X$ is normal and locally noetherian (or more generally, if $X$ is a Krull scheme, i.e. $\mathcal{O}_X(U)$ is a Krull ring, for every affine open subset $U \subset X$) then $\mathcal{D}iv_X$ is an abelian sheaf, and $\text{Div}(X)$ is an abelian group (proposition [6.4.40(i,iii)]).
11.3.13. For future reference, it is useful to recall some preliminaries concerning the determinant functors defined in [94]. Let $X$ be a scheme. We denote by $\text{grPic} X$ the category of graded invertible $\mathcal{O}_X$-modules. An object of $\text{grPic} X$ is a pair $(L, \alpha)$, where $L$ is an invertible $\mathcal{O}_X$-module and $\alpha : X \to \mathbb{Z}$ is a continuous function. A homomorphism $h : (L, \alpha) \to (M, \beta)$ is a homomorphism of $\mathcal{O}_X$-modules $h : L \to M$ such that $h_x = 0$ for every $x \in X$ with $\alpha(x) \neq \beta(x)$. We denote by $\text{grPic}^X X$ the subcategory of $\text{grPic} X$ with the same objects, and whose morphisms are the isomorphisms in $\text{grPic} X$. Notice that $\text{grPic} X$ is a tensor category: the tensor product of two objects $(L, \alpha)$ and $(M, \beta)$ is the pair $(L \otimes_{\mathcal{O}_X} M, \alpha + \beta)$. We denote by $\mathcal{O}_X\text{-Mod}^\text{lift}_{\text{perf}}$ the category whose objects are the locally free $\mathcal{O}_X$-modules of finite type, and whose morphisms are the $\mathcal{O}_X$-linear isomorphisms. The determinant is the functor:

$$\det : \mathcal{O}_X\text{-Mod}^\text{lift}_{\text{perf}} \to \text{grPic}^X X \quad F \mapsto (\Lambda^\text{rk}_F F, \text{rk} F).$$

Let $D(\mathcal{O}_X\text{-Mod})_{\text{perf}}$ be the category of perfect complexes of $\mathcal{O}_X$-modules; recall that, by definition, every perfect complex is locally isomorphic to a bounded complex of locally free $\mathcal{O}_X$-modules of finite type. The category $D(\mathcal{O}_X\text{-Mod})^\text{perf}$ is the subcategory of $D(\mathcal{O}_X\text{-Mod})_{\text{perf}}$ with the same objects, and whose morphisms are the isomorphisms (i.e. the quasi-isomorphisms of complexes). The main theorem of chapter 1 of [94] can be stated as follows.

**Lemma 11.3.14.** ([94] Th.1) With the notation of (11.3.13) there exists, for every scheme $X$, an extension of the determinant functor to a functor:

$$\det : D(\mathcal{O}_X\text{-Mod})^\text{perf} \to \text{grPic} X.$$

These determinant functors commute with every base change. □

**Proposition 11.3.15.** Let $X$ be a regular scheme. Then every reflexive generically invertible $\mathcal{O}_X$-module is invertible.

**Proof.** The question is local on $X$, hence we may assume that $X$ is affine. Let $\mathcal{F}$ be a generically invertible $\mathcal{O}_X$-module, and $U \subset X$ a dense open subset such that $\mathcal{F}|_U$ is invertible. Denote by $Z_1, \ldots, Z_t$ the irreducible components of $Z := X \setminus U$ whose codimension in $X$ equals one, and for every $i = 1, \ldots, t$, let $\eta_i$ be the maximal point of $Z_i$, and set $A_i := \mathcal{O}_{X, \eta_i}$. Since $\mathcal{F}$ is $S_1$ (remark 11.3.5), the stalk $\mathcal{F}_{\eta_i}$ is a torsion-free $A_i$-module of finite type for every $i \leq t$; however, $A_i$ is a discrete valuation ring, hence $\mathcal{F}_{\eta_i}$ is a free $A_i$-module, necessarily of rank one, for $i = 1, \ldots, t$. Since $\mathcal{F}$ is coherent, it follows that there exists an open neighborhood $U_i$ of $\eta_i$ in $X$, such that $\mathcal{F}|_{U_i}$ is a free $\mathcal{O}_{U_i}$-module. Hence, we may replace $U$ by $U \cup U_1 \cup \cdots \cup U_t$ and assume that every irreducible component of $Z$ has codimension $> 1$, therefore $\delta(x, \mathcal{O}_X) \geq 2$ for every $x \in Z$. Now, $\mathcal{F}[0]$ is a perfect complex by Serre’s theorem ([125, Th.4.4.16]), so the invertible $\mathcal{O}_X$-module $\det \mathcal{F}$ is well defined (lemma 11.3.14). Let $j : U \to X$ be the open immersion; in view of proposition 11.3.8 we deduce natural isomorphisms

$$\mathcal{F} \xrightarrow{j_* j^*} \mathcal{F} \xrightarrow{j_* \det(j^* \mathcal{F}[0])} \mathcal{F}[0] \xleftarrow{\det} \mathcal{F}[0]$$

and the assertion follows. □

We wish now to introduce a notion of duality better suited to derived categories of $\mathcal{O}_X$-modules (over a scheme $X$). Hereafter we only carry out a preliminary investigation of such derived duality – the full development of which, will be the task of section 11.5.

**Definition 11.3.16.** Let $X$ be a locally coherent scheme. A complex $\omega^*$ in $D^b(\mathcal{O}_X\text{-Mod})_{\text{coh}}$ (notation of (10.3)) is called dualizing if it fulfills the following two conditions:

(a) The functor $\mathcal{D} : D(\mathcal{O}_X\text{-Mod})^o \to D(\mathcal{O}_X\text{-Mod}) \quad C^* \mapsto R\mathcal{H}\text{om}^\bullet_{\mathcal{O}_X}(C^*, \omega^*)$

restricts to a duality functor $\mathcal{D} : D^b(\mathcal{O}_X\text{-Mod})_{\text{coh}}^o \to D^b(\mathcal{O}_X\text{-Mod})_{\text{coh}}$.  

(b) The natural transformation \( \eta_{\mathcal{O}} \) : \( C^* \to \mathcal{D} \circ \mathcal{D}(C^*) \) restricts to a biduality isomorphism of functors on the category \( D^b(\mathcal{O}_X\text{-Mod})_{\text{coh}} \).

**Remark 11.3.17.** Let \( X \) be a locally coherent scheme, \( \omega^* \) an object of \( D^b(\mathcal{O}_X\text{-Mod})_{\text{coh}} \), and define the functor \( \mathcal{D} \) as in definition [11.3.16]

(i) A standard d\'evissage argument shows that \( \omega^* \) is dualizing on \( X \) if and only if \( \mathcal{D}(\mathcal{F}[0]) \) lies in \( D^b(\mathcal{O}_X\text{-Mod})_{\text{coh}} \), and the biduality map \( \mathcal{F}[0] \to \mathcal{D} \circ \mathcal{D}(\mathcal{F}[0]) \) is an isomorphism for every coherent \( \mathcal{O}_X \)-module \( \mathcal{F} \).

(ii) Suppose that the complex \( \omega^* \) is dualizing on \( X \). From the natural identification \( \omega^* \xrightarrow{\sim} R\mathcal{H}om_{\mathcal{O}_X}(\mathcal{O}_X[0], \omega^*) \), we deduce a natural isomorphism

\[
R\mathcal{H}om_{\mathcal{O}_X}(\omega^*, \omega^*) \xrightarrow{\sim} \mathcal{O}_X[0] \quad \text{in } D^b(\mathcal{O}_X\text{-Mod}).
\]

**Example 11.3.18.** Suppose that \( X \) is a noetherian regular scheme (i.e. all the stalks \( \mathcal{O}_{X,x} \) are regular rings). In light of Serre’s theorem [125, Th.4.4.16], every object of \( D^b(\mathcal{O}_X\text{-Mod})_{\text{coh}} \) is a perfect complex. It follows easily that the complex \( \mathcal{O}_X[0] \) is dualizing. For more general schemes, the structure sheaf does not necessarily work, and the existence of a dualizing complex is a delicate issue. On the other hand, one may ask to what extent a complex is determined by properties (a) and (b) of definition [11.3.16] Clearly, if \( \omega^* \) is dualizing on \( X \), then so is any other complex of the form \( \omega^* \otimes_{\mathcal{O}_X} \mathcal{L} \), where \( \mathcal{L} \) is an invertible \( \mathcal{O}_X \)-module. Also, any shift of \( \omega^* \) is again dualizing. Conversely, the following proposition [11.3.25] says that any two dualizing complexes are related in such manner, up to quasi-isomorphism.

**Lemma 11.3.19.** Let \( (X, \mathcal{O}_X) \) be any locally ringed space, and \( P^* \) and \( Q^* \) two objects of \( D^-(\mathcal{O}_X\text{-Mod}) \) with a quasi-isomorphism:

\[
P^* \otimes_{\mathcal{O}_X} Q^* \xrightarrow{\sim} \mathcal{O}_X[0].
\]

Then there exist an invertible \( \mathcal{O}_X \)-module \( \mathcal{L} \), a continuous function \( \sigma : |X| \to \mathbb{Z} \) and quasi-isomorphisms:

\[
P^* \xrightarrow{\sim} \mathcal{L}[\sigma] \quad \text{and} \quad Q^* \xrightarrow{\sim} \mathcal{L}^{-1}[-\sigma].
\]

**Proof.** It suffices to verify that, locally on \( X \), the complexes \( P^* \) and \( Q^* \) are of the required form; indeed in this case \( X \) will be a disjoint union of open sets \( U_n \) on which \( H^n P^* \) is concentrated in degree \( n \) and \( H^n Q^* \) is concentrated in degree \( -n \). Note that \( \mathcal{O}_X\text{-Mod} \) is equivalent to the product of the categories \( \mathcal{O}_{U_n}\text{-Mod} \) and that the derived category of a product of abelian categories is the product of the derived categories of the factors.

**Claim 11.3.20.** Let \( A \) be a (commutative) local ring, \( K^* \) and \( L^* \) two objects of \( D^-(A\text{-Mod}) \) with a quasi-isomorphism

\[
K^* \otimes_A L^* \xrightarrow{\sim} A[0].
\]

Then there exist \( s \in \mathbb{Z} \) and quasi-isomorphisms:

\[
K^* \xrightarrow{\sim} A[s] \quad L^* \xrightarrow{\sim} A[-s].
\]

**Proof of the claim.** Set:

\[
i_0 := \max(i \in \mathbb{Z} \mid (H^i K^*) \neq 0) \quad \text{and} \quad j_0 := \max(i \in \mathbb{Z} \mid (H^i L^*) \neq 0).
\]

We may assume that \( H^i = 0 \) for every \( i > i_0 \), and that \( L^* \) is a bounded above complex of free \( A \)-modules. Then we may find a filtered system \( (K^*_\lambda \mid \lambda \in \Lambda) \) of complexes of \( A \)-modules bounded from above, such that

- \( H^{i_0}(K^*_\lambda) \) is a finitely generated \( A \)-module, for every \( \lambda \in \Lambda \);
- the colimit of the system \( (K^*_\lambda \mid \lambda \in \Lambda) \) (in the category of complexes of \( A \)-modules) is isomorphic to \( K^* \).
From (11.3.21) we get an isomorphism $H^0(K^* \otimes_A L^*) \xrightarrow{\sim} A$, and it follows easily that the natural map $H^0(K^*_x \otimes_A L^*) \rightarrow H^0(K^* \otimes_A L^*)$ is surjective for some $\lambda \in \Lambda$. For such $\lambda$, we may then find a morphism in $D^-(A\text{-}\text{Mod})$:

$$(11.3.22) \quad A[0] \rightarrow K^*_x \otimes_A L^*$$

whose composition with the natural map $K^*_x \otimes_A L^* \rightarrow K^* \otimes_A L^*$ is the inverse of (11.3.21). Hence

$$K^*_x \otimes_A L^* \xrightarrow{\sim} (K^*_x \otimes_A L^*) \otimes_A K^* \xrightarrow{\sim} K^* \otimes_A (L^* \otimes_A K^*) \xrightarrow{\sim} K^*_x$$

is a well-defined functor $K^* \otimes_A L^*$ of a complex of flat $A$-modules (see [59] Lemma 4.1.5)). Furthermore, we find a complex $K^*_x$ in $D^{<i_0}(A\text{-}\text{Mod})$ (resp. $L^*_i$ in $D^{<j_0}(A\text{-}\text{Mod})$) such that:

$$K^* \simeq A[-i_0] \oplus K^*_x \quad \text{(resp. } L^* \simeq A[-j_0] \oplus L^*_i)$$

whence a quasi-isomorphism:

$$\varphi : A[0] \xrightarrow{\sim} K^* \otimes_A L^* \xrightarrow{\sim} A[0] \oplus K^*_x[-j_0] \oplus L^*_i[-i_0] \oplus (K^* \otimes_A L^*)$$

However, by construction $\varphi^{-1}$ restricts to an isomorphism on the direct summand $A[0]$, therefore $K^*_x \simeq 0 \simeq L^*_i$ in $D(A\text{-}\text{Mod})$, and the claim follows.

Now, for any point $x \in X$, let $i_x : \{x\} \rightarrow X$ be the inclusion map, and set $K^*_x := i^*_x K^*$ for every complex $K^*$ of $\mathcal{O}_X$-modules. Notice that if $K^*$ is a complex of flat $\mathcal{O}_X$-modules, then $K^*_x$ is a complex of flat $\mathcal{O}_{X,x}$-modules ([8] Exp.V, Prop.1.6(1)), therefore the rule $K^* \mapsto K^*_x$ yields a well-defined functor $D^- (\mathcal{O}_X\text{-}\text{Mod}) \rightarrow D^- (\mathcal{O}_{X,x}\text{-}\text{Mod})$, and moreover we have a natural isomorphism

$$(11.3.23) \quad K^*_x \otimes_{\mathcal{O}_X} L^*_x \xrightarrow{\sim} (K^* \otimes_{\mathcal{O}_X} L^*)_x$$

for every objects $K^*_x, L^*_x$ of $D^- (\mathcal{O}_{X-x}\text{-}\text{Mod})$. Especially, under the current assumptions, and in view of claim (11.3.20) we may find $s \in \mathbb{Z}$, and an isomorphism of $\mathcal{O}_{X,x}$-modules

$$(11.3.24) \quad H^s P^*_{\mathcal{O}_x} \otimes_{\mathcal{O}_{X,x}} H^{-s} Q_{\mathcal{O}_x} \xrightarrow{\sim} H^0(P^* L^*_{\mathcal{O}_{X,x}} Q^*_{\mathcal{O}_x}) \xrightarrow{\sim} \mathcal{O}_{X,x}$$

Since $\mathcal{O}_{X,x}$ is local, we may thus find $a_x \in H^s P^*_{\mathcal{O}_x}$ and $b_x \in H^{-s} Q_{\mathcal{O}_x}$ such that (11.3.24) maps $a_x \otimes b_x$ to 1. Then $a_x$ and $b_x$ extend to local sections

$$a \in \Gamma(U, \text{Ker}(d : P^s \rightarrow P^{s-1}) \quad b \in \Gamma(U, \text{Ker}(d : Q^{-s} \rightarrow P^{-s-1}))$$

on some neighborhood $U \subset X$ of $x$, and after shrinking $U$, we may assume that $a \otimes b$ gets mapped to 1, under the induced morphism of $\mathcal{O}_U$-modules

$$H^s P^*_{\mathcal{O}_U} \otimes_{\mathcal{O}_U} H^{-s} Q_{\mathcal{O}_U} \rightarrow H^0(P^* L^*_{\mathcal{O}_U} Q^*)_{|U} \xrightarrow{\sim} \mathcal{O}_U$$

Then we obtain a well defined morphism in $D^- (\mathcal{O}_U\text{-}\text{Mod})$

$$\varphi : \mathcal{O}_U[s] \rightarrow P^*_{\mathcal{O}_U} \quad \text{resp. } \psi : \mathcal{O}_U[-s] \rightarrow Q^*_{\mathcal{O}_U}$$
by the rule : $t \mapsto t \cdot a$ (resp. $t \mapsto t \cdot b$) for every local section $t$ of $\mathcal{O}_Y$. Again by claim 11.3.20 and (11.3.23) we deduce that $\varphi_y : \mathcal{O}_{1,y}[s] \to P_y^*$ is a quasi-isomorphism for every $y \in U$ (and likewise for $\psi_y$); i.e. $\varphi$ and $\psi$ are the sought isomorphisms in $D^-(\mathcal{O}_U \text{-Mod})$.

**Proposition 11.3.25.** Suppose that $\omega_1^*$ and $\omega_2^*$ are two dualizing complexes for the locally coherent scheme $X$. Then there exist an invertible $\mathcal{O}_X$-module $\mathcal{L}$ and a continuous function $\sigma : |X| \to \mathbb{Z}$ such that

$$\omega_2^* \simeq \omega_1^* \otimes_{\mathcal{O}_X} \mathcal{L}[\sigma] \quad \text{in } D^b(\mathcal{O}_X \text{-Mod})_{\text{coh}}.$$

**Proof.** Denote by $\mathcal{D}_1$ and $\mathcal{D}_2$ the duality functors associated with $\omega_1$ and respectively $\omega_2$. By assumption, we can find complexes $P^*, Q^*$ in $D^b(\mathcal{O}_X \text{-Mod})_{\text{coh}}$ such that $\omega_2 \simeq \mathcal{D}_2(P^*)$ and $\omega_1 \simeq \mathcal{D}_2(Q^*)$, and therefore

$$\mathcal{D}_2(\mathcal{F}^*) \simeq R\mathcal{H}om_{\mathcal{O}_X}^*(\mathcal{F}^*, \mathcal{D}_1(P^*)) \simeq \mathcal{D}_1(\mathcal{F}^* \otimes_{\mathcal{O}_X} P^*)$$

for every object $\mathcal{F}^*$ of $D^b(\mathcal{O}_X \text{-Mod})_{\text{coh}}$ ([125 Th.10.8.7]).

**Claim 11.3.26.** Let $C^*$ be an object of $D^-(\mathcal{O}_X \text{-Mod})_{\text{coh}}$, such that $\mathcal{D}_1(C^*)$ is in $D^b(\mathcal{O}_X \text{-Mod})$. Then $C^*$ is in $D^b(\mathcal{O}_X \text{-Mod})_{\text{coh}}$.

**Proof of the claim.** For given $m, n \in \mathbb{N}$, the natural maps: $\tau_{\leq-n} C^* \xrightarrow{\alpha} C^* \xrightarrow{\beta} \tau_{\geq-m} C^*$ induce morphisms

$$\mathcal{D}_1(\tau_{\geq-m} C^*) \xrightarrow{\mathcal{D}_1(\beta)} \mathcal{D}_1(C^*) \xrightarrow{\mathcal{D}_1(\alpha)} \mathcal{D}_1(\tau_{\leq-n} C^*)$$

Say that $\omega^* \simeq \tau_{\geq a} \omega^*$ for some integer $a \in \mathbb{N}$. Then $\mathcal{D}_1(\tau_{\leq-n} C^*)$ lies in $D^{\geq n+a}(\mathcal{O}_X \text{-Mod})$. Since $\mathcal{D}_1(C^*)$ is bounded, it follows that $\mathcal{D}_1(\beta) = 0$ for $n$ large enough. Consider now the commutative diagram:

$$\begin{array}{ccc}
\tau_{\leq-n} C^* & \xrightarrow{\beta \circ \alpha} & \tau_{\geq-m} C^* \\
\downarrow \mathcal{D}_1 \circ \mathcal{D}_1(\tau_{\leq-n} C^*) & & \downarrow \mathcal{D}_1 \circ \mathcal{D}_1(\tau_{\geq-m} C^*) \\
\tau_{\leq-n} C^* & \xrightarrow{\beta \circ \alpha} & \tau_{\geq-m} C^*
\end{array}$$

Since $\tau_{\geq-m} C^*$ is a bounded complex, $\eta$ is an isomorphism in $D(\mathcal{O}_X \text{-Mod})$, so $\beta \circ \alpha = 0$ whenever $n$ is large enough. Clearly this means that $C^*$ is bounded, as claimed.

Applying claim 11.3.26 to $C^* := \mathcal{F}^* \otimes_{\mathcal{O}_X} P^*$ (which is in $D^-(\mathcal{O}_X \text{-Mod})_{\text{coh}}$, since $X$ is coherent) we see that the latter is a bounded complex, and by reversing the roles of $\omega_1$ and $\omega_2$ it follows that the same holds for $\mathcal{F}^* \otimes_{\mathcal{O}_X} Q^*$. We then deduce isomorphisms in $D^b(\mathcal{O}_X \text{-Mod})_{\text{coh}}$

$$\mathcal{D}_1 \circ \mathcal{D}_2(\mathcal{F}^*) \simeq \mathcal{F}^* \otimes_{\mathcal{O}_X} P^* \quad \text{and} \quad \mathcal{D}_2 \circ \mathcal{D}_1(\mathcal{F}^*) \simeq \mathcal{F}^* \otimes_{\mathcal{O}_X} Q^*.$$

Letting $\mathcal{F}^* := \mathcal{O}_X[0]$ we derive:

$$\mathcal{O}_X[0] \simeq \mathcal{D}_2 \circ \mathcal{D}_1 \circ \mathcal{D}_2(\mathcal{O}_X[0]) \simeq \mathcal{D}_2 \circ \mathcal{D}_1(\mathcal{O}^*) \simeq P^* \otimes_{\mathcal{O}_X} Q^*.$$

Then lemma 11.3.19 says that $P^* \simeq \mathcal{O}^*[\tau]$ for an invertible $\mathcal{O}_X$-module $\mathcal{O}$ and a continuous function $\tau : |X| \to \mathbb{Z}$. Consequently : $\omega_2 \simeq \mathcal{O}^*[\tau] \otimes_{\mathcal{O}_X} \omega_1$, so the proposition holds with $\mathcal{L} := \mathcal{O}$ and $\sigma := -\tau$.

**Lemma 11.3.27.** Let $f : X \to Y$ be a morphism of locally coherent schemes, and $\omega_Y^*$ a dualizing complex on $Y$. We have:

(i) If $f$ is finite and finitely presented, then $f^! \omega_Y^*$ is dualizing on $X$.

(ii) If $Y$ coherent and $f$ is an open immersion, then $f^* \omega_Y^*$ is dualizing on $X$. 

\[ \square \]
Proof. (i): Denote by $\map{f}{X, \mathcal{O}_X}{Y, f \mathcal{O}_X}$ the morphism of ringed spaces deduced from $f$. For any object $C^\bullet$ of $\mathcal{D}(\mathcal{O}_X\text{-Mod})_{\text{coh}}$, we have natural isomorphisms:

$$\mathcal{D}(C^\bullet) := R\mathcal{H}\text{om}_{\mathcal{O}_X}(C^\bullet, f^!\omega_Y^\bullet) \simeq R\mathcal{H}\text{om}_{\mathcal{O}_X}(C^\bullet, f^!R\mathcal{H}\text{om}_{\mathcal{O}_X}(f_\mathcal{O}_X, \omega_Y^\bullet)) \simeq f^!R\mathcal{H}\text{om}_{f_\mathcal{O}_X}(f_\mathcal{O}_X, \omega_Y^\bullet).$$

Hence, if $C^\bullet$ is in $\mathcal{D}(\mathcal{O}_X\text{-Mod})_{\text{coh}}$, the same holds for $\mathcal{D}(C^\bullet)$; especially, this applies to $f^\ast\omega_Y \simeq \mathcal{D}(\mathcal{O}_X[0])$, and we can compute:

$$\mathcal{D} \circ \mathcal{D}(C^\bullet) \simeq f^!R\mathcal{H}\text{om}_{\mathcal{O}_X}(R\mathcal{H}\text{om}_{\mathcal{O}_X}(f_\mathcal{O}_X, C^\bullet, \omega_Y^\bullet), \omega_Y^\bullet) \simeq f^!f_\mathcal{O}_X \simeq C^\bullet$$

and by inspecting the definitions, one verifies that the resulting natural transformation $C^\bullet \to \mathcal{D} \circ \mathcal{D}(C^\bullet)$ is the biduality isomorphism. The claim follows.

(ii): Since $\mathcal{O}_Y$ is coherent, the natural map

$$f^!R\mathcal{H}\text{om}_{\mathcal{O}_X}(\mathcal{G}[0], \omega_Y^\bullet) \to R\mathcal{H}\text{om}_{\mathcal{O}_X}(f^!\mathcal{G}[0], f^!\omega_Y^\bullet)$$

is an isomorphism in $\mathcal{D}(\mathcal{O}_X\text{-Mod})_{\text{coh}}$, for every $\mathcal{O}_Y$-module $\mathcal{G}$. Then the assertion follows easily from lemma [10.3.25(ii)] and remark [11.3.17(i)].

**Proposition 11.3.28.** Let $A$ be a noetherian local ring, $\kappa$ its residue field, $M^\bullet$ a bounded below complex of $A$-modules of finite type, and set $X := \text{Spec } A$. We have:

(i) The following conditions are equivalent

(a) There exists $c \in \mathbb{Z}$ such that $R\mathcal{H}\text{om}_A^\bullet(\kappa[0], M^\bullet) \simeq \kappa[c]$.

(b) The complex of $\mathcal{O}_X$-modules $M^\sim$ arising from $M^\bullet$ is dualizing on $X$.

(ii) If the equivalent conditions of (i) hold, then $M^\bullet$ has finite injective dimension.

**Proof.** (i): We show first that (a)$\Rightarrow$(b). To this aim, in view of remark [11.3.17(i)] and corollary [10.3.2(ii)], it suffices to check:

**Claim 11.3.29.** Assume (a). Then, for every finitely generated $A$-module $N$, we have:

(i) $D^\bullet(N) := R\mathcal{H}\text{om}_A^\bullet(N[0], M^\bullet) \in \mathcal{D}_\leq(e)(A\text{-Mod})$ (notation of (7.1)).

(ii) The natural map

$$N[0] \to DD^\bullet(N) := R\mathcal{H}\text{om}_A^\bullet(D^\bullet(N), M^\bullet)$$

is an isomorphism.

**Proof of the claim.** We first show the claim for $N = \kappa$, in which case (i) holds by assumption. To check (ii), let $M^\bullet \to I^\bullet$ be a resolution consisting of a bounded below complex of injective $A$-modules, so that

$$D^\bullet(\kappa[0], M^\bullet) \to \text{Hom}_A^\bullet(\kappa[0], I^\bullet) \to I^\bullet[\mathfrak{m}]$$

where $\mathfrak{m} \subset A$ is the maximal ideal, and $I^k[\mathfrak{m}]$ denotes the submodule of $\mathfrak{m}$-torsion elements in $I^k$, for every $k \in \mathbb{Z}$. Under these isomorphisms, it is easily seen that the biduality map of (ii) is identified with the unique one

$$\kappa \to H := \text{Hot}_{A\text{-Mod}}(I^\bullet[\mathfrak{m}], I^\bullet)$$

that sends $1 \in \kappa$ to the inclusion map $j^\bullet : I^\bullet[\mathfrak{m}] \to I^\bullet$ (details left to the reader). Now, it is clear that any morphism $I^k[\mathfrak{m}] \to I^\bullet$ in $\text{Hot}_{A\text{-Mod}}$ factors through $j^\bullet$, and on the other hand, our assumption implies that $H \simeq \kappa$. Hence, pick a morphism $f^\bullet : I^\bullet[\mathfrak{m}] \to I^\bullet$ representing a generator for the $A$-module $H$, and write $f^\bullet = j^\bullet \circ g^\bullet$ for some endomorphism $g^\bullet$ of $I^\bullet[\mathfrak{m}]$; in other words, $f^\bullet$ is the image of $j^\bullet$ under the $A$-linear map

$$\text{Hot}_{A\text{-Mod}}(g^\bullet, I^\bullet) : H \to H$$
so the class of \(j^*\) cannot vanish in \(H\), and (ii) follows in this case.

Next, we shall argue by induction on \(d := \dim \text{Supp} N\). If \(d = 0\), then \(N\) is an \(A\)-module of finite length, in which case we argue by induction on the length \(l\) of \(N\). If \(l = 1\), we have \(N \cong \mathfrak{n}\), so the assertions are already known. Suppose \(l > 1\), and that both (i) and (ii) are already known for all \(A\)-modules of length \(< d\); we may find an \(A\)-submodule \(N' \subset N\) such that both \(N'\) and \(N'' := N/N'\) have length \(< d\). From the inductive assumption for \(N'\) and \(N''\), and the induced distinguished triangle

\[
D^\bullet(N'') \to D^\bullet(N) \to D^\bullet(N') \to D^\bullet(N'')[1]
\]

deed that (i) holds for \(N\). Likewise, since (ii) is known for both \(N'\) and \(N''\), using the 5-lemma we deduce easily that the same holds also for \(N\).

Lastly, suppose that \(d > 0\), and both (i) and (ii) are already known for all \(A\)-modules of finite type whose support has dimension \(< d\). Let \(N' := \Gamma_{(m)}N\); both (i) and (ii) are already known for \(N'\), so the same \(d\text{évissage}\) argument as in the foregoing reduces to showing the claim for \(N/N'\), i.e. we may assume that \(m \not\in \text{Ass} N\). Thus, let \(t \in m\) be any element such that the scalar multiplication map \(t \cdot 1_N\) is injective, so we have a short exact sequence

\[
0 \to N \xrightarrow{t^k} N \to N_k := N/t^kN \to 0 \quad \text{for every } k > 0.
\]

Notice that \(\dim \text{Supp} N_k < d\): indeed, if \(p\) is a minimal element of \(\text{Supp} N\), then \(p \in \text{Ass} N\) ([100, Th.6.5(iii)]), hence \(t \not\in p\), and therefore \(p \not\in \text{Supp} N_k\). By inductive assumption, both (i) and (ii) hold for \(N_k\) (for every \(k > 0\)), and by considering the induced distinguished triangle

\[
D^\bullet(N_k) \to D^\bullet(N) \xrightarrow{t^k} D^\bullet(N) \to D^\bullet(N_k)[1]
\]

we deduce that scalar multiplication by \(t\) is an epimorphism on \(H^jD^\bullet(N)\) whenever \(j \geq -c\); but the latter is an \(A\)-module of finite type, so it must vanish, by Nakayama’s lemma, and we conclude that (i) holds for \(N\). Furthermore, by the same token we get an exact sequence

\[
H^iDD^\bullet(N) \xrightarrow{t^k} H^iDD^\bullet(N) \to 0 \quad \text{for every } i \neq 0
\]

whence \(H^iDD(N) = 0\) for \(i \neq 0\), again by Nakayama’s lemma. Lastly, for every \(k > 0\) consider the ladder with exact rows:

\[
\begin{array}{cccccccc}
0 & \to & N & \xrightarrow{t^k} & N & \xrightarrow{\alpha} & N_k & \to 0 \\
| & & \alpha | & & \alpha | & & | & \\
0 & \to & H^0DD^\bullet(N) & \xrightarrow{t^k} & H^0DD^\bullet(N) & \xrightarrow{\alpha} & H^0DD^\bullet(N_k) & \to 0
\end{array}
\]

whose right-most vertical arrow is an isomorphism, by inductive assumption. A simple diagram chase then yields

\[
H^0DD^\bullet(N) = t^k \cdot H^0DD^\bullet(N) + \alpha(N)
\]

so \(\alpha\) is surjective, by Nakayama’s lemma. To show the injectivity of \(\alpha\), let \(x \in N\) be any non-zero element, and choose \(k > 0\) such that \(x \not\in t^kN\), so the image of \(x\) does not vanish in \(N_k\), whence necessarily \(\alpha(x) \neq 0\), and the claim follows.

(b)⇒(a): Let \(i : \text{Spec} \kappa \to X\) be the closed immersion; from corollary [10.3.2(ii)] we know that \(i^!M^\bullet\) is the complex arising from the complex of \(\kappa\)-modules \(R\text{Hom}_A(\kappa[0], M^\bullet)\). On the other hand, \(i^!M^\bullet\) is dualizing on \(\text{Spec} \kappa\), by virtue of lemma [11.3.27(i)]; obviously, \(\kappa[0]\) is also dualizing on the same scheme, so the assertion follows from proposition [11.3.25]

(ii): We notice more precisely:

**Claim** 11.3.30. Suppose that the conditions of (i) hold for \(M^\bullet\), and moreover that \(H^0M^\bullet \neq 0\) and \(H^1M^\bullet = 0\) for every \(i < 0\). Then \(c \leq 0\), and the injective dimension of \(M^\bullet\) equals \(-c\).
Proof of the claim. Under the assumptions of the claim, it is clear that \( c \leq 0 \). Pick a quasi-isomorphism \( M^* \xrightarrow{\sim} J^* \), where \( J^* \) is an object of \( \mathbb{C}^{[0,-c]}(A\text{-Mod}) \) such that \( J^\ast \) is an injective \( A \)-module for every \( j < -c \). Notice that \( I^\ast \neq 0 \), since \( H^0 M^* \) does not vanish. Let \( N \) be any \( A \)-module; a standard argument shows that
\[
\text{Ext}^1_A(N, I^c) \simeq R^{1-c}\text{Hom}^*_A(N[0], M^*)
\]
and the latter vanishes if \( N \) is finitely generated, by virtue of claim \([11.3.29]i\). It follows that \( I^c \)
is injective as well (see e.g. [100] Th.B3), so the injective dimension of \( M^* \) is \( \leq -c \). But it is
also \( \geq -c \), due to condition (i.a).

After replacing \( M^* \) by \( M^*[a] \) for a suitable \( a \in \mathbb{Z} \), the assumptions of claim \([11.3.30] \) can obviously be fulfilled, whence (ii).

Let us recall the following:

Definition 11.3.31. Let \( X \) be a noetherian scheme.

(i) We say that \( X \) is Gorenstein, if \( \mathcal{O}_X[0] \) is dualizing on \( X \).

(ii) If \( X = \text{Spec} \ A \) is affine and Gorenstein, we also say that \( A \) is a Gorenstein ring.

Remark 11.3.32. (i) In view of example \([11.3.18] \), every regular noetherian ring is Gorenstein.

(ii) Let \( A \) be any local noetherian ring, and \( \kappa \) the residue field of \( A \). In light of proposition \([11.3.28]i \) (and of corollary \([10.3.2]i \) (ii)), we see that \( A \) is Gorenstein if and only if there exists \( c \in \mathbb{N} \) such that \( R\text{Hom}^*_A(\kappa[0], A[0]) \simeq \kappa[c] \).

11.3.33. Let \( A \to B \) be a flat homomorphism of local noetherian rings, \( \kappa_A \) (resp. \( \kappa_B \)) the residue field of \( A \) (resp. of \( B \)), and \( K^* \) a bounded complex of \( A \)-modules of finite type. Set \( X := \text{Spec} \ A, Y := \text{Spec} \ B \), denote by \( f : Y \to X \) the resulting morphism of local schemes, and let \( K^\sim \) be the complex of \( \mathcal{O}_X \)-modules arising from \( K^* \). We have:

Proposition 11.3.34. In the situation of \([11.3.33] \), the following conditions are equivalent:

(a) \( f^* K^\sim \) is dualizing on \( Y \).

(b) \( K^\sim \) is dualizing on \( X \) and \( B \otimes_A \kappa_A \) is a Gorenstein ring.

Proof. Set \( C := B \otimes_A \kappa_A, F := \text{Spec} \ C \) and \( Z := \text{Spec} \, \kappa_B \), denote \( i_1 : Z \to F \) and \( i_2 : F \to Y \) the closed immersions, and let \( i := i_2 \circ i_1 \). In light of proposition \([11.3.28]i \) (and of corollary \([10.3.2]i \) (ii)) we see that (a) holds if and only if there exists \( c \in \mathbb{Z} \) such that \( i^!(f^* K^\sim) \simeq \mathcal{O}_Z[c] \).

However, recall that \( i^! \simeq i_1^! \circ i_2^! \) (proposition \([11.1.7]i \)); invoking again proposition \([11.3.28]i \) we deduce that (a) holds if and only if \( i_2^!(f^* K^\sim) \) is dualizing on \( F \). The latter is the complex of \( \mathcal{O}_F \)-modules arising from
\[
R\text{Hom}^*_B(C[0], B \otimes_A K^*) \simeq B \otimes_A L^* \quad \text{where} \quad L^* := R\text{Hom}^*_A(\kappa_A[0], K^*)
\]
(proposition \([10.3.3]i \) and corollary \([10.3.2]i \) (ii)). Hence, suppose that (b) holds; from proposition \([11.3.28]i \) we conclude that \( i_2^!(f^* K^\sim) \simeq \mathcal{O}_F[c] \) for some \( c \in \mathbb{Z} \); the latter is dualizing on \( Z \) by assumption, whence (a). Conversely, suppose that (a) holds; from \([11.3.35] \) we see that \( B \otimes_A L^* \) is a bounded complex of \( C \)-modules whose cohomology is a free \( C \)-module in every degree.

We recall the following:

Claim 11.3.36. Let \( R \) be any ring, \( M^* \) a bounded complex of \( R \)-modules, such that \( H^i M^* \) is a projective \( R \)-module, for every \( i \in \mathbb{Z} \). Then we have an isomorphism
\[
M^* \xrightarrow{\sim} \bigoplus_{i \in \mathbb{Z}} (H^i M^*)[-i] \quad \text{in} \ D(R\text{-Mod}).
\]

Proof of the claim. We argue by induction on the cardinality \( c_M \) of \( S_M := \{ i \in \mathbb{Z} \mid H^i M^* \neq 0 \} \). If \( c_M = 0 \), the assertion is obvious. Suppose that \( c_M > 0 \), and that the assertion is known for every complex \( P^* \) as in the claim, with \( c_P < c_M \). Let \( a \in \mathbb{Z} \) be the largest element of \( S_M \); after
replacing $M^\bullet$ by its truncation $\tau^a M^\bullet$, we may assume that $M^i = 0$ for every $i > a$. Then $\hat{H}^a M^\bullet \simeq \text{Coker}(d^{a-1} : M^{a-1} \to M^a)$, and since $\hat{H}^a M^\bullet$ is a projective $R$-module, we may find an $R$-linear isomorphism $M \simeq (\hat{H}^a M^\bullet) \oplus \text{Im} d^{a-1}$. Denote by $P^\bullet$ the complex such that $P^i := M^i$ for every integer $i < a$, and such that $P^a := \text{Im} d^{a-1}$, with differentials induced by those of $M^\bullet$; then $M^\bullet \simeq (\hat{H}^a M^\bullet)[-a] \oplus P^\bullet$ in $\text{D}(\text{R-Mod})$, and $c_p < c_M$, so the assertion is known for $P^\bullet$, and the claim follows. □

In light of claim [11.3.36] and remark [11.3.17](ii), we easily see that $B \otimes_A L^\bullet \simeq C[a]$ in $\text{D}^b(\text{C-Mod})$ for some $a \in \mathbb{Z}$ (details left to the reader), and then clearly $L^\bullet \simeq k_A[c]$ in $\text{D}^b(\text{A-Mod})$. Taking into account proposition [11.3.28](i), assertion (b) follows. 

**Proposition 11.3.37.** Let $X$ be a noetherian scheme, $\mathcal{H}^\bullet$ an object of $\text{D}^b(\mathcal{O}_X\text{-Mod})_{\text{coh}}$. The following conditions are equivalent:

(a) $\mathcal{H}^\bullet$ is dualizing on $X$.

(b) $\mathcal{H}^\bullet(x)$ is dualizing on $X(x)$, for every $x \in X$ (notation of definition [4.9.17](iii)).

**Proof.** (b)⇒(a): We notice the following:

**Claim 11.3.38.** Let $X$ be a noetherian scheme, $\mathcal{H}^\bullet$ an object of $\text{D}^b(\mathcal{O}_X\text{-Mod})_{\text{coh}}$, and $x \in X$ any point. Suppose that the complex of $\mathcal{O}_X(x)$-modules $\mathcal{H}^\bullet(x)$ has finite injective dimension. Then, for every $\mathcal{F}^\bullet \in \text{D}^b(\mathcal{O}_X, x, \text{Mod})_{\text{coh}}$ there exists an open neighborhood $U$ of $x$ in $X$ such that $R\text{Hom}_{\mathcal{O}_x}(\mathcal{F}^\bullet, \mathcal{H}^\bullet)_{|U}$ lies in $\text{D}^b(\mathcal{O}_U\text{-Mod})_{\text{coh}}$.

**Proof of the claim.** The question is local on $X$, so we may assume that $X$ is affine, say $X = \text{Spec } A$ for a noetherian ring $A$; also, by theorem [10.3.24] we may assume that $\mathcal{H}^\bullet$ arises from a bounded complex $K^\bullet$ of $A$-modules of finite type (details left to the reader). Then, remark [11.3.17](i) and corollary [10.3.2](ii) reduce to checking that for every $A$-module $M$ there exists an open neighborhood $U$ of $x$ in $X$, such that the $A$-modules $T^i(M) := H^i R\text{Hom}(M[0], K^\bullet)$ have support in $X \setminus U$, for every sufficiently large $i \in \mathbb{Z}$.

We shall argue by induction on the dimension $d$ of the support of $M$; if $d = 0$, there is nothing to show, hence suppose that $d > 0$, and that the assertion is already known for every $A$-module whose support has dimension strictly less than $d$. By [100, 6.4] we may further reduce to the case where $M = A/p$, where $p \subset A$ is a prime ideal. Then, pick a finite system of generators $t_1, \ldots, t_n \in A$ for $p$, and set $L_* := K_*(t_1, \ldots, t_n)$ (notation of remark [7.8.1](ii)). Now, $H_i L_* \simeq A/p$, and $H_i L_* = 0$ for every $i > n$; moreover, lemma [7.8.2](ii) says that $H_i L_*$ is an $A/p$-module of finite type, for every $i = 0, \ldots, n$, and vanishes for $i \in \mathbb{Z}$ outside this range; therefore, we may find $f \in A \setminus p$ such that $(H_i L_*)_f$ is a free $(A/p)_f$-module of some finite rank $b(i) \in \mathbb{N}$, for every $i \in \mathbb{Z}$ ([100, Th.4.10(ii)]), and there exists an integer $m \leq n$ such that $b(m) \neq 0$ and $b(i) = 0$ for every $i > m$. By choosing an injective resolution of $K^\bullet$, we get a spectral sequence

$$E_2^{pq} := R^p \text{Hom}_A^*(K^\bullet)[0], K^\bullet) \Rightarrow R^{p+q} \text{Hom}_A^*(L_*, K^\bullet)$$

with differentials $d^{pq} : E^{pq} \to E^{p-r+1, q+r}$ for every $p, q \in \mathbb{Z}$ and every $r \geq 2$. Taking into account corollary [10.3.2](ii), we see that

$$E_2^{pq}(x) \simeq (E_2^{00}(x))^\otimes (b(q))$$

for every $p \in \mathbb{Z}$.

By the same token, we also get a natural isomorphism

$$E_2^{pq}(x) := E_2^{pq} \otimes_A \mathcal{O}_{X,x} \simeq R^p \text{Hom}_{\mathcal{O}_{X,x}}^x((A/p)^{-}[0]([x], H^\bullet(x)))$$

for every $p \in \mathbb{Z}$.

Since $\mathcal{H}^\bullet(x)$ has finite injective dimension, it follows that there exists an integer $r$ such that $E_2^{pq}(x) = 0$ whenever $p > r$. Since $E_2^{pq}$ is an $A$-module of finite type for every $p, q \in \mathbb{Z}$, we deduce that there exists an open neighborhood $U'$ of $x$ in $X$, such that, for every $p =
$r + 1, \ldots, r + n$, the support of $E_{2, r}^{p, q}$ is contained in $X \setminus U'$ (\cite{100}, Th.4.10(i)). In this case, the support of $(E_r^{m, q})_p$ is also contained in $X \setminus U'$, for every $(p, q) \in \mathbb{Z}^{\geq 2}$ with $p = r + 1, \ldots, r + n$.

Now, let $q \in U' \cap \text{Spec } A_f$ be any prime ideal, and suppose that $(E_2^{m, 0})_q \neq 0$ for some integer $p \geq r + n$. From \cite{11.3.39}, we deduce that $(E_2^{m, q})_q \neq 0$ as well, and it is easily seen that $(E_\infty^{m, q})_q = (E_2^{m, q})_q$. Especially

\[ R^{p + m} \text{Hom}_A^*(L_*, K^*) \neq 0. \]

However, $L_*$ is also a complex of free $A$-modules, therefore

\[ R\text{Hom}_A^*(L_*, K^*) \simeq \text{Hom}_A^*(L_*, K^*) \quad \text{in D}(A-\text{Mod}). \]

Thus, if we represent $K^*$ via an object of $C^{[a, b]}(A-\text{Mod})$ (for some $a, b \in \mathbb{Z}$ with $a \leq b$ : notation of (1.1)), then $R\text{Hom}_A^*(L_*, K^*)$ is represented by an object of $C^{[a, b + n]}(A-\text{Mod})$, and consequently, $R^i \text{Hom}_A^*(L_*, K^*) = 0$ for $i > b + n$. Taking into account \cite{11.3.40}, we conclude that $p \leq p + m \leq b + n$, so that

\[ \text{(11.3.41)} \quad T^i(M)_q = 0 \quad \text{whenever } i > n + \max(b, r) \text{ and } q \in U' \cap \text{Spec } A_f. \]

On the other hand, from the short exact of $A$-modules

\[ 0 \to M \to M \to M/fM \to 0 \]

we see that $T^i(M)/fT^i(M) \subset T^{i+1}(M/fM)$ for every $i \in \mathbb{Z}$; since the support of $M/fM$ has dimension $< d$, the inductive assumption tells us that there exist $N \in \mathbb{N}$ and an open neighborhood $U''$ of $x$ in $X$ such that the support of $T^{i+1}(M/fM)$ lies in $X \setminus U''$, for every $i > N$. From this, Nakayama’s lemma implies that

\[ T^i(M)_q = 0 \quad \text{for every } q \in \text{Spec } A/fA \text{ and every } i > N. \]

Combining with \cite{11.3.41}, we conclude that $U := U' \cap U''$ will do. \hfill $\Diamond$

Since $X$ is quasi-compact, assumption (b), claim \cite{11.3.38} and proposition \cite{11.3.28}(ii) imply that the rule : $\mathcal{O} \to \mathcal{D}(\mathcal{O}) : = R\text{Hom}_A^*(\mathcal{O}, K^*)$ takes objects of $D^b(\mathcal{O}_X-\text{Mod})_{\text{coh}}$ to objects of the same category. Then, corollary \cite{10.3.2}(ii) and assumption (b) imply that the natural map $\mathcal{O}[x](x) \to D \circ D(\mathcal{O}[x])(x)$ is an isomorphism in $D^b(\mathcal{O}_X-\text{Mod})$ for every $x \in X$ and every coherent $\mathcal{O}_X$-module $\mathcal{F}$, whence (a).

(a)$\Rightarrow$(b): Let $x \in X$ be any point, and $\mathcal{M}$ any coherent $\mathcal{O}_{X(x)}$-module; we may extend $\mathcal{M}$ to a coherent $\mathcal{O}_U$-module on some affine open neighborhood $U$ of $x$ in $X$, and then the latter can be further extended to a coherent $\mathcal{O}_X$-module $\mathcal{F}$ (lemma \cite{10.3.25}(ii)). According to corollary \cite{10.3.2}(ii), the natural map $D(\mathcal{F}[x])(x) \to R\text{Hom}_A^*(\mathcal{O}_{X(x)}[\mathcal{M}[x]], K^*(x))$ is an isomorphism in $D^b(\mathcal{O}_{X(x)}-\text{Mod}),$ whence (b). \hfill $\square$

**Corollary 11.3.42.** Let $f : Y \to X$ be a morphism of finite type between affine noetherian schemes, and $\omega^* \in D^b(\mathcal{O}_{X(x)}-\text{Mod})$ a dualizing complex on $X$. Then $f^!\omega^*$ is a dualizing complex on $Y$.

**Proof.** We may factor $f$ as the composition of a closed immersion $g : Y \to Z$ followed by a smooth and affine morphism $h : Z \to X$. In light of lemmata \cite{11.3.27}(i) and \cite{11.1.16}(i), it then suffices to check that $h^!\omega^*$ is dualizing on $Z$, so we may assume from start that $f$ is smooth, in which case we are reduced to showing that $f^!\omega^*$ is dualizing on $Y$. Let $y \in Y$ be any point, set $x := f(y)$, and denote by $f_y : Y(y) \to X(x)$ the morphism induced by $f$; taking into account proposition \cite{11.3.37}, we are further reduced to checking that $f_y^!\omega^*_{X(x)}$ is dualizing on $Y(y)$. However, the latter assertion follows easily from proposition \cite{11.3.34} and remark \cite{11.3.32(i)} and \cite{100} Th.28.7. \hfill $\square$

**Corollary 11.3.43.** Let $A$ be a noetherian ring, $x \in X := \text{Spec } A$ any point, and $K^*$ any object of $D^b(\mathcal{O}_X-\text{Mod})_{\text{coh}}$. Suppose that the following holds:
(a) Every irreducible reduced closed subscheme \( Z \subset X \) containing \( x \) admits a dense open subset which is Gorenstein (see definition [11.3.31](i)).

(b) \( K^*(x) \) is dualizing on \( X(x) \).

Then there exists an open neighborhood \( U \) of \( x \) in \( X \), such that \( K^*_U \) is dualizing on \( U \).

**Proof.** We begin with the following:

**Claim** 11.3.44. For every reduced and irreducible closed subscheme \( Z \) of \( X \) containing \( x \), there exists a dense open subset \( U_Z \) of \( Z \) such that \( K^*(z) \) is dualizing on \( X(z) \), for every \( z \in U_Z \).

**Proof of the claim.** Let \( i_Z : Z \to X \) be the closed immersion, and set \( i_{Z(x)} := i_Z \times_X X(x) : Z(x) \to X(x) \); in view of proposition [10.3.3](ii), we easily see that there is a natural isomorphism

\[
i_{Z(x)}^* K^*(x) \cong (i_Z^* K^*)(x) \quad \text{in } D(\mathcal{O}_{Z(x)} \text{-Mod}).
\]

Hence, due to (b) and lemma [11.3.27](i), \( (i_Z^* K^*)(x) \) is dualizing on \( Z(x) \). Denote by \( \eta_Z \) the generic point of \( Z \); it follows that \( (i_Z^* K^*)(\eta_Z) \) is dualizing on \( Z(\eta_Z) \) (proposition [11.3.37]), and therefore it is isomorphic to \( \mathcal{O}_{Z(\eta_Z)}[c] \) in \( D(\mathcal{O}_{Z(\eta_Z)} \text{-Mod}) \), due to (a). On the other hand, claim [11.3.38](i) implies that there exists an open neighborhood \( U_Z \) of \( x \) in \( Z \), such that \( (i_Z^* K^*)(U_Z) \) lies in \( D^b(\mathcal{O}_{U_Z} \text{-Mod})_{\text{coh}} \). It then follows easily that there exists a smaller open subset \( \bar{U}_Z \subset U_Z \) of \( Z \), such that \( (i_Z^* K^*)(\bar{U}_Z) \cong \mathcal{O}_{\bar{U}_Z}[c] \) in \( D(\mathcal{O}_{\bar{U}_Z} \text{-Mod}) \) (details left to the reader). In view of (a), we may then further shrink \( U_Z \) and assume that \( (i_Z^* K^*)(U_Z) \) is dualizing on \( U_Z \). Now, let \( y \in U_Z \) be any point, denote by \( i_1 : \text{Spec } k(y) \to Z(y) \) and \( i_2 : Z(y) \to X(y) \) the closed immersions, and set \( i_y := i_2 \circ i_1 \). By proposition [11.3.37], the complex \( i_y^* K^*(y) \cong (i_Z^* K^*)(y) \) is dualizing on \( Z(y) \), so \( i_y^* K^*(y) \cong (i_Z^* K^*)(y) \) is dualizing on \( X(y) \) (lemma [11.3.27](i)), and consequently \( K^*(y) \) is dualizing on \( X(y) \) (proposition [11.3.28](i)). The claim follows. \( \Box \)

Denote by \( \mathcal{U} \) the set of all reduced and irreducible closed subschemes of \( X \) containing \( x \), and for every \( Z \in \mathcal{U} \), let \( U_Z \) be the largest open subset of \( Z \) such that \( K^*(y) \) is dualizing on \( X(y) \) for every \( y \in U_Z \). The subset \( U := \bigcup_{Z \in \mathcal{U}} U_Z \) is ind-constructible in \( X \), and it is clearly generizing (proposition [11.3.37]). Thus, \( U \) is open in \( X \) ([48, Ch.IV, Th.1.10.1]), and to conclude the proof, it suffices – again, by virtue of proposition [11.3.37] – to check that \( x \in U \).

Suppose that the latter fails, and let \( Z \subset X \) be the closure of \( \{x\} \) in \( X \), endowed with its reduced subscheme structure; by assumption, \( Z \cap U = \emptyset \); on the other hand, \( Z \in \mathcal{U} \), so that \( U \neq \emptyset \), by claim [11.3.44]. The contradiction proves the assertion. \( \Box \)

**Remark** 11.3.45. Let \( A \) be a noetherian ring, and set \( X := \text{Spec } A \).

(i) If \( X \) admits a dualizing complex, then every irreducible reduced closed subscheme \( Z \subset X \) admits a dense open subset \( U \) which is Gorenstein. Indeed, let \( \eta_Z \) be the generic point of \( Z \); we know that \( Z \) admits a dualizing complex \( \omega^*_Z \) (lemma [11.3.27](i)), hence \( \omega^*_Z(\eta_Z) \) is dualizing on \( Z(\eta_Z) \) (proposition [11.3.37]). But then there exists an isomorphism \( \mathcal{O}_{Z(\eta_Z)}[c] \cong \omega^*_Z(\eta_Z) \) in \( D^b(\mathcal{O}_{Z(\eta_Z)} \text{-Mod}) \) for some \( c \in Z \) (proposition [11.3.25]), and any such isomorphism extends to an isomorphism \( \mathcal{O}_Z[c] \cong (\omega^*_Z)_U \) on some open subset \( U \subset Z \); since \( (\omega^*_Z)_U \) is dualizing on \( U \) (lemma [11.3.27](ii)), the assertion follows.

(ii) The observation in (i) shows that the converse of corollary [11.3.43] holds as well: if \( x \in X \) is any point, and \( U \) any open neighborhood of \( x \) in \( X \) such that \( U \) admits a dualizing complex, then conditions (a) and (b) of corollary [11.3.43] hold for \( x \).

(iii) If \( A \) is local and \( X \) admits a dualizing complex, then the formal fibres of \( A \) are Gorenstein, i.e., if we denote \( A^\wedge \) the completion of \( A \) and set \( X^\wedge := \text{Spec } A^\wedge \), then \( X^\wedge \times_X \text{Spec } k(x) \) is a Gorenstein scheme, for every \( x \in X \). Indeed, notice that \( A^\wedge \otimes_A A/p \) is the completion of \( A/p \) for every \( p \in \text{Spec } A \), and \( \text{Spec } A/p \) admits a dualizing complex, if \( X \) does (lemma [11.3.27](i)); hence we may replace \( A \) by its image in \( k(x) \) and assume from start that \( A \) is a local
noetherian domain, and \( x \) the generic point of \( X \). Let \( \omega^\bullet \) be a dualizing complex on \( X \), and \( f : X^\wedge \to X \) the natural morphism; by proposition \([11.3.34]\) the complex \( f^*\omega^\bullet \) is dualizing on \( X^\wedge \). On the other hand, by (i) there exists a non-empty open subset \( U \subset X \) which is Gorenstein, and therefore \( \omega^\bullet_U \cong \bigoplus_i [c]^{\oplus i} \) for some \( c \in \mathbb{Z} \). Due to lemma \([11.3.27]\)(ii), it follows that \( f^{-1}U \) is Gorenstein as well, and then the same holds for \( f^{-1}(x) \), by proposition \([11.3.37]\).

(iv) If \( A \) is local and complete, then \( X \) admits a dualizing complex. Indeed, in this case \( A \) is a quotient of a regular local ring (\([102]\) Th.29.4(iii)), so the assertion follows from lemma \([11.3.27]\)(i) and example \([11.3.18]\).

**Corollary 11.3.46.** Let \( X \) be any noetherian scheme, \( \omega^\bullet \) a dualizing complex on \( X \). We have:

(i) For every \( x \in X \) there exists a unique \( c \in \mathbb{Z} \) such that
\[
J(x) := R^{\text{dim}} \Gamma_{\{x\}} \omega^\bullet_{X(x)} \neq 0.
\]

(ii) For every \( x \in X \), the \( A \)-module \( J(x) \) is the injective hull of the residue field \( \kappa(x) \).

**Proof.** In view of proposition \([11.3.37]\) we may assume that \( X \) is local and \( x \) is its closed point; say that \( X = \text{Spec} \ A \) for some local noetherian ring \( A \), in which case \( \omega^\bullet \) is the \( \theta_X \)-module arising from a bounded complex \( M^\bullet \) of \( A \)-modules of finite type. We notice:

**Claim 11.3.47.** Let \( \mathfrak{m} \subset A \) be the maximal ideal. There exists a unique \( c \in \mathbb{Z} \) such that

(i) \( T^i(N) := R^i \text{Hom}^\bullet_{A}(N, M^\bullet) = 0 \) for every \( A \)-module \( N \) of finite type supported at \( \{x\} \) and every \( i \neq c \).

(ii) The map \( T^c(A/m^n) \to T^c(A/m^{n+1}) \) induced by the projection \( A/m^{n+1} \to A/m^n \) is injective, for every \( n \in \mathbb{N} \).

**Proof of the claim.** (i): By proposition \([11.3.28] \)\( i \), we know already that there exists \( c \in \mathbb{N} \) such that \( T^i(A/m) = 0 \) if and only if \( i \neq c \). We must therefore check that the claim holds for this value of \( c \). Now, let \( N \) be any \( A \)-module of finite type supported at \( \{x\} \); we may find a finite filtration \( N_0 := 0 \subset N_1 \subset \cdots \subset N_k \) consisting of \( A \)-submodules, such that \( N_{j+1}/N_j \cong A/m \) for every \( i = 0, \ldots, k - 1 \). We deduce short exact sequences
\[
T^i(A/m) \to T^i(N_{j+1}) \to T^i(N_j) \quad \text{for every } i \in \mathbb{N} \text{ and every } j = 0, \ldots, k - 1
\]
whence the contention, by a simple induction on \( j \).

(ii) is similar: arguing as in the foregoing, we get an exact sequence
\[
T^{c-1}(A/m^{n+1}/m^n) \to T^c(A/m^n) \to T^c(A/m^{n+1})
\]
whence the assertion. \( \diamond \)

On the other hand, corollary \([10.4.35]\) yields a natural identification:
\[
J(x) \overset{\sim}{\to} \text{colim}_{n \in \mathbb{N}} T^c(A/m^n)
\]
and then assertion (i) follows proposition \([11.3.28] \)\( i \) and claim \([11.3.47]\).

(ii): Claim \([11.3.47]\) also implies that \( T^c \) is an exact functor on the full subcategory of \( \text{A-Mod} \) whose objects are the \( A \)-modules supported at \( \{x\} \). By proposition \([7.11.31] \), remark \([7.11.32] \)\( i, ii \) and \([11.3.48]\) we deduce already that \( J(x) \) is an injective \( A \)-module. Next, let \( \kappa(x) \sim \) the quasi-coherent \( \theta_X \)-module arising from \( \kappa(x) \); we have natural identifications
\[
\text{Hom}_{A}(\kappa(x), J(x))[c] \to R\text{Hom}^\bullet_{\theta_X}(\kappa(x)^\wedge[0], R\text{Hom}_{\theta_X}^\bullet)(\sim \text{by corollary } [10.3.2] \text{)(i)})
\]
\[
\sim R\text{Hom}_{\theta_X}(\kappa(x)^\wedge[0], \omega^\bullet) \quad \text{by lemma } [10.4.13] \text{)(iii)}
\]
\[
\sim R\text{Hom}_{\theta_X}(\kappa(x)[0], M^\bullet) \quad \text{as Supp } \kappa(x) = \{x\}
\]
\[
\sim \kappa(x)[c] \quad \text{by corollary } [10.3.2] \text{)(i)}
\]
\[
\sim \kappa(x)[c] \quad \text{by proposition } [11.3.28] \text{)(i)}.
\]
Then the assertion follows immediately from theorem 7.11.22.

11.3.49. Let $X$ be a noetherian scheme that admits a dualizing complex $\omega^\bullet$. According to corollary 11.3.46 we get a well defined function

$$c_X : |X| \to \mathbb{Z}$$

by assigning to each $x \in X$ the unique $c_X(x) \in \mathbb{Z}$ such that $R^{e_X(x)}\Gamma_{\{x\}}(\omega^\bullet_{|X(x)})$ does not vanish. With this notation, we may state:

Lemma 11.3.50. In the situation of (11.3.49), let $x, y \in X$ be any two points, such that $x$ is an immediate specialization of $y$. Then

$$c_X(x) = c_X(y) + 1.$$

Proof. By proposition 11.3.37 we may replace $X$ by $X(x)$, and $\omega$ by $\omega_{|X(x)}$, and assume from start that $X$ is local, and $x$ is its closed point. Let $Z \subset X$ be the topological closure of $\{y\}$, endowed with its reduced closed subscheme structure. If we denote $i : Z \to X$ the corresponding closed immersion, then $i^! \omega$ is dualizing on $Z$ (lemma 11.3.27(i)). Fix $z \in Z$, let $i_z : Z(z) \to X(z)$ be the induced closed immersion, and set $c := c_X(z)$; we get natural isomorphisms:

$$R\Gamma_{\{z\}}(i_z^! \omega^\bullet)|_{\{z\}} \cong R\Gamma_{\{z\}} \circ R\mathcal{H}om_{\mathcal{O}_{X(z)}}(i_{z,*} \mathcal{O}_{Z(y)}, \omega^\bullet_{|X(z)}) \quad \text{(by proposition 10.3.3(ii))}$$

$$\cong R\mathcal{H}om_{\mathcal{O}_{X(z)}}(i_{z,*} \mathcal{O}_{Z(y)}, R\Gamma_{\{z\}} \omega^\bullet_{|X(z)}) \quad \text{(by lemma 10.4.13(iii))}$$

$$\cong \mathcal{H}om_{\mathcal{O}_{X(z)}}(i_{z,*} \mathcal{O}_{Z(y)}, R\Gamma_{\{z\}} \omega^\bullet_{|X(z)})[-c] \quad \text{(by corollary 11.3.46)}$$

which shows that

$$c_Z(z) = c_X(z)$$

provided $c_Z$ is defined via $i_z^! \omega^\bullet$. Hence, we may replace $X$ by $Z$, and assume additionally that $X = \text{Spec} A$, where $A$ is a one-dimensional local noetherian domain, and $y$ is the generic point of $X$. In this case, $\omega^\bullet$ is the complex of $\mathcal{O}_X$-module arising from a bounded complex $M^\bullet$ of $A$-modules of finite type, and clearly

$$R^{e_X(y)}\Gamma_{\{y\}}(\omega^\bullet_{|X(y)}) \cong H^{e_X(y)}(\omega_y^\bullet) \cong H^{e_X(y)}(M^\bullet) \otimes_A K$$

where $K$ is the field of fractions of $A$. To compute $c_X(x)$, we apply proposition 10.4.32(iii); to this aim, let $f$ be any non-zero element of the maximal ideal of $A$; we get

$$R^i\Gamma_{\{x\}} \omega^\bullet \cong \colim_{n \in \mathbb{N}} H^i(f^n, M^\bullet) \quad \text{for every $i \in \mathbb{Z}$}$$

(notation of remark 7.8.1(iii)). By inspecting the definitions, we find a ladder with exact rows

$$\begin{array}{ccc}
H^i M^\bullet & \xrightarrow{f} & H^i M^\bullet \\
\| & & \| \\
H^{i+1} f_n & & H^{i+1} f_n
\end{array}$$

for every $i \in \mathbb{Z}$ and $n \in \mathbb{N}$

whence – after taking colimits – an exact sequence

$$H^i M^\bullet \xrightarrow{\alpha_i} (H^i M^\bullet) \otimes_A K \xrightarrow{\beta_i} R^{i+1} \Gamma_{\{x\}} M^\bullet \quad \text{for every $i \in \mathbb{Z}$}$$

where $\alpha_i$ is induced by the inclusion map $A \to K$. However, if $(H^i M^\bullet) \otimes_A K \neq 0$, clearly $\alpha_i$ cannot be surjective, so $\text{Im} \beta_i \neq 0$, and the lemma follows. □
Example 11.3.51. Let $K$ be any field, and $A$ a $K$-algebra of finite type. Set $S := \text{Spec} K$, $X := \text{Spec} A$, and denote by $f : X \to S$ the structure morphism. Since $\mathcal{O}_S[0]$ is dualizing on $S$, the complex $\omega^\bullet := f^! \mathcal{O}_S[0]$ is dualizing on $X$ (corollary 11.3.42). In this case, the function $c_X$ associated with $\omega_X$ as in (11.3.49) can be determined explicitly as follows. First, we may find a closed immersion $i : X \to \mathbb{A}^n_X := \mathbb{A}^n_S$ for some $n$, and if $p : Y \to S$ is the structure morphism, the proof of lemma 11.3.50 shows that $c_X = c_Y \circ i$, where $c_Y$ is the function of the same type associated with $g^! \mathcal{O}_S[0]$. Hence, we may assume that $X = \mathbb{A}^n_S$, in which case $\omega^\bullet \simeq \mathcal{O}_X[n]$. Then $X$ is regular ([100, Th.28.7]), so for every $x \in X$ we may compute:

$$c_X(x) = \text{depth}_{\{x\}} \mathcal{O}_X(x) - n = n - \text{tr. deg}(\kappa(x)/K) - n = -\text{tr. deg}(\kappa(x)/K).$$

Theorem 11.3.52. Let $A$ be a noetherian ring, and suppose that $X := \text{Spec} A$ admits a dualizing complex. Then $A$ is universally catenary.

Proof. In light of corollary 11.3.42, it suffices to show that $A$ is catenary. But this follows easily from lemma 11.3.50 (details left to the reader).

11.3.53. In the situation of (11.3.49), lemma 11.3.50 shows that $c_X$ is a weak codimension function, with the terminology of (11.2.19). Then corollary 11.3.46(i) means precisely that $\omega^\bullet$ is a $c_X$-Cohen-Macaulay complex of $\mathcal{O}_X$-modules on $X$ (see definition 11.2.24(ii)). By theorem 11.2.27, we then find a Cousin complex of $\mathcal{O}_X$-modules $\mathcal{R}_\omega^\bullet$, unique up to isomorphism of complexes, such that $\omega^\bullet$ is isomorphic to $\mathcal{R}_\omega^\bullet$ in $D^+(\mathcal{O}_X\text{-Mod})$. We call $\mathcal{R}_\omega^\bullet$ the residual complex arising from $\omega^\bullet$. By corollary 11.3.46(ii) we see that

$$\mathcal{R}_\omega^0 = \bigoplus_{c_X(x) = p} E(x)^\sim$$

for every $p \in \mathbb{Z}$, where $E(x)$ is an injective hull of the $A$-module $\kappa(x)$, for every $x \in X$ (notation of (10.3)).

11.3.54. For every coherent scheme $X$, consider the category

$$\text{Dual}_X$$

whose objects are the pairs $(U, \omega_U^\bullet)$, where $U \subset X$ is an open subset, and $\omega_U^\bullet$ is a dualizing complex on $X$. The morphisms $(U, \omega_U^\bullet) \to (U', \omega_U'^\bullet)$ are the pairs $(j, \beta)$, where $j : U \to U'$ is an inclusion map of open subsets of $X$, and $\beta : j^! \omega_U'^\bullet \simeq \omega_U^\bullet$ is an isomorphism in $D^b(\mathcal{O}_U\text{-Mod})$. Let $X_{\text{zar}}$ denote the full subcategory of $\text{Sch}/X$ whose objects are the (Zariski) open subsets of $X$; it follows easily from lemma 11.3.27(ii), that the forgetful functor

$$\text{Dual}_X : X_{\text{zar}} \to (U, \omega_U^\bullet) \mapsto U$$

is a fibration (see definition 3.1.2(ii)) With this notation, we have:

Proposition 11.3.56. Every descent datum for the fibration (11.3.55) is effective.

Proof. Let $((U_i, \omega_{U_i}^\bullet); \beta_{ij} \mid i, j = 1, \ldots, n)$ be a descent datum for the fibration (11.3.55); this means that each $(U_i, \omega_{U_i}^\bullet)$ is an object of $\text{Dual}_X$, and if let $U_{ij} := U_i \cap U_j$ for every $i, j \leq n$, then

$$\beta_{ij} : \omega_{U_{ij}}^\bullet \simeq \omega_{U_{ij}}^\bullet$$

are isomorphisms in $D^b(\mathcal{O}_{U_{ij}}\text{-Mod})$, fulfilling a suitable cocycle condition (see (3.4.22)).

We shall show, by induction on $k = 1, \ldots, n$, that there exists a dualizing complex $\omega_{X_k}$ on $X_k := U_1 \cup \cdots \cup U_k$, such that the descent datum $((U_i, \omega_{U_i}^\bullet); \beta_{ij} \mid i, j = 1, \ldots, k)$ is isomorphic to the descent datum relative to the family $(U_i \mid i = 1, \ldots, k)$ determined by $(X_k, \omega_{X_k}^\bullet)$.

For $k = 1$, there is nothing to prove. Next, suppose that $k > 1$, and $\omega_{X_{k-1}}^\bullet$ with the sought properties has already been constructed. If $k - 1 = n$, we are done; otherwise, let $V_k := X_k \cap U_{k+1}$, set $U_k := (U_{i,k+1} \mid i = 1, \ldots, k)$, and $C^\bullet := R\mathcal{H}om_{\mathcal{O}_{U_k}}(\omega_{X_k}|_{V_k}, \omega_{U_{k+1}}^\bullet|_{V_k})$. The
system of morphisms \((\beta_{i,k+1} \mid i = 1, \ldots, k)\) determines a class \(c_k\) in the Čech cohomology group \(H^0(\Omega_k, C^\bullet)\). However, we have a spectral sequence (see lemma [10.3.15]):

\[
E_2^{pq} := H^p(\Omega_k, H^q C^\bullet) \Rightarrow H^{p+q}R\text{Hom}^\bullet \left( \omega^\bullet_{X_k|V_k}, \omega^\bullet_{k+1|V_k} \right).
\]

**Claim 11.3.57.** \(E_2^{pq} = 0\) for every \(q < 0\).

**Proof of the claim.** More precisely, we check that \(H^q C^\bullet = 0\) for every \(q < 0\). Indeed, by lemma [11.3.27](ii), that both \(\omega^\bullet_{X_k|V_k}\) and \(\omega^\bullet_{k+1|V_k}\) are dualizing on \(V_k\). Moreover, on \(U_{i,k+1}\) they restrict to isomorphic objects of \(D^b(\mathcal{O}_{U_{i,k+1}}\text{-Mod})\), for every \(i = 1, \ldots, k\). It follows easily from proposition [11.3.25] that there exists an invertible \(\mathcal{O}_{V_k}\text{-module} \mathcal{L}\) and an isomorphism

\[
\omega^\bullet_{X_k|V_k} \sim \omega^\bullet_{k+1|V_k} \otimes_{\mathcal{O}_{V_k}} \mathcal{L} \quad \text{in } D^b(\mathcal{O}_{V_k}\text{-Mod}).
\]

Therefore, the biduality map induces an isomorphism

\[
R\text{Hom}^\bullet \left( \omega^\bullet_{X_k|V_k}, \omega^\bullet_{k+1|V_k} \right) \sim \mathcal{L}[0]
\]

whence the claim. \(\diamond\)

Claim [11.3.57] implies that \(c_k\) corresponds to an element of \(H^0R\text{Hom}^\bullet \left( \omega^\bullet_{X_k|V_k}, \omega^\bullet_{k+1|V_k} \right)\), and by construction, it is clear that this global section is an isomorphism \(c_k : \omega^\bullet_{X_k|V_k} \sim \omega^\bullet_{k+1|V_k}\) in \(D^b(\mathcal{O}_{V_k}\text{-Mod})\). By definition, \(c_k\) is represented by a diagram of quasi-isomorphisms:

\[
\omega^\bullet_{X_k|V_k} \leftarrow T^\bullet \rightarrow \omega^\bullet_{k+1|V_k} \quad \text{in } \mathcal{C}(\mathcal{O}_{V_k}\text{-Mod})
\]

for some complex \(T^\bullet\). Let \(T_i\) be the \(\mathcal{O}_{X_{k+1}}\text{-module} obtained as extension by zero of \(T\), and define likewise \((\omega^\bullet_{X_k})!\); and \((\omega^\bullet_{k+1})!\). We let \(\omega^\bullet_{X_{k+1}}\) be the cone of the map of complexes

\[
T_i \rightarrow (\omega^\bullet_{X_k})! \oplus (\omega^\bullet_{k+1})!
\]

deduced from \([11.3.58]\). An easy inspection shows that this complex is dualizing on \(X_{k+1}\), and it fulfills the stated condition. \(\square\)

**Remark 11.3.59.** The proof of proposition [11.3.56] is a special case of a general technique for “glueing perverse sheaves” developed in [15].

In the study of duality for derived categories of modules, the role of reflexive modules is taken by the more general class of Cohen-Macaulay modules. There is a version of this theory for noetherian regular schemes, and a relative variant, for smooth morphisms. Let us begin by recalling the following:

**Definition 11.3.60.** Let \((A, \mathfrak{m}_A)\) be a local ring, \(M\) an \(A\)-module.

(i) Let \(\mathcal{M}\) be the set of all finitely generated \(A\)-submodules \(M\). The **dimension** of \(M\) is

\[
\text{dim}_A M := \sup(\text{dim Supp } M' \mid M' \in \mathcal{M}).
\]

(ii) Suppose that the open subset \(\text{Spec } A \setminus \{ \mathfrak{m}_A \}\) is quasi-compact, and \(\text{depth}_A M < +\infty\). If \(\text{dim}_A M = \text{depth}_A M\), we say that \(M\) is a **Cohen-Macaulay** \(A\)-module. The category \(A\text{-CM}\)

is the full subcategory of \(A\text{-Mod}\) consisting of all finitely presented Cohen-Macaulay \(A\)-modules. For every \(n \in \mathbb{N}\), we let \(A\text{-CM}_n\) be the full subcategory of \(A\text{-CM}\) whose objects are the Cohen-Macaulay \(A\)-modules of dimension \(n\).

(iii) If \(A\) is a Cohen-Macaulay \(A\)-module, we say that \(A\) is a **Cohen-Macaulay** local ring.

(iv) Let \(X\) be a scheme, \(\mathcal{F}\) a quasi-coherent \(\mathcal{O}_X\text{-module. We say that } \mathcal{F}\text{ is a Cohen-Macaulay } \mathcal{O}_X\text{-module, if } \mathcal{F}_x\text{ is a Cohen-Macaulay } \mathcal{O}_{X,x}\text{-module, for every } x \in X.\) We say that \(X\) is a **Cohen-Macaulay** scheme, if \(\mathcal{O}_X\) is a Cohen-Macaulay \(\mathcal{O}_X\text{-module.**}
of $\varphi$-Cohen-Macaulay modules is the full subcategory of $B$-Mod whose objects are all the finitely presented $B$-modules $N$ that are $\varphi$-flat, and such that $N/m_A N$ is a Cohen-Macaulay $B$-module. For every $n \in \mathbb{N}$, we let $\varphi$-CM$_n$ be the full subcategory of $\varphi$-CM whose objects are the $\varphi$-Cohen-Macaulay modules $N$ with $\dim_B N/m_A N = n$.

(vi) Let $f : X \to Y$ be a locally finitely presented morphism of schemes, $\mathcal{F}$ a quasi-coherent $\mathcal{O}_X$-module, $x \in X$ any point, and set $y := f(x)$. We say that $\mathcal{F}$ is $f$-Cohen-Macaulay at the point $x$, if $\mathcal{F}_x$ is a $f^2$-Cohen-Macaulay module. We say that $f$ is Cohen-Macaulay at the point $x$, if $\mathcal{F}_X$ is $f$-Cohen-Macaulay at the point $x$ (cp. [49 Ch.IV, Déf.6.8.1]).

(vii) Let $f$ and $\mathcal{F}$ be as in (vi). We say that $\mathcal{F}$ is $f$-Cohen-Macaulay (resp. that $f$ is Cohen-Macaulay) if $\mathcal{F}$ (resp. $\mathcal{O}_X$) is $f$-Cohen-Macaulay at every point $x \in X$.

(viii) Let $f$ and $\mathcal{F}$ be as in (vi). The $f$-Cohen-Macaulay locus of $\mathcal{F}$ is the subset $CM(f, \mathcal{F}) \subset X$ consisting of all $x \in X$ such that $f$ is Cohen-Macaulay at $x$. The subset $CM(f, \mathcal{O}_X)$ is also called the Cohen-Macaulay locus of $f$ and is denoted briefly $CM(f)$.

**Remark 11.3.61.** Let $(A, m_A)$ be any local ring; set $X := \text{Spec} A$, and for every $A$-module $M$, let $M^\sim$ be the quasi-coherent $\mathcal{O}_X$-module arising from $M$. Then, with the notation of theorem \[10.1.35\](i), we have

$$\dim_A M = d_{M^\sim} \quad \text{for every } A\text{-module } M.$$ 

For the proof, let $\mathcal{M}$ be the set of all finitely generated $A$-submodules of $M$. Clearly $d_{M^\sim} = \sup(d_{M^\sim} \mid M' \in \mathcal{M})$, so we are reduced to the case where $M$ is finitely generated. Then $\text{Supp } M$ is a closed subset of $X$, and $\dim_A M = \dim(\text{Supp } M)$; moreover, clearly $\text{Supp } M = \text{Supp } M^\sim$, and the assertion follows easily.

**Lemma 11.3.62.** Let $f : X \to Y$ be a locally finitely presented morphism of schemes, and $\mathcal{F}$ a finitely presented $\mathcal{O}_X$-module such that $\text{Supp } \mathcal{F} = X$. We have:

(i) $CM(f, \mathcal{F})$ is an open subset of $X$,

(ii) The restriction $CM(f) \to Y$ of $f$ is locally equidimensional.

(iii) Let $g : X' \to X$ be another morphism of schemes, $x' \in X'$ a point such that $g$ is étale at $x'$. Then $g(x') \in CM(f, \mathcal{F})$ if and only if $x' \in CM(f \circ g, g^* \mathcal{F})$.

(iv) If $x \in CM(f)$, then $\delta'(x, \mathcal{O}_X) = \delta'(f(x), \mathcal{O}_Y) + \dim \mathcal{O}_{f^{-1}(x),x}$ (notation of \[10.4.19\]).

**Proof.** (i) and (ii) follow easily from [50 Ch.IV, Prop.15.4.3] and [49 Ch.IV, Prop.2.3.4].

(iii) follows from corollary \[10.4.37\]. Lastly, (iv) is an immediate consequence of corollary \[10.4.47\].

**Remark 11.3.63.** (i) The terminology “locally equidimensional” follows [51 ErrIV,35], which modifies the terminology “equidimensional” of [50 Ch.IV, Déf.13.3.2]. Hence, a morphism of schemes $f : X \to Y$ locally of finite type is locally equidimensional, if it verifies the equivalent conditions of [50 Ch.IV, Prop.13.3.1] at every point $x \in X$. However, the caveat here is that the said conditions are not quite equivalent as stated: they become equivalent if one omits the words “contenant $y$” in line 2 of loc.cit. (with unchanged proof). So, the correct definition of “locally equidimensional” is in terms of the cited proposition thus amended.

(ii) A counterexample to [50 Ch.IV, Prop.13.3.1] is given by the identity morphism $X \to X$ of a scheme $X$ with a point $x$ such that the union of the irreducible components of $X$ passing through $x$ does not contain an open neighborhood of $x$ in $X$ (e.g. take $X$ whose underlying topological space is zero-dimensional and not discrete); then $1_X$ satisfies condition b) of [50 Ch.IV, Prop.13.3.1], but does not satisfy conditions a),a') and a'').
Proposition 11.3.64. Let $A$ be a regular local ring of dimension $d$, and $M$ a finitely generated Cohen-Macaulay $A$-module. Then:

(i) $\text{Ext}^i_A(M, A) = 0$ for every $i \neq c := d - \dim M$.
(ii) The $A$-module $\mathcal{D}(M) := \text{Ext}^c_A(M, A)$ is Cohen-Macaulay.
(iii) The natural map $M \to \text{Ext}^c(\mathcal{D}(M), A)$ is an isomorphism, and $\text{Supp} \mathcal{D}(M) = \text{Supp} M$.
(iv) For every $n \in \mathbb{N}$, we have an equivalence of categories:

$\mathcal{D} : A\text{-CM}_n \to A\text{-CM}^e_n \quad N \mapsto \text{Ext}^{d-n}(N, A)$.

Proof. (i): According to [48 Ch.0, Prop.17.3.4], the projective dimension of $M$ equals $c$, so we may find a minimal free resolution $0 \to L_c \to \cdots \to L_1 \to L_0 \to M$ for $M$ of length $c$. Hence, we need only prove the sought vanishing for every $i < c$. Set $X := \text{Spec } A$, $Z := \text{Supp } M \subset X$. By virtue of proposition 10.4.25, it suffices to show that $\text{depth}_Z \mathscr{O}_X \geq c$.

In light of (10.4.30), this comes down to showing that $\mathscr{O}_{X,z}$ is a regular local ring of depth $\geq c$, for every $z \in Z$. The latter holds, since $\mathscr{O}_{X,z}$ is a regular local ring of dimension $\geq c$ (48 Ch.0, Cor.16.5.12).

(ii): From (i) we deduce that $L^\vee_\bullet := (L^\vee_n \to \cdots \to L^\vee_0)$, together with its natural augmentation $L^\vee_0 \to \mathcal{D}(M)$, is a free resolution of $\mathcal{D}(M)$; especially, the projective dimension of $\mathcal{D}(M)$ is $\leq c$, and therefore

$\text{depth}_A \mathcal{D}(M) \geq \dim M$

again by [48 Ch.0, Prop.17.3.4]. On the other hand, it follows easily from [125 Prop.3.3.10] that $\text{Supp} \mathcal{D}(M) \subset \text{Supp } M$, so $\mathcal{D}(M)$ is Cohen-Macaulay.

(iii): From the proof of (ii) we see that $R\text{Hom}_A(\mathcal{D}(M), A)$ is computed by the complex $L^\vee_\bullet = L^\bullet$, whence the first assertion. Invoking again [125 Prop.3.3.10], we deduce that $\text{Supp } M \subset \text{Supp } \mathcal{D}(M)$; since the converse inclusion is already known, these two supports coincide.

(iv) follows straightforwardly from (ii) and (iii).

□

Corollary 11.3.65. Let $X$ be a regular noetherian scheme, and $j : Y \to X$ a closed immersion. We have:

(i) $Y$ admits a dualizing complex $\omega^\bullet_Y$.
(ii) If $Y$ is a Cohen-Macaulay scheme, then we may find a dualizing complex $\omega^\bullet_Y$ that is concentrated in degree 0. Moreover, $H^0(\omega^\bullet_Y)$ is a Cohen-Macaulay $\mathscr{O}_Y$-module.

Proof. Indeed, lemma 11.3.27(i) shows that the complex $\omega^\bullet_Y := j^! \mathscr{H}\text{om}_{\mathscr{O}_Y}(j_* \mathscr{O}_Y, \mathscr{O}_X)$ will do. According to proposition 11.3.64(i,ii), this complex fulfills the condition of (ii), up to a suitable shift.

□

11.3.66. Let $f : X \to S$ be a smooth quasi-compact morphism of schemes, $\mathscr{F}$ a finitely presented quasi-coherent $\mathscr{O}_S$-module, $x \in X$ any point, and $s := f(x)$. Set

$A := \mathscr{O}_{S,s} \quad B := \mathscr{O}_{X,x} \quad F := \mathscr{F}_x \quad B_0 := B \otimes_A \kappa(s) \quad F_0 := F \otimes_A \kappa(s)$.

Theorem 11.3.67. In the situation of (11.3.66), suppose that $F$ is an $f^\ast_x$-Cohen-Macaulay module. Then we may find an open neighborhood $U \subset X$ of $x$ in $X$ such that the following holds:

(i) There exists a finite resolution of the $\mathscr{O}_U$-module $\mathscr{F}|_U$, of length $n := \dim B_0 - \dim B F_0$

$\Sigma^\bullet : 0 \to \mathcal{L}_n \to \mathcal{L}_{n-1} \to \cdots \to \mathcal{L}_0 \to \mathscr{F}_U \to 0$

consisting of free $\mathscr{O}_U$-modules of finite rank. Moreover, $\Sigma^\bullet$ is universally $\mathscr{O}_S$-exact, i.e.

for every coherent $\mathscr{O}_S$-module $\mathscr{G}$, the complex $\Sigma^\bullet \otimes_{\mathscr{O}_S} f^\ast \mathscr{G}$ is still exact.

(ii) The complex $K^\bullet := R\mathscr{H}\text{om}_{\mathscr{O}_U}(\mathscr{F}|_U, \mathscr{O}_U)$ is concentrated in degree $n$.

(iii) The natural map $\mathscr{F}|_U \to R\mathscr{H}\text{om}_{\mathscr{O}_U}(K^\bullet, \mathscr{O}_U)$ is an isomorphism in $\text{D}(\mathscr{O}_U\text{-Mod})$. 

11.3.69. Keep the notation of (11.3.66), and let $\varphi := f^*_2 : A \to B$. Theorem [11.3.67](iii,iv) implies that, for every $n \in \mathbb{N}$, the functor

$$\mathcal{D}_\varphi : \varphi_\ast \text{-CM}_n \to \varphi_\ast \text{-CM}_{n}^\circ \quad M \mapsto \text{Ext}^\ast_{B_0^{-n}}(M)$$

is an equivalence, and the natural map $M \to \mathcal{D}_\varphi(M)$ is an isomorphism, for every $\varphi_\ast$-Cohen-Macaulay module $M$. We shall see later also a relative variant of corollary [11.3.65] in a more special situation (see proposition [11.3.5]).
11.4. Schemes over a valuation ring. Throughout this section, \((K, \| \cdot \|)\) is a valued field, whose valuation ring (resp. maximal ideal, resp. residue field, resp. value group) shall be denoted \(K^+\) (resp. \(m_K\), resp. \(k\), resp. \(\Gamma\)). Also, we let

\[ S := \text{Spec} K^+ \quad \text{and} \quad S/b := \text{Spec} K^+/bK^+ \quad \text{for every } b \in m_K \]

(so \(S/\eta = S\)) and we denote by \(s := \text{Spec} k\) (resp. by \(\eta := \text{Spec} K\)) the closed (resp. generic) point of \(S\). More generally, for every \(S\)-scheme \(X\) we let as well

\[ X/b := X \times_S S/b \quad \text{for every } b \in m_K. \]

A basic fact, that follows immediately from corollary \(11.3.7\) is that every finitely presented \(S\)-scheme is coherent (this can also be deduced easily from [62 Part I, Th.3.4.6]).

**Proposition 11.4.1.** Let \(f : X \to S\) be a flat and finitely presented morphism, \(\mathcal{F}\) a coherent \(\mathcal{O}_X\)-module, \(x \in X\) any point, \(y := f(x)\), and suppose that \(f^{-1}(y)\) is a regular scheme (this holds e.g. if \(f\) is a smooth morphism). Let also \(n := \dim \mathcal{O}_{f^{-1}(y),x}\). Then:

(i) \(\text{proj.dim}_{\mathcal{O}_{X,x}} \mathcal{F}_x \leq n + 1\) (here we set \(\text{proj.dim}_{\mathcal{O}_{X,x}} 0 := 0\)).

(ii) If \(\mathcal{F}\) is \(f\)-flat at the point \(x\), then \(\text{proj.dim}_{\mathcal{O}_{X,x}} \mathcal{F}_x \leq n\).

(iii) If \(\mathcal{F}\) is reflexive at the point \(x\), then \(\text{proj.dim}_{\mathcal{O}_{X,x}} \mathcal{F}_x \leq \max(0, n - 1)\).

(iv) If \(f\) has regular fibres, and \(\mathcal{F}\) is reflexive and generically invertible (see \(11.3.10\)), then \(\mathcal{F}\) is invertible.

(v) All the fibres of the induced morphism \(f_x : X(x) \to S(y)\) are regular and irreducible.

**Proof.** To start out, we may assume that \(X\) is affine, and then it follows easily from lemma \(11.3.7\) that \(\mathcal{O}_X\) is coherent.

(ii): Since \(\mathcal{O}_X\) is coherent, we can find a possibly infinite resolution

\[ 
\cdots \to E_2 \to E_1 \to E_0 \to \mathcal{F}_x \to 0 
\]

by free \(\mathcal{O}_{X,x}\)-modules \(E_i\) \((i \in \mathbb{N})\) of finite rank; set \(E_{-1} := \mathcal{F}_x\) and \(L := \text{Im}(E_n \to E_{n-1})\).

It suffices to show that the \(\mathcal{O}_{X,x}\)-module \(L\) is free. For every \(\mathcal{O}_{X,x}\)-module \(M\) we shall let \(M(y) := M \otimes_{\mathcal{O}_{X,x}} \mathcal{O}_{f^{-1}(y),x}\). Since \(L\) and \(\mathcal{F}_x\) are torsion-free, hence flat \(K^+\)-modules, the induced sequence of \(\mathcal{O}_{f^{-1}(y),x}\)-modules:

\[ 0 \to L(y) \to E_{n-1}(y) \to \cdots E_1(y) \to E_0(y) \to \mathcal{F}_x(y) \to 0 \]

is exact; since \(f^{-1}(y)\) is a regular scheme, \(L(y)\) is a free \(\mathcal{O}_{f^{-1}(y),x}\)-module of finite rank. Since \(L\) is also flat as a \(K^+\)-module, [50 Ch.IV, Prop.11.3.7] and Nakayama’s lemma show that any set of elements of \(L\) lifting a basis of \(L(y)\), is a free basis of \(L\).

(i): Locally on \(X\) we can find an epimorphism \(\mathcal{O}_X^{\mathbb{N}} \to \mathcal{F}\), whose kernel \(\mathcal{G}\) is again a coherent \(\mathcal{O}_X\)-module, since \(\mathcal{O}_X\) is coherent. Clearly it suffices to show that \(\mathcal{G}\) admits, locally on \(X\), a finite free resolution of length \(\leq n\), which holds by (ii), since \(\mathcal{G}\) is \(f\)-flat.

(iii): Suppose \(\mathcal{F}\) is reflexive at \(x\); by remark \(11.3.5\) we can find a left exact sequence

\[ 0 \to \mathcal{F}_x \to \mathcal{O}_{X,x}^{\mathbb{N}} \to \mathcal{O}_{X,x}. \]

It follows that \(\text{proj.dim}_{\mathcal{O}_{X,x}} \mathcal{F}_x = \max(0, \text{proj.dim}_{\mathcal{O}_{X,x}}(\text{Coker } \alpha) - 2) \leq \max(0, n - 1)\), by (i).

(iv): Suppose that \(\mathcal{F}\) is generically invertible, let \(j : U \to X\) be the maximal open immersion such that \(j^* \mathcal{F}\) is an invertible \(\mathcal{O}_U\)-module, and set \(Z := X \setminus U\). Under the current assumptions, \(X\) is reduced; it follows easily that \(U\) is the set where \(\text{rk } \mathcal{F} = 1\), and that \(j\) is quasi-compact (since the rank function is constructible: see \(11.3.10\)). It follows from (iii) that \(Z \cap f^{-1}(y)\) has codimension \(\geq 2\) in \(f^{-1}(y)\), for every \(y \in S\). Hence the conditions of corollary \(11.3.9\) are fulfilled, and furthermore \(\mathcal{F}[0]\) is a perfect complex by (ii), so the invertible \(\mathcal{O}_X\)-module \(\det \mathcal{F}\) is well defined (lemma \(11.3.14\)). Then (iv) follows from the natural isomorphisms:

\[ \mathcal{F} \xrightarrow{j_*j^*} \mathcal{F} \xrightarrow{j_* \text{det}(j^* \mathcal{F}[0])} j_*j^* \text{det} \mathcal{F}[0] \xrightarrow{j_*j^*} \text{det} \mathcal{F}[0]. \]
(v): Let \( y' \in S(y) \) be any point; we need to check that \( f_x^{-1}(y') \) is an irreducible regular scheme, and after replacing \( K^+ \) by a quotient, we may assume that \( y' \) is the generic point of \( S \); after further replacing \( K^+ \) by a localization, we may also assume that \( y \) is the closed point of \( S \). Set \( A := \mathcal{O}_{X,x} \); by assumption, \( f_x^{-1}(y) \) is a regular scheme, hence \( p := m_K A \) is a prime ideal of \( A \), so that \( A_p \) is a valuation ring (proposition \( \text{[1,32]}(ii) \)), and especially, it is a domain. Moreover, \( \text{[50, Ch.IV, Prop.11.3.7]} \) implies that for every \( h \in A \setminus p \), scalar multiplication by \( h \) is injective on \( A \); thus, the localization map \( A \to A_p \) is injective as well, so \( A \) is a domain. This already proves that \( f_x^{-1}(y') = \text{Spec} K \otimes_{K^+} A \) is irreducible. Next, let \( q \subset A \) be any prime ideal with \( q \cap K^+ = \{0\} \), and \( M \) any \( A_q \)-module of finite type; pick a finitely presented \( A \)-module \( N \) with an isomorphism \( N_q \to M \). By (i), there exists a finite resolution \( L_q \) of \( N \), consisting of free \( A \)-modules of finite rank; then \( A_q \otimes_A L_q \) is a finite resolution of \( M \) by free \( A_q \)-modules of finite rank. By Serre’s theorem \( \text{[100, Th.19.2]} \), this shows that \( A_q \) is regular, as required. \( \square \)

**Proposition 11.4.2.** Let \( X \) be a quasi-compact and quasi-separated scheme, \( n > 0 \) an integer, and denote by \( \pi: \mathbb{P}_X^n \to X \) the natural projection. Then the map

\[
H^0(X, \mathbb{Z}) \otimes \text{Pic } X \to \text{Pic } \mathbb{P}_X^n \quad (r, \mathcal{L}) \mapsto \mathcal{O}_X^n(r) \otimes \pi^* \mathcal{L}
\]

is an isomorphism of abelian groups.

**Proof.** To begin with, let us recall the following well known:

**Claim 11.4.3.** Let \( f: Y \to T \) be a proper morphism of noetherian schemes, \( \mathcal{F} \) a coherent \( f \)-flat \( \mathcal{O}_Y \)-module, \( t \in T \) a point, \( p \in \mathbb{N} \) an integer, and denote \( i_t: f^{-1}(t) \to Y \) the natural immersion. Suppose that \( H^{p+1}(f^{-1}(t), i_t^* \mathcal{F}) = 0 \). Then the natural map

\[
(R^p f_* \mathcal{F})_t \to H^p(f^{-1}(t), i_t^* \mathcal{F})
\]

is surjective.

**Proof of the claim.** In light of \( \text{[46, Ch.III, Prop.1.4.15]} \), we easily reduce to the case where \( T \) is a local scheme, say \( T = \text{Spec} A \) for some noetherian local ring \( A \), and \( t \) is the closed point of \( T \). Set \( k := \kappa(t) \), and for every \( q \in \mathbb{N} \), consider the functor

\[
F_{-q}: \text{A-Mod} \to \text{A-Mod} \quad M \mapsto H^0(T, R^p f_* (f^* M^\sim \otimes_{\mathcal{O}_Y} \mathcal{F}))
\]

(note of \( \text{[10.3]} \)). Since \( \mathcal{F} \) is \( f \)-flat, the system \( (F_{-q} | q \in \mathbb{N}) \) defines a homological functor. The assertion is that \( F_{-p-1}(k) = 0 \), in which case \( \text{[47, Ch.III, Cor.7.5.3]} \) (together with \( \text{[46, Ch.III, Th.3.2.1 and Th.4.1.5]} \)) says that \( F_{-p-1}(M) = 0 \) for every \( A \)-module \( M \). Hence, \( F_{-p-1} \) is trivially an exact functor, and it follows that the natural map \( F_{-p}(A) \to F_{-p}(k) \) is surjective \((\text{[47, Ch.III, Prop.7.5.4]} \), which is the claim. \( \diamond \)

Now, the injectivity of the stated map is clear (details left to the reader). For the surjectivity, let \( \mathcal{G} \) be an invertible \( \mathcal{O}_{\mathbb{P}_X^n} \)-module, write \( X \) as the limit of a filtered system \( (X_\lambda | \lambda \in \Lambda) \) of noetherian schemes, and for every \( \lambda \in \Lambda \), let \( p_\lambda: \mathbb{P}_X^n \to \mathbb{P}_{X_\lambda}^n \) be the induced morphism; for some \( \lambda \in \Lambda \), we may find an invertible \( \mathcal{O}_{\mathbb{P}_{X_\lambda}^n} \)-module \( \mathcal{F}_\lambda \), with an isomorphism \( \mathcal{G} \cong p_\lambda^* \mathcal{F}_\lambda \) of \( \mathcal{O}_{\mathbb{P}_X^n} \)-modules. Clearly, it then suffices to check the sought surjectivity for the scheme \( X_\lambda \); we may therefore replace \( X \) by \( X_\lambda \), and assume from start that \( X \) is noetherian.

Next, let \( x \in X \) be any point, and \( i_x: \mathbb{P}_X^n(r_x) \to \mathbb{P}_X^n \) the natural immersion; we have \( i_x^* \mathcal{G} \cong \mathcal{O}_{\mathbb{P}_X^n(r_x)}(r_x) \) for some \( r_x \in \mathbb{Z} \). Set \( \mathcal{F} := \mathcal{G}(-r_x) \), and notice that \( H^1(\mathbb{P}_X^n, i_x^* \mathcal{F}) = 0 \); moreover, \( H_x := H^0(\mathbb{P}_X^n, i_x^* \mathcal{F}) \) is a one-dimensional \( \kappa(x) \)-vector space. From claim \( \text{[11.4.3]} \), it follows that there exist an open neighborhood \( U \) of \( x \) in \( X \), and a section \( s \in H^0(\pi^{-1} U, \mathcal{F}) \) mapping to a generator of \( H_x \). The section \( s \) defines a map of \( \mathcal{O}_{\mathbb{P}_X^n(r_x)} \)-modules \( \varphi: \mathcal{O}_{\mathbb{P}_X^n(r_x)} \to \mathcal{G}_{\pi^{-1} U} \). Furthermore, since \( i_x^* \mathcal{F} \cong \mathcal{O}_{\mathbb{P}_X^n(r_x)} \), it is easily seen that \( \varphi \) restricts to an isomorphism on some open subset of the form \( \pi^{-1} U' \), where \( U' \subset U \) is an open neighborhood of \( x \) in \( X \).
Summing up, since \(x \in X\) is arbitrary, and since \(X\) is quasi-compact, we may find a finite covering \(X = U_1 \cup \cdots \cup U_d\) consisting of open subsets, and for every \(i = 1, \ldots, d\) an integer \(r_i\) and an isomorphism \(\varphi_i : \mathcal{O}_{\mathbb{P}^n_{U_i}}(r_i) \simRightarrow \mathcal{O}_{\mathbb{P}^n_{U_i}}(r_j)\) of \(\mathcal{O}_{\mathbb{P}^n_{U_i}}\)-modules. Then, for every \(i, j \leq d\) such that \(U_{ij} := U_i \cap U_j \neq \emptyset\), the composition of the restriction of \(\varphi_i\) followed by the restriction of \(\varphi_j^{-1}\), is an isomorphism

\[
\varphi_{ij} : \mathcal{O}_{\mathbb{P}^n_{U_{ij}}}(r_i) \simRightarrow \mathcal{O}_{\mathbb{P}^n_{U_{ij}}}(r_j)
\]

of \(\mathcal{O}_{\mathbb{P}^n_{U_{ij}}}\)-modules. This already implies that \(r_i = r_j\) whenever \(U_{ij} \neq \emptyset\), hence the rule : \(x \mapsto r_i\) if \(x \in U_i\) yields a well defined continuous map \(r : X \to \mathbb{Z}\). Lastly, \(\varphi_{ij}\) is the scalar multiplication by a section

\[
u_{ij} \in H^0(\mathbb{P}^n_{U_{ij}}, \mathcal{O}_{\mathbb{P}^n_{U_{ij}}}^\times) = H^0(U_{ij}, \mathcal{O}^\times_{U_{ij}})\quad \text{for every } i, j = 1, \ldots, d.
\]

The system \((\nu_{ij} \mid i, j = 1, \ldots, d)\) is a 1-cocycle whose class in Čech cohomology \(H^1(U_\bullet, \mathcal{O}^\times_X)\) corresponds to an invertible \(\mathcal{O}_X\)-module \(\mathcal{L}\), with a system of trivializations \(\mathcal{O}_{U_i} \simRightarrow \mathcal{L}_{|U_i}\), for \(i = 1, \ldots, d\); especially, \(\varphi_i\) can be regarded as an isomorphism \((\pi^{-1}\mathcal{L})|_{\pi^{-1}U_i}(r_i) \simRightarrow \mathcal{G}|_{\pi^{-1}U_i}\) for every \(i = 1, \ldots, d\). By inspecting the construction, it is easily seen that these latter maps patch to a single isomorphism of \(\mathcal{O}_{\mathbb{P}^n_X}\)-modules \(\pi^*\mathcal{L}(r) \simRightarrow \mathcal{G}\), as required. □

**Corollary 11.4.4.** Let \(f : X \to S\) be a smooth morphism of finite presentation, set \(\mathbb{G}_{m,X} := X \times_S \text{Spec } K^+[T, T^{-1}]\), and denote by \(\pi : \mathbb{G}_{m,X} \to X\) the natural morphism. Then the map

\[
\text{Pic } X \to \text{Pic } \mathbb{G}_{m,X} \quad \mathcal{L} \mapsto \pi^*\mathcal{L}
\]

is an isomorphism.

**Proof.** To start out, the map is injective, since \(\pi\) admits a section. Next, let \(j : \mathbb{G}_{m,X} \to \mathbb{P}^1_X\) be the natural open immersion, and denote again by \(\pi : \mathbb{P}^1_X \to X\) the natural projection. According to theorem [103, 2.3.24] and proposition [11.4.1], every invertible \(\mathcal{O}_{\mathbb{G}_{m,X}}\)-module extends to an invertible \(\mathcal{O}_{\mathbb{P}^1_X}\)-module (namely the determinant of a coherent extension). Since \(j^*\mathcal{O}_{\mathbb{P}^1_X}(n) \simeq \mathcal{O}_{\mathbb{G}_{m,X}}\), the claim follows from proposition [11.4.2]. □

**Remark 11.4.5.** The proof of proposition [11.4.2] is based on the argument given in [102, Lecture 13, Prop.3]. Of course, statements related to corollary [11.4.4] abound in the literature, and more general results are available: see e.g. [13] and [120].

**Proposition 11.4.6.** Let \(f : X \to S\) be a smooth morphism of finite type, \(j : U \to X\) an open immersion, and \(Z := X \setminus U\); suppose that \(X\) and \(U\) are quasi-compact and quasi-separated. Then:

(i) Every invertible \(\mathcal{O}_U\)-module extends to an invertible \(\mathcal{O}_X\)-module.

(ii) Suppose furthermore, that:

(a) For every point \(y \in S\), the codimension of \(Z \cap f^{-1}(y)\) in \(f^{-1}(y)\) is \(\geq 1\), and

(b) The codimension of \(Z \cap f^{-1}(\eta)\) in \(f^{-1}(\eta)\) is \(\geq 2\).

Then the restriction functors:

\[
\mathcal{O}_X \text{-} \text{Rfli} \to \mathcal{O}_U \text{-} \text{Rfli} \quad \text{Pic } X \to \text{Pic } U
\]

are equivalences.

**Proof.** (i): First let us notice:

**Claim 11.4.8.** \(X\) is a finite disjoint union of normal integral schemes.

**Proof of the claim.** Since \(X\) is quasi-compact, the assertion is easily reduced to the case where \(X = \text{Spec } A\), for a smooth \(K^+\)-algebra \(A\). Then \(A\) is integrally closed in \(A_K := K \otimes_{K^+} A\), by proposition [9.8.3] and \(A_K\) is smooth over \(K\), so it is a product of finitely many normal domains.
The idempotents corresponding to this decomposition are integral over \( A \), hence they lie in \( A \). Thus, \( A \) is itself a product of finitely many normal domains, which is the claim. ☐

In view of claim \([11.4.8]\) we may assume from start that \( X \) is integral, and then \( U \) is either empty (in which case there is nothing to prove), or dense in \( X \), in which case the assertion follows from propositions \([11.3.8](i)\) and \([11.4.1](iv)\).

(ii): We begin with the following:

\textbf{Claim 11.4.9.} Under the assumptions of (ii), the functors \([11.4.7]\) are faithful.

\textbf{Proof of the claim.} Since \( f \) is smooth, all the stalks of \( \mathcal{O}_X \) are reduced (\([51]\, \text{Ch.IV, Prop.17.5.7}\)). Since every point of \( Z \) is specialization of a point of \( U \), the claim follows easily from remark \([11.3.5]\). ☐

Under assumptions (a) and (b), the conditions of corollary \([11.3.9]\) are fulfilled, and one deduces that \([11.4.7]\) are full functors, hence fully faithful, in view of claim \([11.4.9]\). The essential surjectivity of the restriction functor for reflexive \( \mathcal{O}_X \)-modules is already known, by proposition \([11.3.8](i)\).

\textbf{Lemma 11.4.10.} Let \( f : X \to S \) be a flat, finitely presented morphism, and denote by \( U \subset X \) the maximal open subset such that the restriction \( f|_U : U \to S \) is smooth. Suppose that the following two conditions hold:

(a) For every point \( y \in S \), the fibre \( f^{-1}(y) \) is geometrically reduced.

(b) The generic fibre \( f^{-1}(\eta) \) is geometrically normal.

Then the restriction functor induces an equivalence of categories (notation of \([11.3.10]\)):

\begin{equation}
\text{Div } X \xrightarrow{\sim} \text{Pic } U.
\end{equation}

\textbf{Proof.} Let \( \mathcal{F} \) be any generically invertible reflexive \( \mathcal{O}_X \)-module; it follows from proposition \([11.4.11](iv)\) that \( \mathcal{F}|_U \) is an invertible \( \mathcal{O}_U \)-module, so the functor \([11.4.11]\) is well defined. Let \( y \in S \) be any point; condition (a) says in particular that the fibre \( f^{-1}(y) \) is generically smooth over \( \kappa(y) \) (\([100]\, \text{Th.28.7}\)). Then it follows from \([51]\, \text{Ch.IV, Th.17.5.1}\) that \( U \cap f^{-1}(y) \) is a dense open subset of \( f^{-1}(y) \), and if \( x \in f^{-1}(y) \setminus U \), then the depth of \( \mathcal{O}_{f^{-1}(y),x} \) is \( \geq 1 \), since the latter is a reduced local ring of dimension \( \geq 1 \). Similarly, condition (b) and Serre’s criterion \([100]\, \text{Ch.8, Th.23.8}\) say that for every \( x \in f^{-1}(\eta) \setminus U \), the local ring \( \mathcal{O}_{f^{-1}(\eta),x} \) has depth \( \geq 2 \). Furthermore, \([50]\, \text{Ch.IV, Prop.9.9.4}\) implies that the open immersion \( j : U \to X \) is quasi-compact; summing up, we see that all the conditions of corollary \([11.3.9]\) are fulfilled, so that \( \mathcal{F} = j_* j^* \mathcal{F} \) for every reflexive \( \mathcal{O}_X \)-module \( \mathcal{F} \). This already means that \([11.4.11]\) is fully faithful. To conclude, it suffices to invoke proposition \([11.3.8](i)\). ☐

11.4.12. Let \( K(T) \) be the fraction field of the free polynomial \( K \)-algebra \( K[T] \). For every \( \gamma \in \Gamma \) one can define an extension of \( | \cdot | \) to a Gauss valuation \( | \cdot |_{0,\gamma} : K(T) \to \Gamma \) (\([59]\, \text{Ex.6.1.4(iii)}\)).

If \( f(T) := \sum_{i=0}^d a_i T^i \) is any polynomial, then \( |f(T)|_{0,\gamma} = \max\{|a_i| \cdot \gamma^i | i = 0, \ldots, d\} \). We let \( V(\gamma) \) be the valuation ring of \( | \cdot |_{0,\gamma} \), and set

\[ R(\gamma) := K[T, T^{-1}] \cap V(1) \cap V(\gamma) . \]

Since \( K[T, T^{-1}] \) is a Dedekind domain, \( R(\gamma) \) is an intersection of valuation rings of the field \( K(T) \), hence it is a normal domain. By inspecting the definition we see that \( R(\gamma) \) consists of all the elements of the form \( f(T) := \sum_{i=-n}^n a_i T^i \), such that \(|a_i| \leq 1 \) and \(|a_i| \cdot \gamma^i \leq 1 \) for every \( i = -n, \ldots, n \). Suppose now that \( \gamma \leq 1 \), and choose \( c \in K^+ \) with \(|c| = \gamma \); then every such \( f(T) \) can be written uniquely in the form \( \sum_{i=0}^n a_i T^i + \sum_{j=1}^n b_j (cT^{-1})^j \), where \( a_i, b_j \in K^+ \) for every \( i, j \leq n \). Conversely, every such expression yields an element of \( R(\gamma) \). In other words, we obtain a surjection of \( K^+ \)-algebras \( K^+[X,Y] \to R(\gamma) \) by the rule: \( X \mapsto T \), \( Y \mapsto cT^{-1} \).
Obviously the kernel of this map contains the ideal \((XY - c)\), and we leave to the reader the verification that the induced map
\[(11.4.13)\quad K^+[X,Y]/(XY - c) \to R(\gamma)\]
is indeed an isomorphism.

11.4.14. Throughout the following discussion, we shall assume that \(\gamma \leq 1\). Every \(\delta \in \Gamma\) with \(\gamma \leq \delta \leq 1\), determines a prime ideal \(p(\delta) := \{ f \in R(\gamma) \mid ||f||_{0,\delta} < 1\} \subset R(\gamma)\), such that \(m_K R(\gamma) \subset p(\delta)\). Then it is easy to see that \(R(\gamma)p(\delta) \subset V(\delta)\), and moreover:
\[
R(\gamma)p(\gamma) = V(\gamma) \quad R(\gamma)p(1) = V(1)
\]
since \(V(1)\) (resp. \(V(\gamma)\)) is already a localization of \(K^+[T]\) (resp. of \(K^+[cT^{-1}]\)). In case \(\gamma < 1\), \(11.4.13\) implies that \(R(\gamma) \otimes_{K^+} K \simeq \kappa[X,Y]/(XY)\), and it follows easily that \(p(1)\) and \(p(\gamma)\) correspond to the two minimal prime ideals of \(\kappa[X,Y]/(XY)\). In case \(\gamma = 1\), we have \(R(1) \otimes_{K^+} K \simeq \kappa[X,X^{-1}]\), and again \(p(1)\) corresponds to the generic point of \(\text{Spec} \kappa[X,X^{-1}]\).

Notice that the natural morphism
\[f_\gamma : T_K(\gamma) := \text{Spec} R(\gamma) \to S\]
restricts to a smooth morphism \(f_\gamma^{-1}(\eta) \to \text{Spec} K\); moreover the closed fibre \(f_\gamma^{-1}(s)\) is geometrically reduced. Notice also that \(T_K(\gamma) \times_S \text{Spec } E^+ \simeq T_E(\gamma)\) for every extension of valued fields \(K \subset E\). In the following, we will write just \(T(\gamma)\) in place of \(T_K(\gamma)\), unless we have to deal with more than one base ring.

**Proposition 11.4.15.** Keep the notation of \(11.4.14\), and let \(g : X \to T(\gamma)\) be an étale morphism, \(\mathcal{F}\) a coherent \(\mathcal{O}_X\)-module. Set \(h := f_\gamma \circ g : X \to S\) and denote by \(i_s : h^{-1}(s) \to X\) the natural morphism. Then \(\mathcal{F}\) is reflexive at the point \(x \in h^{-1}(s)\) if and only if the following three conditions hold:

(a) \(\mathcal{F}\) is \(h\)-flat at the point \(x\).
(b) \(\mathcal{F}_x \otimes_{K^+} K\) is a reflexive \(\mathcal{O}_{X,x} \otimes_{K^+} K\)-module.
(c) The \(\mathcal{O}_{h^{-1}(s),x}\)-module \(i_s^* \mathcal{F}_x\) satisfies condition \(S_1\) (see definition \(10.5.1\)(iii)).

**Proof.** Suppose that \(\mathcal{F}\) is reflexive at the point \(x\); then it is easy to check that (a) and (b) hold. We prove (c): by remark \(11.3.5\) we can find a left exact sequence
\[0 \to \mathcal{F}_x \xrightarrow{\alpha} \mathcal{O}^{\oplus m}_{X,x} \xrightarrow{\beta} \mathcal{O}^{\oplus n}_{X,x}.
\]
Then \(\text{Im} \beta\) is a flat \(K^+\)-module, since it is a submodule of the flat \(K^+\)-module \(\mathcal{O}^{\oplus n}_{X,x}\), hence \(\alpha \otimes_{K^+} K_\xi : i_s^* \mathcal{F}_x \to \mathcal{O}^{\oplus m}_{h^{-1}(s),x}\) is still injective, so we are reduced to showing that \(h^{-1}(s)\) is a reduced scheme, which follows from [31, Ch.IV, Prop.17.5.7] and the fact that \(f_\gamma^{-1}(s)\) is reduced.

Conversely, suppose that conditions (a)–(c) hold.

**Claim 11.4.16.** Let \(\xi\) be the generic point of an irreducible component of \(h^{-1}(s)\). Then:

(i) \(\mathcal{F}_x\) is a torsion-free \(\mathcal{O}_{X,x}\)-module.
(ii) \(\mathcal{O}_{X,\xi}\) is a valuation ring.
(iii) Suppose that the closure of \(\xi\) contains \(x\). Then \(\mathcal{F}_x\) is a free \(\mathcal{O}_{X,\xi}\)-module of finite rank.

**Proof of the claim.** (i): By (a), the natural map \(\mathcal{F}_x \to \mathcal{F}_x \otimes_{K^+} K\) is injective; since (b) implies that \(\mathcal{F}_x \otimes_{K^+} K\) is a torsion-free \(\mathcal{O}_{X,x}\)-module, the same must then hold for \(\mathcal{F}_x\).

(ii) follows from proposition \(9.1.32\)(ii).

(iii): Suppose that \(x \in \overline{\{\xi\}}\). We derive easily from (i) that \(\mathcal{F}_x\) is a torsion-free \(\mathcal{O}_{X,x}\)-module, so the assertion follows from (ii) and [28, Ch.VI, §3, n.6, Lemma 1].
Claim 11.4.17. $C$ is a flat $K^+$-module.

Proof of the claim. In view of lemma [7.11.35] it suffices to show that $\text{Tor}_1^{K^+}(C, \kappa(s)) = 0$. However, from the foregoing we derive a left exact sequence

$$0 \rightarrow \text{Tor}_1^{K^+}(C, \kappa(s)) \rightarrow \mathcal{F}_x \otimes_{K^+} \mathcal{F}_x^\vee \otimes_{K^+} K.$$ 

We are thus reduced to showing that $\beta_{\mathcal{F}_x} \otimes_{K^+} \mathcal{F}_x^\vee$ is an injective map. In view of condition (c), it then suffices to prove that $\beta_{\mathcal{F}_x}$ is an injective map. The latter assertion holds by virtue of claim [11.4.16(3)].

11.4.18. For a given $\rho \in \Gamma$, let us pick $a \in K \setminus \{0\}$ such that $|a| = \rho$; we define the fractional ideal $I(\rho) \subset K[T, T^{-1}]$ as the $R(\gamma)$-submodule generated by $T$ and $a$. The module $I(\rho)$ determines a quasi-coherent $\mathcal{O}_{T(\gamma)}$-module $\mathcal{I}(\rho)$.

Lemma 11.4.19. With the notation of [11.4.18]:

(i) $\mathcal{I}(\rho)$ is a reflexive $\mathcal{O}_{T(\gamma)}$-module for every $\rho \in \Gamma$.

(ii) There exists a short exact sequence of $R(\gamma)$-modules:

$$0 \rightarrow I(\rho^{-1} \gamma) \rightarrow R(\gamma)^{\oplus 2} \rightarrow I(\rho) \rightarrow 0.$$ 

Proof. To start with, let $a \in K \setminus \{0\}$ with $|a| = \rho$.

Claim 11.4.20. If either $\rho \geq 1$ or $\rho \leq \gamma$, then $I(\rho)$ and $I(\rho^{-1} \gamma)$ are rank one, free $R(\gamma)$-modules.

Proof of the claim. If $\rho \geq 1$ (resp. $\rho \leq \gamma$) then $\rho^{-1} \gamma \leq \gamma$ (resp. $\rho^{-1} \gamma \geq 1$), hence it suffices to show that $I(\rho)$ is free of rank one, in both cases. Suppose first that $\rho \geq 1$; in this case, multiplication by $a^{-1}$ yields an isomorphism of $R(\gamma)$-modules $I(\rho) \xrightarrow{\sim} R(\gamma)$. Next, suppose that $\rho \leq \gamma$. Then $I(\rho)$ is the ideal $(T, a)$, where $a = c \cdot b$ for some $b \in K^+$ and $|c| = \gamma$. Therefore $I(\rho) = (T, T \cdot (cT^{-1} \cdot b) = T \cdot (1, cT^{-1} b) = TR(\gamma)$, and again $I(\rho)$ is a free $R(\gamma)$-module of rank one.

In view of claim 11.4.20, we may assume that $\gamma < \rho < 1$. Let $(e_1, e_2)$ be the canonical basis of the free $R(\gamma)$-module $R(\gamma)^{\oplus 2}$; we consider the $(R(\gamma))$-linear surjection $\pi : R(\gamma)^{\oplus 2} \rightarrow I(\rho)$ determined by the rule: $e_1 \mapsto T$, $e_2 \mapsto a$. Clearly Ker $\pi$ contains the submodule $M(\rho) \subset R(\gamma)^{\oplus 2}$ generated by:

$$f_1 := ae_1 - Te_2 \quad \text{and} \quad f_2 := cT^{-1} e_1 - ca^{-1} e_2.$$ 

Let $N$ be the quasi-coherent $\mathcal{O}_{T(\gamma)}$-module associated with $N := R(\gamma)^{\oplus 2}/M(\rho)$.

Claim 11.4.21. With the foregoing notation:

(i) $N$ is a flat $K^+$-module.

(ii) $K^+[c^{-1}] \otimes_{K^+} N$ is a free $K^+[c^{-1}] \otimes_{K^+} R(\gamma)$-module of rank one.

(iii) $K^+ \otimes_{K^+} M(\rho) = K \otimes_{K^+} \text{Ker} \pi$.

Proof of the claim. (i): We let $\text{gr}_i R(\gamma)$ be the $T$-adic grading on $R(\gamma)$ (i.e. $\text{gr}_i R(\gamma) = T^i \cdot K \cap R(\gamma)$ for every $i \in \mathbb{Z}$), and we define a compatible grading on $R(\gamma)^{\oplus 2}$ by setting: $\text{gr}_i R(\gamma)^{\oplus 2} := (\text{gr}_{i-1} R(\gamma) \cdot e_1) \oplus (\text{gr}_i R(\gamma) \cdot e_2)$ for every $i \in \mathbb{Z}$. Since $f_1$ and $f_2$ are homogeneous elements, we
deduce by restriction a grading $\text{gr}_N M(\rho)$ on $M(\rho)$, and a quotient grading $\text{gr}_N N$ on $N$, whence a short exact sequence of graded $K^+$-modules:
\[ 0 \to \text{gr}_N M(\rho) \xrightarrow{\text{gr}_N j} \text{gr}_N R(\rho) \to \text{gr}_N N \to 0. \]

However, by inspecting the definitions, it is easy to see that $\text{gr}_N j$ is a split injective map of free $K^+$-modules, hence $\text{gr}_N N$ is a free $K^+$-module, and then the same holds for $N$.

(ii) is easy and shall be left to the reader.

(iii) Similarly, one checks easily that $K \otimes_{K^+} I(\rho)$ is a free $K \otimes_{K^+} R(\rho)$-module of rank one; then, by (ii) the quotient map $K \otimes_{K^+} N \to K \otimes_{K^+} I(\rho)$ is necessarily an isomorphism, whence the assertion.

\textbf{Claim 11.4.22.} $\mathcal{N}$ is a reflexive $\mathcal{O}_{T(\gamma)}$-module.

\textit{Proof of the claim.} Since $\mathcal{N}$ is coherent, it suffices to show that $\mathcal{N}_x$ is a reflexive $\mathcal{O}_{T(\gamma), x}$-module, for every $x \in T(\gamma)$ (Lemma [11.3.2] ii)). Let $y := f_s(x)$; we may then replace $\mathcal{N}$ by its restriction to $T(\gamma) \times S(y)$, which allows to assume that $y = s$ is the closed point of $S$. In this case, we can apply the criterion of Proposition [11.4.15] to the morphism $f_s : T(\gamma) \to S$. We already know from claim [11.4.21] i) that $\mathcal{N}$ is $f_s$-flat. Moreover, by claim [11.4.21] ii) we see that the restriction of $\mathcal{N}$ to $f_s^{-1}(\eta)$ is reflexive. As $\gamma < \rho < 1$, by inspecting the definition and using the presentation (11.4.15), we deduce an isomorphism:
\[
\kappa \otimes_{K^+} N \simeq \mathcal{O}^\oplus / (X e_2, Y e_1) \simeq (\mathcal{O}/\mathcal{O} R) \oplus (\mathcal{O}/\mathcal{O} Y \mathcal{R}),
\]
where $\mathcal{R} := \kappa[X, Y]/(XY) \simeq \kappa \otimes_{K^+} R(\gamma)$. Thus, the $\mathcal{R}$-module $\kappa \otimes_{K^+} N$ satisfies condition $S_1$, whence the claim.

It follows from claim [11.4.21] i, iii) that the quotient map $N \to I(\rho)$ is an isomorphism, so $\mathcal{N}(\rho)$ is reflexive, by claim [11.4.22]. Next, let us define an $R(\gamma)$-linear surjection $\pi' : R(\gamma) \to M(\rho)$ by the rule: $e_i \mapsto f_i$ for $i = 1, 2$. One checks easily that $\text{Ker} \pi'$ contains the submodule generated by the elements $ca^{-1} e_1 - Te_2$ and $ce_1 - aTe_2$, and the latter is none else than the module $M(\rho^{-1}),$ according to our notation (notice that $\gamma < \rho^{-1} \gamma < 1$). We deduce a surjection of torsion-free $R(\gamma)$-modules $I(\rho^{-1}) \to R(\gamma) / M(\rho^{-1}) \to M(\rho)$, which induces an isomorphism after tensoring by $K$, therefore $I(\rho^{-1}) \to M(\rho)$, which establishes (ii). \qed

11.4.23. Let $T(\gamma)_{\text{sm}} \subset T(\gamma)$ be the largest open subset which is smooth over $S$. Set $S_\gamma := \text{Spec } K^+ / eK^+$; it is easy to see that $f^{-1}_\gamma(S \setminus S_\gamma) \subset T(\gamma)_{\text{sm}}$, and for every $y \in S_\gamma$, the difference $f^{-1}_\gamma(y) \setminus T(\gamma)_{\text{sm}}$ consists of a single point.

\textbf{Proposition 11.4.24.} Let $\Delta(\gamma) \subset \Gamma$ be the smallest convex subgroup containing $\gamma$. Then there is a natural isomorphism of groups:
\[
\text{Pic } T(\gamma)_{\text{sm}} \sim \Delta(\gamma) / \gamma.\]

\textit{Proof.} We consider the affine covering of $T(\gamma)_{\text{sm}}$ consisting of the two open subsets
\[
U := \text{Spec } K^+ [\mathbf{T}, \mathbf{T}^{-1}] \quad \text{and} \quad V := \text{Spec } K^+ [e\mathbf{T}^{-1}, e^{-1}\mathbf{T}]\]
with intersection $U \cap V = \text{Spec } K^+ [\mathbf{c}^{-1}, \mathbf{T}, \mathbf{T}^{-1}]$. We notice that both $U$ and $V$ are $S$-isomorphic to $\mathbb{G}_m, S$, and therefore
\[
\text{Pic } U = \text{Pic } V = 0\]
by corollary [11.4.4]. From (11.4.25), a standard computation yields a natural isomorphism:
\[
\text{Pic } T(\gamma)_{\text{sm}} \sim \mathcal{O}_{T(\gamma)}(U)^\times / \mathcal{O}_{T(\gamma)}(U \cap V)^\times / \mathcal{O}_{T(\gamma)}(V)^\times.\]
(Here, for a ring $A$, the notation $A^\times$ means the invertible elements of $A$.) However, $\mathcal{O}_{T(\gamma)}(U)^\times = (K^+)^\times \cdot \mathcal{O}_{T(\gamma)}(U \cap V)^\times = (K^+)^\times \cdot \mathcal{O}_{T(\gamma)}(V)^\times = (K^+)^\times \cdot \mathcal{T}^\times$, whence the contention. \qed
11.4.26. Proposition [11.4.24] establishes a natural bijection between the set of isomorphism classes of invertible $\mathcal{O}_{T(\gamma)_{sm}}$-modules and the set:

$$[\gamma, 1] := \{\rho \in \Gamma \mid \gamma < \rho < 1\} \cup \{1\}.$$ 

On the other hand, lemma [11.4.10] yields a natural bijection between Pic $\mathcal{T}(\gamma)_{sm}$ and the set of isomorphism classes of generically invertible reflexive $\mathcal{O}_{\mathcal{T}(\gamma)}$-modules. Furthermore, lemma [11.4.19] provides already a collection of such reflexive modules, and by inspection of the proof, we see that the family of sheaves $\mathcal{I}(\rho)$ is really parametrized by the subset $[\gamma, 1]$ (since the other values of $\rho$ correspond to free $\mathcal{O}_{\mathcal{T}(\gamma)}$-modules of rank one). The two parametrizations are essentially equivalent. Indeed, let $a \in K \setminus \{0\}$ be any element such that $\rho := |a| \in [\gamma, 1]$. With the notation of the proof of proposition [11.4.24], we can define isomorphisms

$$\varphi : \mathcal{O}_U \xrightarrow{\sim} \mathcal{I}(\rho)|_U \quad \psi : \mathcal{O}_V \xrightarrow{\sim} \mathcal{I}(\rho)|_V$$

by letting: $\varphi(1) := T$ and $\psi(1) := a$. To verify that $\varphi$ is an isomorphism, it suffices to remark that $T$ is a unit on $U$, so $\mathcal{I}(\rho)|_U = T\mathcal{O}_U = \mathcal{O}_U$. Likewise, on $V$ we can write $T = a \cdot (a^{-1}c) \cdot (c^{-1}T)$, so $\mathcal{I}(\rho)|_V = a\mathcal{O}_V$, and $\psi$ is an isomorphism. Hence $\mathcal{I}(\rho)$ is isomorphic to the (unique) $\mathcal{O}_{\mathcal{T}(\gamma)}$-module whose global sections consist of all the pairs $(s_U, s_V) \in \mathcal{O}_U(U) \times \mathcal{O}_V(V)$, such that $T^{-1}s_U/s_V = a^{-1}s_U/V$. Clearly, under the bijection of proposition [11.4.24], the invertible sheaf $\mathcal{I}(\rho)|_{\mathcal{T}(\gamma)_{sm}}$ corresponds to the class of $\rho$ in $\Delta(\gamma)/\gamma^Z$. In particular, this shows that the reflexive $\mathcal{O}_{\mathcal{T}(\gamma)}$-modules $\mathcal{I}(\rho)$ are pairwise non-isomorphic for $\rho \in [\gamma, 1]$, and that every reflexive generically invertible $\mathcal{O}_{\mathcal{T}(\gamma)}$-module is isomorphic to one such $\mathcal{I}(\rho)$.

11.4.27. When $\gamma < 1$ and $t \in \mathcal{T}(\gamma)$ is the singular point of the closed fibre, the discussion of [11.4.26] also applies to describe the set $\text{coh.Div}(\mathcal{O}_{\mathcal{T}(\gamma)}, t)$ of isomorphism classes of coherent reflexive fractional ideals of $\mathcal{O}_{\mathcal{T}(\gamma)}$ (remark [11.3.11](ii)). Indeed, any such module $M$ extends to a reflexive $\mathcal{O}_{\mathcal{T}(\gamma)}$-module (first one uses lemma [11.3.7](ii.b) to extend $\mathcal{O}_{\mathcal{T}(\gamma)}$ to some quasi-compact open subset $U \subset \mathcal{T}(\gamma)$, and then one may extend to the whole of $\mathcal{T}(\gamma)$, via proposition [11.3.8](ii)). Hence $M \simeq \mathcal{I}(\rho)$, for some $\rho \in [\gamma, 1]$. It follows already that $\text{coh.Div}(\mathcal{O}_{\mathcal{T}(\gamma)}, t)$ is naturally an abelian group, with multiplication law given by the rule:

$$(M, N) \mapsto M \odot N := j_*j^*(M \otimes_{\mathcal{O}_{\mathcal{T}(\gamma)}, t} N)$$

for any two classes $M, N \in \text{Div}(\mathcal{O}_{\mathcal{T}(\gamma)}, t)$ where $j : \mathcal{T}(\gamma)_{sm} \cap \text{Spec} \mathcal{O}_{\mathcal{T}(\gamma), t} \to \text{Spec} \mathcal{O}_{\mathcal{T}(\gamma), t}$ is the natural open immersion. Indeed, $M \odot N$ is reflexive (by proposition [11.3.8](i) and corollary [11.3.9]), and the composition law $\odot$ is clearly associative and commutative, with $\mathcal{O}_{\mathcal{T}(\gamma), t}$ as neutral element; moreover, for any $\rho \in \Delta(\gamma)$, the class of $\mathcal{I}(\rho)$, admits the inverse $j_!(j^*\mathcal{I}(\rho)|_{\mathcal{T}(\gamma)/t})$. Furthermore, the modules $\mathcal{I}(\rho)|_{\mathcal{T}(\gamma)/t}$ are pairwise non-isomorphic for $\rho \in [\gamma, 1]$. Indeed, using the group law $\odot$, the assertion follows once we know that $\mathcal{I}(\rho)|_{\mathcal{T}(\gamma)/t}$ is not trivial, whenever $\rho \in [\gamma, 1]$. However, from the presentation of lemma [11.4.19](ii) one sees that $\mathcal{I}(\rho)|_{\mathcal{T}(\gamma)/t} \otimes_{\mathcal{O}_{\mathcal{T}(\gamma)}, t} \kappa(t)$ is a two-dimensional $\kappa(t)$-vector space, so everything is clear. Moreover, a simple inspection shows that the composition law thus defined, agrees with the composition law of the monoid $\text{coh.Div}(\mathcal{O}_{\mathcal{T}(\gamma)}, t)$ given in remark [11.3.11](ii). Summing, we get a natural group isomorphism:

$$\text{coh.Div}(\mathcal{O}_{\mathcal{T}(\gamma)}, t) \xrightarrow{\sim} \Delta(\gamma)/\gamma^Z.$$ 

The following theorem generalizes this classification to reflexive modules of arbitrary generic rank.

**Theorem 11.4.28.** Let $g : X \to \mathcal{T}(\gamma)$ be an ind-étale morphism, $x \in X$ any point, $M$ a reflexive $\mathcal{O}_{X,x}$-module. Then there exist $\rho_1, \ldots, \rho_n \in [\gamma, 1]$ and an isomorphism of $\mathcal{O}_{X,x}$-modules:

$$M \xrightarrow{\sim} \bigoplus_{i=1}^n g^*\mathcal{I}(\rho_i)|_x.$$
Proof. Using lemma 11.3.7(ii,b), we are easily reduced to the case where $g$ is étale. Set $t := g(x)$; first of all, if $t \in T(\gamma)_{sm}$, then $X$ is smooth over $S$ at the point $t$, and consequently $M$ (resp. $\mathcal{J}(\rho)_{t}$) is a free $\mathcal{O}_{X,x}$-module (resp. $\mathcal{O}_{T(\gamma),t}$-module) of finite rank (by proposition 11.4.1(iii)), so the assertion is obvious in this case. Hence we may assume that $\gamma < 1$ and $t$ is the unique point in the closed fibre of $T(\gamma) \setminus T(\gamma)_{sm}$. Next, let $K^{sh}$ be the strict henselization of $K^+$; denote by $h : T_{K^{sh}}(\gamma) \to T_K(\gamma)$ the natural map, and set $X' := X \times_{T_K(\gamma)} T_{K^{sh}}(\gamma)$. Choose also a point $x' \in X'$ lying over $x$, and let $t' \in T_{K^{sh}}(\gamma)$ be the image of $x'$; then $t'$ is the unique point of $T_{K^{sh}}(\gamma)$ with $h(t') = t$. We have a commutative diagram of ring homomorphisms:

$$
\begin{array}{ccc}
\mathcal{O}_{T(\gamma),t} & \xrightarrow{g_{\gamma}^*} & \mathcal{O}_{X,x} \\
\downarrow{h_{\gamma}^*} & & \downarrow \\
\mathcal{O}_{T_{K^{sh}}(\gamma),t'} & \xrightarrow{g_{\gamma'}^*} & \mathcal{O}_{X',x'}
\end{array}
$$

whence an essentially commutative diagram of functors:

$$
\begin{array}{ccc}
\mathcal{O}_{T(\gamma),t} \text{-Rflx} & \xrightarrow{g_{\gamma}^*} & \mathcal{O}_{X,x} \text{-Rflx} \\
\downarrow{h_{\gamma}^*} & & \downarrow{\beta} \\
\mathcal{O}_{T_{K^{sh}}(\gamma),t'} \text{-Rflx} & \xrightarrow{\alpha} & \mathcal{O}_{X',x'} \text{-Rflx}.
\end{array}
$$

Since $K$ and $K^{sh}$ have the same value group, the discussion in (11.4.27) shows that $h_{\gamma}^*$ induces bijections on the isomorphism classes of generically invertible modules. On the other hand, proposition 7.11.12 implies that the functor $\beta$ induces injections on isomorphism classes. Consequently, in order to prove the theorem, we may replace the pair $(X, x)$ by $(X', x')$, and assume from start that $K = K^{sh}$.

In terms of the presentation 11.4.13 we can write $T(\gamma) \times_S \text{Spec } \kappa(s) = Z_1 \cup Z_2$, where $Z_1$ (resp. $Z_2$) is the reduced irreducible component on which $X$ (resp. $Y$) vanishes. By inspecting the definitions, it is easy to check that $Z_1 \simeq \mathbb{A}^1_{\mathbb{A}} \simeq Z_2$ as $\kappa$-schemes. Let $\xi_i$ be the generic point of $Z_i$, for $i = 1, 2$; clearly $\{t\} = Z_1 \cap Z_2$, hence $W_i := X \times_{T(\gamma)} Z_i$ is non-empty and étale over $Z_i$, so $\mathcal{O}_{W_i,x}$ is an integral domain, hence $g^{-1}(\xi_i)$ contains exactly one point $\zeta_i$ that specializes to $x_i$ for both $i = 1, 2$. To ease notation, let us set $A := \mathcal{O}_{X,x}$. Then $\text{Spec } A \otimes_{K^+, \kappa} \kappa$ consists of exactly three points, namely $x, \zeta_1$ and $\zeta_2$. Set $M(\zeta_i) := M \otimes_{A} \kappa(\zeta_i)$, and notice that $n := \dim_{\kappa(\zeta_i)} M(\zeta_1) = \dim_{\kappa(\zeta_2)} M(\zeta_2)$, since $M$ restricts to a locally free module over $(\text{Spec } A)_{sm}$, the largest essentially smooth open $S$-subscheme of $\text{Spec } A$, which is connected.

We choose a basis $e_1, \ldots, e_n$ (resp. $e'_1, \ldots, e'_n$) for $M(\zeta_1)^\vee$ (resp. $M(\zeta_2)^\vee$), which we can then lift to a system of sections $e_1, \ldots, e_n \in M_{\zeta_1}^\vee := M^\vee \otimes_{A} \mathcal{O}_{X,\zeta_1}$ (and likewise we construct a system $e'_1, \ldots, e'_n \in M_{\zeta_2}^\vee$). Let $p_i \subset A$ be the prime ideal corresponding to $\zeta_i$ ($i = 1, 2$); after multiplication by an element of $A \setminus p_i$, we may assume that $e_1, \ldots, e_n \in M^\vee$ (and likewise for $e'_1, \ldots, e'_n$). Finally, we set $e_i^\vee := Ye_i + Xe'_i$ for every $i = 1, \ldots, n$; it is clear that the system $(e_1^\vee, \ldots, e_n^\vee)$ induces bases of $M(\zeta_i)^\vee$ for both $i = 1, 2$. We wish to consider the map:

$$j : M \to A^\oplus_n \quad m \mapsto (e_1^\vee(m), \ldots, e_n^\vee(m)).$$

Set $C := \text{Coker } j$, $I := \text{Ann } A C$, and $B := A/I$.

Claim 11.4.29. (i) The maps $M_\zeta \to \mathcal{O}_{X,\zeta}$ induced by $j$ are isomorphisms.

(ii) $\text{Ker } j = \text{Ker } j \otimes_{A} 1_\kappa = 0$.

(iii) $B$ is a finitely presented $K^+$-module, and $C$ is a free $K^+$-module of finite rank.

Proof of the claim. (i) Using Nakayama’s lemma, one deduces easily that these maps are surjective; since $M_\zeta$ is a free $\mathcal{O}_{X,\zeta}$-module of rank $n$, they are also necessarily injective.
(ii): Since $O_{X,Z}$ is normal, $\{0\}$ is its only associated prime; then the injectivity of $j$ (resp. of $j \otimes_A 1_\kappa$) follows from (i), and the fact that $M$ (resp. $M \otimes_A \kappa$) satisfies condition $S_1$, by remark 11.3.5 (resp. by proposition 11.4.15).

(iii): First of all, since $A$ is coherent, $I$ is a finitely generated ideal of $A$. Let $f : \text{Spec} B \to \text{Spec} K^+$ be the natural morphism. Since $C$ is a finitely presented $A$-module, its support $Z$ is a closed subset of $\text{Spec} A$. From (i) we see that $Z \cap \text{Spec} A \otimes_{K^+} \kappa \subset \{x\}$; on the other hand, $Z$ is also the support of the closed subscheme $\text{Spec} B$ of $\text{Spec} A$. Therefore

$$(11.4.30) \quad f^{-1}(s) \cap \text{Spec} B \subset \{x\}.$$ 

Since $K^+$ is henselian, it follows easily from (11.4.30) and [51, Ch.IV, Th.18.5.11(c′)] that $B$ is a finite $K^+$-algebra of finite presentation, hence also a finitely presented $K^+$-module (claim 9.1.33). Since $C$ is a finitely presented $B$-module, we conclude that $C$ is finitely presented as $K^+$-module, as well. From (ii) we deduce a short exact sequence: $0 \to M \to A^\oplus n \to C \to 0$, and then the long exact Tor sequence yields: $\text{Tor}_1^A(C, \kappa) = 0$ (cp. the proof of claim [11.4.17]). We conclude by [28, Ch.II, §3, n.2, Cor.2 of Prop.5].

Claim 11.4.31. The composed morphism: $\text{Spec} B \to \text{Spec} A \to \mathbb{T}(\gamma)$ is a closed immersion.

Proof of the claim. Let $p \subset R(\gamma)$ be the maximal ideal corresponding to $t$, so that $O_{\mathbb{T}(\gamma),t} = R(\gamma)/p$. From claim 11.4.29 (iii) we see that the natural morphism $\psi : R(\gamma)/p \to B$ is finite. Moreover, $A/pA \simeq R(\gamma)/p$, hence $\psi \otimes_{R(\gamma)} 1_{R(\gamma)/p}$ is a surjection. By Nakayama’s lemma we deduce that $\psi$ is already a surjection, i.e. the induced morphism $\text{Spec} B \to \text{Spec} R(\gamma)/p$ is a closed immersion. Let $J_p := \text{Ker} \psi$, $J := R(\gamma) \cap J_p$ and $D := R(\gamma)/J$. We are reduced to showing that the induced map $D \to D_p$ is an isomorphism. However, let $e \in R(\gamma) \setminus p$; since $D_p \simeq B$ is finite over $K^+$, we can find a monic polynomial $P[T] \in K^+[T]$ such that $P(e^{-1}) = 0$, therefore an identity of the form $1 = e \cdot Q(e)$ holds in $D_p$ for some polynomial $Q(T) \in K^+[T]$. But then the same identity holds already in the subring $D$, i.e. the element $e$ is invertible in $D$, and the claim follows. \hfill \Box

Now, $C$ is a finitely generated $B$-module, hence also a finitely generated $R(\gamma)$-module, due to claim 11.4.31. We construct a presentation of $C$ in the following way. First of all, we have a short exact sequence of $R(\gamma) \otimes_{K^+} R(\gamma)$-modules:

$$E : 0 \to \Delta \to R(\gamma) \otimes_{K^+} R(\gamma) \xrightarrow{\mu} R(\gamma) \to 0$$

where $\mu$ is the multiplication map. The homomorphism $R(\gamma) \to R(\gamma) \otimes_{K^+} R(\gamma) : a \mapsto 1 \otimes a$ fixes an $R(\gamma)$-module structure on every $R(\gamma) \otimes_{K^+} R(\gamma)$-module (the right $R(\gamma)$-module structure), and clearly $E$ is split exact, when regarded as a sequence of $R(\gamma)$-modules via this homomorphism. Moreover, in terms of the presentation (11.4.13), the $R(\gamma) \otimes_{K^+} R(\gamma)$-module $\Delta$ is generated by the elements $X \otimes 1 - 1 \otimes X$ and $Y \otimes 1 - 1 \otimes Y$. Let $n$ be the rank of the free $K^+$-module $C$ (claim 11.4.29 (iii)); there follows an exact sequence

$$E \otimes_{R(\gamma)} C : 0 \to \Delta \otimes_{R(\gamma)} C \to R(\gamma)^{\oplus n} \to C \to 0$$

which we may and do view as a short exact sequence of $R(\gamma)$-modules, via the left $R(\gamma)$-module structure induced by the restriction of scalars $R(\gamma) \to R(\gamma) \otimes_{K^+} R(\gamma) : a \mapsto a \otimes 1$. The elements $X, Y \in R(\gamma)$ act as $K^+$-linear endomorphisms on $C$; one can then find bases $(b_i)_{i = 1, \ldots, n}$ and $(b'_i)_{i = 1, \ldots, n}$ of $C$, and elements $a_1, \ldots, a_n \in K^+ \setminus \{0\}$ such that $Xb_i = a_ib'_i$ for every $i \leq n$. Since $XY = e$ in $R(\gamma)$, it follows that $Yb'_i = ca_i^{-1}b_i$ for every $i \leq n$. With this notation, it is clear that $\Delta \otimes_{R(\gamma)} C$, with its left $R(\gamma)$-module structure, is generated by the elements:

$$X \otimes b_i - 1 \otimes a_i b'_i \quad \text{and} \quad Y \otimes b'_i - 1 \otimes ca_i^{-1}b_i \quad (i = 1, \ldots, n).$$
For every $i \leq n$, let $F_i$ be the $R(\gamma)$-module generated freely by elements $(\varepsilon_i, \varepsilon'_i)$, and $\Delta_i \subseteq F_i$ the submodule generated by $X\varepsilon_i - a_i\varepsilon'_i$ and $Y\varepsilon'_i - c_i\varepsilon_i$. Moreover, let us write $b'_i = \sum_{j=1}^n u_{ij}b_j$ with unique $u_{ij} \in K^\times$, let $F$ be the free $R(\gamma)$-module with basis $(\varepsilon_i | i = 1, \ldots, n)$, and define $\varphi : F \to \bigoplus_{i=1}^n F_i$ by the rule: $e_i \mapsto \varepsilon_i' - \sum_{j=1}^n u_{ij}\varepsilon_j$ for every $i \leq n$. We deduce a right exact sequence of $R(\gamma)$-modules:

$$F \oplus \bigoplus_{i=1}^n \Delta_i \xrightarrow{\psi_1} \bigoplus_{i=1}^n F_i \xrightarrow{\psi_2} C \to 0$$

where:

\[
\psi_1(f, d_1, \ldots, d_n) = \varphi(f) + (d_1, \ldots, d_n) \quad \text{for every } f \in F \text{ and } d_i \in \Delta_i
\]

\[
\psi_2(\varepsilon_i) = b_i \quad \text{and} \quad \psi_2(\varepsilon'_i) = b'_i \quad \text{for every } i = 1, \ldots, n.
\]

**Claim 11.4.32.** $\psi_1$ is injective.

**Proof of the claim.** Let $L$ be the field of fractions of $R(\gamma)$; since the domain of $\psi_1$ is a torsion-free $K^\times$-module, it suffices to verify that $\psi \otimes_{R(\gamma)} 1_L$ is injective. However, on the one hand $C \otimes_{R(\gamma)} L = 0$, and on the other hand, each $\Delta_i \otimes_{R(\gamma)} L$ is an $L$-vector space of dimension one, so the claim follows by comparing dimensions. \(\diamondsuit\)

By inspecting the definitions and the proof of lemma 11.4.19 one sees easily that

\[(11.4.33) \quad \Delta_i \cong I([a_i^{-1}c]) \quad \text{for every } i \leq n.\]

Moreover, by remark (7.3.48)(iii), there exist $p \in \mathbb{N}$ and an $R(\gamma)$-linear isomorphism:

\[(11.4.34) \quad \operatorname{Ker} \psi_2 \cong R(\gamma)^{\oplus p} \oplus \operatorname{Syz}_R^1\gamma C.\]

On the other hand, remark (7.3.48)(iii) and claim 11.4.29(ii) also shows that there exist $q \in \mathbb{N}$ and an $A$-linear isomorphism:

\[(11.4.35) \quad M \cong A^{\oplus q} \oplus \operatorname{Syz}_A^1 C.\]

Combining (11.4.34) and (11.4.35) and using lemma 7.3.49 we deduce an $R(\gamma)^h$-linear isomorphism:

\[
(R(\gamma)^h)^{\oplus q} \oplus (R(\gamma)^h \otimes_{R(\gamma)} \operatorname{Ker} \psi_2) \cong (R(\gamma)^h)^{\oplus p+q} \oplus (R(\gamma)^h \otimes_{R(\gamma)} \operatorname{Syz}_R^1\gamma C)
\]

\[
\cong (R(\gamma)^h)^{\oplus p+q} \oplus \operatorname{Syz}_R^1\gamma (R(\gamma)^h \otimes_{R(\gamma)} C)
\]

\[
\cong (R(\gamma)^h)^{\oplus p+q} \oplus (R(\gamma)^h \otimes_A \operatorname{Syz}_A^1 C)
\]

\[
\cong (R(\gamma)^h)^{\oplus p} \oplus (R(\gamma)^h \otimes_A M).
\]

By claim 11.4.32 and (11.4.33) it follows that $(R(\gamma)^h)^{\oplus p} \oplus (R(\gamma)^h \otimes_A M)$ is a direct sum of modules of the form $R(\gamma)^h \otimes_{R(\gamma)} I(\rho_1)$, for various $\rho_1 \in \Gamma$ (recall that $I(1) = R(\gamma)$). Notice that every $I(\rho_1)$ is generically of rank one, hence indecomposable. Then it follows from corollary 7.11.11 that $R(\gamma)^h \otimes_A M$ is a direct sum of various indecomposable $R(\gamma)^h$-modules of the form $R(\gamma)^h \otimes_A g^*F(\rho_1)_x$. Finally, we apply proposition 7.11.12 to conclude the proof of the theorem. \(\square\)

The rest of this section shall be concerned with some results that hold in the special case where the valuation of $K$ has rank one.

**Theorem 11.4.36.** Suppose that $K$ is a valued field of rank one. Let $f : X \to S$ be a finitely presented morphism, $\mathcal{F}$ a coherent $\mathcal{O}_X$-module. Then:

(i) Every coherent proper submodule $\mathcal{G} \subseteq \mathcal{F}$ admits a primary decomposition.

(ii) $\operatorname{Ass} \mathcal{F}$ is a finite set.
Proof. By lemma \[10.5.15\], assertion (ii) follows from (i). Using corollary \[10.5.11\](ii) we reduce easily to the case where \( X \) is affine, say \( X = \text{Spec} \ A \) for a finitely presented \( K^+ \)-algebra \( A \), and \( \mathcal{F} = M^\sim, \mathcal{G} = N^\sim \) for some finitely presented \( A \)-modules \( N \subset M \neq 0 \). By considering the quotient \( M/N \), we further reduce the proof to the case where \( N = 0 \). Let us choose a closed imbedding \( i : X \to \text{Spec} \ B \), where \( B := K^+[T_1, \ldots, T_r] \) is a free polynomial \( K^+ \)-algebra; by proposition \[10.5.19\] the submodule \( 0 \subset \mathcal{F} \) admits a primary decomposition if and only if the submodule \( 0 \subset i_* \mathcal{F} \) does. Thus, we may replace \( A \) by \( B \), and assume that \( A = K^+[T_1, \ldots, T_r] \), in which case we shall argue by induction on \( r \). Let \( \xi \) denote the maximal point of \( f^{-1}(s) \); by claim \[9.1.31\] \( V := \mathcal{O}_{X, \xi} \) is a valuation ring with value group \( \Gamma \). Then [59] Lemma 6.1.14 says that

\[
M_{\xi} \simeq V^\oplus m \oplus (V/b_1 V) \oplus \cdots \oplus (V/b_k V)
\]

for some \( m \in \mathbb{N} \) and elements \( b_1, \ldots, b_k \in m_K \). After clearing some denominators, we may then find a map \( \varphi : M' := A^\oplus m \oplus (A/b_1 A) \oplus \cdots \oplus (A/b_k A) \to M \) whose localization \( \varphi_{\xi} \) is an isomorphism.

Claim 11.4.37. \( \text{Ass} A/bA = \{\xi\} \) whenever \( b \in m_K \).

Proof of the claim. Clearly \( \text{Ass} A/bA \subset f^{-1}(s) \). Let \( x \in f^{-1}(s) \) be a non-maximal point. Thus, the prime ideal \( p \subset A \) corresponding to \( x \) is not contained in \( m_K A \), i.e. there exists \( a \in p \) such that \(|a|_A = 1 \). Suppose by way of contradiction, that \( x \in \text{Ass} A/bA \); then we may find \( c \in A \) such that \( c \notin bA \) but \( a^n c \in bA \) for some \( n \in \mathbb{N} \). The conditions translate respectively as the inequalities:

\[
|c|_A > |b|_A \quad \text{and} \quad |a^n|_A \cdot |c|_A = |a^n c|_A \leq |b|_A
\]

which are incompatible, since \(|a^n|_A = 1 \).

Since \( (\text{Ker} \varphi)_{\xi} = 0 \), claim \[11.4.37\] and proposition \[10.5.6\](ii) imply that \( \text{Ass Ker} \varphi = \emptyset \); therefore \( \text{Ker} \varphi = 0 \), by lemma \[10.5.5\](iii). Moreover, the submodule \( N_1 := A^\oplus m \) (resp. \( N_2 := (A/b_1 A) \oplus \cdots \oplus (A/b_k A) \)) of \( M' \) is either \( \xi \)-primary (resp. \( \emptyset \)-primary), or else equal to \( M' \); in the first case, \( 0 \subset M' \) admits the primary decomposition \( 0 = N_1 \cap N_2 \), and in the second case, \( 0 \) is primary, or else \( M' = 0 \) has the empty primary decomposition. Now, if \( r = 0 \) then \( M = M' \) and we are done. Suppose therefore that \( r > 0 \) and that the theorem is known for all integers \( < r \). Set \( M'' := \text{Coker} \varphi \); clearly \( \xi \notin \text{Supp} M'' \), so by proposition \[10.5.18\] we are reduced to showing that the submodule \( 0 \subset M'' \) admits a primary decomposition. We may then replace \( M \) by \( M'' \) and assume from start that \( \xi \notin \text{Supp} \mathcal{F} \). Let \( \mathcal{F}^t \subset \mathcal{F} \) be the \( K^t \)-torsion submodule; clearly \( \mathcal{F}^t/\mathcal{F}^t \) is a flat \( K^t \)-module, hence it is a finitely presented \( \mathcal{O}_X \)-module (proposition \[9.1.26\]), so \( \mathcal{F}^t \) is a finitely generated \( \mathcal{O}_X \)-module, by [51], Ch.10, §1, n.4, Prop.6]. Hence we may find a non-zero \( a \in m_K \) such that \( a \mathcal{F}^t = 0 \), i.e. the natural map \( \mathcal{F}^t \to \mathcal{F}/a\mathcal{F} \) is injective. Denote by \( i : Z := V(\text{Ann} \mathcal{F}/a\mathcal{F}) \to X \) the closed immersion.

Claim 11.4.38. There exists a finite morphism \( g : Z \to \mathbb{A}^{r-1}_S \).

Proof of the claim. Since \( \xi \notin \text{Supp} \mathcal{F} \), we have \( I \subsetneq m_K A \), i.e. we can find \( b \in I \) such that \(|b|_A = 1 \). Set \( W := V(a, b) \subset X \); it suffices to exhibit a finite morphism \( W \to \mathbb{A}^{r-1}_S \). By [27], §5.2.4, Prop.2], we can find an automorphism \( \sigma : A/aA \to A/aA \) such that \( \sigma(b) = u \cdot b' \), where \( u \) is a unit, and \( b' \in (K^+/aK^+)[T_1, \ldots, T_r] \) is of the form \( b' = T_r^{a_0} + \sum_{j=0}^{r-1} a_j T_r^j \), for some \( a_0, \ldots, a_{r-1} \in (K^+/aK^+)[T_1, \ldots, T_{r-1}] \). Hence the ring \( A/(aA + bA) = A/(aA + b' A) \) is finite over \( K^+[T_1, \ldots, T_{r-1}] \), and the claim follows.

Claim 11.4.39. The \( \mathcal{O}_X \)-submodule \( 0 \subset \mathcal{F}/a\mathcal{F} \) admits a primary decomposition.

Proof of the claim. Let \( \mathcal{G} := (\mathcal{F}/a\mathcal{F})_Z \). By our inductive assumption the submodule \( 0 \subset g_* \mathcal{G} \) on \( \mathbb{A}^{r-1}_S \) admits a primary decomposition; a first application of proposition \[10.5.19\] then shows
that the submodule $0 \subset \mathcal{I}$ on $Z$ admits a primary decomposition, and a second application proves the same for the submodule $0 \subset i_\ast \mathcal{I} = \mathcal{F}/a\mathcal{F}$.

Finally, let $j : Y := V(a) \subset X$ be the closed immersion, and set $U := X \setminus Y$. By construction, the natural map $\Gamma_Y \mathcal{F} \to j_\ast j^\ast \mathcal{F}$ is injective. Furthermore, $U$ is an affine noetherian scheme, so \cite[Th.6.8]{100} ensures that the $\mathcal{O}_U$-submodule $0 \subset \mathcal{F}_U$ admits a primary decomposition. The same holds for $j^\ast \mathcal{F}$, in view of claim \cite[11.4.39]{10.5.21}. To conclude the proof, it remains only to invoke proposition \cite[10.5.21]{10.5.21}.

\begin{corollary}
Let $K$ be a valued field of rank one, $f : X \to S$ a finitely presented morphism, $\mathcal{F}$ a coherent $\mathcal{O}_X$-module, and $\mathcal{I} := (\mathcal{I}_\lambda | \lambda \in \Lambda)$ a cofiltered family such that:

(a) $\mathcal{I}_\lambda \subset \mathcal{O}_X$ is a coherent ideal for every $\lambda \in \Lambda$.

(b) $\mathcal{I}_\lambda \cdot \mathcal{I}_\mu \in \mathcal{I}$ whenever $\mathcal{I}_\lambda, \mathcal{I}_\mu \in \mathcal{I}$.

Then the following holds:

(i) $\mathcal{F}_\lambda := \text{Ann}_\mathcal{F}(\mathcal{I}_\lambda) \subset \mathcal{F}$ is a submodule of finite type for every $\lambda \in \Lambda$.

(ii) There exists $\lambda \in \Lambda$ such that $\mathcal{F}_\mu \subset \mathcal{F}_\lambda$ for every $\mu \in \Lambda$.

\end{corollary}

\begin{proof}
We easily reduce to the case where $X$ is affine, say $X = \text{Spec} \ A$ with $A$ finitely presented over $K^+$, and for each $\lambda \in \Lambda$ the ideal $I_\lambda := \Gamma(X, \mathcal{I}_\lambda) \subset A$ is finitely generated.

(i): For given $\lambda \in \Lambda$, let $f_1, \ldots, f_k$ be a finite system of generators of $I_\lambda$; then $\mathcal{F}_\lambda$ is the kernel of the map $\varphi : \mathcal{F} \to \mathcal{F}^{\oplus k}$ defined by the rule $m \mapsto (f_1m, \ldots, f_km)$, which is finitely generated because $A$ is coherent.

(ii): By theorem \cite[11.4.36]{10.4.36} we can find primary submodules $\mathcal{G}_1, \ldots, \mathcal{G}_n \subset \mathcal{F}$ such that $\mathcal{I}_1 \cap \cdots \cap \mathcal{G}_n = 0$; for every $i \leq n$ and $\lambda \in \Lambda$ set $\mathcal{H}_i := \mathcal{G}_i / \mathcal{G}_i$ and $\mathcal{H}_{\lambda,i} := \text{Ann}_{\mathcal{H}_i}(\mathcal{I}_\lambda)$. Since the natural map $\mathcal{F} \to \oplus_{i=1}^n \mathcal{H}_i$ is injective, we have:

$$\mathcal{F}_\lambda = \mathcal{F} \cap (\mathcal{H}_{1,\lambda} \oplus \cdots \oplus \mathcal{H}_{n,\lambda})$$

for every $\lambda \in \Lambda$.

It suffices therefore to prove that, for every $i \leq n$, there exists $\lambda \in \Lambda$ such that $\mathcal{H}_{i,\lambda} = \mathcal{H}_{i,\lambda}$ for every $\mu \in \Lambda$. Say that $\mathcal{H}_i$ is p-primary, for some prime ideal $p \subset A$; suppose now that there exists $\lambda$ such that $I_\lambda \subset p$; since $I_\lambda$ is finitely generated, we deduce that $I_\lambda^n \mathcal{H}_i = 0$ for $n \in \mathbb{N}$ large enough; from (b) we see that $\mathcal{I}_\lambda^n \subset \mathcal{I}$, so (ii) holds in this case. In case $I_\lambda \not\subset p$ for every $\lambda \in \Lambda$, we have $\text{Ann}_{\mathcal{H}_i}(\mathcal{I}_\lambda) = 0$ for every $\lambda \in \Lambda$, so (ii) holds in this case as well.

\end{proof}

\begin{corollary}
Suppose $A$ is a valuation ring with value group $\Gamma_A$, and $\varphi : K^+ \to A$ is an essentially finitely presented local homomorphism from a valuation ring $K^+$ of rank one. Then:

(i) If the valuation of $K$ is not discrete, $\varphi$ induces an isomorphism $\Gamma \to \Gamma_A$.

(ii) If $\Gamma \simeq \mathbb{Z}$ and $\varphi$ is flat, $\varphi$ induces an inclusion $\Gamma \subset \Gamma_A$, and $(\Gamma_A : \Gamma)$ is finite.

\end{corollary}

\begin{proof}
Suppose first that $\Gamma \simeq \mathbb{Z}$; then $A$ is noetherian, hence $\Gamma_A$ is discrete of rank one as well, and the assertion follows easily. In case $\Gamma$ is not discrete, we claim that $A$ has rank $\leq 1$. Indeed, suppose by way of contradiction, that the rank of $A$ is higher than one, and let $m_A \subset A$ be the maximal ideal; then we can find $a, b \in m_A \setminus \{0\}$ such that $a^{-1}b \in A$ for every $i \in \mathbb{N}$. Let us consider the $A$-module $M := A/bA$; we notice that $\text{Ann}_M(a^i) = a^{-1}bA$ form a strictly increasing sequence of ideals, contradicting corollary \cite[11.4.40]{11.4.40}(ii). Next we claim that $\varphi$ is flat. Indeed, suppose this is not the case; then $\Gamma$ is a $\kappa$-algebra. Let $p \subset A$ be the maximal ideal; by lemma \cite[9.1.30]{9.1.30} we may assume that $A/p$ is a finite extension of $\kappa$. Now, choose any finitely presented quotient $\overline{A}$ of $A$ supported at $p$; it follows easily that $\overline{A}$ is integral over $K^+$, hence it is a finitely presented $K^+$-module by proposition \cite[9.1.32]{9.1.32}(i), and its annihilator contains $m_K$, which is absurd in view of \cite[Lemma 6.1.14]{59}. Next, since $\Gamma$ is not discrete, one sees easily that $m_KA$ is a prime ideal, and in light of the foregoing, it must then be the maximal ideal. Now the assertion follows from proposition \cite[9.1.32]{9.1.32}(ii).

\end{proof}
11.4.42. Let \( K \) be a valued field of rank one, \( B \) a finitely presented \( K \)-algebra, and consider a pair \( A := (A, \text{Fil}_* A) \) consisting of a \( B \)-algebra and a \( B \)-algebra filtration on \( A \); let also \( M \) be a finitely generated \( A \)-module, and \( \text{Fil}_* A \) a good \( A \)-filtration on \( M \) (see definition 7.9.4). By definition, this means that the Rees module \( R(M)_* \) of the filtered \( A \)-module \( M := (M, \text{Fil}_* M) \) is finitely generated over the graded Rees \( B \)-algebra \( R(A)_* \). We have:

**Proposition 11.4.43.** In the situation of (11.4.42), suppose that \( A \) is a finitely presented \( B \)-algebra, \( M \) is a finitely presented \( A \)-module, and \( \text{Fil}_* A \) is a good filtration. Then:

(i) \( R(A)_* \) is a finitely presented \( B \)-algebra, and \( R(M)_* \) is a finitely presented \( R(A)_* \)-module.

(ii) If furthermore, \( \text{Fil}_* A \) is a positive filtration (see definition 7.9.4(ii)), then \( \text{Fil}_* M \) is a finitely presented \( B \)-module, for every \( i \in \mathbb{Z} \).

**Proof.** By lemma 7.9.8 there exists a finite system of generators \( m := (m_1, \ldots, m_n) \) of \( M \), and a sequence of integers \( k := (k_1, \ldots, k_n) \) such that \( \text{Fil}_* M \) is of the form (7.9.7).

(i) Consider first the case where \( A \) is a free \( B \)-algebra of finite type, say \( A = B[t_1, \ldots, t_p] \), such that \( \text{Fil}_* A \) is the good filtration associated with the system of generators \( t := (t_1, \ldots, t_p) \) and the sequence of integers \( r := (r_1, \ldots, r_p) \), and moreover \( M \) is a free \( A \)-module with basis \( m \). Then \( R(A)_* \) is also a free \( B \)-algebra of finite type (see example 7.9.5). Moreover, for every \( j \leq n \), let \( M_j \subset M \) be the \( A \)-submodule generated by \( m_j \), and denote by \( \text{Fil}_* M_j \) the good \( A \)-filtration associated with the pair \((\{m_j\}, \{k_j\})\); clearly \( \text{Fil}_* M = \text{Fil}_* M_1 \oplus \cdots \oplus \text{Fil}_* M_n \), therefore \( R(M)_* = R(M_1)_* \oplus \cdots \oplus R(M_n)_* \), where \( M_j := (M_j, \text{Fil}_* M_j) \) for every \( j \leq n \). Obviously each \( R(A)_* \)-module \( R(M_j)_* \) is free of rank one, so the proposition follows in this case.

Next, suppose that \( A \) is a free \( B \)-algebra of finite type, and \( M \) is arbitrary. Let \( F \) be a free \( A \)-module of rank \( n \), \( e := (e_1, \ldots, e_n) \) a basis of \( F \), and define an \( A \)-linear surjection \( \varphi : F \to M \) by the rule \( e_j \mapsto m_j \) for every \( j \leq n \). Then \( \varphi \) is even a map of filtered \( A \)-modules, provided we endow \( F \) with the good \( A \)-filtration \( \text{Fil}_* F \) associated with the pair \((e, k)\). More precisely, let \( N := \ker \varphi \); then the filtration \( \text{Fil}_* F \) is induced by \( \text{Fil}_* m \), meaning that \( \text{Fil}_* M := (N + \text{Fil}_* F)/N \) for every \( i \in \mathbb{Z} \). Obviously the natural map \( R(F)_* \to R(M)_* \) is surjective, and its kernel is the Rees module \( R(N)_* \), corresponding to the filtered \( A \)-module \( N := (N, \text{Fil}_* N) \) with \( \text{Fil}_* N := N \cap \text{Fil}_* F \) for every \( i \in \mathbb{Z} \). Let \( x := (x_1, \ldots, x_n) \) be a free system of generators of \( N \), and choose a sequence of integers \( j := (j_1, \ldots, j_s) \) such that \( x_i \in \text{Fil}_{j_i} N \) for every \( i \leq s \); denote by \( L \) the filtered \( A \)-module associated as in (7.9.6), with the \( A \)-module \( N \) and the pair \((x, j)\). Thus, \( R(L)_* \) is a finitely generated graded \( R(A)_* \)-submodule of \( R(N)_* \). To ease notation, set \( \overline{N} := R(N)_*/R(L)_* \) and \( \overline{F} := R(F)_*/R(L)_* \). Recall (definition 7.9.1(iii)) that \( R(A)_* \) is a graded \( B \)-subalgebra of \( A[U, U^{-1}] \); then we have:

**Claim 11.4.44.** \( \overline{N} = \bigcup_{n \in \mathbb{N}} \text{Ann}_{\overline{F}}(U^n) \).

**Proof of the claim.** It suffices to consider a homogeneous element \( y := U^i z \in R(F)_i \), for some some \( z \in \text{Fil}_* F \). Suppose that \( U^n y \in R(L)_{i+n} \), especially, \( U^{i+n} z \in R(N)_{i+n} \), so \( z \in N \), hence \( y \in R(N)_i \). Conversely, suppose that \( y \in R(N)_i \); write \( z = x_1 a_1 + \cdots + x_s a_s \) for some \( a_1, \ldots, a_s \in A \). Say that \( a_r \in \text{Fil}_{b_r} A \) for every \( r \leq s \), and set \( l := \max(i, b_1 + j_1, \ldots, b_s + j_s) \). Then \( U^{i+l} y = U^i z \in R(L)_i \).

By the foregoing, \( R(F)_* \) is finitely presented over \( R(A)_* \). It follows that \( \overline{N} \) is finitely generated (corollary 11.4.40), hence \( R(N)_* \) is a finitely generated \( R(A)_* \)-module, so finally \( R(M)_* \) is finitely presented over \( R(A)_* \).

Lastly, consider the case of an arbitrary finitely presented \( B \)-algebra \( A \), endowed with the good \( B \)-algebra filtration associated with a system of generators \( x := (x_1, \ldots, x_p) \) and the sequence of integers \( r \). We map the free \( B \)-algebra \( P := B[t_1, \ldots, t_p] \) onto \( A \), by the rule:
\( t_j \mapsto x_j \) for every \( j \leq p \). This is even a map of filtered algebras, provided we endow \( P \) with the good filtration \( \text{Fil}_n P \) associated with the pair \((t, r)\); more precisely, \( \text{Fil}_n P \) induces the filtration \( \text{Fil}_n A \) on \( A \), hence \( \text{Fil}_n A \) is a good \( P \)-filtration. By the foregoing case, we then deduce that \( R(A)_* \) is a finitely presented \( R(P)_* \)-module (where \( P := (P, \text{Fil}_n P) \)), hence also a finitely presented \( K^+ \)-algebra. Moreover, \( M \) is a finitely presented \( P \)-module, and clearly \( \text{Fil}_n M \) is good when regarded as a \( P \)-filtration, hence \( R(M)_* \) is a finitely presented \( R(P)_* \)-module, so also a finitely presented \( R(A)_* \)-module.

(ii): The positivity condition implies that \( R(A)_{0} = B; \) then, taking into account (i), the assertion is just a special case of proposition [7.6.23(iii)].

**Theorem 11.4.45** (Artin-Rees lemma). Let \( K \) be a valued field of rank one, \( A \) an essentially finitely presented \( K^+ \)-algebra, \( I \subset A \) an ideal of finite type, \( M \) a finitely presented \( A \)-module, \( N \subset M \) a finitely generated submodule. Then there exists an integer \( c \in \mathbb{N} \) such that :

\[
I^n M \cap N = I^n c(I^c M \cap N) \quad \text{for every } n \geq c.
\]

**Proof.** We reduce easily to the case where \( A \) is a finitely presented \( K^+ \)-algebra; then, with all the work done so far, we only have to repeat the argument familiar from the classical noetherian case. Indeed, let us define a filtered \( K^+ \)-algebra \( \hat{A} := (A, \text{Fil}_n A) \) by the rule : \( \text{Fil}_n A := I^{-n} \) if \( n \leq 0 \), and \( \text{Fil}_n A := A \) otherwise; also let \( \hat{M} := (M, \text{Fil}_n M) \) be the filtered \( \hat{A} \)-module such that \( \text{Fil}_n M := M \cdot \text{Fil}_n A \) for every \( n \in \mathbb{Z} \). We endow \( Q := M/N \) with the filtration \( \text{Fil}_n Q \) induced from \( \text{Fil}_n M \), so that the natural projection \( M \to Q := (Q, \text{Fil}_n Q) \). By proposition [11.4.43] there follows a surjective map of finitely presented graded \( R(A)_* \)-modules : \( \pi_* : R(M)_* \to R(Q)_* \), whose kernel in degree \( k \leq 0 \) is the \( A \)-module \( I^{-k} M \cap N \). Hence we can find a finite (non-empty) system \( f_1, \ldots, f_r \) of generators for the \( R(A)_* \)-module \( \text{Ker} \pi_* \); clearly we may assume that each \( f_i \) is homogeneous, say of degree \( d_i \); we may also suppose that \( d_i \leq 0 \) for every \( i \leq r \), since \( \text{Ker} \pi_0 \) generates \( \text{Ker} \pi_n \), for every \( n \geq 0 \). Let \( d := \min \{d_i \mid i = 1, \ldots, r\} \); by inspecting the definitions, one verifies easily that:

\[
\text{R}(A)_i \cdot \text{Ker} \pi_j \subset \text{R}(A)_{i+j-d} \cdot \text{Ker} \pi_d \quad \text{whenever } i + j \leq d \text{ and } 0 \geq j \geq d.
\]

Therefore \( \text{Ker} \pi_{d+k} = \text{R}(A)_k \cdot \text{Ker} \pi_d \) for every \( k \leq 0 \), so the assertion holds with \( c := -d \). \( \square \)

11.4.46. In the situation of theorem [11.4.45] let \( M \) be any finitely presented \( A \)-module; we denote by \( M^\wedge \) the \( I \)-adic completion of \( M \), which is an \( A^\wedge \)-module.

**Corollary 11.4.47.** With the notation of [11.4.46], the following holds : 

(i) The functor \( M \mapsto M^\wedge \) is exact on the category of finitely presented \( A \)-modules.

(ii) For every finitely presented \( A \)-module \( M \), the natural map \( M \otimes_A A^\wedge \to M^\wedge \) is an isomorphism.

(iii) \( A^\wedge \) is flat over \( A \). If additionally \( I \subset \text{rad} \) \( A \) (the Jacobson radical of \( A \)), then \( A^\wedge \) is faithfully flat over \( A \).

**Proof.** (i): Let \( N \subset M \) be any injection of finitely presented \( A \)-modules; by theorem [11.4.45] the \( I \)-adic topology on \( M \) induces the \( I \)-adic topology on \( N \). Then the assertion follows from proposition [8.2.13(i,v)].

(ii): Choose a presentation \( A^\oplus p \to A^\oplus q \to M \to 0 \). By (i) we deduce a commutative diagram with exact rows :

\[
\begin{array}{cccccc}
A^\oplus p \otimes_A A^\wedge & \longrightarrow & A^\oplus q \otimes_A A^\wedge & \longrightarrow & M \otimes_A A^\wedge & \longrightarrow & 0 \\
\downarrow & & \downarrow & & \downarrow & & \\
(A^\oplus p)^\wedge & \longrightarrow & (A^\oplus q)^\wedge & \longrightarrow & M^\wedge & \longrightarrow & 0
\end{array}
\]
and clearly the two left-most vertical arrows are isomorphisms. The claim follows.

(iii): The first assertion means that the functor \( M \mapsto M \otimes_A A^\wedge \) is exact; this follows from (i) and (ii), via a standard reduction to the case where \( M \) is finitely presented. Suppose next that \( I \subset \text{rad} \, A \); to conclude, it suffices to show that the image of the natural map \( \text{Spec} \, A^\wedge \to \text{Spec} \, A \) contains the maximal spectrum \( \text{Max} \, A \) \(^{[100] \, \text{Th.7.3}}\). Since the natural map \( \text{Max} 
abla A/I \to \text{Max} \, A \) is a bijection, the latter assertion follows from the :

\[ \text{Claim 11.4.48.} \quad \text{For every finitely presented } A\text{-module } M, \text{ the natural map } i_M : M \to M^\wedge \text{ induces an isomorphism } M/IM \cong M^\wedge/IM^\wedge. \]

**Proof of the claim.** From (i) we get a natural identification : \( M^\wedge/(IM)^\wedge \cong (M/IM)^\wedge \cong M/IM \), whose inverse is the map induced by \( i_M \). However, by (ii) the image of \( (IM)^\wedge \) in \( M^\wedge \) is the same as the image of \( IM \otimes_A A^\wedge \), which is the same as the image of \( IM^\wedge \). \( \square \)

**Theorem 11.4.49.** Let \( K \) be a valued field of rank one, \( B \to A \) a map of finitely presented \( K^\wedge \)-algebras. Then :

(i) If \( M \) is an \( \omega \)-coherent \( A \)-module, \( M \) is \( \omega \)-coherent as a \( B \)-module.

(ii) If \( J \) is a coh-injective \( B \)-module, and \( I \subset B \) is a finitely generated ideal, we have :

(a) \( \text{Hom}_B(A,J) \) is a coh-injective \( A \)-module.

(b) \( \bigcup_{n \in \mathbb{N}} \text{Ann}_J(I^n) \) is a coh-injective \( B \)-module.

(iii) If \( (J_n, \varphi_n \, | \, n \in \mathbb{N}) \) is a direct system consisting of coh-injective \( B/I^n \)-modules \( J_n \) and \( B \)-linear maps \( \varphi_n : J_n \to J_{n+1} \) (for every \( n \in \mathbb{N} \)), then \( \text{colim}_{n \in \mathbb{N}} J_n \) is a coh-injective \( B \)-module.

**Proof.** (See \([7.11.25]\) for the generalities on coh-injective and \( \omega \)-coherent modules.)

(i): We reduce easily to the case where \( M \) is finitely presented over \( A \). Let \( x_1, \ldots, x_p \) be a system of generators for the \( B \)-algebra \( A \), and \( m_1, \ldots, m_n \) a system of generators for the \( A \)-module \( M \). We let \( A := (A, \text{Fil}_A) \), where \( \text{Fil}_A \) is the good \( B \)-algebra filtration associated with the pair \( x := (x_1, \ldots, x_p) \) and \( r := (1, \ldots, 1) \); likewise, let \( M \) be the filtered \( A \)-module defined by the good \( A \)-filtration on \( M \) associated with \( \mathfrak{m} := (m_1, \ldots, m_n) \) and \( k := (0, \ldots, 0) \) (see definition \([7.9.4]\)). Then claim follows easily after applying proposition \([11.4.43]\) (ii) to the filtered \( B \)-algebra \( A \) and the filtered \( A \)-module \( M \).

(ii.a): Let \( N \subset M \) be two coherent \( A \)-modules, and \( \varphi : N \to \text{Hom}_B(A,J) \) an \( A \)-linear map. According to claim \([10.1.17]\) \( \varphi \) corresponds by adjunction to a unique \( B \)-linear map \( \overline{\varphi} : N \to J \); on the other hand by (i), \( M, \) and \( M/N \) are \( \omega \)-coherent \( B \)-modules, hence \( \overline{\varphi} \) extends to a \( B \)-linear map \( \overline{\psi} : M \to J \) (lemma \([7.11.27]\)). Under the adjunction, \( \overline{\psi} \) corresponds to an \( A \)-linear extension \( \psi : M \to \text{Hom}_B(A,J) \) of \( \varphi \).

(iii): Let \( M \subset N \) be two finitely presented \( B \)-modules, \( f : M \to J := \text{colim}_{n \in \mathbb{N}} J_n \) a \( B \)-linear map. Since \( M \) is finitely generated, \( f \) factors through a map \( f_n : M \to J_n \) and the natural map \( J_n \to J \), provided \( n \) is large enough \(([59] \text{Prop.2.3.16(ii)})\). By theorem \([11.4.45]\) there exists \( c \in \mathbb{N} \) such that \( I^{n+c}N \cap M \subset I^nM \). Hence

\[ f_{n+c} := \varphi_{n+c-1} \circ \cdots \circ \varphi_n \circ f_n : M \to J_{n+c} \]

factors through a unique \( B/I^{n+c} \)-linear map \( \overline{f}_{n+c} : \overline{M} := M/(I^{n+c}N \cap M) \to J_{n+c} \); since \( I^{n+c} \) is finitely generated, \( \overline{M} \) is a coherent submodule of the coherent \( B \)-module \( \overline{N} := N/I^{n+c}N \), therefore \( \overline{f}_{n+c} \) extends to a map \( \overline{g} : \overline{N} \to J_{n+c} \) with the projection \( N \to \overline{N} \) and the natural map \( J_{n+c} \to J \), is the sought extension of \( f \).

(ii.b): Letting \( A := B/I^n \) in (ii.a), we deduce that \( J_n := \text{Ann}_J(I^n) \) is a coh-injective \( B/I^n \)-module, for every \( n \in \mathbb{N} \). Then the assertion follows from (iii). \( \square \)

**11.5. Local duality.** Throughout this section we let \((K, | \cdot |)\) be a valued field of rank one. We shall continue to use the general notation of \([11.4]\).
11.5.1. Let $A$ be a finitely presented $K$-algebra, $I \subset A$ an ideal generated by a finite system $f := (f_i \mid i = 1, \ldots, r)$, and denote by $i : Z := V(I) \to X := \text{Spec} A$ the natural closed immersion. Let also $\mathcal{F} \subset \mathcal{O}_X$ be the ideal arising from $I$. For every $n \geq 0$ there is a natural epimorphism

$$i_*^{-1}\mathcal{O}_X \to \mathcal{O}_X/\mathcal{F}^n$$

whence natural morphisms in $D(\mathcal{A}-\text{Mod})$:

$$(11.5.2) \quad R\text{Hom}^*_\mathcal{O}_X(\mathcal{O}_X/\mathcal{F}^n, \mathcal{F}^{\bullet}) \to R\text{Hom}^*_\mathcal{O}_X(i_*^{-1}\mathcal{O}_X, \mathcal{F}^{\bullet}) \xrightarrow{\sim} R\Gamma_Z\mathcal{F}^{\bullet}$$

for any bounded below complex $\mathcal{F}^{\bullet}$ of $\mathcal{O}_X$-modules.

**Theorem 11.5.3.** In the situation of (11.5.1), let $M^{\bullet}$ be any object of $D^+(\mathcal{A}-\text{Mod})$. Then (11.5.2) induces natural isomorphisms:

$$\text{colim}_{n \in \mathbb{N}} \text{Ext}^i_A(I^n, M^{\bullet}) \xrightarrow{\sim} R^i\Gamma_Z M^{\bullet\sim} \quad \text{for every } i \in \mathbb{N}.$$

**Proof.** For $M^{\bullet} := M^{\bullet\sim}$, trivial duality (theorem 10.1.18) identifies the source of (11.5.2) with $R\text{Hom}^*_A(I^n, M^{\bullet})$; then one takes cohomology in degree $i$ and forms the colimit over $n$ to define the sought map. Next, by usual spectral sequence arguments, we may reduce to the case where $M^{\bullet}$ is a single $A$-module $M$ sitting in degree zero (see e.g. the proof of proposition 10.3.20). By inspecting the definitions, one verifies easily that the morphism thus defined is the composition of the isomorphism of proposition 10.4.32(iii) and the map (7.8.41) (see the proof of proposition 10.4.32(iii)); then it suffices to show that the inverse system $(H_i \mathcal{K}_A(f^n) \mid n \in \mathbb{N})$ is essentially zero when $i > 0$ (lemma 7.8.42). By lemma 7.8.44, this will in turn follow, provided the following holds. For every finitely presented quotient $B$ of $A$, and every $b \in B$, there exists $p \in \mathbb{N}$ such that $\text{Ann}_B(b^q) = \text{Ann}_B(b^p)$ for every $q \geq p$. This latter assertion is a special case of corollary 11.4.40.

**Corollary 11.5.4.** In the situation of theorem 11.5.3 we have natural isomorphisms:

$$\text{colim}_{n \in \mathbb{N}} \text{Ext}^i_A(I^n, M^{\bullet}) \xrightarrow{\sim} H^i(X \setminus Z, M^{\bullet\sim}) \quad \text{for every } i \in \mathbb{N}.$$

**Proof.** Set $U := X \setminus Z$. We may assume that $M^{\bullet}$ is a complex of injective $A$-modules, in which case the sought map is obtained by taking colimits over the direct system of composed morphisms:

$$\text{Hom}_A(I^n, M^{\bullet}) \xrightarrow{\beta_n} \Gamma(U, M^{\bullet}) \to R\Gamma(U, M^{\bullet\sim})$$

where $\beta_n$ is induced by the identification $(I^n|_U) = \mathcal{O}_U$ and the natural isomorphism:

$$\text{Hom}_{\mathcal{O}_U}(\mathcal{O}_U, M^{\bullet\sim}) \simeq \Gamma(U, M^{\bullet\sim}).$$

The complex $R\Gamma(U, M^{\bullet\sim})$ is computed by a Cartan-Eilenberg injective resolution $M^{\bullet\sim} \xrightarrow{q} \mathcal{M}^{\bullet}$ of $\mathcal{O}_X$-modules, and then the usual arguments allow to reduce to the case where $M^{\bullet}$ consists of a single injective $A$-module $M$ placed in degree zero. Finally, from the short exact sequence

$$0 \to I^n \to A \to A/I^n \to 0$$

we deduce a commutative ladder with exact rows:

$$
\begin{array}{c}
0 \\
\text{Hom}_A(A/I^n, M) \\
\text{Hom}_A(I^n, M) \\
\text{Hom}_A(I^n, M) \\
0 \\
\Gamma_Z M^{\sim} \\
M \\
\Gamma(U, M^{\sim}) \\
R^1\Gamma_Z M^{\sim} \\
0
\end{array}
$$

where $\alpha_n$ is induced from (11.5.2). From theorem 11.5.3 it follows that $\text{colim}_{n \in \mathbb{N}} \alpha_n$ is an isomorphism, and $R^i\Gamma_Z M^{\sim}$ vanishes for all $i > 0$; hence $\text{colim}_{n \in \mathbb{N}} \beta_n$ is an isomorphism, and the contention follows.

**Proposition 11.5.5.** Let $X \xrightarrow{f} Y \xrightarrow{b} S$ be two finitely presented morphisms of schemes.
(i) If \( g \) is smooth, \( \mathscr{O}_Y[0] \) is a dualizing complex on \( Y \).

(ii) If \( g \) is smooth and \( f \) is a closed immersion, then \( X \) admits a dualizing complex \( \omega_X^* \).

(iii) If \( X \) and \( Y \) are affine and \( \omega_Y^* \) is a dualizing complex on \( Y \), then \( f^! \omega_Y^* \) is dualizing on \( X \) (notation of (11.1.15)).

(iv) Every finitely presented quasi-separated \( S \)-scheme admits a dualizing complex.

Proof. (i) is an immediate consequence of proposition [11.4.1(i)].

(ii): As in the proof of corollary [11.3.65] this follows directly from (i) and lemma [11.3.27(i)].

(iii): Let us choose a factorization \( f = p_Y \circ i \) where \( i : X \to \mathbb{A}^n_Y \) is a finitely presented closed immersion, and \( p_Y : \mathbb{A}^n_Y \to Y \) the smooth projection onto \( Y \). In view of lemma [11.3.27(i)] and (11.1.15), it suffices to prove the assertion for the morphism \( p_Y \). To this aim, we pick a closed finitely presented immersion \( h : Y \to \mathbb{A}^m_S \) and consider the fibre diagram:

\[
\begin{array}{ccc}
\mathbb{A}^n_Y & \xrightarrow{h'} & \mathbb{A}^{n+m}_S \\
\downarrow{p_Y} & & \downarrow{p_S} \\
Y & \xrightarrow{h} & \mathbb{A}^m_S.
\end{array}
\]

By (i) we know that the scheme \( \mathbb{A}^m_S \) admits a dualizing complex \( \omega^* \), and then lemma [11.3.27(i)] says that \( h^! \omega^* \) is dualizing as well. By proposition [11.3.25] we deduce that \( \omega_Y^* \simeq \mathcal{L}[\sigma] \otimes_{\mathcal{O}_Y} h^! \omega^* \) for some invertible \( \mathcal{O}_Y \)-module \( \mathcal{L} \) and some continuous function \( \sigma : |Y| \to \mathbb{Z} \). Since \( p_Y \) is smooth, we can compute: \( p_Y^! \omega_Y^* \simeq (p_Y^! \circ h^! \omega^*) \otimes_{\mathcal{O}_S} p_S^! \mathcal{L} \otimes \sigma \), hence \( p_Y^! \omega_Y^* \) is dualizing if and only if the same holds for \( p_Y^! \circ h^! \omega^* \). By proposition [11.1.7(iv), the latter complex is isomorphic to \( h^* \circ p_S^! \omega^* \) and again using lemma [11.3.27(i)] we reduce to checking that \( p_S^! \omega^* \) is dualizing, which is clear from (i).

(iv): Let \( f : X \to S \) be a finitely presented morphism, with \( X \) quasi-separated. If \( X \) is affine, (iii) says that \( f^! \mathcal{O}_S[0] \) is dualizing on \( X \). In the general case, let \( (U_i \mid i = 1, \ldots, n) \) be a finite covering of \( X \) consisting of affine open subsets; for each \( i, j, k = 1, \ldots, n \), denote by \( f_i : U_i \to S \) the restriction of \( f \), set \( U_{ijk} := U_i \cap U_j \cap U_k \), and let \( g_{ij} : U_{ij} \to U_i \) be the inclusion map. We know that \( f^!_i \mathcal{O}_S[0] \) is dualizing on \( U_i \), for every \( i = 1, \ldots, n \); moreover, for every \( i, j, k = 1, \ldots, n \) there exists a natural isomorphism

\[ \psi_{ijk} : g_{ij}^* f^!_i \mathcal{O}_S[0] \to g_{jk}^* f^!_j \mathcal{O}_S[0] \]

fulfilling the cocycle condition

\[ \psi_{jkl} | \psi_{ijk} \psi_{ijl} = \psi_{ikl} | \psi_{ijk} \quad \text{for every } i, j, k = 1, \ldots, n \]

(lemma 11.1.16). In other words, \( ((U_i, f^!_i \mathcal{O}_S[0]); \psi_{ijk} \mid i, j, k = 1, \ldots, n) \) is a descent datum for the fibration (11.3.55). Then the assertion follows from proposition [11.3.56].

Example 11.5.6. (i) For given \( b \in m_K \), let \( i_b : S_b \to S \) be the closed immersion. If \( b \neq 0 \), a simple computation yields a natural isomorphism in \( D(\mathcal{O}_{S_b} \text{-Mod}) \):

\[ i^!_b \mathcal{O}_S \sim \mathcal{O}_{S_b}[-1]. \]

By proposition [11.5.5(i,iii), we deduce that \( \mathcal{O}_{S_b}[0] \) is a dualizing complex on \( S_b \), for every \( b \in m_K \).

(ii) Next, let \( f : X \to S_b \) be an affine finitely presented Cohen-Macaulay morphism, of constant fibre dimension \( n \). Then \( \omega_X^* := f^! \mathcal{O}_{S_b}[0] \) is a dualizing complex on \( X \), by (i) and proposition [11.5.5(iii)]. Moreover, \( \omega_X^* \) is concentrated in degree \( -n \), and \( H^{-n} \omega_X^* \) is a finitely presented \( f \)-Cohen-Macaulay \( \mathcal{O}_X \)-module. Indeed, let \( i : X \to Y := \mathbb{A}^m_{S_b} \) be a closed immersion of \( S_b \)-schemes, and denote by \( g : Y \to S_b \) the projection. Fix any \( x \in X \), let \( y := i(x) \)
and set
\[ d_x := \dim O_{f^{-1}(x),x} \quad d_y := \dim O_{g^{-1}(y),y}. \]

We have a natural isomorphism in \( D(O_X-\text{Mod}) \)
\[ \omega_X^* \cong i^! \Omega_Y[m] \cong i^* R\mathcal{H}om_{\mathcal{O}_Y}(i_* \mathcal{O}_X, \mathcal{O}_Y[m]) \]
(lemma \[11.1.16\] (i)), and by assumption \( i_* \mathcal{O}_X \) is a \( g \)-Cohen-Macaulay \( \mathcal{O}_Y \)-module; by theorem \[11.3.67\] (ii), it follows that \( \omega_X^* \) is concentrated in degree \( d_y - d_x - m \), and its cohomology in that degree is \( f \)-Cohen-Macaulay, as asserted. Lastly, since the fibres of \( f \) and \( g \) are equidimensional (\[49\] Ch.IV, Prop.5.2.1) and lemma \[11.3.62\] (ii)), it is easily seen that \( d_y - d_x = m - n \) (details left to the reader), whence the claim.

11.5.7. For any finitely presented morphism \( f : X \to S \) we consider the map:
\[ d : |X| \to \mathbb{Z} \quad x \mapsto \deg(\kappa(x) / \kappa(f(x))) + \dim \{ f(x) \}. \]

**Lemma 11.5.8.** With the notation of (11.5.7), let \( x, y \in X \), and suppose that \( x \) is a specialization of \( y \). We have:

(i) \( x \) is an immediate specialization of \( y \) if and only if \( d(y) = d(x) + 1 \).

(ii) If \( X \) is irreducible, \( d(x) - d(y) = \dim X(y) - \dim X(x) \).

(iii) \( X \) is catenarian and of finite Krull dimension.

(iv) If \( X \) is irreducible and \( f \) is flat, then \( \mathcal{O}_{f^{-1}(x),x} \) is equidimensional.

(v) If \( f \) is flat, then \( \dim \mathcal{O}_{X,x} = \dim \mathcal{O}_{f^{-1}(x),x} + \dim \mathcal{O}_{S,f(x)} \).

(vi) If \( f \) is Cohen-Macaulay at the point \( x \), then \( \mathcal{O}_{X,x} \) is equidimensional.

**Proof.** (i): In case \( f(x) = f(y) \), the assertion follows from \[49\] Ch.IV, Prop.5.2.1. Hence, suppose that \( f(x) = s, f(y) = \eta \); let \( Z \) be the topological closure of \( \{ y \} \) in \( X \), and endow \( Z \) with its reduced subscheme structure; notice that \( Z \) is an \( S \)-scheme of finite type. By assumption, \( X \) is quasi-compact and quasi-separated, hence \( \{ y \} \) is a pro-constructible subset of \( X \), and therefore \( Z \) is the set of all specializations of \( y \) in \( X \) (\[43\] Ch.IV, Th.1.10.1)). Especially, \( y \) is the unique maximal point of \( Z_\eta := Z \cap f^{-1}(\eta) \); also, if \( x \) is an immediate specialization of \( y \), then \( x \) is a maximal point of \( Z_s := Z \cap f^{-1}(s) \), and by \[50\] Ch.IV, Lemma 14.3.10], the latter implies that \( d(y) = d(x) + 1 \).

Conversely, suppose that \( d(y) = d(x) + 1 \); from \[50\] Ch.IV, Lemma 14.3.10] and \[49\] Ch.IV, Prop.5.2.1] we deduce that \( x \) is a maximal point of \( Z_\eta \); then \( x \) is an immediate specialization of \( y \) in \( X \), since otherwise \( x \) would be a specialization in \( X \) of a proper specialization \( y' \) of \( y \) in \( Z_\eta \), and in this case \[50\] Ch.IV, Lemma 14.3.10] would say that \( d(y') = d(x) + 1 \), i.e. \( d(y) = d(y') \), contradicting \[49\] Ch.IV, Prop.5.2.1].

(ii) It is easily seen that \( X \) has finite Krull dimension. Now, consider any sequence \( y_0, \ldots, y_n \) of points of \( X \), with \( y_0 := y, y_n := x \), and such that \( y_{i+1} \) is an immediate specialization of \( y_i \), for \( i = 0, \ldots, n - 1 \); from (i) we deduce that \( n = d(y) - d(x) \), especially \( n \) is independent of the chosen chain of specializations, so \( X \) is catenarian.

(ii): We reduce easily to the case where \( y \) is the maximal point of \( X \), in which case we may argue as in the proof of (iii) (details left to the reader).

(iv): This is trivial, if \( f(x) = \eta \); hence let us assume that \( f(x) = s \), and let \( y_1, y_2 \) be two maximal generizations of \( x \) in \( f^{-1}(s) \). We may find an affine open subset \( U \subset X \) such that \( y_1 \in U \) and \( y_2 \notin U \); arguing as in the proof of (i), we see that the maximal point \( z \) of \( U \) (which is also the maximal point of \( X \)) is an immediate generization of \( y_1 \) in \( U \), hence \( d(z) = d(y_1) + 1 \). Likewise, \( d(z) = d(y_2) + 1 \), hence \( d(y_1) = d(y_2) \). In view of (i), the assertion follows easily.

(v): If \( f(x) = \eta \), the identity is \[49\] Ch.IV, Cor.6.1.2]. Hence, suppose that \( f(x) = s \). In this case, the proof of (iv) shows that the identity holds, when \( X \) is irreducible. In the general case, notice that – by the flatness assumption – every irreducible component of \( X \) intersect \( f^{-1}(\eta) \), and it is therefore itself a flat \( S \)-scheme (with its reduced subscheme structure). Since \( f^{-1}(\eta) \) is
a noetherian scheme, it also follows that the set of irreducible components of \( X \) is finite; thus, let \( X_1, \ldots, X_n \) be the reduced irreducible components of \( X \) containing \( x \), and \( f_i : X_i \to S \) \((i = 1, \ldots, n)\) the corresponding restrictions of \( f \). Then
\[
\dim \mathcal{O}_{X,x} = \max_{1 \leq i \leq n} \dim \mathcal{O}_{X_i,x} \quad \text{and} \quad \dim \mathcal{O}_{f^{-1}(s),x} = \max_{1 \leq i \leq n} \dim \mathcal{O}_{f_i^{-1}(s),x}
\]
whence the contention.

(vi): By lemma \[11.3.62\] (ii), the morphism \( f \) is equidimensional at the point \( x \). Especially, \( f(u) = \eta \) for every maximal point \( u \) of \( \Spec \mathcal{O}_{X,x} \), and there exist an open neighborhood \( U \) of \( x \) in \( X \) and an integer \( e \in \mathbb{N} \), such that \( f^{-1}(y) \) is equidimensional of dimension \( e \), for every \( y \in U \). Since \( f \) is finitely presented, it follows that
\[
\tr. \deg(\kappa(y)/\kappa(f(y))) = e
\]
for every \( y \in U \) such that \( y \) is maximal in \( f^{-1}(f(y)) \) (\[100\] Th.5.6]). Hence, \( d(u) = e + 1 \) for every maximal point \( u \) of \( \Spec \mathcal{O}_{X,x} \), and especially, for every such \( u \), the difference \( d(x) - d(u) \) is independent of \( u \); in light of (i), the assertion follows.

**Lemma 11.5.9.** (i) The \( K^+ \)-module \( K/K^+ \) is coh-injective.

(ii) Let \( A \) be a finitely presented \( K^+ \)-algebra, \( I \subset A \) a finitely generated ideal, \( J \) a coh-injective \( K^+ \)-module. Then the \( A \)-module
\[
J_A := \colim_{n \in \mathbb{N}} \Hom_{K^+}(A/I^n, J)
\]
is coh-injective.

**Proof.** (i): It suffices to show that \( \Ext^1_{K^+}(M, K/K^+) = 0 \) whenever \( M \) is a finitely presented \( K^+ \)-module. This is clear when \( M = K^+ \), and then \[59\] Ch.6, Lemma 6.1.14] reduces to the case where \( M = K^+/aK^+ \) for some \( a \in m_K \setminus \{0\} \); in that case we can compute using the free resolution \( K^+ \xrightarrow{a} K^+ \to M, \) and the claim follows easily.

(ii): According to theorem \[11.4.49\] (ii,a), the \( A \)-module \( J_A' := \Hom_{K^+}(A, J) \) is coh-injective. However, \( J_A = \bigcup_{n \in \mathbb{N}} \Ann_{J_A}(I^n) \), so the assertion follows from theorem \[11.4.49\] (ii.b).

**Theorem 11.5.10.** Let \( f : X \to S \) be a finitely presented affine morphism. Then for every point \( x \in X \), the \( \mathcal{O}_{X,x} \)-module
\[
J(x) := R^{1-d(x)} \Gamma_{[x]}(f^! \mathcal{O}_S[0])|_{X(x)}
\]
is coh-injective, and we have a natural isomorphism in \( \mathcal{D}(\mathcal{O}_{X,x}\text{-Mod}) \):
\[
R \Gamma_{[x]}(f^! \mathcal{O}_S[0])|_{X(x)} \simeq J(x)[d(x) - 1].
\]

**Proof.** Fix \( x \in X \) and set \( d := d(x) \).

**Claim 11.5.11.** The theorem holds in case \( f(x) = \eta \).

**Proof of the claim.** Indeed, let \( f_\eta : f^{-1}(\eta) \to S(\eta) := \Spec K \) be the restriction of \( f \); according to lemma \[11.1.16\] (i), \( f_\eta^! \mathcal{O}_S(\eta)[0] \) is the restriction of \( f^! \mathcal{O}_S[0] \), so the claim follows immediately from example \[11.3.51\].

Hence, suppose that \( f(x) = s \), the closed point of \( S \), and say that \( X = \Spec A \).

**Claim 11.5.12.** We may assume that \( x \) is closed in \( X \), hence that \( \kappa(x) \) is finite over \( \kappa(s) \).

**Proof of the claim.** Arguing as in the proof of lemma \[9.1.30\], we can find a factorization of the morphism \( f \) as a composition \( X \xrightarrow{g} Y := \mathbb{A}^d_S \xrightarrow{h} S \), such that \( \xi := g(x) \) is the generic point of \( h^{-1}(s) \subset Y \), the morphism \( g \) is finitely presented, and the stalk \( \mathcal{O}_Y(\xi) \) is a valuation ring. Moreover, let \( g_y := g \times_Y 1_{Y(y)} : X(y) := X \times_Y Y(y) \to Y(y) \); we have a natural isomorphism
\[
(f^! \mathcal{O}_S[0])|_{X(y)} \simeq g_y^! \mathcal{O}_Y(y)[d].
\]
Then we may replace \( f \) by \( g_y \), and \( K^+ \) by \( \mathcal{O}_Y, \xi \), whence the claim. \( \diamond \)

Hence, suppose now that \( x \) is closed in \( X \), let \( p \subset A \) be the maximal ideal corresponding to \( x \), and \( \mathfrak{p} \) the image of \( p \) in \( \overline{A} := A \otimes_{K^+} \kappa \); we choose a finite system of elements \( b_1, \ldots, b_r \in \mathcal{O}_X(X) \) whose images in \( \overline{A} \) generate \( \mathfrak{p} \). Pick any non-zero \( a \in m_K \), and let \( I \subset A \) be the ideal generated by the system \( \{a, b_1, \ldots, b_r\} \), and \( \mathcal{I} \subset \mathcal{O}_X \) the corresponding coherent ideal; clearly \( V(I) = \{x\} \), hence theorem [11.5.3] yields a natural isomorphism:

\[
\text{colim}_{n \in \mathbb{N}} R^i\text{Hom}^\bullet_{\mathcal{O}_X}(\mathcal{O}_X/\mathcal{I}^n, f^! \mathcal{O}_S[0]) \cong R^i\Gamma_X(f^! \mathcal{O}_S[0]) \quad \text{for every } i \in \mathbb{Z}
\]

where the transition maps in the colimit are induced by the natural maps \( \mathcal{O}_X/\mathcal{I}^n \to \mathcal{O}_X/\mathcal{I}^m, \) for every \( n \geq m \). However, from lemmata [11.1.6(ii), [11.1.16(i)] and corollary [10.3.2(i)] we deduce as well natural isomorphisms:

\[
R\text{Hom}^\bullet_{\mathcal{O}_X}(\mathcal{O}_X/\mathcal{I}^n, f^! \mathcal{O}_S[0]) \cong R\text{Hom}^\bullet_{\mathcal{O}_S}(f_* \mathcal{O}_X/\mathcal{I}^n, \mathcal{O}_S) \cong R\text{Hom}^\bullet_{K^+}(A/I^n, K^+).
\]

We wish to compute these \( \text{Ext} \) groups by means of lemma [7.11.27(iii)]; to this aim, let us remark first that \( A/I^n \) is an integral \( K^+ \)-algebra for every \( n \in \mathbb{N} \), hence it is a finitely presented torsion \( K^+ \)-module, according to proposition [9.1.32(i)].

We may then use the coh-injective resolution \( K^+[0] \to (0 \to K \to K/K^+ \to 0) \) (lemmata [11.5.9(i), [7.11.27(iii)])) to compute:

\[
\text{Ext}^i_{K^+}(A/I^n, K^+) = \begin{cases} J_n := \text{Hom}_{K^+}(A/I^n, K^+) & \text{if } i = 1 \\ 0 & \text{otherwise.} \end{cases}
\]

Now the theorem follows from lemma [11.5.9(i)] and theorem [11.4.49(ii),(i),(iii)].

We could also appeal directly to lemma [11.5.9(ii)], provided we already knew that the foregoing natural identifications transform the direct system whose colimit appears in (11.5.13), into the direct system \( (J_n | n \in \mathbb{N}) \) whose transition maps are induced by the natural maps \( A/I^n \to A/I^m, \) for every \( n \geq m \). For the sake of completeness, we check this latter assertion.

For every \( n \geq m \), let \( j_n : X_n := \text{Spec } A/I^n \to X \) and \( j_{mn} : X_m \to X_n \) be the natural closed immersions. We have a diagram of functors:

\[
\begin{array}{ccccccccc}
& & j_{mn} \\ j_m \circ j_m & \overset{j_{mn} \circ j_m}{\longrightarrow} & j_n \circ (f \circ j_n) & \overset{\xi_1}{\longrightarrow} & j_n \circ (j_{mn} \circ j_m) \circ j_n \circ f^! & \overset{\xi_2}{\longrightarrow} & j_m \circ j_m \circ f^! \\
\downarrow \xi_1 & & & & & & & & \downarrow \xi_2 \\
\xi_1 & & j_n \circ (f \circ j_m) & \overset{j_n \circ j_m}{\longrightarrow} & j_n \circ (f \circ j_n) & \overset{\beta_{mn}}{\longrightarrow} & j_n \circ j_n \circ f^! \\
& & \downarrow \beta_{mn} & & & & & & \downarrow \alpha_{mn}
\end{array}
\]

where:

- \( \xi_1 \) and \( \xi_2 \) are induced by the natural isomorphism \( \psi_{f, j_n} : (f \circ j_n)^! \overset{\sim}{\longrightarrow} j_n^! \circ f^! \) of lemma [11.1.6(ii)].
- \( \xi_1 \) (resp. \( \xi_2 \)) is induced by the isomorphism \( \psi_{f \circ j_n, j_{mn}} \) (resp. \( \psi_{j_{mn}, j_n} \)).
- \( \alpha_{mn} \) and \( \beta_{mn} \) are induced by the counit of adjunction \( j_{mn} \circ j_m \to 1_{D^+(\mathcal{O}_X, \text{Mod})} \).
- \( \beta_{mn} \) (resp. \( \alpha_{mn} \)) is induced by the natural map \( (f \circ j_n)_* \mathcal{O}_X \to (f \circ j_m)_* \mathcal{O}_X \) (resp. by the map \( j_m \circ j_m \mathcal{O}_{X_m} \to j_m \mathcal{O}_{X_m} \)).

It follows from lemma [11.1.22] that the two triangular subdiagrams commute, and it is also clear that the same holds for the inner quadrangular subdiagram. Moreover, lemma [11.1.16(ii)] yields a commutative diagram:

\[
\begin{array}{cccccc}
(f \circ j_m) & \overset{\psi_{f, j_m}}{\longrightarrow} & j_m \circ f^! \\
\downarrow \psi_{f \circ j_n, j_{mn}} & & & & \downarrow \psi_{j_{mn}, j_n} \psi_{f, j_m} \\
\psi_{f, j_n} \circ j_m & \overset{j_n \circ (f \circ j_n)(\psi_{f, j_n})}{\longrightarrow} & j_n \circ j_n \circ f^!
\end{array}
\]
such that $j_{mx}(11.5.14)$ is the diagram:

$$
\begin{array}{ccc}
\varepsilon_1 & & \varepsilon_2 \\
j_{mx} \circ (f \circ j_m)^! & \xrightarrow{j_{mx} (\psi_{f,jm})} & j_{mx} \circ j_m^! \circ f^! \\
\end{array}
$$

We then arrive at the following commutative diagram:

$$
\begin{array}{ccc}
R\text{Hom}_{\mathcal{O}_S}(\mathcal{O}_X/\mathcal{I}^m, \mathcal{O}_S) & \xrightarrow{R\Gamma(\psi_{f,jm})} & R\text{Hom}_{\mathcal{O}_X}(\mathcal{O}_X/\mathcal{I}^m, f^! \mathcal{O}_S[0]) \\
R\text{Hom}_{\mathcal{O}_S}(\mathcal{O}_X/\mathcal{I}^n, \mathcal{O}_S) & \xrightarrow{R\Gamma(\psi_{f,jn})} & R\text{Hom}_{\mathcal{O}_X}(\mathcal{O}_X/\mathcal{I}^n, f^! \mathcal{O}_S[0]) \\
\end{array}
$$

Now, the maps $R\Gamma(\alpha_{mn})$ are the transition morphisms of the inductive system whose colimit appears in (11.5.13), hence we may replace the latter by the inductive system formed by the maps $R\Gamma(\beta_{mn})$. Combining with corollary [11.3.21], we finally deduce natural $A$-linear isomorphisms

$$
colim_{n \in \mathbb{N}} \Ext^i_{K^+}(A/I^n, K^+) \cong R^i\Gamma(\omega) f^! \mathcal{O}_S[0]
$$

where the transition maps in the colimit are induced by the natural maps $A/I^n \to A/I^m$, for every $n \geq m$. Our assertion is an immediate consequence.

11.5.15. Let $A$ be a local ring, set $X := \text{Spec} A$ let $x \in X$ be the closed point, and suppose that

(a) either, $A$ is noetherian and $X$ admits a dualizing complex
(b) or else, $A$ is essentially of finite presentation over $K^+$.

Notice that $X$ admits a dualizing complex in case (b) as well. Indeed, in that case one can find a finitely presented affine $S$-scheme $Y$ and a point $y \in Y$ such that $X \simeq \text{Spec} \mathcal{O}_{Y,y}$; by proposition [11.5.5](iv), $Y$ admits a dualizing complex $\omega_Y^*$, and since every coherent $\mathcal{O}_Y$-module extends to a coherent $\mathcal{O}_X$-module, one verifies easily that the restriction of $\omega_Y^*$ is dualizing for $X$ (cf. the proof of proposition [11.3.37]). Hence, let $\omega^*$ be a dualizing complex for $X$. In case (a) (resp. in case (b)), it follows easily from corollary [11.3.46] (resp. from theorem [11.5.10] and propositions [11.5.5](iii) and [11.3.25]), that there exists a unique $c \in \mathbb{Z}$ such that

$$
J(x) := R^i\Gamma(\omega) \neq 0.
$$

Moreover, $J(x)$ is a cohom-injective $A$-module, hence by lemma [7.11.27](iii), we obtain a well defined functor

$$
(11.5.16) \quad D : D^b(A\text{-Mod}) \to D^b(A\text{-Mod})^o : C^* \mapsto \text{Hom}_A^*(C^*, J(x)).
$$

Furthermore, let $D^b_{(x)}(A\text{-Mod}_{coh})$ be the full subcategory of $D^b(A\text{-Mod}_{coh})$ consisting of all complexes $C^*$ such that $\text{Supp} H^i C^* \subset \{x\}$. We have the following:

**Corollary 11.5.17 (Local duality).** In the situation of (11.5.15), the following holds:

(i) The functor (11.5.16) restricts to an equivalence of categories:

$$
D_x : D^b(A\text{-Mod}_{coh}) \xrightarrow{\sim} D^b_{(x)}(A\text{-Mod}_{coh})^o
$$

and the natural transformation $C^* \to D_x \circ D^b_{(x)}(A\text{-Mod}_{coh})^o$ is an isomorphism of functors.

(ii) For every $i \in \mathbb{Z}$ there exists a natural isomorphism of functors:

$$
R^i\Gamma(\omega) \xrightarrow{\sim} D \circ R^{e-i}\Gamma : D^b(\mathcal{O}_{X\text{-Mod}})_{coh} \to A\text{-Mod}^o
$$

where $\mathcal{O}$ is the duality functor corresponding to $\omega^*$ (see definition [11.3.16]).
(iii) Let \( c \) and \( \mathcal{D} \) be as in (ii), \( I \subset A \) a finitely generated ideal such that \( V(I) = \{ x \} \), and denote by \( A^\wedge \) the \( 1 \)-adic completion of \( A \). Then for every \( i \in \mathbb{Z} \) there exists a natural isomorphism of functors:

\[
D \circ R^i \Gamma_{\{x\}} \circ \mathcal{D} \cong A^\wedge \otimes_A R^{c-i} \Gamma : \mathcal{D}^b(\mathcal{O}_X\text{-Mod})_{\text{coh}} \to A^\wedge \text{-Mod}^o_{\text{coh}}.
\]

**Proof.** Let \( C^\bullet \) be any object of \( \mathcal{D}^b(\mathcal{A}\text{-Mod})_{\text{coh}} \); we denote by \( i : \{ x \} \to X \) the natural closed immersion. Obviously \( C^\bullet = i_* i^{-1}C^\bullet \) (notation of (10.3)), therefore:

\[
\text{Hom}^*_A(C^\bullet, J(x)) \cong R\text{Hom}^*_A(C^\bullet, J(x)) \quad \text{by lemma 7.11.27(iii)}
\]

\[
\cong R\text{Hom}^*_A(C^\bullet, R\Gamma_{\{x\}} \omega^*[c]) \quad \text{by theorem 10.1.18}
\]

\[
\cong R\text{Hom}^*_A(i_* i^{-1}C^\bullet, \omega^*[c]) \quad \text{by lemma 10.4.13(i,b)}
\]

\[
\cong R\text{Hom}^*_A(C^\bullet, \omega^*[c])
\]

which easily implies (i). Next, we compute, for any object \( \mathcal{F}^\bullet \) of \( \mathcal{D}^b(\mathcal{O}_X\text{-Mod})_{\text{coh}} \):

\[
R^i \Gamma_{\{x\}} \mathcal{D}(\mathcal{F}^\bullet) \cong R^i \text{Hom}^*_A(\mathcal{F}^\bullet, R\Gamma_{\{x\}} \omega^*) \quad \text{by lemma 10.4.13(iii)}
\]

\[
\cong R^i \text{Hom}^*_A(\mathcal{F}^\bullet, J(x)[-c])
\]

\[
\cong R^i \text{Hom}^*_A(R\Gamma \mathcal{F}^\bullet, J(x)[-c]) \quad \text{by theorem 10.1.18}
\]

\[
\cong \text{Hom}_A(R^{c-i} \Gamma \mathcal{F}^\bullet, J(x)) \quad \text{by lemma 7.11.27(iii)}
\]

whence (ii). Finally, let \( \mathcal{F}^\bullet \) be any object of \( \mathcal{D}^b(\mathcal{O}_X\text{-Mod})_{\text{coh}} \); if \( A \) is as in case (b) of (11.5.15), we compute:

\[
A^\wedge \otimes_A R^{c-i} \Gamma \mathcal{F}^\bullet \cong \lim_{n \in \mathbb{N}} (A/I^n) \otimes_A R^{c-i} \Gamma \mathcal{F}^\bullet \quad \text{by corollary 11.4.47(ii)}
\]

\[
\cong \lim_{n \in \mathbb{N}} D \circ D((A/I^n) \otimes_A R^{c-i} \Gamma \mathcal{F}^\bullet) \quad \text{by (i)}
\]

\[
\cong \lim_{n \in \mathbb{N}} D(\text{Hom}_A(A/I^n, R^i \Gamma_{\{x\}} \mathcal{D}(\mathcal{F}^\bullet))) \quad \text{by (ii)}
\]

\[
\cong D(\text{colim} \text{Hom}_A(A/I^n, R^i \Gamma_{\{x\}} \mathcal{D}(\mathcal{F}^\bullet)))
\]

\[
\cong D(R^i \Gamma_{\{x\}} \mathcal{D}(\mathcal{F}^\bullet))
\]

so (iii) holds as well. If \( A \) is as in case (a) of (11.5.15), the same proof works: instead of corollary 11.4.47(ii), one has just to appeal to \([100, \text{Th.8.7 and Th.8.8}]. \)

**Definition 11.5.18.** Let \( A \) and \( J(x) \) be as in (11.5.15), and \( E \) an \( A \)-module. We say that \( E \) is *finitely copresented* if there exist a finitely presented \( A \)-module \( M \) and an \( A \)-linear isomorphism \( E \cong \text{Hom}_A(M, J(x)) \).

**Lemma 11.5.19.** Let \( A \) be as in (11.5.15), and \( I \subset A \) a finitely generated ideal, whose radical is the maximal ideal of \( A \). For every \( A \)-module \( E \), the following conditions are equivalent:

(a) \( E \) is finitely copresented and finitely generated.

(b) \( E \) is finitely copresented and \( I^k E = 0 \) for some \( k \in \mathbb{N} \).

(c) \( E \) is finitely presented and \( I^k E = 0 \) for some \( k \in \mathbb{N} \).

**Proof.** To ease notation, for every ideal \( L \subset A \) and every \( A \)-module \( M \) set

\[
D(M) := \text{Hom}_A(M, J(x)) \quad \text{and} \quad M[L] := \text{Ann}_M(L).
\]

**Claim 11.5.20.** Let \( E \) be any finitely copresented \( A \)-module. Then \( E[I^k] \) is a finitely presented \( A \)-module for every \( k \in \mathbb{N} \), and \( E = \bigcup_{k \in \mathbb{N}} E[I^k] \).
Proof of the claim. We may assume that $E = D(M)$ for some finitely presented $A$-module $M$; then clearly every element of $E$ is annihilated by some power of $I$, since the same holds for $J(x)$. Moreover, we have a natural identification

$$E[I^n] \xrightarrow{\sim} D(M/I^n M) \quad \text{for every } n \in \mathbb{N}.$$  

But $M/I^n M$ is finitely presented and supported at $\{x\}$, so $D(M/I^n M)$ is finitely presented as well, by corollary [11.5.17](i).

It follows immediately from claim [11.5.20] that (a)⇒(b)⇒(c).

(c)⇒(a): If $E$ is finitely presented and $I^n E = 0$, then the same holds for $D(E)$, by corollary [11.5.17](i), and moreover $D \circ D(E) = E$, by the same token, whence (a).

\begin{proposition}
Let $A$ be as in [11.5.15], and $f : E \to N$ a homomorphism of $A$-modules, with $E$ finitely copresented and $N$ finitely presented. Then we have :

(i) $\text{Ker } f$ is a finitely copresented $A$-module.

(ii) $\text{Im } f$ and $\text{Coker } f$ are finitely presented $A$-modules.
\end{proposition}

\begin{proof}
 Clearly, it suffices to show the assertions concerning $\text{Ker } f$ and $\text{Im } f$. To this aim, pick any finitely generated ideal $I \subset A$ such that $\text{Supp } A/I = \{x\}$ (where $x$ denotes the closed point of $\text{Spec } A$); by corollary [11.4.40] ii) there exists $n \in \mathbb{N}$ such that $N[I^n] = N[I^n]$ for every integer $m \geq n$. In view of claim [11.5.20] we see that there exists $n \in \mathbb{N}$ such that $\text{Im } f = (\text{Im } f)[I^n]$. Taking into account corollary [11.4.40](i), we may then replace $N$ by $N[I^n]$, and assume from start that $I^n N = 0$, so $N$ is also finitely copresented, by lemma [11.5.19].

Now, more generally, let $E$ and $F$ be two finitely copresented $A$-modules, and say that $E = D(M)$, $F = D(P)$, where $D$ is defined as in the proof of lemma [11.5.19] in view of claim [11.5.20] and corollary [11.5.17](i) we get natural identifications:

$$\text{Hom}_A(E, F) \xrightarrow{\sim} \varprojlim \text{Hom}_A(E[I^n], F[I^n])$$

$$\xrightarrow{\sim} \varprojlim \text{Hom}_A(P/I^n P, M/I^n M)$$

$$\xrightarrow{\sim} \varprojlim \text{Hom}_A(P, M/I^n M)$$

$$\xrightarrow{\sim} \varprojlim \text{Hom}_A(P, M^\wedge)$$

where $M^\wedge$ denotes the $I$-adic completion of $M$. Recall that the natural map $M \to M^\wedge$ is injective (corollary [11.4.47] ii,iii), so the same holds for the induced map

$$\text{(11.5.22)} \quad \text{Hom}_A(P, M) \to \text{Hom}_A(E, F) \quad f \mapsto D(f).$$

\begin{claim}
11.5.23. With the foregoing notation, we have :

(i) Let $g : E \to F$ be any morphism. If $g$ lies in the image of (11.5.22), then $\text{Ker } g$, $\text{Coker } g$ and $\text{Im } g$ are all finitely copresented $A$-modules.

(ii) If either $I^k M = 0$ or $I^k P = 0$ for some $k \in \mathbb{N}$, then (11.5.22) is an isomorphism.
\end{claim}

\begin{proof}
(i): Indeed, say that $g$ is the image of $h : P \to M$ under (11.5.22); since $J(x)$ is coh-injective, we get natural identifications

$$\text{Ker } g \xrightarrow{\sim} D(\text{Coker } h) \quad \text{Coker } g \xrightarrow{\sim} D(\text{Ker } h) \quad \text{Im } g \xrightarrow{\sim} D(\text{Im } h)$$

whence the contention.

(ii): If $I^k M = 0$ for some $k \in \mathbb{N}$, then the natural map $M \to M^\wedge$ is an isomorphism, and the assertion follows. If $I^k P = 0$, then any morphism $P \to M^\wedge$ factors through $M^\wedge[I^k]$ (notation of the proof of lemma [11.5.19]); however, corollaries [11.4.40](i) and [11.4.47](i) yield natural identifications

$$M[I^n] \xrightarrow{\sim} (M[I^n])^\wedge \xrightarrow{\sim} M^\wedge[I^n]$$
whence the contention (details left to the reader).

Now, letting \( F := N \) in claim \([11.5.23]\) we deduce that both \( \ker f \) and \( \operatorname{Im} f \) are finitely copresented. Lastly, since \( I^n \cdot \operatorname{Im} f = 0 \), lemma \([11.5.19]\) says that \( \operatorname{Im} f \) is finitely presented, as sought.

**Theorem 11.5.24.** In the situation of \([11.5.15]\), let \( I \subseteq A \) be any finitely generated ideal, \( C^* \) any object of \( \mathcal{D}^b(\mathcal{O}_X \mathcal{M}_{\operatorname{coh}}) \), and set \( U := X \setminus \{ x \} \). For every \( i \in \mathbb{Z} \), the following conditions are equivalent:

1. \( I \cdot H^i(U, C^*) \) is a finitely presented \( A \)-module.
2. \( I \cdot H^i(U, C^*) \) is a finitely generated \( A \)-module.
3. \( I \cdot R^{i+1}\Gamma_{(x)} C^* \) is a finitely presented \( A \)-module.
4. \( I \cdot R^{i+1}\Gamma_{(x)} C^* \) is a finitely generated \( A \)-module.
5. The radical of \( \operatorname{Ann}_A(I \cdot R^{i+1}\Gamma_{(x)} C^*) \) contains the maximal ideal of \( A \).
6. \( I \cdot R^i\Gamma_{(y)} C^*_X(y) = 0 \) for every closed point \( y \in U \).

**Proof.** Let \( \omega^* \) be a dualizing complex for \( X \) and \( y \in X \) any point; then \( \omega^*_{(y)} \) is a dualizing complex for \( X(y) \), and according to \([11.5.15]\), there is a unique integer \( c(y) \) such that \( J(y) := R^{c(y)}\Gamma_{(y)}(\omega^*_{(y)}) \neq 0 \). If \( A \) is as in case (b) (resp. as in case (a)) of \([11.5.15]\), we may invoke theorem \([11.5.10]\) and lemma \([11.5.8]\) (resp. lemma \([11.3.50]\)) to see that

\[ (11.5.25) \quad c(y) + 1 = c := c(x) \iff y \text{ is a closed point of } U. \]

By corollary \([11.5.17] (i,ii)\), the rule

\[ M \mapsto D_y(M) := \operatorname{Hom}_A(M, J(y)) \quad \text{for every } \mathcal{O}_{X,y} \text{-module } M \]

restricts to an equivalence \( \mathcal{O}_{X,y} \mathcal{M}_{\operatorname{coh}} \sim \mathcal{O}_{X,y} \mathcal{M}_{\operatorname{coh}}^\omega \), and there is a natural isomorphism

\[ (11.5.26) \quad R^i\Gamma_{(y)} C^*_X(y) \sim D_y(H^{c(y)-i}(X(y), (\mathcal{D} C^*)_{X(y)})) \quad \text{in } \mathcal{O}_{X,y} \mathcal{M} \]

where \( \mathcal{D} \) is the duality functor corresponding to \( \omega^* \). Notice that \( a \cdot 1_{D_y M} = D_y (a \cdot 1_M) \) for every \( a \in \mathcal{O}_{X,y} \), so \([11.5.26]\) and \([11.5.25]\) imply that (f) holds if and only if

\[ (11.5.27) \quad I \cdot H^{c-i-1}(X(y), (\mathcal{D} C^*)_{X(y)}) = 0 \quad \text{for every closed point } y \text{ of } U. \]

However, if \( A \) is as in case (b) (resp. as in case (a)) of \([11.5.15]\), lemma \([11.5.8]\) (iii) (resp. theorem \([11.3.52]\)) says that every point of \( U \) specializes to a closed point, so \([11.5.27]\) holds if and only if \( I \cdot H^{c-i-1}((\mathcal{D} C^*)_{U}) = 0 \). Since \( \mathcal{D} C^* \) is a complex of coherent \( \mathcal{O}_X \)-module, the latter condition is equivalent to saying that there exists an ideal \( I' \) whose radical is the maximal ideal of \( A \), and such that \( I' I \cdot H^{c-i-1}((\mathcal{D} C^*)_{U}) = 0 \). By invoking \([11.5.26]\) with \( y := x \), we see that this holds if and only if \( I' I \cdot R^{i+1} C^* = 0 \). Summing up, we have shown that (e)\(\iff(f)\).

**Claim 11.5.28.** The \( A \)-module \( I \cdot R^i\Gamma_{(x)} C^* \) is finitely copresented, for every \( i \in \mathbb{Z} \).

**Proof of the claim.** Notice first that, due to \([11.5.26]\), the \( A \)-module \( E := R^i\Gamma_{(x)} C^* \) is finitely copresented, so the same holds for \( E^\oplus m \), for every \( m \in \mathbb{N} \). Since \( I \) is finitely generated, it is the image of a morphism \( f : A^\oplus m \rightarrow A \), for some \( m \in \mathbb{N} \), and then \( IE \) is naturally identified with the image of \( f \otimes_A 1_E \). Say that \( E = D_x(M) \) for a finitely presented \( A \)-module \( M \); then clearly \( f \otimes 1_E = D_x(f') \otimes_A 1_M \), where \( f' : A \rightarrow A^\oplus m \) is the transpose of \( f \). Now the assertion follows from claim \([11.5.23]\).\(\diamondsuit\)

Taking into account claim \([11.5.28]\) and lemma \([11.5.19]\) we deduce that (c)\(\iff(d)\iff(e)\).

Obviously, (a)\(\implies(b)\). Next, consider the exact sequence

\[ H^i(X, C^*) \xrightarrow{\alpha} H^i(U, C^*) \xrightarrow{\beta_i} R^{i+1}\Gamma_{(x)} C^* \xrightarrow{\gamma_{i+1}} H^{i+1}(X, C^*) \]

(see \([10.4.1]\)). Assume (b), which implies that \( I \cdot \operatorname{Im} \beta_i \) is a finitely generated \( A \)-module, so there exists an ideal \( I' \subseteq A \) whose radical is the maximal ideal, and such that \( I' I \cdot \operatorname{Im} \beta_i = 0 \).
On the other hand, by claim \[11.5.28\] and proposition \[11.5.21\] we know that \(\text{Im} \gamma_{i+1}\) is a finitely presented \(A\)-module, hence there exists an ideal \(I'' \subseteq A\) whose radical is the maximal ideal, and such that \(I'' \cdot \text{Im} \gamma_{i+1} = 0\). We conclude that \(I''I' \cdot R^{i+1}\Gamma(x)C^\bullet = 0\), whence (b) \(\Rightarrow\) (e).

Lastly, we suppose that (e) holds, and we show that (a) follows. To this aim, set \(M := I \cdot H^i(U, C^\bullet) \cap \text{Im} \alpha_i\), and consider the induced ladder with exact rows

\[
\begin{array}{ccccccccc}
0 & \rightarrow & M & \rightarrow & I \cdot H^i(U, C^\bullet) & \rightarrow & I \cdot \text{Ker} \gamma_{i+1} & \rightarrow & 0 \\
\downarrow & & \downarrow & & \downarrow & & \downarrow & & \\
0 & \rightarrow & \text{Coker} \gamma_i & \rightarrow & H^i(U, C^\bullet) & \rightarrow & \text{Ker} \gamma_{i+1} & \rightarrow & 0.
\end{array}
\] (11.5.29)

From (11.5.26) we know that \(\text{Ker} \gamma_{i+1}\) is finitely copresented and arguing as in the proof of claim \[11.5.28\] we conclude that the same holds for \(I \cdot \text{Ker} \gamma_{i+1}\). But (e) implies that the latter \(A\)-module is annihilated by a finitely generated ideal whose radical is the maximal ideal of \(A\), so it is finitely presented, by lemma \[11.5.19\]. We are thus reduced to checking that \(M\) is a finitely presented \(A\)-module. Now, set \(N := \text{Ker}(\pi_i \otimes_A 1_{A/I})\) and notice the short exact sequence

\[0 \rightarrow I \cdot \text{Coker} \gamma_i \rightarrow M \rightarrow N \rightarrow 0.\]

By proposition \[11.5.21\](ii) and (11.5.26), the \(A\)-module \(\text{Coker} \gamma_i\) is finitely presented, so the same holds for \(I \cdot \text{Coker} \gamma_i\), because \(A\) is coherent and \(I\) is finitely generated. So, we are further reduced to showing that \(N\) is finitely presented. However, \(N\) is naturally identified with the image of the map

\[\text{Tor}_1^A(\text{Ker} \gamma_{i+1}, A/I) \rightarrow (\text{Coker} \gamma_i) \otimes_A A/I\]

induced by the bottom row of (11.5.29). On the other hand, we have already noticed that \(\text{Coker} \gamma_i\) is finitely presented, so the same holds for \((\text{Coker} \gamma_i) \otimes_A A/I\); also, proposition \[11.5.21\](i) and (11.5.26) say that \(\text{Ker} \gamma_{i+1}\) is finitely copresented. Taking into account proposition \[11.5.21\](ii) it finally suffices to show:

**Claim 11.5.30.** If \(Q\) is any finitely copresented \(A\)-module and \(P\) any finitely presented \(A\)-module, the \(A\)-module \(\text{Tor}_1^A(Q, P)\) is finitely copresented as well, for every \(i \in \mathbb{N}\).

**Proof of the claim.** Since \(I\) is finitely generated and \(A\) is coherent, we may find a resolution \(F_\bullet \xrightarrow{\sim} P[0]\) consisting of free \(A\)-modules of finite type (details left to the reader), and then \(\text{Tor}_1^A(Q, P) \simeq H_i(F_\bullet \otimes_A Q)\), so the assertion follows easily from claim \[11.5.23\](i) (details left to the reader).

**Proposition 11.5.31.** In the situation of (11.5.15), let \(d \in \mathbb{N}\) be any integer, and suppose additionally that:

(a') If \(A\) is as in case (a), then \(A\) is regular of dimension \(d + 1\).

(b') If \(A\) is as in case (b), the structure morphism \(f : X \rightarrow S\) is flat, \(f(x) = s\) and \(f^{-1}(s)\) is a regular scheme of dimension \(d\).

Let \(j : U := X \setminus \{x\} \rightarrow X\) be the open immersion, \(\mathcal{F}\) a flat quasi-coherent \(\mathcal{O}_U\)-module. Then the following two conditions are equivalent:

(c) \(\Gamma(U, \mathcal{F})\) is a flat \(A\)-module.

(d) \(\delta(x, j, \mathcal{F}) \geq d + 1\).

**Proof.** If \(d = 0\), then \(A\) is a valuation ring (proposition \[9.1.32\](ii)), and \(U\) is the spectrum of the field of fractions of \(A\), in which case both (c) and (d) hold trivially. Hence we may assume that \(d \geq 1\). Suppose now that (c) holds, and set \(F := \Gamma(U, \mathcal{F})\). In view of (10.4.3), we need to show that \(H^i(U, \mathcal{F}) = 0\) whenever \(1 \leq i \leq d - 1\). If \(F^\infty\) denotes the \(\mathcal{O}_X\)-module determined by \(F\), then \(F^\infty_{\mathcal{O}_U} = \mathcal{F}\). Moreover, by [95, Ch.I, Th.1.2], \(F\) is the colimit of a filtered family \((L_i \mid i \in I)\) of free \(A\)-modules of finite rank, hence \(H^i(U, \mathcal{F}) = \text{colim}_{i \in I} H^i(U, L_i^\sim)\) by
A simple induction on the length of the filtration reduces the assertion to the following

\[ \text{Proof.} \]

Lemma 11.5.37. The special case of proposition 11.5.31 where \( F = \mathcal{O}_U \), and therefore \( j_* F = \mathcal{O}_X \) (corollary 11.3.9). In case (a'), assertion (d) follows already, by virtue of [100, Th.17.8]. So, suppose that (b') holds; since \( f^{-1}(s) \) is regular, we have \( \delta(x, \mathcal{O}_{f^{-1}(s)}) = d \); then, since the topological space underlying \( X \) is noetherian, lemma 10.4.20(ii) and corollary 10.4.47 imply that \( \delta(x, \mathcal{O}_X) \geq d + 1 \), which is (d).

Conversely, suppose that (d) holds; we consider first the case (b'), and we shall derive (c) by induction on \( d \), the case \( d = 0 \) having already been dealt with. Let \( m_A \) (resp. \( \overline{m}_A \)) be the maximal ideal of \( A \) (resp. of \( \overline{A} := A/m_K A \)). Suppose then that \( d \geq 1 \) and that the assertion is known whenever \( \dim f^{-1}(s) < d \). Pick \( \overline{t} \in \overline{m}_A \setminus \overline{m}_A^2 \), and let \( t \in m_A \) be any lifting of \( \overline{t} \). Since \( f^{-1}(s) \) is regular, \( \overline{t} \) is a regular element of \( \overline{A} \), so that \( t \) is regular in \( A \) and the induced morphism \( g : X' := \text{Spec} A/tA \to S \) is flat ([50, Ch.IV, Th.11.3.8]). Let \( j' : U' := U \cap X' \to X' \) be the restriction of \( j \); our choice of \( \overline{t} \) ensures that \( g^{-1}(s) \) is a regular scheme, so the pair \( (X', \mathcal{F}/t\mathcal{F}_{U'}) \) fulfills the conditions of the proposition, and \( \dim g^{-1}(s) = d - 1 \). Furthermore, since \( F \) is a flat \( \mathcal{O}_U \)-module, the sequence \( 0 \to F \to \mathcal{F} \to F/t\mathcal{F} \to 0 \) is short exact. Assumption (d) means that

\[ H^i(U, \mathcal{F}) = 0 \quad \text{whenever} \quad 1 \leq i \leq d - 1. \]

Therefore, from the long exact cohomology sequence we deduce that \( H^i(U, \mathcal{F}/t\mathcal{F}) = 0 \) for \( 1 \leq i \leq d - 2 \), i.e.

\[ \delta(x, j'_* \mathcal{F}/t\mathcal{F}) \geq d. \]

The same sequence also yields a left exact sequence:

\[ 0 \to H^0(U, \mathcal{F}) \otimes_A A/tA \to H^0(U, \mathcal{F}/t\mathcal{F}) \to H^1(U, \mathcal{F}). \]

Claim 11.5.35. \( H^0(U, \mathcal{F}) \otimes_A A/tA \) is a flat \( A/tA \)-module.

Proof of the claim. By (11.5.33) and our inductive assumption, \( H^0(U, \mathcal{F}/t\mathcal{F}) \) is a flat \( A/tA \)-module. In case \( d = 1 \), proposition 9.1.32(ii) shows that \( A/tA \) is a valuation ring, and then the claim follows from (11.5.34), and [28, Ch.VI, §3, n.6, Lemma 1]. If \( d > 1 \), (11.5.32) implies that \( \alpha \) is an isomorphism, so the claim holds also in such case.

Set \( V := \text{Spec} A[t^{-1}] = X \setminus V(t) \subset U \); since \( \mathcal{F}|_V \) is a flat \( \mathcal{O}_V \)-module, the \( A[t^{-1}] \)-module \( H^0(U, \mathcal{F}) \otimes_A A[t^{-1}] \simeq H^0(V, \mathcal{F}|_V) ) \) is flat. Moreover, since \( t \) is regular on both \( A \) and \( H^0(U, \mathcal{F}) \), an easy calculation shows that \( \text{Tor}_1^A(A/tA, H^0(U, \mathcal{F})) = 0 \) for \( i > 0 \). Then the contention follows from claim 11.5.35 and [59, Lemma 5.2.1].

Lastly, in case (a') holds, one picks any element \( t \in m_A \setminus m_A^2 \) and argues in the same way (with some simplifications: details left to the reader).

Remark 11.5.36. The special case of proposition 11.5.31 where \( A \) is regular local ring and \( \mathcal{F} \) is a locally free \( \mathcal{O}_U \)-module of finite rank has been studied in detail in [77].

Lemma 11.5.37. Let \( A \) be a noetherian ring, \( M \) an \( A \)-module endowed with a finite filtration \( M_0 := 0 \subset M_1 \subset \cdots \subset M_k := M \), and denote by \( \text{gr} M \) the associated graded \( A \)-module. Suppose that, for every \( i = 1, \ldots, k \), there exists an ideal \( I_i \subset A \) such that \( I_i \cdot \text{gr}^i M \) is an \( A \)-module of finite type. Then \( \prod_{i=1}^k I_i M \) is an \( A \)-module of finite type.

Proof. A simple induction on the length of the filtration reduces the assertion to the following

Claim 11.5.38. Let \( A \) be a noetherian ring, \( I, J \subset A \) two ideals, and

\[ 0 \to M_1 \to M_2 \to M_3 \to 0 \]

a short exact sequence of \( A \)-modules, such that \( IM_1 \) and \( JM_3 \) are finitely generated. Then \( IJM_2 \) is finitely generated.
Proof of the claim. Indeed, the induced map \( N := JM_2/(M_1 \cap JM_2) \to JM_3 \) is injective, so \( N \) is finitely generated, and then the same holds for \( I \otimes_A N \); but the latter maps surjectively onto \( IJM_2/(IM_1 + JM_2) \cong (IJM_2 + IM_1)/IM_1 \), so the latter is also of finite type, and therefore the same holds for \( IJM_2 + IM_1 \), whence the lemma.

11.5.39. Let \( A \) be a noetherian ring, \( \omega^* \) a dualizing complex on \( X := \text{Spec} A \), and \( I \subset A \) an ideal. Let also \( U \subset X \) be any open subset, and \( K^* \) any object of \( D^b(\mathcal{O}_U\text{-}\text{Mod})_{\text{coh}} \). We denote:

- \( \mathcal{U} \) the topological closure of \( U \) in \( X \)
- \( Z := X \setminus \mathcal{U} \) and \( \partial U := \mathcal{U} \setminus U \), endowed with the reduced closed subscheme structures
- \( U_1 := \{ x \in U \mid \text{there exists } y \in \partial U \text{ which is an immediate specialization of } x \text{ in } \mathcal{U} \} \)
- \( \mathcal{D}_U : D^b(\mathcal{O}_U\text{-}\text{Mod})_{\text{coh}} \to D^b(\mathcal{O}_U\text{-}\text{Mod})_{\text{coh}} \) the duality functor associated with \( \omega^*_U \)
- \( n(K^*) \) the cardinality of \( \{ i \in \mathbb{Z} \mid H^i(\mathcal{D}_U K^*) \neq 0 \} \)
- \( d(K^*) := \min(n(K^*), 1 + \dim \partial U) \)
- \( \partial U(x) := U \cap X(x) \) and \( \delta(x) := \dim \partial U(x) \) for every \( x \in X \)
- \( e(x) := \min(1 + \delta(y) \mid y \text{ is a specialization of } x \text{ in } \mathcal{U}) \) for every \( x \in U_1 \).

Here we use the convention that \( \dim \partial U = -1 \) if \( \partial U = \emptyset \), and likewise we define the dimension of \( \partial U(y) \), for any \( y \in X \) such that this set is empty. On the other hand, the dimension of \( \partial U \) can be infinite, in the current setting. Notice that the integer \( n(K^*) \) depends only on \( K^* \), and does not depend on the choice of \( \omega^* \).

Lemma 11.5.40. For every \( x \in \partial U \), every closed point of \( U \cap X(x) \) is an immediate generalization of \( x \) in \( X(x) \). Especially, every such point lies in \( U_1 \).

Proof. Fix any \( y \in \partial U \), set \( A := \mathcal{O}_{X,x} \), and for any closed point \( z \) of \( U \cap X(x) \), denote by \( p_z \subset A \) the prime ideal corresponding to \( z \), so that \( p_z \) is strictly contained in the maximal ideal \( m_A \) of \( A \). Let also \( I \subset A \) be any ideal such that \( \text{Spec } A/I = X(x) \), so \( I \not\subseteq p_z \) by construction. Set \( B := A/p_z \), and denote by \( m_B, \mathcal{T} \subset B \) the images of respectively \( m_A \) and \( I \). It suffices to show that \( \dim B = 1 \); suppose by contradiction that the latter fails, and pick any \( f \in \mathcal{T} \setminus \{0\} \).

Claim 11.5.41. If \( \dim B > 1 \), there exists a prime ideal \( \mathfrak{q} \subset B \) of height 1, such that \( f \notin \mathfrak{q} \).

Proof of the claim. Clearly, every prime ideal of height one containing \( f \) is a maximal point of \( \text{Supp } B/fB \), hence it lies in \( \text{Ass } B/fB \) (lemma 10.5.31)); therefore, the set \( \Sigma \) of prime ideals of \( B \) of height one containing \( f \) is finite (100 Th.6.5(iii)). If \( \Sigma \) is empty, Krull’s Hauptidealsatz (100 Th.13.5) implies that \( f \) must be invertible, in which case the claim is obvious. If \( \Sigma \) contains a single prime ideal \( \mathfrak{q}_1 \), notice that \( \mathfrak{q}_1 \neq m_B \), since \( \dim B > 1 \), and pick any \( g \in m_B \setminus \mathfrak{q}_1 \); again by Krull’s theorem we know that there exists a prime ideal \( \mathfrak{q} \subset B \) of height one containing \( g \), and by construction \( \mathfrak{q} \neq \mathfrak{q}_1 \), whence the claim, in this case. Otherwise, say that \( \Sigma = \{ \mathfrak{q}_1, \ldots, \mathfrak{q}_n \} \) for some \( n \geq 2 \). For every \( i, j \leq n \) with \( i \neq j \) we may find an element \( g_{ij} \in \mathfrak{q}_i \setminus \mathfrak{q}_j \), and we set \( g := \sum_{j=1}^n \prod_{i \neq j} g_{ij} \). It is easily seen that \( g \in m_B \setminus (\mathfrak{q}_1 \cup \cdots \cup \mathfrak{q}_n) \), so we may apply again Krull’s theorem to exhibit a prime ideal \( \mathfrak{q} \) which cannot lie in \( \Sigma \), since it contains \( g \).

Let \( \mathfrak{q} \) be as in claim 11.5.41, and denote by \( q \subset A \) the preimage of \( \mathfrak{q} \); then \( q \) corresponds to a point \( y \in U \cap X(x) \) which is different from \( x \), and is a proper specialization of \( z \) in \( X(x) \), which is impossible, since by assumption \( z \) is closed in \( U \).

Theorem 11.5.42. In the situation of 11.5.39, let \( i \in \mathbb{Z} \) be any integer, and consider the following conditions:

(a) \( I \cdot R^j \Gamma_{\{x\}} K^*|_{X(x)} = 0 \) for every \( x \in U_1 \).
(b) \( I^{d(K^*)} \cdot H^i(U, K^*) \) is an \( A \)-module of finite type.
(c) \( I \cdot H^j(U, K^*) \) is an \( A \)-module of finite type, for every \( j \leq i \).
(d) \( I^c(x) \cdot R^j \Gamma_x K_{|U(x)} = 0 \) for every \( x \in U \) and every \( j \leq i \).

Then (a) \( \Rightarrow \) (b) and (c) \( \Rightarrow \) (d).

**Proof.** (a) \( \Rightarrow \) (b): By corollary 10.3.37, we may find an object \( L^\bullet \) of \( D^b(\mathcal{O}_X \text{-Mod})_{\text{coh}} \) with an isomorphism \( L_{|U}^\bullet \sim \sim K^\bullet \) in \( D^b(\mathcal{O}_U \text{-Mod})_{\text{coh}} \), whence an exact sequence

\[
H^i(X, L^\bullet) \to H^i(U, K^\bullet) \to R^{i+1} \Gamma_Z L^\bullet \to H^{i+1}(X, L^\bullet)
\]

(see (10.4.1)) whose first and last terms are finitely generated \( A \)-modules. By an easy diagram chase, it follows that condition (b) is equivalent to

\[ (11.5.45) \]

\[ \text{is an isomorphism in } D \]

where \( \Gamma_Z \) is the dualizing functor on \( D^b(\mathcal{O}_X \text{-Mod})_{\text{coh}} \), defined by \( \omega^\bullet \). By choosing an injective resolution for \( \omega^\bullet \), we obtain a spectral sequence

\[
E_2^{pq} := R^p \mathcal{H}om \omega^\bullet(\mathcal{O}_X L^\bullet)[0], \omega^\bullet) \Rightarrow R^{p+q} \mathcal{H}om \omega^\bullet(\mathcal{O}_X L^\bullet, \omega^\bullet).
\]

Now, for every \( q \in \mathbb{Z} \), define the \( \mathcal{O}_X \)-module \( \mathcal{H}^{-q} \) by the short exact sequence

\[
0 \to \Gamma_Z H^{-q}(\mathcal{O}_X L^\bullet) \to H^{-q}(\mathcal{O}_X L^\bullet) \to \mathcal{H}^{-q} \to 0.
\]

There results an exact sequence

\[ (11.5.43) \]

\[
F^{pq} := R^p \mathcal{H}om \omega^\bullet(\mathcal{H}^{-q}[0], \omega^\bullet) \to E_2^{pq} \to G^{pq} := R^p \mathcal{H}om \omega^\bullet(\Gamma_Z H^{-q}(\mathcal{O}_X L^\bullet)[0], \omega^\bullet)
\]

**Claim 11.5.44.** For every \( p, q \in \mathbb{Z} \) we have:

(i) \( E_2^{pq} \) and \( F^{pq} \) are quasi-coherent \( \mathcal{O}_X \)-modules.

(ii) \( G^{pq} \) and \( \mathcal{H}^{-q} \) are coherent \( \mathcal{O}_X \)-modules.

**Proof of the claim.** The assertions about \( E_2^{pq} \) and \( F^{pq} \) follow immediately from lemmata 10.4.17(i) and 10.4.13(iii) and corollary 10.3.2(ii), and the assertion for \( \mathcal{H}^{-q} \) follows from lemma 10.4.17(ii). Next, notice that the natural map

\[
\Gamma_Z H^{-q}(\mathcal{O}_X L^\bullet) \to R \Gamma Z \circ \Gamma_Z H^{-q}(\mathcal{O}_X L^\bullet)
\]

is an isomorphism in \( D(\mathcal{O}_X \text{-Mod}) \), whence an isomorphism of \( \mathcal{O}_X \)-modules

\[ (11.5.45) \]

\[ G^{pq} \sim R^p \mathcal{H}om \omega^\bullet(\Gamma_Z H^{-q}(\mathcal{O}_X L^\bullet)[0], \omega^\bullet) \]

(lemma 10.4.13(vi)). But since \( X \) is noetherian, \( \Gamma_Z H^{-q}(\mathcal{O}_X L^\bullet) \) is a coherent \( \mathcal{O}_X \)-module, so the same holds for the target of \( (11.5.45) \) (proposition 10.3.3(ii)), and the claim follows.

**Claim 11.5.46.** In order to show (e), it suffices to check that:

(i) \( I \cdot F^{pq} = 0 \) for every \( p, q \in \mathbb{Z} \) such that \( p + q = i + 1 \).

(ii) \( F_x^{pq} = 0 \) for every \( x \in X \) and every \( p \in \mathbb{Z} \) such that \( p \notin [c_X(x) - \dim \partial U(x), c_X(x)] \).

**Proof of the claim.** Say that \( \mathcal{O}_X L^\bullet \in D^{[a,b]}(\mathcal{O}_X \text{-Mod}) \) for some \( a, b \in \mathbb{Z} \) with \( a \leq b \); to begin with, we show that – under assumptions (i) and (ii) of the claim – there exist for every \( q = a, \ldots, b \) and every \( p = i + 1 - b, \ldots, i + 1 - a \) and \( x \in X \), integers \( \nu(q), \mu(p, x) \in \mathbb{N} \) such that \( I^{\nu(q)} F^{pq} = 0 \) and \( I^{\mu(p, x)} F_x^{pq} = 0 \), and moreover

\[ (11.5.47) \]

\[
\sum_{q=a}^{b} \nu(q) \leq n(K^\bullet) \quad \sum_{p=i+1-b}^{i+1-a} \mu(p, x) \leq 1 + \delta(x) \quad \text{for every } x \in X.
\]
Indeed, if \( q \in [a, b] \) is an index such that \( H^{-q}(\mathcal{O}_U K^*) = 0 \), it follows that \( H^{-q}(\mathcal{O}_X L^*)|_U = 0 \), so \( \mathcal{H}^{-q} = 0 \), therefore \( F^{pq} = 0 \) for every \( p \in \mathbb{Z} \), and we may take \( \nu(q) = 0 \) in this case. But assumption (i) says that in any case we may take \( \nu(q) \leq 1 \) for every \( q = a, \ldots, b \). This already suffices to achieve the sought upper bound for the sum of the values \( \nu(q) \). The other upper bound is treated similarly: we may in any case take \( \mu(p, x) \leq 1 \), due to condition (i), and moreover condition (ii) says that we may take \( \mu(p, x) = 0 \) for every \( p \in \mathbb{Z} \) such that \( p \notin [c_X(x) - \dim \partial U(x), c_X(x)] \), whence the contention.

Next, recall that \( M := R^{1+\sum b}L^* \) admits a finite filtration \( \text{Fil}^*M \) whose associated graded \( \mathcal{O}_X \)-module is \( \bigoplus_{q=i+1}^{q+1} E_{pq}^q \), and by construction, each term \( E_{pq}^q \) is a quasi-coherent subquotient of \( E_{pq}^q \) (claim \( 11.5.44(i) \)), so \( \text{Fil}^*M \) is a quasi-coherent \( \mathcal{O}_X \)-module as well, for every \( q = a, \ldots, b \). Using claims \( 11.5.38 \) and \( 11.5.44(i,ii) \) we deduce that \( I^{(q)} \) is a coherent \( \mathcal{O}_X \)-module for every \( q = a, \ldots, b \), so the same holds for \( I^{(q)} \), and then \( (11.5.47) \) and lemma \( 11.5.37 \) imply that \( I^{n(K^*)}M \) is a coherent \( \mathcal{O}_X \)-module.

Set \( \delta := \dim \mathcal{O}_X \in \mathbb{N} \cup \{\infty\} \); if \( \delta \geq n(K^*) - 1 \), the proof is complete; otherwise \( \delta \in \mathbb{N} \), and it remains only to check that \( I^{1+\delta}M \) is also a coherent \( \mathcal{O}_X \)-module. To this aim, notice that \( (11.5.43) \) induces a short exact sequence

\[
0 \to F^{pq} \to E^{pq} \to G^{pq} \to 0
\]

where \( F^{pq} \) (resp. \( G^{pq} \)) is a certain quasi-coherent subquotient of \( F^{pq} \) (resp. of \( G^{pq} \)); from claim \( 11.5.44(ii) \) it follows that \( G^{pq} \) is a coherent \( \mathcal{O}_X \)-module, and the foregoing implies that \( F^{pq} = 0 \) for every \( x \in X \) and every \( p = i + 1 - b, \ldots, i + 1 - a \). We may then find, for every \( q = a, \ldots, b \) a coherent \( \mathcal{O}_X \)-submodule \( N^q \subset \text{Fil}^*M \) such that the induced morphism \( \text{Fil}^*M \to G^{pq} \) restricts to an epimorphism \( N^q \to G^{pq} \). Set \( N := \sum_{q=a}^b N^q \subset M \), and moreover condition (ii) says that we may take \( \mu(P, x) = 0 \) for every \( p \in \mathbb{Z} \) such that \( p \notin [c_X(x) - \dim \partial U(x), c_X(x)] \), so the same holds for \( I^{(q)} \), and then \( (11.5.47) \) and lemma \( 11.5.37 \) to conclude the proof.

Let \( \mathcal{B}^* \) be the residual complex arising from \( \omega^* \), introduced in \( (11.3.53) \). With this notation, \( F^{pq} \) is a subquotient of the \( \mathcal{A} \)-module \( \text{Hom}_{\mathcal{O}_X}(\mathcal{H}^{-q}, \Gamma_Z \mathcal{B}^p) \). From lemma \( 10.4.4(iii,b) \), we get

\[
\Gamma_Z \mathcal{B}^p = \bigoplus_{x \in X|Z \cap X^*} E(x)^\circ \quad \text{with} \quad X_p := \{x \in X \mid c_X(x) = p\} \quad \text{for every} \quad p \in \mathbb{Z}
\]

where \( c_X : |X| \to \mathbb{Z} \) is the weak codimension function associated with \( \omega^* \) as in \( (11.3.49) \) and \( E(x) \) is an injective hull of the \( \mathcal{A} \)-module \( \kappa(x) \), for every \( x \in X \) (notation of \( (10.3) \)). Hence, denote by \( X_p \) the set of all specializations in \( X \) of the points of \( X_p \); we deduce

\[
(11.5.48) \quad \text{Supp} \Gamma_Z \mathcal{B}^p = Z \cap X_p
\]

(we caution the reader that \( X_p \) is usually not a pro-constructible subset of \( X \), so \( X_p \) is usually strictly contained in the topological closure of \( X_p \) in \( X \)). Moreover, since \( \mathcal{H}^{-q} \) is a coherent \( \mathcal{O}_X \)-module (claim \( 11.5.44(ii) \)) and \( \Gamma_Z \mathcal{B}^p \) is quasi-coherent (lemma \( 10.4.17(i) \)), we also see that

\[
(11.5.49) \quad \text{Hom}_{\mathcal{O}_X}(\mathcal{H}^{-q}, \Gamma_Z \mathcal{B}^p)_x \simeq \text{Hom}_{\mathcal{O}_X}(\mathcal{H}^{-q}_x, (\Gamma_Z \mathcal{B}^p)_x) \quad \text{for every} \quad x \in X
\]

(58, Lemma 2.4.29(i,ii)). Combining \( (11.5.48) \) and \( (11.5.49) \) we conclude that

\[
\text{Supp} F^{pq} \subset Z \cap X_p \cap \text{Supp} \mathcal{H}^{-q}.
\]

From this, we can already show condition (ii) of claim \( 11.5.46 \): indeed, say that \( F^{pq} \neq 0 \); then \( x \in X_p \), so \( c_X(x) \geq p \), and on the other hand, by construction we have \( \Gamma_Z \mathcal{H}^{-q} = 0 \), so
Supp $H^{-q}$ is the topological closure in $X$ of $U \cap \text{Supp } \overline{H}^{-q}$, therefore $x \in \partial U$ and furthermore there exists a generalization $z$ of $x$ in $X$ with $c_X(z) = p$, so $z \in X_p \cap \partial U(x)$, which forces the bound $c_X(x) \leq p + \dim \partial U(x)$, as required.

Lastly, to get condition (i) of claim [11.5.46] it suffices to check assertions (i) and (ii) of the following:

**Claim 11.5.50.** (i) $\text{Supp } (I \cdot F_{pq}) \subseteq \text{Supp } \mathcal{H}om_{\mathcal{O}_x}(I \cdot \overline{H}^{-q}, \Gamma_\mathcal{O}_x^p)$ for every $p, q \in \mathbb{Z}$.

(ii) $\mathcal{H}om_{\mathcal{O}_x}(I \cdot \overline{H}^{-q}, \Gamma_\mathcal{O}_x^p) = 0$ whenever $p + q = i + 1$.

(iii) $Z \cap X_p \cap \text{Supp } (I \cdot \overline{H}^{-q}) = \emptyset$ whenever $p + q = i + 1$.

**Proof of the claim.** (i): Consider arbitrary $x \in X$, $a \in I$ and $f \in F_{pq}$; by virtue of [11.5.49], the element $f$ is represented by an $\mathcal{O}_{X,x}$-linear map $\varphi : \overline{H}^{-q} \to \Gamma_\mathcal{O}_x^p$, and therefore $af$ is represented by $a \varphi$; the latter obviously factors through the submodule $I \cdot \overline{H}^{-q}$, so the contention follows from the natural identification

$$\mathcal{H}om_{\mathcal{O}_x}(I \cdot \overline{H}^{-q}, \Gamma_\mathcal{O}_x^p)_x \simeq \mathcal{H}om_{\mathcal{O}_{X,x}}(I \cdot \overline{H}^{-q}, (\Gamma_\mathcal{O}_x^p)_x)$$

for every $x \in X$ which is proven as [11.5.49].

(ii): Let $x \in X$ be any point, and $\varphi : I \cdot \overline{H}^{-q} \to (\Gamma_\mathcal{O}_x^p)_x$ any $\mathcal{O}_{X,x}$-linear map; taking into account [11.5.51], we are reduced to showing that $\varphi = 0$. Now, notice that

$$\left(\Gamma_\mathcal{O}_x^p\right)_x = \bigoplus_{y \in Z(x)_p} E(y) \quad \text{where } Z(x)_p := X_p \cap Z \cap X(x).$$

If $Z(x)_p = \emptyset$, we are done; otherwise, for every $y \in Z(x)_p$ denote by $p_y : \left(\Gamma_\mathcal{O}_x^p\right)_x \to E(y)$ the natural projection; it suffices to check that $p_y \circ \varphi = 0$ for every such $y$. However, $p_y \circ \varphi$ factors through an $\mathcal{O}_{X,y}$-linear map $I \cdot \overline{H}^{-q} \to \left(\Gamma_\mathcal{O}_x^p\right)_y$, so we may replace $x$ by $y$, and assume from start that $x \in X_p \cap Z$, in which case the contention will follow from assertion (iii) of the claim.

(iii): Fix any point $y \in X_p \cap Z$. We have already noticed that $\text{Supp } \overline{H}^{-q}$ is the topological closure in $X$ of $U \cap \text{Supp } \overline{H}^{-q}$; we are then reduced to showing that $I \cdot \overline{H}^{-q} = 0$ for every closed point $z$ of $X(y) \cap U$. But for any such $z$, we have an isomorphism

$$H^{-q}(\mathcal{O}_U \cdot K^*)_z \simeq \overline{H}^{-q}_z$$

of $\mathcal{O}_{X,z}$-modules. On the other hand, corollary [11.5.17](iii) yields an isomorphism of $\mathcal{O}_{X,z}$-modules

$$\mathcal{O}_{X,z}^\wedge \otimes_{\mathcal{O}_{X,z}} H^{-q}(\mathcal{O}_U \cdot K^*)_z \simeq D_z \circ R^{q+c_X(z)}(\Gamma_z) K^*_{U(z)}$$

where $\mathcal{O}_{X,z}^\wedge$ denotes the completion of the ring $\mathcal{O}_{X,z}$ and $D_z$ denotes the local duality functor corresponding to the point $z$. We remark now that

$$c_X(z) = c_X(y) - 1 = p - 1.$$

Indeed, in view of lemma [11.3.50], identity [11.5.54] asserts that $y$ is an immediate specialization of $z$ in $X(y)$, and this is already known from lemma [11.5.40].

Finally, let $a \in I$ be any element; taking into account [11.5.52], we are reduced to checking that scalar multiplication by $a$ is the zero endomorphism of $H^{-q}(\mathcal{O}_U \cdot K^*)_z$, which – by virtue of [11.5.53] and [11.5.54] – is equivalent to showing that scalar multiplication by $a$ is the zero endomorphism on $R^\Gamma_z K^*_{U(z)}$, and the latter is ensured by our condition (a).

(c)⇒(d): Let $x \in U_1$, be any point, pick any immediate specialization $y \in \partial U$ of $x$ in $X$ such that $1 + \dim \partial U(y) = e(x)$, let $U(y) := U \cap X(y)$, and notice that the natural map

$$H^3(U, K^*) \otimes_A \mathcal{O}_{X,y} \to H^3(U(y), K^*_{U(y)})$$
is an isomorphism for every \( j \in \mathbb{Z} \), so we may replace \( X \) by \( X(y) \), \( U \) by \( U(y) \) and \( K^\bullet \) by \( K^\bullet_{U(y)} \) and assume from start that \( A \) is a local ring, and \( y \) is the closed point of \( X \). In this situation, we need to show that \( I^e R^j \Gamma_{\{x\}} K^\bullet_{U(x)} = 0 \), with \( e := 1 + \dim \partial U \) and every \( j \leq i \). Then, let \( V := X \setminus \{ y \} \), denote \( j : U \to V \) the induced open immersion, and set

\[
L^\bullet := \tau^{\leq i} R_j K^\bullet
\]

(where \( \tau^{\leq i} \) denotes the usual truncation functor), so that \( L \in \text{Ob}(D^b(\mathcal{O}_V\text{-Mod})_{\text{qcoh}}) \) and \( L^\bullet_{|U} = \tau^{\leq i} K^\bullet \). Notice also that the natural morphism of \( \mathcal{O}_X\text{-modules} \)

\[
H^j(U, K^\bullet) \to H^j L^\bullet
\]

is an isomorphism for every \( j \leq i \). Taking into account proposition \([10.3.32]\) (ii), it follows that we may find a morphism \( \varphi^\bullet : C^\bullet \to L^\bullet \) in \( D^b(\mathcal{O}_X\text{-Mod}) \) such that

- \( C^\bullet \in \text{Ob}(D^b(\mathcal{O}_X\text{-Mod})_{\text{coh}}) \).
- The induced morphism \( C^\bullet_{|U} \to \tau^{\leq i} K^\bullet_{|U} \) is an isomorphism in \( D^b(\mathcal{O}_U\text{-Mod})_{\text{coh}} \).
- \( H^j \varphi^\bullet : H^j C^\bullet \to H^j L^\bullet \) is a monomorphism for every \( j \in \mathbb{Z} \), and its image contains the \( \mathcal{O}_X\)-submodule \( I \cdot H^j(U, K^\bullet)^{\leq i} \), for every \( j \leq i \).

Set \( D^\bullet := \text{Cone}(\varphi) \); by construction, for every \( j \in \mathbb{Z} \) we have

\[
(11.5.55) \quad \text{Supp } H^j L^\bullet \subset \overline{U} \cap V \quad \text{Supp } H^j D^\bullet \subset Z \cap \text{Supp } H^j L^\bullet \subset \partial U \cap V \quad I \cdot H^j D^\bullet = 0.
\]

Now, consider the spectral sequence

\[
E^{pq}_2 := H^p(V, H^q D^\bullet) \Rightarrow H^{p+q}(V, D^\bullet).
\]

It follows from \((11.5.55)\) that \( E^{pq}_2 = 0 \) for every \( p > \dim \partial U \cap V + 2 \), and \( I \cdot E^{pq}_2 = 0 \) for every \( p, q \in \mathbb{Z} \), whence

\[
I^{e-1} H^j(V, D^\bullet) = 0 \quad \text{for every } j \in \mathbb{Z}.
\]

On the other hand, we have an exact sequence of \( A\)-modules

\[
H^{j-1}(V, D^\bullet) \to H^j(V, C^\bullet) \to H^j(V, L^\bullet) = H^j(U, K^\bullet) \quad \text{for every } j \leq i.
\]

In view of lemma \([11.5.37]\), we conclude that \( I^e R^j \Gamma_{\{x\}} C^\bullet_{|U(x)} = 0 \) for every \( j \leq i \) (theorem \([11.5.24]\)). To conclude the proof, it now suffices to observe that the natural map \( R^j \Gamma_{\{x\}} K^\bullet_{|U(x)} \to R^j \Gamma_{\{x\}} K^\bullet_{U(x)} \) is an isomorphism, for every \( j \leq i \).

**Corollary 11.5.56.** In the situation of \((11.5.39)\), for every \( i \in \mathbb{Z} \) we have:

(i) If \( R^i \Gamma_{\{x\}} K^\bullet = 0 \) for every \( x \in U_1 \), then \( H^i(U, K^\bullet) \) is an \( A\)-module of finite type.

(ii) The following conditions are equivalent:

(a) \( R^i \Gamma_{\{x\}} K^\bullet = 0 \) for every \( x \in U_1 \) and every \( j \leq i \).

(b) \( H^j(U, K^\bullet) \) is an \( A\)-module of finite type for every \( j \leq i \).

**Proof.** It is the special case of theorem \([11.5.42]\) with \( I := A \). \( \square \)

11.6. **Hochster’s theorem and Stanley’s theorem.** The two main results of this section are theorems \([11.6.34]\) and \([11.6.42]\), which were proved originally respectively by Hochster in \([74]\), and by Stanley in \([119]\). Our proofs follow in the main the posterior methods presented by Bruns and Herzog in \([36]\) (which in turns, partially rely on some ideas of Danilov). These results shall be used in section \([12.5]\) in order to show that regular log schemes are Cohen-Macaulay. We begin with some preliminaries from algebraic topology, which we develop only to the extent that is required for our special purposes: a much more general theory exists, and is well known to experts (see e.g. \([98]\) Ch. IX).

For any topological space \( X \), and any subset \( T \subset X \), we denote by \( \overline{T} \) the topological closure of \( T \) in \( X \), endowed with the topology induced from \( X \). We let \( H_\bullet(X) \) (resp. \( H_\bullet(X, T) \)) be the
singular homology groups of $X$ (resp. of the pair $(X,T)$). Also, for every $n \in \mathbb{N}$ fix a Banach norm $\| \cdot \|$ on $\mathbb{R}^n$, and for every real number $\rho > 0$, let $\mathbb{B}^n(\rho) := \{ v \in \mathbb{R}^n \mid \|v\| < \rho \}$, and set $\mathbb{S}^{n-1} := \mathbb{B}^n(1) \setminus \mathbb{B}^n(1)$ (so $\mathbb{S}^{-1} = \emptyset$).

**Definition 11.6.1.** (i) A finite regular cell complex (or briefly : a cell complex) is the datum of a topological space $X$, together with a finite filtration

$$X^{-1} := \emptyset \subset X^0 \subset X^1 \subset X^2 \subset \cdots \subset X^k := X$$

consisting of closed subspaces, such that $X^0$ is a discrete topological space, and for every $i = 0, \ldots , k$ we have a decomposition

$$X^i \setminus X^{i-1} = \bigcup_{\lambda \in \Lambda_i} e^i_{\lambda}$$

where :

(a) $\Lambda_i$ is a finite set, and for every $\lambda \in \Lambda_i$ there exists a homeomorphism

$$f^i_\lambda : \mathbb{B}^i(1) \overset{\sim}{\rightarrow} \mathbb{S}^i_\lambda$$

such that $f^{-1}_\lambda (e^i_{\lambda}) = \mathbb{B}^i(1)$.

(b) $e^i_{\lambda} \cap e^i_{\mu} = \emptyset$ for any two distinct indices $\lambda, \mu \in \Lambda_i$.

(c) $\mathbb{S}^i_\lambda \setminus e^i_{\lambda} \subset X^{i-1}$ for every $\lambda \in \Lambda_i$.

(ii) The smallest $k \in \mathbb{N}$ such that $X^k = X$ is called the dimension of $X^*$, and is denoted $\dim X^*$. For every $i = 0, \ldots , k$, the subsets $e^i_{\lambda}$ are called the $i$-dimensional cells of $X^*$.

(iii) A subcomplex of the cell complex $X^*$ is a closed subset $Y \subset X$ which is a union of cells of $X$. Then the filtration such that $Y^i := Y \cap X^i$ for every $i \geq -1$ defines a cell complex structure $Y^*$ on $Y$.

**Lemma 11.6.2.** With the notation of definition 11.6.1, we have:

(i) For every $i = 0, \ldots , \dim X$ and $q \in \mathbb{Z}$, we have natural isomorphisms of abelian groups :

$$H_q(X^i, X^{i-1}) \overset{\sim}{\rightarrow} \begin{cases} \mathbb{Z}^{\Lambda_i} & \text{if } q = i \\ 0 & \text{otherwise} \end{cases}$$

(ii) More precisely, let $(b_{\lambda} \mid \lambda \in \Lambda_i)$ be the canonical basis of the free $\mathbb{Z}$-module $\mathbb{Z}^{\Lambda_i}$; for every $\lambda \in \Lambda_i$, the isomorphism of (i) maps the image of the induced map

$$H_i f^i_\lambda : H_i(\mathbb{B}^i(1), \mathbb{S}^{i-1}) \rightarrow H_i(X^i, X^{i-1})$$

isomorphically onto the direct summand generated by $b_{\lambda}$.

**Proof.** (i): This is obvious for $i = 0$. For $i = 1, \ldots , k := \dim X^*$ and every $\lambda \in \Lambda_i$, set

$$Y^i_\lambda := f^i_\lambda (\mathbb{B}^i(1/2)) \quad Y^i := \bigcup_{\lambda \in \Lambda_i} Y^i_\lambda \quad A^i := \bigcup_{\lambda \in \Lambda_i} \{ f^i_\lambda(0) \}$$

and for any $q \in \mathbb{Z}$, consider the natural group homomorphisms

$$H_q(\mathbb{B}^i(1/2), \mathbb{B}^i(1) \setminus \{ 0 \}) \overset{\alpha'}{\longrightarrow} H_q(\mathbb{B}^i(1), \mathbb{B}^i(1) \setminus \{ 0 \}) \overset{\beta'}{\longrightarrow} H_q(\mathbb{B}^i(1), \mathbb{S}^{i-1})$$

$$\downarrow \quad \gamma \quad \downarrow \quad \beta$$

$$H_q(Y^i, Y^i \setminus A^i) \overset{\alpha}{\longrightarrow} H_q(X^i, X^i \setminus A^i)$$

The map $\alpha$ is an isomorphism, by excision; the same holds for $\beta$, since $X^{i-1}$ is a deformation retract of $X^i \setminus A^i$. However, for every $\lambda \in \Lambda_i$ we have natural isomorphisms

$$H_q(Y^i_\lambda, Y^i_\lambda \setminus A) \overset{\sim}{\rightarrow} \begin{cases} \mathbb{Z} & \text{if } q = i \\ 0 & \text{otherwise} \end{cases}$$
whence the contention.

(ii): Take \( q := \ell \) in (11.6.3); then clearly \( \gamma \) is a monomorphism whose image is the direct summand \( H_i(Y'_\lambda, Y'_\lambda \setminus A) \); on the other hand, arguing as in the foregoing, we see that both \( \alpha' \) and \( \beta' \) are isomorphisms. The assertion follows easily. \( \square \)

**Remark 11.6.4.** (i) In the situation of lemma 11.6.2, notice that there is a natural bijection from \( \Lambda_i \) to the set of connected components \( \pi_0(X^i \setminus X^{i-1}) \) of \( X^i \setminus X^{i-1} \), for every \( i = 0, \ldots, \dim X \).

(ii) The direct sum decomposition of \( H_i(X^i, X^{i-1}) \) provided by lemma 11.6.2(ii) depends only on the filtration \( X^* \) (and not on the choice of homeomorphisms \( f_\lambda \)). Indeed, this is clear, since the map \( H_i f_\lambda \) factors as a composition:

\[
H_i(\mathbb{B}_1, S^{i-1}) \xrightarrow{\epsilon} H_i(\overline{\tau}_\lambda, \overline{\tau}_\lambda \setminus e_i^j) \xrightarrow{\lambda} H_i(X^i, X^{i-1})
\]

where \( \lambda \) is the homomorphism induced by the obvious map of pairs \((\overline{\tau}_\lambda, \overline{\tau}_\lambda \setminus e_i^j) \to (X^i, X^{i-1}) \).

(iii) In view of (ii), the maps \( l_\lambda \) admit natural left inverse homomorphisms

\[
p_\lambda : H_i(X^i, X^{i-1}) \to H_i(\overline{\tau}_\lambda, \overline{\tau}_\lambda \setminus e_i^j)
\]

such that

\[
p_\mu \circ l_\lambda = 0 \quad \text{for every } \lambda, \mu \in \Lambda_i \text{ with } \lambda \neq \mu.
\]

These maps can be described as follows. For any \( \lambda \in \Lambda_i \), the natural map of pairs \((X^i, X^{i-1}) \to (X^i, X^i \setminus e_i^j) \) induces a homomorphism

\[
m_\lambda : H_i(X^i, X^{i-1}) \to H_i(X^i, X^i \setminus e_i^j).
\]

Arguing by excision as in the proof of lemma 11.6.2(ii), it is easily seen that \( q_\lambda := m_\lambda \circ l_\lambda \) is an isomorphism (details left to the reader), and we set \( p_\lambda := q_\lambda^{-1} \circ m_\lambda \). Obviously \( p_\lambda \) is left inverse to \( l_\lambda \), and in order to check (11.6.5) it suffices to show that \( m_\mu \circ l_\lambda = 0 \) for every \( \mu \neq \lambda \). However, \( m_\mu \circ l_\lambda \) is the homomorphism arising from the map of pairs \((\overline{\tau}_\lambda, \overline{\tau}_\lambda \setminus e_i^j) \to (X^i, X^i \setminus e_i^\mu) \), so the assertion follows, after remarking that \( \overline{\tau}_\lambda \subset X^i \setminus e_i^\mu \).

11.6.6. We attach to any cell complex \( X^* \) a complex of abelian groups \( \mathcal{C}_i(X^*) \), as follows.

- For \( i < 0 \) and for \( i > k := \dim X^* \), we set \( \mathcal{C}_i(X^*) := 0 \), and for \( i = 1, \ldots, k \) we let

\[
\mathcal{C}_i(X^*) := H_i(X^i, X^{i-1}).
\]

Sometimes we write just \( \mathcal{C}_i(X) \), unless it is useful to stress which filtration \( X^* \) on \( X \) we are considering. For every \( i > 0 \), the differential \( d_i : \mathcal{C}_i(X^*) \to \mathcal{C}_{i-1}(X^*) \) is the composition

\[
H_i(X^i, X^{i-1}) \xrightarrow{\partial_i} H_{i-1}(X^{i-1}) \xrightarrow{j_{i-1}} H_{i-1}(X^{i-1}, X^{i-2})
\]

where \( \partial_i \) is the boundary operator of the long exact homology sequence associated with the pair \((X^i, X^{i-1}) \), and \( j_{i-1} \) is the homomorphism induced by the obvious map of pairs \((X^{i-1}, \emptyset) \to (X^{i-1}, X^{i-2}) \). In order to check that \( d_i \circ d_{i+1} = 0 \) for every \( i \in \mathbb{Z} \), recall that every element of \( H_{i+1}(X^{i+1}, X^i) \) is the class \( \tau \) of a singular \((i + 1)\)-chain \( c \) of \( X^{i+1} \), whose boundary \( \partial_{i+1} c \) is a singular \( i \)-chain of \( X^i \); then \( d_{i+1}(\tau) \) is the class of \( \partial_{i+1} c \) in \( H_i(X^i, X^{i-1}) \), and \( d_i \circ d_{i+1}(\tau) \) is the class of \( \partial_i \circ \partial_{i+1} c \) in \( H_{i-1}(X^{i-1}, X^{i-2}) \), so it vanishes.

- It is also useful to consider an augmented version of the above complex; namely, let us set

\[
\overline{\mathcal{C}}_{-1}(X^*) := \mathbb{Z} \quad \text{and} \quad \overline{\mathcal{C}}_i(X^*) := \mathcal{C}_i(X^*) \quad \text{for every } i \neq -1
\]

with differential \( d_0 \) given by the rule: \( d_0(b^\lambda_0) = 1 \) for every \( \lambda \in \Lambda_0 \).

**Proposition 11.6.7.** With the notation of (11.6.6), there exist natural isomorphisms of abelian groups

\[
H_q \overline{\mathcal{C}}_i(X^*) \xrightarrow{\sim} H_q(X) \quad \text{for every } q \in \mathbb{N}.
\]
Lemma 11.6.9. \(\sigma\) attach to

Let (11.6.10. The generalities of the previous paragraphs shall be applied to the following situation. □

11.6.8. Keep the notation of definition 11.6.1 and set \(\Lambda_0 := X^0\). For every \(i = 0, \ldots, \dim X\) and every \(\lambda \in \Lambda_i\), the abelian group \(H_{i,\lambda} := H_0(\bar{\sigma}_\lambda^i \setminus \bar{e}_\lambda^i \setminus \bar{e}_\lambda^0)\) is free of rank one; if \(i > 0\), we fix one of the two generators of this group, and we denote by \(b_\lambda^i\) its image in \(\mathcal{C}_i(X^*)\) (see remark 11.6.4). For \(i = 0\), each \(e_\lambda^0\) is a point, hence \(H_{0,\lambda}\) admits a canonical identification with \(\mathbb{Z}\), and we let \(b_\lambda^0\) be the image of 1, under the resulting map \(\mathbb{Z} \xrightarrow{\sim} H_{0,\lambda} \rightarrow \mathcal{C}_0(X^*)\). The system of classes \((b_\lambda^i \vert 0 \leq i \leq \dim X, \lambda \in \Lambda_i)\) is called an orientation for \(X^*\). We may write

\[ d_i(b_\lambda^i) = \sum_{\mu \in \Lambda_{i-1}} [b_\lambda^i : b_\mu^{i-1}] b_\mu^{i-1} \quad \text{for every } i \leq \dim X^* \text{ and every } \lambda \in \Lambda_i \]

for a system of uniquely determined integers \([b_\lambda^i : b_\mu^{i-1}]\), called the incidence numbers of the cells \(e_\lambda^i\) and \(e_\mu^{i-1}\) (relative to the chosen orientation of \(X^*)\). With this notation, we may state:

Lemma 11.6.9. The incidence numbers of a cell complex \(X^*\) fulfill the following conditions:

(i) \(\sum_{\mu \in \Lambda_{i-1}} [b_\lambda^i : b_\mu^{i-1}] [b_\mu^{i-1} : b_\nu^{i-2}] = 0\) for every \(i \geq 2\), every \(\lambda \in \Lambda_i\) and every \(\nu \in \Lambda_{i-2}\).

(ii) Let \(\lambda \in \Lambda_1\) be any index, and say that \(\bar{\sigma}_\lambda^1 \setminus \bar{e}_\lambda^1 \setminus \bar{e}_\lambda^0\). Then \([b_\lambda^1 : b_\mu^0] + [b_\mu^0 : b_\lambda^1] = 0\).

Proof. Condition (i) translates the identity \(d_{i-1} \circ d_i = 0\) for the differential \(d^*_\bullet\) of the complex \(\mathcal{C}^*_\bullet(X^*)\). The identity of (ii) follows by a simple inspection of the definition of \(d_1\) details left to the reader. □

11.6.10. The generalities of the previous paragraphs shall be applied to the following situation. Let \((V, \sigma)\) be a strictly convex polyhedral cone such that \(\langle \sigma \rangle = V\), and set \(d := \dim_\mathbb{R} V\). We attach to \(\sigma\) a cell complex \(\mathcal{C}^*_\sigma\) as follows. Fix \(u_0 \in \sigma^\circ\) such that \(\sigma \cap \text{Ker} u_0 = \{0\}\) (corollary 6.3.14). Let \(\sigma^\circ\) be the topological interior of \(\sigma\) (in \(V\)) and set

\[ C_\sigma := \sigma \cap u_0^{-1}(1) \quad C'^\circ_\sigma := \sigma^\circ \cap u_0^{-1}(1). \]

Let \(v_1, \ldots, v_k\) be a minimal system of generators for \(\sigma\); we may assume that \(u_0(v_i) = 1\) for \(i = 1, \ldots, k\), in which case

\[ C_\sigma = \left\{ \sum_{i=1}^k \lambda_i v_i \mid \lambda_1, \ldots, \lambda_k \geq 0 \quad \text{and} \quad \sum_{i=1}^k \lambda_i = 1 \right\} \]

which shows that \(C_\sigma\) is a compact topological space (with the topology inherited from \(V\)).

Lemma 11.6.12. There exists a homeomorphism \(\mathbb{B}^{d-1}(1) \cong C_\sigma\) that maps \(\mathbb{B}^{d-1}(1)\) onto \(C'^\circ_\sigma\).

Proof. Set \(v_0 := k^{-1} \cdot (v_1 + \cdots + v_k)\) and \(W := \text{Ker} u_0\). It suffices to show that there exists a homeomorphism \(\mathbb{B}^{d-1}(1) \cong D_\sigma := C_\sigma - v_0 \subset W\) that maps \(\mathbb{B}^{d-1}(1)\) onto \(D'^\circ_\sigma := C'^\circ_\sigma - v_0\). However, pick a minimal system \(u_1, \ldots, u_t\) of generators of \(\sigma^\circ\) (corollary 6.3.12)); since \(\sigma\) spans \(V\), for every \(i = 1, \ldots, t\) there exists \(j \leq k\) such that \(u_i(v_j) > 0\). Hence – after replacing the \(u_i\) by suitable scalar multiples – we may assume that \(u_i(v_0) = 1\) for every \(i = 1, \ldots, t\), and then lemma 6.3.2 implies that

\[ D_\sigma = \{ v \in W \mid u_i(v) \geq -1 \quad \text{for every } i = 1, \ldots, t \}. \]
Also, proposition 6.3.11(i) implies that
\[ D^i_\sigma = \{ v \in W \mid u_i(v) > -1 \} \text{ for every } i = 1, \ldots, t. \]

For every \( v \in W \), set \( \mu(v) := \min(u_i(v) \mid i = 1, \ldots, t) \). It is easily seen that \( \mu(v) < 0 \) for every \( v \in W \setminus \{0\} \); indeed, if \( \mu(v) \geq 0 \), then the subset \( \{ \lambda w \mid \lambda \in \mathbb{R}_+ \} \) lies in \( D_\sigma \), and since the latter is compact, it follows that \( w = 0 \). Moreover we have
\[
(11.6.13) \quad (\mathbb{R}_+ \cap D_\sigma) = \{ \lambda w \mid \lambda \in [0, -1/\mu(w)] \} \quad \text{for every } w \in W \setminus \{0\}.
\]

Fix a Banach norm \( \| \cdot \|_V \) on \( V \), and consider the mapping
\[
\varphi : D_\sigma \to W \quad \text{such that } \varphi(0) := 0 \text{ and } \varphi(v) := -\frac{\mu(v)}{\|v\|} \cdot v \text{ for } v \neq 0.
\]

It is easily seen that \( \varphi \) is injective; since \( \mu \) is a continuous mapping, the same follows for \( \varphi \), and since \( D_\sigma \) is compact, we conclude that \( \varphi \) induces a homeomorphism \( D_\sigma \to \varphi(D_\sigma) \). However, from (11.6.13) it follows that
\[
\varphi(D_\sigma) = \{ v \in W \mid \|v\| \leq 1 \} \quad \text{and} \quad \varphi(D^i_\sigma) = \{ v \in W \mid \|v\| < 1 \}
\]
whence the claim. \( \square \)

11.6.14. Keep the notation of (11.6.10); we consider the finite filtration \( C^*_\sigma \) of \( C_\sigma \), defined as follows. For every \( i = -1, \ldots, d - 1 \), we let \( C^i_\sigma \subset C_\sigma \) be the union of the subsets \( \tau \cap u_{i-1}^{-1}(1) \), where \( \tau \) ranges over the (finite) set of all faces of \( \sigma \) of dimension \( i + 1 \). Clearly \( C_{d-1}^i = \emptyset \), \( C_{i-1}^i = C_\sigma \), and \( C^i_\sigma \) is a closed subset of \( C_\sigma \), for every \( i = 0, \ldots, d - 1 \). Moreover, it follows easily from lemma 11.6.12 and proposition 6.3.11(i) that the datum of \( C_\sigma \) and its filtration \( C^*_\sigma \) is a cell complex. With the notation of definition 11.6.1, the indexing set \( \Lambda_i \) can be taken to be the set of all \( (i + 1) \)-dimensional faces of \( \sigma \), for every \( i = 0, \ldots, d - 1 \); indeed, if \( \tau \) is such a face, denote by \( \tau^0 \) the relative interior of \( \tau \) (see example 6.3.16(iii)); then it is clear that \( e^i_\tau := \tau^0 \cap C_\sigma \neq \emptyset \) and \( \tau^i_\tau = \tau \cap C_\sigma \).

Remark 11.6.15. (i) Notice that the cell complex \( C^*_\sigma \) is independent – up to homeomorphism – of the choice of \( u_0 \). Indeed, say that \( u'_0 \in \sigma^{\vee} \) is any other linear form such that \( \sigma \cap \text{Ker } u'_0 = \{0\} \), and let \( C'^i_\sigma := \sigma \cap u_0^{-1}(1) \). We define a homeomorphism \( \psi : C'_\sigma \to C_\sigma \), by the rule:
\[
v \mapsto u'_0(v)^{-1} \cdot v \quad \text{for every } v \in C'^i_\sigma.
\]
It is easily seen that \( \psi \) restricts to homeomorphisms \( C^i_\sigma \to C^i_\sigma \) for every \( i = 0, \ldots, d - 1 \).

(ii) For any integer \( i = 0, \ldots, d - 3 \), and any cells \( e^i_\tau, e^{i+2}_\lambda \) of \( C^*_\sigma \) such that \( e^i_\tau \subset \bar{e}^{i+2}_\lambda \), there exist exactly two \( (i + 1) \)-dimensional cells \( e^{i+1}_\mu, e^{i+1}_\rho \) such that \( e^i_\tau \subset \bar{e}^{i+2}_\mu \cap \bar{e}^{i+1}_\rho \) and \( e^{i+1}_\mu \cup e^{i+1}_\rho \subset \bar{e}^{i+2}_\lambda \); indeed, this assertion is a direct translation of claim 6.3.9(ii).

Proposition 11.6.16. With the notation of (11.6.8) and (11.6.14), the following holds for every \( i = 0, \ldots, d - 2 \):

(i) If \( \tau \in \Lambda_{i+1} \) and \( \mu \in \Lambda_i \) is not a facet of \( \tau \), we have \( [b^{i+1}_\tau : b^i_\mu] = 0 \).
(ii) If \( \tau \in \Lambda_{i+1} \) and \( \mu \in \Lambda_i \) is a facet of \( \tau \), then \( [b^{i+1}_\tau : b^i_\mu] \in \{1, -1\} \).
(iii) In the situation of remark 11.6.15(ii), we have:
\[
[b^{i+2}_\lambda : b^{i+1}_\mu] \cdot [b^{i+1}_\mu : b^i_\rho] + [b^{i+2}_\lambda : b^{i+1}_\rho] \cdot [b^{i+1}_\rho : b^i_\lambda] = 0.
\]

Proof. (i) Consider the commutative diagram
\[
(11.6.17) \quad H_{i+1}(\bar{e}^{i+1}_\tau, \bar{e}^{i+1}_\lambda \setminus \bar{e}^{i+1}_\mu) \xrightarrow{\partial} H_i(\bar{e}^{i+1}_\tau \setminus \bar{e}^{i+1}_\mu) \xrightarrow{j^*_\tau} H_i(C^i_\sigma, C^i_\sigma \setminus \bar{e}^{i+1}_\mu)
\]

\[
H_{i+1}(C^i_\sigma, C^i_\sigma) \xrightarrow{\partial^r} H_i(C^i_\sigma) \xrightarrow{j^*_i} H_i(C^i_\sigma, C^{i-1}_\sigma)
\]
where \( l_i \) and \( m_\mu \) are defined as in remark 11.6.4(ii,iii) and \( g \) is induced by the inclusion map \( \tilde{\tau}_{\tau}^{i+1} \setminus e_i^{j+1} \rightarrow C^0_\sigma \), the maps \( \partial \) and \( \partial' \) are the boundary operators of the long exact sequences attached to the pairs \((\tilde{\tau}_{\tau}^{i+1} \setminus e_i^{j+1}, \tilde{\tau}_{\tau}^{i+1})\) and \((C^0_\sigma, C^1_\sigma)\), and \( j_i \) (resp. \( j_\tau \)) is deduced from the obvious map of pairs \((\tilde{\tau}_{\tau}^{i+1} \setminus e_i^{j+1}, \emptyset) \rightarrow (C^0_\sigma, C^1_\sigma)\) (resp. \((C^0_\sigma, \emptyset) \rightarrow (C^1_\sigma, C^{-1}_\sigma)\)). In light of remark 11.6.4(iii), we need to check that \( m_\mu \circ j_{i-1} \circ \partial' \circ l_i = 0 \), and to this aim, it suffices to show that \( j_\tau = 0 \). However, the assumption implies that \( \mu \cap \tau \) is a (proper) face of both \( \mu \) and \( \tau \); this translates as the identity \((\tilde{\tau}_{\tau}^{i+1} \setminus e_i^{j+1}) \cap e^j_\mu = \emptyset\), whence the claim.

(ii): Clearly \( C^*_\tau \) is a cell subcomplex of \( C^*_\sigma \), and \( e_i^{j+1} \) and \( e^j_\mu \) are cells of this subcomplex. Moreover, any orientation for \( C^*_\tau \) restricts to an orientation for \( C^*_\sigma \), and the resulting incidence number of \( e_i^{j+1} \) and \( e^j_\mu \) is the same for either cell complex. Thus, we may replace \( \sigma \), by \( \tau \), in which case the map \( g \) of (11.6.17) is the identity.

Claim 11.6.18. If \( \sigma = \tau \) and \( i > 0 \), both \( \partial \) and \( k_\mu := m_\mu \circ j_i \) in (11.6.17) are isomorphisms.

Proof of the claim. For \( \partial \), we use the long exact homology sequence of the pair \((\tilde{\tau}_{\tau}^{i+1} \setminus e_i^{j+1}, \tilde{\tau}_{\tau}^{i+1})\); since \( i \geq 0 \), lemma 11.6.12 implies that \( H_{i+1}(\tilde{\tau}_{\tau}^{i+1}) = 0 \), so \( \partial \) is injective; since \( i > 0 \), the same argument shows that \( \partial \) is surjective. Next, \( k_\mu \) is the homomorphism deduced from the long exact homology sequence of the pair \((C^0_\sigma, C^1_\sigma \setminus e^j_\mu)\), and we remark that \( C^0_\mu \setminus e^j_\mu \) is contractible: indeed, \( e^j_i \) is homeomorphic to \( \mathbb{B}^1(1) \) (lemma 11.6.12), hence \( C^0_\mu \setminus e^j_\mu \) is a retraction of \( C^0_\mu \setminus \{x\} \), for any \( x \in e^j_\mu \), and the latter is homeomorphic to \( \mathbb{R}^1 \) (again by lemma 11.6.12). If \( i > 1 \), we deduce already that \( k_\mu \) is an isomorphism. For \( i = 1 \), the same argument shows that \( k_\mu \) is injective, so its cokernel is a cyclic torsion group that injects into \( H_0(C^0_\sigma \setminus e^j_\mu) \cong \mathbb{Z} \), hence it must vanish as well. Since (11.6.17) commutes, claim 11.6.18 yields the assertion, in case \( i > 0 \). If \( i = 0 \), \( C^0_\sigma \) is isomorphic to \( \mathbb{B}^1(1) \), and \( e^j_\mu \) is one of the two points of \( \mathbb{B}^1(1) \setminus \mathbb{B}^1(1) \), so the assertion can be checked easily, by inspecting the definitions. 

(iii) follows from (i), lemma 11.6.9(i) and remark 11.6.15(ii).

The following result says that the properties of proposition 11.6.16 completely characterize the incidence numbers of \( C^*_\sigma \).

Proposition 11.6.19. Keep the notation of (11.6.14), and consider a system of integers 

\[
(\beta^i_\lambda_\mu \mid i = 1, \ldots, d - 1, \lambda \in \Lambda_i, \mu \in \Lambda_{i-1})
\]

such that : 

(a) If \( \lambda \in \Lambda_i \) and \( \mu \in \Lambda_{i-1} \) is not a facet of \( \lambda \), then \( \beta^i_\lambda_\mu = 0 \).

(b) If \( \lambda \in \Lambda_i \) and \( \mu \in \Lambda_{i-1} \) is a facet of \( \lambda \), then \( \beta^i_\lambda_\mu \in \{1, -1\} \).

(c) If \( \mu \) and \( \tau \) are the two 1-dimensional facets of the 2-dimensional face \( \lambda \) of \( \sigma \), then 

\[
\beta^j_\lambda_\mu + \beta^i_\lambda_\tau = 0.
\]

(d) Let \( \lambda \in \Lambda_{i+1} \) and \( \mu \in \Lambda_{i-1} \) be two faces, such that \( \mu \) is a face of \( \lambda \), and denote by \( \tau \) and \( \rho \) the two facets of \( \lambda \) that contain \( \mu \). Then 

\[
\beta^{i+1}_\lambda_\tau \beta^i_\tau_\mu + \beta^{i+1}_\lambda_\rho \beta^{i+1}_\rho_\mu = 0.
\]

Then there exists a unique orientation of \( C^*_\sigma \)

\[
(b^i_\lambda : b^i_\mu^{-1}) = \beta^i_\lambda_\mu \quad \text{for every} \ \lambda \in \Lambda_i, \mu \in \Lambda_{i-1}.
\]

such that for every \( i = 1, \ldots, d - 1 \) we have : 

(11.6.20) 

\[
[b^i_\lambda : b^i_\mu^{-1}] = \beta^i_\lambda_\mu \quad \text{for every} \ \lambda \in \Lambda_i, \mu \in \Lambda_{i-1}.
\]
Proof. We construct the orientation classes $b^i_\lambda$ fulfilling condition (11.6.20), by induction on $i$. For $i = 0$, the condition is empty, and the classes $b^0_\lambda$ are prescribed by (11.6.8). For $i = 1$, and a given $\lambda \in \Lambda_1$, denote by $\tau$ and $\rho$ the two faces of $\lambda$; clearly the condition $[b^1_\lambda : b^0_\tau] = \beta^1_{\lambda \tau}$ (and assumption (b)) determines $b^1_\lambda$ univocally, and in view of (c) and lemma (11.6.9)(ii), for this choice of orientation of $e^1_\lambda$, we have as well $[b^1_\lambda : b^0_\rho] = \beta^1_{\lambda \rho}$. Moreover, if $\mu \in \Lambda_0 \setminus \{\tau, \rho\}$, then (11.6.20) is verified as well, by virtue of (a) and proposition (11.6.16)(i).

Now, suppose that $i > 1$ and that we have already constructed orientation classes $b^j_\mu$ as sought, for every $j < i$ and every $\mu \in \Lambda_j$. Let $\lambda \in \Lambda_i$ be any face, and fix a facet $\tau$ of $\lambda$; again, the identity

\begin{equation}
[ b^i_\lambda : b^j_\tau ] = \beta^i_{\lambda \tau}
\end{equation}

determines $b^i_\lambda$, and it remains to check that – with this choice of $b^i_\lambda$ – condition (11.6.20) holds for every $\mu \in \Lambda_{i-1} \setminus \{\tau\}$, and by virtue of (a) and proposition (11.6.16)(i), it suffices to consider the facets $\mu$ of $\lambda$. However, notice that the system of orientation classes $(b^j_\mu \mid j = 0, \ldots, i-1, \mu \subset \lambda)$ amounts to an orientation of $C^{i-1}_\lambda$ (regarded as a cell subcomplex of $C^*_\lambda$), and the incidence numbers for the complex $(C^{i-1}_\lambda)^*$ relative to these classes agree with the incidence numbers of $C^*_\lambda$, relative to the same classes. Especially, the sums

\begin{equation}
c := \sum_{\mu \in \Lambda_{i-1}} \beta^i_{\lambda \mu} b^{i-1}_\mu, \quad c' := \sum_{\mu \in \Lambda_{i-1}} [b^i_\lambda : b^{i-1}_\mu] b^{i-1}_\mu
\end{equation}

are well defined elements of $\mathcal{C}_{i-1}(C^{i-1}_\lambda)$, and in fact:

\begin{align*}
d_{i-1}(c) &= \sum_{\mu \in \Lambda_{i-1}} \beta^i_{\lambda \mu} \cdot d_{i-1}(b^{i-1}_\mu) \\
&= \sum_{\mu \in \Lambda_{i-1}} \beta^i_{\lambda \mu} \cdot \sum_{\rho \in \Lambda_{i-2}} [b^{i-1}_\mu : b^{i-2}_\rho] b^{i-2}_\rho \\
&= \sum_{\mu \in \Lambda_{i-1}} \sum_{\rho \in \Lambda_{i-2}} \beta^i_{\lambda \mu} \beta^{i-1}_{\mu \rho} b^{i-2}_\rho \quad \text{(by inductive assumption)} \\
&= 0 \quad \text{(by (d))}
\end{align*}

and a similar calculation yields $d_{i-1}(c') = 0$ as well. However, $C^{i-1}_\lambda$ is homeomorphic to $S^{i-1}$ (lemma (11.6.12)), hence

\[ \ker(d_{i-1} : \mathcal{C}_{i-1}(C^{i-1}_\lambda) \to \mathcal{C}_{i-2}(C^{i-1}_\lambda)) \simeq \mathbb{Z} \]

which, in view of (b), implies that $c = \pm c'$. Taking into account (11.6.21), we see that actually $c = c'$, whence the claim. The uniqueness of the orientation fulfilling condition (11.6.20) can be checked easily by induction on $i$: the details shall be left to the reader. \hfill \Box

11.6.22. Let now $L$ be a free abelian group of finite rank $d$, and $(L_\mathbb{R}, \sigma)$ a strictly convex $L$-rational polyhedral cone (see (6.3.20)), such that $\langle \sigma \rangle = L_\mathbb{R}$; set

\[ P := L \cap \sigma \quad F_\lambda := L \cap \lambda \quad P^\lambda := F_\lambda^{-1}P \quad \text{for every face } \lambda \text{ of } \sigma \]

so $P$ and its localization $P^\lambda$ are fine and saturated monoids (proposition (6.3.22)(i)), and $F_\lambda$ is a face of $P$, for every such $\lambda$. Let $R$ be any ring, and if $\lambda, \mu \subset \sigma$ are any two faces with $\lambda \subset \mu$, denote by

\[ j_{\lambda \mu} : R[P^\lambda] \to R[P^\mu] \]
the natural localization map; notice that if \( 0 \subset \sigma \) is the unique 0-dimensional face, then \( P_0 = P \), and \( j_{0\mu} \) is the localization map \( R[P] \to R[P_\mu] \). We attach to \( P \) the complex \( \mathcal{C}_P \) of \( R[P] \) modules such that:

\[
\mathcal{C}_P := R[P] \quad \text{and} \quad \mathcal{C}_P^i := \bigoplus_{\lambda \in \Lambda_{i-1}} R[P\lambda] \quad \text{for every} \ i = 1, \ldots, \dim P
\]

with differentials given by the rule:

\[
d^i(x_\lambda) := \sum_{\mu \in \Lambda_i, \lambda \subset \mu} [b^i_\mu : b^{i-1}_\lambda] \cdot j_{\mu \lambda}(x_\lambda) \quad \text{for every} \ i \geq 1, \ \lambda \in \Lambda_{i-1} \text{ and } x_\lambda \in R[P\lambda]
\]

and

\[
d^0(x) := \sum_{\mu \in \Lambda_0} j_{0\mu}(x) \quad \text{for every} \ x \in R[P]
\]

where \((b^i_j \mid j = 0, \ldots, \dim \sigma - 1, \ \tau \in \Lambda_j)\) is a chosen orientation for \( C^*_\sigma \). Taking into account lemma \[11.6.9\](ii) and proposition \[11.6.16\](iii), it is easily seen that \( d^{i+1} \circ d^i = 0 \) for every \( i \geq 0 \) (essentially, the differential \( d^i \) is the transpose of the differential \( d_{i-1} \) of \( \mathcal{C}_P(C^*_\sigma) \)).

Set as well \( X := \text{Spec} R[P] \), and notice that \( Z := \text{Spec} R(P/m_P) \simeq \text{Spec} R \) is a closed subset of \( X \). For any \( R[P] \)-module \( M \), we denote as usual by \( \tilde{M} \) the quasi-coherent \( \mathcal{O}_X \)-module arising from \( M \).

**Theorem 11.6.23.** With the notation of \[11.6.22\], for every \( R[P] \)-module \( M \) we have a natural isomorphism

\[
\Gamma_Z \tilde{M} \simeq M \otimes_{R[P]} \mathcal{C}_P \quad \text{in } \mathcal{D}(R[P]-\text{Mod}).
\]

**Proof.** For every face \( \lambda \) of \( \sigma \), set \( U_\lambda := \text{Spec} R[P_\lambda] \), and denote by \( g_\lambda : U_\lambda \to X \) the open immersion. We consider the chain complex \( \mathcal{R}_\bullet \) of \( \mathcal{Z}_X \)-modules such that:

\[
\mathcal{R}_0 := \mathcal{Z}_X \quad \text{and} \quad \mathcal{R}_i := \bigoplus_{\lambda \in \Lambda_{i-1}} g_\lambda \mathcal{Z}_U_\lambda \quad \text{for every} \ i = 1, \ldots, \dim P.
\]

The differential \( d_1 : \mathcal{R}_1 \to \mathcal{R}_0 \) is just the sum of the natural morphisms \( g_\lambda \mathcal{Z}_U_\lambda \to \mathcal{Z}_X \), for \( \lambda \) ranging over the one-dimensional faces of \( \sigma \). For \( i > 1 \), the differential \( d_i \) is the sum of the maps

\[
d_\lambda := \sum_{\mu \in \Lambda_i, \mu \subset \lambda} [b^i_\mu : b^{i-1}_\lambda] \cdot d_{\mu \lambda} : g_\lambda \mathcal{Z}_U_\lambda \to \mathcal{R}_{i-1} \quad \text{for every} \ \lambda \in \Lambda_{i-1}
\]

where \( d_{\lambda \mu} : g_\lambda \mathcal{Z}_U_\lambda \to g_\mu \mathcal{Z}_U_\mu \subset \mathcal{R}_{i-1} \) is induced by the inclusion \( U_\lambda \subset U_\mu \). With this notation, a simple inspection of the definitions yields a natural identification

\[
\mathcal{C}_P \simeq \text{Hom}_R(\mathcal{R}_\bullet, \tilde{M}[-i]) \quad \text{in } \mathcal{D}(R[P]-\text{Mod}).
\]

On the other hand, let \( \lambda_1, \ldots, \lambda_n \) be the one-dimensional faces of \( \sigma \); then \( \lambda_i \) is \( L \)-rational (see \[6.3.20\]), and \( F_\lambda \) is a fine, sharp and saturated monoid of dimension one (propositions \[6.3.22\](i) and \[6.4.7\](ii)), so \( F_\lambda \simeq \mathbb{N} \) for \( i = 1, \ldots, n \) (theorem \[6.4.16\](ii)). For each \( i = 1, \ldots, n \), let \( y_i \) be the unique generator of \( F_\lambda \), and denote by \( I \subset P \) the ideal generated by \( y_1, \ldots, y_n \); we remark

**Claim 11.6.25.** The radical of \( I \) is \( m_P \).

**Proof of the claim.** For any \( x \in m_P \), pick a subset \( S \subset \{1, \ldots, n\} \) such that \( x = \sum_{i \in S} a_i y_i \), with \( a_i > 0 \) for every \( i \in S \). Let \( N \in \mathbb{N} \) be large enough such that \( Na_i \geq 1 \) for every \( i \in S \), and pick \( b_i \in \mathbb{N} \) such that \( Na_i \geq b_i \geq 1 \) for every \( i \in S \). It follows that \( Nx - \sum_{i \in S} b_i y_i \in P \), and the claim follows.

Now, let \( i : Z \to X \) be the closed immersion; we have: 

\[
\text{...}
\]
Claim 11.6.26. The natural map $\mathbb{Z}_X \to i_*\mathbb{Z}_Z$ induces an isomorphism

$$\mathcal{R}_* \cong i_*\mathbb{Z}_Z[0]$$

in $D^+(\mathbb{Z}_X\text{-Mod})$.

Proof of the claim. The assertion can be checked on the stalks at the points of $X$, hence let $x \in X$ be any such point; if $x \in Z$, claim 11.6.25 easily implies that $(\mathcal{R}_*)_x$ is concentrated in degree zero, and then (11.6.27) $x$ is clearly an isomorphism of complexes of $\mathbb{Z}$-modules. If $x \notin Z$, let $p \subset R[P]$ be the prime ideal corresponding to $x$, and $\lambda \subset \sigma$ the unique face such that $P \setminus F_\lambda = p \cap P$; a simple inspection of the construction shows that

$$(\mathcal{R}_*)_x \cong \mathcal{G}_\sigma (C^*_\lambda)$$

(notation of (11.6.6)). But proposition 11.6.7 and lemma 11.6.12 imply that $\mathcal{G}_\sigma (C^*_\lambda)$ is acyclic, whence the claim.

In view of (11.6.24) and claim 11.6.26, we are reduced to showing that the natural map

$$\text{Hom}_\bullet^*(\mathcal{R}_*, M^\sim [0]) \to R\text{Hom}_\mathbb{Z}^\bullet (\mathcal{R}_*, M^\sim [0])$$

is an isomorphism in $D^+(R[P]\text{-Mod})$. This can be done by a spectral sequence argument, along the lines of proposition 10.4.18 (which indeed includes a special case of the situation we are considering here, namely the case where $P$ is a free monoid : the details shall be left to the reader). \hfill $\square$

11.6.28. Notice that $\mathcal{G}_p^*$ is a complex of $L$-graded $R$-modules, hence its cohomology is $L$-graded as well, and we wish next to compute the graded terms $\text{gr}_\bullet H^\bullet (\mathcal{G}_p^*)$. To this aim, we make the following :

Definition 11.6.29. Let $V$ be a finite dimensional $\mathbb{R}$-vector space, $X \subset V$ any subset, and $z \in V$ any point. Then :

(a) We say that a point $x \in X$ is visible from $z$, if $\{tz + (1-t)x \mid 0 \leq t \leq 1\} \cap X = \{x\}$.

(b) We say that a subset $S \subset X$ is visible from $z$, if every point of $S$ is visible from $z$.

Lemma 11.6.30. In the situation of (11.6.14), let $z \in V \setminus C_\sigma$ be any point, and denote by $S$ the set of points of $C_\sigma$ that are visible from $z$. Then :

(i) $S$ is a subcomplex of $C_\sigma^*$.

(ii) $S$ (with the topology induced from $V$) is homeomorphic to $\mathbb{F}^e$, for $e \in \{d-2, d-1\}$.

Proof. Pick a system of generators $\rho_1, \ldots, \rho_n$ for $\sigma^\vee$, and choose $\rho_0 \in \sigma^\vee$ so that $C_\sigma = \sigma \cap \rho_0^{-1}(1)$; we may assume that, for some integer $k \leq n$ we have

$$\rho_i(z) < 0 \quad \text{if and only if} \quad 1 \leq i \leq k.$$ 

Say that $y \in C_\sigma$, so that $\rho_i(y) \geq 0$ for every $i = 1, \ldots, n$, and set $y_t := tz + (1-t)y$ for every $t \in [0,1]$; then clearly $\rho_i(y_t) \geq 0$ for every $i = k + 1, \ldots, n$. Now, if $\rho_0(z) \neq 1$, we get $\rho_0(y_t) \neq 1$ for every $t \neq 0$, therefore the whole of $C_\sigma$ is visible from $z$, in which case (i) is trivial, and (ii) follows from 11.6.12. Hence we may assume that $\rho_0(z) = 1$, so $\rho_0(y_t) = 1$ for every $t \in [0,1]$. Suppose now that $\rho_i(y) > 0$ for some $i \leq k$; then there exists a unique $t_i \in [0,1]$ such that $\rho_i(y_{t_i}) = 0$. Hence, if $s := \min(\rho_i(y) \mid i = 1, \ldots, k) > 0$, let $t := \min(t_i \mid i = 1, \ldots, k)$; it follows that $\rho_i(y_t) \geq 0$ for every $i = 1, \ldots, n$, so $y_t \in C_\sigma$, which says that $y$ is not visible from $z$. Conversely, if $s = 0$, then it follows easily that $y$ is visible from $z$. We conclude that

$$S = C_\sigma \cap \bigcup_{i=1}^k \text{Ker } \rho_i$$

which shows (i). Next, set $W := \text{Ker } \rho_0$, and denote by $\tau_z : \rho_0^{-1}(1) \sim W$ the translation map given by the rule : $x \mapsto x - z$ for every $x \in \rho_0^{-1}(1)$. To conclude, it suffices to check
that $S' := \tau_{l}(S)$ is homeomorphic to $\overline{B}^{d-2}(1)$. To this aim, denote by $\lambda$ the convex cone in $W$
 generated by $\tau_{l}(C_{l})$. Explicitly, if $v_{1}, \ldots, v_{k} \in \sigma$ have been chosen so that $[11.6.11]$ holds, then $\lambda$ is the cone generated by $v_{1} - z, \ldots, v_{k} - z$; especially, $\lambda$ is a polyhedral cone, and it is easily seen that $(\lambda) = W$. Moreover, $\lambda$ is strictly convex; indeed, otherwise there exist real numbers $a_{1}, \ldots, a_{k} \geq 0$, with $a_{i} > 0$ for at least an index $i \leq k$, such that $\sum_{i=1}^{k} a_{i} \cdot (v_{i} - z) = 0$, i.e. $\sum_{i=1}^{k} a_{i} v_{i} = (\sum_{i=1}^{k} a_{i}) \cdot z$, which is absurd, since $z \notin \sigma$. Pick $u \in \lambda^{\vee}$ such that $\lambda \cap \text{Ker } u = 0$, and set $C_{\lambda} := \lambda \cap u^{-1}(1)$; by lemma $[11.6.12]$, the subset $C_{\lambda}$ is homeomorphic to $\overline{B}^{d-2}(1)$.

Lastly, let $\pi : W \setminus \text{Ker } u \to u^{-1}(1)$ be the radial projection (so $\pi(w)$ is the intersection point of $\mathbb{R} w$ with $u^{-1}(1)$, for every $w \in W \setminus \text{Ker } u$). It is easily seen that $\pi$ maps $S'$ bijectively onto $C_{\lambda}$, so the restriction of $\pi$ is a homeomorphism $S' \sim C_{\lambda}$, as required. \hfill $\square$

**Lemma 11.6.31.** In the situation of $[11.6.22]$, let $\lambda \subset \sigma$ be any face. For every $l \in L_{R}$ we have:

(i) The set of points of $\sigma$ that are visible from $l$ is a union of faces of $\sigma$.

(ii) Suppose $l \in L$, and endow $R[P_{l}]$ with its natural $L$-grading. Then

$$\text{gr}_{l}R[P_{l}] = \begin{cases} Rl & \text{if } \lambda \subset \sigma \text{ is not visible from } l \\ 0 & \text{otherwise.} \end{cases}$$

**Proof.** Let $\rho_{l}, \ldots, \rho_{n}$ be a system of generators of $\sigma^{\vee}$; we may assume that, for some integer $k \leq n$ we have

$$\rho_{i}(l) < 0 \quad \text{if and only if } 1 \leq i \leq k.$$

Arguing as in the proof of lemma $[11.6.30]$, we check easily that the set of points of $\sigma$ visible from $l$ equals $S := \sigma \cap \bigcup_{i=1}^{k} \text{Ker } \rho_{i}$, which already shows (i).

(ii): Suppose first that $\lambda \subset \sigma$ is not visible from $l$; then there exists $x \in \lambda \setminus S$, and since $F_{\lambda}$ generates $\lambda$ (see $[6.3.20]$), we may assume that $x \in F_{\lambda}$ (details left to the reader). A simple inspection then shows that there exists a sufficiently large $N \in \mathbb{N}$ such that $l + N x \in \sigma$, whence $l \in R[P_{\lambda}]$, and so $\text{gr}_{l}R[P_{\lambda}] = Rl$. Conversely, if the latter identity holds, then there exists $x \in F_{\lambda}$ such that $l + x \in P$, whence $\rho_{i}(x) > 0$ for $i = 1, \ldots, k$, so $x$ is not visible from $l$. \hfill $\square$

**11.6.32.** In the situation of $[11.6.22]$, let us fix a linear form $u_{0} \in \sigma^{\vee}$ such that $\sigma \cap \text{Ker } u_{0} = 0$, and define $\sigma^{\circ}$ and $C_{\sigma}$ as in $[11.6.10]$. For any $l \in L_{R}$, denote by $S_{l}$ the set of points of $\sigma$ that are visible from $l$, so $S_{l}$ is a union of faces of $\sigma$, by lemma $[11.6.31]$ (ii), and therefore $C_{l} := S_{l} \cap C_{\sigma}$ is a subcomplex of $C_{\sigma}^{\bullet}$.

**Proposition 11.6.33.** With the notation of $[11.6.32]$, suppose $l \in L$. Then the following holds:

(i) If $-l \in \sigma^{\circ}$, the complex of $R$-modules $\text{gr}_{l}C_{l}^{\bullet}$ is isomorphic to $R[-d]$.

(ii) If $-l \notin \sigma^{\circ}$, there is a natural isomorphism of complexes of $R$-modules:

$$\text{gr}_{l}C_{l}^{\bullet} \sim \text{Hom}_{R}(C_{\sigma}^{\bullet}/C_{\sigma}^{\bullet}(C_{l}^{\bullet}), R[-1]).$$

Moreover, in this case, both $\text{Hom}_{R}(C_{\sigma}^{\bullet}, C_{l}^{\bullet})$ and $\text{Hom}_{R}(C_{l}^{\bullet}, C_{\sigma}^{\bullet})$ are acyclic complexes.

**Proof.** (i): If $-l \in \sigma^{\circ}$, then $l \in P_{\lambda}$, and only if $\lambda = \sigma$, so the assertion is clear.

(ii): The sought identification of complexes follows from lemma $[11.6.7]$ (ii), by a direct inspection of the constructions (and indeed, this holds even if $-l \notin \sigma^{\circ}$: details left to the reader). Moreover, it is already known from proposition $[11.6.7]$ and lemma $[11.6.12]$ that $\text{Hom}_{R}(C_{\sigma}^{\bullet}, C_{l}^{\bullet})$ is acyclic.

- Next, if $l \in P$, then clearly $S_{l} = \varnothing$, so the assertion for $\text{Hom}_{R}(C_{\sigma}^{\bullet}, C_{l}^{\bullet})$ is trivial in this case.

- Thus, suppose that $l \notin P$; if furthermore $-l \notin P$, then the convex cone $\tau$ generated by $P$ and $l$ is still strictly convex, so we may find $u_{1} \in \tau^{\vee}$ such that $u_{1}(l) = 1$ and $\tau \cap \text{Ker } u_{1} = 0$. Set $C_{\sigma}^{\prime} := \sigma \cap u_{1}^{-1}(1)$ and $C_{l}^{\prime} := S_{l} \cap C_{\sigma}^{\prime}$. In remark $[11.6.15]$ (i) we have exhibited a homeomorphism $C_{\sigma}^{\prime} \sim C_{l}^{\prime}$ that preserves the respective cell complex structures, and a simple inspection shows
that this homeomorphism maps \( C'_l \) onto \( C_l \). On the other hand, it is easily seen that \( C'_l \) is also the set of points of \( C'_g \) that are visible from \( l \) (indeed, the segment that joins any point of \( C'_g \) to \( l \) lies in \( u^{-1}_l(1) \), so its intersection with \( \sigma \) equals its intersection with \( C'_g \); details left to the reader). By virtue of lemma \[11.6.30\](ii) (and proposition \[11.6.7\]), it follows that \( \overline{\mathcal{C}}_\bullet(C'_g) \) is acyclic, so the same holds for \( \overline{\mathcal{C}}_\bullet(C'_l) \).

- Lastly, suppose \( -l \in P \setminus \sigma^v \); we let \( \rho_1, \ldots, \rho_n \) be a system of generators of \( \sigma^v \), and \( k \leq n \) an integer such that \( \rho_i(l) < 0 \) if and only if \( 1 \leq i \leq k \). Denote by \( \tau^v \) (resp. \( \mu^v \)) the convex cone in \( L^v_R \) generated by \( (\rho_{k+1}, \ldots, \rho_n) \) (resp. by \( (-\rho_1, \ldots, -\rho_k) \)), and let \( \tau \) (resp. \( \mu \)) be the dual of \( \tau^v \) (resp. of \( \mu^v \)) in \( L^v_R \); with this notation, we have \( l \in \tau \cap \mu^v \). Especially, \( \tau \cap \mu^v \neq \emptyset \), and since \( \tau^v \) is dense in \( \tau \) (by proposition \[6.3.13\](i)), we deduce that \( \tau^v \cap \mu^v \neq \emptyset \) as well. Pick \( z \in \tau^v \cap \mu^v \); by inspecting the proof of lemma \[11.6.31\](i), it is easily seen that \( S_\ell = S_z \).

But by construction, \( -z \notin \sigma \), therefore – arguing as in the previous case – we conclude that \( \overline{\mathcal{C}}_\bullet(C'_g) = \overline{\mathcal{C}}_\bullet(C'_l) \) is acyclic.

\[ \square \]

**Theorem 11.6.34 (Hochster).** Let \( R \) be a Cohen-Macaulay noetherian ring, \( P \) a fine, sharp and saturated monoid. Then \( R[P] \) is a Cohen-Macaulay ring.

**Proof.** In view of \[100\], p.181, Cor.] we may assume that \( R \) is a field. We argue by induction on \( d := \dim P \). If \( d = 0 \), we have \( P = 0 \), and there is nothing to show. Suppose that \( d > 0 \) and that the assertion is already known for every Cohen-Macaulay ring \( R \) and every monoid as above, of dimension \( < d \). Set \( L := P^{gp} \), and let \( \sigma \subset L^v_R \) be the unique convex polyhedral cone such that \( P = L \cap \sigma \). The ideal \( n := R[m_p] \) is maximal in \( R[P] \), and proposition \[11.6.33\] and theorem \[11.6.23\] show that

\[ \text{(11.6.35)} \quad \depth R[P]_n = \dim P. \]

On the other hand, we have the more general:

**Claim 11.6.36.** Let \( F \) be a field, \( P \) a fine monoid, \( A \) an integral domain which is an \( F \)-algebra of finite type, and \( F^v \) the field of fractions of \( A \). Then we have:

(i) For every maximal ideal \( m \subset A \), the Krull dimension of \( A_m \) equals the transcendence degree of \( F^v \) over \( F \).

(ii) For every maximal ideal \( m \subset F[P] \), the Krull dimension of \( F[P]_m \) equals \( \text{rk}_Z P^{gp} \).

**Proof of the claim.** (i): This is a straightforward consequence of \[100\], Th.5.6).

(ii): Choose an isomorphism : \( P^{gp} \cong L \oplus T \), where \( T \) is the torsion subgroup of \( P^{gp} \), and \( L \) is a free abelian group of finite rank; there follows an induced isomorphism \[4.8.12\] :

\[ F[P^{gp}] \cong F[L] \otimes_F F[T]. \]

Let \( B \) be the maximal reduced quotient of \( F[P^{gp}] \) (so the kernel of the projection \( F[P^{gp}] \to B \) is the nilradical); we deduce that \( B \) is a direct product of the type \( \prod_{i=1}^n F'_i[L] \), where each \( F'_i \) is a finite field extension of \( F \). By (i), the Krull dimension of \( F'_i[L]_m \) equals \( r := \text{rk}_Z P^{gp} \) for every maximal ideal \( m \subset F'_i[L] \), hence every irreducible component of \( \text{Spec} B \) has dimension \( r \).

Let also \( C \) be the maximal reduced quotient of \( F[P] \); the natural map \( C \to B \) is an injective localization, obtained by inverting a finite system of generators of \( P \), hence the induced morphism \( \text{Spec} B \to \text{Spec} C \) is an open immersion with dense image. Let \( Z \) be any (reduced) irreducible component of \( \text{Spec} C \); again by (i) it follows that every non-empty open subset of \( Z \) has dimension equal to \( \dim Z \), so necessarily the latter equals \( r \).

\[ \diamond \]

From \( \text{(11.6.35)}, \) corollary \[6.4.10\](i) and claim \[11.6.36\](ii) we see already that \( R[P]_n \) is a Cohen-Macaulay ring. Next, let \( \lambda_1, \ldots, \lambda_k \) be the one-dimensional faces of \( \sigma \), and define \( P_{\lambda_i} \).
as in (11.6.22), for every \( i = 1, \ldots, k \). In light of claim [11.6.25] we have

\[
\Spec R[P] \setminus \{ n \} = \bigcup_{i=1}^{k} \Spec R[P_{\lambda_i}]
\]

so it remains to check that \( R[P_{\lambda_i}] \) is Cohen-Macaulay for every \( i = 1, \ldots, k \). However, we may find a decomposition \( P_{\lambda_i} \rightarrow Q_i \times G_i \), where \( G_i \) is a free abelian group of finite type, and \( Q_i \) is a fine, sharp and saturated monoid of dimension \( d - 1 \) (lemma 6.2.10). Set \( S_i := R[G_i] \); then \( R[P_{\lambda_i}] = S_i \langle Q_i \rangle \), and \( S_i \) is a Cohen-Macaulay ring ([100 Th.17.7]), so the claim follows by inductive assumption. \( \square \)

11.6.37. In the situation of (11.6.22), we endow \( R[P] \) with its natural \( L \)-grading, and denote by \( A := (R[P], \gr \cdot R[P]) \) the resulting \( L \)-graded \( R \)-algebra. Let \( (M, \gr \cdot M) \) be an \( L \)-graded \( A \)-module (see definition 7.6.9(ii)); we set

\[
M^\dagger := \bigoplus_{l \in L} \Hom_R(\gr_l M, R)
\]

which is naturally an \( R \)-submodule of \( M^* := \Hom_R(M, R) \) : indeed, any \( R \)-linear map \( \gr_l M \rightarrow R \) yields a linear form \( M \rightarrow R \), after composition with the projection \( M \rightarrow \gr_l M \). Notice that \( M^* \) is naturally an \( R[P] \)-module; namely for any linear form \( f : M \rightarrow R \) and any \( x \in P \), one defines \( x \cdot f : M \rightarrow R \) by the rule : \( x \cdot f(m) := f(xm) \) for every \( m \in M \). Then, it is easily seen that \( M^\dagger \) is an \( R[P] \)-submodule of \( M^* \); more precisely, we have

(11.6.38) \[ x \cdot \Hom_R(\gr_l M, R) \subset \Hom_R(\gr_{l-x} M, R) \quad \text{for every } x \in P. \]

In light of (11.6.38), it is convenient to define an \( L \)-grading on \( M^\dagger \) by the rule :

\[
\gr_l M^\dagger := \Hom_R(\gr_{l-x} M, R) \quad \text{for every } l \in L
\]

and then \((M^\dagger, \gr \cdot M^\dagger)\) is naturally an \( L \)-graded \( A \)-module.

**Remark 11.6.39.** (i) Clearly, the rule \( M \mapsto M^\dagger \) yields a functor from the category \( A \Mod \) of \( L \)-graded \( A \)-modules to \( A \Mod^\circ \).

(ii) Let \( A \Mod_{\text{flx}} \) denote the full subcategory of \( A \Mod \) whose objects are all the \( L \)-graded \( A \)-modules \((M, \gr \cdot M)\) such that \( \gr_l M \) is a projective \( R \)-module of finite type, for every \( l \in L \). A simple inspection of the definition shows that the functor \((-)^\dagger\) of (i) restricts to an equivalence of categories :

\[
A \Mod_{\text{flx}} \rightarrow (A \Mod^\circ)^\circ.
\]

**Example 11.6.40.** If \( S \subset L \) is any \( P \)-submodule, notice that \( L \setminus (-S) \) is also a \( P \)-submodule of \( L \), and set

\[
S^\dagger := L / (L \setminus (-S))
\]

where the quotient is a pointed \( P \)-module, as in remark 4.8.17(iii). Explicitly, \( S^\dagger \) is the set \((S) \cup \{ 0_{SI} \} \) (where the zero element \( 0_{SI} \) should not be confused with the neutral element 0 of the abelian group \( L \)); the \( P \)-module structure on \( S^\dagger \) is determined by the rule :

\[
x \cdot s := \begin{cases} 
x + s & \text{if } x + s \in -S \\0_{SI} & \text{otherwise} \end{cases} \quad \text{for every } s \in -S.
\]

Then it is easily seen that there exists a natural isomorphism of \( L \)-graded \( A \)-modules :

\[
R[S]^\dagger \rightarrow R\langle S^\dagger \rangle
\]

(note of (6.1.32)). On the other hand, the natural map \( R[S] \rightarrow (R[S]^\dagger)^* \) induces an isomorphism \( R[S] \rightarrow (R[S]^\dagger)^\dagger \) whence an isomorphism of \( L \)-graded \( A \)-modules

(11.6.41) \[ R[S] \rightarrow R\langle S^\dagger \rangle^\dagger. \]
Theorem 11.6.42 (Stanley, Danilov). In the situation of \((11.6.22)\), set \(P^o := L \cap \sigma_o\). We have:

(i) There exists a natural isomorphism:

\[
R\text{Hom}_{R[P]}^\bullet(R, R[P^o]) \xrightarrow{\sim} R[-d] \quad \text{in} \ D(R[P]-\text{Mod})
\]

(here \(R\) is regarded as an \(R[P]-\text{module}\), via the augmentation map \(R[P] \to R\)).

(ii) If \(R\) is a Gorenstein noetherian ring, the complex of coherent \(\mathcal{O}_X\)-modules \(R[P^o]^\sim[0]\) is dualizing on \(X\).

Proof. (i): From proposition \((11.6.33)\) we deduce a map of complexes of \(L\)-graded \(\mathcal{A}\)-modules

\[
\varphi^\bullet : \mathcal{E}_p \to R((P^o)^\dagger)[-d]
\]

(note of example \((11.6.40)\) with \(\text{gr}_l \varphi^\bullet\) a quasi-isomorphism of complexes of \(R\)-modules, for every \(l \in L\). Since \(\text{gr}_l \mathcal{E}_p\) is a finite dimensional \(R\)-vector space for every \(l \in L\), there follows – in view of \((11.6.41)\) – a quasi-isomorphism of complexes of \(L\)-graded \(\mathcal{A}\)-modules

\[
R[P^o][0] \xrightarrow{\sim} (\mathcal{E}_p)^\dagger[1][-d].
\]

whence a convergent spectral sequence

\[
E_1^{pq} := \text{Ext}^p_{R[P]}(R, (\mathcal{E}_p)^\dagger[0]) \Rightarrow \text{Ext}^{p+q}_{R[P]}(R, R[P^o]).
\]

Hence, the assertion follows immediately from the:

Claim 11.6.44. With the foregoing notation, we have:

(i) \(E_1^{pq} = 0\) whenever \(q < d\).

(ii) \(E_1^{0d} \simeq R\), and \(E_1^{pd} = 0\) for every \(p > 0\).

Proof of the claim. (i): Let \(\lambda \subset \sigma\) be any face with \(\dim \lambda > 0\); it suffices to check that \(E^i := \text{Ext}^i_{R[P]}(R, R[P^\lambda]) = 0\) for every \(i \in \mathbb{N}\). To this aim, pick any \(x \in F_\lambda \setminus \{0\}\); since \(R[P^\lambda]^\dagger = R\langle P^\lambda \rangle\) (example \((11.6.40)\)), we see that scalar multiplication by \(x\) is an automorphism on \(R[P^\lambda]^\dagger\), hence also on \(E^i\). On the other hand, scalar multiplication by \(x\) is the zero endomorphism on \(R\), hence also on \(E^i\), and the claim follows.

(ii): Pick a resolution \(F_\bullet\) of the \(P\)-graded \(\mathbb{Z}[P]\)-module \(Z := \mathbb{Z}[P]/\mathbb{Z}[m_P]\) as in remark \((7.6.30)\) (iii), so that \(F_n\) is a free \(\mathbb{Z}[P]\)-module of finite type for every \(n \in \mathbb{N}\), and the differential \(d_n : F_n \to F_{n-1}\) is a morphism of \(P\)-graded \(\mathbb{Z}[P]\)-modules, for every \(n > 0\). Since the augmented complex \(F_\bullet\) is flat as a complex of \(\mathbb{Z}\)-modules, the complex of \(R[P]\)-modules \(R \otimes_{\mathbb{Z}} F_\bullet\) is still a free resolution of the \(R[P]\)-module \(R\), and we get natural isomorphisms

\[
E_1^{pd} \xrightarrow{\sim} H^p\text{Hom}_{R[P]}^\bullet(R \otimes_{\mathbb{Z}} F_\bullet, R[P^\lambda]^\dagger[0]) \xrightarrow{\sim} H^p((R \otimes_{\mathbb{Z}} F_\bullet)^\dagger) \quad \text{for every} \ p \in \mathbb{N}.
\]

(where the differentials of the complex \((R \otimes_{\mathbb{Z}} F_\bullet)^\dagger\) are the maps \(d^*_n\)). However, remark \((11.6.39)\) (ii) implies that the complex \((R \otimes_{\mathbb{Z}} F_\bullet \to R)^\dagger\) is still acyclic, whence the contention.

(ii): To ease notation, set \(S := \text{Spec} R\) and \(\omega_p := R[P^p]^\sim\); in view of proposition \((11.3.37)\) it suffices to check that the complex of coherent \(\mathcal{O}_X\)-modules \(\omega_p(x)[0]\) is dualizing on \(X(x)\), for every \(x \in X\) (notation of definition \((4.9.17)\) (iii)). Hence, fix any such point \(x\), and let \(p \subset R[P]\) be the prime ideal corresponding to \(x\); after replacing \(R\) by its localization at the prime ideal \(p \cap R\), we may assume that \(R\) is a local ring, and the structure morphism \(X \to S\) maps \(x\) to the closed point of \(S\), corresponding to the maximal ideal \(m_R\) of \(R\). Denote by \(\lambda \subset \sigma\) the unique face such that \(P \setminus F_\lambda = p \cap P\), so that \(x \in U_\lambda := \text{Spec} R[P_\lambda]\). We may find a decomposition \(P \xrightarrow{\sim} F_\lambda^{\text{gp}} \times Q\), where \(Q\) is also a fine, sharp and saturated monoid (lemma \((6.2.10)\)), whence an isomorphism of \(S\)-schemes

\[
U_\lambda \xrightarrow{\sim} \text{Spec} R[F_\lambda^{\text{gp}}] \times_S Y \quad \text{where} \ Y := \text{Spec} R[Q]
\]

and by construction, \(F^{-1}(p \cap P)\) is the maximal ideal of \(P_\lambda\), so the induced projection \(p : U_\lambda \to Y\) maps \(x\) to the maximal ideal \(R[m_Q] + m_R[Q] \subset R[Q]\). Let \(\tau \subset Q^{\text{gp}}_R\) be the unique
polyhedral cone such that $Q = \tau \cap Q^{\op}$, set $Q^0 := Q \cap \tau^0$, and define the coherent $\mathcal{O}_T$-module $\omega_Q := R[Q^0]^\sim$. It is easily seen that there is a natural identification

$$\omega_{p[U]} \overset{\sim}{\rightarrow} p^* \omega_Q.$$  

In view of proposition 11.3.34 and remark 11.3.32(i), it then suffices to check that $\omega_Q(p(x))$ is dualizing on $Y(p(x))$. Thus, we may replace $P$ by $Q$, and assume from start that $p = R[m_P] + m_R[P] \subset R[P]$. In this case, set $S_0 := \text{Spec} R/m_R$, and denote by $i_1 : S_0 \rightarrow S$ and $i_2 : S \rightarrow X(S)$ the closed immersions (where $i_2$ corresponds to the ring homomorphism $R[P]_p \rightarrow R$ deduced from augmentation map); according to (i) and corollary [10.3.2](ii), we have a natural identification

$$\omega_{i_2^*} \omega_p(x)[0] \cong \mathcal{O}_S[-d].$$

On the other hand, since $R$ is Gorenstein, $\mathcal{O}_S[-d]$ is a dualizing complex on $S$; from lemma 11.3.27(i) and proposition 11.1.7(i) it follows that $i_1^* \mathcal{O}_S[-d] \overset{\sim}{\rightarrow} (i_2 \circ i_1)^! \omega_p(x)[0]$ is dualizing on $S_0$, and therefore it is isomorphic to $\mathcal{O}_S[c]$ for some $c \in \mathbb{Z}$. Lastly, proposition 11.3.28(i) and corollary [10.3.2](ii) now say that $\omega_p(x)[0]$ is dualizing on $X(x)$. \hfill \Box

Remark 11.6.45. Suppose that $R$ is a field; then example 7.11.33 shows that $(\mathcal{O}_R^\oplus)^!$ is the injective hull of the $R[P]$-module $R$. In this case, claim 11.6.44(ii) is therefore a special case of claim 7.11.24. For a general $R$, the $R[P]$-module $(\mathcal{O}_R^\oplus)^!$ shall not be injective, but it can be viewed as a graded variant of the injective hull construction.

12. Logarithmic geometry

12.1. Log topos. Henceforth, all topoi under consideration will be locally ringed and with enough points, and all morphisms of topoi will be morphisms of locally ringed topoi (see (4.9.13)). The purpose of this restriction is to insure that we obtain the right notions, when we specialize to the case of schemes.

Definition 12.1.1. Let $T := (T, \mathcal{O}_T)$ be a locally ringed topos.

(i) A pre-log structure on $T$ is the datum of a pair

$$(M, \alpha)$$

where $M$ is a $T$-monoid, and $\alpha : M \rightarrow \mathcal{O}_T$ is a morphism of $T$-monoids, called the structure map of $M$, and where the monoid structure on $\mathcal{O}_T$ is induced by the multiplication law (hence, by the multiplication in the ring $\mathcal{O}_T(U)$, for every object $U$ of $T$).

(ii) A morphism $(M, \alpha) \rightarrow (N, \beta)$ of pre-log structures on $T$, is a map $\gamma : M \rightarrow N$ of $T$-monoids, such that $\beta \circ \gamma = \alpha$. We denote by

$$\text{pre-log}_T$$

the category of pre-log structures on $T$.

(iii) A pre-log structure $(M, \alpha)$ on $T$ is a log structure if $\alpha$ restricts to an isomorphism:

$$\alpha^{-1} \mathcal{O}_T^\times \overset{\sim}{\rightarrow} M^\times \overset{\sim}{\rightarrow} \mathcal{O}_T^\times.$$  

The datum of a locally ringed topos $(T, \mathcal{O}_T)$ and a log structure on $T$ is also called, for short, a log topos. We denote by

$$\text{log}_T$$

the full subcategory of $\text{pre-log}_T$ consisting of all log structures on $T$. When there is no danger of ambiguity, we shall often omit mentioning explicitly the map $\alpha$, and therefore only write $M$ to denote a pre-log or a log structure.
12.1.2. The category $\log_T$ admits an initial object, namely the log structure $(\mathcal{O}_T^\times, j)$, where $j$ is the natural inclusion; this is called the trivial log structure. $\log_T$ admits a final object as well: this is $(\mathcal{O}_T, 1_{\mathcal{O}_T})$. A morphism of locally ringed topoi $f : T \to S$ induces a pair of adjoint functors:

$$f^* : \text{pre-log}_S \to \text{pre-log}_T \quad f_* : \text{pre-log}_T \to \text{pre-log}_S.$$ 

Namely, let $(\mathcal{M}, \alpha)$ (resp. $(\mathcal{N}, \beta)$) be a pre-log structure on $S$ (resp. on $T$) and

$$f^* : \mathcal{O}_S \to f_* \mathcal{O}_T \quad f^! : f^{-1} \mathcal{O}_S \to \mathcal{O}_T$$

the natural morphisms (corresponding to each other under the adjunction $(f^{-1}, f_*)$ that defines the morphism $f$); then

$$f^{-1} \mathcal{M} \xrightarrow{f^{-1} \alpha} f^{-1} \mathcal{O}_S \xrightarrow{f^*} \mathcal{O}_T$$

defines $f^*(\mathcal{M}, \alpha)$, and $f_*(\mathcal{N}, \beta)$ is the pair $(P, \gamma)$, where $P$ is the fibre product in the cartesian diagram

\[
\begin{array}{ccc}
P & \xrightarrow{\gamma} & \mathcal{O}_S \\
\downarrow & & \downarrow \\
f_* \mathcal{N} & \xrightarrow{f_* \beta} & f_* \mathcal{O}_T.
\end{array}
\]

Lemma 12.1.4. Let $T$ be a topos with enough points, $\varphi : \mathcal{M} \to \mathcal{N}$ a morphism of integral $T$-monoids inducing isomorphisms $\mathcal{M}^\times \cong \mathcal{N}^\times$ and $\mathcal{M}^1 \cong \mathcal{N}^1$. Then $\varphi$ is an isomorphism.

Proof. This can be checked on the stalks, hence we are reduced to the corresponding assertions for a morphism $M \to N$ of monoids. Moreover, $M^1$ is just the set-theoretic quotient of $M$ by the translation action of $M^\times$ (lemma 4.8.31(iii)), so the assertion is straightforward, and shall be left as an exercise for the reader. □

Definition 12.1.5. Let $\gamma : (\mathcal{M}, \alpha) \to (\mathcal{N}, \beta)$ be a morphism of pre-log structures on the locally ringed topos $T$, and $\xi$ a $T$-point.

(i) We say that $(\mathcal{M}, \alpha)$ is integral (resp. saturated) if $\mathcal{M}$ is an integral (resp. integral and saturated) $T$-monoid.

(ii) We say that $\gamma$ is flat (resp. saturated) at the point $\xi$, if $\gamma_\xi : \mathcal{M}_\xi \to \mathcal{N}_\xi$ is a flat morphism of monoids (resp. a saturated morphism of integral monoids) (see remark 4.8.23(vi)).

(iii) We say that $\gamma$ is flat (resp. saturated), if $\gamma$ is a flat morphism of $T$-monoids (resp. a saturated morphism of integral $T$-monoids) (see definition 6.2.28). In view of proposition 4.8.26 (resp. corollary 6.2.29), this is the same as saying that $\gamma$ is flat (resp. saturated) at every $T$-point.

12.1.6. The forgetful functor:

$$\log_T \to \text{pre-log}_T : \mathcal{M} \mapsto \mathcal{M}^{\text{pre-log}}$$

admits a left adjoint:

$$\text{pre-log}_T \to \log_T : (\mathcal{M}, \alpha) \mapsto (\mathcal{M}, \alpha)^{\log}$$

such that the resulting diagram:

$$\begin{array}{ccc}
\alpha^{-1}(\mathcal{O}_T^\times) & \to & \mathcal{M} \\
\downarrow & & \downarrow \\
\mathcal{O}_T^\times & \to & \mathcal{M}^{\log}
\end{array}$$

(12.1.7)
is cocartesian in the category of pre-log structures. One calls $M^\text{log}$ the log structure associated to $M$. From this description, it is easily seen that the counit of adjunction

$$\tag{12.1.8} (M^{\text{pre-log}})^{\log} \to M$$

is an isomorphism for every log structure $M$ on $T$.

Composing with the adjunction $\{12.1.3\}$, we deduce a pair of adjoint functors:

$$f^* : \log_S \to \log_T \quad f_* : \log_T \to \log_S$$

for any map of locally ringed topoi $f : T \to S$. Explicitly, if $N$ is any log structure on $S$, then $f^*N$ is the push-out in the cocartesian diagram of $T$-monoids:

$$\begin{array}{ccc}
\sigma_S^x & \longrightarrow & \sigma_T^x \\
\downarrow & & \downarrow \\
\sigma_T^x & \longrightarrow & f^*N
\end{array}$$

and on the other hand, if $M$ is any log structure on $T$, then it is easily seen that the pre-log structure $f_* (M^{\text{pre-log}})$ is actually a log structure (this can be checked on the stalks over the points of $T$). It follows easily that the induced map of $T$-monoids:

$$\tag{12.1.9} f^*(N^2) \to (f^*N)^2$$

is an isomorphism. As a consequence, for every point $\xi$ of $T$, the natural map $N_{f(\xi)} \to (f^*N)_\xi$ is a local morphism of monoids.

**Remark 12.1.10.** The category $\log_T$ admits arbitrary colimits: indeed, since the counit $\{12.1.8\}$ is an isomorphism, it suffices to construct such colimits in the category of pre-log structures, and then apply the functor $(-) \mapsto (-)^{\log}$ which preserves colimits, since it is a left adjoint.

12.1.11. Let $(M, \alpha)$ be a pre-log structure on $T$. The morphism $\alpha$ extends to a unique morphism of pointed $T$-monoids $\alpha_0 : M_o \to \mathcal{O}_T$, whence a new pre-log structure

$$(M, \alpha)_0 := (M_o, \alpha_0).$$

Clearly, $(M, \alpha)$ is a log structure if and only if the same holds for $(M_o, \alpha_0)$. More precisely, for any pre-log structure $M$ there is a natural isomorphism of log structures:

$$(M_o)^{\log} \sim (M^{\log})_0.$$}

Furthermore, for any morphism $f : T \to S$ of topos, we have natural isomorphisms of pre-log (resp. log) structures

$$f^*(N_o) \sim (f^*N)_o \quad f_*(M_o) \sim (f_*M)_o$$

for every pre-log (resp. log) structure $N_o$ on $S$ and $M$ on $T$ (details left to the reader).

**Example 12.1.12.** (i) Let $T \to S$ be a morphism of topos. Since the initial object of a category is the empty coproduct, it follows formally that the inverse image $f^*(\mathcal{O}_S^x, j)$ of the trivial log structure on $S$, is the trivial log structure on $T$.

(ii) Let $T$ be a topos, and $j_U : T/U \to T$ an open subtopos (see example $4.7.8$ (i)). Consider the subsheaf of monoids $M \subset \mathcal{O}_T$ such that:

$$M(V) := \{ s \in \mathcal{O}_T(V) \mid s|_{U \times V} \in \mathcal{O}_T^x(U \times V) \} \quad \text{for every object } V \text{ of } T.$$}

Then it is easily seen that the natural map $M \to \mathcal{O}_T$ is a log structure on $T$. This log structure is (naturally isomorphic to) the extension $j_{U*}\mathcal{O}_T^x$ of the trivial log structure on $T/U$.

(iii) Let $U$ be any object of the topos $T$, and $M$ a log structure on $T$. Since $\mathcal{O}_{T/U} = (\mathcal{O}_T)_{j_U}$, it is easily seen that the natural morphism of pre-log structures

$$(M^{\text{pre-log}})_U \to (M_{j_U})^{\text{pre-log}}$$
is an isomorphism.

(iv) Let $\beta : M \to O_T$ be a pre-log structure on a topos $T$. Then $\beta^{-1}(0) \subset M$ is an ideal, and $\beta$ factors uniquely through the natural map $M \to M/\beta^{-1}(0)$, and a pre-log structure

$$(M, \beta)_{\text{red}} := (M/\beta^{-1}(0), \beta)$$

called the reduced pre-log structure associated to $M$. As usual, we shall often write just $M_{\text{red}}$ instead of $(M, \beta)_{\text{red}}$. We say that $\beta$ is reduced if the induced morphism of pre-log structures $M \to M_{\text{red}}$ is an isomorphism.

Suppose now that $M$ is a log structure; then it is easily seen that the same holds for $M_{\text{red}}$. More precisely, since the tensor product is right exact (see (4.8.19)), for any pre-log structure $M$ the natural morphism of log structures

$$(M_{\text{red}})^{\log} \to (M^{\log})_{\text{red}}$$

is an isomorphism.

Lemma 12.1.13. Let $\gamma : (M, \alpha) \to (N, \beta)$ be a morphism of pre-log structures on $T$. We have:

(i) If $M$ is integral (resp. saturated), then the same holds for $M^{\log}$.

(ii) The unit of adjunction $M \to M^{\log}$ is a flat morphism.

(iii) If $\gamma$ is flat (resp. saturated) at a $T$-point $\xi$, the same holds for the induced morphism $\gamma^{\log} : M^{\log} \to N^{\log}$ of log structures.

(iv) Especially, if $\gamma$ is flat (resp. saturated), the same holds for $\gamma^{\log}$.

Proof. In view of lemma 4.8.46(ii) and proposition 4.8.26, both (i) and (ii) can be checked on stalks. Taking into account lemma 4.8.46(i), we are reduced to showing the following. Let $P$ be a monoid, $A$ a ring, $\beta : P \to (A, \cdot)$ a morphism of monoids; then the natural map $P \to P' := P \otimes_{\beta^{-1}A} A^\times$ is flat, and if $P$ is integral (resp. saturated), the same holds for $P'$.

The first assertion follows easily from example 6.1.24(vi), and the second follows from remark 6.2.5(i) (resp. from corollary 6.2.25(ix) and proposition 6.2.26).

(iii): The map $\gamma^{\log}$ can be factored as the composition of

$$\gamma' := \gamma \otimes_{\beta^{-1}O_T^\times} O_T^\times : N^{\log} \to P := M \otimes_{\beta^{-1}O_T^\times} O_T^\times$$

and the natural unit of adjunction $\gamma'' : P \to P^{\log} = M^{\log}$. If $\gamma_\xi$ is flat, the same clearly holds for $\gamma'_\xi$, and (ii) says that $\gamma''$ is flat, hence $\gamma^{\log}$ is flat in this case. Lastly, suppose that $\gamma$ is saturated, and we wish to show that $\gamma^{\log}$ is saturated. Set $P := \alpha_\xi^{-1}O_{T,\xi}$ and $Q := \beta_\xi^{-1}O_{T,\xi}^\times$. Then the induced map $P^{-1}M_{\xi}^\times \to Q^{-1}N_{\xi}^\times$ is saturated (lemma 6.2.12(ii,iii)). But the latter is the same as the morphism $(\gamma^{\log})^{\xi} \otimes_{O_{T,\xi}^\times}$, and then also $\gamma^{\log}$ is saturated, again by lemma 6.2.12(iii).

Lemma 12.1.14. Let $f : T' \to T$ be a morphism of topoi, $\xi$ a $T'$-point, and $\gamma : (M, \alpha) \to (N, \beta)$ a morphism of integral log structures on $T$. The following conditions are equivalent:

(a) $\gamma$ is flat (resp. saturated) at the $T$-point $f(\xi)$.

(b) $f^*\gamma$ is flat (resp. saturated) at the $T'$-point $\xi$.

(c) $\gamma^{\xi}$ is a flat (resp. saturated) morphism of monoids.

Proof. The equivalence of (a) and (c) follows from corollary 6.1.50 (resp. lemma 6.2.12(ii)). By the same token, (b) holds if and only if $(f^*\gamma)^{\xi}$ is flat (resp. saturated); in light of the isomorphism (12.1.9), the latter condition is equivalent to (c).

12.1.15. For any locally ringed topos $T$, let us write the objects of $\text{Mnd}/\Gamma(T, O_T)$ in the form $(M, \varphi)$, where $M$ is any monoid, and $\varphi : M \to \Gamma(T, O_T)$ a morphism of monoids. There is an obvious global sections functor :

$$\Gamma(T, -) : \text{pre-log}_T \to \text{Mnd}/\Gamma(T, O_T) : (M, \alpha) \mapsto (\Gamma(T, N), \Gamma(T, \alpha))$$
which admits a left adjoint:

\[ \text{Mnd}/\Gamma(T, \mathcal{O}_T) \to \text{pre-log}_T : (M, \varphi) \mapsto (M, \varphi)_{\Omega} := (M_{\Omega}, \varphi_{\Omega}). \]

Indeed, \( M_T \) is the constant sheaf on \((T, C_T)\) with value \( M \), and \( \varphi_{\Omega} \) is the composition of the map of constant sheaves \( M_T \to \Gamma(T, \mathcal{O}_T) \) induced by \( \varphi \), with the natural map \( \Gamma(T, \mathcal{O}_T) \to \mathcal{O}_T \).

Again, we shall often just write \( M_T \) to denote this pre-log structure.

After taking associated log structures, we deduce a left adjoint:

\[ \text{Mnd}/\Gamma(T, \mathcal{O}_T) \to \text{log}_T : (M, \varphi) \mapsto M^{\log} := (M, \varphi)^{\log} \]

to the global sections functor. \( M^{\log} \) is called the constant log structure associated to \((M, \varphi)\).

**Definition 12.1.17.** Let \( T \) be a locally ringed topos, \((M, \alpha)\) a log structure on \( T \).

(i) A chart for \( M \) is an object \((P, \beta)\) of \( \text{Mnd}/\Gamma(T, \mathcal{O}_T) \), together with a map of pre-log structures \( \omega_P : (P, \beta)_{\Omega} \to M \), inducing an isomorphism on the associated log structures. (Notation of \(12.1.15\)).

(ii) We say that a chart \((P, \beta)\) is finite (resp. integral, resp. fine, resp. saturated) if \( P \) is a finitely generated (resp. integral, resp. fine, resp. integral and saturated) monoid.

(iii) Let \( \varphi : M \to N \) be a morphism of log structures on \( T \). A chart for \( \varphi \) is the datum of charts:

\[ \omega_P : (P, \beta)_{\Omega} \to M \quad \text{and} \quad \omega_Q : (Q, \gamma)_{\Omega} \to N \]

for \( M \), respectively \( N \), and a morphism of monoids \( \varphi : Q \to P \), fitting into a commutative diagram:

\[
\begin{array}{ccc}
Q_T & \overset{\varphi^{\log}}{\longrightarrow} & P_T^{\log} \\
\downarrow{\omega_Q} & & \downarrow{\omega_P} \\
N & \overset{\varphi}{\longrightarrow} & M.
\end{array}
\]

We say that such a chart is finite (resp. integral, resp. fine, resp. saturated) if the monoids \( P \) and \( Q \) are finitely generated (resp. integral, resp. fine, resp. integral and saturated). We say that the chart is flat (resp. saturated), if \( \varphi \) is a flat morphism of monoids (resp. a saturated morphism of integral monoids).

(iv) We say that \( M \) is quasi-coherent (resp. coherent) if there exist a covering family \((U_\lambda \to 1_{\Omega} | \lambda \in \Lambda)\) of the final object \( 1_{\Omega} \) in \((T, C_T)\), and for every \( \lambda \in \Lambda \), a chart (resp. a finite chart) \((P_\lambda, \beta_\lambda)\) for \( M_{\Omega_{U_\lambda}} \).

(v) We say that \((M, \alpha)\) is quasi-fine (resp. fine) if it is integral and quasi-coherent (resp. and coherent).

(vi) Let \( \xi \) be any \( T \)-point. We say that a chart \((P, \beta)\) is local (resp. sharp) at the point \( \xi \), if the morphism \( \beta_\xi : P \to \mathcal{O}_{T, \xi} \) is local (resp. if \( P \) is sharp and \( \beta_\xi \) is local).

**Lemma 12.1.18.** Let \( f : T \to S \) be a morphism of locally ringed topoi, \( Q \) a log structure on \( S \), and \( \xi \) any point of \( S \). The following holds:

(i) If \( Q \) is quasi-coherent (resp. coherent, resp. integral, resp. saturated, resp. quasi-fine, resp. fine), then the same holds for \( f^*Q \).

(ii) Suppose that \( Q \) is an integral log structure. Then \( Q^f \) is an integral \( S \)-monoid, and \( Q \) is saturated if and only if \( Q^f \) is a saturated \( S \)-monoid.

(iii) Suppose that \( Q \) is quasi-coherent. Then \( Q \) is integral (resp. integral and saturated, resp. fine, resp. fine and saturated) if and only if there exist a covering family \((U_\lambda \to 1_{S} | \lambda \in \Lambda)\) of the final object of \( S \), and for every \( \lambda \in \Lambda \), an integral (resp. integral and saturated, resp. fine, resp. fine and saturated) chart \((P_\lambda)_{U_\lambda} \to Q_{U_\lambda} \).

(iv) If \( P \) is any coherent log structure on \( S \), and \( \omega : P_{\xi} \to Q_{\xi} \) is a map of monoids, then:
(a) There exist a neighborhood $U$ of $\xi$ and a morphism $\vartheta : P_U \to Q_U$ of log structures, such that $\vartheta_{|\xi} = \omega$.

(b) Moreover, for any two morphisms $\vartheta, \vartheta' : P_U \to Q_U$ with the property of (a), we may find a smaller neighborhood $V \to U$ of $\xi$ such that $\vartheta_{|V} = \vartheta'_{|V}$.

(c) Especially, if $Q$ is also coherent, and $\omega$ is an isomorphism, we may find $\vartheta$ and a small enough $U$ as in (a), such that $\vartheta_{|\xi} = \omega$.

(d) If $M$ is a finitely generated monoid, and $\omega : M \to \mathcal{O}_{S,\xi}$ a morphism of monoids, then we may find a neighborhood $U$ of $\xi$ and a morphism $\vartheta : M_U \to \mathcal{O}_U$ of $S/U$-monoids, such that $\vartheta_{|\xi} = \omega$.

Proof. (i): If $Q$ is the constant log structure associated to a map of monoids $\alpha : Q \to \Gamma(S, \mathcal{O}_S)$, then $f^*Q$ is the constant log structure associated to $\Gamma(S, f^\sharp) \circ \alpha$ (where $f^\sharp : \mathcal{O}_S \to f_*\mathcal{O}_T$ is the natural map). The assertions concerning quasi-coherent or coherent log structures are a straightforward consequence. Next, suppose that $Q$ is integral (resp. saturated); we wish to show that $f^*Q$ is integral (resp. saturated). To this aim, let $M := f^*(Q^{\text{pre-log}})$; by lemma 4.8.45(i), $M$ is an integral (resp. saturated) $T$-monoid; then the assertion follows from lemma 12.1.13(i).

(ii): By lemma 4.8.46(ii) the assertion can be checked on stalks. Hence, suppose that $Q$ is integral; then $Q_{|\xi}$ is integral by loc.cit., consequently, the same holds for $Q_{|\xi}/Q_{|\xi}^{\text{pre-log}}$ (lemma 4.8.38). The second assertion follows from lemma [6.2.9(ii)].

(iii): Suppose first that $Q$ is quasi-coherent and integral. Hence, there is a covering family $(U_\lambda \to 1_S | \lambda \in \Lambda)$, and for every $\lambda \in \Lambda$ a monoid $M_\lambda$, a pre-log structure $\alpha_\lambda : (M_\lambda)_{U_\lambda} \to \mathcal{O}_{U_\lambda}$, and an isomorphism $((M_\lambda)_{U_\lambda}, \alpha_\lambda)^{\log} \to Q_{|U_\lambda}$; whence a cocartesian diagram of $S$-monoids, as in (12.1.7):

\[
\begin{array}{ccc}
N := \alpha_\lambda^{-1}(\mathcal{O}_{U_\lambda}^{\log}) & \longrightarrow & (M_\lambda)_{U_\lambda} \\
\downarrow & & \downarrow \\
\mathcal{O}_{U_\lambda}^{\log} & \longrightarrow & Q_{|U_\lambda}.
\end{array}
\]

The induced diagram (12.1.19) of integral $S$-monoids is still cocartesian. Moreover, since $Q_{|U_\lambda}$ is integral, $\alpha_\lambda$ factors through a unique map $\beta_\lambda : ((M_\lambda)_{U_\lambda})^{\int} \to Q_{|U_\lambda} \to \mathcal{O}_{U_\lambda}$, and the morphism in $S$ underlying the induced morphism of $S$-monoids $N^{\int} \to N' := \beta_\lambda^{-1}(\mathcal{O}_{U_\lambda}^{\log})$ is an epimorphism (this can be checked easily on the stalks). Furthermore, $((M_\lambda)_{U_\lambda})^{\int} \simeq (M_\lambda^{\int})_{U_\lambda}$ (see (4.8.49)). It follows that the natural map

$$Q_{|U_\lambda} \to \mathcal{O}_{U_\lambda}^{\log} \Pi_{N'} (M_\lambda^{\int})_{U_\lambda} \simeq (M_\lambda^{\int})_{U_\lambda}^{\log}$$

is an isomorphism, so the claim holds with $P_\lambda := M_\lambda^{\int}$. If $Q$ is fine, we can find $M_\lambda$ as above which is also finitely generated, in which case the resulting $P_\lambda$ shall be fine.

Suppose additionally, that $Q$ is saturated. By the previous case, we may then find a covering family $(U_\lambda \to e_S | \lambda \in \Lambda)$, and for every $\lambda \in \Lambda$ an integral monoid $M_\lambda$, a pre-log structure $\alpha_\lambda : (M_\lambda)_{U_\lambda} \to \mathcal{O}_{U_\lambda}$, and an isomorphism $((M_\lambda)_{U_\lambda}, \alpha_\lambda)^{\log} \to Q_{|U_\lambda}$; whence a cocartesian diagram (12.1.19) consisting of integral $S$-monoids. The induced diagram (12.1.19) is still cocartesian; one may then argue as in the foregoing, to obtain a natural isomorphism $Q_{|U_\lambda} \to (M_\lambda^{\int})_{U_\lambda}^{\log}$. Furthermore, if $M_\lambda$ is finitely generated, the same holds for $M_\lambda^{\text{sat}}$ (corollary 6.4.1(ii)), hence the chart thus obtained shall be fine and saturated, in this case.

Conversely, if a family $(P_\lambda | \lambda \in \Lambda)$ of integral (resp. saturated) monoids can be found fulfilling the condition of (iii), then $(P_\lambda)_{U_\lambda}$ is an integral (resp. saturated) pre-log structure on...
admits a finite chart $\beta : Q \to \mathcal{O}_S$ of $Q$ (lemma [12.1.13(ii)]), and thus also for $Q$ (lemma [4.8.46(ii)], example [4.7.12], and example [12.1.12(iii)]). Moreover, if each $P_\alpha$ is fine, then $Q$ is fine as well.

(iv.a): We may assume that $P$ admits a finite chart $\alpha : M_S \to P$, for some finitely generated monoid $M$, denote by $\beta : Q \to \mathcal{O}_S$ the structure map of $Q$, and set $\omega' := \omega \circ \alpha_\xi : M \to Q_\xi$. According to lemma 6.1.7(ii), the morphism $\omega'$ factors through a map $\omega'' : M \to \Gamma(U', \mathcal{O}_Q)$, for some neighborhood $U'$ of $\xi$. By adjunction, $\omega''$ determines a morphism of $S/U'$-monoids $\psi : M_{U'} \to Q_{U'}$ whence a morphism of pre-log structures

\[(12.1.20) \quad (M_{U'}, \beta_{U'} \circ \psi) \to (Q_{U'}, \beta_{U'}).\]

Let us make the following general observation:

Claim 12.1.21. Let $N$ be a finite monoid, $F$ any $S$-monoid, $f, g : N_S \to F$ two morphisms of $S$-monoids, such that $f_\xi = g_\xi$. Then there exists a neighborhood $U$ of $\xi$ in $S$ such that $f_\xi = g_\xi$.

Proof of the claim. By adjunction, the morphisms $f$ and $g$ correspond to unique maps of monoids $\Gamma(f), \Gamma(g) : N \to \Gamma(S, F)$; since $N$ is finite and $f_\xi = g_\xi$, we may find a neighborhood $U$ of $\xi$ such that the maps $N \to F(U)$ induced by $\Gamma(f)$ and $\Gamma(g)$ coincide. Again by adjunction, we deduce a unique morphism of $S/U$-monoids $N_U \to F_U$, which by construction is just the restriction of both $f$ and $g$. 

Let $\gamma : P \to \mathcal{O}_S$ be the structure map of $P$; we apply claim [12.1.21] with $S$ replaced by $S/U'$, to deduce that there exists a small enough neighborhood $U \to U'$ of $\xi$ such that the restriction $(\gamma \circ \alpha)_U : M_U \to \mathcal{O}_{SU'}$ agrees with $\beta_U \circ \psi_U$. Then it is clear that the morphism of log structure associated to $(12.1.20)_U$ yields the sought extension $\vartheta$ of $\omega$.

(iv.b): By assumption we have the identity : $\vartheta_\xi = \vartheta'_\xi$; however, any morphism of log structures $P_{U'} \to Q_{U'}$ is already determined by its restriction to the image of any finite local chart $M_U \to P_{U'}$. Hence the assertion follows from claim [12.1.21].

(iv.c): We apply (iv.a) to $\omega^{-1}$ to deduce the existence of a morphism $\sigma : Q_{U'} \to P_{U'}$ such that $\sigma_\xi = \omega^{-1}$ on some neighborhood $U$ of $\xi$. Hence, $(\vartheta \circ \sigma)_\xi = 1_{Q_\xi}$ and $(\sigma \circ \vartheta)_\xi = 1_{P_\xi}$. By (iv.b), these identities persist on some smaller neighborhood.

(v): The proof is similar to that of (iv.a), though simpler : we leave it as an exercise for the reader. \hfill $\Box$

Definition 12.1.22. (i) A morphism $(T, M) \to (S, N)$ of topoi with pre-log (resp. log) structures, is a pair $f := (f, \log f)$ consisting of a morphism of locally ringed topoi $f : T \to S$, and a morphism

$$\log f : f^* N \to M$$

of pre-log structures (resp. log structures) on $T$. We say that $f$ is log flat (resp. saturated) if $\log f$ is a flat (resp. saturated) morphism of pre-log structures.

(ii) Let $(f, \log f)$ as in (i) be a morphism of log topoi, $\xi$ a $T$-point; we say that $f$ is strict at the point $\xi$, if $\log f_\xi$ is an isomorphism. We say that $f$ is strict, if it is strict at every $T$-point.

(iii) A chart for $\varphi$ is the datum of charts

$$\omega_P : (P, \beta)_T \to M \quad \text{and} \quad \omega_Q : (Q, \gamma)_S \to N$$

for $M$, respectively $N$, and a morphism of monoids $\vartheta : Q \to P$, such that $(f^* \omega_Q, \omega_P, \vartheta)$ is a chart for the morphism $\log f$. We say that such a chart $(\omega_Q, \omega_P, \vartheta)$ is finite (resp. fine, resp. flat, resp. saturated) if the same holds for the corresponding chart $(f^* \omega_Q, \omega_P, \vartheta)$ of $\log f$.

Remark 12.1.23. (i) Let $f : (T, M) \to (S, N)$ be a morphism of log topoi, $g : T' \to T$ a morphism of topoi, and $f' : (T', g^* M) \to (S, N)$ the composition of $f$ and the natural morphism of log topoi $(T', g^* M) \to (T, M)$; let also $\xi$ be a $T'$-point. Then $f'$ is strict at the
point $\xi$ if and only if $f$ is strict at the point $g(\xi)$. Indeed, $f'$ is strict at $\xi$ if and only if $(\log f')^\sharp_\xi$ is an isomorphism (lemma 12.1.4), if and only if $(\log f)^\sharp_{g(\xi)}$ is an isomorphism (by (12.1.9)), if and only if $f_{g(\xi)}$ is an isomorphism (again by lemma 12.1.4).

(ii) For any log topos $(T, M)$, let us set $(T, M)_o := (T, M_o)$. Then $(T, M)_o$ is a log topos (see (12.1.11)), and clearly, every morphism $f : (T, M) \to (S, N)$ of log topos extends naturally to a morphism $f_o : (T, M)_o \to (S, N)_o$ of log topos.

12.1.24. The 2-category of log topos admits arbitrary 2-limits indexed by usual categories. Indeed, if $\mathcal{S} := \{(T, M_\lambda) \mid \lambda \in \Lambda\}$ is any pseudo-functor (from a small category $\Lambda$, to the category of log topos), the 2-limit of $\mathcal{S}$ is the pair $(T, M)$, where $T$ is the 2-limit of the system of ringed topos $(T_\lambda \mid \lambda \in \Lambda)$, and $M$ is the colimit of the induced system of log structures $(p_\lambda^* M_\lambda \mid \lambda \in \Lambda)$ on $T$, where $p_\lambda : T \to T_\lambda$ denotes the natural projection, for every $\lambda \in \Lambda$ (see remark 12.1.10).

12.1.25. Consider a 2-cartesian diagram of log topos:

$$
\begin{array}{ccc}
(T', M') & \xrightarrow{g} & (T, M) \\
\downarrow{f'} & & \downarrow{f} \\
(S', N') & \xrightarrow{h} & (S, N).
\end{array}
$$

The following result yields a relative variant of the isomorphism (12.1.9):

**Lemma 12.1.26.** In the situation of (12.1.25), the morphism

$$g^* \text{Coker} (\log f) \to \text{Coker} (\log f')$$

induced by $\log g$ is an isomorphism of $T'$-monoids.

**Proof.** Indeed, denote by $\beta : M \to O_T$ and $\gamma : N' \to O_{S'}$ the log structures of $T$ and $S'$. Fix any $T'$-point $\xi$, let $\xi := g(\xi')$, and set

$$P := M_\xi \otimes_{N_{f(\xi')}} N'_{f'(\xi')} \quad \text{and} \quad \rho := \beta_\xi \otimes \gamma_{f'(\xi')} : P \to O_{T'}. $$

Then $M'_{\xi'} = P \otimes_{\rho^{-1}O_{T', \xi'}} O_{T', \xi'}^x$, and it is easily seen that $\rho^{-1}O_{T', \xi'} = O_{T, \xi'}^x \otimes_{N_{f(\xi')}} O_{S', f'(\xi')}^x$.

Therefore $(M'_{\xi'})^2 = P / \rho^{-1}O_{T', \xi'} = M_\xi^2 \otimes_{N_{f(\xi')}} N'_{f'(\xi')}^2$, and

$$\text{Coker}(\log f'_{\xi'}) = \text{Coker}(N'_{f'(\xi')} \to M_\xi^2 \otimes_{N_{f(\xi')}} N'_{f'(\xi')}^2) = \text{Coker}(N_{f(\xi')}^2 \to M_\xi^2)$$

whence the contention. $\square$

12.1.27. We consider now a special situation that we will encounter in proposition 12.1.30. Namely, let $Q$ be a monoid, and $H \subset Q^{sp}$ a subgroup. Let also $G$ be an abelian group, $\rho : G \to Q^{sp}$ a group homomorphism, and set:

$$H_\rho := G \times_{Q^{sp}} H \quad Q_\rho := G \times_{Q^{sp}} Q.$$

The natural inclusion $H \to Q$ and the projection $Q_\rho \to Q$ determine a unique morphism:

$$Q_\rho \otimes_{H_\rho} H \to Q. \quad (12.1.28)$$

**Lemma 12.1.29.** In the situation of (12.1.27), suppose furthermore that the composition:

$$G \xrightarrow{\rho} Q^{sp} \to (Q/H)^{sp}$$

is surjective. Then (12.1.28) is an isomorphism.
Proof. Set \( G' := G \oplus H \), and let \( \rho' : G' \to Q^{\text{gp}} \) be the unique group homomorphism that extends \( \rho \) and the natural map \( H \to Q \to Q^{\text{gp}} \). Under the standing assumptions, \( \rho' \) is clearly surjective. Define \( Q_{\rho'} \) and \( H_{\rho'} \) as in (12.1.27); there is a natural isomorphism of monoids : \( Q_{\rho'} \to Q_{\rho} \oplus H \), inducing an isomorphism \( H_{\rho'} \to H_{\rho} \oplus H \), and defined as follows. To every \( g \in G, h \in H, q \in Q \) such that \( [(g, h), q] \in Q_{\rho'} \), we assign the element \( [(g, h^{-1} q), a] \in Q_{\rho} \oplus H \) (details left to the reader). Under this isomorphism, the projection \( H_{\rho'} \to H \) is identified with the map \( H_{\rho} \oplus H \to H \) given by the rule : \( (h_1, h_2) \mapsto \pi_H(h_1) \cdot h_2 \), where \( \pi_H : H_{\rho} \to H \) is the projection. It then follows that the natural map :
\[
Q_{\rho} \otimes_{H_{\rho}} H \to Q_{\rho'} \otimes_{H_{\rho'}} H
\]
is an isomorphism. Thus, we may replace \( G \) and \( \rho \) by \( G' \) and \( \rho' \), which allows to assume from start that \( \rho \) is surjective. However, we have natural isomorphisms :
\[
\text{Ker}(Q_{\rho} \xrightarrow{\pi_Q} Q) \simeq \text{Ker} \rho \simeq \text{Ker}(H_{\rho} \xrightarrow{\pi_H} H).
\]
Moreover, the set underlying \( Q \) (resp. \( H \)) is the set-theoretic quotient of the set \( Q_{\rho} \) (resp. \( H_{\rho} \)) by the translation action of \( \text{Ker} \rho \); hence the natural maps \( Q_{\rho}/\text{Ker} \pi_Q \to Q \) and \( H_{\rho}/\text{Ker} \pi_H \to H \) are isomorphisms (lemma 4.8.31(ii)). We can then compute :
\[
Q_{\rho} \otimes_{H_{\rho}} H \simeq (Q_{\rho}/\text{Ker} \pi_Q) \otimes_{H_{\rho}/\text{Ker} \pi_H} H \simeq Q \otimes_H H \simeq Q
\]
as stated. \( \square \)

Proposition 12.1.30. Let \( T \) be a locally ringed topos, \( \xi \) any \( T \)-point, and \( M \) a coherent (resp. fine) log structure on \( T \). Suppose that \( G \) is a finitely generated abelian group with a group homomorphism \( G \to M^{\text{gp}}_\xi \) such that the induced map \( G \to (M^{\text{gp}})_\xi \) is surjective. Set \( P := G \times_{M^{\text{gp}}} M_\xi \).
Then the induced morphism \( P \to M_\xi \) extends to a finite (resp. fine) chart \( P_U \to M_{U, \xi} \) on some neighborhood \( U \) of \( \xi \).

Proof. We begin with the following :

Claim 12.1.31. Let \( Y \) be any locally ringed topos, \( \xi \) a \( Y \)-point, and \( \alpha : Q_Y \to \mathcal{O}_Y \) the constant pre-log structure associated to a map of monoids \( \vartheta : Q \to \Gamma(Y, \mathcal{O}_Y) \), where \( Q \) is finitely generated. Set \( S := \alpha_{-1} \mathcal{O}_Y^\times \subset Q_{Y, \xi} = Q \). Then :
(i) \( S \) and \( S^{-1} Q \) are finitely generated monoids.
(ii) There exists a neighborhood \( U \) of \( \xi \) such that \( \alpha_{|U} \) factors as the composition of the natural map of sheaves of monoids \( j_{U} : Q_U \to (S^{-1} Q)_U \), and a (necessarily unique) pre-log structure \( \alpha_S : (S^{-1} Q)_U \to \mathcal{O}_U \).
(iii) The induced map of log structures \( j_{U}^{\log} : Q^{\log}_U \to (S^{-1} Q)^{\log}_U \) is an isomorphism.
(iv) \( \alpha_{S, U, \xi}^{-1} (\mathcal{O}_{U, \xi}^\times) = (S^{-1} Q)^{\times} \) is a finitely generated group.

Proof of the claim. (i) follows from lemma 6.1.21(iv).
(ii): Since \( \mathcal{O}_{Y, \xi}^\times \) is the filtered colimit of the groups \( \Gamma(U, \mathcal{O}_U^\times) \), where \( U \) ranges over the neighborhoods of \( \xi \), lemma 6.1.7(ii) and (i) imply that the induced map \( S \to \mathcal{O}_{Y, \xi}^\times \) factors through \( \Gamma(U, \mathcal{O}_U^\times) \) for some neighborhood \( U \) of \( \xi \). Then the composition of \( \vartheta \) and the natural map \( \Gamma(Y, \mathcal{O}_Y) \to \Gamma(U, \mathcal{O}_U) \) extends to a unique map \( S^{-1} Q \to \Gamma(U, \mathcal{O}_U) \) , whence the sought pre-log structure \( \alpha_S \) on \( U \).
(iii): Let \( N \) be any log structure on \( U \); it is clear that every morphism of pre-log structures \( Q_U \to N \) factors uniquely through \( (S^{-1} Q)_U \), whence the contention.
(iv): Indeed, by construction we have : \( \alpha_{S, U, \xi}^{-1} (\mathcal{O}_{U, \xi}^\times) = S^{\text{gp}} \).

Let \( Y \) be a neighborhood of \( \xi \) such that \( M_{Y, \xi} \) admits a finite local chart \( \alpha : Q_Y \to \mathcal{O}_Y \); we lift \( \xi \) to some \( Y \)-point, \( \xi_Y \), and choose a neighborhood \( U \in \text{Ob}(T/Y) \) of \( \xi_Y \), as provided by
We may then replace $T$ by $U$, $\xi$ by $\xi_Y$ and $\alpha$ by the chart $\alpha_S$ of claim \ref{claim12.1.31} ii, which allows to assume from start that $S := \alpha_\xi^{-1}(\mathcal{O}_{T,\xi}^\times)$ is a finitely generated group. Moreover, let $H := \text{Ker}(S \to \mathcal{O}_{T,\xi}^\times)$; clearly $\alpha_\xi : Q \to \mathcal{O}_{T,\xi}$ factors through the quotient $Q' := Q/H$, hence we may find a neighborhood $U$ of $\xi$ such that $\alpha_H$ factors through a (necessarily unique) map of pre-log structures $\alpha_H : Q'_U \to \mathcal{O}_U$. Furthermore, if $N$ is any log structure on $U$, every map of pre-log structures $Q'_U \to N$ factors through $Q'_U$, so that $\alpha_H$ is a chart for $\mathcal{M}_{\xi,H}$. We may therefore replace $T$ by $U$ and $\alpha$ by $\alpha_H$, which allows to assume additionally, that $\alpha_\xi$ is injective on the subgroup $S$. Now, for any finitely generated subgroup $H \subset S \subset H$, we set $\mathcal{M}_{\xi,H} := H \amalg Q$; clearly, the monoids $\mathcal{M}_{\xi,H}$ are finitely generated, and moreover:

$$M_\xi = \colim_{S \subset H \subset \mathcal{O}_{T,\xi}} \mathcal{M}_{\xi,H}.$$  

Furthermore, we deduce a natural sequence of maps of monoids:

\begin{align*}
\{1\} & \to \mathcal{M}_{\xi,H} \xrightarrow{\psi_H} M_\xi \xrightarrow{\psi_H} \mathcal{O}_{T,\xi}^\times/H \to \{1\}.
\end{align*}

\textbf{Claim 12.1.33.} For every subgroup $H$ as above, the sequence \eqref{12.1.32} is exact, i.e. $\mathcal{M}_{\xi,H}$ is the kernel of $\psi_H$, and $\mathcal{O}_{T,\xi}^\times/H$ is the cokernel of $\varphi_H$.

\textbf{Proof of the claim.} By lemma \ref{lemma4.8.29}(iii), the assertion concerning $\text{Ker} \psi_H$ can be verified on the underlying map of sets; however, lemma \ref{lemma4.8.31}(ii) says that the set $M_{\xi}$ is the set-theoretic quotient $(Q \times \mathcal{O}_{T,\xi}^\times)/S$, for the natural translation action of $S$, and a similar description holds for $\mathcal{M}_{\xi,H}$, therefore $\text{Ker} \varphi_H$ is the set-theoretic quotient $(H \times Q)/S$, as required.

The assertion concerning $\text{Coker} \varphi_H$ holds by general categorical nonsense. \hfill \Box

Let $\varepsilon : M_{\xi} \to M_{\xi}^{gp}$ be the natural map; claim \ref{claim12.1.33} implies that the sequence of abelian groups \eqref{12.1.32} is right exact, and then a little diagram chase shows that:

\begin{align*}
\varepsilon^{-1}(\text{Im} \varphi_H) &= M_{\xi,H} \quad \text{whenever } S \subset H \subset \mathcal{O}_{T,\xi}^\times.
\end{align*}

Since $G$ is finitely generated, we may find $H$ as above, large enough, so that $M_{\xi,H}^{gp}$ contains the image of $G$. In view of \eqref{12.1.34}, we deduce that the natural map

$$G \times M_{\xi,H}^{gp} \to M_{\xi,H}$$

is an isomorphism, so $P$ is finitely generated, by corollary \ref{corollary6.4.2} moreover $P$ is integral whenever $M_{\xi}$ is. Then, lemma \ref{lemma12.1.18}(iv.a) implies that the natural map $P \to M_{\xi}$ extends to a morphism of log structures $\vartheta : P_{U}^{gp} \to \mathcal{M}_{U}$ on some neighborhood $U$ of $\xi$. It remains to show that $\vartheta$ restricts to a chart for $\mathcal{M}_{\xi',V}$ on some smaller neighborhood $V$ of $\xi$. To this aim, it suffices to show that the map of stalks $\vartheta_\xi$ is an isomorphism (lemma \ref{lemma12.1.18}(iv.c)). The latter assertion follows from lemma \ref{lemma12.1.29} \hfill \square

Proposition \ref{proposition12.1.30} is the basis of several frequently used tricks that allow to construct “good” charts for a given coherent log structure (and for a morphism of such structures), or to “improve” given charts. We conclude this section with a selection of these tricks.

\textbf{Corollary 12.1.35.} Let $T$ be a topos, $\xi$ a $T$-point, $M$ a fine log structure on $T$. Then there exist a neighborhood $U$ of $\xi$ in $T$, and a chart $P_U \to \mathcal{M}_{U}$ such that:

\begin{itemize}
  \item[(a)] $P^{gp}$ is a free abelian group of finite rank.
  \item[(b)] The induced morphism of monoids $P \to \mathcal{O}_{T,\xi}$ is local.
\end{itemize}

\textbf{Proof.} Choose a group homomorphism $G := \mathbb{Z}^{\oplus m} \to M_{\xi}^{gp}$ (for some integer $n \geq 0$), such that the induced map $G \to (M_{\xi})^{gp}$ is surjective, and set $P := G \times_{M_{\xi}^{gp}} M_{\xi}$. By proposition \ref{proposition12.1.30} the induced map $P \to M_{\xi}$ extends to a chart $P_U \to \mathcal{M}_{U}$, for some neighborhood $U$ of $\xi$. According to example \ref{example4.8.36}(v), $P^{gp}$ is a subgroup of $G$, whence (a). Next, claim \ref{claim12.1.31}
implies that, after replacing $P$ by some localization (which does not alter $P^{\text{gp}}$), and $U$ by a smaller neighborhood of $\xi$, we may achieve (b) as well.

\[ \square \]

**Corollary 12.1.36.** Let $T$ be a topos, $\xi$ a $T$-point, $M$ a coherent log structure on $T$, and suppose that $M_{\xi}$ is integral and saturated. Then we have:

(i) There exist a neighborhood $U$ of $\xi$ in $T$, and a fine and saturated chart $P_U \to M_{\{U\}}$ which is sharp at the point $\xi$.

(ii) Especially, there exists a neighborhood $U$ of $\xi$ in $T$, such that $M_{\{U\}}$ is a fine and saturated log structure.

**Proof.** (i): By lemma 6.2.10, we may find a decomposition $M_{\xi} = P \times M_{\xi}^{\times}$, for a sharp submonoid $P \subset M_{\xi}$. Set $G := P^{\text{gp}}$; we deduce an isomorphism $G \cong M_{\xi}^{\text{gp}} / M_{\xi}^{\times}$, and clearly $P = G \times M_{\xi}^{\text{gp}} / M_{\xi}$. By proposition 12.1.30, it follows that the induced map $P \to M_{\xi}$ extends to a chart $\beta : P_U \to M_{\{U\}}$ on a neighborhood $U$ of $\xi$. By construction, $\beta$ is sharp at the $T$-point $\xi$; moreover, since $M_{\xi}$ is saturated, it is easily seen that the same holds for $P$. Finally, $P$ is finitely generated, by corollary 6.4.2.

(ii): This follows immediately from (i) and lemma 12.1.18(iii).

\[ \square \]

**Theorem 12.1.37.** Let $T$ be a locally ringed topos, $\xi$ a $T$-point, $f : M \to N$ a morphism of coherent (resp. fine) log structures on $T$. Then:

(i) There exists a neighborhood $U$ of $\xi$, such that $f_U$ admits a finite (resp. fine) chart.

(ii) More precisely, given a finite (resp. fine) chart $\omega_P : P_T \to M$, we may find a neighborhood $U$ of $\xi$, a finite (resp. fine) monoid $Q$, and a chart of $f_U$ of the form

$$\omega_P, \omega_Q : Q_U \to N_U, \vartheta : P \to Q.$$

(iii) Moreover, if $f$ is a flat (resp. saturated) morphism of fine log structures and $(\omega_P, \omega_Q, \vartheta)$ is a fine chart for $f$, then we may find a neighborhood $U$ of $\xi$, a localization map $j : Q \to Q'$, and a flat (resp. saturated) chart for $f_U$ of the form $(\omega_P, \omega_Q, j \circ \vartheta)$, such that

(a) $\omega_Q|_U = \omega_{Q'}|_U \circ j_U$.

(b) The chart $\omega_{Q'}$ is local at the point $\xi$.

**Proof.** Up to replacing $T$ by $T/U'_{i}$ for a covering $(U'_{i} \to 1_T \mid i \in I)$ of the final object, we may assume that we have finite (resp. fine) charts $\omega_P : P_T \to M$ and $Q_T \to N$ (lemma 12.1.18(iii)), whence a morphism of pre-log structures:

$$\omega : P_T \xrightarrow{\omega_P} M \xrightarrow{f} N.$$

Let $\xi$ be any $T$-point; there follow maps of monoids $\varphi : P \to M_{\xi} \to N_{\xi}$ and $\psi : Q' \to N_{\xi}$. Set $G := (P \oplus Q')^{\text{gp}}$, and apply proposition 12.1.30 to the group homomorphism $G \to N_{\xi}$ induced by $\varphi$ and $\psi$; for $Q := G \times N_{\xi}$, we obtain a finite (resp. fine) local chart $Q_U \to N_U$ on some neighborhood $U$ of $\xi$. Then, $\varphi$ and the natural map $P \to G$ determine a unique map $P \to Q$, whence a morphism $\omega' : P_U \to Q_U \to N_U$ of pre-log structures; by construction, $\omega' : P = P_{U,\xi} \to N_{\xi}$ is none else than $\varphi$. By lemma 12.1.18(iv.b), we may then find a smaller neighborhood $V \to U$ of $\xi$ such that $\omega|_V = \omega|_V$. This proves (i) and (ii).

Next, we suppose that $f$ is flat (resp. saturated) and both $M, N$ are fine, and we wish to show (iii). In view of claim 12.1.31, we may find – after replacing $T$ by a neighborhood of $\xi$ – a fine chart for $f$ of the form $(\omega_P, \omega'_{Q'}, \vartheta')$, such that:

- $P'$ and $Q'$ are localizations of $P$ and $Q$, and $\vartheta'$ is induced by $\vartheta$;
- $\omega_P = \omega_P' \circ (j_P)_T$ and $\omega_Q = \omega_{Q'} \circ (j_Q)_T$, where $j_P : P \to P'$ and $j_Q : Q \to Q'$ are the localization maps;
- the induced maps $Q'' \to M_{\xi}$ and $P'' \to N_{\xi}$ are isomorphisms.
Now, by proposition 4.8.26 (resp. corollary 6.2.29), the map $f_{\xi}$ is flat (resp. saturated), hence the same holds for the induced map $M_{f_{\xi}} \to N_{f_{\xi}}$ by corollary 6.1.50(i) (resp. by lemma 6.2.12(iii)). Then the map $P_{\xi} \to Q_{\xi}$ induced by $\vartheta'$ is flat (resp. saturated) as well, so the same holds for $\vartheta'$, by corollary 6.1.50(ii) (resp. again by lemma 6.2.12(iii)). Finally, $j_P \circ \vartheta' : P \to Q'$ is flat (resp. saturated), by example 6.1.24(iii) (resp. by lemma 6.2.12(i)), and $(\omega_P, \omega_Q', j_P \circ \vartheta')$ is a chart for $f$ with the sought properties. □

**Corollary 12.1.38.** Let $T$ be a topos, $\xi$ a $T$-point, and $\varphi : M \to N$ a saturated morphism of fine and saturated log structures on $T$. We have:

(i) There exist a neighborhood $U$ of $\xi$, and a fine and saturated chart $(\omega_P, \omega_Q, \vartheta : P \to Q)$ of $\varphi|_U$, such that $\omega_P$ and $\omega_Q$ are sharp at the point $\xi$.

(ii) More precisely, suppose that $(\omega_P, \omega_Q, \vartheta : P \to Q)$ is a fine and saturated chart for $\varphi$, such that $M$ is sharp at the point $\xi$, and $\omega_Q$ is local at $\xi$. Then there exists a section $\sigma : Q^\xi \to Q$ of the projection $Q \to Q^\xi$, such that $(\omega_P, \omega_Q \circ \sigma_T, \vartheta^\xi)$ is a chart for $\varphi$.

**Proof.** After replacing $T$ by some neighborhood of $\xi$, we may assume that $M$ admits a chart $\omega_P : P_T \to M$ which is fine, saturated, and sharp at the point $\xi$ (corollary 12.1.36(i)). Then, by theorem 12.1.37(iii), we may find a neighborhood $U$ of $\xi$, and a fine and saturated chart $(\omega_P|_U, \omega_Q, \vartheta : P \to Q)$ for $\varphi|_U$, such that $\omega_Q$ is local at $\xi$, so that $\vartheta$ is also a local morphism. Hence, it suffices to show assertion (ii).

(ii) We notice the following:

**Claim 12.1.39.** Let $\vartheta : P \to Q$ a local and saturated morphism of fine and saturated monoids, and suppose that $P$ is sharp. Then there exists a section $\sigma : Q^\xi \to Q$ of the projection $Q \to Q^\xi$, such that $\vartheta(P)$ lies in the image of $\sigma$.

**Proof of the claim.** Pick an isomorphism $\beta : Q \cong Q^\xi \times Q^\xi$ as in lemma 6.2.10 and denote by $\psi : P \to Q^\xi$ the composition of $\vartheta$ with the induced projection $Q \to Q^\xi$. The morphism $\vartheta^\xi$ is still local and saturated (lemma 6.2.12(iii)), hence corollary 6.2.32(ii) implies that $\vartheta^{\text{sep}}$ extends to an isomorphism $P^{\text{sep}} \cong L \to Q^\xi$, where $L$ is a free abelian group of finite rank. Thus, we may extend $\psi^{\text{sep}}$ to a group homomorphism $\psi^0 : Q^\xi \to Q^\xi$. Define an automorphism $\alpha$ of $Q^\xi \times Q^\xi$, by the rule $(x, g) \mapsto (x, g \cdot \psi^0(x)^{-1})$. The restriction $\sigma : Q^\xi \to Q$ of $(\alpha \circ \beta)^{-1}$ will do.

With the notation of claim 12.1.39 it is easily seen that $\omega_Q \circ \sigma_T$ is still a chart for $N$, hence $(\omega_P, \omega_Q \circ \sigma_T, \vartheta^\xi)$ is a chart for $\varphi$ as required. □

**Corollary 12.1.40.** Let $f : (T, M) \to (S, N)$ a morphism of log topoi with coherent (resp. fine) log structures, and suppose that $N$ admits a finite (resp. fine) chart $\omega_Q : Q_S \to N$. Let also $\xi$ be any $T$-point; we have:

(i) There exist a neighborhood $U$ of $\xi$, and a finite (resp. fine) chart $(\omega_Q|_U, \omega_P, \vartheta : Q \to P)$ for the morphism $f|_U$.

(ii) Moreover, if $M$ and $N$ are finite and $f$ is log flat (resp. saturated) then, on some neighborhood $U$ of $\xi$, we may also find a chart $(\omega_Q|_U, \omega_P, \vartheta)$ which is flat (resp. saturated) and fine.

**Proof.** This is an immediate consequence of theorem 12.1.37. □

### 12.2. Log schemes.

We specialize now to the case of a scheme $X$. Whereas in [59, §6.4] we considered only pre-log structures on the Zariski site of a scheme, hereafter we shall treat uniformly the categories of log structures on the topoi $X_{\text{ét}}$ and $X_{\text{Zar}}$ (notation of (4.9.13)).
12.2.1. Henceforth, we choose \( \tau \in \{ \text{ét}, \text{Zar} \} \) (see (4.9.19)), and whenever we mention a topology on a scheme \( X \), it will be implicitly meant that this is the topology \( X_\tau \) (unless explicitly stated otherwise). Let \( X \) be a scheme; a pre-log structure (resp. a log structure) on \( X \) is a pre-log structure (resp. a log structure) on the topos \( X_\tau \). The datum of a scheme \( X \) and a log structure on \( X \) is called briefly a log scheme. It is known that a morphism of schemes \( X \to Y \) is the same as a morphism of locally ringed topos \( X_\tau \to Y_\tau \), hence we may define a morphism of log schemes \( (X, M) \to (Y, N) \) as a morphism of log topoi \( (X_\tau, M) \to (Y_\tau, N) \) (and likewise for morphisms of schemes with pre-log structures). We denote by pre-log\( _\tau \) (resp. log\( _\tau \)) the category of schemes with pre-log structures (resp. of log schemes) on the chosen topology \( \tau \). We denote by:

\[
\begin{align*}
\text{int. log}_\tau & \quad \text{sat. log}_\tau & \quad \text{qcoh. log}_\tau & \quad \text{coh. log}_\tau \\
\text{qf. log}_\tau & \quad \text{f. log}_\tau & \quad \text{qfs. log}_\tau & \quad \text{fs. log}_\tau
\end{align*}
\]

the full subcategory of the category log\( _\tau \), consisting of all log schemes with integral (resp. integral and saturated, resp. quasi-coherent, resp. coherent) log structures.

A scheme with a quasi-fine (resp. fine, resp. quasi-fine and saturated, resp. fine and saturated) log structure is called, briefly, a quasi-fine log scheme (resp. a fine log scheme, resp. a qfs log scheme, resp. a fs log scheme), and we denote by

\[
\begin{align*}
\text{qf. log}_\tau & \quad \text{f. log}_\tau & \quad \text{qfs. log}_\tau & \quad \text{fs. log}_\tau
\end{align*}
\]

the full subcategory of log\( _\tau \) consisting of all quasi-fine (resp. fine, resp. qfs, resp. fs) log schemes on the topology \( \tau \). In case it is clear (or indifferent) which topology we are dealing with, we will usually omit the subscript \( \tau \). There is an obvious (forgetful) functor:

\[
F : \text{log} \to \text{Sch}
\]

to the category of schemes, and it is easily seen that this functor is a fibration. For every scheme \( X \), we denote by log\( _X \) the fibre category \( F^{-1}(X) \) i.e. the category of all log structures on \( X \) (or log\( _X \), if we need to specify the topology \( \tau \)). The same notation shall be used also for the various subcategories: so for instance we shall write int.log\( _X \) for the full subcategory of all integral log structures on \( X \). Moreover, we shall say that the log scheme \( (X, M) \) is locally noetherian if the underlying scheme \( X \) is locally noetherian.

12.2.2. Most of the forthcoming assertions hold in both the étale and Zariski topoi, with the same proof. However, it may occasionally happen that the proof of some assertion concerning \( X_\tau \) (for \( \tau \in \{ \text{ét}, \text{Zar} \} \)), is easier for one choice or the other of these two topologies; in such cases, it is convenient to be able to change the underlying topology, to suit the problem at hand. This is sometimes possible, thanks to the following general considerations.

The morphism of locally ringed topos \( \tilde{u} \) of (4.9.15) induces a pair of adjoint functors:

\[
\tilde{u}^* : \text{log}_{\text{Zar}} \to \text{log}_{\text{ét}}, \quad \tilde{u}_* : \text{log}_{\text{ét}} \to \text{log}_{\text{Zar}}
\]
as well as analogous adjoint pairs for the corresponding categories of sheaves of monoids (resp. of pre-log structures) on the two sites. It follows formally that \( \tilde{u}^* \) sends constant log structures to constant log structures, i.e. for every scheme \( X \), and every object \( M := (\hat{M}, \varphi) \) of \( \text{Mnd}/\Gamma(X, \hat{\mathcal{O}}_X) \) we have a natural isomorphism:

\[
\tilde{u}^* (X_{\text{Zar}}, M_{\text{X}_{\text{Zar}}}) \simeq (X_{\text{ét}}, M_{\text{X}_{\text{ét}}})
\]

More generally, lemma [12.1.18(i)] shows that \( \tilde{u}^* \) preserves the subcategories of quasi-coherent (resp. coherent, resp. integral, resp. fine, resp. fine and saturated) log structures.

**Proposition 12.2.3.** (i) The functor \( \tilde{u}^* \) on log structures is faithful and conservative.

(ii) The functor \( \tilde{u}^* \) restricts to a fully faithful functor:

\[
\tilde{u}^* : \text{int. log}_{\text{Zar}} \to \text{int. log}_{\text{ét}}.
\]
(iii) Let \((X_{\text{ét}}, M)\) be any log scheme. Then the counit of adjunction \(\tilde{u}^*\tilde{u}_*(X_{\text{ét}}, M) \rightarrow (X_{\text{ét}}, M)\) is an isomorphism if and only if the same holds for the counit of adjunction \(\tilde{u}^*\tilde{u}_*(M^\sharp) \rightarrow M^\sharp\).

Proof. (i): Let \((X_{\text{Zar}}, M)\) be any log structure; set \((X_{\text{ét}}, M_{\text{ét}}) := \tilde{u}^*(X, M)\), and denote by \(\tilde{u}_X^* : \tilde{u}_*\mathcal{O}_{X_{\text{Zar}}} \rightarrow \mathcal{O}_{X_{\text{ét}}}\) the natural map of structure rings. Since \(\tilde{u}\) is a morphism of locally ringed topoi, we have:

\[
(\tilde{u}_X^*)^{-1}\mathcal{O}_{X_{\text{ét}}}^\times = \tilde{u}^*(\mathcal{O}_{X_{\text{Zar}}}^\times).
\]

It follows easily that \(M_{\text{ét}}\) is the push-out in the cocartesian diagram:

\[
\begin{array}{ccc}
\tilde{u}^* M^\times & \xrightarrow{\alpha} & \mathcal{O}^\times_{X_{\text{ét}}} \\
\downarrow & & \downarrow \\
\tilde{u}^* M & \xrightarrow{\beta} & M_{\text{ét}}.
\end{array}
\]

However, for every geometric point \(\xi\) of \(X\), the natural map \(\mathcal{O}_{X,\xi} \rightarrow \mathcal{O}_{X,\xi}\) is faithfully flat, hence \(\alpha_\xi\) is injective, and therefore also \(\beta_\xi\), in light of lemma [4.8.31(ii)]. The faithfulness of \(\tilde{u}^*\) is an easy consequence. Next, let \(f : M \rightarrow N\) be a morphism of log structures on \(X_{\text{Zar}}\), set \((X_{\text{ét}}, N_{\text{ét}}) := \tilde{u}^*(X, N)\), and suppose that \(\tilde{u}^*f : M_{\text{ét}} \rightarrow N_{\text{ét}}\) is an isomorphism; we wish to show that \(f\) is an isomorphism. However, \(\beta\) induces an isomorphism of monoids:

\[(12.2.4) \quad \tilde{u}^*(M^\sharp) \sim \tilde{u}^*(N^\sharp),\]

and likewise for \(N\); it follows already that \(f\) induces an isomorphism \(\tilde{u}_*\tilde{u}^*(M^\sharp) \sim \tilde{u}_*\tilde{u}^*(N^\sharp).\) To conclude, it suffices to invoke lemma [12.1.4].

(ii): Let us suppose that \(M\) is integral. According to [22, Prop.3.4.1], it suffices to show that the unit of adjunction \((X, M) \rightarrow \tilde{u}_*(X_{\text{ét}}, M_{\text{ét}})\) is an isomorphism. Now, from the isomorphism \((12.2.4)\) we deduce a commutative diagram:

\[
\begin{array}{ccc}
M^\sharp & \xrightarrow{\alpha} & (\tilde{u}_*M_{\text{ét}})^\sharp \\
\downarrow & & \downarrow \\
\tilde{u}_*\tilde{u}^*(M) & \xrightarrow{\beta} & \tilde{u}_*(M_{\text{ét}}^\sharp),
\end{array}
\]

whose bottom arrow is an isomorphism, and whose left vertical arrow is an isomorphism as well, by lemma [4.9.27(iii)] (and again [22, Prop.3.4.1]). We claim that also the right vertical arrow is an isomorphism. Indeed, since \(\tilde{u}_*\) is left exact, the latter arrow is a monomorphism, hence it suffices to show it is an epimorphism; however, since \(M_{\text{ét}}\) is an integral log structure (lemma [12.1.18(i)]), it is easily seen that the projection \(M_{\text{ét}} \rightarrow M_{\text{ét}}^\sharp\) is a \(\mathcal{O}_{X_{\text{ét}}}^\times\)-torsor (in the topos \(X_{\text{ét}}^\sharp/M_{\text{ét}}^\sharp\)). Then the contention follows from the exact sequence of pointed sheaves (4.9.12), and the vanishing result of lemma [4.9.27(iv)].

Summing up, we conclude that the top horizontal arrow in the above diagram is an isomorphism, so the assertion follows from lemma [12.1.4].

(iii): Set \((X_{\text{ét}}, (\tilde{u}_*M)_{\text{ét}}) := \tilde{u}^*\tilde{u}_*(X_{\text{ét}}, M).\) To begin with, lemma [4.9.27(iv)] easily implies that the natural morphism \((\tilde{u}_*M)_{\text{ét}} \rightarrow \tilde{u}_*(M_{\text{ét}}^\sharp)\) is an isomorphism; together with the general isomorphism \((12.1.9)\), this yields a short exact sequence of \(X_{\text{ét}}\)-monoids:

\[0 \rightarrow \mathcal{O}_{X_{\text{ét}}}^\times \rightarrow (\tilde{u}_*M)_{\text{ét}} \rightarrow \tilde{u}^*\tilde{u}_*(M_{\text{ét}}^\sharp) \rightarrow 0\]

which easily implies the assertion: the details shall be left to the reader. \(\square\)

We shall prove later on some more results in the same vein (see corollary [12.2.22]).
12.2.5. Arguing as in (12.1.24), we see easily that all finite limits are representable in the category of log schemes. The rule \( X \mapsto (X, O_X^\xi) \) defines a fully faithful inclusion of the category of schemes into the category of log schemes. Hence, we shall regard a scheme as a log scheme with trivial log structure. Especially, if \((X, M)\) is any log scheme, and \(Y \to X\) is any morphism of schemes, we shall often use the notation:

\[
(12.2.6) \quad Y \times_X (X, M) := (Y, O_Y^\xi) \times_{(X, O_X^\xi)} (X, M).
\]

Especially, if \(\xi\) is any \(\tau\)-point of \(X\), the localization of \((X, M)\) at \(\xi\) is the log scheme

\[
(X(\xi), M(\xi)) := X(\xi) \times_X (X, M)
\]

(see definition 4.9.17(ii,iii)). If \(\tau = \text{ét}\), this operation is also called the strict henselization of \(X\) at \(\xi\).

**Definition 12.2.7.** (i) For every integer \(n \in \mathbb{N}\), we have the subset:

\[
(X, M)_n := \{ x \in X \mid \dim M_x \leq n \text{ for every } \tau\text{-point } \xi \to X \text{ localized at } x \}.
\]

Especially \((X, M)_0\) consists of all points \(x \in X\) such that \(M_x = O_{X, \xi}^\times\) for every \(\tau\)-point \(\xi\) of \(X\) localized at \(x\); this subset is called the trivial locus of \((X, M)\), and is also denoted \((X, M)_{tr}\).

(ii) If \(f : (X, M) \to (Y, N)\) is a morphism of log schemes, we denote by \(\text{Str}(f) \subset X\) the strict locus of \(f\), which is the subset consisting of all points \(x \in X\) such that \(f\) is strict at every \(\tau\)-point localized at \(x\) (see definition 12.2.2(ii)).

**Remark 12.2.8.** Let \(f : (X, M) \to (Y, N)\) be any morphism of log schemes.

(i) Since log \(f\) induces local morphisms on stalks, it is easily seen that \(f\) restricts to a map

\[
f_{tr} : (X, M)_{tr} \to (Y, N)_{tr}.
\]

(ii) Especially, we have \((X, M)_{tr} \subset \text{Str}(f)\).

12.2.9. Let \(X := (X_i \mid i \in I)\) be a cofiltered family of quasi-separated schemes, with affine transition morphisms \(f_\varphi : X_j \to X_i\), for every morphism \(\varphi : j \to i \in I\). Denote by \(X\) the limit of \(X_i\), and for each \(i \in I\) let \(\pi_i : X \to X_i\) be the natural projection.

**Lemma 12.2.10.** In the situation of (12.2.9), let \(\mathcal{X} := ((X_i, M_i) \mid i \in I)\) be a cofiltered system of log schemes, with transition morphisms \((f_\varphi, \log f_\varphi) : (X_i, M_i) \to (X_j, M_j)\) for every morphism \(\varphi : i \to j \in I\). We have:

(i) The limit of the system \(\mathcal{X}\) exists in the category log.

(ii) Let \((X, M)\) denote the limit of the system \(\mathcal{X}\). If \(X_i\) is quasi-compact for every \(i \in I\), then the natural map

\[
\colim_{i \in I} \Gamma(X_i, N_i) \to \Gamma(X, N)
\]

is an isomorphism.

**Proof.** (i): Let \(X\) be the limit of the system of schemes \(X_i\) and endow \(X\) with the sheaf of monoids \(M := \colim_{i \in I} \pi_i^* M_i\), where \(\pi^*\) is the pull-back functor for sheaves of monoids (see (4.8.43)), and the transition maps \(\pi_i^* M_j \to \pi_i^* M_i\) are induced by the morphisms \(\log f_\varphi : f_j^* M_j \to f_i^* M_i\), for every \(\varphi : i \to j \in I\). Then the structure maps of the log structures \(M_i\) induce a well defined morphism of \(X\)-monoids \(M \to O_X\), and we claim that the resulting scheme with pre-log structure \((X, M)\) is actually a log scheme. Indeed, the assertion can be checked on the stalks, and notice that, for every \(\tau\)-point \(\xi\) of \(X\) we have a natural identification

\[
O_{X, \xi} \to \colim_{i \in I} O_{X_i, \pi_i(\xi)}.
\]
Example 12.2.11. Let $X$ be a scheme. For the following example we choose to work with the étale topology $X_{\acute{e}t}$ on $X$. A divisor on $X$ is a closed subscheme $D \subset X$ which is regularly embedded in $X$ and of codimension 1 ([51] Ch.IV, Déf.19.1.3, §21.2.12]). Suppose moreover that $X$ is noetherian, let $D \subset X$ be a divisor, and denote by $(D_i \mid i \in I)$ the irreducible reduced components of $D$. We say that $D$ is a strict normal crossings divisor, if:

- $\mathcal{O}_{X,x}$ is a regular ring, for every $x \in D$.
- $D$ is a reduced subscheme.
- For every subset $J \subset I$, the (scheme theoretic) intersection $\bigcap_{j \in J} D_j$ is regular of pure codimension $\sharp J$ in $X$.

A closed subscheme $D$ of a noetherian scheme $X$ is a normal crossings divisor if, for every $x \in X$ there exists an étale neighborhood $f : U \to X$ of $x$ such that $f^{-1}D$ is a strict normal crossings divisor in $U$.

Suppose that $D$ is a normal crossings divisor of a noetherian scheme $X$, and let $j : U := X \setminus D \to X$ be the natural open immersion. We claim that the log structure $j_*\mathcal{O}_{U,x}^\times$ is fine (this is the direct image of the trivial log structure on $U_{\acute{e}t}$; see example [12.1.12(ii)]). To see this, let $\xi$ be any geometric point of $X$ localized at a point of $D$; up to replacing $X$ by an étale neighborhood of $\xi$, we may assume that $D$ is a strict normal crossings divisor; we can assume as well that $X$ is affine and small enough, so that the irreducible components $(D_\lambda \mid \lambda \in \Lambda)$ are of the form $V(I_\lambda)$, where $I_\lambda \subset A := \Gamma(X,\mathcal{O}_X)$ is a principal divisor, say generated by an element $x_\lambda \in A$, for every $\lambda \in \Lambda$. We claim that $j_*\mathcal{O}_{U,x}^\times$ is the constant log structure associated to the pre-log structure:

$$\alpha : N_X^{(A)} \to \mathcal{O}_X : e_\lambda \mapsto x_\lambda$$

where $(e_\lambda \mid \lambda \in \Lambda)$ is the standard basis of $N_X^{(A)}$. Indeed, let $S \subset \Lambda$ be the largest subset such that the image of $\xi$ lies in $D_S := \bigcap_{\lambda \in S} D_\lambda$, we have $x_\lambda \in \mathcal{O}_{X,\xi}^\times$ for all $\lambda \notin S$, so that the push-out of the induced diagram of stalks $\mathcal{O}_{X,\xi}^\times \leftarrow \alpha^{-1}\mathcal{O}_{X,\xi}^\times \to N_X^{(A)}$ is the same as the push-out $P_S$ of the analogous diagram $\mathcal{O}_{X,\xi}^\times \leftarrow \alpha_S^{-1}\mathcal{O}_{X,\xi}^\times \to N_X^{(S)}$, where $\alpha_S : N_X^{(S)} \to \mathcal{O}_X$ is the restriction of $\alpha$. Suppose that $a \in \mathcal{O}_{X,\xi}^\times$, so that $a$ is invertible on $X(\xi) \setminus D_S$; the minimal associated primes of $A/\langle a \rangle$ are all of height one, and they must therefore be found among the prime ideals $Ax_\lambda$, with $\lambda \in S$. It follows easily that $a$ is of the form $u \prod_{\lambda \in S} x_\lambda^{k_\lambda}$ for certain $k_\lambda \in \mathbb{N}$ and $u \in \mathcal{O}_{X,\xi}^\times$. Therefore, the natural map $\beta_\xi : P_S \to (j_*\mathcal{O}_{U,x}^\times)_{\xi}$ is surjective. Moreover, the family $(x_\lambda \mid \lambda \in S)$ is a regular system of parameters of $\mathcal{O}_{X,\xi}$ ([48], Ch.0, Prop.17.1.7)), therefore the natural map $\text{Sym}_{\mathbb{N}(\xi)}^n(m_{\xi}/m_{\xi}^2) \to m_{\xi}^n/m_{\xi}^{n+1}$ is an isomorphism for every $n \in \mathbb{N}$ (here $m_{\xi} \subset \mathcal{O}_{X,\xi}$ is the maximal ideal); it follows easily that $\beta_\xi$ is also injective.

Example 12.2.12. Suppose that $X$ is a regular noetherian scheme, and $D \subset X$ a divisor on $X$; let $U := X \setminus D$. If $D$ is not a normal crossings divisor, the log structure $\bar{M} := j_*\mathcal{O}_{U,x}^\times$ on $X_{\acute{e}t}$ is not necessarily fine. For a counterexample, let $K$ be an algebraically closed field, $C \subset \mathbb{A}_K^3$ a nodal cubic; take $D \subset X := \mathbb{A}_K^3$ to be the (reduced, affine) cone over the cubic $C$, with vertex $x_0 \in \mathbb{A}^3$, and pick a geometric point $\xi$ localized at $x_0$. It is easily seen that, away from the vertex, $D$ is a normal crossings divisor, hence $\bar{M}|_{X \setminus \{x_0\}}$ is a fine log structure on $X \setminus \{x_0\}$, by example [12.2.11]. More precisely, let $y_0 \in C$ be the unique singular point, $L \subset D$ the line spanned by $x_0$ and $y_0$, and $\eta$ a geometric point localized at the generic point of $L$. By inspecting
the argument in example 12.2.11, we find that:

\[ M_\eta \simeq \mathbb{N}^{\oplus 2} \oplus \mathcal{O}_{X,\eta}^\times \]

(Indeed, an isomorphism is obtained by choosing \( a, b \in \mathcal{O}_{C_{y_0}} \) such that \( V(a) \) and \( V(b) \) are the two branches of the cubic \( C \) in an étale neighborhood of \( y_0 \)). On the other hand, let \( p \subset A := K[T_1, T_2, T_3] \) be the prime ideal corresponding to \( x_0 \), and \( I \subset A_p \) the ideal defining the closed subscheme \( X(x_0) \cap D \subset X(x_0) \); we claim that \( I \cdot \mathcal{O}_{X,\xi} \) is still a prime ideal, necessarily of height one. Indeed, let \( B := A_p/I \), and denote by \( A^\wedge \) (resp. \( B^\wedge \)) the \( p \)-adic completion of \( A_p \) (resp. of \( B \)); then \( B^\wedge \) is also the completion of the reduced ring \( \mathcal{O}_{X,\xi}/I \), hence it suffices to show that \( \text{Spec } B^\wedge \) is irreducible. However, we may assume that \( C \subset \text{Spec } K[T_1, T_2] \) is the affine cubic defined by the ideal \( J \subset K[T_1, T_2] \) generated by \( T_1^3 - T_2^2 + T_1T_2 \). Then \( I \) is generated by the element \( f := T_1^3 - T_2^2T_3 + T_1T_2T_3 \); also, \( p = (T_1, T_2, T_3) \), so that \( A^\wedge \simeq K[[T_1, T_2, T_3]] \) and \( B^\wedge \simeq A^\wedge/(f) \). Suppose \( \text{Spec } B^\wedge \) is not irreducible. This means that \( V(f) \subset \text{Spec } A^\wedge \) is a union \( V(f) = Z_1 \cup \cdots \cup Z_n \) of \( n \geq 2 \) irreducible components \( Z_i \). Since \( A^\wedge \) is a local regular ring, each such irreducible component \( Z_i \) is a divisor, defined by some principal prime ideal \( q_i \) in \( A^\wedge \). Let \( a_i \) be a generator for \( q_i \); then \( f \) admits factorizations of the form \( f = a_ib_i \) for some non-invertible \( b_i \in A^\wedge \). Fix some \( i \), and set \( \alpha := a_i, b := b_i \); since \( f \) is homogeneous of degree 3, we must have \( a \in p^{k}\setminus p^{k+1} \) for every \( k = 1 \) or \( 2 \) \( (k \neq 0 \) since \( a \) is not a unit, and \( k \neq 3 \), since \( b \) is not a unit); then \( b \in p^{3-k}\setminus p^{4-k} \cdot \) Write \( a = a' + a'' \) and \( b = b' + b'' \), where \( a'' \in p^{k+1}, b'' \in p^{4-k} \), and \( a' \) (resp. \( b' \)) is homogeneous of degree \( k \) (resp. \( 3 - k \)). Then \( f = ab = a'b' + c \), where \( c \in p^4 \) and \( a'b' \) is homogeneous of degree 3. This means that \( f = a'b' \) is a factorization of \( f \) in \( A \). However, \( f \) is irreducible in \( A \), a contradiction. (Instead of this elementary argument, one can appeal to [103, Th.43.20], which runs as follows. If \( R \) is a local domain, then there is a natural bijection between the set of minimal prime ideals of the henselization \( R^h \) of \( R \) and the set of maximal ideals of the normalization of \( R \) in its ring of fractions. In our case, the normalization \( D^\vee \) of \( D \) is the cone over the normalization of \( C \), hence the only point of \( D^\vee \) lying over \( x_0 \) is the vertex of \( D^\vee \).)

It follows that any choice of a generator of \( I \) yields an isomorphism:

\[ M_\xi \simeq \mathbb{N} \oplus \mathcal{O}_{X,\xi}^\times \]

Suppose now that \( V \) is an étale neighborhood of \( \xi \) – the log structure \( M \) is associated to a pre-log structure \( \alpha : P_V \to \mathcal{O}_V \), for some monoid \( P \); hence \( M_{|V} \) is the push-out of the diagram \( \mathcal{O}_V^\times \leftarrow \alpha^{-1}(\mathcal{O}_V^\times) \to P_V \), whence isomorphisms:

\[ P/\alpha^{-1}(\mathcal{O}_{X,\xi}^\times) \simeq M_\xi/\mathcal{O}_{X,\xi}^\times \simeq \mathbb{N} \quad P/\alpha_{\eta}^{-1}(\mathcal{O}_{X,\eta}^\times) \simeq M_\eta/\mathcal{O}_{X,\eta}^\times \simeq \mathbb{N}^{\oplus 2}. \]

But clearly \( \alpha_{\xi}^{-1}(\mathcal{O}_{X,\xi}^\times) \subset \alpha_{\eta}^{-1}(\mathcal{O}_{X,\eta}^\times) \), so we would have a surjection of monoids \( \mathbb{N} \to \mathbb{N}^{\oplus 2} \), which is absurd.

On the other hand, we remark that the log structure \( j_* \mathcal{O}_U^\times \) on the Zariski site \( X_{zar} \) is fine: indeed, one has a global chart \( \mathbb{N}_{X_{zar}} \to j_* \mathcal{O}_U^\times \), provided by the equation defining the divisor \( D \).

12.2.13. Let \( R \) be a ring, \( M \) a monoid, and set \( S := \text{Spec } R[M] \). The unit of adjunction \( \varepsilon_M : M \to R[M] \) can be regarded as an object \( (M, \varepsilon_M) \) of \( \text{Mon} / \Gamma(S, \mathcal{O}_S) \), whence a constant log structure \( M_S^{\log} \) on \( S \) (see 12.1.15). The rule

\[ M \mapsto \text{Spec}(R, M) := (S, M_S^{\log}) \]

is clearly functorial in \( M \). Namely, to any morphism \( \lambda : M \to N \) of monoids, we attach the morphism of log schemes

\[ \text{Spec}(R, \lambda) := (\text{Spec } R[\lambda], \lambda^{\log}_{\text{Spec } R[N]} : \text{Spec } (R, N) \to \text{Spec } (R, M). \]
Likewise, if $P$ is a pointed monoid, $\text{Spec} R(P)$ is a closed subscheme of $\text{Spec} R[P]$, and we may define

$$\text{Spec}(R, P) := \text{Spec}(R, P) \times_{\text{Spec} R[P]} \text{Spec} R(P).$$

Lastly, if $M$ is a non-pointed monoid, notice the natural isomorphism of log schemes

$$\text{Spec}(R, M) \cong \text{Spec}(R, M).$$

(Notation of remark \ref{remark12.1.23}: the details shall be left to the reader.)

**Lemma 12.2.14.** With the notation of \ref{12.2.13}, let $a \in M$ be any element, and set $M_a := S_a^{-1}M$, where $S_a := \{a^n \mid n \in \mathbb{N}\}$. Then $U_a := \text{Spec} R[M_a]$ is an open subscheme of $S$, and the induced morphism of log schemes

$$\text{Spec}(R, M_a) \to \text{Spec}(R, M) \times_S U_a$$

is an isomorphism.

**Proof.** Let $\beta_S : M_S \to \mathcal{O}_S$ and $\beta_{U_a} : (M_a)_{U_a} \to \mathcal{O}_{U_a}$ be the natural charts, and denote by $\varphi : M \to M_a$ the localization map. For every $\tau$-point $\xi$ of $U_a$, we have the identity:

$$\beta_S \xi = \beta_{U_a} \xi \circ \varphi : M \to \mathcal{O}_{S, \xi}.$$

Let $Q := \beta_{U_a}^{-1} \mathcal{O}_{U_a, \xi}^\times$. The assertion is a straightforward consequence of the following:

**Claim 12.2.15.** The induced commutative diagram of monoids:

$$\begin{array}{ccc}
\varphi^{-1}Q & \longrightarrow & M \\
\downarrow & & \downarrow \\
Q & \longrightarrow & M_a
\end{array}$$

is cocartesian.

**Proof of the claim.** Let $b \in M$, and suppose that $\beta_{U_a, \xi}(a^{-1}b) \in \mathcal{O}_{U_a, \xi}^\times$. Since $\beta_{U_a, \xi}(a) \in \mathcal{O}_{U_a, \xi}^\times$, we deduce that the same holds for $\beta_{U_a, \xi}(b)$, i.e. $b \in \varphi^{-1}Q$. Let $Q^\prime := \varphi(\varphi^{-1}Q)$; we conclude that $Q = S_a^{-1}Q^\prime$, the submonoid of $M_a$ generated by $Q^\prime$ and $a^{-1}$. The claim follows easily.

**12.2.16.** In the same vein, let $X$ be a $R$-scheme, and $(M, \varphi)$ any object of $\text{Mnd}/\Gamma(X, \mathcal{O}_X)$. The map $\varphi$ induces, via the adjunction of \ref{4.8.50}, a homomorphism of $R$-algebras $R[M] \to \Gamma(X, \mathcal{O}_X)$, whence a map of schemes $f : X \to S := \text{Spec} R[M]$, inducing a morphism

$$X \times_S \text{Spec}(R, M) \to (X, (M, \varphi)_{X}^{\log})$$

of log schemes.

**Lemma 12.2.18.** In the situation of \ref{12.2.16}, we have:

(i) The map \ref{12.2.17} is an isomorphism.

(ii) The log scheme $\text{Spec}(R, M)$ represents the functor

$$\text{log} \to \text{Set} : (Y, N) \mapsto \text{Hom}_{\text{Alg}}(R, \Gamma(Y, N)) \times \text{Hom}_{\text{Mnd}}(P, \Gamma(Y, N)).$$

**Proof.** (i): The log structure $f^*(M_{S}^{\log})$ of $\text{Spec}(R, M) \times_S X$ represents the functor:

$$F : \text{log} \to \text{Set} : N \mapsto \text{Hom}_{\text{Mnd}/\Gamma(S, \mathcal{O}_S)}((M, \varepsilon_M), \Gamma(S, f_1N)).$$

However, if $N$ is any log structure on $X$, the pre-log structure $(f_1N)^{\text{pre-log}}$ is the same as $f_*(N^{\text{pre-log}})$ (see \ref{[59](6.4.8)})]. From the explicit construction of direct images for pre-log
structures, and since the global sections functor is left exact (because it is a right adjoint), we
deduce a cartesian diagram of monoids:

\[
\begin{array}{ccc}
\Gamma(S, f_* N) & \longrightarrow & \Gamma(S, O_S) \\
\downarrow & & \downarrow \\
\Gamma(X, N) & \longrightarrow & \Gamma(X, O_X).
\end{array}
\]

It follows easily that \( F \) is naturally isomorphic to the functor given by the rule:

\[
N \mapsto \text{Hom}_{\text{Mnd}/\Gamma(X, O_X)}((M, \varphi), \Gamma(X, N)).
\]

The latter is of course the functor represented by \((M, \varphi)_{\log}\).

(ii) can now be deduced formally from (i), or proved directly by inspecting the definitions. \(\square\)

12.2.19. From (12.2.13) it is also clear that the rule

\[
(R, M) \mapsto \text{Spec}(R, M)
\]

defines a functor

\[
\text{Z-Alg}^0 \times \text{Mnd}^\circ \rightarrow \text{log}
\]

which commutes with fibre products; namely, say that

\[
(R', M') \leftarrow (R, M) \rightarrow (R'', M'')
\]

are two morphisms of \(\text{Z-Alg} \times \text{Mnd}^\circ\); then there is a natural isomorphism of log schemes:

\[
\text{Spec}(R' \otimes_R R'', M' \otimes_M M'') \cong \text{Spec}(R', M') \times_{\text{Spec}(R, M)} \text{Spec}(R'', M'').
\]

For the proof, one compares the universal properties characterizing these log schemes, using
lemma 12.2.18(ii) : details left to the reader.

12.2.20. Let \( X \) be a scheme, \( M \) a sheaf of monoids on \( X_{\tau} \). We say that \( M \) is \textit{locally constant}
if there exist a covering family \((U_\lambda \rightarrow X \mid \lambda \in \Lambda)\) and for every \( \lambda \in \Lambda \), a monoid \( P_\lambda \) and
an isomorphism of sheaves of monoids \( M_{U_\lambda} \cong (P_\lambda)_{U_\lambda} \). We say that \( M \) is \textit{constructible} if, for
every affine open subset \( U \subset X \) we can find finitely many constructible subsets \( Z_1, \ldots, Z_n \subset U \) such that :

- \( U = Z_1 \cup \cdots \cup Z_n \)
- \( M_{|Z_i} \) is a locally constant sheaf of monoids, for every \( i = 1, \ldots, n \).

If moreover, \( M_\xi \) is a finitely generated monoid for every \( \tau \)-point \( \xi \) of \( X \), we say that \( M \) is \textit{of finite type}. If \( \varphi : M \rightarrow N \) is a morphism of constructible sheaves of monoids on \( X_{\tau} \), then it is
easily seen that \( \text{Ker } \varphi, \text{Coker } \varphi \) and \( \text{Im } \varphi \) are also constructible. Moreover, if \( M \) and \( N \) are of
finite type, then the same holds for \( \text{Coker } \varphi \) and \( \text{Im } \varphi \).

Suppose that \( M \) is a sheaf of monoids on \( X_{\tau} \), and for every \( x \in X \) choose a \( \tau \)-point \( \overline{x} \)
localized at \( x \); the \textit{rank} of \( M \) is the function

\[
\text{rk}_M : X \rightarrow \mathbb{N} \cup \{ \infty \} \quad x \mapsto \dim_Q M_{\overline{x}}^\text{gp} \otimes_{\mathbb{Z}} \mathbb{Q}.
\]

It is clear from the definitions that the rank function of a constructible sheaf of monoid of finite
type is constructible on \( X \).

\textbf{Lemma 12.2.21.} Let \( X \) be a scheme, \( \varphi : Q \rightarrow Q' \) a morphism of coherent log structures on
\( X_{\tau} \). Then :

(i) The sheaves \( Q^0 \) and \( \text{Coker } \varphi \) are constructible of finite type.
(ii) \( (X, Q)_n \) is an open subset of \( X \), for every integer \( n \geq 0 \). (See definition 12.2.7(i).)
(iii) The rank functions of \( Q^0 \) and \( \text{Coker } \varphi \) are (constructible and) upper semicontinuous.
Proof. Suppose that $Q$ admits a finite chart $\alpha : M_X \to Q$. Pick a finite system of generators $\Sigma \subset M$, and for every $S \subset \Sigma$, set:

$$Z_S := \bigcap_{s \in S} D(s) \cap \bigcap_{t \in \Sigma \setminus S} V(t)$$

where, as usual $D(s)$ (resp. $V(s)$) is the open (resp. closed) subset of the points $x \in X$ such that the image $s(x) \in \kappa(x)$ of $s$ is invertible (resp. vanishes). Clearly each $Z_S$ is a constructible subset of $X$, and their union equals $X$. Moreover, for every $S \subset \Sigma$, and every $\tau$-point $\xi$ supported on $Z_S$, the submonoid $N_\xi := \alpha_\xi^{-1}(\Theta_\xi) \subset M$ is a face of $M$ (lemma 6.1.21(ii)), hence it is the submonoid $\langle S \rangle$ generated by $\Sigma \cap N_\xi = S$ (lemma 6.1.21(ii)). It follows easily that $Q^2_{\xi | Z_S} \simeq (M/(S))|_{Z_S}$.

More generally, suppose that $Q$ is coherent. We may assume that $X$ is quasi-compact. Then, by the foregoing, we may find a finite set $\Lambda$ and a covering family $(f_\lambda : U_\lambda \to X \mid \lambda \in \Lambda)$ of $X$, such that $Q^2_{| U_\lambda}$ is a constructible sheaf of monoids on $U_\lambda$. Since $f_\lambda$ is finitely presented, it maps constructible subsets to constructible subsets ([51, Ch.IV, Th.1.8.4]); it follows easily that the restriction of $Q^2_{| U}$ to $f_\lambda(U_\lambda)$ is constructible, therefore $Q^2_{| U}$ is constructible. Next, notice that $\text{Coker}\varphi = \text{Coker}\varphi^*$; by the foregoing, $Q^2_{| U}$ is constructible as well, so the same holds for $\text{Coker}\varphi$.

Next, let $x \in X$ be any point, and $\xi$ a $\tau$-point of $X$ localized at $x$; by theorem 12.1.37(i) we may find a neighborhood $f : U \to X$ of $\xi$ in $X_\tau$ and a finite chart $(\omega_P, \omega_P^r, \vartheta)$ for $\varphi^{| U}$. By claim 12.1.31 we may assume, after replacing $U$ by a smaller neighborhood of $\xi$, that $\omega_P$ and $\omega_P^r$ are local at the point $\xi$, in which case $Q^2_{| U} = P^\xi$ and $\text{Coker}\varphi_\xi = \text{Coker}\vartheta$. Let $r : X \to \mathbb{N}$ (resp. $r' : U \to \mathbb{N}$) denote the rank function of $Q^2_{| U}$ (resp. of $Q^2_{| U}$); then it is clear that $r' = r \circ f$.

On the other hand, for every $y \in U$ and every $\tau$-point $\eta$ of $U$ localized at $y$, the stalk $Q^2_{| y}$ is a quotient of $P^\xi$, hence $r'(y) \leq r(x)$ and $\dim Q_{\eta} \leq \dim Q_{\xi}$. Since $f$ is an open mapping, this shows (ii), and also that the rank function of $Q^2_{| U}$ is upper semicontinuous. Likewise, let $s$ (resp. $s'$) denote the rank function of $\text{Coker}\varphi$ (resp. $\text{Coker}\varphi_{| U}$); then $s' = s \circ f$, and $\text{Coker}\varphi_{| y}^\eta$ is a quotient of $\text{Coker}\vartheta$ for every $\tau$-point $\eta$ of $U$; the latter implies that $s'(y) \leq s(x)$ for every $y \in U$, which shows that $s$ is upper semicontinuous.

\[\square\]

Corollary 12.2.22. Let $X$ be a scheme, $M$ a log structure on $X_{\text{Zar}}$, and set

$$(X_{\text{et}}, M_{\text{et}}) := \bar{u}^*(X_{\text{Zar}}, M).$$

Then $M_{\text{et}}$ is integral (resp. coherent, resp. fine, resp. fine and saturated) if and only if the same holds for $M_{\text{et}}$.

Proof. It has already been remarked that $(X_{\text{et}}, M_{\text{et}})$ is coherent (resp. fine, resp. fine and saturated) whenever the same holds for $(X_{\text{Zar}}, M)$; furthermore, the proof of proposition [12.2.3] shows that the natural map on stalks $M_{\xi} \to M_{\text{et}, \xi}$ is injective for every geometric point $\xi$ of $X$, therefore $M$ is integral whenever the same holds for $M_{\text{et}}$.

Next, we suppose that $M_{\text{et}}$ is coherent, and we wish to show that $M$ is coherent.

Let $x \in X$ be any point, $\xi$ a geometric point localized at $x$. By assumption there exists a finitely generated monoid $P^\xi$, with a morphism $\alpha : P^\xi \to M_{\text{et}, \xi}$ inducing an isomorphism:

$$P^\xi \otimes_{\beta^{-1}M_{\text{et}, \xi}} M_{\text{et}, \xi} \to M_{\text{et}, \xi} \simeq M_{X, \xi}^\times;$$

It follows easily that we may find a finitely generated submonoid $Q \subset M_x$, such that the image of $\alpha$ lies in $(Q \cdot M_x^\times) \otimes_{M_x^\times} \mathcal{O}_{X, \xi}^\times$, and therefore the natural map:

$$(Q \cdot M_x^\times) \otimes_{M_x^\times} \mathcal{O}_{X, \xi}^\times \to M_{\text{et}, \xi}$$
is surjective. Then lemma [4.8.31] iii) implies that \( Q \cdot M_x^\times = M_x \), in other words, the induced map \( Q \to M_x^\times \) is surjective. Set
\[
P := Q^{\text{gp}} \times_{M^{\text{gp}}_{\text{etz}, \xi}} M^{\text{gp}}_{\text{etz}, \xi}.
\]

In this situation, proposition [12.1.30] tells us that the induced map \( \beta_\xi : P \to M^{\text{etz}, \xi} \) extends to an isomorphism of log structures \( \beta^{\text{log}}_\xi : P^{\text{log}}_{U_{\text{zar}}} \to M^{\text{etz}, \xi}_{U_{\text{zar}}} \) on some étale neighborhood \( U \to X \) of \( \xi \). On the other hand, it is easily seen that the diagram of monoids:
\[
\begin{array}{ccc}
M_x & \rightarrow & M^{\text{etz}}_x \\
\downarrow & & \downarrow \\
M^{\text{etz}, \xi} & \rightarrow & M^{\text{etz}, \xi}_x
\end{array}
\]
is cartesian, therefore \( \beta_\xi \) factors uniquely through a morphism \( \beta'_\xi : P \to M_x \). The latter extends to a morphism of log structures \( \beta'_{\xi, \log} : P^{\text{log}}_{U_{\text{zar}}} \to M^{\text{log}}_{U_{\text{zar}}} \) on some (Zariski) open neighborhood \( U' \) of \( x \) in \( X \) (lemma [12.1.18] iv)). By inspecting the construction, we find a commutative diagram of monoids:
\[
\begin{array}{ccc}
(u^*_\xi P^{\text{log}}_{U_{\text{zar}}} \xi) & \rightarrow & P^{\text{log}}_{U_{\text{zar}}, \xi} \\
\downarrow & & \downarrow \\
(u^*\beta'_{\log, \xi}) & \rightarrow & \beta^{\log}_{\xi}
\end{array}
\]
(where \( u^* \) is the functor on log structures of (12.2.2)) whose horizontal arrows and right vertical arrow are isomorphisms; it follows that \( u^*_\xi \beta^{\log}_{\xi} \) is an isomorphism as well, therefore \( u^* \beta'_{\log} \) restricts to an isomorphism on some smaller étale neighborhood \( f : U'' \to U' \) of \( \xi \) (lemma [12.1.18] iv). Since \( f \) is an open morphism, we deduce that the restriction of \( (u^*_\xi \beta^{\log}_{\xi})_\xi \) is already an isomorphism on \( f(U'')_{\text{etz}} \), and \( f(U'') \) is a (Zariski) open neighborhood of \( x \) in \( X \). Finally, in light of proposition [12.2.3] i), we conclude that the restriction of \( \beta^{\log}_{\xi} \) is an isomorphism on \( f(U'')_{\text{zar}} \), so \( M \) is coherent, as stated.

Lastly, we suppose that \( M_{\text{etz}} \) is fine and saturated, and we wish to show that \( M \) is saturated. However, the assertion can be checked on the stalks, hence let \( \xi \) be any geometric point of \( X \); the proof of proposition [12.2.3] shows that the natural map \( M^{\text{etz}, \xi}_\xi \to M^{\text{etz}, \xi}_{\text{etz}, \xi} \) is bijective, so the assertion follows from lemma [6.2.9] ii).

\[\square\]

**Corollary 12.2.23.** The category \( \text{coh.log} \) admits all finite limits. More precisely, the limit (in the category of log structures) of a finite system of coherent log structures, is coherent.

**Proof.** Let \( \Lambda \) be a finite category, \( \mathcal{X} := \{(X_\lambda, M_\lambda) \mid \lambda \in \Lambda\} \) an inverse system of schemes with coherent log structures indexed by \( \Lambda \). Denote by \( Y \) the limit of the system \( (X_\lambda)_{\lambda \in \Lambda} \) of underlying schemes, and by \( \pi_\lambda : Y \to X_\lambda \) the natural morphism, for every \( \lambda \in \Lambda \). It is easily seen that the limit of \( \mathcal{X} \) is naturally isomorphic to the limit of the induced system \( \mathcal{Y} := \{(Y, \pi_\lambda^* M_\lambda) \mid \lambda \in \Lambda\} \), and in view of lemma [12.1.18] i), we may therefore replace \( \mathcal{X} \) by \( \mathcal{Y} \), and assume that \( \mathcal{Y} \) is a finite inverse system in the category \( \text{log}X \), for some scheme \( X \) (especially, the underlying maps of schemes are \( 1_X \), for every morphism \( \lambda \to \mu \) in \( \Lambda \)).

It suffices then to show that the push-out of two morphisms \( g : N \to M, h : N \to M' \) of coherent log structures on \( X \), is coherent. However, notice that the assertion is local on the site \( X_r \), hence we may assume that \( N \) admits a finite chart \( Q_X \to N \). Then, thanks to theorem [12.1.37] ii), we may further assume that both \( f \) and \( g \) admit finite charts of the form \( Q_X \to P_X \) and respectively \( Q_X \to P'_X \), for some finitely generated monoids \( P \) and \( P' \). We deduce a natural map \( (P \sqcup P')_X \xrightarrow{\sim} P_X \sqcup Q_X P'_X \to M \sqcup N M' \), which is the sought finite chart. \[\square\]
Lemma 12.2.24. In the situation of (12.2.9), suppose that $X_i$ is quasi-compact for every $i \in I$, and that there exist $i \in I$, and a coherent log structure $\mathcal{N}_j$ on $X_i$, such that the log structure $\mathcal{N} := \pi'_i \mathcal{N}_j$ on $X_\tau$ admits a finite chart $\beta : Q_X \to \mathcal{N}$. Then there exist a morphism $\varphi : j \to i$ in $I$ and a chart $\beta_j : Q_{X_j} \to \mathcal{N}_j := f'_j \mathcal{N}_i$ for $\mathcal{N}_j$, such that $\pi'_j \beta_j = \beta$.

Proof. After replacing $I$ by $I/i$, we may assume that $\mathcal{N}_j$ is well defined for every $j \in I$, and $i$ is the final object of $I$. In this case, notice that $(X, \mathcal{N})$ is the limit of the cofiltered system of log schemes $(\mathcal{N}_j)_{j \in I}$. We begin with the following:

Claim 12.2.25. In order to prove the lemma, it suffices to show that, for every $\tau$-point $\xi$ of $X$ there exist $j(\xi) \in I$, a neighborhood $U_\xi \to X_{j(\xi)}$ of $\pi_{j(\xi)}(\xi)$ in $X_{j(\xi),\tau}$, and a chart $\beta_{j(\xi)} : Q_{U_\xi} \to \mathcal{N}_{j(\xi)}$ such that $\beta_{j(\xi)} = \beta$.

Proof of the claim. Clearly we may assume that $\mathcal{N}_j$ is an affine scheme, for every $\tau$-point $\xi$ of $X$. Under the stated assumptions, $X$ is quasi-compact, hence we may find a finite set $\{\xi_1, \ldots, \xi_n\}$ of $\tau$-points of $X$, such that $(U_{\xi_k} \times_{X_{j(\xi_k)}} X \to X | k = 1, \ldots, n)$ is covering in $X_\tau$. Since $I$ is cofiltered, we may then find $j \in I$ and morphisms $\varphi_k : j \to j(\xi_k)$ for every $k = 1, \ldots, n$. After replacing each $\beta_{j(\xi_k)}$ by $f'_{j(\xi_k)} \beta_{j(\xi_k)}$, we may assume that $j(\xi_k) = j$ for every $k \leq n$.

In this case, set $\beta_k := \beta_{j(\xi_k)}$, and let $U_k := U_{\xi_k}$ for every $k \leq n$; let also $U_{kl} := U_k \times_{X_j} U_l$, $U_{kl} := U_k \times X_j$ for every $k, l \leq n$, and denote by $\pi_{kl} : U_{kl} \to U_k$ the natural projection. Hence, for every $k, l \leq n$ we have a morphism of $U_{kl}$-monoids:

$$\beta_{kl} := \pi_{kl}^* \beta_{lk}$$

and by construction we have $\pi_{kl}^* \beta_{lk} = \pi_{lk}^* \beta_{lk}$ under the natural identification : $U_{kl} \sim U_{lk}$. Notice now that $U_{kl}$ is quasi-compact and quasi-separated for every $k, l \leq n$, hence the natural map

$$\colim_{i \in I} \Gamma(U_{kl} \times_{X_i} X_i, \mathcal{N}_i) \to \Gamma(U_{kl}, \mathcal{N})$$

is an isomorphism (Lemma 12.2.10(iii)). On the other hand, $\beta_{kl}$ is given by a morphism of monoids $b_{kl} : Q \to \Gamma(U_{kl}, \mathcal{N}_j)$, and likewise $\pi_{kl}^* \beta_{lk}$ is given by the morphism $Q \to \Gamma(U_{kl}, \mathcal{N})$ obtained by composition of $b_{kl}$ and the natural map $\Gamma(U_{kl}, \mathcal{N}_j) \to \Gamma(U_{kl}, \mathcal{N})$. By Lemma 6.1.7(ii), we may then find a morphism $j' \to j$ in $I$ such that the following holds. Set

$$V_k := U_k \times X_j X_j \quad V_{kl} := V_k \times_{X_j} V_l$$

for every $k, l \leq n$ and let $p_k : V_k \to U_k$ be the projection for every $k \leq n$; let also $\beta'_k := p_k^* \beta_k$, which is a chart $Q_{U_k} \to \mathcal{N}_{j'}|_{V_k}$ for the restriction of $\mathcal{N}_{j'}$. Then

$$\beta'_{kl}|_{V_{kl}} = \beta'_{kl}|_{V_{kl}}$$

under the natural identification $V_{kl} \sim V_{lk}$. By construction, the system of morphisms $(V_k \times X_{j'}, X \to X | k = 1, \ldots, n)$ is covering in $X_\tau$; after replacing $j'$ by a larger index, we may then assume that the system of morphisms $(V_k \to X_{j'} | k = 1, \ldots, n)$ is covering in $X_{j',\tau}$ (50 Ch.IV, Th.8.10.5)). In this case, (12.2.26) implies that the local charts $\beta'_k$ glue to a well defined chart $\beta'_{j'} : Q_{X_{j'}} \to \mathcal{N}_{j'}$, and a direct inspection shows that we have indeed $\pi_{j'}^* \beta_{j'} = \beta$.

Now, denote by $\alpha : Q_X \to O_X$ the composition of $\beta$ and the structure map of $\mathcal{N}$, and let $\xi$ be a $\tau$-point of $X$; we have a natural isomorphism

$$\mathcal{N}_\xi = \mathcal{N}_{i,\tau}(\xi) \otimes_{\mathcal{N}_{i,\tau}(\xi)} O_{X,\xi} \sim \colim_{j \in I} \mathcal{N}_{i,\tau}(\xi) \otimes_{\mathcal{N}_{i,\tau}(\xi)} O_{X,\xi,\tau} \sim \colim_{i \in I} \mathcal{N}_{j,\tau}(\xi)$$

(51 Ch.IV, Prop.18.8.18(ii))). It follows that $\beta_\xi$ and $\alpha_\xi$ factor through morphisms of monoids $\beta_{\xi,j} : Q \to \mathcal{N}_{j,\tau}(\xi)$ and $\alpha_{\xi,j} : O_{X,\xi,j}(\xi)$ for some $j \in I$ (Lemma 6.1.7(ii)), and again we may replace $I$ by $I/j$, after which we may assume that $\beta_{\xi,j}$ and $\alpha_{\xi,j}$ are defined for every $j \in I$. Then $\alpha_{\xi,j}$ extends to a pre-log structure $\alpha_j : Q_{U_j} \to O_{U_j}$ on some neighborhood $U_j \to X_j$ of
and we may also assume that $\beta_{\xi,j}$ extends to a morphism of pre-log structures $\beta_j : (Q_{U_j}, \alpha_j) \to N_j[U_j]$ (lemma 12.1.18(iv.a)). Notice as well that
\[ N_{\beta_{\xi,j}}^+ \simeq N_{\xi}^+ \quad \text{and} \quad \beta_{\xi,j}^{-1} N_{\xi}^\times = \beta_{\xi}^{-1} N_{\xi}^\times \quad \text{for every } j \in I \]
and since $\beta_{\xi}$ induces an isomorphism $Q / \beta_{\xi}^{-1} N_{\xi}^\times \simeq N_{\xi}^+$, we deduce that $\beta_{\xi,j}$ (which is the same as $\beta_{\xi,j}$) induces an isomorphism $Q / \alpha^{-1}_j \mathcal{O}^\times_{X_j, \pi_j(\xi)} \simeq N_{\beta_{\xi,j}}^+$ for every $j \in I$. In turn, it then follows from lemma 12.1.4 that $\beta_{\xi,j}$ induces an isomorphism $(Q_{U_j}, \alpha_j)^{\log}_{\pi_j(\xi)} \simeq N_{j, \pi_j(\xi)}$.

Next, by lemma 12.1.18(iv.b,c) we may find, for every $I \in \xi,\ldots,\xi,\ldots,\xi,\ldots,\xi$, such that the restriction $Q_{U_j' \alpha_j[U_j')} \simeq N_{j,U_j'} \beta_j$ is a chart for $N_{j,U_j'}$.

By construction, the morphism $((U_j \times X_j, \pi_j)^* \beta_j) : Q \to N_{\xi}$ is the same as $\beta_{\xi}$, so by lemma 12.1.18(iv.b) we may find a neighborhood $V_j \to U_j' \times X_j$ of $\xi$ in $X_\tau$, such that
\[ ((U_j \times X_j, \pi_j)^* \beta_j)|_{V_j} = \beta_{V_j} \quad \text{and} \quad ((U_j \times X_j, \pi_j)^* \alpha_j)|_{V_j} = \alpha|_{V_j}. \]

**Claim 12.2.27.** In the situation of (12.2.9), let $Y \to X$ be an object of the site $X_\tau$, with $Y$ quasi-compact and quasi-separated. We have:

(i) There exist $i \in I$, an object $Y_i \to X_i$ of $X_{i,\tau}$, and an isomorphism of $X$-schemes $Y \simeq Y_i \times_{X_i} X$.

(ii) Moreover, if $Y \to X$ is covering in $X_\tau$, then we may find $i \in I$ and $Y_i \to X_i$ as in (i), which is covering in $X_{i,\tau}$.

**Proof of the claim.** (i) is obtained by combining [50, Ch.IV, Th.8.8.2(ii)] and [51, Ch.IV, Prop.17.7.8(ii)] (and [50, Ch.IV, Cor.8.6.4] if $\tau = \text{Zar}$). Assertion (ii) follows from (i) and [50, Ch.IV, Th.8.10.5].

By claim 12.2.27(ii), we may assume that $V_j = U_j'' \times X_j, X$ for some neighborhood $U_j'' \to U_j$ of $\pi_j(\xi)$ in $X_{j,\tau}$. To conclude, it suffices to invoke claim 12.2.25.

**Proposition 12.2.28.** In the situation of (12.2.9), suppose that $X_i$ is quasi-compact for every $i \in I$. Then the natural functor:

(12.2.9)
\[
\text{2-colim}_{i} \text{coh.log}_{X_i} \to \text{coh.log}_{X}
\]
is an equivalence.

**Proof.** To begin with, we show:

**Claim 12.2.30.** The functor (12.2.29) is faithful. Namely, for a given $i \in I$, let $M_i$ and $N_i$ be two coherent log structures on $X_i$, and $f_i, g_i : M_i \to N_i$ two morphisms, such that $\pi_i^* f_i$ agrees with $\pi_i^* g_i$. Then there exists a morphism $\psi : j \to i$ in $I$ such that $f_j^* f_i = f_j^* g_i$.

**Proof of the claim.** Set $M_i := \pi_i^* M_i$, and define likewise the coherent log structure $N_i$ on $X_i$. For any $\tau$-point $\xi$ of $X$, pick a neighborhood $U_{\xi} \to X_i$ of $\pi_i(\xi)$ in $X_i$, and a finite chart $\beta : P_{U_{\xi}} \to M_i[U_{\xi}]$ for the restriction of $M_i$. The morphisms $f_i[U_{\xi}]$ and $g_i[U_{\xi}]$ are determined by the induced maps $\varphi := \Gamma(U_{\xi}, f_i) \circ \beta$ and $\gamma := \Gamma(U_{\xi}, g_i) \circ \beta$, and the assumption means that the composition of $\varphi$ and the natural map $\Gamma(U_{\xi}, N_i) \to \Gamma(U_{\xi} \times X_i, X_i, N_i)$ equals the composition of $\gamma$ with the same map.

It then follows from lemmata 12.2.10(ii) and 6.1.7(ii) that there exists a morphism $\psi : i(\xi) \to i$ in $I$ such that the composition of $\varphi$ with the natural map $\Gamma(U_{\xi}, N_i) \to \Gamma(U_{\xi} \times X_i, X_i, N_i)$ equals the composition of $\gamma$ with the same map; in other words, if we set $U_{\xi}' := U_{\xi} \times X_i, X_i(\xi)$, we have $f_j^* f_i[U_{\xi}'] = f_j^* g_i[U_{\xi}]$. Next, since $X$ is quasi-compact, we may find finitely many $\tau$-points $\xi_1, \ldots, \xi_n$ such that the family $(U_{\xi_k} \times_{X_{i(\xi_k)}} X \to X)$ is covering in $X_\tau$. Then, by [50, Ch.IV,
Th.8.10.5] we may find \( j \in I \) and morphisms \( \psi_k: j \to i(\xi_k) \) in \( I \), for \( k = 1, \ldots, n \), such that the induced family \( (U''_k := U'_k \times_{X'_i(\xi_k)} X_j \to X_j) \) is covering in \( X_{j, \tau} \). By construction we have
\[
f_{\psi_k \circ \alpha_k}^* f_i|_{U''_k} = f_{\psi_k \circ \alpha_k}^* g_i|_{U''_k} \quad \text{for} \quad k = 1, \ldots, n
\]
therefore \( f_{\psi_k \circ \alpha_k}^* f_i = f_{\psi_k \circ \alpha_k}^* g_i \), as required.

**Claim 12.2.31.** The functor \([12.2.29]\) is full. Namely, let \( i \in I \) and \( M_i, N_i \) as in \([12.2.30]\) and suppose that \( f: \pi_i^* M_i \to \pi_i^* N_i \) is a given morphism of log structures; then there exist a morphism \( \psi: j \to i \) in \( I \), and a morphism of log structures \( f_j: f_{\psi}^* M_i \to f_{\psi}^* N_i \) such that \( \pi_j^* f_j = f \).

**Proof of the claim.** Indeed, by theorem \([12.1.37]\) we may find a covering family \((U_\lambda \to X \mid \lambda \in \Lambda)\) in \( X_\tau \), and for each \( \lambda \in \Lambda \) a finite chart
\[
\beta_\lambda: P_{\lambda, U_\lambda} \to M_{\lambda, U_\lambda} \quad \gamma_\lambda: Q_{\lambda, U_\lambda} \to N_{\lambda, U_\lambda} \quad \vartheta_\lambda: P_\lambda \to Q_\lambda
\]
for the restriction \( f_{U_\lambda} \). Clearly we may assume that each \( U_\lambda \) is affine, and since \( X \) is quasi-compact, we may assume as well that \( \Lambda \) is a finite set; in this case, claim \([12.2.27]\) implies that there exist a morphism \( j \to i \) in \( I \), a covering family \((U_{j, \lambda} \to X_j \mid \lambda \in I)\), and isomorphism of \( X \)-schemes \( U_\lambda \to U_{j, \lambda} \times_{X_j} X \) for every \( \lambda \in \Lambda \). Next, lemma \([12.2.24]\) says that, after replacing \( j \) by some larger index – that the induced family \((12.2.32)\) for the restriction \( U \) in \([12.2.29]\) is essentially surjective. Indeed, let \( M \) be a coherent log structure on \( X \); let us pick a covering family \( \mathcal{U} := (U_\lambda \to X \mid \lambda \in \Lambda) \) and finite charts \( \beta_\lambda: P_{\lambda, U_\lambda} \to M_{\lambda, U_\lambda} \) for every \( \lambda \in \Lambda \). As in the foregoing, we may assume that each \( U_\lambda \) is affine, and \( \Lambda \) is a finite set, in which case, according to claim \([12.2.27]\) we may find \( i \in I \) and a covering family \((U_{i, \lambda} \to X_i \mid \lambda \in \Lambda)\) with isomorphisms of \( X \)-schemes \( U_{i, \lambda} \times_{X_i} X \to U_\lambda \) for every \( \lambda \in \Lambda \); for every \( j \in I/\ i \) and every \( \lambda \in \Lambda \), let us set \( U_{j, \lambda} := U_{i, \lambda} \times_{X_i} X_j \). The composition \( \alpha_\lambda: P_{\lambda, U_\lambda} \to \mathcal{O}_{U_\lambda} \) of \( \beta_\lambda \) and the structure map of \( M_{\lambda, U_\lambda} \) is determined by a morphism of monoids
\[
P_\lambda \to \Gamma(U_\lambda, \mathcal{O}_{U_\lambda}) = \colim_{i \in I/\ i} \Gamma(U_{i, \lambda}, \mathcal{O}_{U_{i, \lambda}})
\]
Then, as usual, lemma \([6.1.7]\) implies that there exists \( j \in I/\ i \) such that \( \alpha_\lambda \) descends to a pre-log structure \( P_{\lambda, U_{j, \lambda}} \to \mathcal{O}_{U_{j, \lambda}} \) on \( U_{j, \lambda} \), whose associated log structure we denote by \( M_{j, \lambda} \).

For every \( \lambda, \mu \in \Lambda \), let \( U_{j, \lambda, \mu} := U_{j, \lambda} \times_{X_j} U_{j, \mu} \); by construction we have isomorphisms
\[
(12.2.32) \quad (1_{U_{j, \lambda, \mu}} \times_{X_j} \pi_j)^* M_{j, \lambda, \mu, U_{j, \lambda, \mu}} \sim (1_{U_{i, \lambda, \mu}} \times_{X_j} \pi_j)^* M_{j, \mu, U_{j, \mu, \lambda}} \quad \text{for} \quad \lambda, \mu \in \Lambda
\]
By applying claim \([12.2.31]\) to the cofiltered system \((U_{j, \lambda, \mu} \times_{X_j} X_j' \mid j' \in I/\ j)\), we can then obtain – after replacing \( j \) by a larger index – isomorphisms \( \omega_{\lambda, \mu}: M_{j, \lambda, \mu, U_{j, \lambda, \mu}} \to M_{j, \mu, U_{j, \mu, \lambda}} \) for every \( \lambda, \mu \in \Lambda \), whose pull-back to \( U_{j, \lambda, \mu} \times_{X_j} X \) are the isomorphisms \([12.2.32]\). Lastly, in view of claim \([12.2.30]\) we may achieve – after further replacement of \( j \) by a larger index – that the system \( \mathcal{D} := (M_{j, \lambda, \omega_{\lambda, \mu} \mid \lambda, \mu \in \Lambda}) \) is a descent datum for the fibration \( F \) of \([12.2.1]\), whose pull-back to \( X \) is isomorphic to the natural descent datum for \( M \), associated to the covering family \( \mathcal{U} \). Then \( \mathcal{D} \) glues to a log structure \( M_j \), such that \( \pi_j^* M_j \sim M \).
Corollary 12.2.33. In the situation of (10.1.8), suppose that \( X_\lambda \) is quasi-compact for every \( \lambda \in \text{Ob}(\Lambda) \), and that we have a morphism of log schemes with coherent log structures

\[(g, \log g) : (Y, N) \to (X, M).\]

Then there exist \( \lambda \in \Lambda \), and a morphism of log schemes with coherent log structures

\[(g_\lambda, \log g_\lambda) : (Y_\lambda, N_\lambda) \to (X_\lambda, M_\lambda) \quad \text{such that} \quad \log g = \psi_\lambda^* \log g_\lambda.\]

Proof. The assertion is an immediate consequence of proposition 12.2.28. \( \square \)

Corollary 12.2.34. In the situation of (10.1.8), let \( 0 \in \text{Ob}(\Lambda) \) be an index such that \( N_0 \) and \( M_0 \) are coherent log structures on \( Y_0 \) and respectively \( X_0 \), and \((g_0, \log g_0) : (Y_0, N_0) \to (X_0, M_0)\) a morphism of log schemes. Suppose also that \( X_\lambda \) is quasi-compact (as well as quasi-separated) for every \( \lambda \in \text{Ob}(\Lambda) \); then we have:

(i) If the morphism of log schemes

\[(g, \psi_0^* \log g_0) : Y \times_{Y_0} (Y_0, N_0) \to X \times_{X_0} (X_0, M_0)\]

admits a chart \((\omega, \omega', \vartheta) : P \to Q\), there exists a morphism \( u : \lambda \to 0 \) in \( \Lambda \) such that the morphism of log schemes

\[(g_\lambda, \psi_\lambda^* \log g_0) : Y_\lambda \times_{Y_0} (Y_0, N_0) \to X_\lambda \times_{X_0} (X_0, M_0)\]

admits a chart \((\omega_\lambda, \omega_\lambda', \vartheta)\).

(ii) If \((g, \psi_0^* \log g_0)\) is a log flat (resp. saturated) morphism of fine log schemes, there exists a morphism \( u : \lambda \to 0 \) in \( \Lambda \) such that \((g_\lambda, \psi_\lambda^* \log g_0)\) is a log flat (resp. saturated) morphism of fine log schemes.

Proof. (i): Under the current assumptions, \( X \) and \( Y \) are quasi-compact. In view of lemma 12.2.24 we may then find a morphism \( v : \mu \to 0 \), such that \( \omega \) and \( \omega' \) descend to charts \( \omega_\nu : \varphi_{\nu\mu}^* M_0 \to Y_\nu \) and \( \omega'_\nu : Q_{\nu\mu} \to \psi_\nu^* N_0 \). We deduce two morphisms of pre-log structures

\[P_{\nu\mu} \to \psi_\nu^* N_0,\]

namely

\[\beta_1 := \psi_\nu^* (\log g_0) \circ g_\mu^* \omega_\nu \quad \text{and} \quad \beta_2 := \omega'_\nu \circ \vartheta_{\mu\nu},\]

and by construction we have \( \psi_\nu^* \beta_1^\log = \psi_\mu^* \beta_2^\log \). By proposition 12.2.28 it follows that there exists \( w : \lambda \to \mu \) such that \( \psi_\nu^* \beta_1^\log = \psi_\mu^* \beta_2^\log \). The latter means that \((\varphi_{\nu\mu}^* \omega_\nu, \psi_\nu^* \omega_\nu, \vartheta)\) is a chart for the morphism of log schemes \((g_\lambda, \psi_\nu^* \log g_0) : (Y_\lambda, \psi_\nu^* N_0) \to (X_\lambda, \varphi_{\nu\mu}^* M_0)\), i.e. the claim holds with \( u := v \circ w \).

(ii): Suppose therefore that \((g, \psi_0^* \log g_0)\) is a log flat (resp.saturated) morphism, and let \( \mathcal{W} := (U_i \to X \mid i \in I) \) be a covering family for \( X_\tau \), such that \( U_i \times_{X_\nu} (X_\nu, M_0) \) admits a finite (resp. fine) chart, and \( U_i \) is affine for every \( i \in I \). Since \( X \) is quasi-compact, we may assume that \( I \) is a finite set, and then there exists \( \lambda \in \Lambda \) such that \( \mathcal{W} \) descends to a covering family \( \mathcal{W}_\lambda := (U_{\lambda, i} \to X_\lambda \mid i \in I) \) for \( X_{\lambda, \tau} \) (claim 12.2.27(ii)). After replacing \( \Lambda \) by \( \Lambda/\lambda \), we may assume that \( \lambda = 0 \), in which case we set \( U_{\lambda, i} := U_{0, j} \times_{X_0} X_\lambda \) for every object \( \lambda \) of \( \Lambda \), and every \( i \in I \). Clearly, it suffices to show that there exists \( u : \lambda \to 0 \) such that \( U_{\lambda, i} \times_{X_0} (g_\lambda, \psi_\nu^* \log g_0) \) is flat (resp. saturated) for every \( i \in I \). Set \( Y_{\lambda, i} := Y_\lambda \times_{X_\lambda} U_{\lambda, i} \) for every \( \lambda \in \Lambda \); we may then replace the cofiltered system \( X \) and \( Y \), by respectively \((U_{\lambda, i} \mid \lambda \in \Lambda)\) and \((Y_{\lambda, i} \mid \lambda \in \Lambda)\), which allows to assume from start, that \( X \times_{X_0} (X_0, M_0) \) admits a finite (resp. fine) chart. In this case, lemma 12.2.24 allows to further reduce to the case where \( M_0 \) admits a finite (resp. fine) chart.

Then, by theorem 12.1.37(iii), we may find a covering family \( \mathcal{V}' := (V_j \to Y \mid j \in J) \) for \( Y_\tau \), consisting of finitely many affine schemes \( V_j \), and for every \( j \in J \), a flat (resp. saturated) and fine chart for the induced morphism \( V_j \times_{X_\nu} (Y_0, N_0) \to X \times_{X_\nu} (X_0, M_0) \). As the foregoing, after replacing \( \Lambda \) by some category \( \Lambda/\lambda \), we may assume that \( \mathcal{V}' \) descends to a covering family \( \mathcal{V}_0 := (V_{0, j} \to Y_0 \mid j \in J) \) for \( Y_{0, \tau} \), in which case we set \( V_{\lambda, j} := V_{0, j} \times_{Y_0} Y_\lambda \) for every
\( \lambda \in \Lambda \). Clearly, it suffices to show that there exists \( \lambda \in \Lambda \) such that the induced morphism 
\[ V_{\lambda,j} \times Y_0 (Y_0, N_0) \to X_\lambda \times X_0 (X_0, M_0) \] is log flat (resp. saturated). Thus, we may replace \( Y \) by the cofiltered system \( (V_{\lambda,j} \mid \lambda \in \Lambda) \), which allows to assume that \( (g, \psi_0^* \log g_0) \) admits a flat (resp. saturated) and fine chart. In this case, the assertion follows from (i).

\[ \square \]

**Proposition 12.2.35.** The inclusion functors:

\[ \text{qf.log} \to \text{qcoh.log} \quad \text{qfs.log} \to \text{qf.log} \]

admit right adjoints:

\[ \text{qcoh.log} \to \text{qf.log} : (X, M) \mapsto (X, M)^{\text{qf}} \quad \text{qf.log} \to \text{qfs.log} : (X, M) \mapsto (X, M)^{\text{qfs}}. \]

**Proof.** Let \((X, M)\) be a scheme with quasi-coherent (resp. quasi-fine) log structure. We need to construct a morphism of log schemes

\[ \varphi : (X, M)^{\text{qf}} \to (X, M) \] (resp. \( \varphi : (X, M)^{\text{qfs}} \to (X, M) \))

such that \((X, M)^{\text{qf}}\) (resp. \((X, M)^{\text{qfs}}\)) is a quasi-fine (resp. qfs) log scheme, and the following holds. Every morphism of log schemes \( \psi : (Y, N) \to (X, M) \) with \((Y, N)\) quasi-fine (resp. qfs), factors uniquely through \( \varphi \). To this aim, suppose first that \( M \) admits a chart (resp. a quasi-fine chart) \( \alpha : P_X \to M \). By lemma [12.2.18(i)], \( \alpha \) determines an isomorphism

\[ (X, M) \sim \text{Spec}(Z, P) \times \text{Spec}(Z[P]) X. \]

Since \( N \) is integral (resp. and saturated), the morphism \( (Y, N) \to \text{Spec}(Z, P) \) induced by \( \psi \) factors uniquely through \( \text{Spec}(Z, P^{\text{int}}) \) (resp. \( \text{Spec}(Z, P^{\text{sat}}) \)) (lemma [12.2.18(ii)]). Taking into account lemma [12.1.18(iii)], it follows easily that we may take

\[ (X, M)^{\text{qf}} := \text{Spec}(Z, P^{\text{int}}) \times Z[P] X \quad (X, M)^{\text{qfs}} := \text{Spec}(Z, P^{\text{sat}}) \times Z[P] X \]

Next, notice that the universal property of \((X', M') := (X, M)^{\text{qf}}\) (resp. \((X', M') := (X, M)^{\text{qfs}}\)) is local on \( X \); namely, suppose that \((X', M')\) has already been found, and let \( U \to X \) be an object of \( X \), with a morphism \( (Y, N) \to (X, M)^{\text{qf}} \) (resp. \( (Y, N)^{\text{qfs}} \)) log scheme; there follows a unique morphism

\[ (Y, N) \to (U, M_U^{\text{qf}}) \times (X, M) (X', M') \sim U \times X (X', M') \]

(notation of [12.2.6]). Thus \((U, M_U^{\text{qf}}) \times (X, M)^{\text{qf}} \) (resp. \((U, M_U^{\text{qfs}}) \times (X, M)^{\text{qfs}} \)) is the latter is a quasi-fine (resp. qfs) log scheme. Therefore, for a general quasi-coherent (resp. quasi-fine) log structure \( M \) choose a covering family \( (U_\lambda, M_{U_\lambda}) \) admits a chart for every \( \lambda \in \Lambda \); it follows that the family \( \mathbb{M} := ((U_\lambda, M_{U_\lambda})^{\text{qf}} \mid \lambda \in \Lambda) \), together with the natural isomorphisms:

\[ U_\mu \times X U_\mu, M_{U_\mu}^{\text{qf}}) \sim U_\mu \times X (U_\mu, M_{U_\mu}^{\text{qfs}}) \]

for every \( \mu, \mu \in \Lambda \)

is a descent datum for the fibred category over \( X \), whose fibre over any object \( U \to X \) is the category of affine \( U \)-schemes endowed with a log structure (resp. likewise for the family \( \mathbb{M} := ((U_\lambda, M_{U_\lambda})^{\text{qfs}} \mid \lambda \in \Lambda) \)). Using faithfully flat descent ([65, Exp.VIII, Th.2.1]), one sees that \( \mathbb{M} \) comes from a quasi-fine (resp. qfs) log scheme which enjoys the sought universal property.

\[ \square \]

**Remark 12.2.36.** (i) By inspecting the proof of proposition [12.2.35] we see that the quasi-fine log scheme associated to a coherent log scheme, is actually fine, and the qfs log scheme associated to a fine log scheme, is a fs log scheme (one applies corollary [6.4.1(i)]). Hence we obtain functors

\[ \text{coh.log} \to \text{f.log} : (X, M) \mapsto (X, M)^{\text{f}} \quad \text{f.log} \to \text{fs.log} : (X, M) \mapsto (X, M)^{\text{fs}} \]

which are right adjoint to the inclusion functors \( \text{f.log} \to \text{coh.log} \) and \( \text{fs.log} \to \text{f.log} \).
(ii) Notice as well that, for every log scheme \((X, \underline{M})\) with quasi-coherent (resp. fine) log structure, the \(\text{mor}_*\) of schemes underlying the counit of adjunction \((X, \underline{M})_{qf} \to (X, \underline{M})\) (resp. \((X, \underline{M})^{qs} \to (X, \underline{M})\)) is a closed immersion (resp. is finite).

(iii) Furthermore, let \(f : Y \to X\) be any morphism of schemes; the proof of proposition \[12.2.35\] also yields a natural isomorphism of \((Y, f^* \underline{M})\)-schemes:

\[
(Y, f^* \underline{M})_{qf} \cong Y \times_X (X, \underline{M})_{qf} \quad \text{(resp.} \quad Y, f^* \underline{M})_{qs} \cong Y \times_X (X, \underline{M})_{qs}).
\]

(iv) Let \((X, \underline{M})\) be a quasi-fine log scheme, and suppose that \(X\) is a normal, irreducible scheme, and \((X, \underline{M})_{tr}\) is a dense subset of \(X\). Denote by \(X^{qs}\) the scheme underlying \((X, \underline{M})^{qs}\); then we claim that the projection \(X^{qs} \to X\) (underlying the counit of adjunction) admits a natural section:

\[
\sigma_X : X \to X^{qs}.
\]

The naturality means that if \(f : (X, \underline{M}) \to (Y, \underline{N})\) is any morphism of quasi-fine log schemes, where \(Y\) is also normal and irreducible, and \((Y, \underline{N})_{tr}\) is dense in \(Y\), then the induced diagram of schemes:

\[
\begin{array}{ccc}
X & \xrightarrow{\sigma_X} & X^{qs} \\
\downarrow f & & \downarrow f^{qs} \\
Y & \xrightarrow{\sigma_Y} & Y^{qs}
\end{array}
\]

commutes, and therefore it is cartesian, by virtue of (iii). Indeed, suppose first that \(X\) is affine, say \(X = \text{Spec} A\) for some normal domain \(A\), and \(\underline{M}\) admits an integral chart, given by a morphism \(\beta : P \to A\), for some integral monoid \(P\); we have to exhibit a ring homomorphism \(P^{\text{sat}} \otimes_P A \to A\), whose composition with the natural map \(A \to P^{\text{sat}} \otimes_P A\) is the identity of \(A\). The latter is the same as the datum of a morphism of monoids \(P^{\text{sat}} \to A\) whose restriction to \(P\) agrees with \(\beta\). However, since the trivial locus of \(\underline{M}\) is dense in \(X\), the image of \(P\) in \(A\) does not contain 0, hence \(\beta\) extends to a group homomorphism \(\beta^{\text{gp}} : P^{\text{gp}} \to \text{Frac}(A)^\times\); since \(A\) is integrally closed in \(\text{Frac}(A)\), we have \(\beta^{\text{gp}}(P^{\text{sat}}) \subset A\), as required. Next, suppose that \(U \to X\) is an object of \(X_{tr}\), with \(U\) also affine and irreducible; then \(U\) is normal and the trivial locus of \((U, \underline{M}_U)\) is dense in \(U\). Thus, the foregoing applies to \((U, \underline{M}_{U_{tr}})\) as well, and by inspecting the constructions we deduce a natural identification:

\[
\sigma_U = 1_U \times_X \sigma_X.
\]

Lastly, for a general \((X, \underline{M})\), we can find a covering family \((U_\lambda \to X \mid \lambda \to \Lambda)\) in \(X_{tr}\), such that \(U_\lambda\) is affine, and \((U_\lambda, \underline{M}_{U_\lambda})\) admits an integral chart for every \(\lambda \in \Lambda\); proceeding as above, we obtain a system of morphisms \((\sigma_\lambda : U_\lambda \to U^{qs}_\lambda \mid \lambda \in \Lambda)\), as well as natural identifications:

\[
1_{U_{\mu}} \times_X \sigma_\lambda = 1_{U_{\lambda}} \times_X \sigma_\mu \quad \text{for every} \quad \lambda, \mu \in \Lambda.
\]

In other words, we have defined a descent datum for the category fibred over \(X_{tr}\), whose fibre over any object \(U \to X\) is the category of all morphisms of schemes \(U \to U^{qs}\). By invoking faithfully flat descent ([65] Exp.VIII, Th.2.1]), we see that this descent datum yields a morphism \(\sigma_X : X \to X^{qs}\) such that \(1_{U_\lambda} \times_X \sigma_X = \sigma_\lambda\) for every \(\lambda \in \Lambda\). The verification that \(\sigma_X\) is a section of the projection \(X^{qs} \to X\), and that \((12.2.37)\) commutes, can be carried out locally on \(X_{tr}\), in which case we can assume that \(\underline{M}\) admits a chart as above, and one can check explicitly these assertions, by inspecting the constructions.

12.3. **Logarithmic differentials and smooth morphisms.** In this section we introduce the logarithmic version of the usual sheaves of relative differentials, and we study some special classes of morphisms of log schemes.
Definition 12.3.1. Let \((X, M) \xrightarrow{\alpha} \mathcal{O}_X\) and \((Y, N) \xrightarrow{\beta} \mathcal{O}_Y\) be two schemes with pre-log structures, and \(f : (X, M) \rightarrow (Y, N)\) a morphism of schemes with pre-log structures. Let also \(\mathcal{F}\) be an \(\mathcal{O}_X\)-module. An \(f\)-linear derivation of \(M\) with values in \(\mathcal{F}\) is a pair \((\partial, \log \partial)\) consisting of maps of sheaves:

\[
\partial : \mathcal{O}_X \rightarrow \mathcal{F} \quad \log \partial : \log M \rightarrow \mathcal{F}
\]

such that :

- \(\partial\) is a derivation (in the usual sense).
- \(\log \partial\) is a morphism of sheaves of (additive) monoids on \(X\).
- \(\partial \circ f^2 = 0\) and \(\log \partial \circ \log f = 0\).
- \(\partial \circ \alpha(m) = \alpha(m) \cdot \log \partial(m)\) for every object \(U\) of \(X\), and every \(m \in M(U)\).

The set of all \(f\)-linear derivations with values in \(f\) shall be denoted by :

\[
\text{Der}_{(Y, N)}((X, M), \mathcal{F}).
\]

The \(f\)-linear derivations shall also be called \((Y, N)\)-linear derivations, when there is no danger of ambiguity.

12.3.2. The set \(\text{Der}_{(Y, N)}((X, M), \mathcal{F})\) is clearly functorial in \(\mathcal{F}\), and moreover, for any object \(U\) of \(X\), any \(s \in \mathcal{O}_X(U)\), and any \(f\)-linear derivation \((\partial, \log \partial)\), the restriction \((s \cdot \partial_U, s \cdot \log \partial_U)\) is an element of \(\text{Der}_{(Y, N)}((U, M(U)), \mathcal{F})\), hence the rule \(U \mapsto \text{Der}_{(Y, N)}((U, M(U)), \mathcal{F})\) defines an \(\mathcal{O}_X\)-module :

\[
\text{Der}_{(Y, N)}((X, M), \mathcal{F}).
\]

In case \(M = \mathcal{O}_X^\times\) and \(N = \mathcal{O}_Y^\times\) are the trivial log structures, the \(f\)-linear derivations of \(M\) are the same as the usual \(f\)-linear derivations, i.e. the natural map

\[
\text{Der}_{(Y, \mathcal{O}_Y^\times)}((X, \mathcal{O}_X^\times), \mathcal{F}) \rightarrow \text{Der}_Y(X, \mathcal{F})
\]

is an isomorphism. In the category of usual schemes, the functor of derivations is represented by the module of relative differentials. This construction extends to the category of schemes with pre-log structures. Namely, let us make the following :

Definition 12.3.4. Let \((X, M) \xrightarrow{\alpha} \mathcal{O}_X\) and \((Y, N) \xrightarrow{\beta} \mathcal{O}_Y\) be two schemes with pre-log structures, and \(f : (X, M) \rightarrow (Y, N)\) a morphism of schemes with pre-log structures. The sheaf of logarithmic differentials of \(f\) is the \(\mathcal{O}_X\)-module :

\[
\Omega^1_{X/Y}(\log M/N) := (\Omega^1_{X/Y} \oplus (\mathcal{O}_X \otimes \mathbb{Z} \log M^\text{gp}))/R
\]

where \(R\) is the \(\mathcal{O}_X\)-submodule generated locally on \(X\) by local sections of the form :

- \((d\alpha(a), -\alpha(a) \otimes \log a)\) with \(a \in M(U)\)
- \((0, 1 \otimes \log a)\) with \(a \in \text{Im}(f^{-1}(N))(U) \rightarrow M(U)\)

where \(U\) ranges over all the objects of \(X\) (here we use the notation of [6.1]). For arbitrary \(a \in M(U)\), the class of \((0, 1 \otimes \log a)\) in \(\Omega^1_{X/Y}(\log M/N)\) shall be denoted by \(d\log a\).

12.3.5. It is easy to verify that \(\Omega^1_{X/Y}(\log M/N)\) represents the functor

\[
\mathcal{F} \mapsto \text{Der}_{(Y, \mathcal{O}_Y^\times)}((X, M), \mathcal{F})
\]

on \(\mathcal{O}_X\)-modules. Consequently, \((12.3.3)\) translates as a natural isomorphism of \(\mathcal{O}_X\)-modules :

\[
\Omega^1_{X/Y} \xrightarrow{\sim} \Omega^1_{X/Y}(\log \mathcal{O}_X^\times/\mathcal{O}_Y^\times).
\]

Furthermore, let us fix a scheme with pre-log structure \((S, N)\), and define the category :

\[
\text{pre-log}/(S, N)
\]
as in (1.1.1). Also, let \( \text{Mod.prelog}/(S, N) \) be the category whose objects are all the pairs \( ((X, M), \mathcal{F}) \), where \( (X, M) \) is a \((S, N)\)-scheme, and \( \mathcal{F} \) is an \( \mathcal{O}_X \)-module. The morphisms

\[(X, M), \mathcal{F}) \rightarrow ((Y, N), \mathcal{G})\]

in \( \text{Mod.prelog}/(S, N) \) are the pairs \((f, \varphi)\) consisting of a morphism \( f : (X, M) \rightarrow (Y, N) \) of \((S, N)\)-schemes, and a morphism \( \varphi : f^* \mathcal{G} \rightarrow \mathcal{F} \) of \( \mathcal{O}_X \)-modules. With this notation, we claim that the rule :

\[(12.3.7) \quad (X, M) \mapsto ((X, M), \Omega^1_{X/S}(\log M/N))\]

defines a functor \( \text{pre-log}/(S, N) \rightarrow \text{Mod.prelog}/(S, N) \). Indeed, slightly more generally, consider a commutative diagram of schemes with pre-log structures :

\[(12.3.8) \quad (X, M) \xrightarrow{g} (X', M') \]

\[f \quad \]

\[(S, N) \xrightarrow{h} (S', N').\]

An \( \mathcal{O}_X \)-linear map :

\[(12.3.9) \quad g^* \Omega^1_{X'/S'}(\log M'/N') \xrightarrow{dg} \Omega^1_{X/S}(\log M/N)\]

is the same as a natural transformation of functors :

\[(12.3.10) \quad \text{Der}_{(S, N)}((X, M), \mathcal{F}) \rightarrow \text{Der}_{(S', N')}(X', M'), \mathcal{F})\]

on all \( \mathcal{O}_X \)-modules \( \mathcal{F} \). The latter can be defined as follows. Let \((\partial, \log \partial)\) be an \((S, N)\)-linear derivation of \( M \) with values in \( \mathcal{F} \); then we deduce morphisms :

\[\partial' : \mathcal{O}_X, \xrightarrow{g^*} \mathcal{O}_{X', \xrightarrow{g_0} g_* \mathcal{F}} \log \partial' : M' \xrightarrow{\log g} g_* M \xrightarrow{g_* \log \partial} g_* \mathcal{F}\]

and it is easily seen that \((\partial', \log \partial')\) is a \((S', N')\)-linear derivation of \( M' \) with values in \( g_* \mathcal{F} \).

12.3.11. Consider two morphisms \((X, M) \xrightarrow{f} (Y, N) \xrightarrow{g} (Z, P)\) of schemes with pre-log structures. A direct inspection of the definitions shows that :

\[\text{Der}_{(Y, N)}((X, M), \mathcal{F}) = \text{Ker}(\text{Der}_{(Z, P)}((X, M), \mathcal{F}) \rightarrow \text{Der}_{(Z, P)}((Y, N), f_* \mathcal{F}))\]

for every \( \mathcal{O}_X \)-module \( \mathcal{F} \), whence a right exact sequence of \( \mathcal{O}_X \)-modules :

\[(12.3.12) \quad f^* \Omega^1_{Y/Z}(\log N/P) \xrightarrow{df} \Omega^1_{X/Z}(\log M/P) \rightarrow \Omega^1_{X/Y}(\log M/N) \rightarrow 0\]

extending the standard right exact sequence for the usual sheaves of relative differentials.

**Proposition 12.3.13.** Suppose that the diagram (12.3.8) is cartesian. Then the map (12.3.9) is an isomorphism.

**Proof.** If (12.3.8) is cartesian, \( X \) is the scheme \( X' \times_{S'} S \), and \( M \) is the push-out of the diagram:

\[f^{-1} N \leftarrow (f' \circ g)^{-1} N' \xrightarrow{\varphi} g^* M'.\]

Suppose now that \( \log \partial : M' \rightarrow g_* \mathcal{F} \) and \( \partial : \mathcal{O}_{X'} \rightarrow g_* \mathcal{F} \) define a \( f' \)-linear derivation of \( M' \). By adjunction, we deduce morphisms \( \alpha : g^{-1} \mathcal{O}_{X'} \rightarrow \mathcal{F} \) and \( \beta : g^{-1} M' \rightarrow \mathcal{F} \). By construction, we have \( \beta \circ \varphi = 0 \), hence \( \beta \) extends uniquely to a morphism \( \log \partial' : M \rightarrow \mathcal{F} \) such that \( \log \partial' \circ \log f = 0 \). Likewise, \( \alpha \) extends by linearity to a unique \( f \)-linear derivation \( \partial : \mathcal{O}_X \rightarrow \mathcal{F} \). One checks easily that \((\partial', \log \partial')\) is a \( f \)-linear derivation of \( M \), and that every \( f \)-linear derivation of \( M \) with values in \( \mathcal{F} \) is obtained in this fashion. ∎
12.3.14. The functor \( (12.3.7) \) admits a left adjoint. Indeed, let \( ((X, M) \xrightarrow{\alpha} \mathcal{O}_X, \mathcal{F}) \) be any object of \( \text{Mod.pre-log}/(S, N) \); we define an \((S, N)\)-scheme \((X \oplus \mathcal{F}, M \oplus \mathcal{F})\) as follows. \( X \oplus \mathcal{F} \) is the spectrum of the \( \mathcal{O}_X \)-algebra \( \mathcal{O}_X \oplus \mathcal{F} \), whose multiplication law is given by the rule:

\[
(s, t) \cdot (s', t') := (ss', st' + s't) \quad \text{for every local section } s \text{ of } \mathcal{O}_X \text{ and } t \text{ of } \mathcal{F}.
\]

Likewise, we define a composition law on the sheaf \( M \oplus \mathcal{F} \), by the rule:

\[
(m, t) \cdot (m', t') := (mm', \alpha(m) \cdot t' + \alpha(m') \cdot t) \quad \text{for every local section } m \text{ of } M \text{ and } t \text{ of } \mathcal{F}.
\]

Then \( M \oplus \mathcal{F} \) is a sheaf of monoids, and \( \alpha \) extends to a pre-log structure \( \alpha \oplus 1_{\mathcal{F}} : M \oplus \mathcal{F} \to \mathcal{O}_X \oplus \mathcal{F} \). The natural map \( \mathcal{O}_X \to \mathcal{O}_X \oplus \mathcal{F} \) is a morphism of algebras, whence a natural map of schemes \( \pi : X \oplus \mathcal{F} \to X \), which extends to a morphism of schemes with pre-log structures \((X \oplus \mathcal{F}, M \oplus \mathcal{F}) \to (X, M)\), by letting \( \log \pi : \pi^*M \to M \oplus \mathcal{F} \) be the map induced by the natural monomorphism (notice that \( \pi^* \) induces an equivalence of sites \( X_{\tau} \xrightarrow{\sim} (X \oplus \mathcal{F})_{\tau} \)).

Now, let \((Y, P)\) be any \((S, N)\)-scheme, and:

\[
\varphi : \mathcal{F} := ((X, M), \mathcal{F}) \to \Omega := ((Y, P), \Omega^1_S/(\log P/\mathcal{N}))
\]
a morphism in \( \text{Mod.pre-log}/(S, N) \). By definition, \( \varphi \) consists of a morphism \( f : (X, M) \to (Y, P) \) and an \( \mathcal{O}_X \)-linear map \( f^*\Omega^1_S/(\log P/\mathcal{N}) \to \mathcal{F} \), which is the same as a \((S, N)\)-linear derivation:

\[
\partial : \mathcal{O}_Y \to f_*\mathcal{F} \quad \log \partial : P \to f_*\mathcal{F}.
\]

In turns, the latter yields a morphism of \((S, N)\)-schemes:

\[
(12.3.15) \quad (Y \oplus f_*\mathcal{F}, P \oplus f_*\mathcal{F}) \to (Y, P)
\]
determined by the map of algebras:

\[
\mathcal{O}_Y \to \mathcal{O}_Y \oplus f_*\mathcal{F} \quad s \mapsto (s, \partial s) \quad \text{for every local section } s \text{ of } \mathcal{O}_Y
\]

and the map of monoids:

\[
P \mapsto P \oplus f_*\mathcal{F} \quad p \mapsto (p, \log \partial p) \quad \text{for every local section } p \text{ of } P.
\]

Finally, we compose \((12.3.15)\) with the natural morphism

\[
(X \oplus \mathcal{F}, M \oplus \mathcal{F}) \to (Y \oplus f_*\mathcal{F}, P \oplus f_*\mathcal{F})
\]

that extends \( f \), to obtain a morphism \( g_{\varphi} : (X \oplus \mathcal{F}, M \oplus \mathcal{F}) \to (Y, P) \). We leave to the reader the verification that the rule \( \varphi \mapsto g_{\varphi} \) establishes a natural bijection:

\[
\text{Hom}_{\text{Mod.pre-log}/(S, N)}(\mathcal{F}, \Omega) \xrightarrow{\sim} \text{Hom}_{\text{pre-log}/(S, N)}((X \oplus \mathcal{F}, M \oplus \mathcal{F}), (Y, P))
\]

12.3.16. In the situation of definition \(12.3.4\) let \((\partial, \log \partial)\) be an \( f \)-linear derivation of \( M \) with values in an \( \mathcal{O}_X \)-module \( \mathcal{F} \). Consider the map:

\[
\partial' : \mathcal{O}_X^\times \to \mathcal{F} : \quad u \mapsto u^{-1} \cdot \partial u \quad \text{for all local sections } u \text{ of } \mathcal{O}_X^\times.
\]

By definition, \( \partial' \circ \alpha : \alpha^{-1}M \to \mathcal{F} \) agrees with the restriction of \( \log \partial \); in view of the cocartesian diagram \((12.1.7)\), we deduce that \( \log \partial \) extends uniquely to an \( f \)-linear derivation \( \log \partial_{\mathcal{F}} \) of \( M_{\mathcal{F}} \). Let \( f^\log : (X, M_{\mathcal{F}}) \to (Y, N_{\mathcal{F}}) \) be the map deduced from \( f \); a similar direct verification shows that \( \log \partial_{\mathcal{F}} \) is a \( f^\log \)-linear derivation. There follow natural identifications:

\[
(12.3.17) \quad \Omega_{X/Y}(\log(M/\mathcal{N})) = \Omega^1_{X/Y}(\log(M_{\mathcal{F}}/\mathcal{N}_{\mathcal{F}})) = \Omega^1_{X/Y}(\log(M_{\mathcal{F}}/\mathcal{N}_{\mathcal{F}}))
\]

Moreover, if \( M \) and \( N \) are log structures, the natural map:

\[
(12.3.18) \quad \mathcal{O}_X \otimes_{\mathcal{Z}} \log M_{\mathcal{F}} \to \Omega^1_{X/Y}(\log(M/\mathcal{N})) \quad a \otimes b \mapsto a \cdot d \log(b)
\]
is an epimorphism. Indeed, we have \( da = d(a + 1) \) for every local section \( a \in \mathcal{O}_X(U) \) (for any étale \( X \)-scheme \( U \)), and locally on \( X_{\tau} \), either \( a \) or \( 1 + a \) is invertible in \( \mathcal{O}_X \) (this holds certainly
Example 12.3.19. Let $R$ be a ring, $\varphi : N \to M$ be any map of monoids, and set:

Also, let $f : \text{Spec}(R, M) \to \text{Spec}(R, N)$ be the morphism of log schemes induced by $\varphi$ (see [12.2.13]). With this notation, we claim that [12.3.18] induces an isomorphism:

$$\mathcal{O}_{S[M]} \otimes \mathbb{Z} \text{ Coker } \varphi^\text{gp} \cong \Omega^1_{S[M]/S[N]}(\log M^\text{log}_{S[M]}/N^\text{log}_{S[N]}).$$

To see this, we may use [12.3.12] to reduce to the case where $N = \{1\}$. Next, notice that the functor

$$\text{Mnd}^0 \to \text{pre-log}/(S, \mathcal{O}_S^\times) : M \to \text{Spec}(R, M)$$

commutes with limits, and the same holds for the functor [12.3.7], since the latter is a right adjoint. Hence, we may assume that $M$ is finitely generated; then lemma [6.1.7](i) further reduces to the case where $M = \mathbb{N}^m$ for some integer $n \geq 0$, and even to the case where $n = 1$. Set $X := S[N]$; it is easy to see that a $S$-linear derivation of $\mathbb{N}^\text{log}_S$ with values in an $\mathcal{O}_X$-module $\mathcal{F}$, is completely determined by a map of additive monoids $\mathbb{N} \to \Gamma(X, \mathcal{F})$, and the latter is the same as an $\mathcal{O}_X$-linear map $\partial_X \to \mathcal{F}$, whence the contention.

Lemma 12.3.20. Let $f : (X, M) \to (Y, N)$ be a morphism of schemes with quasi-coherent log structures. Then:

(i) The $\mathcal{O}_X$-module $\Omega^1_{X/Y}(\log M/N)$ is quasi-coherent.

(ii) If $M$ is coherent, $X$ is noetherian, and $f : X \to Y$ is locally of finite type, then $\Omega^1_{X/Y}(\log M/N)$ is a coherent $\mathcal{O}_X$-module.

(iii) If both $M$ and $N$ are coherent, and $f : X \to Y$ is locally of finite presentation, then $\Omega^1_{X/Y}(\log M/N)$ is a quasi-coherent $\mathcal{O}_X$-module of finite presentation.

Proof. Applying the right exact sequence [12.3.12] to the sequence $(X, M) \to (Y, N)$, we may easily reduce to the case where $N = \mathcal{O}_Y^\times$ is the trivial log structure on $Y$. In this case, $N$ admits the chart given by the unique map of monoids : $\{1\} \to \Gamma(Y, \mathcal{O}_Y)$, and $f$ admits the chart $\{1\} \to P$, whenever $M$ admits a chart $P \to \Gamma(X, \mathcal{O}_X)$.

Hence, everything follows from the following assertion, whose proof shall be left to the reader. Suppose that $\varphi : A \to B$ is a ring homomorphism, $M$ (resp. $N$) is the constant log structure on $X := \text{Spec } B$ (resp. on $Y := \text{Spec } A$) associated to a map of monoids $\alpha : P \to B$ (resp. $\beta : Q \to A$), and $f : (X, M) \to (Y, N)$ is defined by $\varphi$ admits a chart $\vartheta : Q \to P$. Then $\Omega^1_{X/Y}(\log M/N)$ is the quasi-coherent $\mathcal{O}_X$-module $L^\sim$, associated to the $B$-module $L := (\Omega^1_{B/A} \oplus (B \otimes \mathbb{Z} \vartheta^\text{gp}))/R$, where $R$ is the submodule generated by the elements of the form $(0, 1 \otimes \vartheta(q))$ for all $q \in Q$, and those of the form $(\partial \alpha(m), -\alpha(m) \otimes \log m)$, for all $m \in M$.

12.3.21. Let us fix a log scheme $(Y, N)$. To any pair of $(Y, N)$-schemes $X := (X, M)$, $X' := (X', M')$, we attach a contravariant functor

$$\mathcal{H}_Y(X', X) : (X'_+)^\text{o} \to \text{Set}$$

by assigning, to every object $U$ of $X'_+$, the set of all morphisms $(U, M'_R) \to (X, M)$ of $(Y, N)$-schemes. It is easily seen that $\mathcal{H}_Y(X', X)$ is a sheaf on $X'_+$. Any morphism $\varphi : (X'', M'') \to (X', M')$ (resp. $\psi : (X, M) \to (X'', M''))$ of $(Y, N)$-schemes induces a map of sheaves:

$$\varphi^* : \varphi^* \mathcal{H}_Y(X', X) \to \mathcal{H}_Y(X'', X) \quad \text{(resp. } \psi^* : \mathcal{H}_Y(X', X) \to \mathcal{H}_Y(X', X''))$$

in the obvious way.
Definition 12.3.22. With the notation of \([12.3.21]\):

(i) We say that a morphism \(i : (T', L') \to (T, L)\) of log schemes is a closed immersion (resp. an exact closed immersion) if the underlying morphism of schemes \(T' \to T\) is a closed immersion, and \(\log i : i^* L \to L\) is an epimorphism (resp. an isomorphism) of \(T'_\mathbb{Z}\)-monoids.

(ii) We say that a morphism \(i : (T', L') \to (T, L)\) of log schemes is an exact nilpotent immersion if \(i\) is an exact closed immersion, and the ideal \(\mathcal{I} := \text{Ker}(\mathcal{O}_T \to i_* \mathcal{O}_{T'})\) is nilpotent.

(iii) We say that a morphism \(f : (X, M) \to (Y, N)\) of log schemes is formally smooth (resp. formally unramified, resp. formally étale) if, for every exact nilpotent immersion \(i : T' \to T\) of fine \((Y, N)\)-schemes, the induced map of sheaves \(i^* : i_* \mathcal{H}_Y(T, X) \to \mathcal{H}_Y(T', X)\) is an epimorphism (resp. a monomorphism, resp. an isomorphism).

(iv) We say that a morphism \(f : (X, M) \to (Y, N)\) of log schemes is smooth (resp. unramified, resp. étale) if the underlying morphism \(X \to Y\) is locally of finite presentation, and \(f\) is formally smooth (resp. formally unramified, resp. formally étale).

Example 12.3.23. Let \((S, P)\) be a log scheme, \((f, \log f) : (X, M) \to (Y, N)\) be a morphism of \(S\)-schemes, such that \(Y\) is a separated \(S\)-scheme. The pair \((\mathcal{I}(X, M), (f, \log f))\) induces a morphism

\[ \Gamma_f : (X, M) \to (X', M') := (X, M) \times_S (Y, N) \]

the graph of \(f\). Then it is easily seen that \(\Gamma_f\) is a closed immersion of log schemes. Indeed, the morphism of schemes underlying \(\Gamma_f\) is a closed immersion ([44, Ch.I, 5.4.3]) and it is easily seen that the morphism \(\log \Gamma_f : \Gamma_f^* M' \to M\) is an epimorphism on the underlying sheaves of sets, so it is a fortiori an epimorphism of \(X_\tau\)-monoids.

Proposition 12.3.24. Let \(f : (X, M) \to (Y, N)\), \(g : (Y, N) \to (Z, P)\), and \(h : (Y', N') \to (Y, N)\) be morphisms of log schemes. Denote by \(P\) either one of the properties: "formally smooth", "formally unramified", "formally étale", "smooth", "unramified", "étale". The following holds:

(i) If \(f\) and \(g\) enjoy the property \(P\), then the same holds for \(g \circ f\).

(ii) If \((f, \log f)\) enjoys the property \(P\), then the same holds for

\[ (f, \log f) \times_{(Y, N)} (Y', N') : (X, M) \times_{(Y, N)} (Y', N') \to (Y', N'). \]

(iii) Let \((j_\lambda : U_\lambda \to X \mid \lambda \in \Lambda)\) be a covering family in \(X_\tau\); endow \(U_\lambda\) with the log structure \((M)_\mid U_\lambda\), and suppose that \(f_\lambda := (f \circ j_\lambda, (\log f)|_{U_\lambda}) : (U_\lambda, (M)_\mid U_\lambda) \to (Y, N)\) enjoys the property \(P\), for every \(\lambda \in \Lambda\). Then \(f\) enjoys the property \(P\) as well.

(iv) An open immersion of log schemes is étale.

(v) A closed immersion of log schemes is formally unramified.

Proof. (i), (ii) and (iv) are left to the reader.

(iii): To begin with, if each \(f_\lambda\) is locally of finite presentation, the same holds for \(f\), by [51 Ch.IV, lemme 17.7.5], hence we may assume that \(P\) is either "formally smooth" or "formally unramified". (Clearly, the case where \(P\) is "formally étale" will follow.)

Now, let \(i : T' \to T\) be an exact nilpotent immersion of \((Y, N)\)-schemes, and \(\xi\) a \(\tau\)-point of \(T'\). By inspecting the definitions, it is easily seen that the stalk \(\mathcal{H}_Y(T, X)_\xi\) is the union of the images of the stalks \(\mathcal{H}_Y(T, U_\lambda)_\xi\), for every \(\lambda \in \Lambda\), and likewise for \(\mathcal{H}_Y(T', X)_\xi\). It readily follows that \(f\) is formally smooth whenever all the \(f_\lambda\) are formally smooth.

Lastly, suppose that all the \(f_\lambda\) are formally unramified, and let \(s_\xi, t_\xi \in \mathcal{H}_Y(T, X)|_{i(\xi)}\) be two sections whose images in \(\mathcal{H}_Y(T', X)_\xi\) agree; after replacing \(T\) by a neighborhood of \(i(\xi)\) in \(T_\tau\), we may assume that \(s_\xi, t_\xi\) are represented by two \((Y, N)\)-morphisms \(s, t : T \to (X, M)\) such that \(s \circ i = t \circ i\). Choose \(\lambda \in \Lambda\) such that \(U_\lambda\) is a neighborhood of \(s \circ i(\xi) = t \circ i(\xi)\); this means
that there exist a neighborhood $p' : U' \to T'$ of \( \xi \), and a morphism $s_U : U' \to U_\lambda$ lifting $s \circ i$ (and thus, also $t \circ i$). Then we may find a neighborhood $p : U \to T$ of $i(\xi)$ which identifies $p'$ with $p \times_T 1_T$ (\cite{14}, Ch.IV, Th.18.1.2), and since $j_\lambda$ is étale, we may furthermore find morphisms $s_U, t_U : U \to U_\lambda$ such that $j_\lambda \circ s_U = s \circ i = t \circ i = j_\lambda \circ t_U$. Set $i_U := i \times_T 1_U : U' \to U$; by construction, $s_U$ and $t_U$ yield two sections of $i_U^* \mathcal{H}_Y(U, U_\lambda)_{\xi}$, whose images in $\mathcal{H}_Y(U', U_\lambda)_{\xi}$ coincide. Since $j_\lambda$ is formally unramified, it follows that -- up to replacing $U$ by a neighborhood of $i(\xi)$ in $U_T$ -- we must have $s_U = t_U$, so $s_\xi = t_\xi$, and we conclude that $f$ is formally unramified.

(v): Consider a commutative diagram of log schemes:

\[
\begin{array}{ccc}
(T', L') & \xrightarrow{h'} & (X, M) \\
\downarrow i & & \downarrow f \\
(T, L) & \xrightarrow{h} & (Y, N)
\end{array}
\]

where $f$ is a closed immersion, and $i$ is an exact closed immersion. We are easily reduced to showing that there exists at most a morphism $(g, \log) : (T, L) \to (X, M)$ such that $f \circ g = h$ and $h' = g \circ i$. Since $f : X \to Y$ is a closed immersion of schemes, there exists at most one morphism of schemes $g : T \to X$ lifting $h$ and extending $h'$ (\cite{14}, Ch.IV, Prop.17.1.3(i)). Hence we may assume that such a $g$ is given, and we need to check that there exists at most one morphism $\log g : g^* M \to L$ whose composition with $g^*(\log f) : h^* N \to g^* M$ equals $\log h$. However, by assumption $\log f$ is an epimorphism, hence the same holds for $g^*(\log f)$ (proposition \[1.3.25(iv)]), whence the contention. \qed

**Corollary 12.3.25.** Let $f$ and $g$ be as proposition \[12.3.24\] We have:

(i) If $g \circ f$ is formally unramified, the same holds for $f$.

(ii) If $g \circ f$ is formally smooth (resp. formally étale) and $g$ is formally unramified, then $f$ is formally smooth (resp. formally étale).

(iii) Suppose that $g$ is formally étale. Then $f$ is formally smooth (resp. formally unramified, resp. formally étale) if and only if the same holds for $g \circ f$.

**Proof.** (i): Let $Y = \bigcup_{\lambda \in \Lambda} U_\lambda$ be an affine open covering of $Y$, and for each $\lambda \in \Lambda$, let $f_\lambda : U_\lambda \times_Y (X, M) \to (U_\lambda, N_{U,\lambda})$ be the restriction of $f$; in light of proposition \[12.3.24(iii)] it suffices to show that each $f_\lambda$ is formally unramified, and on the other hand, the restriction $g_\lambda \circ f_\lambda : U_\lambda \times_Y (X, M) \to (Z, P)$ of $g \circ f$ is formally unramified, by proposition \[12.3.24(i),(iv)]. It follows that we may replace $f$ and $g$ respectively by $f_\lambda$ and $g_\lambda$, which allows to assume that $Y$ is affine, especially separated, so that $g$ is a separated morphism of schemes. In such situation, one may -- in view of example \[12.3.23] -- argue as in the proof of \cite{14}, Ch.IV, Prop.17.1.3 : the details shall be left to the reader.

(ii) is a formal consequence of the definitions (cp. the proof of \cite{14}, Ch.IV, Prop.17.1.4), and (iii) follows from (ii) and proposition \[12.3.24(i)]. \qed

**Proposition 12.3.26.** Let $f : (X, M) \to (Y, N)$ be a morphism of log schemes, and $i$ an exact closed immersion of $(Y, N)$-schemes, defined by an ideal $\mathcal{J} := \ker(\mathcal{O}_T \to i_* \mathcal{O}_T)$ with $\mathcal{J}^2 = 0$. For any global section $s : T' \to \mathcal{H}_Y(T', X)$, denote by $\mathcal{T}_s$ the morphism:

\[ i^* \mathcal{H}_Y(T, X) \times_{\mathcal{H}_Y(T', X)} T' \to T' \]

deduced from $i^* : i^* \mathcal{H}_Y(T, X) \to \mathcal{H}_Y(T', X)$. Let also $U \subset T'$ be the image of $\mathcal{T}_s$ (i.e. the subset of all $t' \in T'$ such that $\mathcal{T}_{s,t'} \neq \emptyset$ for every $t$-point $\xi$ localized at $t'$), and suppose that $U \neq \emptyset$. We have:

(i) $U$ is an open subset of $T'$, and $\mathcal{T}_{s|U}$ is a torsor for the abelian sheaf

\[ \mathcal{G} := \mathcal{H}om_{\mathcal{O}_{T'}}(s^* \Omega^1_{X/Y}(\log(M/N)), \mathcal{J})_{|U}. \]
(ii) If \( f \) is a smooth morphism of log schemes with coherent log structures, we have:

(a) The \( \mathcal{O}_X \)-module \( \Omega^1_{X/Y}(\log(M/N)) \) is locally free of finite type.

(b) If \( T' \) is affine, \( \mathcal{T}_s \) is a trivial \( \mathcal{G} \)-torsor.

**Proof.** (i): To any \( \tau \)-point \( \xi \) of \( U \), and any two given local sections \( h \) and \( g \) of \( \mathcal{T}_s \), we assign the \( f \)-linear derivation of \( M_s(\xi) \) with values in \( s \cdot \mathcal{T}_s \) given by the rule:

\[
a \mapsto h^*(a) - g^*(a) \quad \text{for every } a \in \mathcal{O}_X, s(\xi) \\
d\log m \mapsto \log u(m) := u(m) - 1 \quad \text{for every } m \in M_s(\xi)
\]

where \( u(m) \) is the unique local section of \( \ker(\mathcal{O}_{T,s} \to i_* \mathcal{O}_{T',s}) \) such that

\[
\log(g(m) \cdot u(m)) = \log h(m).
\]

We leave to the reader the laborious, but straightforward verification that the above map is well-defined, and yields the sought bijection between \( \mathcal{T}_s \) and \( \mathcal{G}_s \).

(ii.b) is standard: first, since \( f \) is smooth, we have \( U = T' \); by lemma [12.3.20][iii], the \( \mathcal{O}_X \)-module \( \Omega^1_{X/Y}(\log(M/N)) \) is quasi-coherent and finitely presented, hence \( \mathcal{G} \) is quasi-coherent; however, the obstruction to gluing local sections of a \( \mathcal{G} \)-torsor lies in \( H^1(T, \mathcal{G}) \) (see [4.9.11]); the latter vanishes whenever \( T \) is affine.

(ii.a) We may assume that \( X \) is affine, say \( X = \text{Spec } A \); then \( \Omega^1_{X/Y}(\log(M/N)) \) is the quasi-coherent \( \mathcal{O}_X \)-module arising from a finitely presented \( A \)-module \( \Omega \) (lemma [12.3.20][iii]). Let \( I \) be any \( A \)-module, and set:

\[
T_I := X \oplus I^\sim \\
L_I := M \oplus I^\sim
\]

(notation of [12.3.14]). Let \( i : X \to T_I \) (resp. \( \pi : T_I \to X \)) be the natural closed immersion (resp. the natural projection); then \( (T_I, L_I) \) is a fine log scheme, and \( \pi \) (resp. \( i \)) extends to a morphism of log schemes \( (\pi, \log \pi) : (T_I, L_I) \to (X, M) \) (resp. \( (i, \log i) : (X, M) \to (T_I, L_I) \)) with \( \log \pi = \pi^* M \to L_I \) (resp. \( \log i = i^* L_I \to M \)) induced by the obvious inclusion (resp. projection) map. Notice that \( (i, \log i) \) is an exact immersion and \( (I^\sim)^2 = 0 \), hence (i) says that the set \( \mathcal{T}(T_I) \) of all morphisms \( g : (T_I, L_I) \to (X, M) \) such that

\[
f \circ g = f \circ \pi \\
g \circ i = 1_{(X,M)}
\]

is in bijection with \( \text{Hom}_A(\Omega, I) \). Moreover, any map \( \varphi : I \to J \) of \( A \)-modules induces a morphism \( i_\varphi : (T_J, L_J) \to (T_I, L_I) \) of log schemes, and if \( \varphi \) is surjective, \( i_\varphi \) is an exact nilpotent immersion. Furthermore, we have a commutative diagram of sets:

\[
\begin{array}{ccc}
\mathcal{T}(T_I) & \overset{i_\varphi^*}{\longrightarrow} & \mathcal{T}(T_J) \\
\downarrow & & \downarrow \\
\text{Hom}_A(\Omega, I) & \overset{\varphi_*}{\longrightarrow} & \text{Hom}_A(\Omega, J)
\end{array}
\]

whose vertical arrows are bijections, and where \( i_\varphi^* \) (resp. \( \varphi_* \)) is given by the rule \( g \mapsto g \circ i_\varphi \), (resp. \( \psi \mapsto \varphi \circ \psi \)). Assertion (ii.b) implies that \( i_\varphi^* \) is surjective when \( f \) is smooth and \( \varphi \) is surjective, hence the same holds for \( \varphi_* \), i.e. \( \Omega \) is a projective \( A \)-module, as stated. \( \square \)

**Corollary 12.3.27.** Let \( (f, \log f) : (X, M) \to (Y, N) \) be a morphism of log schemes. We have:

(i) If \( M \) and \( N \) are fine log structures, and \( f \) is strict (see definition [12.1.22][ii]), then \( (f, \log f) \) is smooth (resp. étale) if and only if the underlying morphism of schemes \( f : X \to Y \) is smooth (resp. étale).

(ii) Suppose that \( (f, \log f) \) is a smooth (resp. étale) morphism of log schemes on the Zariski sites of \( X \) and \( Y \), and either:

(a) \( M \) and \( N \) are both integral log structures,
(b) or else \( N \) is coherent (on \( X_{zar} \)) and \( M \) is fine (on \( X_{zar} \)). Then the induced morphism of log schemes on \( etale \) sites:

\[
\overline{u}^*(f, \log f) := (f, \overline{u}_X \log f) : \overline{u}_X(X, M) \to \overline{u}_Y(Y, N)
\]

is smooth (resp. \( etale \)). (Notation of \( \{12.2.2\} \)).

(iii) Suppose that \((f, \log f)\) is a morphism of log schemes on the Zariski sites of \( X \) and \( Y \), and \( M \) is an integral log structure on \( X_{zar} \). Suppose also that \( \overline{u}^*(f, \log f) \) is smooth (resp. \( etale \)). Then the same holds for \((f, \log f)\).

**Proof.** (i): Suppose first that \((f, \log f)\) is smooth (resp. \( etale \)). Let \( i : T' \to T \) be a nilpotent immersion of affine schemes, defined by an ideal \( \mathcal{I} \subset \mathcal{O}_T \) such that \( \mathcal{I}^2 = 0 \); let \( s : T' \to X \) and \( t : T \to Y \) be morphisms of schemes such that \( f \circ s = t \circ i \). By lemma \( \{12.1.18\} \), the log structures \( L := t^*N \) and \( L' := s^*M \) are fine, and by choosing the obvious maps \( \log s \) and \( \log t \), we deduce a commutative diagram:

\[
\begin{array}{ccc}
(T', L') & \xrightarrow{s} & (X, M) \\
\downarrow{i} & & \downarrow{f} \\
(T, L) & \xrightarrow{t} & (Y, N).
\end{array}
\]

(12.3.28)

Then proposition \( \{12.3.26\} \) (ii,b) says that there exists a morphism (resp. a unique morphism) of schemes \( g : T \to X \) such that \( g \circ i = s \) and \( f \circ g = t \), i.e. \( f \) is smooth (resp. \( etale \)).

The converse is easy, and shall be left as an exercise for the reader.

(ii): Suppose first that \((f, \log f)\) is smooth, \( N \) is coherent and \( M \) is fine. By proposition \( \{12.3.24\} \) (iii), the assertion to prove is local on \( X_{et} \), hence we may assume that \( f \) admits a chart, given by a morphism of finite monoids \( P \to P' \) and commutative diagrams:

\[
P_{X_{zar}} \to M \quad \omega : P_{Y_{zar}} \to N
\]

(12.3.29)

(theorem \( \{12.1.37\} \) i)). Now, consider a commutative diagram of log schemes on \( etale \) sites:

\[
\begin{array}{ccc}
(T', L') & \xrightarrow{s} & \overline{u}_X(X, M) \\
\downarrow{i} & & \downarrow{\overline{u}^*f} \\
(T, L) & \xrightarrow{t} & \overline{u}_Y(Y, N)
\end{array}
\]

(12.3.30)

where \( i \) is an exact nilpotent immersion of fine log schemes, defined by an ideal \( \mathcal{I} \subset \mathcal{O}_T \) such that \( \mathcal{I}^2 = 0 \). Since the assertion to prove is local on \( T_{et} \), we may assume that \( T \) is affine and – in view of theorem \( \{12.1.37\} \) ii) – that \( t \) admits a chart, given by a morphism of finite monoids \( \varphi : P \to Q \), and commutative diagrams:

\[
P_{T_{et}} = t^*P_{Y_{et}} \xrightarrow{t^*u_Y^*\varphi} t^*u_Y^*N \quad P \xrightarrow{\log t} \Gamma(Y, \mathcal{O}_Y)
\]

(12.3.31)

\[
Q_{T_{et}} \xrightarrow{\beta} L \quad Q \xrightarrow{\psi} \Gamma(T, \mathcal{O}_T)
\]

Since \( i \) is an exact closed immersion, it follows that the morphism:

\[
Q_{T_{et}} \xrightarrow{i^*\beta} i^*L \xrightarrow{\log \eta} L'
\]

is a chart for \( L' \). Especially, \((T', L')\) is isomorphic to \((T'_{et}, Q^log_{T'})\), the constant log structure deduced from the morphism \( i^* \circ \psi : Q \to \Gamma(T', \mathcal{O}_{T'}) \). The latter is also the log scheme \( \overline{u}_T^*(T_{zar}, Q^log_{T}) \). From proposition \( \{12.2.3\} \) (ii) we deduce that there exists a unique morphism \( s_{zar} : (T_{zar}, Q^log_{T}) \to (X, M) \), such that \( \overline{u}^*s_{zar} = s \). On the other hand, by inspecting (12.3.30)
we find that there exists a unique morphism \( t_{Zar} : (T_{Zar}, Q^\text{log}_T) \to (Y, N) \) such that \( \tilde{u}^* t_{Zar} = t \). These morphisms can be assembled into a diagram:

\[
\begin{array}{ccc}
(T'_{Zar}, Q^\text{log}_{T'}) & \xrightarrow{i_{Zar}} & (X, M) \\
\downarrow & & \downarrow f \\
(T_{Zar}, Q^\text{log}_T) & \xrightarrow{t_{Zar}} & (Y, N)
\end{array}
\]

(12.3.31)

where \( i_{Zar} \) is an exact closed immersion. By construction, the diagram \( \tilde{u}^* (12.3.31) \) is naturally isomorphic to (12.3.29); especially, (12.3.31) commutes (proposition 12.2.3(i)). Now, since \( f \) is smooth, proposition 12.2.3(ii) implies that there exists a morphism \( v : (T_{Zar}, Q^\text{log}_T) \to (X, M) \) such that \( f \circ v = t_{Zar} \) and \( v \circ i_{Zar} = s_{Zar} \); then \( \tilde{u}^* v \) provides an appropriate lifting of \( t \), which allows to conclude that \( \tilde{u}^* (f, \log f) \) is smooth.

Next, suppose that \( (f, \log f) \) is étale (and we are still in case (b) of the corollary); then there exists a unique morphism \( v \) with the properties stated above. However, from proposition 12.2.3(i),(ii) we deduce easily that the natural map:

\[
\mathcal{H}_Y((T_{Zar}, Q^\text{log}_T), (X, M))(T) \to \mathcal{H}_{\tilde{u}^*(Y, N)}((T, L), \tilde{u}^*(X, M))(T)
\]

is a bijection, and the same holds for the analogous map for \( T' \). In view of the foregoing, this shows that the map \( \mathcal{H}_{\tilde{u}^*(Y, N)}((T, L), \tilde{u}^*(X, M))(T) \to \mathcal{H}_{\tilde{u}^*(Y, N)}((T', L'), \tilde{u}^*(X, M))(T') \) is bijective, whenever \( t \) admits a chart and \( T \) is affine. We easily conclude that \( \tilde{u}^*(f, \log f) \) is étale.

The case where both \( N \) and \( M \) are both integral, is similar, though easier: we may assume that \( L \) admits a chart, in which case \( (T, L) \) is of the form \( \tilde{u}^*(T_{Zar}, Q^\text{log}_T) \) for some finite integral monoid \( Q \); then \( (T', L') \) admits a similar description, and again, by appealing to proposition 12.2.3(ii) we deduce that (12.3.29) is of the form \( \tilde{u}^*(12.3.31) \), in which case we conclude as in the foregoing.

Conversely, if \( \tilde{u}^*(f, \log f) \) is smooth, consider again a commutative diagram (12.3.28) of log schemes on Zariski sites, with \( i \) an exact closed immersion, defined by a sheaf of ideals \( \mathcal{I} \subset \mathcal{O}_T \) such that \( \mathcal{I}_2 = 0 \). By applying everywhere the pull-back functors from Zariski to étale sites, we deduce a commutative diagram \( \tilde{w} \) (12.3.28) of log schemes on étale sites, and it is easy to see that \( \tilde{w}^*(i, \log i) \) is again an exact nilpotent immersion. According to proposition 12.3.26(ii.b), after replacing \( T \) by any affine open subset, we may find a morphism of log schemes \( g : \tilde{w}^*_Y(T, L) \to \tilde{u}^*_X(X, M) \), such that \( g \circ \tilde{w}^*_i = \tilde{u}^* s \) and \( \tilde{w}^* f \circ g = t \). By proposition 12.2.3(i),(ii) there exists a unique morphism \( g' : (T, L) \to (X, M) \) such that \( \tilde{w}^* g' = g \), and necessarily \( g' \circ i = s \) and \( f \circ g' = t \). We conclude that \( (f, \log f) \) is smooth.

Finally, if \( \tilde{u}^*(f, \log f) \) is étale, the morphism \( g \) exhibited above is unique, and therefore the same holds for \( g' \), so \( (f, \log f) \) is étale as well.

\[
\square
\]

**Proposition 12.3.32.** In the situation of (12.3.11), suppose that the log structures \( M, N, P \) are coherent, and consider the following conditions:

1. (a) \( f \) is smooth (resp. étale).
2. (b) \( df \) is a locally split monomorphism (resp. an isomorphism).

Then (a)⇒(b), and if \( g \circ f \) is smooth, then (b)⇒(a).

**Proof.** We may assume that the schemes under consideration are affine, say \( X = \text{Spec} \, A \), \( Y = \text{Spec} \, B \), \( Z = \text{Spec} \, C \); then (12.3.12) amounts to an exact sequence of \( A \)-modules:

\[
A \otimes_B \Omega(g) \overset{df}{\rightarrow} \Omega(g \circ f) \overset{\circ}{\rightarrow} \Omega(f) \to 0.
\]

On the other hand, let \( i : (T', L') \to (T, L) \) be an exact closed immersion of \((Y, N)\)-schemes, defined by an ideal \( \mathcal{I} \subset \mathcal{O}_T \) with \( \mathcal{I}^2 = 0 \). Suppose that \( s : T' \to \mathcal{H}_Y(T', X) \) is a global
section, i.e. a given morphism of $(Y, N)$-schemes $(T', L') \to (X, M)$. In this situation, we have a natural sequence of morphisms:

$$
\mathcal{H}_1 := \mathcal{H}_Y(T, X) \xrightarrow{\alpha} \mathcal{H}_2 := \mathcal{H}_Z(T, X) \xrightarrow{f} \mathcal{H}_3 := \mathcal{H}_Z(T, Y)
$$

where $\alpha$ is the obvious monomorphism. Let us consider the pull-back of these sheaves along the global section $s$:

$$
\mathcal{T} := T' \times_{\mathcal{H}_Y(T, X)} \mathcal{H}_1, \quad \mathcal{T}' := T' \times_{\mathcal{H}_Z(T, X)} \mathcal{H}_2, \quad \mathcal{T}'' := T' \times_{\mathcal{H}_Z(T, Y)} \mathcal{H}_3.
$$

By proposition 12.3.26(i), any choice of a global section of $\mathcal{T}(T)$ determines a commutative diagram of sets:

$$
\begin{array}{ccc}
\text{Hom}_A(\Omega(f), \mathcal{I}(T)) & \xrightarrow{\omega} & \text{Hom}_B(\Omega(g \circ f), \mathcal{I}(T)) \\
\downarrow & & \downarrow \\
\mathcal{I}(T) & \xrightarrow{f_*} & \mathcal{I}'(T)
\end{array}
$$

whose vertical arrows are bijections.

In order to show that $df$ is a locally split monomorphism (resp. an isomorphism), it suffices to show that the map $df^* := \text{Hom}_A(df, I)$ is surjective for every $A$-module $I$. To this aim, we take $(T, L) := (T_1, L_1), (T', L') := (X, M)$, and let $i$ be the nilpotent immersion defined by the ideal $I \subset A \oplus I$, as in the proof of proposition 12.3.26(ii.a). If $\mathcal{I} \subset \mathcal{O}_T$ is the corresponding sheaf of ideals, then $\mathcal{I}(T) = I$; moreover, the inclusions $A \to A \oplus I$ and $M \subset M \oplus I$ determine a morphism $h : (T_1, L_1) \to (X, M)$, which is a global section of $\mathcal{T}(T)$. Having made these choices, consider the resulting diagram (12.3.33) : if $f$ is étale, $f_*$ is an isomorphism, and when $f$ is smooth, $f_*$ is surjective (proposition 12.3.26(ii.b)), whence the contention.

For the converse, we may suppose that $df$ is a split monomorphism, hence $df^*$ in (12.3.33) is a split surjection. We have to show that $\mathcal{T}(T)$ is not empty, and by assumption (and proposition 12.3.26(ii.b)) we know that $\mathcal{T}'(T) \neq \emptyset$. Choose any $\tilde{h} \in \mathcal{T}'(T)$; then $t$ and $f_\ast \tilde{h}$ are two elements of $\mathcal{T}''(T)$, so we may find $\varphi \in \text{Hom}_B(\Omega(g), \mathcal{I}(T))$ such that $\varphi + f_\ast \tilde{h} = t$ (where the sum denotes the action of $\text{Hom}_B(\Omega(g), \mathcal{I}(T))$ on its torsor $\mathcal{T}''$). Then we may write $\varphi = \psi \circ df$ for some $\psi : \Omega(g \circ f) \to \mathcal{I}(Y)$, and it follows easily that $\psi + \tilde{h}$ lies in $\mathcal{T}(T)$. Finally, if $df$ is an isomorphism, we have $\Omega(f) = 0$, hence $\mathcal{T}(T)$ contains exactly one element.

**Proposition 12.3.34.** Let $R$ be a ring, $\varphi : P \to Q$ a morphism of finitely generated monoids, such that $\text{Ker} \varphi^{sp}$ and the torsion subgroup of $\text{Coker} \varphi^{sp}$ (resp. $\text{Ker} \varphi^{sp}$ and $\text{Coker} \varphi^{sp}$) are finite groups whose orders are invertible in $R$. Then, the induced morphism

$$
\text{Spec}(R, \varphi) : \text{Spec}(R, Q) \to \text{Spec}(R, P)
$$

is smooth (resp. étale).

**Proof.** To ease notation, set

$$
f := \text{Spec}(R, \varphi), \quad (X, M) := \text{Spec}(R, Q), \quad (Y, N) := \text{Spec}(R, P).
$$

Clearly $f$ is finitely presented. We have to show that, for every commutative diagram like (12.3.28) with $i$ an exact nilpotent immersion of fine log schemes, there is, locally on $T$, at least one morphism (resp. a unique morphism) $h : (T, L) \to (X, M)$ such that $f \circ h = h \circ i$.

Let $\mathcal{I} := \ker(\mathcal{O}_T \to i_* \mathcal{O}_{T'})$; by considering the $\mathcal{I}$-adic filtration on $\mathcal{O}_T$, we reduce easily to the case where $\mathcal{I}^2 = 0$, and then we may embed $\mathcal{I}$ in $L$ via the morphism:

$$
\mathcal{I} \to \mathcal{O}_T^{x} \subset L \quad x \mapsto 1 + x.
$$
(Here $\mathcal{F}$ is regarded as a sheaf of abelian groups, via its addition law.) Since $i$ is exact, the natural morphism $L/I \to i_*L'$ is an isomorphism, whence a commutative diagram:

\[
\begin{array}{ccc}
L & \overset{\log i}{\longrightarrow} & i_*L' \\
\downarrow & & \downarrow \\
L^{\text{gp}} & \overset{(\log i)^{\text{gp}}}{\longrightarrow} & i_*(L')^{\text{gp}} \cong L^{\text{gp}}/I
\end{array}
\]

and since $L$ is integral, one sees easily that (12.3.35) is cartesian (it suffices to consider the stalks over the $\tau$-points).

- On the other hand, suppose first that both $\text{Ker} \varphi^{\text{gp}}$ and $\text{Coker} \varphi^{\text{gp}}$ are finite groups whose order is invertible in $R$, hence in $\mathcal{F}$; then a standard diagram chase shows that we may find a unique map $g : P_T^{\text{gp}} \to L^{\text{gp}}$ of abelian sheaves that fits into a commutative diagram:

\[
\begin{array}{ccc}
Q_T^{\text{gp}} & \overset{(\log i)^{\text{gp}}}{\longrightarrow} & L^{\text{gp}} \\
\downarrow & & \downarrow \\
P_T^{\text{gp}} & \overset{i_*s^*M^{\text{gp}}}{\longrightarrow} & i_*(L')^{\text{gp}}
\end{array}
\]

More generally, we may write : $\text{Coker} \varphi^{\text{gp}} \cong G \oplus H$, where $H$ is a finite group with order invertible in $R$, and $G$ is a free abelian group of finite rank. The direct summand $G$ lifts to a direct summand $G' \subset P^{\text{gp}}$. Extend $\varphi^{\text{gp}}$ to a map $\psi : Q^{\text{gp}} \oplus G' \to P^{\text{gp}}$, by the rule : $(x, g) \mapsto \varphi^{\text{gp}}(x) \cdot g$. Given any $\tau$-point $\xi$ of $T$, we may extend the morphism $Q^{\text{gp}} = Q_{T, \xi}^{\text{gp}} \to L^{\text{gp}}_{\xi}$ in (12.3.36)$_\xi$, to a map $\omega : Q^{\text{gp}} \oplus G' \to L_{\xi}^{\text{gp}}$ whose composition with $(\log i)^{\text{gp}}$ agrees with the composition of $\psi$ and the bottom map $P^{\text{gp}} = P_{T, \xi}^{\text{gp}} \to i_*(L')^{\text{gp}}_{\xi}$ of (12.3.36)$_\xi$. By the usual arguments, $\omega$ extends to a map of abelian sheaves $\vartheta : (Q^{\text{gp}} \oplus G')_U \to (L^{\text{gp}})_U$ on some neighborhood $U \to T$ of $\xi$, and if $U$ is small enough, the composition $(\log i)^{\text{gp}}_U \circ \vartheta$ agrees with the composition of $\psi_U$ and the bottom map $\beta : P^{\text{gp}}_U \to i_*(L^{\text{gp}})_U$ of (12.3.36)$_U$. We may then replace $T$ by $U$, and since $\text{Ker} \psi = \text{Ker} \varphi^{\text{gp}}$, and $\text{Coker} \psi = H$, the same diagram chase as in the foregoing shows that we may again find a morphism $g : P_T^{\text{gp}} \to L^{\text{gp}}$ fitting into a commutative diagram:

\[
\begin{array}{ccc}
(Q^{\text{gp}} \oplus G')_T & \overset{\vartheta}{\longrightarrow} & L^{\text{gp}} \\
\downarrow & & \downarrow \\
P_T^{\text{gp}} & \overset{g}{\longrightarrow} & i_*(L')^{\text{gp}}
\end{array}
\]

In either case, in view of (12.3.35), the morphisms

$$P_T \to P_T^{\text{gp}} \overset{g}{\longrightarrow} L^{\text{gp}}$$

and

$$P_T \to i_*s^*M \overset{i_*\log a}{\longrightarrow} i_*L'$$

determine a unique morphism $P_T \to L$, which induces a morphism of log schemes $(T, L) \to (X, M)$ with the sought property.

\[\square\]

**Theorem 12.3.37.** Let $f : (X, M) \to (Y, N)$ be a morphism of fine log schemes. Assume we are given a fine chart $\beta : Q_Y \to \text{N}$. Then the following conditions are equivalent :

(a) $f$ is smooth (resp. \'{e}tale).

(b) There exist a covering family $(g_\lambda : U_\lambda \to X \mid \lambda \in \Lambda)$ in $X_{\text{et}}$, and for every $\lambda \in \Lambda$, a fine chart $(\beta, (P_\lambda)_U) \mapsto g_\lambda^*M, \varphi_\lambda : Q \to P_\lambda$ of the induced morphism of log schemes

$$f|_{U_\lambda} := (f \circ g_\lambda, g_\lambda^*\log f) : (U_\lambda, g_\lambda^*M) \to (Y, N)$$

such that :
(i) Ker \( \varphi^{SP}_\lambda \) and the torsion subgroup of Coker \( \varphi^{SP}_\lambda \) (resp. Ker \( \varphi^{SP}_\lambda \) and Coker \( \varphi^{SP}_\lambda \)) are finite groups of orders invertible in \( \mathcal{O}_{U_\lambda} \).

(ii) The natural morphism of \( Y \)-schemes \( p_\lambda : U_\lambda \to Y \times_{\text{Spec } \mathbb{Z}[Q]} \text{Spec } \mathbb{Z}[P_\lambda] \) is étale.

**Proof.** Suppose first that \( \tau = \text{ét} \), so \( M \) and \( N \) are log structures on étale sites. Then the log structure \( g^*_\lambda M \) on \( (U_\lambda)_{\text{ét}} \) is just the restriction of \( M \), and \( g^*_\lambda \log f \) is the restriction of \( \log f \) to \( (U_\lambda)_{\text{ét}} \). In case \( \tau = \text{Zar} \), the log structure \( g^*_\lambda M \) can be described as follows. Form the log scheme \( (X, M') := \tilde{u}_X^*(X, M) \) (notation of (12.2.2)), take the restriction \( M'|_{U_\lambda} \) of \( M' \) to \( (U_\lambda)_{\text{ét}} \), and push forward to the Zariski site to obtain \( \tilde{u}_X^*(M'|_{U_\lambda}) = g^*_\lambda M \) (by proposition 12.3.3(ii)). Since \( f \) is smooth (resp. étale) if and only if \( \tilde{u}^* f \) is (corollary 12.3.27(ii),(iii)), we conclude that the assertion concerning \( f \) holds if and only if the corresponding assertion for \( \tilde{u}^* f \) does. Hence, it suffices to consider the case of log structures on étale sites. Set \( S := \text{Spec } \mathbb{Z}[Q] \).

(b)⇒(a): Taking into account lemma 12.2.18(i), we deduce a commutative diagram of log schemes:

\[
\begin{array}{ccc}
(U_\lambda, M|_{U_\lambda}) & \xrightarrow{\sim} & \text{Spec } (Z, P_\lambda) \times_{\text{Spec } \mathbb{Z}[P_\lambda]} U_\lambda \\
g_\lambda \downarrow & & \downarrow \pi_\lambda \\
(X, M) & \xrightarrow{f} & (Y, N) \\
& \xrightarrow{\sim} & \text{Spec } (Z, Q) \times_{\text{Spec } \mathbb{Z}[Q]} Y.
\end{array}
\]

It follows by corollary 12.3.27(i) (resp. by propositions 12.3.24(ii) and 12.3.34) that \( p_\lambda \) (resp. \( \pi_\lambda \)) is smooth. Hence \( f \circ g_\lambda \) is smooth, by proposition 12.3.24(i). Finally, \( f \) is smooth, by proposition 12.3.24(iii).

(a)⇒(b): Suppose that \( f \) is smooth, and fix a geometric point \( \xi \) of \( X \). Since (12.3.18) is a surjection, we may find elements \( t_1, \ldots, t_r \in M_\xi \) such that \( (d \log f_i | i = 1, \ldots, r) \) is a basis of the free \( \mathcal{O}_{X,\xi} \)-module \( \Omega_{X/Y}^{1}(\log M/N)_\xi \) (proposition 12.3.26(ii)). Moreover, the kernel of (12.3.18) is generated by sections of the form:

\[
\begin{align*}
&1 \otimes \log a \text{ where } a \in N' := \text{Im}(\log f_\xi : N_\xi(\xi) \to M_\xi) \\
&\sum_{j=1}^{s} \alpha(m_i) \otimes \log m_i \text{ where } m_1, \ldots, m_s \in M_\xi \text{ and } \sum_{j=1}^{s} \alpha(m_i) = 0 \text{ in } \Omega_{X/Y}^{1}
\end{align*}
\]

whence a well-defined \( \mathcal{O}_{X,\xi} \)-linear map:

\[
(12.3.38) \quad \Omega_{X/Y}^{1}(\log M/N)_\xi \to \kappa(\xi) \otimes_{\mathbb{Z}} (M^{SP}_\xi / (M^{\times}_\xi \cdot N')) : d \log a \mapsto 1 \otimes a.
\]

Consider the map of monoids:

\[
\varphi : P_1 := \mathbb{N}^{SP}_1 \oplus Q \to M_\xi
\]

which is given by the rule: \( e_i \mapsto t_i \) on the canonical basis \( e_1, \ldots, e_r \) of \( \mathbb{N}^{SP}_1 \), and on the summand \( Q \) it is given by the map \( Q \xrightarrow{\partial_\xi} N_\xi(\xi) \xrightarrow{\log f_\xi} M_\xi \). Since (12.3.38) is a surjection, we see that the same holds for the induced map

\[
\kappa(\xi) \otimes_{\mathbb{Z}} P_1^{SP} \xrightarrow{1_{\kappa(\xi) \otimes \mathbb{Z}} \varphi^{SP}} \kappa(\xi) \otimes_{\mathbb{Z}} M^{SP}_\xi \to \kappa(\xi) \otimes_{\mathbb{Z}} (M^{\times}_\xi / (M^{\times}_\xi \cdot N')).
\]

It follows that the cokernel of the map \( \varphi : P_1^{SP} \to M^{SP}_\xi / M^{\times}_\xi \) induced by \( \varphi^{SP} \), is a finite group (lemma 12.2.21(i)) annihilated by an integer \( n \) which is invertible in \( \mathcal{O}_{X,\xi} \). Let \( m_1, \ldots, m_s \in M^{SP}_\xi \) be finitely many elements, whose images in \( M^{SP}_\xi / M^{\times}_\xi \) generate Coker \( \varphi \); therefore we may find \( u_1, \ldots, u_s \in M^{\times}_\xi \), and \( x_1, \ldots, x_s \in P_1^{SP} \), such that \( m_i^{x_i} \cdot u_i = \varphi(x_i) \) for every \( i \leq s \). However, since \( \mathcal{O}_{X,\xi} \) is strictly henselian, \( M^{\times}_\xi \simeq \mathcal{O}_{X,\xi}^{\times} \) is \( n \)-divisible, hence we may find \( v_1, \ldots, v_s \in M^{\times}_\xi \) such that \( u_i = v_i^n \) for \( i = 1, \ldots, s \). Define group homomorphisms:

\[
\mathbb{Z}^{\oplus s} \xrightarrow{\gamma} \mathbb{Z}^{\oplus s} \oplus P_1^{SP} \xrightarrow{\delta} M^{SP}_\xi
\]

by the rules: \( \gamma(e_i) = (-ne_i, x_i) \) and \( \delta(e_i, y) = m_i v_i \cdot \varphi(y) \) for every \( i = 1, \ldots, s \) and every \( y \in P_1^{SP} \). It is easily seen that \( \delta \) factors through a group homomorphism \( h : G := \text{Coker } \gamma \to \mathbb{Z}^{\oplus s} \).
Moreover, the natural map $P_{1}^{\text{gp}} \to G$ is injective, and its cokernel is annihilated by $n$; furthermore, the induced map $G \to M_{\xi}^{\text{gp}}$ is surjective. Let $P := h^{-1}M_{\xi}$. Then, the natural map $Q_{\text{gp}} \to P_{\text{gp}}$ is injective, and the torsion subgroup of $P_{\text{gp}}/Q_{\text{gp}}$ is annihilated by $n$. We deduce that the rule : $x \mapsto d\log h(x)$ for every $x \in P_{\text{gp}}$, induces an isomorphism:

$$(12.3.39) \quad \Theta_{X,\xi} \otimes_{\mathbb{Z}} (P_{\text{gp}}/Q_{\text{gp}}) \xrightarrow{\sim} \Omega_{X/Y}^{1}(\log M/N)_{\xi}.$$ 

It follows that we may find an étale neighborhood $U \to X$ of $\xi$, such that (12.3.39) extends to an isomorphism of $\Theta_U$-modules:

$$(12.3.40) \quad \Theta_U \otimes_{\mathbb{Z}} (P_{\text{gp}}/Q_{\text{gp}}) \xrightarrow{\sim} \Omega_{U/Y}^{1}(\log M_{U}/N).$$

Next, proposition [12.1.30] says that, after replacing $U$ by a smaller étale neighborhood of $\xi$, the restriction $h_{|P} : P \to M_{\xi}$ extends to a chart $P_U \to M_{U}$, whence a strict morphism

$$p : (U, M_{U}) \to (Y', P_{Y}^{\text{gp}}) := (Y, N) \times_{\text{Spec}(\mathbb{Z}, Q)} \text{Spec}(\mathbb{Z}, P).$$

as sought. Taking into account corollary [12.3.27(i)], it remains only to show :

Claim 12.3.41. $p$ is étale.

Proof of the claim. By proposition [12.3.13] and example [12.3.19] we have natural isomorphisms

$$\Omega_{Y'/Y}^{1}(\log P_{Y}^{\text{gp}}/N) \xrightarrow{\sim} \Theta_{Y'} \otimes_{\mathbb{Z}} (P_{\text{gp}}/Q_{\text{gp}}).$$

In view of (12.3.40), it follows that the map

$$dp : p^{*}\Omega_{Y'/Y}^{1}(\log P_{Y}^{\text{gp}}/N) \to \Omega_{U/Y}^{1}(\log M_{U}/N)$$

is an isomorphism, and then the claim follows from proposition [12.3.32].

Corollary 12.3.42. Keep the notation of theorem 12.3.37. Suppose that $f$ is a smooth morphism of fs log schemes, and that $Q$ is fine, sharp and saturated. Then there exist a covering family $(g_{\lambda} : U_{\lambda} \to X)$ in $X_{\text{et}}$, and fine and saturated charts $(\beta, (P_{\lambda})_{U_{\lambda}} \to g_{\lambda}^{*}M, \varphi_{\lambda} : Q \to P_{\lambda})$ of $f|_{U_{\lambda}}$, fulfilling conditions (b.i) and (b.ii) of the theorem, and such that moreover $\varphi_{\lambda}$ is injective, and $P_{\lambda}^{\text{gp}}$ is a torsion-free abelian group, for every $\lambda \in \Lambda$.

Proof. Notice that, under the stated assumptions, $Q_{\text{gp}}$ is a torsion-free abelian group; hence theorem 12.3.37 already implies the existence of a covering family $(g_{\lambda} : U_{\lambda} \to X)$ in $X_{\text{et}}$, and of fine charts $(\beta, \omega_{\lambda}^{*} : (P_{\lambda})_{U_{\lambda}} \to g_{\lambda}^{*}M, \varphi_{\lambda} : Q \to P_{\lambda})$ such that $\varphi_{\lambda}$ is injective and $\text{Coker}(\varphi_{\lambda}^{*})_{\text{gp}}$ is a finite group of order invertible in $\Theta_{U_{\lambda}}$, for every $\lambda \in \Lambda$. Since $g_{\lambda}^{*}M$ is saturated (lemma [12.1.18](i)), it is clear that $\omega_{\lambda}^{*}$ factors through a morphism $(P_{\lambda})_{U_{\lambda}}^{\text{gp}} \to g_{\lambda}^{*}M_{\lambda}$ of pre-log structures, which is again a chart, so we may assume that $P_{\lambda}$ is fine and saturated, for every $\lambda \in \Lambda$ (corollary [6.4.1](iii)), in which case we may find an isomorphism of monoids $P_{\lambda}^{\text{gp}} = P_{\lambda} \times G$, where $P_{\lambda}^{\text{gp}}$ is torsion-free, and $G$ is a finite group (lemma [6.2.10]). Let $d$ be the order of $\text{Coker}(\varphi_{\lambda}^{*})_{\text{gp}}$, and denote by $\varphi_{\lambda}$ the composition of $\varphi_{\lambda}$ and the projection $P_{\lambda}^{\text{gp}} \to P_{\lambda}$; since $Q_{\text{gp}}$ is a torsion-free abelian group, we deduce a short exact sequence :

$$(12.3.43) \quad 0 \to G \to \text{Coker}(\varphi_{\lambda}^{*})_{\text{gp}} \to \text{Coker} \varphi_{\lambda}^{*} \to 0$$

and notice that $\varphi_{\lambda}$ is also injective. We may assume that $U_{\lambda}$ and $Y$ are affine, say $U_{\lambda} = \text{Spec} B_{\lambda}$ and $Y = \text{Spec} A$, and since $d$ is invertible in $\Theta_{U_{\lambda}}$, we reduce easily – via base change by a finite morphism $Y' \to Y$ – to the case where $A$ contains the subgroup $\mu_{d} \subset \mathbb{G}^{\times}$ of $d$-th power roots of 1. The chart $\omega_{\lambda}^{*}$ determines a morphism of monoids $P_{\lambda}^{\text{gp}} \to B_{\lambda}$, and the map $f^{*} : A \to B_{\lambda}$ factors through the natural ring homomorphism

$$A \to A \otimes_{R[Q]} R[P_{\lambda}] \xrightarrow{\sim} A \otimes_{R[Q]} (R[P_{\lambda}] \otimes_{R} R[G]) \quad \text{where} \quad R := \mathbb{Z}[d^{-1}, \mu_{d}].$$
On the other hand, let $\Gamma := \text{Hom}_Z(G, \mu_d)$; then we have a natural decomposition

$$R[G] \simeq \prod_{\chi \in \Gamma} e_\chi R[G]$$

where $e_\chi$ is the idempotent of $R[G]$ defined as in (14.6.11) (cp. the proof of theorem 14.6.23(i)); each factor is a ring isomorphic to $R$, whence a corresponding decomposition of $U_\lambda$ as a disjoint union of $Y$-schemes $U_\lambda = \coprod_{\chi \in \Gamma} U_{\lambda, \chi}$. We are then further reduced to the case where $U_\lambda = U_{\lambda, \chi}$ for some character $\chi$ of $G$. In view of (12.3.43), it is easily seen that the composition

$$(Q^{gp} \to (P^\lambda)^{gp}) \to G \cong \mu_d$$

extends to a well defined group homomorphism $\chi : P^\lambda \to \mu_d$, whence a map $\chi_{U_\lambda} : P_{\lambda, U_\lambda} \to \mu_{d, U_\lambda} \subset G^\lambda_{\mu_d}$ of sheaves on $U_{\lambda, \tau}$. Define $\omega_{\lambda} : P_{\lambda, U_\lambda} \to g^\lambda M$ by the rule : $s \mapsto \omega_{\lambda}(s) \cdot \chi_{U_\lambda}(s)$ for every local section $s$ of $P_{\lambda, U_\lambda}$. It is easily seen that $\omega_{\lambda}$ is again a chart for $g^\lambda M$ (e.g. one may apply lemma 12.1.4). Lastly, a direct inspection shows that $(\beta, \omega_{\lambda}, \varphi_{\lambda})$ is a chart of $f_{U_\lambda}$ with the sought properties.

12.3.44. Let $(Y_i | i \in I)$ be a cofiltered system of quasi-compact and quasi-separated schemes, with affine transition morphisms, and suppose that 0 is an initial object of the indexing category $I$. Suppose also that $g_0 : X_0 \to Y_0$ is a finitely presented morphism of schemes. Let $X_i := X_0 \times_{Y_0} Y_i$ for every $i \in I$, and denote $g_i : X_i \to Y_i$ the induced morphism. Let also $g : X \to Y$ be the limit of the family of morphisms $(g_i | i \in I)$.

**Corollary 12.3.45.** In the situation of (12.3.44), suppose that $(g, \log g) : (X, M) \to (Y, N)$ is a smooth morphism of fine log schemes. Then there exist $i \in I$, and a smooth morphism $(g_i, \log g_i) : (X_i, M_i) \to (Y_i, N_i)$ of fine log schemes, such that $\log g = \pi^*_i \log g_i$.

**Proof.** First, using corollary 12.2.33 we may find $i_0 \in I$ such that $(g, \log g)$ descends to a morphism $(g_{i_0}, \log g_{i_0})$ of log schemes with coherent log structures. After replacing $I$ by $I/i_0$, we may then suppose that $i_0 = 0$, in which case we set $(X_i, M_i) := X_i \times (X_0, M_0)$, and define likewise $(Y_i, N_i)$ for every $i \in I$.

Next, arguing as in the proof of corollary 12.2.34(ii), we may assume that $N_0$ admits a fine chart. In this case, also $N$ admits a fine chart, and then we may find a covering family $\mathcal{U} := (U_{\lambda, \mu} \to X | \lambda \in \Lambda)$ for $X_{\pi^*}$, such that the induced morphism $(U_{\lambda, M_{U_{\lambda, \mu}}}) \to (Y, N)$ admits a chart fulfilling conditions (i) and (ii) of theorem 12.3.37. Moreover, under the current assumptions, $X$ is quasi-compact, hence we may assume that $\Lambda$ is a finite set, in which case there exists $i \in I$ such that $\mathcal{U}$ descends to a covering family $(U_{i, \lambda} \to X_i | \lambda \in \Lambda)$ for $X_{\pi^i}$, and as usual, we may then reduce to the case where $i = 0$. It then suffices to show that there exists $i \in I$ such that the induced morphism $U_{0, \lambda} \times_{X_0} (X_i, M_i) \to (Y_i, N_i)$ is smooth (proposition 12.3.24(ii)). Thus, we may replace the system $(X_i | i \in I)$ by the system of schemes $(U_{0, \lambda} \times_{X_0} X_i | i \in I)$, and assume from start that $(g, \log g)$ admits a fine chart fulfilling conditions (i) and (ii) of theorem 12.3.37. In this case, corollary 12.2.34(i) and [50, Ch.IV, Prop.17.7.8(ii)] imply more precisely that there exists $i \in I$ such that the morphism $(X_i, M_i) \to (Y_i, N_i)$ fulfills conditions (i) and (ii) of theorem 12.3.37, whence the contention.

12.4. **Logarithmic blow up of a coherent ideal.** This section introduces the logarithmic version of the scheme-theoretic blow up of a coherent ideal, which will be exhibited as the logarithmic homogeneous spectrum of a certain graded algebra, naturally attached to any sheaf of ideals in a log structure.
12.4.1. We shall consider first the logarithmic counterparts of the notions introduced in section 10.6. To begin with, let $X$ be any scheme, $N$ a monoid, and $P$ a (commutative) $N$-graded monoid of the topos $X_r$ (see definition 4.8.8). Notice that $P^\times = \coprod_{n \in \mathbb{N}} (P^\times \cap P_n)$, hence the sheaf of invertible sections of a $N$-graded monoid on $X$ is a $N$-graded abelian sheaf.

**Definition 12.4.2.** Let $X$ be a scheme, and $\beta : M \to \mathcal{O}_X$ a log structure on $X_r$.

(i) A $\mathbb{N}$-graded $\mathcal{O}_{(X,M)}$-algebra is a datum $(\mathcal{A}, P, \alpha, \beta_\mathcal{A})$ consisting of a $\mathbb{N}$-graded $\mathcal{O}_X$-algebra $\mathcal{A} := \oplus_{n \in \mathbb{N}} \mathcal{A}_n$ (on the site $X_r$), a graded monoid $P$ on $X_r$, and a commutative diagram:

$$
\begin{array}{ccc}
M & \xrightarrow{\alpha} & P \\
\downarrow{\beta} & & \downarrow{\beta_\mathcal{A}} \\
\mathcal{O}_X & \longrightarrow & \mathcal{A}
\end{array}
$$

where $\beta_\mathcal{A}$ restricts to a morphism of graded monoids $P \to \coprod_{n \in \mathbb{N}} \mathcal{A}_n$ (and the composition law on the target is induced by the multiplication law of $\mathcal{A}$), $\alpha$ is a morphism of monoids $M \to (P)_0$, and the bottom map is the natural morphism $\mathcal{O}_X \to \mathcal{A}_0$. We say that the $\mathbb{N}$-graded $\mathcal{O}_{(X,M)}$-algebra $(\mathcal{A}, P, \alpha, \beta_\mathcal{A})$ is quasi-coherent, if $\mathcal{A}$ is a quasi-coherent $\mathcal{O}_X$-algebra.

(ii) A morphism $(g, \log g) : (\mathcal{A}, P, \alpha, \beta_\mathcal{A}) \to (\mathcal{A}', P', \alpha', \beta'_\mathcal{A})$ of $\mathbb{N}$-graded $\mathcal{O}_{(X,M)}$-algebras is a commutative diagram:

$$
\begin{array}{ccc}
P & \xrightarrow{\log g} & P' \\
\downarrow{\beta_\mathcal{A}} & & \downarrow{\beta'_\mathcal{A}} \\
\mathcal{A} & \longrightarrow & \mathcal{A}'
\end{array}
$$

where $\log g$ is a morphism of $\mathbb{N}$-graded monoid such that $\log g \circ \alpha = \alpha'$, and $g$ is a morphism of $\mathcal{O}_Z$-algebras.

12.4.3. Let $M$ be a monoid, $S$ an $M$-module; we say that an element $s \in S$ is invertible, if the translation map $M \to S : m \mapsto m \cdot s$ (for all $m \in M$) is an isomorphism. It is easily seen that the subset $S^\times$ consisting of all invertible elements of $S$, is naturally an $M^\times$-module.

Let $M$ be a sheaf of monoids on $X_r$, and $\mathcal{N}$ an $M$-module; by restriction of scalars, $\mathcal{N}$ is naturally an $M^\times$-module. We define the $M^\times$-submodule $\mathcal{N}^\times \subset \mathcal{N}$, by the rule:

$$
\mathcal{N}^\times(U) := \mathcal{N}(U)^\times \quad \text{for every object } U \text{ of } X_r.
$$

Conversely, for any $M^\times$-module $\mathcal{P}$, the extension of scalars $\mathcal{N} \otimes_{M^\times} M$ defines a functor $M^\times$-$\text{Mod} \to M$-$\text{Mod}$. It is easily seen that the latter restricts to an equivalence from the full subcategory $M^\times$-$\text{Inv}$ of $M^\times$-torsors to the subcategory $(M$-$\text{Inv})^\times$ of $M$-$\text{Mod}$ whose objects are all invertible $M$-modules, and whose morphisms are the isomorphisms of $M$-modules (see definition 4.8.6(iv)); the functor $\mathcal{N} \mapsto \mathcal{N}^\times$ provides a quasi-inverse $(M$-$\text{Inv})^\times \to M^\times$-$\text{Inv}$.

Especially, if $(X, M)$ is a log scheme, we see that the category of invertible $M$-modules is equivalent to that of invertible $\mathcal{O}_X^\times$-modules, hence also to that of invertible $\mathcal{O}_X$-modules.

If $\varphi : (Z, N) \to (X, M)$ is a morphism of log schemes, and $\mathcal{N}$ a $M$-module, we let:

$$
\varphi^* \mathcal{N} := \varphi^{-1} \mathcal{N} \otimes_{\mathcal{O}_{(Z,N)}^{-1}} \mathcal{N}.
$$

Clearly, $\varphi^* \mathcal{N}$ is an invertible $N$-module, whenever $\mathcal{N}$ is an invertible $M$-module.
12.4.5. Keep the notation of definition [12.4.2]; by faithfully flat descent, the restriction of \( \mathcal{A} \) to the Zariski site of \( X \) is again a quasi-coherent \( \mathcal{O}_X \)-algebra, which we denote again by \( \mathcal{A} \).

We may then set \( Y := \text{Proj} \mathcal{A} \), and let \( \pi : Y \to X \) be the natural morphism. The composition of \( \pi^{-1} \beta_\mathcal{A} \) and the morphism (10.6.24), yields a map on the site \( Y \) of

\[
\pi^{-1} P_n \to \mathcal{O}_Y(n) \quad \text{for every } n \in \mathbb{N}.
\]

Set \( \mathcal{O}_Y(\bullet) := \prod_{n \in \mathbb{Z}} \mathcal{O}_Y(n) \); it is easily seen that the morphisms (10.6.21) induce a natural \( \mathbb{Z} \)-graded monoid structure on \( \mathcal{O}_Y(\bullet) \), and the coproduct of the maps (12.4.6) amounts to a morphism of graded monoids:

\[
\omega_\bullet : \pi^{-1} P \to \mathcal{O}_Y(\bullet).
\]

We let \( \underline{Q} \) be the push-out in the cocartesian diagram:

\[
\begin{array}{ccc}
\omega_\bullet^{-1}(\mathcal{O}_Y(\bullet)^\times) & \longrightarrow & \pi^{-1} P \\
\downarrow & & \downarrow \\
\mathcal{O}_Y(\bullet)^\times & \longrightarrow & Q.
\end{array}
\]

Clearly \( \underline{Q} \) is naturally a \( \mathbb{Z} \)-graded monoid, in such a way that all the arrows in (12.4.7) are morphisms of \( \mathbb{Z} \)-graded monoids. For every \( n \in \mathbb{Z} \), let \( Q_n \) be the degree \( n \) subsheaf of \( Q \); the map \( \omega_{\bullet} \) and the natural inclusion \( \mathcal{O}_Y(\bullet)^\times \to \mathcal{O}_Y(\bullet) \) determine a unique morphism \( \underline{Q} \to \mathcal{O}_Y(\bullet) \), whose restriction in degree zero is a pre-log structure:

\[
\beta_\mathcal{A} : Q_0 \to \mathcal{O}_Y.
\]

Clearly \( \alpha \) induces a unique morphism \( \alpha^\sim : \pi^{-1} M \to Q_0 \), such that the diagram of monoids:

\[
\begin{array}{ccc}
\pi^{-1} M & \xrightarrow{\alpha^\sim} & Q_0 \\
\pi^{-1} \beta & \downarrow & \beta_\mathcal{A} \\
\pi^{-1} \mathcal{O}_X & \longrightarrow & \mathcal{O}_Y
\end{array}
\]

commutes. Denote by \( P^\sim \) the log structure associated to \( \beta_\mathcal{A}^\circ \); the homogeneous spectrum of the quasi-coherent \( \mathbb{N} \)-graded algebra \( (\mathcal{A}, P, \alpha, \beta_\mathcal{A}) \) is defined as the \( (X, M) \)-scheme:

\[
\text{Proj}(\mathcal{A}, P) := (Y, P^\sim).
\]

We also let:

\[
U_1(\mathcal{A}, P) := U_1(\mathcal{A}) \times_Y \text{Proj}(\mathcal{A}, P).
\]

Furthermore, for every \( n \in \mathbb{Z} \) we have a natural morphism of \( Q_0 \)-monoids:

\[
(12.4.8) \quad Q_0 \otimes_{\mathcal{O}_Y} \mathcal{O}_Y(n)^\times \to Q_n
\]

and it is easily seen that (12.4.8) \( U_1(\mathcal{A}) \) is an isomorphism. We set:

\[
(12.4.9) \quad P^\sim(n) := (P^\sim \otimes Q_0 Q_n)_{U_1(\mathcal{A})} \quad \text{for every } n \in \mathbb{Z}.
\]

Hence (12.4.8) induces a natural isomorphism:

\[
(12.4.10) \quad (P^\sim \otimes_{\mathcal{O}_Y} \mathcal{O}_Y(n)^\times)_{U_1(\mathcal{A})} \simeq P^\sim(n).
\]

Especially, \( P^\sim(n) \) is an invertible \( P^\sim_{U_1(\mathcal{A})} \)-module, for every \( n \in \mathbb{Z} \). From (12.4.9), we also deduce natural isomorphisms of \( P^\sim_{U_1(\mathcal{A})} \)-modules:

\[
(12.4.11) \quad P^\sim(n) \otimes P^\sim P^\sim(m) \simeq P^\sim(n + m) \quad \text{for every } n, m \in \mathbb{Z}
\]
Additionally, the morphism $\pi^{-1} P_n \to Q_n$ deduced from (12.4.7), yields a natural map of $P_{u_1(\mathscr{A})}$-modules:

$$\lambda_n : (\pi^* P_n)_{u_1(\mathscr{A})} \to P_\sim(n) \quad \text{for every } n \in \mathbb{N}. \tag{12.4.12}$$

**Example 12.4.13.** Let $(Z, \gamma : N \to O_Z)$ be a log scheme, $\mathcal{L}$ an invertible $N$-module, and set:

$$\beta_{\mathscr{A}(\mathcal{L})} := \text{Sym}_N^* \mathcal{L} \otimes_N \gamma : \text{Sym}_N^* \mathcal{L} \to \mathcal{A}(\mathcal{L}) := \text{Sym}_{O_Z}(\mathcal{L} \otimes_N O_Z)$$

which is a morphism of $\mathbb{N}$-graded monoids (notation of example 4.8.10). Clearly $\mathcal{A}(\mathcal{L})$ is also a $\mathbb{N}$-graded quasi-coherent $O_Z$-algebra. Denote also:

$$\alpha_{\mathcal{L}} : N \to \text{Sym}_N^* \mathcal{L}$$

the natural morphism that identifies $N$ to $\text{Sym}_N^* \mathcal{L}$; then the datum

$$(\mathcal{A}(\mathcal{L}), \text{Sym}_N^* \mathcal{L}, \alpha_{\mathcal{L}}, \beta_{\mathcal{A}(\mathcal{L})})$$

is a quasi-coherent $O_{(Z,N)}$-algebra, and a direct inspection of the definitions shows that the induced morphism of log schemes:

$$\pi_{(Z,N)} : \mathbb{P}(\mathcal{L}) := \text{Proj}(\mathcal{A}(\mathcal{L}), \text{Sym}_N^* \mathcal{L}) \to (Z, N)$$

is an isomorphism. Furthermore, we have natural isomorphisms as in (10.6.34):

$$\pi_{(Z,N)}(\mathcal{L} \otimes_n O_Z) \sim \mathcal{O}_{\mathbb{P}(\mathcal{L})}(n) \quad \text{for every } n \in \mathbb{Z}. \tag{12.4.14}$$

Let $P_{\mathcal{L}} \to \mathcal{O}_{\mathbb{P}(\mathcal{L})}$ be the log structure of $\mathbb{P}(\mathcal{L})$; there follows a natural identification:

$$\pi_{(Z,N)}(\mathcal{L} \otimes_n O_Z) \sim P^\sim(n) \otimes_{\mathcal{O}_{\mathbb{P}(\mathcal{L})}} \mathcal{O}_{\mathbb{P}(\mathcal{L})}(n)^{\times} \sim P_{\mathcal{L}}(n) \quad \text{for every } n \in \mathbb{Z} \tag{12.4.15}$$

where the last isomorphism is (12.4.9), in view of the fact that $U_1(\mathcal{A}(\mathcal{L})) = \text{Proj} \mathcal{A}(\mathcal{L})$.

**Example 12.4.16.** (i) Let $(Z, N)$ be a log scheme, and $n \in \mathbb{N}$ any integer. We define an $\mathbb{N}$-grading on $\mathbb{N}^{\oplus n}$, by setting:

$$\text{gr}^k \mathbb{N}^{\oplus n} := \{a_\bullet := (a_1, \ldots, a_n) \mid a_1 + \cdots + a_n = k\} \quad \text{for every } k \in \mathbb{N}.$$ 

We then define the $\mathbb{N}$-graded monoid

$$\text{Sym}_{\mathbb{N}}^* N^{\oplus n} := \mathbb{N}^{\oplus n} \times N$$

whose $\mathbb{N}$-grading is deduced in the obvious way from the foregoing grading of $\mathbb{N}^{\oplus n}$. The log structure $\gamma : N \to O_Z$ extends naturally to a map of $\mathbb{N}$-graded $Z$-monoids:

$$\text{Sym}_{\mathbb{N}}^* \gamma^{\oplus n} : \text{Sym}_{\mathbb{N}}^* N^{\oplus n} \to \text{Sym}_{O_Z}^{\oplus n}.$$ 

Namely, if $e_1, \ldots, e_n$ is the canonical basis of the free $O_Z$-module $O_Z^{\oplus n}$, then $\text{Sym}_{O_Z}^{\oplus n}$ is a free $O_Z$-module with basis

$$\{e_{a_\bullet} := e_1^{a_1} \cdots e_n^{a_n} \mid a_\bullet \in \text{gr}^k \mathbb{N}^{\oplus n}\}$$

and $\text{Sym}_{\mathbb{N}}^* \gamma^{\oplus n}$ is given by the rule: $(a_\bullet, x) \mapsto \gamma(x) e_{a_\bullet}$ for every $a_\bullet \in \mathbb{N}^{\oplus n}$, every $\tau$-open subset of $Z$, and every section $x \in N(U)$. Clearly $\text{Sym}_{\mathbb{N}}^* \gamma^{\oplus n}$ defines an $\mathbb{N}$-graded $O_{(Z,N)}$-algebra

$$\text{Sym}_{O_Z}^{\oplus n}(Z, N^{\oplus n}) := (\text{Sym}_{O_Z}^{\oplus n}, \text{Sym}_{\mathbb{N}}^* N^{\oplus n}) \quad \text{for every } n \in \mathbb{N}.$$ 

We set:

$$\mathbb{P}^n(Z, N) := \text{Proj} \text{Sym}_{O_Z}^{\oplus n}(Z, N)^{\oplus n+1}$$

and we call it the projective $n$-dimensional space over $(Z, N)$.
(ii) Denote by $N^\sim$ the log structure of $\mathbb{P}^n_{(\mathbb{Z},\mathbb{N})}$ and by $N^\sim(k)$ the $N^\sim$-modules defined as in (12.4.9), for every $k \in \mathbb{Z}$. By simple inspection we get a commutative diagram of monoids:

$$
\begin{align*}
\Gamma(Z, \text{Sym}^k_\mathbb{Z} N^{\oplus n+1}) & \rightarrow \Gamma(Z, \text{Sym}^k_\mathbb{Z} \mathcal{O}_Z^{\oplus n+1}) \\
\Gamma(\mathbb{P}^n_{(\mathbb{Z},\mathbb{N})}, N^\sim(k)) & \rightarrow \Gamma(\mathbb{P}^n_{(\mathbb{Z},\mathbb{N})}, \mathcal{O}_{\mathbb{P}^n_{(\mathbb{Z},\mathbb{N})}}(k))
\end{align*}
$$

for every $k \in \mathbb{N}$

whose right vertical arrow is an isomorphism. Especially, the natural basis of the free $N(\mathbb{Z})$-module $\Gamma(Z, \text{Sym}^k_\mathbb{Z} N^{\oplus n+1}) = N(\mathbb{Z})^{\oplus n+1}$ yields a distinguished system of $n+1$ elements $\varepsilon_0, \ldots, \varepsilon_n$ in $\Gamma(\mathbb{P}^n_{(\mathbb{Z},\mathbb{N})}, N^\sim(1))$.

On the other hand, we have as well the distinguished system of global sections

$$
T_0, \ldots, T_n \in \Gamma(\mathbb{P}^n_{(\mathbb{Z},\mathbb{N})}, \mathcal{O}_{\mathbb{P}^n_{(\mathbb{Z},\mathbb{N})}}(1))
$$

corresponding to the natural basis of $\Gamma(Z, \text{Sym}^k_\mathbb{Z} \mathcal{O}_Z^{\oplus n+1}) = \mathcal{O}_Z(Z)^{\oplus n+1}$. For each $i = 0, \ldots, n$, the largest open subset $U_i \subset \mathbb{P}^n_{(\mathbb{Z},\mathbb{N})}$ such that $T_i \in \Gamma(U_i, \mathcal{O}_{\mathbb{P}^n_{(\mathbb{Z},\mathbb{N})}}(1))$ is the complement of the hyperplane where $T_i$ vanishes. Moreover, notice that

$$
T_i^{-1}T_j \in N^\sim(U_i) \quad \text{for every } i, j = 0, \ldots, n.
$$

With this notation, the isomorphism (12.4.9) yields the identification:

$$
\varepsilon_j = T_i^{-1}T_j \otimes T_i \quad \text{on } U_i \quad \text{for every } i, j = 0, \ldots, n
$$

from which we also see that, for every $i = 0, \ldots, n$, the open subset $U_i$ is the largest such that $\varepsilon_i \in \Gamma(U_i, N^\sim(1)^\times)$. By the same token, we obtain:

$$
(\mathbb{P}^n_{(\mathbb{Z},\mathbb{N})}, N^\sim)_{\text{tr}} = U_0 \cap \cdots \cap U_n \simeq \mathbb{G}_{m,\mathbb{Z}}^n.
$$

12.4.18. Let $(Z, N)$ be a log scheme, $(\varphi, \log \varphi): (\mathcal{A}, P) \rightarrow (\mathcal{A}', P')$ a morphism of quasicoherent $\mathbb{N}$-graded $\mathcal{O}_{(Z, N)}$-algebras. We let (notation of (10.6.26)):

$$
G(\varphi, \log \varphi) := G(\varphi) \times_{\text{Proj } \mathcal{A}'} \text{Proj}(\mathcal{A}', P').
$$

Denote also by $\pi: Y := \text{Proj } \mathcal{A} \rightarrow Z$ and $\pi': Y' := \text{Proj } \mathcal{A}' \rightarrow Z'$ the natural projections; there follows, on the one hand, a morphism of $\mathbb{N}$-graded monoids:

$$
\pi'^{-1}(\log \varphi): (\text{Proj } \varphi)^{-1}(\pi^{-1}P) \rightarrow (\pi'^{-1}P')|_{G(\varphi)}
$$

and on the other hand, a morphism of $\mathbb{Z}$-graded monoids:

$$(\text{Proj } \varphi)^{-1}\mathcal{O}_Y(\bullet)^\times \rightarrow \mathcal{O}_{\text{Proj } \varphi}(\bullet)^\times_{\mathcal{G}(\varphi)}$$

deduced from (10.6.28). Define the $\mathbb{Z}$-graded monoid $Q$ on $Y$ as in (12.4.7), and the analogous $\mathbb{Z}$-graded monoid $Q'$ on $Y'$. Then (12.4.19) and (12.4.20) determine a unique morphism of $\mathbb{Z}$-graded monoids:

$$
\vartheta: (\text{Proj } \varphi)^{-1}Q \rightarrow Q'|_{\mathcal{G}(\varphi)}
$$

and by construction, the restriction of $\vartheta$ in degree zero is a morphism of pre-log structures:

$$
\vartheta_0: (\text{Proj } \varphi)^{\times}(Q)_0(\beta_{\mathcal{G}(\varphi)}) \rightarrow ((Q')_0(\beta_{\mathcal{G}(\varphi)})
$$

whence a morphism of $(Z, N)$-schemes:

$$
\text{Proj}(\varphi, \log \varphi): G(\varphi, \log \varphi) \rightarrow \text{Proj}(\mathcal{A}, P).
$$

Moreover, on the one hand, (10.6.28) induces an isomorphism of $\mathcal{O}_{\text{Proj } \varphi}$-modules:

$$
\nu_{\mathcal{A}(n)}^{\times}: (\mathcal{O}_{\mathcal{A}}^{\times} \otimes_{(\text{Proj } \varphi)^{-1}\mathcal{O}_Y(\bullet)} (\text{Proj } \varphi)^{-1}\mathcal{O}_Y(\bullet)^{\times})_{\mathcal{G}(\varphi)} \rightarrow \mathcal{O}_{\text{Proj } \varphi}(\bullet)^{\times}_{\mathcal{G}(\varphi)}
$$

for every $n \in \mathbb{Z}$.
(notation of \([10.6.27]\)). On the other hand, for every \(n \in \mathbb{Z}\), the morphism of \((\text{Proj } \phi)^{−1}(\mathcal{Q})_{0}\)-modules \(\vartheta_n\) determines a morphism of \(P^\sim\)-modules:

\[
\vartheta_n^\sim : \text{Proj}(\phi, \log \phi)^{\ast} P^\sim(n)|_{\mathcal{G}_1(\phi)} \to P^\sim(n)|_{\mathcal{G}_1(\phi)}
\]

and by inspecting the construction, it is easily seen that the isomorphism \([12.4.9]\) (and the corresponding one for \(P^\sim(n)\)) identifies \(\vartheta_n^\sim\) with \(\nu_{\mathcal{G}_1(n)}^\sim \otimes \sigma_n^\sim\); especially, \(\vartheta_n^\sim\) is an isomorphism.

12.4.22. Let \(\psi : (Z', N') \to (Z, N)\) be a morphism of log schemes, and \((\mathcal{A}, P, \alpha, \beta_{\mathcal{A}})\) a \(N\)-graded quasi-coherent \(\mathcal{O}_{(Z, N)}\)-algebra. We may view \(P\) as a \(N\)-module, via the morphism \(\alpha\), hence we may form the \(N\)-module \(\psi^\ast P\), as in \([12.4.4]\). Moreover, by remark \([6.1.26]\)(i), \(\psi^\ast P\) is a \(N\)-graded sheaf of monoids on \(Z', n\), such that

\[
\psi^\ast(\mathcal{A}, P) := (\psi^\ast \mathcal{A}, \psi^\ast P, \psi^\ast \alpha, \psi^\ast \beta_{\mathcal{A}})
\]

is a \(N\)-graded quasi-coherent \(\mathcal{O}_{(Z', N')}\)-algebra, and in view of the isomorphism \([6.1.27]\), we obtain a natural isomorphism of \((Z', N')\)-schemes:

\[
\text{Proj } \psi^\ast(\mathcal{A}, P) \xrightarrow{\sim} (Z', N') \times_{(Z, N)} \text{Proj}(\mathcal{A}, P).
\]

Furthermore, denote by \(\pi_{\mathcal{A}, P}^\ast : U_1(\psi^\ast(\mathcal{A}, P)) \to U_1(\mathcal{A}, P)\) the morphism deduced from \([12.4.24]\), and by \(\pi_{\mathcal{Y}} : \mathcal{Y}' := \text{Proj } \psi^\ast(\mathcal{A}, P) \to \mathcal{Y} := \text{Proj } \mathcal{A}\) the underlying morphism of schemes. From \([10.6.31]\) we obtain natural isomorphisms:

\[
(\mathcal{O}_{\mathcal{Y}'} \otimes \pi_{\mathcal{A}, P}^\ast \mathcal{O}_{\mathcal{Y}})^{\sim} \mathcal{Y}'(n)^{\sim} \xrightarrow{\sim} \mathcal{O}_{\mathcal{Y}}(n)^{\sim}_{U_1(\psi^\ast \mathcal{A})}
\]

for every \(n \in \mathbb{Z}\) and the latter induce natural identifications:

\[
\pi_{\mathcal{A}, P}^\ast P^\sim(n) \xrightarrow{\sim} (\psi^\ast P)^\sim(n) \quad \text{for every } n \in \mathbb{Z}.
\]

12.4.26. Keep the notation of \([12.4.5]\), and let \(\log \mathcal{C}_{(X, M)}\) be the category whose objects are the pairs \(((Z, N), \mathcal{L})\), where \((Z, N)\) is a \((X, M)\)-scheme, and \(\mathcal{L}\) is an invertible \(N\)-module. The morphisms \(((Z, N), \mathcal{L}) \to ((Z', N'), \mathcal{L}')\) are the pairs \((\phi, h)\), where \(\phi : (Z, N) \to (Z', N')\) is a morphism of \((X, M)\)-schemes, and \(h : \psi^\ast \mathcal{L}' \to \mathcal{L}\) is an isomorphism of \(N\)-modules (with composition of morphisms defined in the obvious way). There is an obvious forgetful functor:

\[
p : \log \mathcal{C}_{(X, M)} \to \mathcal{C}_X : ((Z, N), \mathcal{L}) \mapsto (Z, \mathcal{L} \otimes_{\mathcal{O}_Z} \mathcal{O}_Z)
\]

and the functor \(\psi_{\mathcal{L}}\) can be lifted to a functor:

\[
\psi_{\mathcal{L}} : \log \mathcal{C}_{(X, M)} \to \text{Set}
\]

which assigns to any object \(((Z, \gamma : N \to \mathcal{O}_Z), \mathcal{L})\) the set consisting of all morphisms of \(N\)-graded quasi-coherent \(\mathcal{O}_{(Z, N)}\)-algebras:

\[
\begin{array}{ccc}
\psi^\ast P & \xrightarrow{\log g} & \text{Sym}^\bullet_{\mathcal{Y}, \mathcal{L}} \\
\psi^\ast \mathcal{A} & \xrightarrow{g} & \mathcal{A}(\mathcal{L}) \\
\end{array}
\]

where \(\psi : (Z, N) \to (X, M)\) is the structural morphism, and \(g\) is an epimorphism on the underlying \(\mathcal{O}_Z\)-modules.

**Proposition 12.4.27.** \((U_1(\mathcal{A}, P), P^\sim(1)) \in \text{Ob}(\log \mathcal{C}_{(X, M)})\) represents the functor \(\psi_{\mathcal{L}}\).

**Proof.** Given \(((Z, N) \xrightarrow{\psi} (X, M), \mathcal{L}) \in \text{Ob}(\log \mathcal{C}_{(X, M)})\) and \((g, \log g) \in F_{(\mathcal{A}, P)}((Z, N), \mathcal{L})\), define \(\mathbb{P}(\mathcal{L})\) as in \([12.4.14]\); there follows a morphism of \((Z, N)\)-schemes:

\[
\text{Proj}(g, \log g) : \mathbb{P}(\mathcal{L}) \to \text{Proj } \psi^\ast(\mathcal{A}, P).
\]
In view of (12.4.14) and (12.4.24), this is the same as a morphism of \((X, M)\)-schemes:

\[ \mathbb{P}(g, \log g) : (Z, N) \to \text{Proj}(\mathcal{A}, \mathcal{P}) \]

and arguing as in the proof of lemma [10.6.33], we see that the image of \(\mathbb{P}(g, \log g)\) lands in \(U_1(\mathcal{A}, \mathcal{P})\). Next, combining (12.4.15), (12.4.21) and (12.4.25), we deduce a natural isomorphism:

\[
\pi^*_{(Z, N)} \circ \mathbb{P}(g, \log g)^* \mathcal{P}^-(1) \cong \text{Proj}(g, \log g)^* \circ \pi^*_{(\mathcal{A}, \mathcal{P})} \mathcal{P}^-(1)
\]

whence an isomorphism \(h(g, \log g) : \mathbb{P}(g, \log g)^* \mathcal{P}^-(1) \cong \mathcal{L}\), and the datum:

\[
(\mathbb{P}(g, \log g), h(g, \log g)) : ((Z, N), \mathcal{L}) \to (U_1(\mathcal{A}, \mathcal{P}), \mathcal{P}^-(1))
\]

is a well defined morphism of \(\log \mathcal{C}_{(X, M)}\).

Conversely, let \(\varphi := (\beta, \log \beta) : (Z, N) \to U_1(\mathcal{A}, \mathcal{P})\) be a morphism of \((X, M)\)-schemes, and \(h : \varphi^* \mathcal{P}^-(1) \cong \mathcal{L}\) an isomorphism of \(N\)-modules. In view of (12.4.10), we deduce an isomorphism:

\[
h^{\otimes n} : \varphi^* \mathcal{P}^-(n) \cong \mathcal{L}^{\otimes n} \quad \text{for every } n \in \mathbb{Z}.
\]

Combining with (12.4.12), we may define the map of \(\mathcal{N}\)-modules:

\[
\log \widehat{g}(\varphi, h) := \bigoplus_{n \in \mathbb{N}} h^{\otimes n} \circ \beta^*(\lambda_n) : \psi^* \mathcal{P} \to \text{Sym}^n \mathcal{L}.
\]

On the other hand, in view of (12.4.11), we have an isomorphism of \(\mathcal{O}_Z\)-modules:

\[
h \otimes_N \mathcal{O}_Z : \beta^* \mathcal{O}_Y(1)|_{U_1(\mathcal{A})} \cong \varphi^* \mathcal{P}^-(1) \otimes_N \mathcal{O}_Z \cong \mathcal{L} \otimes_N \mathcal{O}_Z
\]

(where, as usual, \(Y := \text{Proj} \mathcal{A}\)). We let (notation of (10.6.36)):

\[
\widehat{g}(\varphi, h) := g(\beta, h \otimes_N \mathcal{O}_Z)
\]

and notice that the pair \((\widehat{g}(\varphi, h), \log \widehat{g}(\varphi, h))\) is an element of \(F(\mathcal{A}, \mathcal{P})((Z, N), \mathcal{L})\). Summing up, we have exhibited two natural transformations:

\[ \vartheta : F(\mathcal{A}, \mathcal{P}) \Rightarrow \text{Hom}_{\log \mathcal{C}_{(X, M)}}(-, (U_1(\mathcal{A}, \mathcal{P}), \mathcal{P}^-(1))) \quad (g, \log g) \mapsto \mathbb{P}(g, \log g) \]

\[ \sigma : \text{Hom}_{\log \mathcal{C}_{(X, M)}}(-, (U_1(\mathcal{A}, \mathcal{P}), \mathcal{P}^-(1))) \Rightarrow F(\mathcal{A}, \mathcal{P}) \quad (\varphi, h) \mapsto (\widehat{g}(\varphi, h), \log \widehat{g}(\varphi, h)) \]

and it remains to show that these transformations are isomorphisms of functors. However, the latter fit into an essentially commutative diagram of natural transformations:

\[
\begin{array}{ccc}
F(\mathcal{A}, \mathcal{P}) & \xrightarrow{\vartheta} & \text{Hom}_{\log \mathcal{C}_{(X, M)}}(-, (U_1(\mathcal{A}, \mathcal{P}), \mathcal{P}^-(1))) \\
\downarrow & & \downarrow \\
F(\mathcal{A}, \mathcal{P}) & \xrightarrow{\sigma} & F(\mathcal{A}, \mathcal{P})
\end{array}
\]

whose bottom line is given by the natural transformations (10.6.37). Moreover, given an isomorphism \(h\) of invertible \(\mathcal{N}\)-modules, the discussion in (12.4.3) leads to the identity:

\[
(12.4.28) \quad h = (h \otimes_N \mathcal{O}_Z)^{\otimes} \otimes \mathcal{O}_Z \otimes \mathcal{N}.
\]

Likewise, we have natural identifications:

\[
\text{Sym}^n_{\mathcal{N}} \mathcal{L} = (\text{Sym}^n \mathcal{O}_Z \otimes \mathcal{N} \otimes \mathcal{O}_Z \otimes \mathcal{N}) \quad \text{for every } n \in \mathbb{Z}
\]

which show that \(\beta_{\mathcal{A}}\) and \(g\) determine uniquely \(\log g\). This – and an inspection of the proof of lemma [10.6.33] – already implies that \(\sigma \circ \vartheta\) is the identity automorphism of the functor
Finally, let \( \varphi = (\beta, \log \beta) \) and \( h \) as in the foregoing, so that \((\varphi, h)\) is a morphism in \( \log \mathcal{G}(X, M) \); to conclude we have to show that \((\varphi', h') := \varphi \circ (\varphi, h)\) equals \((\varphi, h)\). Say that \( \varphi' := (\beta', \log \beta') \); by the above (and by the proof of lemma \([10.6.33]\)) we already know that \( \beta = \beta' \), and \((12.4.28)\) implies that \( h = h' \). Hence, it remains only to show that \( \log \beta = \log \beta' \), which can be checked directly on the stalks over the \( \tau \)-points of \( Z \) : we leave the details to the reader. \( \square \)

**Example 12.4.29.** (i) Let \( \psi : (Z', N') \to (Z, N) \) be a morphism of log schemes, \( n \in \mathbb{N} \) any integer, and \( \mathbb{P}_{(Z, N)}^n \) the \( n \)-dimensional projective space over \((Z, N)\), defined as in example \([12.4.16] \). A simple inspection of the definitions yields a natural isomorphism of \( \mathcal{O}(Z, N) \)-algebras
\[
\text{Sym}^n(\mathcal{O}(Z', N')) \cong \psi^* \text{Sym}^n(\mathcal{O}(Z, N))
\]
whence a natural isomorphism of \((Z', N')\)-schemes:
\[
\mathbb{P}_{(Z', N')}^n \cong (Z', N') \times (Z, N) \mathbb{P}_{(Z, N)}^n
\]
for every \( n \in \mathbb{N} \).

(ii) Let \( \mathcal{L} \) be any invertible \( N \)-module; notice that a morphism of \( N \)-graded monoids
\[
\text{Sym}^n N \to \text{Sym}^n \mathcal{L}
\]
which is the identity map in degree zero, is the same as the datum of a sequence
\[
(\beta_i : N \to \mathcal{L} \mid i = 1, \ldots, n)
\]
of morphisms of \( N \)-modules, and the latter is the same as a sequence \((b_1, \ldots, b_n)\) of global sections of \( \mathcal{L} \). Since \( \text{Sym}^1 \mathcal{O}(Z, N)^{\oplus n+1} \) generates \( \text{Sym}^n \mathcal{O}(Z, N)^{\oplus n+1} \), proposition \([12.4.27] \) and (i) imply that \( \mathbb{P}_{(Z, N)}^n \) represents the functor \( \log \mathcal{G}(Z, N) \to \text{Set} \), that assigns to any pair \(((X, M), \mathcal{L})\) the set of all sequences \((b_0, \ldots, b_n)\) of global sections of \( \mathcal{L} \). The bijection
\[
(12.4.30)
\text{Hom}_{\log \mathcal{G}(Z, N)}(((X, M), \mathcal{L}), ((\mathbb{P}_{(Z, N)}^n, N^\sim(1)))) \cong \Gamma(X, \mathcal{L})^{n+1}
\]
can be explicit as follows. Let \( (\varphi, h) : ((X, M), \mathcal{L}) \to ((\mathbb{P}_{(Z, N)}^n, N^\sim(1))) \) be a given morphism in \( \log \mathcal{G}(Z, N) \); then \( h : \varphi^* N^\sim(1) \to \mathcal{L} \) is an isomorphism of \( M \)-modules, which induces a map on global sections
\[
\Gamma(h) : \Gamma((\mathbb{P}_{(Z, N)}^n, N^\sim(1))) \to \Gamma(X, \mathcal{L}).
\]
Now, \( N^\sim(1) \) admits a distinguished system of global sections \( \varepsilon_0, \ldots, \varepsilon_n \) (example \([12.4.16(ii)] \)), and the bijection \((12.4.30)\) assigns to \((\varphi, h)\) the sequence \( (\Gamma(h)(\varepsilon_0), \ldots, \Gamma(h)(\varepsilon_n)) \).

(iii) Given a sequence \( b_* := (b_0, \ldots, b_n) \) as in (ii), denote by
\[
f_{b_*} : (X, M) \to \mathbb{P}_{(Z, N)}^n
\]
the corresponding morphism. A direct inspection of the definitions shows that the formation of \( f_{b_*} \) is compatible with arbitrary base changes \( h : (Z', N') \to (Z, N) \). Namely, set \( (X', M') := (Z', N') \times (Z, N) (X, M) \), let \( g : (X', M') \to (X, M) \) be the induced morphism, \( \mathcal{L}' := g^* \mathcal{L} \), and suppose that \( \mathcal{L}' \) is also invertible (which always holds, if \( M' \) is an integral log structure); the sequence \( b_* \) pulls back to a corresponding sequence \( b_{*}' := (b_0', \ldots, b_n') \) of global sections of \( \mathcal{L}' \), and there follows a cartesian diagram of log schemes:
\[
\begin{array}{ccc}
(X', M') & \xrightarrow{f_{b_*}} & \mathbb{P}_{(Z', N')}^n \\
\downarrow g & & \downarrow \mathbb{P}_{(Z', N')}^n \\
(X, M) & \xrightarrow{f_{b_*}} & \mathbb{P}_{(Z, N)}^n
\end{array}
\]
The details shall be left to the reader.

**Definition 12.4.31.** Let \((X, M)\) be a log scheme, and \( \mathcal{I} \subset M \) an ideal of \( M \) (see \([3.6.22] \)).
(i) Let $f : (Y, N) \to (X, M)$ be a morphism of log schemes; then $f^{-1} \mathcal{I}$ is an ideal in the sheaf of monoids $f^{-1} M$; we let:

$$
\mathcal{I} N := \log f(f^{-1} \mathcal{I}) \cdot N
$$

which is the smallest ideal of $N$ containing the image of $f^{-1} \mathcal{I}$.

(ii) A logarithmic blow up of the ideal $\mathcal{I}$ is a morphism of log schemes

$$
\varphi : (X', M') \to (X, M)
$$

which enjoys the following universal property. The ideal $\mathcal{I} M'$ is invertible, and every morphism of log schemes $(Y, N) \to (X, M)$ such that $\mathcal{I} N \subset N$ is invertible, factors uniquely through $\varphi$.

**Remark 12.4.32.** (i) Keep the notation of definition 12.4.31. By the usual general nonsense, it is clear that the blow up $(X', M')$ is determined up to unique isomorphism of $(X, M)$-schemes.

(ii) Moreover, let $f : Y \to X$ be a morphism of schemes. Then we claim that the natural projection :

$$
\pi(P, \mathcal{I}) : \mathrm{Proj} \mathcal{B}(X, M, \mathcal{I}) \to (X, M)
$$

is a logarithmic blow up of $\mathcal{I} M$, provided $\mathcal{I} M'$ is an invertible ideal; especially, this holds whenever $M'$ is an integral log structure (lemma 12.1.18(i)). The proof is left as an exercise for the reader.

12.4.33. Let $(X, M)$ be a log scheme, $\mathcal{I} \subset M$ an ideal; we shall show the existence of the logarithmic blow up of $\mathcal{I}$, under fairly general conditions. To this aim, we introduce the graded blow up $\mathcal{O}_X$-algebra :

$$
\mathcal{B}(X, M, \mathcal{I}) := \bigoplus_{n \in \mathbb{N}} \mathcal{I}^n \otimes_M \mathcal{O}_X
$$

where $\mathcal{I}^n \otimes_M \mathcal{O}_X$ is the sheaf associated to the presheaf $U \mapsto \mathcal{I}^n(U) \otimes_M \mathcal{O}_X(U)$ on $X_\tau$. Here $\mathcal{I}^0 := M$, and for every $n > 0$ we let $\mathcal{I}^n$ be the sheaf associated to the presheaf $U \mapsto \mathcal{I}(U)^n$ on $X_\tau$. The graded multiplication law of the blow up $\mathcal{O}_X$-algebra is induced by the multiplication $\mathcal{I}^n \times \mathcal{I}^m \to \mathcal{I}^{n+m}$, for every $n, m \in \mathbb{N}$.

The natural map $\mathcal{I}^n \to \mathcal{I}^n \otimes_M \mathcal{O}_X$ induces a morphism of sheaves of monoids :

$$
\prod_{n \in \mathbb{N}} \mathcal{I}^n \to \mathcal{B}(X, P, \mathcal{I}).
$$

The latter defines a $\mathbb{N}$-graded $\mathcal{O}_{(X, M)}$-algebra, which we denote $\mathcal{B}(X, M, \mathcal{I})$.

12.4.34. Suppose first that $\mathcal{I}$ is invertible; then it is easily seen that, locally on $X_\tau$, $\mathcal{I}$ is generated by a regular local section (see example 4.8.36(i)), hence the same holds for the power $\mathcal{I}^n$, for every $n \in \mathbb{N}$. Therefore $\mathcal{I}^n$ is a locally free $M$-module of rank one, and we have a natural isomorphism :

$$
\mathcal{B}(X, M, \mathcal{I}) \cong (\mathcal{O}(\mathcal{I}), \mathrm{Sym}_M^{\bullet} \mathcal{I})
$$

(notation of example (12.4.13)). It follows that in this case, the natural projection :

$$
\pi_{(X, M, \mathcal{I})} : \mathrm{Proj} \mathcal{B}(X, M, \mathcal{I}) \to (X, M)
$$

is an isomorphism of log schemes.
12.4.35. The formation of \( \mathcal{B}(X, M, \mathcal{I}) \) is obviously functorial with respect to morphisms of log schemes; more precisely, such a morphism \( f : (Y, N) \to (X, M) \) induces a morphism of \( \mathbb{N} \)-graded \( \mathcal{O}_{Y,N} \)-algebras:

\[
\mathcal{B}(f, \mathcal{I}) : f^* \mathcal{B}(X, M, \mathcal{I}) \to \mathcal{B}(Y, N, \mathcal{I} N)
\]

(notation of (12.4.23)) which is an epimorphism on the underlying \( \mathcal{O}_Y \)-modules. Moreover, if \( g : (Z, Q) \to (Y, N) \) is another morphism, we have the identity:

\[
\mathcal{B}(f \circ g, \mathcal{I}) = \mathcal{B}(g, \mathcal{I} N) \circ g^* \mathcal{B}(f, \mathcal{I}).
\]

Furthermore, the construction of the blow up algebra is local for the topology of \( X_\tau \) : if \( U \to X \) is any object of \( X_\tau \), we have a natural identification

\[
\mathcal{B}(U, M|_U, \mathcal{I}|_U) \cong \mathcal{B}(X, M, \mathcal{I})|_U.
\]

In the presence of charts for the log structure \( M \), we can give a handier description for the blow up algebra; namely, we have the following:

**Lemma 12.4.37.** Let \( X \) be a scheme, \( \alpha : P \to \mathcal{O}_X \) a pre-log structure, \( \beta : P \to P_{\text{log}} \) the natural morphism of pre-log structures. Let also \( \mathcal{I} \subset P \) be an ideal, and set \( \mathcal{I} P_{\text{log}} := \beta(\mathcal{I}) \cdot P_{\text{log}} \) (which is the ideal of \( P_{\text{log}} \) generated by the image of \( \mathcal{I} \)). Then:

(i) There is a natural isomorphism of graded \( \mathcal{O}_X \)-algebras:

\[
\bigoplus_{n\in\mathbb{N}} \mathcal{I}^n \otimes_P \mathcal{O}_X \cong \mathcal{B}(X, P_{\text{log}}, \mathcal{I} P_{\text{log}}).
\]

(ii) Especially, suppose \((X, M)\) is a log scheme that admits a chart \( \beta : P_X \to M \), let \( I \subset P \) be an ideal, and set \( IM := \beta(I_X) \cdot M \). Then \( \mathcal{B}(X, M, IM) \) is a \( \mathbb{N} \)-graded quasi-coherent \( \mathcal{O}_{(X,M)} \)-algebra.

(iii) In the situation of (ii), set \( (S, P^\log) := \text{Spec}(\mathbb{Z}, P) \) (see (12.2.13)), and denote by \( f : (X, M) \to (S, P^\log) \) the natural morphism. Then the map:

\[
\mathcal{B}(f, IP^\log) : f^* \mathcal{B}(S, P^\log, IP^\log) \to \mathcal{B}(X, M, IM)
\]

is an isomorphism of \( \mathbb{N} \)-graded \( \mathcal{O}_{(X,M)} \)-algebras.

**Proof.** (i): Since the functor (4.8.51) commutes with all colimits, we have a natural isomorphism of sheaves of rings on \( X_\tau \):

\[
\mathbb{Z}[P^\log] \cong \mathbb{Z}[P] \otimes_{\mathbb{Z}[\alpha]} \mathbb{Z}[\mathcal{O}_X].
\]

We are therefore reduced to showing that the natural morphism

\[
\mathbb{Z}[\mathcal{I}^n] \otimes_{\mathbb{Z}[\alpha]} \mathbb{Z}[\mathcal{O}_X] \to \mathcal{I}^n \mathbb{Z}[P^\log]
\]

is an isomorphism for every \( n \in \mathbb{N} \). The latter assertion can be checked on the stalks over the \( \tau \)-points of \( X \); to this aim, we invoke the more general:

**Claim 12.4.38.** Let \( G \) be an abelian group, \( \varphi : H \to P' \) and \( \psi : H \to G \) two morphisms of monoids, \( I \subset P' \) an ideal. Then the natural map

\[
\mathbb{Z}[I] \otimes_{\mathbb{Z}[H]} \mathbb{Z}[G] \to I\mathbb{Z}[P' \otimes_{\mathbb{Z}} G]
\]

is an isomorphism.

**Proof of the claim.** Recall that \( \mathbb{Z}[I] = I\mathbb{Z}[P'] \), and the map (12.4.39) is induced by the natural identification: \( \mathbb{Z}[P'] \otimes_{\mathbb{Z}[H]} \mathbb{Z}[G] \cong \mathbb{Z}[P' \otimes_{\math{Z}} G] \) (see (4.8.52)). Especially, (12.4.39) is clearly surjective, and it remains to show that it is also injective. To this aim, notice first that \( \psi \) factors through the unit of adjunction \( \eta : H \to H^{\text{gp}} \); the morphism \( \mathbb{Z}[\eta] : \mathbb{Z}[H] \to \mathbb{Z}[H^{\text{gp}}] = H^{-1}\mathbb{Z}[H] \) is a localization map (see (4.8.53)), especially it is flat, hence (12.4.39) is injective when \( G = \)
$H^{sp}$ and $\psi = \eta$. It follows easily that we may replace $H$ by $H^{sp}$, $P'$ by $P' \otimes_H H^{sp}$, and therefore assume that $H$ is a group. Let $L := \psi(H)$; arguing as in the foregoing, we may consider separately the case where $\psi$ is the surjection $H \to L$ and the case where $\psi$ is the injection $i : L \to G$. However, one sees easily that $\mathbb{Z}[i] : \mathbb{Z}[L] \to \mathbb{Z}[G]$ is a flat morphism, hence it suffices to consider the case where $\psi$ is a surjective group homomorphism.

Set $K := \text{Ker } \psi$; we have a natural identification : $P' \otimes_H G \simeq P' \otimes_K \{1\}$, hence we may further reduce to the case where $G = \{1\}$. Then the contention is that the augmentation map $\mathbb{Z}[K] \to \mathbb{Z}$ induces an isomorphism $\omega : \mathbb{Z}[I] \otimes \mathbb{Z}[K] \xrightarrow{\sim} \mathbb{Z}[P'/K]$. From lemma 4.8.31(ii), we derive easily that $\mathbb{Z}[P'/K] = \mathbb{Z}[I/K]$, where $I/K$ is the set-theoretic quotient of $I$ for the $K$-action deduced from $\varphi$. However, any set-theoretic section $I/K \to I$ of the natural projection $I \to I/K$ yields a well-defined surjection $\mathbb{Z}[I/K] \to \mathbb{Z}[I] \otimes \mathbb{Z}[K]$ whose composition with $\omega$ is the identity map. The claim follows.

(ii): Let $U$ be an affine object of $X_r$, say $U = \text{Spec } A$; from (i), we see that $\mathcal{B}(X, M, IM)_{U}$ is the quasi-coherent $\mathcal{O}_U$-algebra associated to the $A$-algebra $\oplus_{n \in \mathbb{N}} \mathbb{Z}[I^n] \otimes \mathbb{Z}[P]$ $A$.

(iii): In view of (i) we know already that $\mathcal{B}(f, IP^\log_S)$ induces an isomorphism on the underlying $\mathcal{O}_X$-algebras; hence, by lemma [12.2.18(i)], it remains to show that $\mathcal{B}(f, IP^\log_S)$ induces an isomorphism:

$$f^*(I^n P^\log_S) \xrightarrow{\sim} I^n f^*(P^\log_S)$$

for every $n \in \mathbb{N}$.

Let $\gamma : f^{-1} P^\log_S \to f^{-1} \mathcal{O}_S \to \mathcal{O}_X$ be the natural map; after replacing $I$ by $I^n$, we come down to showing that the natural map:

$$f^{-1}(IP^\log_S) \otimes I^{-1} \mathcal{O}_X^\times \to I \cdot (f^{-1} P^\log_S \otimes f^{-1} \mathcal{O}_X^\times)$$

is an isomorphism. This assertion can be checked on the stalks over the $\tau$-points of $X$; if $x$ is such a point, let $G := \mathcal{O}_X^\times_x, H := \gamma^{-1} G$ and $P' := IP^\log_{S(f(x))}$. The map under consideration is the natural morphism of $P'$-modules:

$$\omega : (IP') \otimes_H G \to I(P' \otimes_H G)$$

and it suffices to show that $\mathbb{Z}[\omega]$ is an isomorphism; however, the latter is none else than (12.4.39), so we may appeal to claim [12.4.38] to conclude.

12.4.40. We wish to generalize lemma [12.4.37] ii) to log structures that do not necessarily admit global charts. Namely, suppose now that $M$ is a quasi-coherent log structure on $X$, and $\mathcal{J} \subset M$ is a coherent ideal (see definition [4.8.6(v)]). For every $\tau$-point $\xi$ of $X$, we may then find a neighborhood $U$ of $\xi$ in $X_r$, a chart $\beta : P_U \to M_U$, and local sections $s_1, \ldots, s_n \in \mathcal{J}(U)$ which form a system of generators for $\mathcal{J}_U$. We may then write $s_{i,\xi} = u_i \cdot \beta(x_i)$ for certain $x_1, \ldots, x_n \in P$ and $u_1, \ldots, u_n \in \mathcal{O}_X^\times(U)$. Up to shrinking $U$, we may assume that $u_1, \ldots, u_n \in \mathcal{O}_X^\times(U)$, and it follows that $\mathcal{J}_U = I \cdot M_U$, where $I \subset P$ is the ideal generated by $x_1, \ldots, x_n$. In other words, locally on $X_r$, the datum $(X, M, \mathcal{J})$ is of the type considered in lemma [12.4.37] ii); therefore the blow up $\mathcal{O}_X$-algebra $\mathcal{B}(X, M, \mathcal{J})$ is quasi-coherent. We may then consider the natural projection:

$$\pi_{(X, M, \mathcal{J})} : \text{Bl}_\mathcal{J}(X, M) := \text{Proj } \mathcal{B}(X, M, \mathcal{J}) \to (X, M).$$

Next, let $f : (Y, N) \to (X, M)$ be a morphism of log schemes; it is easily seen that $\mathcal{J} N$ is a coherent ideal of $N$, hence $\mathcal{B}(Y, N, \mathcal{J} N)$ is quasi-coherent as well, and since the map $\mathcal{B}(f, \mathcal{J})$ of (12.4.35) is an epimorphism on the underlying $\mathcal{O}_Y$-modules, we have:

$$G(\mathcal{B}(f, \mathcal{J})) = \text{Bl}_\mathcal{J}N(Y, N)$$

(notation of [12.4.18]) whence a closed immersion of $(Y, N)$-schemes:

$$\text{Proj } \mathcal{B}(f, \mathcal{J}) : \text{Bl}_\mathcal{J}N(Y, N) \to (Y, N) \times_{(X, M)} \text{Bl}_\mathcal{J}(X, M)$$
which is the same as a morphism of \((X, M)\)-schemes:

\[ \varphi(f, \mathcal{I}) : \text{Bl}_\mathcal{I}(Y, N) \to \text{Bl}_\mathcal{I}(X, M). \]

Moreover, if \(g : (Z, Q) \to (Y, N)\) is another morphism, (12.4.36) induces the identity:

\[ (12.4.42) \quad \varphi(f, \mathcal{I}) \circ \varphi(g, \mathcal{I}N) = \varphi(f \circ g, \mathcal{I}). \]

**Example 12.4.43.** In the situation of lemma (12.4.37)ii, notice that \(O_S\) is a flat \(\mathbb{Z}[P_S]\)-algebra, and therefore:

\[ (12.4.43) \quad \text{Bl}(S, P_S^\log, IP_S^\log) = \bigoplus_{n \in \mathbb{N}} IP^n O_S. \]

Moreover, (12.4.24) specializes to a natural isomorphism of \((X, M)\)-schemes:

\[ (12.4.44) \quad \text{Bl}_M(X, M) \to X \times S \text{Bl}_{IP_S^\log}(S, P_S^\log). \]

We wish to give a more explicit description of the log structure of \(\text{Bl}_{IP_S^\log}(S, P_S^\log)\). To begin with, recall that \(S' := \text{Proj}_S \text{Bl}(S, P_S^\log, IP_S^\log)\) admits a distinguished covering by (Zariski) affine open subsets: namely, for every \(a \in I\), consider the localization

\[ P_a := T_a^{-1}P \quad \text{where} \quad T_a := \{a^n \mid n \in \mathbb{N}\} \]

and let \(Q_a \subset P_a\) be the submonoid generated by the image of \(P\) and the subset \(\{a^{-1}b \mid b \in I\}\); then

\[ S' = \bigcup_{a \in I} \text{Spec} \mathbb{Z}[Q_a]. \]

Hence, let us set

\[ U_a := \text{Spec}(\mathbb{Z}, Q_a) \quad \text{for every} \quad a \in I. \]

We claim that these locally defined log structures glue to a well defined log structure \(Q\) on the whole of \(S'\). Indeed, let \(a, b \in I\); we have

\[ U_{a,b} := \text{Spec} \mathbb{Z}[Q_a] \cap \text{Spec} \mathbb{Z}[Q_b] = \text{Spec} \mathbb{Z}[Q_a \otimes_P Q_b] \]

and it is easily seen that \(Q_a \otimes_P Q_b = Q_a[b^{-1}a], i.e.\) the localization of \(Q_a\) obtained by inverting its element \(a^{-1}b\), and this is of course the same as \(Q_b[a^{-1}b]\). Then lemma (12.2.14) implies that the log structures of \(U_a\) and \(U_b\) agree on \(U_{a,b}\), whence the contention. It is easy to check that the resulting log scheme is precisely \(\text{Bl}_{IP_S^\log}(S, P_S^\log)\): the details shall be left to the reader.

**Proposition 12.4.45.** Let \((X, M)\) be a log scheme with quasi-coherent log structure, and \(\mathcal{I} \subset M\) a coherent ideal. Then, the morphism (12.4.41) is a logarithmic blow up of \(\mathcal{I}\).

*Proof.* Let \(f : (Y, N) \to (X, M)\) be a morphism of log schemes, and suppose that \(\mathcal{I}N\) is an invertible ideal of \(N\); in this case, we have already remarked (see (12.4.34)) that the projection

\[ (12.4.46) \quad \varphi(f, \mathcal{I}) \circ \pi_{(Y,N,\mathcal{I}N)^{-1}} : (Y, N) \to \text{Bl}_\mathcal{I}(X, M). \]

To conclude, it remains to show that (12.4.46) is the only morphism of log schemes whose composition with \(\pi_{(X,M,\mathcal{I})}\) equals \(f\). The latter assertion can be checked locally on \(X\), hence we may assume that \(M\) admits a chart \(P_X \to M\), such that \(\mathcal{I} = IP\) for some finitely generated ideal \(I \subset P\). In this case, in view of (12.4.44), the set of morphisms of \((X, M)\)-schemes \((Y, N) \to \text{Bl}_\mathcal{I}(X, M)\) is in natural bijection with the set of \((S, P_S^\log)\)-morphisms \((Y, N) \to B := \text{Bl}_{IP_S^\log}(S, P_S^\log)\) (notation of example (12.4.43)). In other words, we may assume that \((X, M) = (S, P_S^\log)\), and \(\mathcal{I} = IP_S^\log\). Then \(f\) is determined by \(\log f\), i.e. by a map \(\beta : P \to \)
Let \( a_1, \ldots, a_k \) be a system of generators for \( I \); for each \( i = 1, \ldots, k \), we let \( U_i \subset Y \) be the subset of all \( y \in Y \) for which there exists a \( \tau \)-point \( \xi \) of \( Y \) with \(|\xi| = y \) and

\[
a_i N_\xi = IN_\xi.
\]

Notice that if \( y \in U_i \), then (12.4.47) holds for every \( \tau \)-point \( \xi \) of \( Y \) localized at \( y \) (details left to the reader).

**Claim 12.4.48.** The subset \( U_i \) is open in \( Y \); for every \( i = 1, \ldots, k \), and \( Y = \bigcup_{i=1}^k U_i \).

**Proof of the claim.** Say that \( y \in U_i \), and let \( \xi \) be a \( \tau \)-point of \( Y \) localized at \( y \), such that (12.4.47) holds. This means that, for every \( j = 1, \ldots, k \), there exists \( u_j \in N_\xi \) such that \( a_j = u_ja_i \). Then, we may find a \( \tau \)-neighborhood \( h : U' \to \xi \) such that this identity persists in \( N(U') \); thus, \( h(U') \subset U_i \). Since \( h \) is an open map, this shows that \( U_i \) is an open subset.

Next, let \( \xi \) be any \( \tau \)-point of \( Y \); by assumption, we have \( IN_\xi = bN_\xi \) for some \( b \in N_\xi \); this means that for every \( i = 1, \ldots, k \) there exists \( u_i \in N_\xi \) such that \( a_i = u_i b \). Since \( a_1, \ldots, a_k \) generate \( I \), we must have \( u_i \in N_\xi \) for at least an index \( i \leq k \), in which case \(|\xi| \in U_i \), and this shows that the \( U_i \) cover the whole of \( Y \), as claimed. \( \blacklozenge \)

It is easily seen that, for every \( i = 1, \ldots, k \), any morphism \((U_i, N_i|U_i) \to (S, P^\log_S)\)-schemes factors through the open immersion \( \text{Spec} (Z, Q_{a_i}) \to B \) (where \( Q_{a_i} \), for an element \( a \in P \), is defined as in example 12.4.43). Conversely, by construction \( \beta \) extends to a unique morphism of \((S, P^\log_S)\)-schemes \((U_i, N_i|U_i) \to B \). In light of claim 12.4.48, the proposition follows. \( \square \)

**12.4.49.** Keep the notation of proposition 12.4.45 by inspecting the construction, it is easily seen that the log structure \( M' \) of \( \text{Bl}_\mathcal{I}(X, M) \) is quasi-coherent, and if \( M \) is coherent (resp. quasi-fine, resp. fine), then the same holds for \( M' \). However, simple examples show that \( M' \) may fail to be saturated, even in cases where \((X, M) \) is a fs log scheme. Due to the prominent role played by fs log schemes, it is convenient to introduce the special notation :

\[
\text{sat.Bl}_\mathcal{I}(X, M) := (\text{Bl}_\mathcal{I}(X, M))^{qfs}
\]

for the **saturated logarithmic blow up** of a coherent ideal \( \mathcal{I} \) in a quasi-fine log structure \( M \) (notation of proposition 12.2.35). Clearly the projection \( \text{sat.Bl}_\mathcal{I}(X, M) \to (X, M) \) is a final object of the category of saturated \((X, M)\)-schemes in which the preimage of \( \mathcal{I} \) is invertible. If \((X, M) \) is a fine log scheme, \( \text{sat.Bl}_\mathcal{I}(X, M) \) is a fs log scheme. Moreover, for any morphism of schemes \( f : Y \to X \), let \( M_Y := f^* M \); from remarks (12.4.32)(ii) and 12.2.36(iii), we deduce a natural isomorphism of \((Y, M_Y)\)-schemes :

\[
\text{sat.Bl}_\mathcal{I}(Y, M_Y) \cong Y \times_X \text{sat.Bl}_\mathcal{I}(X, M).
\]

**Theorem 12.4.51.** Let \((X, M) \) be a quasi-fine log scheme with saturated log structure, \( \mathcal{I} \subset M \) an ideal, \( \xi \) a \( \tau \)-point of \( X \). Suppose that, in a neighborhood of \( \xi \), the ideal \( \mathcal{I} \) is generated by at most two sections, and denote :

\[
\varphi : \text{Bl}_\mathcal{I}(X, M) \to (X, M) \quad \text{(resp. } \varphi_{\text{sat}} : \text{sat.Bl}_\mathcal{I}(X, M) \to (X, M)\text{)}
\]

the logarithmic (resp. saturated logarithmic) blow up of \( \mathcal{I} \). Then :

(i) If \( \mathcal{I}_\xi \) is an invertible ideal of \( M_\xi \), the natural morphisms

\[
\varphi^{-1}(\xi) \to \text{Spec } \kappa(\xi) \quad \varphi_{\text{sat}}^{-1}(\xi) \to \text{Spec } \kappa(\xi)
\]

are isomorphisms.

(ii) Otherwise, \( \varphi^{-1}(\xi) \) is a \( \kappa(\xi) \)-scheme isomorphic to \( \mathbb{P}^1_{\kappa(\xi)} \); furthermore, the same holds for the reduced fibre \( \varphi_{\text{sat}}^{-1}(\xi)_{\text{red}} \), provided \( M \) is fine.
Proof. After replacing $X$ by a $\tau$-neighborhood of $\xi$, we reduce to the case where $M$ admits an integral and saturated chart $\alpha : P_X \to M$ (lemma [12.1.18](iii)), and if $M$ is a fs log structure, we may also assume that the chart $\alpha$ is fine and sharp at $\xi$ (corollary [12.1.36](i)). Furthermore, we may assume that $\mathcal{I}$ is generated by at most two elements of $M(X)$, and if $\mathcal{I}_\xi$ is principal, we may assume that the same holds for $\mathcal{I}$. In the latter case, since $\mathcal{M}$ is integral, $\mathcal{I}$ is invertible, hence $\varphi$ and $\varphi_{\mathrm{sat}}$ are isomorphisms, so (i) follows already.

Now, suppose that $\mathcal{I}_\xi$ is not invertible, and let $a', b' \in M(X)$ be a system of generators for $\mathcal{I}$; we can write $a' = \alpha(a) \cdot u$, $b' = \alpha(b) \cdot v$ for some $a, b \in P$ and $u, v \in \kappa^\times$. Set $t := a^{-1}b$, and let $J \subset P$ be the ideal generated by $a$ and $b$; clearly $JM = \mathcal{I}_\xi$ and $Pa, Pb \notin J$.

Consider first the case where $X = \mathrm{Spec} \kappa$, where $\kappa$ is a field (resp. a separably closed field, in case $\tau = \bar{\eta}$). In this situation, a pre-log structure on $X$ is the same as a morphism of monoids $\beta : P \to \kappa$, the associated log structure is the induced map of monoids $\beta^\log : P \otimes_{\kappa^\times} \kappa^\times \to \kappa^\times$ and $\alpha$ is the natural map $P \to P \otimes_{\kappa^\times} \kappa^\times$. After replacing $P$ by its localization $P_0^{-1}P$, we may also assume that $P_0 = \kappa^\times$. Let

$$(S, P_S^\log) := \mathrm{Spec}(\kappa, P) \quad J^\sim := JP_S^\log \quad (Y, N) := \mathrm{Bl}_{J^\sim}(S, P_S^\log).$$

Denote by $\varepsilon : \kappa[P] \to \kappa$ the homomorphism of $\kappa$-algebras induced by $\beta$ via the adjunction (4.8.50), and set $I := \ker \varepsilon$. In view of lemma [12.4.37(i)] and (12.4.50), we have natural cartesian diagrams of $\kappa$-schemes:

$$\begin{array}{ccc}
\varphi^{-1}(\xi) & \longrightarrow & (Y, N) \\
|\xi| & \downarrow & |\xi| \\
\mathrm{Spec} \varepsilon & \longrightarrow & S \\
\varphi_{\mathrm{sat}}^{-1}(\xi) & \longrightarrow & (Y, N)_{\mathrm{sat}} \\
|\xi| & \downarrow & |\xi| \\
\mathrm{Spec} \varepsilon & \longrightarrow & S.
\end{array}$$

On the other hand, $(a, b)$ can be regarded as a pair of global sections of $J^\sim N$, so the universal property of example [12.4.29(ii)] yields a morphism of $(S, P_S^\log)$-schemes:

$$f_{(a,b)} : (Y, N) \to \mathbb{P}^1_{(S, P_S^\log)}.$$ 

In light of example [12.4.29(i)], the assertion concerning $\varphi^{-1}(\xi)$ will then follow from the

Claim 12.4.53. The morphism $|\xi| \times_S f_{(a,b)}$ is an isomorphism of $\kappa$-schemes.

Proof of the claim. Let $Q_a \subset P^\gp$ (resp. $Q_b \subset P^\gp$) be the submonoid generated by $P$ and $t$ (resp. by $P$ and $t^{-1}$); by inspecting example [12.4.43] we see that $Y$ is covered by two affine open subsets:

$$U_a := \mathrm{Spec} \kappa[Q_a] \quad U_b := \mathrm{Spec} \kappa[Q_b]$$

and $U_a \cap U_b = \mathrm{Spec} \kappa[Q_a \oplus_P Q_b]$. On the other hand, $\mathbb{P}^1_{(S, P_S^\log)}$ is covered as well by two affine open subsets $U_a'$ and $U_b'$, both isomorphic to $\mathrm{Spec} \kappa[P \oplus N]$, and such that $U_0' \cap U_\infty' = \mathrm{Spec} \kappa[P \oplus \mathbb{Z}]$, as usual. Moreover, a direct inspection shows that $f_{(a,b)}$ restricts to morphisms

$$U_a \to U_0' \quad U_b \to U_\infty'$$

induced respectively by the maps of $\kappa$-algebras

$$\omega_0 : \kappa[P \oplus N] \to \kappa[Q_a] \quad \omega_\infty : \kappa[P \oplus N] \to \kappa[Q_b]$$

such that $\omega_0(x, n) = x \cdot t^n$ and $\omega_\infty(x, n) = x \cdot t^{-n}$ for every $(x, n) \in P \oplus \mathbb{N}$. We show that $\varpi_0 := \omega_0 \otimes_{\kappa[P]} \kappa[P]/I$ is an isomorphism; the same argument will apply also to $\omega_\infty$, so the claim shall follow.

Indeed, clearly the $\kappa[P]$-algebra $\kappa[Q_a]$ is generated by $t$, hence $\omega_0$ is surjective, and then the same holds for $\varpi_0$. Next, set $H_a := I \cdot \kappa[Q_a]$; it is easily seen that $H_a$ consists of all sums of the
form $\sum_{j=0}^{n} c_j t^j$, for arbitrary $n \in \mathbb{N}$, with $c_j \in I$ for every $j = 0, \ldots, n$. Clearly, an element $p(T) \in \kappa[N] = \kappa[T]$ lies in $\text{Ker} \varpi_0$ if and only if $p(t) \in H_a$, so we come down to the following assertion. Let $c_0, \ldots, c_n \in \kappa[P]$ such that

$$\sum_{j=0}^{n} c_j t^j = 0$$

in $\kappa[Q_a]$; then $c_j$ lies in the ideal $\kappa[\beta^{-1}(0)]$ of $\kappa[P]$, for every $j = 0, \ldots, n$. Since $P$ is integral, \textbf{(12.4.54)} is equivalent to the identity: $\sum_{j=0}^{n} c_j a^n \beta^{-j} b^j = 0$ in $\kappa[P]$. For every $x \in P$, denote by $\pi_x : \kappa[P] \rightarrow \kappa$ the $\kappa$-linear projection such that $\pi_x(x) = 1$, and $\pi_x(y) = 0$ for every $y \in P \setminus \{x\}$.

Suppose, by way of contradiction, that $c_i \notin \kappa[\beta^{-1}(0)]$ for some $i \leq n$, hence $\pi_x(c_i) \neq 0$ for some $x \in P_0$; since $P_0 = P^x$, we may replace $c_j$ by $x^{-1} c_j$, for every $j \leq n$, and assume that $\pi_1(c_1) \neq 0$, hence $\pi_{a^n \beta^{-j}}(c_i a^n \beta^{-j} b^j) \neq 0$ (again, using the assumption that $P$ is integral). Thus, there exists $j \neq i$ with $j \leq n$, such that $\pi_{a^n \beta^{-j}}(c_j a^n \beta^{-j} b^j) \neq 0$, and we may then find an element $c \in P$ such that $\pi_{a^n \beta^{-j}}(c a^n \beta^{-j} b^j) = 1$, i.e. $c \alpha a^n \beta^{-j} b^j$; up to swapping the roles of $a$ and $b$, we may assume that $i > j$, in which case we may write $t^{i-j} = c$; since $P$ is saturated, it follows that $t \in P$, hence $J$ is generated by $a$, which is excluded. \hfill \diamond

Next, we assume that $M$ is a $\text{Spec} \kappa$ log structure (and $X$ is still $\text{Spec} \kappa$), and consider the morphism $\varphi_{\text{sat}}$. As already remarked, we may assume that $\alpha$ is sharp at $\xi$, and $P$ fine and saturated; the sharpness condition amounts to saying that $\beta(x) = 0$ for every $x \in P \setminus \{1\}$, therefore $I$ is the augmentation ideal of the graded $\kappa$-algebra $\kappa[P]$. By inspecting the proof of proposition \textbf{12.2.35} we see that $(Y, N)_{\text{sat}}$ is covered by two affine open subsets

$$U_a^\text{fs} := \text{Spec} \kappa[Q_a], \quad U_b^\text{fs} := \text{Spec} \kappa[Q_b]$$

and $U_a^\text{fs} \cap U_b^\text{fs} = \text{Spec} \kappa[Q_a^\text{sat} \otimes_P Q_b^\text{sat}]$. Since $J$ is not principal, we have $t \notin P$, and since $P$ is saturated, we deduce that $t$ is not a torsion element of $P_{\text{gp}}$; as the latter is a finitely generated abelian group, it follows that we may find a unimodular element $u \in P_{\text{gp}}$ such that $t$ lies in the submonoid $\mathbb{N} u \subset P_{\text{gp}}$ generated by $u$; this condition means that $t = u^k$ for some $k \in \mathbb{N}$, and $\mathbb{N} u$ is not properly contained in another rank one free submonoid of $P_{\text{gp}}$. Write $u = a' b'$ for some $a', b' \in P$, let $J' \subset P$ be the ideal generated by $a'$ and $b'$, and $R_{a'}$ (resp. $R_{b'}$) the submonoid of $P_{\text{gp}}$ generated by $P$ and $u$ (resp. by $P$ and $u^{-1}$); clearly $R_{a'} = Q_{a}^\text{sat}$, and $R_{b'} = Q_{b}^\text{sat}$. Denote by $N'$ the log structure of $(Y, N)_{\text{sat}}$, and $J' := J'_{\text{sat}}$; it is easily seen that

$$J'_{U_a^\text{fs}} = a' N'_{U_a^\text{fs}} \quad J'_{U_b^\text{fs}} = b' N'_{U_b^\text{fs}}$$

hence $J'$ is invertible, and example \textbf{12.4.29}(ii) yields a morphism of $(S, P_S^{\text{log}})$-schemes

$$f_{(a', b')} : (Y, N)_{\text{sat}} \rightarrow \mathbb{P}^1_{(S, P_S^{\text{log}})}.$$ 

In light of example \textbf{12.4.29}(i), the assertion concerning $\varphi_{\text{sat}}^{-1}(\xi)$ will then follow from the :

\textbf{Claim 12.4.55.} $((\xi) \times_S f_{(a', b')})_{\text{red}} : \varphi_{\text{sat}}^{-1}(\xi)_{\text{red}} \rightarrow \mathbb{P}^1_\kappa$ is an isomorphism of $\kappa$-schemes.

\textbf{Proof of the claim.} As in the proof of claim \textbf{12.4.53}, the morphism $f_{(a', b')}$ restricts to morphisms $U^\text{fs} \rightarrow U^\prime_0$ and $U^\text{fs} \rightarrow U^\prime_0$ induced by maps of $\kappa$-algebras :

$$\omega_0 : \kappa[P \oplus \mathbb{N}] \rightarrow \kappa[Q_a^\text{sat}] \quad \omega_\infty : \kappa[P \oplus \mathbb{N}] \rightarrow \kappa[Q_b^\text{sat}]$$

such that $\omega_0(x, n) = x \cdot u^n$ and $\omega_\infty(x, n) = x \cdot u^{-n}$ for every $(x, n) \in P \oplus \mathbb{N}$, and again, it suffices to show that

$$(\omega_0 \otimes_{\kappa[P]} \kappa[P]/I)_{\text{red}} : \kappa[T] \rightarrow (\kappa[P_a^\text{sat}]/I \kappa[P_a^\text{sat}])_{\text{red}}$$
is an isomorphism (where for any ring $A$, we denote $A_{\text{red}}$ be the maximal reduced quotient of $A$, i.e. $A_{\text{red}} := A/\text{nil}(A)$, where nil$(A)$ is the nilradical of $A$). We break the latter verification in two steps: first, let us check that the map

$$\varpi_0' : \kappa[T] \to \kappa[R_a]/I\kappa[R_a]$$

is an isomorphism. Indeed, $\varpi_0'$ is induced by the map of monoids $\varphi : \mathbb{N} \to R_a$ such that $n \mapsto u^n$ for every $n \in \mathbb{N}$; if $t = u^k$, the map $\varphi$ fits into the cocartesian diagram:

$$\begin{array}{ccc}
\mathbb{N} & \xrightarrow{\psi} & Q_a \\
\downarrow^{k_\mathbb{N}} & & \downarrow^j \\
\mathbb{N} & \xrightarrow{\varphi} & R_a
\end{array}$$

where $k_\mathbb{N}$ is the $\kappa$-Frobenius map, $\psi$ is given by the rule : $n \mapsto t^n$ for every $n \in \mathbb{N}$, and $j$ is the natural inclusion. Hence:

$$\varpi_0' = (\kappa[\psi] \otimes_{\kappa[P]} \kappa[P]/I) \otimes_{\kappa[T]} \kappa[T].$$

However, the proof of claim [12.4.53] shows that $\kappa[\psi] \otimes_{\kappa[P]} \kappa[P]/I$ is an isomorphism, whence the contention. Lastly, let show that the natural map

$$\varpi_0'' : \kappa[R_a]/I\kappa[R_a] \to (\kappa[R_{a_{\text{sat}}}] / I\kappa[R_{a_{\text{sat}}}] )_{\text{red}}$$

is an isomorphism. Indeed, it is clear that the natural map $\omega_0'' : \kappa[R_a] \to \kappa[R_{a_{\text{sat}}}]$ is integral and injective, hence $\text{Spec} \omega_0''$ is surjective; therefore $\text{Spec} \varpi_0''$ is still surjective and integral. However, the foregoing shows that $\kappa[R_a]/I\kappa[R_a]$ is reduced, so we deduce that $\varpi_0''$ is injective. To show that $\varpi_0''$ is surjective, it suffices to show that the classes of the generating system $R_{a_{\text{sat}}} \subset \kappa[R_{a_{\text{sat}}}]$ lie in the image of $\varpi_0''$. Hence, let $x \in R_{a_{\text{sat}}}$, with $x^m \in R_a$ for some $m > 0$, so that $x^m = y \cdot u^n$ for some $n \in \mathbb{N}$ and $y \in P$. If $y \neq 1$, we have $y \in I$, hence the image of $x^m$ vanishes in $\kappa[R_{a_{\text{sat}}}]/I\kappa[R_{a_{\text{sat}}}],$ and the image of $x$ vanishes in the reduced quotient; finally, if $y = 1$, the identity $x^m = u^n$ implies that $m$ divides $n$, since $u$ is unimodular; hence $x = u^{n/m}$ and the image of $x$ agrees with $\varpi_0''(u^{n/m})$.

Finally, let us return to a general quasi-fine log scheme $\mathcal{X}$ ; the theorem will follow from the more precise :

Claim 12.4.56. In the situation of the theorem, suppose moreover that

(a) $\mathcal{M}$ admits a saturated chart $\alpha : P_{\mathcal{X}} \to \mathcal{M}$

(b) $\mathcal{J} = J\mathcal{M}$, where $J \subset P$ is an ideal generated by two elements $a, b \in P$

(c) $\mathcal{J}_\xi$ is not invertible.

Then we have :

(i) There exists a morphism of $(\mathcal{X}, \mathcal{M})$-schemes : $\text{Bl}_{\mathcal{J}}(\mathcal{X}, \mathcal{M}) \to \mathbb{P}^1_{(\mathcal{X}, \mathcal{M})}$ inducing an isomorphism of $\kappa(\xi)$-schemes $\varphi^{-1}(\xi) \cong \mathbb{P}^1_{(\kappa(\xi))}$.

(ii) If furthermore, $P$ is fine (and saturated) and $\alpha$ is sharp at $\xi$, then there exists a morphism of $(\mathcal{X}, \mathcal{M})$-schemes : $\text{sat}.\text{Bl}_{\mathcal{J}}(\mathcal{X}, \mathcal{M}) \to \mathbb{P}^1_{(\mathcal{X}, \mathcal{M})}$ inducing an isomorphism of $\kappa(\xi)$-schemes $\varphi_{\text{sat}}^{-1}(\xi)_{\text{red}} \cong \mathbb{P}^1_{(\kappa(\xi))}$.

Proof of the claim. (i): Denote by $\mathcal{N}$ the log structure of $\text{Bl}_{\mathcal{J}}(\mathcal{X}, \mathcal{M})$; the elements $a, b$ define global sections of the invertible $\mathcal{N}$-module $\mathcal{J}N$, and we claim that the corresponding morphism of $(\mathcal{X}, \mathcal{M})$-schemes $f_{(a,b)} : \text{Bl}_{\mathcal{J}}(\mathcal{X}, \mathcal{M}) \to \mathbb{P}^1_{(\mathcal{X}, \mathcal{M})}$ will do. Indeed, set $(|\xi|, \mathcal{M}_\xi) := |\xi| \times_{\mathcal{X}} (\mathcal{X}, \mathcal{M})$, and recall that there exists natural isomorphisms

$$|\xi| \times \mathbb{P}^1_{(\mathcal{X}, \mathcal{M})} \cong \mathbb{P}^1_{(|\xi|, \mathcal{M}_\xi)}$$

$$|\xi| \times \text{Bl}_{\mathcal{J}}(\mathcal{X}, \mathcal{M}) \cong \text{Bl}_{\mathcal{J}}(\mathcal{X}, \mathcal{M})_{(|\xi|, \mathcal{M}_\xi)}$$
(example 12.4.29 i) and remark 12.4.32 (ii). Denote by \( \mathcal{N}_\xi \) the log structure of \( \text{Bl}_{\mathcal{J}_\xi}([\xi], [\xi]) \); by example 12.4.29 (iii), the base change
\[
[\xi] \times_X f : \text{Bl}_{\mathcal{J}_\xi}([\xi], [\xi]) \to \mathbb{P}^1_{([\xi], [\xi])}
\]
is the unique morphism \( f_{(\pi, b)} \) of \( ([\xi], [\xi]) \)-schemes corresponding to the pair \((\pi, b)\) of global sections of \( \mathcal{J}_\xi \) obtained by pulling back the pair \((a, b)\). Therefore, in order to check that \( [\xi] \times_X f \) is an isomorphism, we may replace from start \((X, M)\) by \((\xi, [\xi])\) (whose log structure is still quasi-fine, by lemma 12.4.35), and assume that \( X = \text{Spec} \kappa \), where \( \kappa \) is a field (resp. a separably closed field, in case \( \tau = \hat{\eta} \)), in which case the assertion is just claim 12.4.50.

(ii): Denote by \( \mathcal{N}' \) the log structure of \( \text{sat.}\text{Bl}_{\mathcal{J}}(X, M) \), define \( a', b' \) and \( J' \) as in the foregoing, and set again \( J' := J' \mathcal{N}' \). Again, it is easily seen that \( J' \) is an invertible \( N' \)-module, and the pair \((a', b')\) yields a morphism \( f_{(a', b')} : \text{sat.}\text{Bl}_{\mathcal{J}}(X, M) \to \mathbb{P}^1_{(X, M)} \) which fulfills the sought condition. Indeed, denote by \( \mathcal{N}'_\xi \) the log structure of \( \text{sat.}\text{Bl}_{\mathcal{J}_\xi}([\xi], [\xi]) \); in light of (12.4.50) and example 12.4.29 (iii), the base change
\[
[\xi] \times_X f_{(a', b')} : \text{sat.}\text{Bl}_{\mathcal{J}_\xi}([\xi], [\xi]) \to \mathbb{P}^1_{([\xi], [\xi])}
\]
is the unique morphism \( f_{(\pi', b')} \) of \( ([\xi], [\xi]) \)-schemes corresponding to the pair \((\pi', b')\) of global sections of \( \mathcal{J}' \mathcal{N}'_\xi \) obtained by pulling back the pair \((a', b')\). Thus, the assertion is just claim 12.4.55.

\[\Box\]

12.5. Regular log schemes. In this section we introduce the logarithmic version of the classical regularity condition for locally noetherian schemes. This theory is essentially due to K.Kato (89), and we mainly follow his exposition, except in a few places where his original arguments are slightly flawed, in which cases we supply the necessary corrections.

Lemma 12.5.1. Let \( A \) be a noetherian local ring, \( N \) an \( A \)-module of finite type, \( \alpha : P \to A \) and \( \beta : Q \to A \) two morphisms of pointed monoids, with \( P^\times \) and \( Q^\times \) both fine. Suppose that \( \alpha \) and \( \beta \) induce the same constant log structure on \( \text{Spec} A \) (see 12.1.15). Then \( N \) is \( \alpha \)-flat if and only if it is \( \beta \)-flat.

Proof. Let \( \xi \) be a \( \tau \)-point localized at the closed point \( X := \text{Spec} A \), set \( B := \mathcal{O}_{X, \xi} \) and let \( \varphi : A \to B \) be the natural map. Let also \( M \) be the push-out of the diagram of monoids \( P \leftarrow (\varphi \circ \alpha)^{-1} A^\times \to B^\times \) deduced from \( \alpha \); then \( M \cong P^\log_{X, \xi} \), the stalk at the point \( \xi \) of the constant log structure on \( X \) associated to \( \alpha \). Since \( \varphi \) is faithfully flat, it is easily seen that \( N \) is \( \alpha \)-flat if and only if \( N \otimes_A B \) is \( \varphi \circ \alpha \)-flat.

Hence we may replace \( A \) by \( B \), \( \alpha \) by \( \varphi \circ \alpha \), \( N \) by \( N \otimes_A B \), and \( Q \) by \( M \), after which we may assume that \( Q = P \coprod_{\alpha^{-1}(A^\times)} A^\times \); especially, there exists a morphism of monoids \( \gamma : P \to Q \) such that \( \alpha = \beta \circ \gamma \), and moreover \( \beta \) is a local morphism.

Next, set \( S := \alpha^{-1}(A^\times) \); clearly \( \gamma \) extends to a morphism of monoids \( \gamma' : S^{-1} P \to Q \), and \( \alpha \) and \( \beta \circ \gamma' \) induce the same constant log structure on \( X' \). Arguing as in the proof of proposition 6.4.29 we see that \( N \) is \( P \)-flat if and only if it is \( S^{-1} P \)-flat. Hence, we may replace \( P \) by \( S^{-1} P \), which allows to assume that \( \gamma \) induces an isomorphism \( P \coprod_{A^\times} A^\times \cong Q \), therefore also an isomorphism \( P^\times \cong Q^\times \). The latter implies that \( m_Q = m_P Q \); moreover, notice that the morphism of monoids \( P^\times \to A^\times \) is faithfully flat, so the natural map:
\[
\text{Tor}_1^Z(P)(N, Z(P/m_P)) \to \text{Tor}_1^Z(Q)(N, Z(P/m_P) \otimes_P Q)) \to \text{Tor}_1^Z(Q)(N, Z(Q/m_Q))
\]
is an isomorphism. The assertion follows. \[\Box\]

Lemma 12.5.2. Let \( M \) be an integral monoid, \( A \) a ring, \( \varphi : M \to A \) a morphism of monoids, and set \( S := \text{Spec} A \). Suppose that \( A \) is \( \varphi \)-flat. Then the log structure \( (M, \varphi)^{\log}_S \) on \( S \) is the subsheaf of monoids of \( \mathcal{O}_S \) generated by \( \mathcal{O}_S^{\times} \) and the image of \( M \).
Proof. To ease notation, set $M := (M, \varphi)_S^{\log}$, let $\xi$ be any $\tau$-point of $S$. Then the stalk $M_\xi$ is the push-out of the diagram : $\mathcal{O}_{S,\xi}^x \leftarrow \varphi^{-1}_\xi(\mathcal{O}_{S,\xi}^x) \rightarrow M$ where $\varphi_\xi : M \rightarrow \mathcal{O}_{S,\xi}$ is deduced from $\varphi$. Hence $M_\xi$ is generated by the ideal $\mathcal{O}_{S,\xi}$ and the image of $M$, and it remains only to show that the structure map $M_\xi \rightarrow \mathcal{O}_{S,\xi}$ is injective. Therefore, let $a, b \in M$ and $u, v \in \mathcal{O}_{S,\xi}^x$ such that :

\begin{equation} \varphi_\xi(a) \cdot u = \varphi_\xi(b) \cdot v. \tag{12.5.3} \end{equation}

We come down to showing :

\textbf{Claim 12.5.4.} There exist $c, d \in M$ such that :

\[ \varphi_\xi(c), \varphi_\xi(d) \in \mathcal{O}_{S,\xi}^x \quad ac = bd \quad \varphi_\xi(c) \cdot v = \varphi_\xi(d) \cdot u. \]

\textbf{Proof of the claim.} Let $m_\xi \subset \mathcal{O}_{S,\xi}$ be the maximal ideal, and set $p := \varphi^{-1}_\xi(m_\xi)$, so that $\varphi_\xi$ extends to a local morphism $\varphi_p : M_p \rightarrow \mathcal{O}_{S,\xi}$. Since $\mathcal{O}_{S,\xi}$ is a flat $A$-algebra, $\mathcal{O}_{S,\xi}$ is $\varphi$-flat, and consequently it is faithfully $\varphi_p$-flat (lemma [6.1.37]). Then, assumption (12.5.3) leads to the identity:

\[ aM_p \otimes M_p \mathcal{O}_{S,\xi} = \varphi_\xi(a) \mathcal{O}_{S,\xi} = \varphi_\xi(b) \mathcal{O}_{S,\xi} = bM_p \otimes M_p \mathcal{O}_{S,\xi} \]

whence $aM_p = bM_p$, by faithful $\varphi_p$-flatness. It follows that there exist $x, y \in M_p$ such that $ax = b$ and $by = a$, hence $axy = a$, which implies that $xy = 1$, since $M_p$ is an integral module. The latter means that there exist $c, d \in M \setminus p$ such that $ac = bd$ in $M$. We deduce easily that

\[ \varphi_\xi(a) \cdot \varphi_\xi(c) \cdot v = \varphi_\xi(a) \cdot \varphi_\xi(d) \cdot u. \]

Thus, to complete the proof, it suffices to show that $\varphi_\xi(a)$ is regular in $\mathcal{O}_{S,\xi}$. However, the morphism of $M$-modules $\mu_a : M \rightarrow M : m \mapsto am$ (for all $m \in M$) is injective, hence the same holds for the map $\mu_a \otimes_M \mathcal{O}_{S,\xi} : \mathcal{O}_{S,\xi} \rightarrow \mathcal{O}_{S,\xi}$, which is just multiplication by $\varphi(a)$. \hfill $\square$

12.5.5. Let $(X, M)$ be a locally noetherian log scheme, with coherent log structure (on the site $X_{\tau}$, see [12.2.1]), and let $\xi$ be any $\tau$-point of $X$. We denote by $I(\xi, M) \subset \mathcal{O}_{X,\xi}$ the ideal generated by the image of the maximal ideal of $M_\xi$, and we set :

\[ d(\xi, M) := \dim \mathcal{O}_{X,\xi}/I(\xi, M) + \dim M_\xi. \]

\textbf{Lemma 12.5.6.} In the situation of (12.5.5), suppose furthermore that $(X, M)$ is a $\text{fs}$ log scheme. Then we have the inequality :

\[ \dim \mathcal{O}_{X,\xi} \leq d(\xi, M). \]

\textbf{Proof.} According to corollary [12.1.36](i), there exist a neighborhood $U \rightarrow X$ of $\xi$ in $X_{\tau}$, and a fine and saturated chart $\alpha : PU \rightarrow M_U$, which is sharp at the point $\xi$. Especially, $P \simeq M_\xi^2$, therefore $\dim P = \dim M_\xi$ (corollary 6.4.10(ii)). Notice that $\mathcal{O}_{X,\xi}$ is a noetherian local ring (this is obvious for $\tau = \text{Zar}$, and follows from [51, Ch.IV, Prop.18.8.8(iv)] for $\tau = \text{ét}$), hence to conclude it suffices to apply corollary 6.4.25(i) to the induced map of monoids $P \rightarrow \mathcal{O}_{X,\xi}$. \hfill $\square$

\textbf{Definition 12.5.7.} Let $(X, M)$ be a locally noetherian $\text{fs}$ log scheme, $\xi$ a $\tau$-point of $X$.

(i) We say that $(X, M)$ is regular at the point $\xi$, if the following holds :

(a) the inequality of lemma (12.5.6) is actually an equality, and

(b) the local ring $\mathcal{O}_{X,\xi}/I(\xi, M)$ is regular.

(ii) We denote by $(X, M)_{\text{reg}} \subset X$ the set of points $x$ such that $(X, M)$ is regular at any (hence all) $\tau$-points of $X$ localized at $x$.

(iii) We say that $(X, M)$ is regular, if $(X, M)_{\text{reg}} = X$.

(iv) Suppose that $K$ is a field, and $X$ a $K$-scheme. We say that the $K$-log scheme $(X, M)$ is geometrically regular, if $E \times_K (X, M)$ is regular, for every field extension $E$ of $K$. 

Remark 12.5.8. (i) Certain constructions produce log structures $M \to O_X$ that are morphisms of pointed monoids. It is then useful to extend the notion of regularity to such log structures. We shall say that $(X, M)$ is a pointed regular log scheme, if there exists a log structure $N$ on $X$, such that $M = N_\emptyset$ (notation of [12.1.11]), and $(X, N)$ is a regular log scheme.

(ii) Likewise, if $K$ is a field, $X$ a $K$-scheme, and $M$ a log structure on $X$, we shall say that the $K$-log scheme $(X, M)$ is geometrically pointed regular, if $M = N_\emptyset$ for some log structure $N$ on $X$, such that $(X, N)$ is geometrically regular.

12.5.9. Let $(X, M)$ be a locally noetherian fs log scheme, $\xi$ a $\tau$-point of $X$, and $O_{X,\xi}^\wedge$ the completion of $O_{X,\xi}$. The next result is the logarithmic version of the classical characterization of complete regular local rings ([100, Th.29.7 and Th.29.8]).

Theorem 12.5.10. With the notation of (12.5.9), the log scheme $(X, M)$ is regular at the point $\xi$ if and only if there exist:

(a) a complete regular local ring $(R, m_R)$, and a local ring homomorphism $R \to O_{X,\xi}^\wedge$;
(b) a fine and saturated chart $P_X(\xi) \to M(\xi)$ which is sharp at the closed point $\xi$ of $X(\xi)$, such that the induced continuous ring homomorphism

$$R[[P]] \to O_{X,\xi}^\wedge$$

is an isomorphism if $O_{X,\xi}^\wedge$ contains a field, and otherwise it is a surjection, with kernel generated by an element $\vartheta \in R[[P]]$ whose constant term lies in $m_R \setminus m_R^2$.

Proof. Suppose first that (a) and (b) hold. If $R$ contains a field, then it follows that

$$\dim O_{X,\xi} = \dim O_{X,\xi}^\wedge = \dim R + \dim P$$

by corollary [6.4.25(ii)]; moreover, in this case $I(\xi, M) = m_R O_{X,\xi}$, hence $O_{X,\xi}/I(\xi, M) = O_{X,\xi}/m_R O_{X,\xi}$, whose completion is $O_{X,\xi}^\wedge/m_R O_{X,\xi}^\wedge \simeq R$ so that $O_{X,\xi}/I(\xi, M)$ is regular ([48, Ch.0, Prop.17.3.3(i)]). Furthermore,

$$\dim R = \dim O_{X,\xi}/m_R O_{X,\xi} = \dim O_{X,\xi}/I(\xi, M)$$

([100, Th.15.1]). Hence $(X, M)$ is regular at the point $\xi$. If $R$ does not contain a field, we obtain $\dim O_{X,\xi} = \dim R + \dim P - 1$. On the other hand, let $\vartheta_0$ be the image of $\vartheta$ in $m_R$; then we have $O_{X,\xi}/m_R O_{X,\xi} \simeq R/\vartheta_0R$, which is regular of dimension $\dim R - 1$, and again we invoke [48, Ch.0, Prop.17.3.3(ii)] to see that $(X, M)$ is regular at $\xi$.

Conversely, suppose that $(X, M)$ is regular at $\xi$. Suppose first that $O_{X,\xi}$ contains a field; then we may find a field $k \subset O_{X,\xi}^\wedge$ mapping isomorphically to the residue field of $O_{X,\xi}^\wedge$ ([100, Th.28.3]). Pick a sequence $(t_1, \ldots, t_r)$ of elements of $O_{X,\xi}$ whose image in the regular local ring $O_{X,\xi}/I(\xi, M)$ forms a regular system of parameters. Let also $P$ a fine saturated monoid for which there exist a neighborhood $U \to X$ of $\xi$ and a chart $P_U \to M_{\{U\}}$, sharp at the point $\xi$. There follows a map of monoids $\alpha : P \to O_{X,\xi}$, and necessarily the image of $m_R$ lies in the maximal ideal of $O_{X,\xi}$, and generates $I(\xi, M)$. We deduce a continuous ring homomorphism

$$k[[P \times \mathbb{N}^{[r]}]] \to O_{X,\xi}^\wedge$$

which extends $\alpha$, and which maps the generators $T_1, \ldots, T_r$ of $\mathbb{N}^{[r]}$ onto respectively $t_1, \ldots, t_r$. This map is clearly surjective, and by comparing dimensions (using corollary [6.4.25(ii)]) one sees that it is an isomorphism. Then the theorem holds in this case, with $R := k[[\mathbb{N}^{[r]}]]$.

Next, if $O_{X,\xi}$ does not contain a field, then its residue characteristic is a positive integer $p$, and we may find a complete discrete valuation ring $V \subset O_{X,\xi}^\wedge$ whose maximal ideal is $pV$, and such that $V/pV$ maps isomorphically onto the residue field of $O_{X,\xi}$ ([100, Th.29.3]). Again, we choose a morphism of monoids $\alpha : P \to O_{X,\xi}$ as in the foregoing, and a sequence $(t_1, \ldots, t_r)$
of elements of $\mathcal{O}_{X,\xi}$ lifting a regular system of parameters for $\mathcal{O}_{X,\xi}/I(\xi, M)$, by means of which we define a continuous ring homomorphism

$$\varphi : V[[P \times \mathbb{N}^{\oplus r}]] \to \mathcal{O}_{X,\xi}$$

as in the previous case. Again, it is clear that $\varphi$ is surjective. The image of the ideal $J$ generated by the maximal ideal of $P \times \mathbb{N}^{\oplus r}$ is the maximal ideal of $\mathcal{O}_{X,\xi}$; in particular, there exists $x \in J$ such that $\vartheta := p - x$ lies in $\text{Ker} \varphi$. If we let $R := V[[\mathbb{N}^{\oplus r}]]$, it is clear that $\vartheta \in m_{R} \setminus m_{R}^{2}$.

**Claim 12.5.11.** Let $A$ be a ring, $\pi$ a regular element of $A$ such that $A/\pi A$ is an integral domain, $P$ a fine and sharp monoid. Let also $\vartheta$ be an element of $A[[P]]$ whose constant term is $\pi$ (see (6.4.23)). Then $A[[P]]/(\vartheta)$ is an integral domain.

**Proof of the claim.** To ease notation, set $A_{0} := A/\pi A$, $B := A[[P]]$ and $C := B/\vartheta B$. Choose a decomposition (6.4.24), and set $\text{Fil}_{n}^{\gamma} B := \bigcap_{i \geq n} A[[\text{gr}_{i}^{\gamma} P]]$ for every $n \in \mathbb{N}$. $\text{Fil}_{n}^{\gamma} B$ is a separated filtration by ideals of $B$, and we may consider the induced filtration $\text{Fil}_{n}^{\gamma} C$ on $C$. First, we remark that $\text{Fil}_{n}^{\gamma} C$ is also separated. This comes down to checking that

$$\bigcap_{n \geq 0} \vartheta B + \text{Fil}_{n}^{\gamma} B = \vartheta B.$$ 

To this aim, suppose that, for a given $x \in B$ we have identities of the type $x = \vartheta y_{n} + z_{n}$, with $y_{n} \in B$ and $z_{n} \in \text{Fil}_{n}^{\gamma} B$ for every $n \in \mathbb{N}$. Then, since $\pi$ is regular, an easy induction shows that $\text{gr}_{i}^{\gamma} (y_{n}) = \text{gr}_{i}^{\gamma} (y_{m})$ whenever $n, m > i$, and moreover $x = \vartheta \sum_{i \in \mathbb{N}} \text{gr}_{i}^{\gamma} (y_{i+1})$, which shows the contention. It follows that, in order to show that $C$ is a domain, it suffices to show that the same holds for the graded ring $\text{gr}_{n}^{\gamma} C$ associated to $\text{Fil}_{n}^{\gamma} C$. However, notice that :

$$\text{Fil}_{n}^{\gamma} B \cap \vartheta B = \vartheta \cdot \text{Fil}_{n}^{\gamma} B \quad \text{for every } n \in \mathbb{N}.$$ 

(Indeed, this follows easily from the fact that $\pi$ is a regular element ; the verification shall be left to the reader). Hence, we may compute :

$$\text{gr}_{n}^{\gamma} C = \frac{\text{Fil}_{n}^{\gamma} B + \vartheta B}{\text{Fil}_{n+1}^{\gamma} B + \vartheta B} \simeq \frac{\text{Fil}_{n}^{\gamma} B}{\text{Fil}_{n+1}^{\gamma} B + \vartheta \text{Fil}_{n}^{\gamma}} \simeq A[[\text{gr}_{n}^{\gamma} P]]/\vartheta A[\text{gr}_{n}^{\gamma} P] \simeq A_{0}[\text{gr}_{n}^{\gamma} P].$$

Thus, $\text{gr}_{n}^{\gamma} A \simeq A_{0}[P]$, which is a domain, since by assumption $A_{0}$ is a domain. \qed

**Remark 12.5.12.** Resume the notation of (12.5.9), and suppose that $\mathcal{O}_{X,\xi}/I(\xi, M)$ is a regular local ring. Let $P_{X(\xi)} \to M(\xi)$ be a chart as in theorem 12.5.10(b), and $\alpha : P \to \mathcal{O}_{X,\xi}$ the corresponding morphism of monoids. Moreover, if $\mathcal{O}_{X,\xi}$ contains a field, let $V$ denote a coefficient field of $\mathcal{O}_{X,\xi}$, and otherwise, let $V$ be a complete discrete valuation ring whose maximal ideal is generated by $p$, the residue characteristic of $\mathcal{O}_{X,\xi}$. In either case, pick a ring homomorphism $V \to \mathcal{O}_{X,\xi}$ inducing an isomorphism of $V/pV$ onto the residue field of $\mathcal{O}_{X,\xi}$. Let as well $t_{1}, \ldots, t_{r} \in \mathcal{O}_{X,\xi}$ be any sequence of elements whose image in $\mathcal{O}_{X,\xi}/I(\xi, M)$ forms a regular system of parameters, and extend the map $\alpha$ to a morphism of monoids $P \times \mathbb{N}^{\oplus r} \to \mathcal{O}_{X,\xi}$, by the rule : $e_{i} \mapsto t_{i}$, where $e_{1}, \ldots, e_{r}$ is the natural basis of $\mathbb{N}^{\oplus r}$. Then by inspecting the proof of theorem (12.5.10) we see that the induced continuous ring homomorphism :

$$V[[P \times \mathbb{N}^{\oplus r}]] \to \mathcal{O}_{X,\xi}$$

is always surjective, and if $V$ is not a field, its kernel contains an element $\vartheta$ whose constant term in $V$ is $\vartheta_{0} = p$. If $V$ is a field (resp. if $V$ is a discrete valuation ring) then $(X, M)$ is regular at the point $\xi$, if and only if this map is an isomorphism (resp. if and only if the kernel of this map is generated by $\vartheta$).
Corollary 12.5.13. Let \((X, M)\) be a regular log scheme. Then the scheme \(X\) is normal and Cohen-Macaulay.

Proof. Let \(x \in X\) be any point, and \(\xi\) a \(\tau\)-point localized at \(x\); we have to show that \(\mathcal{O}_{X,x}\) is Cohen-Macaulay; in light of \([51]\) Ch.IV, Cor.18.8.13(a) (when \(\tau = \emptyset\)), it suffices to show that the same holds for \(\mathcal{O}_{X,\xi}\). Then \([100]\) Th.17.5 further reduces to showing that the completion \(\mathcal{O}_{X,\xi}^\wedge\) is Cohen-Macaulay; the latter follows easily from theorems \([12.5.10]\) and \([11.6.34]\) i. Next, in order to prove that \(X\) is normal, it suffices to show that \(\mathcal{O}_{X,x}\) is regular, whenever \(x\) has codimension one in \(X\) (\([100]\) Th.23.8). Again, by \([51]\) Ch.IV, Cor.18.8.13(c) (when \(\tau = \emptyset\)) and \([48]\) Ch.0, Prop.17.1.5], we reduce to showing that \(\mathcal{O}_{X,\xi}^\wedge\) is regular for such a point \(x\). However, for a point of codimension one we have \(r := \dim M_\xi \leq 1\). If \(r = 0\), then \(I(\xi, M) = \{0\}\), hence \(\mathcal{O}_{X,\xi}\) is regular. Lastly, if \(r = 1\), we see that \(M_\xi^2 \simeq \mathbb{N}\) (theorem 6.4.16 iii); consequently, there exist a regular local ring \(R\) and an isomorphism \(\mathcal{O}_{X,\xi}^\wedge \simeq R[[\mathbb{N}]]/(\vartheta)\), where \(\vartheta = 0\) if \(\mathcal{O}_{X,\xi}\) contains a field, and otherwise the constant term of \(\vartheta\) lies in \(m_R\setminus m_R^2\). Since \(R[[\mathbb{N}]]\) is again regular, the assertion follows in either case.

Corollary 12.5.14. Let \(i: (X', M') \to (X, M)\) be an exact closed immersion of regular log schemes (see definition \([12.3.22]\) i)). Then the underlying morphism of schemes \(X' \to X\) is a regular closed immersion.

Proof. Let \(\xi\) be a \(\tau\)-point of \(X\), and denote by \(J\) the kernel of \(i_\xi^*: \mathcal{O}_{X,\xi} \to \mathcal{O}_{X',\xi}\). To ease notation, let as well \(A := \mathcal{O}_{X,\xi}/I(\xi, M)\) and \(A' := \mathcal{O}_{X',\xi}/I(\xi, M')\). Since \(\log i : i^*M \to M'\) is an isomorphism, \(i_\xi^*\) induces an isomorphism:

\[\mathcal{O}_{X,\xi}(J + I(\xi, M)) \xrightarrow{i} A'.\]

Since \(A\) and \(A'\) are regular, there exists a sequence of elements \(t_1, \ldots, t_k \in J\), whose image in \(A\) forms the beginning of a regular system of parameters and generate the kernel of the induced map \(A \to A'\) (\([48]\) Ch.0, Cor.17.1.9)). Extend this sequence by suitable elements of \(\mathcal{O}_{X,\xi}\), to obtain a sequence \((t_1, \ldots, t_r)\) whose image in \(A\) is a regular system of parameters. We deduce a surjection \(\varphi : V[[P \times \mathbb{N}^r]] \to \mathcal{O}_{X,\xi}^\wedge\) as in remark \([12.5.12]\) where \(V\) is either a field or a complete discrete valuation ring. Denote by \((e_1, \ldots, e_r)\) the natural basis of \(\mathbb{N}^r\). Now, suppose first that \(V\) is a complete discrete valuation ring; then \(\text{Ker} \varphi\) is generated by an element \(\vartheta \in V[[P \times \mathbb{N}^r]]\), whose constant term is a uniformizer in \(V\); we deduce easily from claim \([12.5.11]\) that \((e_1, \ldots, e_r, \vartheta)\) is a regular sequence in \(V[[P \times \mathbb{N}^r]]\); hence the same holds for the sequence \((\vartheta, e_1, \ldots, e_r)\), in view of \([100]\) p.127, Cor.]. This implies that \((t_1, \ldots, t_r)\) is a regular sequence in \(\mathcal{O}_{X,\xi}\), hence \((t_1, \ldots, t_k, t, \vartheta)\) is a regular sequence in \(\mathcal{O}_{X,\xi}\), which is the contention. The case where \(V\) is a field is analogous, though simpler: the details shall be left to the reader.

Remark 12.5.15. In the situation of remark \([12.5.12]\), suppose that \(P\) is a free monoid of finite rank \(d\), let \(\{f_1, \ldots, f_d\} \subset \mathcal{O}_{X,\xi}\) be the image of the (unique) basis of \(P\), and for every \(i \leq d\) let \(Z_i \subset X\) be the zero loci of \(f_i\); then \(\bigcup_{i=1}^d Z_i\) is a strict normal crossings divisor in the sense of example \([12.2.11]\). The proof is analogous to that of corollary \([12.5.14]\): the sequence \((f_1, \ldots, f_d, \vartheta)\) is regular in \(V[[P \oplus \mathbb{N}^d]]\), hence also its permutation \((\vartheta, f_1, \ldots, f_d)\) is regular, whence the claim (the details shall be left to the reader).

Proposition 12.5.16. Resume the situation of \([12.5.9]\). We have:

(i) The log scheme \((X, M)\) is regular at the \(\tau\)-point \(\xi\) if and only if the following two conditions hold:

(a) The ring \(\mathcal{O}_{X,\xi}/I(\xi, M)\) is regular.

(b) There exists a morphism of monoids \(P \to \mathcal{O}_{X,\xi}\) from a finite monoid \(P\), whose associated constant log structure on \(X(\xi)\) is the same as \(M(\xi)\), and such that \(\mathcal{O}_{X,\xi}\) is \(P\)-flat.
(ii) Moreover, if the equivalent conditions of (i) hold, and \( Q_X \to M(\xi) \) is any fine chart, then \( \Theta_{X,\xi} \) is \( Q \)-flat, for the induced map of monoids \( Q \to \Theta_{X,\xi} \).

**Proof.** (i): Suppose first that \((X, M)\) is regular at the point \( \xi \); then by definition (a) holds. Next, we may find a fine monoid \( P \) and a local morphism \( \alpha : P \to A := \Theta_{X,\xi} \) whose associated constant log structure on \( X(\xi) \) is the same as \( M(\xi) \), and a regular local ring \( R \), with a ring homomorphism \( R \to A \) such that the induced continuous map \( R[[P]] \to A^\wedge \) fulfills condition (b) of theorem [12.5.10](where \( A^\wedge \) is the completion of \( A \)). Since the completion map \( \varphi : A \to A^\wedge \) is faithfully flat, \( A \) is \( \varphi \)-flat if and only if \( A^\wedge \) is \( \varphi \circ \alpha \)-flat; in light of proposition [6.1.40](i), it then suffices to show that, for every ideal \( I \subset P \), the natural map

\[
A^\wedge \otimes_P P/I \to A^\wedge \otimes_P P/I
\]

is an isomorphism in \( D^{-}(A^\wedge\text{-Mod}) \) (notation of [6.1.34]). To this aim we remark :

**Claim** 12.5.17. For any ideal \( I \subset P \), the natural morphism

\[
R[P] \otimes_P P/I \to R\langle P/I \rangle
\]

is an isomorphism in \( D^{-}(R[P]\text{-Mod}) \).

**Proof of the claim.** We consider the change of ring spectral sequence for \( \text{Tor} \):

\[
E^2_{ij} := \text{Tor}^Z_i(R, \mathbb{Z}[P]) \Rightarrow \text{Tor}^Z_j(R, \mathbb{Z}[P/I])
\]

([125, Th.5.6.6]). Clearly \( E^2_{ij} = 0 \) whenever \( j > 0 \), whence isomorphisms :

\[
\text{Tor}^Z_i(R, \mathbb{Z}[P/I]) \sim \text{Tor}^Z_i(R, \mathbb{Z}[P/I])
\]

for every \( i \in \mathbb{N} \). The claim follows easily. \( \square \)

In light of claim [12.5.17] we deduce natural isomorphisms :

\[
A^\wedge \otimes_P P/I \sim A^\wedge \otimes_{R[P]} (R[P] \otimes_P P/I) \sim A^\wedge \otimes R[P] R\langle P/I \rangle
\]

in \( D^{-}(A^\wedge\text{-Mod}) \). Now, if \( A \) contains a field, we have \( A^\wedge \sim R[[P]] \), which is a flat \( R[P] \)-algebra ([100, Th.8.8]), and the contention follows. If \( A \) does not contain a field, the complex

\[
0 \to R[[P]] \to R[[P]] \to A^\wedge \to 0
\]

is a \( R[P] \)-flat resolution of \( A^\wedge \). Since \( R[[P]]/IR[[P]] \simeq \lim_{n\in\mathbb{N}} R\langle P/(I \cup m^n_P) \rangle \), we come down to the following :

**Claim** 12.5.18. Let \( \vartheta \in R[P] \) be any element whose constant term \( \vartheta_0 \) is a regular element in \( R \). Then, for every ideal \( I \subset P \), the image of \( \vartheta \) in \( R\langle P/I \rangle \) is a regular element.

**Proof of the claim.** In view of (6.4.20), \( P \) can be regarded as a graded monoid \( P = \coprod_{n \in \mathbb{N}} P_n \), so \( R[P] \) is a graded algebra, and \( I = \coprod_{n \in \mathbb{N}}(I \cap P_n) \) is a graded ideal. Thus, \( \langle P/I \rangle \) is a graded \( R \)-algebra as well, and the claim follows easily (details left to the reader). \( \square \)

Conversely, suppose that conditions (a) and (b) hold. By virtue of lemma [12.5.1] we may assume that \( P \) is fine, sharp and saturated, and that the map \( P \to \Theta_{X,\xi} \) is local. According to remark [12.5.12], we may find a regular local ring \( R \) of dimension \( \leq 1 + \dim A/m_P A \), and a surjective ring homomorphism :

\[
\varphi : R[[P]] \to A^\wedge
\]

Suppose first that \( \dim R = 1 + \dim A/m_P A \); then \( \ker \varphi \) contains an element \( \vartheta \) whose constant term \( \vartheta_0 \) lies in \( m_R \setminus m^2_R \), and \( \varphi \) induces an isomorphism \( R_0 := R/\vartheta_0 R \sim A^\wedge/m_P A^\wedge \). We have
to show that $\varphi$ induces an isomorphism $\varphi : R[[P]]/(\vartheta) \xrightarrow{\sim} A^\wedge$. To this aim, we consider the $m_P$-adic filtrations on these rings; for the associated graded rings we have:

$$\text{gr}_nR[[P]]/(\vartheta) \simeq R_0(m_P/m_P^{n+1}) \quad \text{gr}_nA^\wedge = m_P^nA^\wedge/m_P^{n+1}A^\wedge.$$ 

Hence $\text{gr}_n\varphi$ is the natural map $A^\wedge/m_PA^\wedge \otimes_P (m_P/m_P^{n+1}) \to m_P^nA^\wedge/m_P^{n+1}A^\wedge$, and the latter is an isomorphism, since $A^\wedge$ is $P$-flat. The assertion follows in this case. The remaining case where $\dim R = \dim A/m_PA$ is similar, but easier, so shall be left to the reader, as an exercise.

(ii) follows immediately from (i) and lemma [2.5.1]□

**Corollary 12.5.19.** Let $(X, M)$ be a log scheme, $\xi$ a $\tau$-point of $X$, and suppose that $(X, M)$ is regular at $\xi$. Then the following conditions are equivalent:

(a) $\mathcal{O}_{X,\xi}$ is a regular local ring.

(b) $\mathcal{M}_\xi^p$ is a free monoid of finite rank.

**Proof.** (b)$\Rightarrow$(a) : Indeed, it suffices to show that $\mathcal{O}_{X,\xi}^\wedge$ is regular ([48, Ch.0, Prop.17.3.3(i)]); by theorem [12.5.10], the latter is isomorphic to either $R[[P]]$ or $R[[P]]/\vartheta R[[P]]$, where $R$ is a regular local ring, $P := M_\xi$, and the constant term of $\vartheta$ lies in $m_R \setminus m_R^2$. Since, by assumption, $P$ is a free monoid of finite rank, it is easily seen that rings of the latter kind are regular ([48, Ch.0, Cor.17.1.8]).

(a)$\Rightarrow$(b) : By proposition [12.5.16(ii)], $R := \mathcal{O}_{X,\xi}$ is $P$-flat, for a morphism $P := M^p_\xi \to R$ that induces the log structure $\mathcal{M}(\xi)$ on $X(\xi)$. It follows that

$$m_PR/m^2_PR = (m_P/m_P^2) \otimes_P R = R^{\otimes r}$$

where $r := \text{rk}_{\mathcal{O}_X} m_P/m_P^2$ is the cardinality of $m_P \setminus m_P^2$. In view of [51, Ch.IV, Prop.16.9.3, Cor.16.9.4, Cor.19.1.2], we deduce that the image of $m_P \setminus m_P^2$ is a regular sequence of $R$ of length $r$, hence $\dim P = \dim R - \dim R/m_PR = r$, since $(X, M)$ is regular at $\xi$. Then the assertion follows from proposition [6.4.21].□

**Corollary 12.5.20.** Let $(X, M)$ be a regular log scheme, $\xi$ any $\tau$-point of $X$, and $p \subset M_\xi$ an ideal. We have:

(i) If $p$ is a prime ideal, $p\mathcal{O}_{X,\xi}$ is a prime ideal of $\mathcal{O}_{X,\xi}$, and $\text{ht} p = \text{ht} p\mathcal{O}_{X,\xi}$.

(ii) If $p$ is a radical ideal, $p\mathcal{O}_{X,\xi}$ is a radical ideal of $\mathcal{O}_{X,\xi}$.

**Proof.** To ease notation, set $A := \mathcal{O}_{X,\xi}$. Pick a chart $\beta : P_X(\xi) \to M(\xi)$ with $P$ finite, sharp and saturated (corollary [12.1.36(i)]; by proposition [12.5.16(ii)], the ring $A$ is $P$-flat for the resulting map $P \to A$. Let $q := \beta^{-1}p \subset P$; then $pA = qA$.

(i): Since $p$ is a prime ideal, $q$ is a prime ideal of $P$, and in order to prove that $pA$ is a prime ideal, it suffices therefore to show that the completion $(A/qA)^\wedge$ of $A/qA$ is an integral domain. However, remark [12.5.12] implies that $(A/qA)^\wedge \simeq B/\vartheta B$, where $B := R[[P/q]]$, with $(R, m_R)$ a regular local ring, and $\vartheta$ is either zero, or else it is an element whose constant term $\vartheta_0 \in R$ lies in $m_R \setminus m_R^2$. The assertion is obvious when $\vartheta = 0$, and otherwise it follows from claim [12.5.11].

Next, by going down (corollary [6.4.32]), we see that:

$$\text{ht} pA \geq \text{ht} p.$$ 

On the other hand, notice that we have a natural identification $\text{Spec } M_\xi \xrightarrow{\sim} \text{Spec } P$, especially $\text{ht} p = \text{ht} q$, hence $\dim A/pA = \dim (A/qA)^\wedge = \dim R + \dim (P/q) - \varepsilon$, where $\varepsilon$ is either 0 or 1 depending on whether $R$ does or does not contain a field (corollary [6.4.25(ii)]). Thus:

$$\text{ht} pA \leq \dim A - \dim A/pA = \dim P - \dim (P/q) = \text{ht} p$$

(corollary [6.4.10(iii)]), which completes the proof.

(ii): In this case, $q$ is a radical ideal of $P$, so it can be written as a finite intersection of prime ideals of $P$ (lemmata [6.1.16] and [6.1.21(iii)]); then the assertion follows from (i) and lemma [6.1.38] (details left to the reader). □
Lemma 12.5.21. Let $X$ be a scheme, $\mathcal{M}$ a fs log structure on $X_{zar}$, and $\xi$ a geometric point of $X$. Then $(X, \mathcal{M})$ is regular at the point $|\xi|$ if and only if $\widetilde{u}_X^*(X, \mathcal{M})$ is regular at $\xi$.

Proof. Set $(Y, N) := \widetilde{u}_X^*(X, \mathcal{M})$ (notation of (12.2.22): of course $Y = X$, but the sheaf $\mathcal{O}_Y$ is defined on the site $X_{et}$, hence $B := \mathcal{O}_{Y, \xi}$ is the strict henselization of $A := \mathcal{O}_{X, |\xi|}$, and the map $\alpha: M_{|\xi|} \to B$ is the induced morphism of monoids; since $\alpha$ is local, it is easily seen that $N_{|\xi}$ is isomorphic to the push-out of the diagram $M_{|\xi|} \leftarrow M_{|\xi|}^x \to B^x$, especially $\dim M_{|\xi|} = \dim N_{|\xi}$. Moreover, $I(\xi, N) = I(\xi, M)B$, so that $B_0 := B/I(\xi, N)$ is the strict henselization of $A_0 := A/I(\xi, M)$ (51 Ch.IV, Prop.18.6.8)); hence $A_0$ is regular if and only if the same holds for $B_0$ (51 Ch.IV, Cor.18.8.13)). Finally, $\dim A = \dim B$ and $\dim A_0 = \dim B_0$ ([100, Th.15.1]). The lemma follows. □

12.5.22. Let $(Y, N)$ be a log scheme, $\eta$ a $\tau$-point of $Y$, and $\alpha: Q^\log_Y \to N$ a fine and saturated chart which is sharp at $\eta$. Let also $\varphi: Q \to P$ be an injective morphism of monoids, with $P$ fine and saturated, and such that $P^x$ is a torsion-free abelian group. Define $(X, \mathcal{M})$ as the fibre product in the cartesian diagram of log schemes:

$$
\begin{array}{ccc}
(X, \mathcal{M}) & \xrightarrow{f} & (Y, N) \\
\ Spec(\mathbb{Z}, P) & \xrightarrow{h} & \ Spec(\mathbb{Z}, Q)
\end{array}
$$

(12.5.23)

where $h$ is induced by $\alpha$; especially, $h$ is strict.

Lemma 12.5.24. In the situation of (12.5.22), let $\bar{\tau}$ be any $\tau$-point of $X$ such that $f(\bar{\tau}) = \eta$, and suppose that $(Y, N)$ is regular at $\eta$. Then $(X, \mathcal{M})$ is regular at $\bar{\tau}$.

Proof. To begin with, we show:

Claim 12.5.25. The natural map:

$$
\mathcal{O}_{X, \bar{\tau}} \otimes_P P/I \to \mathcal{O}_{X, \bar{\tau}} \otimes_P P/I
$$

is an isomorphism in $D^-(\mathcal{O}_{X, \bar{\tau}} \text{-Mod})$, for every ideal $I \subset P$ (notation of (6.1.34)).

Proof of the claim. It suffices to show that this map is an isomorphism in $D^-(\mathcal{O}_{Y, \bar{\tau}} \text{-Mod})$, and in the latter category we have a commutative diagram:

$$
\begin{array}{ccc}
(\mathcal{O}_{Y, \bar{\tau}} \otimes_Q P) \otimes_P P/I & \to & \mathcal{O}_{Y, \bar{\tau}} \otimes_Q P/I \\
(\mathcal{O}_{Y, \bar{\tau}} \otimes_Q P) \otimes_P P/I & \to & (\mathcal{O}_{Y, \bar{\tau}} \otimes_Q P) \otimes_P P/I \xrightarrow{\sim} \mathcal{O}_{Y, \bar{\tau}} \otimes_Q P/I.
\end{array}
$$

(12.5.26)

Since $\mathcal{O}_{Y, \bar{\tau}}$ is a localization of $\mathcal{O}_{Y, \bar{\tau}} \otimes_Q P$, we are reduced to showing that the bottom arrow of (12.5.26) is an isomorphism. However, the top arrow of (12.5.26) is always an isomorphism. Moreover, on the one hand, since $(Y, N)$ is regular at $\eta$, the ring $\mathcal{O}_{Y, \bar{\tau}}$ is $Q$-flat (proposition 12.5.16(ii)), and on the other hand, since $\varphi$ is injective, $P/I$ is an integral $Q$-module, so the two vertical arrows are isomorphisms as well, and the claim follows. □

Claim 12.5.27. $\mathcal{O}_{X, \bar{\tau}} \otimes_P I(\bar{\tau}, \mathcal{M})$ is a regular ring.

Proof of the claim. Let $\beta: P \to A := \mathcal{O}_{X, \bar{\tau}}$ be the morphism deduced from $h$, and set:

$$
S := \beta^{-1}(\mathcal{O}_{X, \bar{\tau}}^x) \quad I(\bar{\tau}, P) := P \setminus S.
$$

Then the \( \mathbb{Z}[P] \)-algebra \( A \) is a localization of the \( \mathbb{Z}[P] \)-algebra

\[
B := S^{-1}(\mathcal{O}_{Y,\overline{\mathfrak{y}}} \otimes_{Q} P)
\]

and it suffices to show that \( B/I(\overline{\pi}, M) \) is regular.

It is easily seen that \( I(\overline{\pi}, M) = I(\overline{\pi}, P)A \) and \( \varphi(m_{Q}) \subset I(\overline{\pi}, P) \); on the other hand, since \( \alpha \) is sharp at the point \( \overline{y} \), we have \( I(\overline{y}, N) = m_{Q}\mathcal{O}_{Y,\overline{y}} \) and \( Q \setminus m_{Q} = \{ 1 \} \). Let \( p \) be the residue characteristic of \( \mathcal{O}_{Y,\overline{y}} \); there follow isomorphisms of \( \mathbb{Z}(p) \)-algebras:

\[
B/I(\overline{\pi}, M)B \simeq S^{-1}\mathcal{O}_{Y,\overline{y}} \otimes_{Q} P/I(\overline{\pi}, P) \simeq \mathcal{O}_{Y,\overline{y}}/I(\overline{y}, N) \otimes_{\mathbb{Z}(p)} \mathbb{Z}(p)[S^{\text{gp}}].
\]

By assumption, \( \mathcal{O}_{Y,\overline{y}}/I(\overline{y}, N) \) is regular, hence we are reduced to showing that \( \mathbb{Z}(p)[S^{\text{gp}}] \) is a smooth \( \mathbb{Z}(p) \)-algebra (\cite{Hartshorne} Ch.IV, Prop.17.5.8(ii)). However, under the current assumptions \( P^{\text{gp}} \) is a free abelian group of finite rank, hence the same holds for \( S^{\text{gp}} \), and the contention follows easily.

In light of proposition \( \[6.1.41\] \), claims \( \[12.5.25\] \) and \( \[12.5.27\] \) assert that conditions (a) and (b) of proposition \( \[12.5.16\] \) are satisfied for the \( \tau \)-point \( \overline{\pi} \) of \( (X, M) \), so the latter is regular at \( \overline{\pi} \), as stated.

\( \Box \)

**Theorem 12.5.28.** Let \( f : (X, M) \rightarrow (Y, N) \) be a smooth morphism of locally noetherian fs log schemes, \( \xi \) a \( \tau \)-point of \( X \), and suppose that \( (Y, N) \) is regular at the point \( f(\xi) \). Then \( (X, M) \) is regular at the point \( \xi \).

**Proof.** In case \( \tau = \text{Zar} \), lemma \( \[12.5.21\] \) and corollary \( \[12.3.27\] (ii) \) reduce the assertion to the corresponding one for \( \widetilde{\tau}^{*}f \). Hence, we may assume that \( \tau = \text{ét} \). Next, since the assertion is local on \( X_{\overline{\tau}} \), we may assume that \( N \) admits a fine and saturated chart \( \alpha : Q_{Y}^{\text{log}} \rightarrow N \) which is sharp at \( f(\xi) \) (corollary \( \[12.1.36\] (ii) \)); then, by corollary \( \[12.3.42\] \) we may further assume that there exist an injective morphism of fine and saturated monoids \( \varphi : Q \rightarrow P \), such that \( P^{\times} \) is torsion-free, and a cartesian diagram as in \( \[12.5.23\] \). Then the assertion follows from lemma \( \[12.5.24\] \).

**Corollary 12.5.29.** Let \( f : (X, M) \rightarrow (Y, N) \) be a smooth morphism of locally noetherian fine log schemes. Then, for every \( y \in (Y, N)_{\text{fs}} \), the log scheme \( \text{Spec} \kappa(y) \times_{Y} (X, M) \) is geometrically regular.

**Proof.** The trivial log structure on \( \text{Spec} \kappa(y) \) is obviously saturated, so the same holds for the log structure of \( \text{Spec} \kappa(y) \times_{Y} (X, M) \). Hence, the assertion is an immediate consequence of theorem \( \[12.5.28\] \).

In the same vein we have:

**Proposition 12.5.30.** Let \( f : (X, M) \rightarrow (Y, N) \) be a strict morphism of locally noetherian fs log schemes, \( \xi \) a \( \tau \)-point of \( X \), and suppose that the morphism of schemes \( f_{\xi} : X(\xi) \rightarrow Y(f(\xi)) \) is flat. The following holds:

(i) If \( (X, M) \) is regular at the point \( \xi \), then \( (Y, N) \) is regular at the point \( f(\xi) \).

(ii) Conversely, if \( (Y, N) \) is regular at the point \( f(\xi) \), and the fibre \( f_{\xi}^{-1}(f(\xi)) \) is a regular scheme (notation of \( \[4.9.20\] \)), then \( (X, M) \) is regular at the point \( \xi \).

**Proof.** Set \( A := \mathcal{O}_{Y,f(\xi)} \) and \( B := \mathcal{O}_{X,\xi} \), let \( g : A \rightarrow B \) be the induced ring homomorphism, pick a fine chart \( \beta : P \rightarrow A \) for the log structure \( N(f(\xi)) \), and denote by \( I \subset A \) the ideal generated by the image of the maximal ideal of \( N(f(\xi)) \).

(i): By proposition \( \[12.5.16\] (ii) \), the local ring \( B/I\overline{B} \) is regular, \( g \circ \beta : P \rightarrow B \) is a fine chart for the log structure \( M(\xi) \), and \( B = (g \circ \beta)^{-1}(f(\xi)) \). Since the induced map \( A/I \rightarrow B/I\overline{B} \) is flat and local, also \( A/I \) is regular ((\cite{Oka} Ch.0, Prop.17.3.3(i))) and since \( g \) is faithfully flat, \( A \) is \( \beta \)-flat (remark \( \[6.1.36\] (iii) \)). Then the assertion follows from proposition \( \[12.5.16\] \).
(ii): By proposition 12.5.16(ii), the local ring $A/I$ is regular, and $A$ is $\beta$-flat. Since $g$ is flat, the same holds for the induced map $A/I \to B/IB$; it follows that also $B/IB$ is regular ([48 Ch.0, Prop.17.3.3(ii)]), the induced map $P \to B$ is a chart for $\mathcal{M}(\xi)$ and $B$ is $(g \circ \beta)$-flat, whence the contention, again by proposition 12.5.16(i).

**Theorem 12.5.31.** Let $(X, \mathcal{M})$ be a locally noetherian fs log scheme. Then the subset $(X, \mathcal{M})_{\text{reg}}$ is closed under generalization.

**Proof.** Let $\xi$ be a $\tau$-point of $X$, with support $x \in (X, \mathcal{M})_{\text{reg}}$, and let $\eta$ be a generization of $\xi$, whose support is a strict generization $y$ of $x$. We have to show that $(X, \mathcal{M})$ is regular at the point $\eta$. Since the assertion is local on $X$, we may assume that $(X, \mathcal{M})$ admits a fine and saturated chart $\beta : P_X \to \mathcal{M}_x$, sharp at the point $\xi$ (corollary 12.1.36(i)). Let $\alpha : P \to \mathcal{O}_{X,\eta}$ be the morphism deduced from $\beta_\eta$, and set $p := \alpha^{-1}m_\eta$, where $m_\eta \subset \mathcal{O}_{X,\eta}$ is the maximal ideal. We consider the cartesian diagram of log schemes:

$$
\begin{array}{ccc}
(X', \mathcal{M}') & \longrightarrow & (X, \mathcal{M}) \\
\downarrow g & & \downarrow \\
\text{Spec}(\mathbb{Z}, P/p) & \longrightarrow & \text{Spec}(\mathbb{Z}, P)
\end{array}
$$

where $g$ is induced by $\beta$ (notation of (12.2.13)). Clearly $\xi$ and $\eta$ induce $\tau$-points on $X'$, which we denote by the same names. We have natural identifications:

$$\mathcal{O}_{X,\xi} / I(\xi, M) \cong \mathcal{O}_{X',\xi} / I(\xi, M') \quad M'_\eta = \mathcal{O}_{X',\eta}^{\times} \quad \mathcal{O}_{X,\eta} / I(\eta, M) \cong \mathcal{O}_{X',\eta}^{\times}$$

([51 Ch.IV, Prop.18.6.8]). Moreover, from proposition 12.5.16(ii) we know that $\mathcal{O}_{X,\xi}$ is $P$-flat; then corollary 6.4.32 yields the inequality:

$$\dim \mathcal{O}_{X',\xi} = \dim \mathcal{O}_{X,\xi} \otimes_{P} P/p \geq \dim \mathcal{O}_{X,\xi} - \text{ht}(p) = \dim \mathcal{O}_{X,\xi} / I(\xi, M) + \dim P/p$$

in other words: $\dim \mathcal{O}_{X',\xi} = d(\xi, M')$ (notation of definition 12.5.7), so $(X', M')$ is regular at $\xi$. By the same token, $\mathcal{O}_{X,\eta}$ is $P_{\eta}$-flat; from proposition 12.5.16(i), it follows that $(X, M)$ is regular at $\eta$ if and only if the same holds for $(X', M')$.

Hence we may replace $(X, M)$ by $(X', M')$, and $P$ by $P \setminus p$, after which we may assume that $y \in (X, M)_{\text{tr}}$. In this case:

$$\alpha(P) \subset \mathcal{O}_{X,\eta}^{\times}$$

and we have to show that $\mathcal{O}_{X,\eta}$ is a regular local ring, or equivalently, that $\mathcal{O}_{X,y}$ is regular ([51 Ch.IV, Cor.18.8.13(c)]). Now, if $P = 0$, then $\mathcal{O}_{X,y}$ is regular, and the assertion follows from [100, Th.19.3]; thus, we may assume that $P \neq 0$.

Denote by $Y$ the topological closure of $y$ in $X$, endowed with its reduced subscheme structure. According to [45 Ch.II, Prop.7.1.7] (and [51 Ch.IV, Prop.18.8.8(iv)] in case $\tau = \acute{e}t$), we may find a local injective homomorphism $j : \mathcal{O}_{Y,\xi} \to V$, where $V$ is a discrete valuation ring. Let also $\overline{\beta} : P \to \mathcal{O}_{Y,\xi}$ be the morphism deduced from $\beta$. Then (12.5.32) implies that $\overline{j} \circ \overline{\beta}(P) \subset V \setminus \{0\}$, hence $\overline{j} \circ \overline{\beta}$ extends to a homomorphism of groups $\mathbb{P}^{gp} \to K^{\times}$, where $K^{\times} := (V \setminus \{0\})^{gp}$ is the multiplicative group of the field of fractions of $V$; after composition with the valuation $K^{\times} \to \mathbb{Z}$ of $V$, there follows a group homomorphism

$$\varphi : \mathbb{P}^{gp} \to \mathbb{Z}.$$  

Notice also that $\overline{j} \circ \overline{\beta}$ is a local morphism, since the same holds for $j$ and $\beta$; consequently, $\varphi(\mathbb{P}^{gp}) \neq \{0\}$. Set $Q := \varphi^{-1}\mathbb{N}$; then $\varphi(Q)$ is a non-trivial submonoid of $\mathbb{N}$, and $\dim Q = \dim Q / \text{Ker} \varphi = \dim \varphi(Q) = 1$. Set

$$T := \text{Spec} V \quad (S, Q) := \text{Spec}(\mathbb{Z}, Q).$$
Notice that $Q$ is saturated and fine (corollary 6.4.2), so there exists an isomorphism:

$$
\mathbb{Z}^{op} \times \mathbb{N} \sim \to Q \quad \text{for some } r \in \mathbb{N}
$$

(theorem 6.4.16(iii)); the latter determines a chart:

(12.5.33) \quad \mathbb{N}_S \to Q

which is sharp at every $\tau$-point of $S$ localized outside the trivial locus $\text{Spec}(\mathbb{Z}, Q)_\text{tr}$. We consider the cartesian diagram of log schemes:

$$
\begin{array}{ccc}
(X', g'^* Q) & \xrightarrow{g'} & \text{Spec}(\mathbb{Z}, Q) \\
\downarrow f' & & \downarrow f \\
(X, M) & \xrightarrow{g} & \text{Spec}(\mathbb{Z}, P)
\end{array}
$$

where $f$ is the morphism of log schemes induced by the inclusion map $\psi : P \to Q$. Notice that $f$ is a smooth morphism (proposition 12.3.34); moreover, the restriction $f'_\text{tr}$ to the trivial loci, is an isomorphism.

The homomorphism $j$ induces a morphism $h : T \to X$, such that the closed point of $T$ maps to $x$ and the generic point maps to $y$. By construction $g \circ h$ lifts to a morphism of schemes $h' : T \to S$, and the pair $(h, h')$ determines a morphism $T \to X'$. Let $x', y' \in X'$ be the images of respectively the closed point and the generic point of $T$, and choose $\tau$-points $\xi'$ and $\eta'$ localized at $x'$ and respectively $y'$; then the image of $x'$ in $X$ is the point $x$, therefore $(X', g'^* Q)$ is regular at the point $\xi'$, by theorem 12.5.28. Furthermore, $g'((\xi'))$ lies outside $\text{Spec}(\mathbb{Z}, Q)_\text{tr}$, hence (12.5.33) induces a chart $\mathbb{N}_{X'} \to g'^* Q$, which is sharp at $\xi'$. In light of corollary 12.5.19, we deduce that $\mathcal{O}_{X', x'}$ is a regular ring, and then the same holds also for $\mathcal{O}_{X', y'}$ (48 Ch.0, Cor.17.3.2). However, $y'$ lies in the trivial locus of $(X', g'^* Q)$, and its image in $X$ is $y$, so by the foregoing the natural map $\mathcal{O}_{X, y} \to \mathcal{O}_{X', y'}$ is an isomorphism, and the contention follows. 

\[ \Box \]

Remark 12.5.34. Notice that the proof of [45 Chap.II, Prop.7.1.7] (that is invoked in the proof of theorem 12.5.31) is slightly incorrect: indeed, with the notation of the proof of loc.cit., it is implicitly assumed that $B/mB \neq 0$, which may fail, e.g. take $A := k[[x_2]]$ (for any field $k$), whose maximal ideal is generated by $x_1 := x^2$ and $x_2$, so that $B = k((x_2))$ in this case. The proof can be amended by considering the scheme $X := \text{Spec} A$ and the blow-up $\pi : E \to X$ of the coherent ideal $m \mathcal{O}_X$; since $\pi$ is proper and surjective, we see that there exists $i \in \{1, \ldots, n\}$ such the image of the restriction $\text{Spec} A[x_1/x_i, \ldots, x_n/x_i] \to X$ of $\pi$ contains $m$, and the argument then carries through with $B := A[x_1/x_i, \ldots, x_n/x_i]$. See also [81 Th.6.4.3].

12.5.35. Let $(X, M)$ be any log scheme, $\xi$ a $\tau$-point of $X$. There follows a continuous map

$$
\psi_\xi : X(\xi) \to T_\xi := \text{Spec } \overline{M}_\xi
$$

that sends the closed point of $X(\xi)$ to the closed point of $T_\xi$. For every point $p \in T_\xi$, let $\{p\}$ be the topological closure of $\{p\}$ in $T_\xi$; then

$$
X(p) := \psi^{-1}_\xi \{p\}
$$

is a closed subset of $X(\xi)$, which we endow with its reduced subscheme structure, and we set

$$(X(p), \overline{M}(p)) := ((X(\xi), \overline{M}(\xi)) \times_X X(p))_{\text{red}}$$
(notation of example 12.1.12(iv)). Notice that $U_p := \psi^{-1}_\xi(p)$ is an open subset of $X(p)$, for every $p \in T_\xi$. We call the family 

$$(U_p \mid p \in T_\xi)$$

of locally closed subschemes of $X(\xi)$, the logarithmic stratification of $(X(\xi), M(\xi))$. For instance, $U_\emptyset = (X(\pi), \bar{M}(\pi))_{tr}$. More generally, it is clear from the definition that

(12.5.36) \hspace{1cm} U_p = (X(p), \bar{M}(p))_{tr} \quad \text{for every } p \in T_\xi.

**Corollary 12.5.37.** In the situation of (12.5.35), suppose that $(X, M)$ is regular at $\xi$. Then:

(i) The log scheme $(X(p), \bar{M}(p))$ is pointed regular, for every $p \in T_\xi$.

(ii) The scheme $X(p)$ is irreducible, and its codimension in $X$ equals the height of $p$ in $T_\xi$, for every $p \in T_\xi$.

(iii) The scheme $U_p$ is regular and irreducible, for every $p \in T_\xi$.

**Proof.** (i): By theorem 12.5.31 it suffices to show that $(X(p), \bar{M}(p))$ is pointed regular at $\xi$, for every $p \in T_\xi$. However, say that $X(\xi) = \text{Spec } A$, and let $P \to \bar{M}(\xi)$ be a fine and saturated chart, sharp at the $\tau$-point $\xi$. Then $X(p) = \text{Spec } A_0$, where $A_0 := A/p, A$, and $\bar{M}(p) = N_0$, where $N$ is the fs log structure deduced from the induced map $\beta : P \setminus p \to A_0$. By proposition 12.5.16(ii), the ring $A$ is $P$-flat; then $A_0$ is $\beta$-flat, and the assertion follows from proposition 12.5.16(i).

Next, (ii) is a rephrasing of corollary 12.5.20(i), and (iii) follows from (i),(ii) and (12.5.36), by virtue of corollary 12.5.19. □

**Proposition 12.5.38.** Let $(X, \beta : M \to \mathcal{O}_X)$ be a regular log scheme, set $U := (X, M)_{tr}$, and denote by $j : U \to X$ the open immersion. Then the morphism $\beta$ induces identifications:

$$M \xrightarrow{j_*} \mathcal{O}_U^\approx \cap \mathcal{O}_X \quad \text{and} \quad M^{gp} \xrightarrow{j_*} \mathcal{O}_U^\approx.$$

**Proof.** Notice that the scheme $X$ is normal (corollary 12.5.13), hence both $j_*\mathcal{O}_U^\approx$ and $\mathcal{O}_X$ are subsheaves of the sheaf $i_*\mathcal{O}_{X_0}$, where $X_0$ is the subscheme of maximal points of $X$, and $i : X_0 \to X$ is the natural morphism; so we may intersect these two sheaves inside the latter.

In view of lemma 12.5.2 and proposition 12.5.16(ii), we know already that $\beta$ is injective, and clearly the image of $\beta$ lands in $j_*\mathcal{O}_U^\approx$, so it remains only to show that $\beta$ (resp. $\beta^{gp}$) induces an epimorphism onto $j_*\mathcal{O}_U^\approx \cap \mathcal{O}_X$ (resp. onto $j_*\mathcal{O}_U^{gp}$). The assertions can be checked on the stalks, hence let $\xi$ be any $\tau$-point of $X$; to begin with, we show :

**Claim 12.5.39.** The induced map $\beta^{gp}_\xi : M^{gp}_\xi \to (j_*\mathcal{O}_U^\approx)_\xi$ is a surjection.

**Proof of the claim.** Set $A := \mathcal{O}_{X,\xi}$; notice that $(X(\xi), M(\xi))_{tr}$ is the complement of the union of the finitely many closed subsets of the form $Z_p := \text{Spec } A/pA$, where $p \subset M_\xi$ runs over the prime ideals of height one. Due to corollary 12.5.20(i), each $Z_p$ is an irreducible divisor in $\text{Spec } A$. Now, let $s \in (j_*\mathcal{O}_U^\approx)_\xi$; then the divisor of $s$ is of the form $\sum_{ht_p=1} n_p[p]$, for some $n_p \in \mathbb{Z}$. By lemmata 12.1.18(ii) and 12.2.21(i), $M^{\hat{}}_\xi$ is a fine and saturated monoid; then lemma 6.4.37 and proposition 6.4.48 say that the fractional ideal $I := \bigcap_{ht_p=1} m_p^{n_p}$ of $M_\xi$ is reflexive, and therefore the fractional ideal $IA$ of $A$ is reflexive as well (lemma 6.4.43(ii)). Since $A$ is normal, by considering the localizations of $I\mathcal{O}_{X,\xi}$ at the prime ideals of height one of $A$, we deduce easily that $IA = sA$. By Cor. du Th.2). Thus, we may write $s = \sum_{i=1}^n \beta^{gp}_\xi(x_i) a_i$ for certain $a_i \in A$ and $x_i \in I$ (for $i = 1, \ldots, n$). Then we must have $\beta^{gp}_\xi(x_i) a_i \notin s \cdot M_\xi$ for at least one index $i \leq n$ (where $m_\xi \subset A$ is the maximal ideal); for such $i$, it follows that $s^{-1} \cdot \beta^{gp}_\xi(x_i) \in A^\times$, whence $s \in M^{gp}_\xi$, as required.

Now, let $s \in (j_*\mathcal{O}_U^\approx)_\xi \cap A$; by claim 12.5.39 we may find $x \in M^{gp}_\xi$ such that $\beta^{gp}_\xi(x) = s$. To conclude, it suffices to show that $x \in M^{gp}_\xi$. By theorem 6.4.16(i), we are reduced to showing that $x \in (M^{gp}_\xi)_p$ for every prime ideal $p \subset M_\xi$ of height one. Set $q := p.A$; then $q$ is a prime
ideal of height one (corollary [12.5.20]), and \( \beta_e \) extends to a well defined map of monoids
\( \beta_p : (\mathcal{M}_p)_p \to A_\mathfrak{q} \). Furthermore, \( A_\mathfrak{q} \) is a discrete valuation ring (corollary [12.5.13]), whose valuation we denote \( v : A_\mathfrak{q} \setminus \{0\} \to \mathbb{N} \). In view of theorem 6.4.16(ii), we see that \( x \in (\mathcal{M}_p)_p \) if and only if \( (v \circ \beta_p)^{\mathbb{N}}(x) \geq 0 \). However, clearly \( v(x) \geq 0 \), whence the contention. \( \square \)

Remark 12.5.40. Let \( \text{reg.log}_r \) denote the full subcategory of \( \text{log}_r \), whose objects are the regular log schemes. As an immediate consequence of proposition 12.5.38 (and of remark 12.2.8(ii)) we see that the forgetful functor \( F \) of (12.2.1) restricts to a fully faithful functor

\[
\text{reg.log}_r \to \text{Open} \quad (X, M) \mapsto ((X, M)_{\text{tr}} \to X)
\]

where \( \text{Open} \) is full subcategory of \( \text{Morph}(\text{Sch}) \) whose objects are the open immersions.

12.5.41. Let \( (X, M) \) be a quasi-compact and regular log scheme. Set \( Z := X \setminus (X, M)_{\text{tr}} \); then \( Z \) is a closed subset of \( X \) (lemma 12.2.21(ii)), and we endow it with its reduced subscheme structure. Denote by \( \omega_X \subset \mathcal{O}_X \) the sheaf of ideals corresponding to \( Z \). We have:

Theorem 12.5.42. In the situation of (12.5.41), the complex \( \omega_X[0] \) is dualizing on \( X \). (See definition [11.3.16].)

Proof. In light of proposition [11.3.37], we may assume that \( X \) is local, say \( X = \text{Spec} A \), for a local noetherian ring \( A \). Next, pick any \( \tau \)-point \( \xi \) localized at the closed point of \( X \); by virtue of proposition [11.3.34] and [51, Ch.IV, Prop.18.8.8(iv) and Prop.18.8.12(ii)], we may further reduce to the case where \( (X, M) = (X(\mathfrak{p}), M(\mathfrak{p})) \). Let \( X^\wedge := \text{Spec} A^\wedge \), where \( A^\wedge \) denotes the completion of the local ring \( A \), and denote by \( f : X^\wedge \to X \) the natural morphism; by applying again proposition 11.3.34, we reduce to checking that \( f^* \omega_X[0] \) is dualizing on \( X^\wedge \). However, theorem 12.5.10 says that there exist a local ring homomorphism \( R \to A^\wedge \), with \( R \) a complete regular local ring, and a fine and saturated chart \( P_X \to M \), sharp at the closed point of \( X \), such that the induced continuous ring homomorphism \( \varphi : R[[P]] \to A^\wedge \) is an isomorphism if \( A \) contains a field, and otherwise it is a surjection, whose kernel is generated by a regular element \( \vartheta \in R[[P]] \).

This, with this notation, a simple inspection shows that \( Z \) is the union of the closed subsets \( X(\mathfrak{p}) \subset X \), where \( \mathfrak{p} \subset P \) ranges over all prime ideals \( \mathfrak{p} \neq \emptyset \) (notation of (12.5.35)). Then, corollary [12.5.20] says that \( \omega_X \) is the intersection of the ideals of \( \mathcal{O}_X \) of the form \( \mathcal{O}_X/\mathfrak{p} \), where \( \mathfrak{p} \subset P \) is an arbitrary non-empty prime ideal. Denote by \( P^0 \subset P \) the intersection of all the (finitely many) non-empty prime ideals of \( P \); lemma 6.1.38 and proposition 12.5.16(ii) imply that \( \omega_X = P^0 \cdot \mathcal{O}_X \) (details left to the reader), and since \( f \) is a flat morphism, we deduce that \( f^* \omega_X = P^0 \cdot \mathcal{O}_{X^\wedge} \). The ideal \( P^0 \) can also be described as follows. Set \( V := P^0_{\mathfrak{p}} \), denote by \( \sigma \) the unique strictly convex polyhedral cone such that \( P = \sigma \cap P^0_{\mathfrak{p}} \), and let \( \sigma^0 \) be the topological interior of \( \sigma \) in \( V \); then it is easily seen that \( P^0 = P \cap \sigma^0 \).

Set \( Y := \text{Spec} R[P], \omega_Y := P^0 \cdot \mathcal{O}_Y \), and let \( \varphi \) be the image of the closed point of \( Y^\wedge := \text{Spec} R[[P]] \), under the natural morphism \( g : Y^\wedge \to Y \). Theorem 11.6.42(ii) says that \( \omega_Y[0] \) is dualizing on \( Y \); then, since \( g \) is flat, propositions 11.3.34 and 11.3.37 imply that \( g^* \omega_Y[0] \) is dualizing on \( Y^\wedge \).

Now, suppose that \( A \) contains a field; then \( \varphi \) induces an isomorphism \( X^\wedge \sim Y^\wedge \), which identifies \( f^* \omega_X \) with \( g^* \omega_Y \), whence the contention.

Lastly, if \( A \) does not contain a field, \( \varphi \) induces a regular closed immersion \( i : X^\wedge \to Y^\wedge \), so \( i^!(g^* \omega_Y[0]) \) is dualizing on \( X^\wedge \) (lemma [11.3.27](i)). The latter is the complex of \( \mathcal{O}_{X^\wedge} \)-modules arising from the complex of \( A^\wedge \)-modules \( L^* := R\text{Hom}_R^*((A^\wedge[0], R[[P^0]])) \) (corollary [10.3.2]), here \( R[[P^0]] := P^0 \cdot R[[P]] \). However, \( A^\wedge[0] \) is naturally isomorphic (in \( D(R[[P]][-\text{Mod}]) \)) to the Koszul complex \( K \diamond (\vartheta) \) (notation of remark 7.8.1(ii) : this is a bounded complex of free \( R[[P]] \)-modules), so we see that

\[
L^* \simeq (R[[P^0]] \otimes R[[P]] A^\wedge)[-1].
\]
However, we have natural $A^\wedge$-linear isomorphisms:

$$R[[P^o]] \otimes_{R[[P]]} A^\wedge \xrightarrow{\sim} R[[P^o]] \otimes_{R[[P]]} A^\wedge \quad (\text{since } g \text{ is flat})$$

$$\xrightarrow{\sim} \mathbb{Z}[P^o] \otimes_{\mathbb{Z}[P]} A \otimes_A A^\wedge$$

$$\xrightarrow{\sim} (P^o \cdot A) \otimes_A A^\wedge \quad (\text{by proposition 12.5.16(ii)})$$

which shows that $i^!(g^*\omega_Y[0]) \simeq f^*\omega_X[-1]$, and concludes the proof of the theorem. 

\[\Box\]

12.6. Resolution of singularities of regular log schemes. Most of this section concerns results that are special to the class of log schemes over the Zariski topology; these are then applied to étale fs log structures, after we have shown that every such log structure admits a logarithmic blow up which descends to the Zariski topology (proposition 12.6.52). The same statement – with an unnecessary restriction to regular log schemes – can be found in the article [105] by W.Niziol: see theorem 5.6 of loc.cit. We mainly follow her treatment, except for fleshing out some details, and correcting some inaccuracies.

Therefore, we let here $\tau = \text{Zar}$, and all log structures considered in this section until (12.6.48) are defined on the Zariski sites of their underlying schemes.

12.6.1. Let $f : (Y, N) \rightarrow (X, M)$ be any morphism of log schemes; we remark that $f$ is a morphism of monoidal spaces, i.e. for every $y \in Y$, the map $M_{f(y)} \rightarrow N_y$ induced by $\log f$, is local. Indeed, it has been remarked in (12.1.6) that the natural map $M_{f(y)} \rightarrow (\log f)_y$ is local, and on the other hand, a section $s \in (\log f)_y$ is invertible if and only if its image in $\mathcal{O}_{Y,y}$ is invertible, if and only if if $\log f_y(s)$ is invertible in $N_y$, whence the contention. We shall denote

$$f^\sharp : (Y, N)^\sharp \rightarrow (X, M)^\sharp$$

the morphism of sharp monoidal spaces induced by $f$ in the obvious way (i.e. the underlying continuous map is the same as the continuous map underlying $f$), and $\log f^\sharp : f^* M^\sharp \rightarrow N^\sharp$ is $(\log f)^\sharp :$ see definition 6.5.1.

12.6.2. We let $\mathcal{K}$ be the category whose objects are all data of the form $X := ((X, M), F, \psi)$, where $(X, M)$ is a log scheme, $F$ is a fan, and $\psi : (X, M)^\sharp \rightarrow F$ is a morphism of sharp monoidal spaces, such that $\log \psi : \psi^* \mathcal{O}_F \rightarrow M^\sharp$ is an isomorphism. The morphisms:

$$((Y, N), F', \psi') \rightarrow X$$

in $\mathcal{K}$ are all the pairs $(f, \varphi)$, where $f : (Y, N) \rightarrow (X, M)$ is a morphism of log schemes, and $\varphi : F' \rightarrow F$ is a morphism of fans, such that the diagram

$$\xymatrix{ (Y, N)^\sharp \ar[d]_{\psi'} \ar[r]^{f^\sharp} & (X, M)^\sharp \ar[d]_{\psi} \\
F' \ar[r]_{\varphi} & F }$$

commutes. Especially, notice that lemma 12.1.4 implies the identity:

$$\text{Str}(f) = \psi^{-1}\text{Str}(\varphi). \quad (\text{notation of definitions 6.5.1(ii) and 12.2.7(ii)})$$

We shall say that an object $X$ is locally noetherian, if the same holds for the scheme $X$. Likewise, a morphism $(f, \varphi)$ in $\mathcal{K}$ is quasi-compact, (resp. quasi-separated, resp. separated, resp. locally of finite type, resp. of finite type) if the same holds for the morphism of schemes underlying $f$. We say that $f$ is étale, if the same holds for the morphism of log schemes underlying $f$. Also, the trivial locus of $X$ is defined as the subset $(X, M)_\text{tr}$ of $X$. 

12.6.4. There is an obvious (forgetful) functor:

\[ F : \mathcal{X} \to \text{Sch} \quad ((X, M), F, \psi) \mapsto X \]

which is a fibration. More precisely, every morphism of schemes \( S' \to S \) induces a base change functor (notation of (1.1.27)):

\[ F, \mathcal{X} / S \to F, \mathcal{X} / S' \quad X \mapsto S' \times_S X \]

unique up to natural isomorphism of functors. Namely, for \( X := ((X, M), F, \psi) \) one lets

\[ S' \times_S X := (S' \times_S (X, M), F, \psi') \]

where \( \psi' := \psi \circ \pi^\sharp \), and \( \pi : S' \times_S (X, M) \to (X, M) \) is the natural projection.

Example 12.6.5. (i) Let \( P \) be a monoid, \( R \) a ring, and set \( (S, P^\log_S) := \text{Spec}(R, P) \) (see (12.2.13)). The unit of adjunction \( \varepsilon_P : P \to R[P] \) determines a unique morphism of sharp monoidal spaces

\[ \psi_P : \text{Spec}(R, P)^\sharp \to T_P := (\text{Spec } P)^\sharp \]

(proposition 6.5.6), and we claim that \( \mathcal{S} := (\text{Spec}(R, P), T_P, \psi_P) \) is an object of \( \mathcal{X} \).

The assertion can be checked on the stalks, hence let \( \xi \) be a point of \( S \); then \( \xi \) corresponds to a prime ideal \( p_\xi \in R[P] \), and by inspecting the definitions, we see that \( \psi_P(\xi) = \varepsilon_P^{-1}(p_\xi) = q_\xi := P \cap p_\xi \in \text{Spec } P \). Again, a direct inspection shows that the morphism

\[ (\log \psi_P)_\xi : \mathcal{O}_{T_P, \alpha_\xi} \to (P^\log_{S, P})^{\sharp}_{\xi} \]

is none other than the natural isomorphism \( P^\sharp_{q_\xi} \xrightarrow{\sim} P^\log_{S, P}/\mathcal{O}^\times_{S, \xi} \) deduced from \( \varepsilon_P \) and the natural identifications

\[ P^\log_{S, \xi} = \mathcal{O}^\times_{S, \xi} \otimes_{P^\sharp_{q_\xi}} P = \mathcal{O}^\times_{S, \xi} \otimes_{P^\sharp_{q_\xi}} P_{q_\xi}. \]

(ii) The construction of \( \mathcal{S} \) is clearly functorial in \( P \). Namely, say that \( \lambda : P \to Q \) is a morphism of monoids, and set \( S' := \text{Spec } R[Q], T_Q := (\text{Spec } Q)^\sharp \). There follows a morphism

\[ \mathcal{S}' := (\text{Spec}(R, Q), T_Q, \psi_Q) \to \mathcal{S} \]

in \( \mathcal{X} \), whose underlying morphism of log schemes is \( \text{Spec}(R, \lambda) \), and whose underlying morphism of fans is just \( (\text{Spec } \lambda)^\sharp \).

12.6.7. Example 12.6.5 can be globalized to more general log schemes, at least under some additional assumptions. Namely, let \( (X, M) \) be a regular log scheme. For every point \( x \) of \( X \), let \( m_x \subset \mathcal{O}_{X, x} \) be the maximal ideal; we set:

\[ F(x) := \{ x \in X \mid I(x, M) = m_x \} \]

(notation of (12.5.5)), and we endow \( F(X) \) with the topology induced from \( X \). The fan of \( (X, M) \) is the sharp monoidal space

\[ F(X, M) := (F(X), M_{F(X)})^{\sharp}. \]

We wish to show that \( F(X, M) \) is indeed a fan. Let \( U \subset X \) be any open subset; to begin with, it is clear that \( F(U, M_{||U}) \) is naturally an open subset of \( F(X, M) \); hence the contention is local on \( X \), so we may assume that \( X \) is affine, say \( X = \text{Spec } A \) for a noetherian ring \( A \), and that \( M \) admits a finite chart \( P_X \to M \); denote by \( \beta : P \to A \) the induced morphism of monoids. Let now \( \xi \) be a point of \( X \), and \( p_\xi \subset A \) the corresponding prime ideal; set \( q_\xi := \beta^{-1}p_\xi \in \text{Spec } P \).

By inspecting the definitions, it is easily seen that \( I(\xi, M) = q_\xi A_{p_\xi} \). Therefore, for any prime ideal \( q \subset P \), let \( V(q)_{\text{max}} \) be the finite set consisting of all the maximal points of the closest
subset \( V(q) := \text{Spec } A/\mathfrak{q}A \) (i.e. the minimal prime ideals of \( A/\mathfrak{q}A \)); in light of corollary [12.5.20(i)], it follows easily that
\[
F(X) = \bigcup_{q \in \text{Spec } P} V(q)_{\text{max}}
\]
especially, \( F(X) \) is a finite set (lemma [6.1.21(iii)]. Let \( t \in F(X) \) be any element, and denote by \( U(t) \subset F(X) \) the subset of all generalizations of \( t \) in \( F(X) \); as a corollary, we see that \( U(t) \) is an open subset of \( F(X) \). Moreover, (12.6.8) also implies that:
\[
U(t) = \bigcup_{q \in \text{Spec } P} (\text{Spec } \mathcal{O}_{X,t}/\mathfrak{q}\mathcal{O}_{X,t})_{\text{max}}.
\]
However, corollary [12.5.20(i)] says that \( \text{Spec } \mathcal{O}_{X,t}/\mathfrak{q}\mathcal{O}_{X,t} \) is irreducible for every \( q \in \text{Spec } P \), therefore the set \( U(t) \) is naturally identified with a subset of \( \text{Spec } P \). Furthermore, arguing as in example [12.6.5(i)] we find a natural isomorphism \( P_{\mathfrak{q}t}^\beta \cong \mathcal{O}_{F(X,M),t} \). Moreover, if \( t' \in U(t) \) is any other point, the specialization map \( \mathcal{O}_{F(X,M),t} \to \mathcal{O}_{F(X,M),t'} \) corresponds – under the above isomorphism – to the natural morphism \( P_{\mathfrak{q}t}^\beta \to P_{\mathfrak{q}t'}^\beta \) induced by the localization map \( P_{\mathfrak{q}t} \to P_{\mathfrak{q}t'} \). This shows that the open monoidal subspace \( (U(t), M_{U(t)}) \) is naturally isomorphic to \( (Spec P_{\mathfrak{q}t})^\beta \), hence \( F(X,M) \) is a fan, as stated.

**Remark 12.6.9.** (i) The discussion in (12.6.7) shows more precisely that if:
- (a) \( (U, M) \) is a log scheme with \( U = \text{Spec } A \) affine,
- (b) there exists a morphism \( \beta : P \to A \) from a finitely generated monoid \( P \), inducing the log structure \( M \) on \( U \), and
- (c) \( \beta(q)A \) is a prime ideal for every \( q \in \text{Spec } P \)

then \( F(U, M) \) is naturally identified with \( (\text{Spec } P)^\beta \). In this situation, denote by
\[
f_\beta : (U, M)^\beta \to T_P := (\text{Spec } P)^\beta
\]
the morphism of sharp monoidal spaces deduced from \( \beta \) (proposition [6.5.6]); by inspecting the definitions, we see that the associated map \( \log f_\beta : f_\beta^* \mathcal{O}_{T_P} \to M^\beta \) is an isomorphism. Via the foregoing natural identification, there results a morphism \( \pi_U : (U, M)^\beta \to F(U,M) \) which can be described without reference to \( P \). Indeed, let \( x \in U \) be any point, and \( \mathfrak{p} \in \text{Spec } A \) the corresponding prime ideal; by inspecting the definitions we find that
\[
\pi_U(x) = I(x, M) \text{ which is the largest prime ideal in } \text{Spec } A_\mathfrak{p} \cap F(U,M).
\]
Especially, \( \pi_U(x) \) is a generization of \( x \), and the inverse of \( (\log \pi_U)_x : \mathcal{O}_{F(U,M),\pi_U(x)} \to M_x^\beta \) is induced by the specialization map \( M_x \to M_{\pi_U(x)} \) (which induces an isomorphism on the associated sharp quotient monoids).

(ii) Finally, it follows easily from corollary [12.5.20(i)] and [50] Ch.IV, Cor.8.4.3], that every regular log scheme \( (X,M) \) admits an affine open covering \( X = \bigcup_{i \in I} U_i \), such that each \( (U_i, M_{U_i}) \) fulfills conditions (a)–(c) above, and the intrinsic description in (i) shows that the morphisms \( \pi_U \) glue to a well defined morphism \( \pi_X : (X, M)^\beta \to F(X, M) \) of sharp monoidal spaces, such that the datum
\[
\mathcal{K}(X, M) := ((X, M), F(X, M), \pi_X)
\]
is an object of \( \mathcal{K} \).

(iii) Notice that \( \pi_X^{-1}(t) \) is an irreducible locally closed subset of \( X \) of codimension equal to the height of \( t \), for every \( t \in F(X,M) \); also \( \pi_X^{-1}(t) \) is a regular scheme, for its reduced subscheme structure. Indeed, we have already observed that \( t \) is the unique maximal point of \( \pi_X^{-1}(t) \), and then the assertion follows immediately from corollary [12.5.37(ii,iii)]. Furthermore, the inclusion map \( j : F(X,M) \to X \) is a continuous section of \( \pi_X \), and notice that \( j \circ \pi_X(U) = \)
$j^{-1}U$ for every open subset $U \subset X$, since $j$ maps every $t \in F(X, M)$ to the unique maximal point of $\pi_{X}^{-1}(t)$. It follows easily that $\pi_{X}$ is an open map.

12.6.10. Denote by $\mathcal{X}_{\text{int}}$ the full subcategory of $\mathcal{X}$ whose objects are the data $((X, M), F, \psi)$ such that $M$ is an integral log structure, and $F$ is an integral fan. There is an obvious functor

$$\mathcal{X}_{\text{int}} \to \text{int.Fan} : ((X, M), F, \psi) \mapsto F$$

to the category of integral fans, which shall be used to construct useful morphisms of log schemes, starting from given morphisms of fans. This technique rests on the following three results:

**Lemma 12.6.11.** Let $((X, M), F, \psi)$ be an object of $\mathcal{X}_{\text{int}}$, with $F$ locally fine. Then, for each point $x \in X$ there exist an open neighborhood $U \subset X$ of $x$, a fine chart $Q_{U} \to M_{U}$ (for some fine monoid $Q$ depending on $x$), and an isomorphism of monoids $Q \cong \mathcal{O}_{F, \psi(x)}$.

**Proof.** The assertion is local on $X$, hence we may assume that $F = (\text{Spec } P)^{\dagger}$ for a fine monoid $P$. In this case, $\psi$ is determined by the corresponding map

$$\overline{\beta} : P_{X} \to M_{x}^{\sharp}.$$ 

Indeed, for any $x \in X$, the point $\psi(x)$ is the prime ideal $\overline{\beta}^{-1}(m_{x}) \subset P$, where $m_{x} \subset M_{x}^{\sharp}$ is the maximal ideal; moreover:

$$\mathcal{O}_{F,\psi(x)} = P/\overline{S}_{x} \quad \text{where} \quad \overline{S}_{x} := \overline{\beta}^{-1}(1)$$

and – under this identification – the isomorphism $\log \psi_{x} : \mathcal{O}_{F,\psi(x)} \cong M_{x}^{\dagger}$ is deduced from $\overline{\beta}_{x}$ in the obvious way.

Now, let $x \in X$ be any point; after replacing $X$ by the open subset $\psi^{-1}U(\psi(x))$, we may assume that $P = \mathcal{O}_{F,\psi(x)}$ (notation of (6.5.16)), and by assumption $\log \psi_{x} : P \to M_{x}^{\sharp}$ is an isomorphism. Pick a surjection $\alpha : \mathbb{Z}^{\geq 0} \to P^{\text{gp}}$, and let $Q$ be the pull-back in the cartesian diagram:

$$\begin{array}{ccc}
Q & \longrightarrow & \mathbb{Z}^{\geq 0} \\
\downarrow & & \downarrow (\log \psi_{x})^{\text{gp}} \circ \alpha \\
M_{x}^{\sharp} & \longrightarrow & M_{x}^{\sharp}/M_{x}^{\infty}.
\end{array}$$

By construction, $\alpha$ restricts to a morphism of monoids $\vartheta : Q \to P$, inducing an isomorphism $Q^{\sharp} \cong P$; whence an isomorphisms of fans $(\text{Spec } P)^{\dagger} \cong (\text{Spec } Q)^{\dagger}$, and $Q$ is fine, by corollary 6.4.2. Moreover, the choice of a lifting $\mathbb{Z}^{\geq 0} \to M_{x}^{\text{gp}}$ of $(\log \psi_{x})^{\text{gp}} \circ \alpha$ determines a morphism

$$\beta_{x} : Q \to M_{x}^{\sharp} \times_{M_{x}^{\text{gp}}} \mathbb{M}_{x}^{\text{gp}} = M_{x}$$

which lifts $\log \psi_{x} \circ \vartheta$ (here it is needed that $M$ is integral). Next, after replacing $X$ by an open neighborhood of $x$, we may assume that $\beta_{x}$ extends to a map of pre-log structures $\beta : Q_{X} \to M$ lifting $\overline{\beta}$ (lemma 12.1.18(iv.b),(v)). It remains only to show that $\beta$ is a chart for $M$, which can be checked on the stalks. Thus, let $y \in X$ be any point, and set $S_{y} := \beta_{y}^{-1}M_{y}^{\infty}$; with the foregoing notation, the stalk $Q_{X,y}^{\log}$ of the induced log structure is naturally isomorphic to $(S_{y}^{-1}Q \times \mathcal{O}_{X,y}^{\infty})/S_{y}^{\text{gp}}$; therefore

$$(Q_{X,y}^{\log})^{\sharp} \cong Q/S_{y} \cong P/\overline{S}_{y}$$

and the induced map $P/\overline{S}_{y} \to M_{y}^{\sharp}$ is again deduced from $\overline{\beta}_{y}$, so it is an isomorphism; then the same holds for $\beta_{y}^{\log} : Q_{X,y}^{\log} \to M_{y}$ (lemma 12.1.4). \(\square\)
Lemma 12.6.12. Let $\mu : P \to P'$ be a morphism of integral monoids such that $\mu^{\flat\frak{p}}$ is surjective, $\varphi : (\text{Spec } P')^\frac{1}{2} \to (\text{Spec } P)^\frac{1}{2}$ the induced morphism of affine fans, and denote by
\[ \lambda : P \to Q := P^{\frak{p}} \times_{P^{\frak{p}}} P' \]
the map of monoids determined by $\mu$ and the unit of adjunction $P \to P^{\frak{p}}$. Then:

(i) The natural projection $Q \to P'$ induces an isomorphism $\omega : (\text{Spec } P')^\frac{1}{2} \to (\text{Spec } Q)^\frac{1}{2}$ of affine fans, such that $(\text{Spec } \lambda)^\frac{1}{2} \circ \omega = \varphi$.

(ii) The induced morphism (12.6.11) in $\mathcal{X}_{\text{int}}$ (with $R := \mathbb{Z}$) is int.$\text{Fan}$-cartesian.

(iii) If $P$ and $P'$ are fine, the morphism (12.6.11) is étale.

Proof. (See (5.1) for generalities concerning inverse images and cartesian morphisms relative to a functor.) Notice first that, since $\mu^{\frak{p}}$ is surjective, the projection $Q \to P'$ induces an isomorphism $Q^\frac{1}{2} \simeq P'^{\frac{1}{2}}$, whence (i).

(ii): Notice that the log structure of $\text{Spec}(\mathbb{Z}, Q)$ is integral, by lemma [12.1.18](iii). Next, set $\mathcal{F}' := (\text{Spec } P')^\frac{1}{2}$.

Define $\mathcal{S}$, $\mathcal{S}'$ as in example 12.6.5 (with $R := \mathbb{Z}$), let $g : (\mathcal{S}^\alpha, F''', \psi_Y) \to \mathcal{S}'$ be any morphism of $\mathcal{X}_{\text{int}}$, and $\varphi' : F''' \to F'$ a morphism of integral fans, such that the image of $g$ in $\text{int.Fan}$ equals $\varphi \circ \varphi'$; we must show that $g$ factors through a unique morphism $h : ((Y, N), F''', \psi_Y) \to \mathcal{S}'$, whose image in $\text{int.Fan}$ equals $\varphi'$. As usual, we may reduce to the case where $Y = \text{Spec } A$ is affine, $F''' = \text{Spec } P'''$ is an affine fan for a sharp integral monoid $P'''$, and $\psi_Y$ is given by a map of sheaves $P'''_Y \to N^\sharp$. In such situation, the morphism $(Y, N) \to \text{Spec}(\mathbb{Z}, P)$ underlying $g$ is determined by a morphism of monoids $P \to N(Y)$, or which is the same, a map of sheaves $\gamma_Y : P_Y \to N$; likewise, $\varphi'$ is given by a morphism of monoids $P' \to P'''$, and composing with $\psi_Y$, we get a map of sheaves $\alpha_Y : P'_Y \to N^\sharp$. Finally, the condition that $g$ lies over $\varphi \circ \varphi'$ translates as the commutativity of the following diagram of sheaves:

\[
\begin{array}{ccc}
P_Y^{\frak{p}} & \longrightarrow & P_Y'^{\frak{p}} \\
\gamma_Y^{\frak{p}} \downarrow & & \downarrow \alpha_Y \\
N^{\frak{p}} & \longrightarrow & N'^{\frak{p}}/N^\times \\
\end{array}
\]

There follows a unique morphism of sheaves:

\[ Q_Y \to N^{\frak{p}} \times N'^{\frak{p}}/N^\times N^\sharp = N \]

(here it is needed that $N$ is integral) such that the diagram:

\[
\begin{array}{ccc}
P_Y & \longrightarrow & Q_Y \\
\gamma_Y \downarrow & & \downarrow \alpha_Y \\
N & \longrightarrow & N^\sharp \\
\end{array}
\]

commutes. Then (12.6.13) determines a morphism of log schemes $h_Y : (Y, N) \to \text{Spec}(\mathbb{Z}, Q)$, such that the pair $(h_Y, \varphi')$ is the unique morphism $h$ in $\mathcal{X}_{\text{int}}$ with the sought properties.

(iii): If both $P$ and $P'$ are fine, so is $Q$ (corollary 6.4.2), and by construction, $\lambda^{\frak{p}}$ is an isomorphism. Then the assertion follows from theorem 12.3.37.

Proposition 12.6.14. Let $X := \langle (X, M), F, \psi \rangle$ be an object of $\mathcal{X}_{\text{int}}$. Let also $\varphi : F' \to F$ be an integral partial subdivision, with $F$ locally fine and $F'$ integral. We have:

(i) $(X, M)$ is a fine log scheme.

(ii) If $F$ is saturated, $(X, M)$ is a fs log scheme.

(iii) $X$ admits an inverse image over $\varphi$ (relative to the functor of (12.6.10)).

(iv) If $\varphi$ is finite, then the cartesian morphism $(f, \varphi) : \varphi^* X \to X$, is quasi-compact.
(v) If \( F' \) is locally fine, the morphism \((f, \varphi)\) is quasi-separated and étale.

**Proof.**

(i): This is just a restatement of lemma 12.6.11.

(ii): In light of (i), we only have to show that \( M^\beta_\mathfrak{p} \) is a saturated monoid, for every \( x \in X \). Since by assumption \( M^\beta_\mathfrak{p} \) is saturated, the assertion follows from lemma 6.2.9(ii).

**Claim 12.6.15.** In order to show (iii)–(v), we may assume that:

(a) \( F = (\text{Spec} \, P)^{\#} \) for a fine monoid \( P \), and \( X \) is an affine scheme.

(b) The map of global sections \( P \to \Gamma(X, M^\beta) \) determined by \( \psi \), comes from a morphism of pre-log structures \( \beta : PX \to M \) which is a fine chart for \( M \).

**Proof of the claim.** To begin with, suppose that \( ((X', M'), F', \psi') \) is the sought preimage of \( X \); let \( U \subset X \) be any open subset, and \( V \subset F \) an open subset such that \( \psi(U) \subset V \). Then it is easily seen that the object

\[
\varphi^* X \times_X (U, V) := ((f^{-1}U, M'_{f^{-1}U}, \varphi^{-1}V, \psi'_{f^{-1}U})
\]

is a preimage of \( ((U, M_U), V, \psi_U) \) over the restriction \( \varphi^{-1}V \to V \) of \( \varphi \). Now, suppose that we have found an affine open covering \( X = \bigcup_{i \in I} U_i \), and for every \( i \in I \) an affine open subset \( V_i \subset F \) with \( \psi(U_i) \subset V_i \), such that the object \( U_i := ((U_i, M_{U_i}), V_i, \psi_{U_i}) \) admits a preimage over the restriction \( \varphi_i : \varphi^{-1}V_i \to V_i \) of \( \varphi \); then the foregoing implies that there are natural isomorphisms:

\[
\varphi^*_i U_{ij} \times U_{ij} (U_{ij}, (U_{ij}, V_{ij})) \sim \varphi^*_j U_{ij} \times U_{ij} (U_{ij}, V_{ij})
\]

for every \( i, j \in I \), where \( U_{ij} := U_i \cap U_j \) and \( V_{ij} := V_i \cap V_j \). Thus, we may glue all these inverse images along these isomorphisms, to obtain the sought inverse image of \( X \).

Moreover, if \( \varphi \) is finite, the same will hold for the restrictions \( \varphi_i \), and if each cartesian morphism \( \varphi^*_i U_i \to U_i \) is quasi-compact, the same will hold also for \( (f, \varphi) \) ([43 Ch. I, §6.1]). Likewise, if each morphism \( \varphi^*_i U_i \to U_i \) is étale and quasi-separated, then the same will hold for \( (f, \varphi) \) ([43 Ch. I, Prop. 6.1.11] and proposition 12.3.24(iii)).

Therefore, we may replace \( X \) by any \( U_i \), and \( F \) by the corresponding \( V_i \), which reduces the proof of (iii)–(v) to the case where condition (a) is fulfilled. Lastly, in light of lemma 12.6.11 we may suppose that the open subsets \( U_i \) are small enough, so that also condition (b) is fulfilled. \( \diamond \)

In view of claim 12.6.15, we shall assume henceforth that conditions (a) and (b) are fulfilled. Let \( S := (\text{Spec} \, (\mathbb{Z}, P), T_P, \psi_P) \) be the object of \( \mathcal{X}_{\text{int}} \) considered in example 12.6.5(i) (with \( R := \mathbb{Z} \)); in this situation, \( \beta \) determines a morphism of schemes \( f_\beta : X \to S \), and in view of lemma 12.2.14 we have \( X \simeq X \times_S S' \) (notation of (12.6.4)). Therefore, if we find an inverse image \( S' \) for \( S \) over \( \varphi \), the object \( X \times_S S' \) will provide the sought inverse image of \( X \). Thus, in order to show (iii)–(v), we may further reduce to the case where \( X = S \) ([43 Ch. I, Prop. 6.1.5(iii), Prop. 6.1.9(iii)] and proposition 12.3.24(ii)).

**Claim 12.6.16.** In order to prove (iii)–(v), we may assume that \( F' \) is affine.

**Proof of the claim.** Indeed, say that \( F' = \bigcup_{i \in I} V_i \) is an open covering, and let \( \varphi_i : V_i \to T_P \) be the restriction of \( \varphi \); suppose that we have found, for each \( i \in I \), an inverse image \( \varphi^*_i S \) of \( S \) over \( \varphi_i \); again, it follows easily that an inverse image for \( S \) over \( \varphi \) can be constructed by gluing the objects \( \varphi^*_i S \). This already implies that, in order to show (iii), we may assume that \( F' \) is affine.

Now, suppose that \( \varphi \) is finite, so we may find an open covering as above, such that furthermore each \( V_i \) is affine, and \( I \) is a finite set. Suppose that each of the corresponding morphisms \( \varphi^*_i S \to S \) is quasi-compact; by the foregoing, the schemes underlying the objects \( \varphi^*_i S \) give a finite open covering of the scheme underlying \( \varphi^*_i S \), and then it is clear that (iv) holds.

Next, suppose furthermore that each morphism \( \varphi^*_i S \to S \) is étale. It follows that the morphism \( \varphi^* S \to S \) is also étale (proposition 12.3.24(ii)); then, since \( S \) is noetherian, the
scheme underlying $\varphi^* S$ is locally noetherian ([43, Ch.I, Prop.6.2.2]), and therefore the morphism $\varphi^* S \to S$ is quasi-separated ([43, Ch.I, Cor.6.1.13]).

In view of claim 12.6.16 we shall assume that $F' = (\text{Spec } P')^\sharp$ is affine as well, for a sharp and integral $P'$, and that $\varphi$ is given by a morphism $\lambda : P \to P'$ inducing a surjection on the associated groups (details left to the reader). Then assertions (iii) and (iv) are now straightforward consequences of lemma 12.6.12(i,ii), and (v) follows from lemma 12.6.12(iii), after one remarks that, when $F'$ is fine, one may choose for $P'$ a fine monoid.

\begin{remark}
Keep the assumptions of proposition 12.6.14 and let $t \in F_0$ a point of $F$ of height zero (see 6.5.16). Notice that the inclusion map $j_t : \{t\} \to F$ is an open immersion, hence the fibre $X_t := \psi^{-1}(t) \subset X$ is open; indeed, it is clear from the definitions, that $\psi^{-1}(F_0)$ is precisely the trivial locus of $X$. Moreover, let $t' \in \varphi^{-1}(t)$ since the group homomorphism $\mathcal{O}_{F,t}^{gp} \to \mathcal{O}_{F',t'}^{gp}$ is surjective, we see that $t'$ is of height zero in $F'$, and $\varphi$ restricts to an isomorphism of fans ($\{t'\}, \mathcal{O}_{F,t'} \sim (\{t\}, \mathcal{O}_{F,t})$. Set $X_t := j_t^* X$ (whose underlying scheme is $X_t$), and define likewise $\varphi^* X_t' := (\varphi \circ j_t)^* X_t'$ (whose underlying scheme is an open subset of the trivial locus of $\varphi^* X$). We deduce that:

- The trivial locus of $\varphi^* X$ is the preimage of $(X, M)_tr$.
- For every $t' \in F_0'$, the restriction of $((f, \varphi) : \varphi^* X_{t'} \to X_t$, is an isomorphism.

\begin{corollary}
In the situation of proposition 12.6.14 let $((X', M'), (F', \psi')) := \varphi^* X$. The following holds:

(i) If $F' = F^{\text{sat}}$, and $\varphi : F^{\text{sat}} \to F$ is the counit of adjunction, then $(X', (M')) = (X, M)^{\sharp}$, and $f$ is the counit of adjunction.

(ii) If $\varphi$ is the blow up of a coherent ideal $\mathcal{I}$ of $\mathcal{O}_F$, then $f$ is the blow up of $\mathcal{I}M$, the unique ideal of $M$ whose image in $M^\sharp$ equals $\psi^{-1}\mathcal{I}$.

(iii) Suppose moreover, that $(X, M)$ is regular, $F'$ is saturated, and $X = \mathcal{K}(X, M)$ (notation of remark 12.6.9(iii)). Then $(X', (M'))$ is regular, and $\varphi^* X$ is isomorphic to $\mathcal{K}(X', (M'))$.

\end{corollary}

\begin{proof}
To start with, we remark that the assertions are local on $X$. Indeed, this is clear for (i), and for (ii) it follows easily from remark 12.6.9(i,ii); concerning (ii), suppose that $X = \bigcup_{i \in I} U_i$ is an open covering, such that $\varphi^*(U_i, M_{U_i})$ is the blow up of the ideal $\mathcal{I}M_{U_i}$, for every $i \in I$. For every $i, j \in I$ set $U_{ij} := U_i \cap U_j$; by the universal property of the blow up, there are unique isomorphisms of $(U_{ij}, M_{U_{ij}})$-schemes:

$U_{ij} \times U_i \varphi^*(U_i, M_{U_i}) \xrightarrow{\sim} U_{ij} \times U_j \varphi^*(U_j, M_{U_j})$.

Then both $\varphi^*(X, M)$ and the blow up of $\mathcal{I}M$ are necessarily obtained by gluing along these isomorphisms, so they are isomorphic.

Thus, we may assume that $F = (\text{Spec } P)^\sharp$ for some fine monoid $P$, and $(X, M) = X \times_S (S, P^{\log}_S)$ for some morphism of schemes $X \to S$, where as usual $(S, P^{\log}_S, F, \psi_P)$ is defined as in example 12.6.5(i). In this case, (i) follows from remarks 12.2.36(iii), 6.5.8(ii) and lemma 12.6.12(ii).

Likewise, remark 12.4.32(ii) allows to reduce (ii) to the case where $\mathcal{K} = (S, P^{\log}_S, F, \psi_P)$, and $\mathcal{I} = I^\sim$ for some ideal $I \subset P$; in which case we conclude by inspecting the explicit description in example 12.4.43.

(iii): From proposition 12.6.14(ii,v) and theorem 12.5.28 we already see that $(X', M')$ is regular. Next, we are easily reduced to the case where $X$ is affine, say $X = \text{Spec } A$, and $F' = (\text{Spec } Q)^\sharp$, for some saturated monoid $Q$, and by lemma 12.6.12 we may assume that $\varphi$ is induced by a morphism of monoids $\lambda : P \to Q$ such that $\lambda^{\text{gp}}$ is an isomorphism, and $(X', M') = \varphi^* X = X \times_S S'$, where $S' := (\text{Spec } (\mathbb{Z}, Q)), F', \psi_Q$ is defined as in example

\end{proof}
Let $q \subset Q$ be any prime ideal, and set $p := q \cap P$; in light of remark [12.6.9(i)], it then suffices to show that $Q/q \otimes_P A = Q/q \otimes_{P/p} A/pA$ is an integral domain. To this aim, let us remark:

**Claim 12.6.19.** Let $\lambda : P \to Q$ be a morphism of fine monoids, such that $\lambda^{\text{gp}}$ is an isomorphism, $F \subset Q$ any face, and denote $\lambda_F : F \cap P \to P$ the inclusion map. Then:

(i) The natural map $\text{Coker } \lambda^{\text{gp}}_F \to P^{\text{gp}}/(F \cap P)^{\text{gp}}$ is injective.

(ii) If moreover, $P$ is saturated, then $\text{Coker } \lambda^{\text{gp}}_F$ is a free abelian group of finite rank.

**Proof of the claim.** The map of (i) is obtained via the snake lemma, applied to the ladder of abelian groups:

$$
\begin{array}{cccccc}
0 & \to & (F \cap P)^{\text{gp}} & \to & P^{\text{gp}} & \to & P^{\text{gp}}/(F \cap P)^{\text{gp}} & \to & 0 \\
0 & \to & F^{\text{gp}} & \to & Q^{\text{gp}} & \to & Q^{\text{gp}}/(F^{\text{gp}}) & \to & 0.
\end{array}
$$

taking into account that both $\text{Ker } \lambda^{\text{gp}}$ and $\text{Coker } \lambda^{\text{gp}}$ vanish. Then (i) is obvious, and (ii) comes down to checking that $P^{\text{gp}}/(F \cap P)^{\text{gp}}$ is torsion-free, in case $P$ is fine and saturated. But since $F \cap P$ is a face of $P$, the latter assertion is an easy consequence of proposition [6.4.7].

Now, set $F := Q \setminus q$; we come down to checking that $B := F \otimes_{F \cap P} A/pA$ is an integral domain, and remark [12.6.9(i)] tells us that $A/pA$ is a domain. However, $A/pA$ is $(F \cap P)$-flat (proposition [12.5.16(ii)]), hence the natural map

$$
B \to C := F^{\text{gp}} \otimes_{(F \cap P)^{\text{gp}}} \text{Frac}(A/pA)
$$

is injective; on the other hand, claim [12.6.19(ii)] implies that $C = A[\text{Coker } \lambda^{\text{gp}}_F]$ is a free (polynomial) $A$-algebra, whence the contention. $\square$

**Example 12.6.20.** In the situation of example [6.5.27] take $T := \text{Spec } P$ for a fine monoid $P$, and define $S$ as in example [12.6.5(i)]. The $k$-Frobenius map $k_P$ (example [6.5.10(i)]) induces an endomorphism $k_S := (\text{Spec } (R, k_F), k_F)$ of $S$ in $\mathcal{X}$. By proposition [12.6.14(iii)] and example [6.5.27] there exists a unique morphism $\varphi$ fitting into a commutative diagram of $\mathcal{X}_{\text{int}}$:

$$
\begin{array}{ccc}
\varphi^* S & \longrightarrow & S \\
\varphi^* S & \xrightarrow{\varphi} & S \\
\varphi & \downarrow & k_S \\
\varphi^* S & \xrightarrow{\varphi} & S
\end{array}
$$

(where the horizontal arrows are the cartesian morphisms). Say that $\varphi^* S = ((Y, N'), F, \psi)$; then we have $\varphi = (g, k_F)$ for a unique endomorphism $g := (g, \log g)$ of the log scheme $(Y, N)$. Let $U := \text{Spec } P' \subset F$ be any open affine subset; since $k_F$ is the identity on the underlying topological spaces, $g$ restricts to an endomorphism $g_{\psi^{-1}U}$ of $\psi^{-1}U \times_Y (Y, N)$. In view of lemma [12.6.12] the latter log scheme is of the form $S'$ as in example [12.6.5(ii)], with $Q := P^{\text{gp}} \times_{P^{\text{gp}}} P'$. Then $g_{\psi^{-1}U}$ is induced by an endomorphism $\nu$ of $Q$, fitting into a commutative diagram:

$$
\begin{array}{ccc}
P & \longrightarrow & Q \\
k_F & \downarrow & \nu \\
P & \longrightarrow & Q
\end{array}
$$

whose horizontal arrows are the natural injections. Since $Q \subset P^{\text{gp}}$, it is clear that $\nu = k_Q$. Especially, $g : Y \to Y'$ is a finite morphism of schemes. Furthermore, for every point $y \in Y$, especially...
we have a commutative diagram of monoids:

\[
\begin{array}{ccc}
N_{g(y)} & \xrightarrow{\log g_y} & N^\ast_{g(y)} \\
\downarrow \log g_y & & \downarrow \log g_y \\
N_y & \xrightarrow{\sim} & N^\ast_y \\
\end{array}
\]

(12.6.22)

12.6.23. Let \((K, | \cdot |)\) be a valued field, \(\Gamma\) and \(K^+\) respectively the value group and the valuation ring of \(| \cdot |\); denote by \(1 \in \Gamma\) the neutral element, and by \(\Gamma_+ \subseteq \Gamma\) the submonoid consisting of all elements \(\leq 1\). Let \(S := \text{Spec} K^+\); we consider the log scheme \((S, \mathcal{O}_S^+\)) where \(\mathcal{O}_S^+ \subseteq \mathcal{O}_S\) is the subsheaf such that \(\mathcal{O}_S^+(U) := \mathcal{O}_S(U) \setminus \{0\}\) for every open subset \(U \subseteq S\). To this log scheme we associate the object of \(X_\text{int}\):

\[
f(K, i) := ((S, \mathcal{O}_S^+), \text{Spec} \Gamma, \psi_T)
\]

where \(\psi_T\) is the morphism of monoidal spaces arising from the isomorphism

\[
\Gamma_+ \xrightarrow{\sim} (K^+ \setminus \{0\})/(K^+)\times
\]
deduced from the valuation \(| \cdot |\). It is well known that \(\psi_T\) is a homeomorphism (see e.g. [59 §6.1.26]). We shall use objects of this kind to state some separation and properness criteria for log schemes whose existence is established via proposition [12.6.14]. To this aim, we need to digress a little, to prove the following auxiliary results, which are refinements of the standard valuative criteria for morphisms of schemes.

12.6.24. Let \(f : X \rightarrow Y\) be a morphism of schemes, \(R\) an integral ring, and \(K\) the field of fractions of \(R\). Let us denote by \(X(R)_\text{max} \subseteq X(R)\) the set of morphisms \(\text{Spec} R \rightarrow X\) which map \(\text{Spec} K\) to a maximal point of \(X\). There follows a commutative diagram of sets:

\[
\begin{array}{ccc}
X(R)_\text{max} & \rightarrow & X(K)_\text{max} \\
\downarrow & & \downarrow \\
Y(R) & \rightarrow & Y(K).
\end{array}
\]

(12.6.25)

Proposition 12.6.26. Let \(f : X \rightarrow Y\) be a morphism of schemes. The following conditions are equivalent:

1. \(f\) is separated.
2. \(f\) is quasi-separated, and for every valued field \((K, | \cdot |)\), the map of sets:

\[
X(K^+)_\text{max} \rightarrow X(K)_\text{max} \times_{Y(K)} X(K^+)_\text{max}
\]

deduced from diagram (12.6.25) (with \(R := K^+, \) the valuation ring of \(| \cdot |)\), is injective.

Proof. (a) \(\Rightarrow\) (b) by the valuative criterion of separation ([43 Ch.I, Prop.5.5.4]). Conversely, we shall show that if (b) holds, then the assumptions of the criterion of loc.cit. are fulfilled. Indeed, let \((L, | \cdot |_L)\) be any valued field, with valuation ring \(L^+\), and suppose we have two morphisms \(\sigma_1, \sigma_2 : \text{Spec} L^+ \rightarrow X\) whose restrictions to \(\text{Spec} L\) agree, and such that \(f \circ \sigma_1 = f \circ \sigma_2\).

Let \(s, \eta \in \text{Spec} L^+\) be respectively the closed point and the generic point, set \(x := \sigma_1(\eta) = \sigma_2(\eta) \in X\), and denote by \(\varphi : \mathcal{O}_{X,x} \rightarrow L\) the ring homomorphism corresponding to the restriction of \(\sigma_1\) (and \(\sigma_2\)); then \(x\) admits two specializations \(x_i := \sigma_i(s) \in X\) (for \(i = 1, 2\)) such that \(\varphi\) sends the image \(A_i \subseteq \mathcal{O}_{X,x}\) of the specialization map \(\mathcal{O}_{X,x} \rightarrow \mathcal{O}_{X,x_i}\), into \(L^+\), and the maximal ideal of \(A_i\) into the maximal ideal \(m_L\) of \(L^+\), for both \(i = 1, 2\). Moreover, \(y := f(x_1) = f(x_2)\).

Denote by \(B \subseteq \mathcal{O}_{X,x}\) the smallest subring containing \(A_1\) and \(A_2\), and set \(p := B \cap \varphi^{-1}m_L\). Then \(\varphi(B_p) \subseteq L^+\) as well, and \(B_p\) dominates both \(A_1\) and \(A_2\). Now, let \(t \in X\) be a maximal point which specializes to \(x\); by [43 Ch.I, Prop.5.5.2] we may find a valued field \((E, | \cdot |_E)\)
with a local ring homomorphism $\mathcal{O}_{X,t} \to E$, such that the valuation ring $E^+$ of $|\cdot|_E$ dominates the image of the specialization map $\mathcal{O}_{X,x} \to \mathcal{O}_{X,t}$. Let $\kappa(E)$ be the residue field of $E^+$, and $B_{\mathcal{O}} \subset \kappa(E)$ the image of $B_p$. By the same token, we may find a valuation ring $V \subset \kappa(E)$ with fraction field $\kappa(E)$, and dominating $B_{\mathcal{O}}$; then it is easily seen that the preimage $K^+ \subset E^+$ of $V$ is a valuation ring with field of fractions $K = E$, which dominates the image of $B_\mathcal{O}$ in $\mathcal{O}_{X,t}$. Hence, $K^+$ dominates the images of $\mathcal{O}_{X,t}$, for both $i = 1, 2$, and therefore, also the image of $\mathcal{O}_{Y,y}$, in other words, in this way we obtain two elements in $X(K^+)_{\text{max}}$ whose images agree in $Y(K^+)$, and whose restrictions $\text{Spec } K \to X$ coincide. By assumption, these two $K^+$-points must then coincide, especially $x_1 = x_2$, and therefore $\sigma_1 = \sigma_2$, as required. □

**Proposition 12.6.28.** Let $f : X \to Y$ be a quasi-compact morphism of schemes. The following conditions are equivalent:

(a) $f$ is universally closed.
(b) For every valued field $(K, | \cdot |)$, the corresponding map [12.6.27] is surjective.

**Proof.** (a) ⇒ (b) by the valuative criterion of [43] Ch.I, Prop.5.5.8. Conversely, we will show that (b) implies that the conditions of loc.cit. are fulfilled. Hence, let $(L, | \cdot |_L)$ be any valued field, with valuation ring $L^+$, and suppose that we have a morphism $\sigma : \text{Spec } L \to X$, whose composition with $f$ extends to a morphism $\text{Spec } L^+ \to Y$; we have to show that $\sigma$ extends to a morphism $\text{Spec } L^+ \to X$. Denote by $\eta, s \in \text{Spec } L^+$ respectively the generic and the closed point, let $x \in X$ be the image of $\eta$, and $y \in Y$ the image of $s$. Then $\sigma$ corresponds to a ring homomorphism $\sigma^\sharp : \mathcal{O}_{X,x} \to L$, and $L^+$ dominates the image of the map $\mathcal{O}_{Y,y} \to \mathcal{O}_{X,x}$ determined by $f$. Moreover, $\sigma^\sharp$ factors through the residue field $\kappa(x)$ of $\mathcal{O}_{X,x}$. Then $\kappa(x)^+ := \kappa(x) \cap L^+$ is a valuation ring with fraction field $\kappa(x)$, and we are reduced to showing that there exists a specialization $x' \in X$ of $x$, such that $f(x') = y$, and such that $\kappa(x)^+$ dominates the image of the specialization map $\mathcal{O}_{X,x'} \to \mathcal{O}_{X,x}$.

Let now $t \in X$ be a maximal point which specializes to $x$; by [43] Ch.I, Prop.5.5.8 we may find a valued field $(E, | \cdot |_E)$ with a local ring homomorphism $\mathcal{O}_{X,t} \to E$, whose valuation ring $E^+$ dominates the image of the specialization map $\mathcal{O}_{X,x} \to \mathcal{O}_{X,t}$. Let $\kappa(E)$ be the residue field of $E^+$; the induced map $\mathcal{O}_{X,x} \to \kappa(E)$ factors through $\kappa(x)$, and by [100] Th.10.2 we may find a valuation ring $V \subset \kappa(E)$ with field of fractions $\kappa(E)$, which dominates $\kappa(x)^+$. The preimage $K^+ \subset E^+$ of $V$ is a valuation ring with field of fractions $K = E$ ([100] Th.10.1)). By construction, $K^+$ dominates the image of $\mathcal{O}_{X,y}$, in which case assumption (b) says that there exists a specialization $x' \in X$ of $x$ such that $f(x') = y$, and such that $K^+$ dominates the image of the specialization map $\mathcal{O}_{X,x'} \to \mathcal{O}_{X,t}$. A simple inspection then shows that $\kappa(x)^+$ dominates the image of $\mathcal{O}_{X,x'}$ in $\mathcal{O}_{X,x}$, as required. □

**Corollary 12.6.29.** Let $f : X \to Y$ be a morphism of schemes which is quasi-separated and of finite type. Then the following conditions are equivalent:

(a) $f$ is proper.
(b) For every valued field $(K, | \cdot |)$, the corresponding diagram [12.6.25] (with $R := K^+$ the valuation ring of $| \cdot |$) is cartesian.

**Proof.** It is immediate from propositions [12.6.26] and [12.6.28]. □

12.6.30. We are now ready to return to log schemes. Resume the situation of (12.6.23), let $\underline{X} := ((X, \mathcal{M}), F, \psi)$ be any object of $\mathcal{K}$, and denote by $\alpha : \mathcal{M} \to \mathcal{O}_{X}$ the structure map of $\mathcal{M}$.

Suppose we are given a morphism $\sigma : S \to X$ of schemes, and we ask whether there exists a morphism of log structures $\beta : \mathcal{O}_S \to \mathcal{O}_{\underline{X}}$, such that the pair $(\sigma, \beta)$ is a morphism of log schemes $(S, \mathcal{O}_S) \to (X, \mathcal{M})$. By definition, this holds if and only if the composition

$$\beta : \mathcal{O}_S \xrightarrow{\sigma^*} \mathcal{O}_X \xrightarrow{\sigma^* \alpha} \mathcal{O}_{\underline{X}} \xrightarrow{\sigma^*} \mathcal{O}_S$$
factors through $\theta_S^\ast$. Moreover, in this case the factorization is unique, so $\sigma$ determines $\beta$ uniquely. Let $\eta \in S$ be the generic point; we claim that the stated condition is fulfilled, if and only if $t := \sigma(\eta)$ lies in $(X, M)_\text{tr}$ (see definition 12.2.7(i)). Indeed, if $t$ lies in the trivial locus, $M_t = \theta_{X,t}^\ast$, so certainly the image of $\overrightarrow{\beta}_x : M_t \to \theta_{S,\eta}^\ast$ lies in $\theta_{S,\eta}^\ast = K$. Now, if $s \in S$ is any other point, the composition $M_{\sigma(s)} \xrightarrow{\overrightarrow{\beta}_{\sigma(s)}} \theta_{S,s} \to \theta_{S,\eta} = K$

factors through $M_t$, hence its image lies in $K \cap \theta_{S,s} = \theta_{S,s}^\ast$, whence the contention. Conversely, if $\overrightarrow{\beta}$ factors through $\theta_S^\ast$, it follows especially that the image of the stalk of the structure map $M_t \to \theta_{X,t}$ lies in the preimage of $\theta_{S,\eta}^\ast = \theta_{S,\eta}^\ast$, and the latter is just $\theta_{X,t}^\ast$, so $t$ lies in the trivial locus.

Next, let $f : (S, \theta_S^\ast) \to (X, M)$ be any morphism of log schemes. We claim that there exists a unique morphism of fans $\varphi := (\varphi, \log \varphi) : \text{Spec} \Gamma_+ \to F$, such that the pair $(f, \varphi)$ is a morphism $f(K, | \cdot |) \to X$ in $\mathcal{X}$. Indeed, since $\psi_T$ is a homeomorphism, there exists a unique continuous map $\varphi$ on the underlying topological spaces, such that $\varphi \circ \psi_T = \psi \circ f$, and for the same reason, the map $\log f : f^* M/\theta_S^\ast \to \theta_S^\ast/\theta_S^\ast$ is of the form $\psi_T(\log \varphi)$ for a unique morphism of sheaves $\log f$ as sought. Then $\log f$ will be a local morphism, since the same holds for $\log f$ (see (12.6.1)).

Summing up, we have shown that the natural map

$$\text{Hom}_{\mathcal{X}}(f(K, | \cdot |), X) \to X(K^+) : (\sigma, \varphi) \mapsto \sigma$$

is injective, and its image is the set of all the morphisms $S \to X$ which map $\eta$ into $(X, M)_\text{tr}$.

**Proposition 12.6.31.** Let $X := ((X, M), F, \psi)$ be an object of $\mathcal{X}_\text{int}$, and $\varphi : F' \to F$ an integral partial subdivision, with $F$ and $F'$ locally fine. We have:

(i) If the induced map $F'(N) \to F(N)$ is injective, the cartesian morphism $\varphi^* X \to X$ is separated.

(ii) If $\varphi$ is a proper subdivision, the cartesian morphism $\varphi^* X \to X$ is proper, and induces an isomorphism of schemes $(\varphi^* X)_{\text{tr}} \xrightarrow{\sim} (X, M)_{\text{tr}}$.

**Proof.** The assertions are local on $X$ (cp. the proof of claim 12.6.15), so we may assume – by lemma 12.6.11 – that $M$ admits a chart $P_X \to M$, and $F = (\text{Spec} P)^\ast$. In this case, let $S := \text{Spec} \mathbb{Z}[P]$, and denote by $S$ the object of $\mathcal{X}_\text{int}$ attached to $P$, as in example 12.6.5(i) (with $R := \mathbb{Z}$); then $(X, M)$ is isomorphic to $X \times_S (S, P_S^\log)$, and if $f_S : \varphi^* S \to S$ is the cartesian morphism over $\varphi$, then the cartesian morphism $f : \varphi^* X \to X$ is given by the pair $(1_X \times_S f_S, \varphi)$ (see the proof of proposition 12.6.14(iii)). Thus, we may replace $X$ by $S$ (13 Ch.I, Prop.5.3.1(iv))), in which case lemma 12.6.12 shows that the log scheme $(X', M'_t)$ underlying $\varphi^* S$ admits an open covering consisting of affine log schemes of the form $\text{Spec} \mathbb{Z}[Q]$, for a fine monoid $Q$. Notice that, for such $Q$ we have:

$$\text{Spec} \mathbb{Z}[Q]_{\text{tr}} = \mathbb{Z}[Q^\text{sp}]$$

which is a dense open subset of $\text{Spec} \mathbb{Z}[Q]$.

(i): According to proposition 12.6.14(v), the morphism $f$ is quasi-separated, so we may apply the criterion of proposition 12.6.26. Indeed, let $(K, | \cdot |)$ be any valued field, and suppose that $\sigma_1 \in X'(K^+_\text{max})$ for $i = 1, 2$ are two sections, whose images in $X'(K^+_\text{max}) \times_S(K^+_\text{max})$ coincide; we have to show that $\sigma_1 = \sigma_2$. However, we have just seen that the maximal points of $X'$ lie in $(X', M')_{\text{tr}}$, so the discussion of (12.6.30) shows that both $\sigma_i$ extend uniquely to morphisms $\sigma_i' : f(K, | \cdot |) \to \varphi^* S$ in $\mathcal{X}$, and it suffices to show that $\sigma_1' = \sigma_2'$. By definition, the datum of $\sigma_i'$ is equivalent to the datum of a morphism $\sigma_i'' : f(K, | \cdot |) \to \tilde{S}$, and a morphism of fans $\varphi_i : \text{Spec} \Gamma_+ \to F'$. Again by (12.6.30), the morphisms $\sigma_1''$ and $\sigma_2''$ agree if and only if
they induce the same morphisms of schemes; the latter holds by assumption, since \( \sigma_1 \) and \( \sigma_2 \) yield the same element of \( S(K^+) \). On the other hand, in view of (b) and proposition 6.5.24, the elements \( \varphi_1, \varphi_2 \in F'(\Gamma_+) \) coincide if and only if their images in \( F(\Gamma_+) \) coincide; but again, this last condition holds since the images of both \( \sigma_i \) agree in \( S(K^+) \).

(ii): In view of (i) and proposition 12.6.14(iv),(v) we know already that \( f \) is separated and of finite type, so we may apply the criterion of corollary 12.6.29. Hence, let \( \sigma \in S(K^+) \) be a section, and \( x \in X'(K)_{\text{max}} \) a \( K \)-rational point such that \( f(x) \) is the image of \( \sigma \) in \( S(K) \); in view of (i), it suffices to show that \( \sigma \) lifts to a section \( \tilde{\sigma} \in X'(K^+)_{\text{max}} \), whose image in \( X'(K) \) is \( x \). Since \( x \in (X', \mathcal{M}_'), \) remark 12.6.17 implies that \( f(x) \in (S, \mathcal{P}_S^{\text{reg}})_{\text{tr}} \), and then the discussion in (12.6.30) says that \( \sigma \) underlies a unique morphism \( (\sigma', \beta) : f(K, | \cdot |) \to S \). By proposition 6.5.26 the element \( \beta \in F(\Gamma_+) \) lifts to an element \( \beta' \in F'(\Gamma_+) \), and finally the pair \(( (\sigma, \beta), \beta' ) \) determines a unique morphism \( f(K, | \cdot |) \to \varphi^* S \), whose underlying morphism of schemes is the sought \( \tilde{\sigma} \). Lastly, notice that the map \( F'(|\{1\}|) \to F(|\{1\}|) \) induced by \( \varphi \), is bijective by propositions 6.5.24 and 6.5.26 (where \( \{1\} \) is the monoid with one element), which means that \( \varphi \) restricts to a bijection on the points of height zero; then remark 12.6.17 implies the second assertion of (ii).

**Theorem 12.6.32.** Let \(( X, \mathcal{M} )\) be a regular log scheme. Then there exists a smooth morphism of log schemes \( f : (X', \mathcal{M}') \to (X, \mathcal{M}) \), whose underlying morphism of schemes is proper and birational, and such that \( X' \) is a regular scheme. More precisely, \( f \) restricts to an isomorphism of schemes \( f^{-1}X_{\text{reg}} \to X_{\text{reg}} \) on the preimage of the open locus of regular points of \( X \).

**Proof.** We use the object \( X : = ((X, \mathcal{M}), F(X, \mathcal{M}), \pi_X) \) attached to \(( X, \mathcal{M} )\) as in remark 12.6.9(ii). Indeed, it is clear that \( F(X, \mathcal{M}) \) is locally fine and saturated, hence theorem 6.6.31 yields an integral, proper, simplicial subdivision \( \varphi : F' \to F(X, \mathcal{M}) \) which restricts to an isomorphism \( \varphi^{-1}F(X, \mathcal{M})_{\text{sim}} \to F(X, \mathcal{M})_{\text{sim}} \). Take \(( f, \varphi ) : \varphi^* X \to X \) to be the cartesian morphism over \( \varphi \), and denote by \(( X', \mathcal{M}' )\) the log scheme underlying \( \varphi^* X \); it follows already from proposition 12.6.31(ii) that \( f \) is proper on the underlying schemes. Next, corollary 12.5.19 shows that \( X_{\text{reg}} = \pi^{-1}F(X, \mathcal{M})_{\text{sim}} \), so \( f \) restricts to an isomorphism \( f^{-1}X_{\text{reg}} \to X_{\text{reg}} \). Furthermore, \( f \) is étale, by proposition 12.6.14(v), hence the log scheme \(( X', \mathcal{M}' )\) is regular (theorem 12.5.28). Finally, again by corollary 12.5.12 we see that \( X' \) is regular.

12.6.33. Let now \(( Y, \mathcal{N} )\) be a regular log scheme, such that \( F(Y, \mathcal{N}) \) is affine (notation of remark 12.6.9(ii)), say isomorphic to \(( \text{Spec} \, P)^g \), for some fine, sharp and saturated monoid \( P \). Let \( I \subset P \) be an ideal generated by two elements \( a, b \in P \), and denote by \( f : (Y', \mathcal{N}') \to (Y, \mathcal{N}) \) the saturated blow up of the ideal \( I \mathcal{N} \) of \( \mathcal{N} \) (see 12.4.49). Set \( U' : = (Y', \mathcal{N}')_{\text{tr}}, U : = (Y, \mathcal{N})_{\text{tr}}, \) and denote \( j : U \to Y, j' : U' \to Y' \) the open immersions. In this situation we have:

**Lemma 12.6.34.** (i) \( H^1(Y', \mathcal{N}'^{\text{gp}}) = 0 \).

(ii) Suppose moreover, that \( R^1 j_U^* \mathcal{O}^g_{U'} = 0 \). Then \( R^1 j_* \mathcal{O}^g_U = 0 \).

**Proof.** (i): Since \( \mathcal{N}'^{\text{gp}} = \pi_X^* \mathcal{O}^{\text{gp}}_{F(Y', \mathcal{N}')} \); claim 12.6.39(ii) and remark 12.6.9(iii) reduce to showing

\[
(12.6.35) \quad H^1(F(Y', \mathcal{N}'), \mathcal{O}^{\text{gp}}_{F(Y', \mathcal{N}')} ) = 0.
\]

However, by corollary 12.6.18(iii), the fan \( F(Y', \mathcal{N}') \) is the saturated blow up of the ideal \( I \mathcal{O}_{F(Y, \mathcal{N})} \) of \( \mathcal{O}_{F(Y, \mathcal{N})} \), hence it admits the affine covering

\[
F(Y', \mathcal{N}') = (\text{Spec} \, P[a^{-1}b]^{\text{sat}})^g \cup (\text{Spec} \, P[b^{-1}a]^{\text{sat}})^g.
\]

Notice now that every affine fan is a local topological space, hence the left hand-side of (12.6.35) is computed by the Čech cohomology of \( \mathcal{O}^{\text{gp}}_{F(Y', \mathcal{N}')} \) relative to this covering (theorem 10.2.24(ii)).
However, the intersection of the two open subsets is \((\text{Spec } P[a^{-1}b, b^{-1}a])^t\), and clearly the restriction map
\[
H^0(\text{Spec } P[a^{-1}b]^{\text{un}}, \mathcal{O}_{F(Y', N')}^0) \to H^0(\text{Spec } P[a^{-1}b, b^{-1}a], \mathcal{O}_{F(Y', N')}^0)
\]
is surjective. The assertion is an immediate consequence.

(ii): Let \(y \in Y\) be any point; according to (12.6.50), the morphism
\[
f \times_Y Y'(y) : (Y,N') \times_Y Y(y) \to (Y(y), N(y))
\]
is the saturated blow up of the ideal \(I_N(y)\); on the other hand, let \(U(y) := U \times_Y Y(y), U'(y) := U' \times_Y Y(y)\) and denote by \(j_y : U(y) \to Y(y)\) and \(j'_y : U'(y) \to Y' \times_Y Y(y)\) the open immersions; in light of proposition 10.1.10(ii), it suffices to show that \(R^1 j'_y \mathcal{O}_{U(y)} = 0\), and the assumption implies that \(R^1 j'_y \mathcal{O}_{U'(y)} = 0\). Summing up, we may replace \(Y\) be \(Y(y)\), and assume from start that \(Y\) is local, and \(y\) is its closed point. From the assumption we get:
\[
H^1(Y', j'_y \mathcal{O}_{U(y)}^\times) = H^1(U', \mathcal{O}_{Y'}^\times) = \text{Pic } U'.
\]
On the other hand, recall that \(N'_{\mathcal{O}^p} = j'_y \mathcal{O}_{U(y)}^\times/\mathcal{O}_{Y'}^\times\) (proposition 12.5.38); combining with (i), we deduce that the natural map
\[
\text{Pic } Y' \to \text{Pic } U'
\]
is surjective. Set \(Y'_0 := f^{-1}(y) \subset Y'\), endow \(Y'_0\) with its reduced subscheme structure, and let \(i : Y'_0 \to Y'\) be the closed immersion. If \(I\) is an invertible ideal of \(P\), then \(f\) is an isomorphism, in which case the assertion is obvious. We may then assume that \(I\) is not invertible, in which case claim 12.4.56(ii) says that there exists a morphism of \((Y, N)\)-schemes \(h : (Y', N') \to \mathbb{P}^1_{(Y, N)}\) inducing an isomorphism of \(\kappa(y)\)-schemes
\[
(12.6.36) \quad (h \times_Y \text{Spec } \kappa(y))_{\text{red}} : Y'_0 \to \mathbb{P}^1_{\kappa(y)}.
\]
Let us remark:

Claim 12.6.37. Let \(S\) be a noetherian local scheme, \(s\) the closed point of \(S\), and \(f : X \to S\) a proper morphism of schemes. Suppose that \(\dim X(s) \leq 1\), and \(H^1(X(s), \mathcal{O}_{X(s)}) = 0\). Then the natural map
\[
\text{Pic } X \to \text{Pic } X(s)
\]
is injective.

Proof of the claim. Say that \(S = \text{Spec } A\) for a local ring \(A\), and denote by \(m_A \subset A\) the maximal ideal. For every \(k \in \mathbb{N}\), set \(S_n := \text{Spec } A/m_A^{k+1}\), and let \(i_n : X_n := X \times_S S_n \to X\) be the closed immersion. Let \(\mathcal{L}\) be any invertible \(\mathcal{O}_X\)-module, and suppose that \(i_0^* \mathcal{L} \simeq \mathcal{O}_{X_0}\); we have to show that \(\mathcal{L} \simeq \mathcal{O}_X\). We notice that, for every \(k \in \mathbb{N}\), the natural map
\[
H^0(X_{k+1}, i_{k+1}^* \mathcal{L}) \to H^0(X_k, i_k^* \mathcal{L})
\]
is surjective: indeed, its cokernel is an \(A\)-submodule of \(H^1(X_0, m_A^k \mathcal{L}/m_A^{k+1} \mathcal{L})\), and since \(\dim X_0 \leq 1\), the natural map
\[
(m_A^k/m_A^{k+1}) \otimes_{\kappa(s)} H^1(X_0, i_0^* \mathcal{L}) \to H^1(X_0, m_A^k/m_A^{k+1} \otimes_{\kappa(s)} \mathcal{L}) \to H^1(X_0, m_A^k \mathcal{L}/m_A^{k+1} \mathcal{L})
\]
is surjective; on the other hand, our assumptions imply that \(H^1(X_0, i_0^* \mathcal{L}) = 0\), whence the contention. Let \(A^\wedge\) be the \(m_A\)-adic completion of \(A\); taking into account [46, Ch.III, Th.4.1.5], we deduce that the natural map
\[
H^0(X, \mathcal{L}) \otimes_A A^\wedge \to H := H^0(X_0, i_0^* \mathcal{L})
\]
is a continuous surjection, for the \(m_A\)-adic topologies. Since \(H\) is a discrete space for this topology, and since the image of \(H^0(X, \mathcal{L})\) is dense in the \(m_A\)-adic topology of \(H^0(X, \mathcal{L}) \otimes_A A^\wedge\), we conclude that the restriction map \(H^0(X, \mathcal{L}) \to H\) is surjective as well. Let \(\pi \in H\) be a global section of \(i_0^* \mathcal{L}\) whose image in \(i_0^* \mathcal{L}_S\) is a generator of the latter \(A_0\)-module, for every
$x \in X_0$, and pick $s \in H^0(X, \mathcal{L})$ whose image in $H$ equals $\pi$. It remains only to check that, for every $x \in X$, the $A$-module $\mathcal{L}_x$ is generated by the image $s_x$ of $s$. However, since $X$ is proper, every $x \in X$ specializes to a point of $X_0$, hence we may assume that $x \in X_0$, in which case one concludes easily, by appealing to Nakayama’s lemma (details left to the reader).

Combining claim [12.6.37] and [96] Prop.11.1(i), we see that the induced map

$$i^* : \text{Pic} Y' \to \text{Pic} Y_0'$$

is injective. Let now $\mathcal{L}$ be any invertible $\mathcal{O}_U$-module; we have to show that $\mathcal{L}$ extends to an invertible $\mathcal{O}_Y$-module (which is then isomorphic to $\mathcal{O}_Y$). However, notice that $f$ restricts to an isomorphism $g : U' \to_U U$, hence $g^* \mathcal{L}$ is an invertible $\mathcal{O}_U$-module, and by the foregoing there exists an invertible $\mathcal{O}_U$-module $\mathcal{L}'$ such that $\mathcal{L}' \mid U' \simeq g^* \mathcal{L}$. In light of the isomorphism ([12.6.36]), there exists an invertible $\mathcal{O}_{\mathbb{P}^1}$-module $\mathcal{L}''$ such that $i^* \mathcal{L}' \simeq i^* h^* \mathcal{L}''$. Therefore

$$\mathcal{L}' \simeq h^* \mathcal{L}''.$$ 

Now, on the one hand, claim 12.6.37 implies that $\mathcal{L}'' = \mathcal{O}_{\mathbb{P}^1}(n)$ for some $n \in \mathbb{N}$; on the other hand, (12.4.17) implies that $h$ restricts to a morphism of schemes $h_{tr} : U' \to \mathbb{G}_{m,Y}$, and $\mathcal{L}_{\mathbb{G}_{m,Y}}'' = \mathcal{O}_{\mathbb{P}^1}(n)|_{\mathbb{G}_{m,Y}} = \mathcal{O}_{\mathbb{G}_{m,Y}}$, so finally $g^* \mathcal{L} = \mathcal{O}_U$, hence $\mathcal{L} = \mathcal{O}_U$, whence the contention.

The following result complements proposition [12.5.38].

**Theorem 12.6.38.** Let $(X, M)$ be any regular log scheme, set $U := (X, M)_{tr}$ and denote by $j : U \to X$ the open immersion. Then we have:

$$R^1 j_* \mathcal{O}_U^\times = 0.$$

**Proof.** We begin with the following general:

**Claim 12.6.39.** Let $\pi : T_1 \to T_2$ be a continuous open and surjective map of topological spaces, such that $\pi^{-1}(t)$ is an irreducible topological space (with the subspace topology) for every $t \in T_2$. Then, we have:

(i) For every sheaf $S$ on $T_2$, the natural map $S \to S_\pi \pi^* S$ is an isomorphism.

(ii) For every abelian sheaf $S$ on $T_2$, the natural map $S[0] \to R\pi_* \pi^* S$ is an isomorphism in $\text{D}(\mathbb{Z}_{T_2^{-}\text{-Mod}})$.

**Proof of the claim.** (i): Since $\pi$ is open, $\pi^* S$ is the sheaf associated to the presheaf $U \mapsto S(\pi U)$, for every open subset $U$ of $T_1$. We show, more precisely, that this presheaf is already a sheaf; since $\pi$ is surjective, the claim shall follow immediately. Now, let $U \subset T_1$ be an open subset, and $(U_i \mid i \in I)$ a family of open subsets of $X$ covering $U$; for every $i,j \in I$, set $U_{ij} := U_i \cap U_j$. It suffices to show that $S(\pi U)$ is the equalizer of the two maps:

$$\prod_{i \in I} S(\pi U_i) \longrightarrow \prod_{i,j \in I} S(\pi U_{ij}).$$

Since $S$ is a sheaf, the latter will hold, provided we know that $\pi U_i \cap \pi U_j = \pi U_{ij}$ for every $i,j \in I$. Hence, let $t \in \pi U_i \cap \pi U_j$; this means that $\pi^{-1}(t) \cap U_i \neq \emptyset$ and $\pi^{-1}(t) \cap U_j \neq \emptyset$. Since $\pi^{-1}(t)$ is irreducible, we deduce that $\pi^{-1}(t) \cap U_{ij} \neq \emptyset$, as required.

(ii): The proof of (i) also shows that, for every flabby abelian sheaf $J$ on $T_2$, the abelian sheaf $\pi^* J$ is flabby on $T_1$. Hence, if $S$ is any abelian sheaf on $T_2$, we obtain a flabby resolution of $\pi^* S$ of the form $\pi^* J_\bullet$, by taking a flabby resolution $S \to J_\bullet$ of $S$ on $T_2$. According to remark [1.3.29] iv), there is a natural isomorphism

$$\pi_\ast \pi^* J \sim R\pi_* \pi^* S$$

in $\text{D}(\mathbb{Z}_{T_2^{-}\text{-Mod}})$. Then the assertion follows from (i).

\[ \diamond \]
After these preliminaries, let us return to the log scheme \((X, M)\), and its associated object
\[ X := ((X, M), F(X, M), \pi_X) \] . The assertion to prove is local on \(X\), hence we may assume that \(F(X, M) = (\text{Spec } P)^{\dagger}\), for some sharp, fine and saturated monoid \(P\). Next, by theorem 12.6.32 (and its proof) there exists an integral proper simplicial subdivision \(\varphi : F' \to F(X, M)\), such that the log scheme \((X', M')\) underlying \(\varphi^* X\) is regular, \(X'\) is regular, and the morphism \(X' \to X\) restricts to an isomorphism \(U' := (X', M')_{tr} \to U\). In this situation, we may find a further subdivision \(\varphi' : F'' \to F'\) such that both \(\varphi'\) and \(\varphi \circ \varphi'\) are compositions of saturated blow up of ideals generated by at most two elements of \(P\) (example 6.6.15(iii)). Say that \(\varphi \circ \varphi' = \varphi' \circ \varphi_{r-1} \cdots \circ \varphi_1\), where each \(\varphi_i\) is a saturated blow up of the above type. By proposition 12.6.14(iii), we deduce a sequence of morphisms of log schemes

\[ (X_1, M_1) \twoheadrightarrow \cdots \twoheadrightarrow (X_{r-1}, M_{r-1}) \xrightarrow{g_{r-1}} (X_r, M_r) \xrightarrow{g_r} (X_{r+1}, M_{r+1}) := (X, M) \]

each of which is the blow up of a corresponding ideal, and by the same token, \(\varphi'\) induces a morphism \(g : (X_1, M_1) \to (X', M')\) of \((X, M)\)-schemes. For every \(i = 1, \ldots, r + 1\), set \(U_i := (X_i, M_i)_{tr}\), and let \(j_i : U_i \to X_i\) be the open immersion; especially, \(U_{r+1} = U\). We shall show, by induction on \(i\), that

\[ R^1 j_i \mathcal{O}_{U_i}^{\times} = 0 \quad \text{for } i = 1, \ldots, r + 1. \]

Notice first that the stated vanishing translates the following assertion. For every \(x \in X_i\) and every invertible \(\mathcal{O}_{U_i}\)-module \(\mathcal{L}\), there exists an open neighborhood \(U_x\) of \(x\) in \(X_i\) such that \(\mathcal{L}_{|U_x \cap U_i}\) extends to an invertible \(\mathcal{O}_{U_i}\)-module. However, it follows immediately from propositions 11.3.8 and 11.3.15 that every invertible \(\mathcal{O}_{U_i}\)-module extends to an invertible \(\mathcal{O}_{X_i}\)-module. Since \(g\) restricts to an isomorphism \(U_i = g^{-1}U' \cong U'\), we easily deduce that every invertible \(\mathcal{O}_{U_i}\)-module extends to an invertible \(\mathcal{O}_{X_i}\)-module (namely : if \(\mathcal{L}\) is such a module, extend \(g_{|U_i} \mathcal{L}\) to an invertible \(\mathcal{O}_{X_i}\)-module, and pull the extension back to \(X_i\), via \(g^*\)). Summing up, we see that (12.6.40) holds for \(i = 1\).

Next, suppose that (12.6.40) has already been shown to hold for a given \(i \leq r\); by lemma 12.6.34(ii), it follows that (12.6.40) holds for \(i + 1\), so we are done. \(\square\)

12.6.41. Let \(X\) be a scheme, \(M\) a fine log structure on the Zariski site of \(X\), \(x\) a point of \(X\), and notice that every fractional ideal of \(M_x\) is finitely generated (lemma 6.4.37(iv)). Say that \(X(x) = \text{Spec } A\); in view of lemma 6.4.43(ii) there is a natural map of abelian groups

\[ \text{Div}(M_x) \to \text{Div}(A). \]

Composing with the map \(I \mapsto I^{-}\) as in (11.3.12), we get, by virtue of loc.cit., a map

\[ \text{Div}(M_x) \to \text{Div}(X(x)). \]

Corollary 12.6.43. With the notation of 12.6.41, suppose furthermore that \((X, M)\) is regular at the point \(x\). Then (12.6.42) induces an isomorphism

\[ \overline{\text{Div}}(M_x) \cong \overline{\text{Div}}(X(x)). \]

Proof. By virtue of proposition 6.4.53(ii) (and remark 11.3.11(i)), the map under investigation is already known to be injective. To show surjectivity, let \(K\) be the field of fractions of \(A\), and \(L \subset K\) any reflexive fractional ideal of \(A\); we may then regard \(\mathcal{L}' := L^{-}\) as a coherent \(\mathcal{O}_X\)-submodule of \(i_* \mathcal{O}_{X_0}\), where \(i : X_0 \to X\) is the inclusion map of the subscheme \(X_0 := \text{Spec } K\). By proposition 11.3.15, the \(\mathcal{O}_U\)-module \(\mathcal{L}'\) is invertible, hence it extends to an invertible \(\mathcal{O}_{X(x)}\)-module \(\mathcal{L}'\), by virtue of theorem 12.6.38. Since \(X(x)\) is local, \(\mathcal{L}'\) is a free \(\mathcal{O}_{X(x)}\)-module, and therefore \(\mathcal{L}' \cong \mathcal{O}_U\). Thus, pick \(a \in \mathcal{L}(U) \subset K\) which generates \(\mathcal{L}_U\); after replacing \(L\) by \(a^{-1}L\), we may assume that \(\mathcal{L}_U = \mathcal{O}_U\) as subsheaves of \(i_* \mathcal{O}_{X_0}\). Let \(\Sigma\) be the set of points of height one of \(X(x)\) contained in \(X(x) \setminus U\); for each \(y \in \Sigma\), the maximal ideal \(m_y\) of \(\mathcal{O}_{X(x), y}\) is
generated by a single element \( a_y \), and there exists \( k_y \in \mathbb{Z} \) such that \( a_y^{k_y} \) generates the \( \mathcal{O}_{X(x), y} \)-submodule \( \mathcal{L}_y \) of \( K \). To ease notation, let \( P := M_x \), and denote \( \psi : X(x) \to \text{Spec} \, P \) the natural continuous map; also, let \( m_{\psi(y)} \) be the maximal ideal of the localization \( P_{\psi(y)} \) for every \( y \in X(x) \), and set
\[
I := \bigcap_{y \in \Sigma} m_{\psi(y)}^{k_y}.
\]
In light of lemma [6.4.37](i,ii) and proposition [6.4.48], it is easily seen that \( I/P \) is a reflexive fractional ideal of the fine and saturated monoid \( P^* \), so \( I \) is a reflexive fractional ideal of \( P \). Then \( IA \subset K \) is a reflexive fractional ideal of \( A \). Set \( \mathcal{L}'' := (IA)^\circ \subset \mathcal{O}_{X_0}^\circ \), then \( \mathcal{L}''_{U_y} = \mathcal{L}_{U_x} \) and \( \mathcal{L}''_y = \mathcal{L}_y \) for every \( y \in \Sigma \). It follows that, for every \( y \in \Sigma \), there exists an open neighborhood \( U_y \) of \( y \) in \( X(x) \) such that \( \mathcal{L}''_{U_y} = \mathcal{L}_{U_y} \). Let \( U' := U \cup \bigcup_{y \in \Sigma} U_y \), and denote by \( j' : U' \to X(x) \) the open immersion. Notice that \( \delta'(y, \mathcal{O}_X) \geq 2 \) for every \( y \in X \setminus U' \) (corollary [12.5.13]). In light of proposition [11.3.38](ii) (and remark [11.3.11](i)), we deduce
\[
\mathcal{L} = j_*^* \mathcal{L}|_{U_x} = j'_*^* \mathcal{L}|_{U_x} = \mathcal{L}''
\]
whence the contention. □

12.6.44. Let \( M \) be a log structure on the Zariski site of a local scheme \( X \), such that \( (X, M) \) is a regular log scheme. Let \( x \in X \) be the closed point, say that \( X = \text{Spec} \, B \) for some local ring \( B \), and let \( \beta : P \to B \) a chart for \( M \) which is sharp at \( x \). As usual, if \( M \) is any \( B \)-module, we denote \( M^\circ \) the quasi-coherent \( \mathcal{O}_X \)-module arising from \( M \).

**Theorem 12.6.45.** In the situation of (12.6.44), suppose as well that \( \dim P = 2 \) and \( \dim X = 2 \). Then every indecomposable reflexive \( \mathcal{O}_X \)-module is isomorphic to \( (IB)^\circ \), for some reflexive fractional ideal \( I \) of \( P \). (Notation of (6.4.42).)

**Proof.** Set \( Q := \text{Div}_+(P) \) and define \( \varphi : P \to Q \) as in example [6.4.62]. The chart \( \beta \) defines a morphism \( \psi : (X, M) \to \text{Spec} (\mathbb{Z}, P) \), and we let \( (X', M') \) be the fibre product in the cartesian diagram
\[
\begin{array}{ccc}
(X', M') & \longrightarrow & \text{Spec} (\mathbb{Z}, Q) \\
\downarrow & & \downarrow \\
(X, M) & \psi & \text{Spec} (\mathbb{Z}, P).
\end{array}
\]
Arguing as in the proof of claim [13.3.35], it is easily seen that \( X' \) is a local scheme and \( (X', M') \) is regular. Moreover, \( X' \) is a regular scheme, since \( Q \) is a free monoid (corollary [12.5.19], and \( f \) is a finite morphism of Kummer type (lemma [13.3.6]).

**Claim 12.6.46.** The \( \mathcal{O}_X \)-module \( f_* \mathcal{O}_{X'} \) is isomorphic to a finite direct sum \( (I_1 B \oplus \cdots \oplus I_k B)^\circ \), where \( I_1, \ldots, I_k \) are reflexive fractional ideals of \( P \), and \( \mathcal{O}_X \) is a direct summand of \( f_* \mathcal{O}_{X'} \).

**Proof of the claim.** In view of example [6.4.62] we see that \( f_* \mathcal{O}_{X'} = (Q \otimes P B)^\circ \) is the direct sum of the \( \mathcal{O}_X \)-modules \( (\text{gr}_Q \otimes P B)^\circ \), where \( \gamma \) ranges over the elements of \( Q^{sp} / P^{sp} \), and \( \text{gr}_Q \) denotes the \( \varphi \)-grading of \( Q \). But for each such \( \gamma \), the natural map \( \text{gr}_\gamma Q \otimes P B \to \text{gr}_\gamma Q \cdot B \) is an isomorphism, since \( B \) is \( P \)-flat (proposition [12.5.16](ii)). This shows the first assertion, and the second is clear as well, since \( \text{gr}_0 Q = P \). □

Denote by \( x' \) the closed point of \( X' \); from corollary [12.5.20](i) we see that \( U := (X, M)_1 \) is the complement of \( \{x\} \) and \( U' := (X', M')_1 \) is the complement of \( \{x'\} \) (notation of definition [12.2.7](ii)). Let also \( j : U \to X \) and \( j' : U' \to X' \) be the open immersions.

**Claim 12.6.47.** (i) The restriction \( g : U' \to U \) of \( f \) is a flat morphism of schemes.

(ii) The functor \( j^* : \mathcal{O}_X - \text{Rflx} \to \mathcal{O}_{U'} - \text{Rflx} \) is an equivalence (see definition [11.3.1](iii)).
Proof of the claim. (i): It suffices to check that the restriction \( \text{Spec}(\mathbb{Z}, Q)_1 \to \text{Spec}(\mathbb{Z}, P)_1 \) of \( \text{Spec}(\mathbb{Z}, \varphi) \) is flat. However, we have the affine open covering

\[
\text{Spec}(\mathbb{Z}, P)_1 = \text{Spec} \mathbb{Z}[P_{p_1}] \cup \text{Spec} \mathbb{Z}[P_{p_2}]
\]

where \( p_1, p_2 \subset P \) are the two prime ideals of height one (see example 6.4.17(i)). Hence, we are reduced to showing that the morphism of log schemes underlying

\[
\text{Spec}(\mathbb{Z}, \varphi_{p_1}) : \text{Spec}(\mathbb{Z}, Q_{p_1}) \to \text{Spec}(\mathbb{Z}, P_{p_1})
\]

is flat for \( i = 1, 2 \). However, it is clear that \( Q_{p_i} \) is an integral \( P_{p_i} \)-module, hence it suffices to check that \( Q_{p_i} \) is a flat \( P_{p_i} \)-module, for \( i = 1, 2 \) (proposition 6.1.53), or equivalently, that \( Q_{p_i}^{\sharp} \) is a flat \( P_{p_i}^{\sharp} \)-module (corollary 6.1.50(ii)). The latter assertion follows immediately from the discussion of (6.4.59).

(ii): From proposition 11.3.8 we see that \( j^* \) is full and essentially surjective. Moreover, it follows from remark 11.3.5 that every reflexive \( \mathcal{O}_X \)-module is \( S_1 \), so \( j^* \) is also faithful (details left to the reader).

In light of claim 12.6.47(ii), it suffices to show that every indecomposable reflexive \( \mathcal{O}_U \)-module \( \mathcal{F} \) is isomorphic to \( (IB)_{\mid U}^{\gamma} \), for some reflexive fractional ideal \( I \) of \( P \). However, for such \( \mathcal{F} \), claim 12.6.47(i) and lemma 11.3.7(i) imply that \( g^* \mathcal{F} \) is a reflexive \( \mathcal{O}_U \)-module. From proposition 11.3.8 and corollary 10.4.23 we deduce that \( \delta'((x), j^*g^* \mathcal{F}) \geq 2 \), so \( j^*g^* \mathcal{F} \) is a free \( \mathcal{O}_X \)-module of finite rank (cfr. Ch.0, Prop.17.3.4), and finally, \( g^* \mathcal{F} \) is a free \( \mathcal{O}_U \)-module of finite rank. Taking into account claim 12.6.46 it follows that \( g_*g^* \mathcal{F} = \mathcal{F} \otimes_{\mathcal{O}_U} g_* \mathcal{O}_U \) is a direct sum of \( \mathcal{O}_U \)-modules of the type \( (IB)_{\mid U}^{\gamma} \), for various \( I \in \text{Div}(P) \); moreover, \( \mathcal{F} \) is a direct summand of \( g_*g^* \mathcal{F} \). Then, we may find a decomposition \( g_*g^* \mathcal{F} = \mathcal{F}_1 \oplus \cdots \oplus \mathcal{F}_t \) such that \( \mathcal{F}_i \) is an indecomposable \( \mathcal{O}_U \)-module for \( i = 1, \ldots, t \), and \( \mathcal{F} = \mathcal{F} \) (details left to the reader).

On the other hand, notice that

\[
\text{End}_{\mathcal{O}_U}((IB)_{\mid U}^{\gamma}) = \text{End}_B(IB) \quad \text{(claim 12.6.47(ii))}
\]

\[
= (IB : IB) \quad \text{(by 6.4.51)}
\]

\[
= (I : I)B \quad \text{(lemma 6.4.43(i))}
\]

\[
= B \quad \text{(proposition 6.4.53(i))}
\]

for every \( I \in \text{Div}(P) \). Now the contention follows from theorem 7.11.3.

12.6.48. Let now \( (X_{\acute{e}t}, M) \) be a quasi-coherent log scheme on the étale site of \( X \). Pick a covering family \( (U_\lambda \mid \lambda \in \Lambda) \) of \( X_{\acute{e}t} \), and for every \( \lambda \in \Lambda \), a chart \( P_{\lambda, U_\lambda} \to M_{U_\lambda} \). The latter induce isomorphisms of log schemes \( (U_\lambda, M_{U_\lambda}) \to \tilde{u}^*(U_{\lambda, \text{Zar}}, P_{U_\lambda}^{\text{log}}) \) (see (12.2.2)); in other words, every quasi-coherent log structure on \( X_{\acute{e}t} \) descends, locally on \( X_{\acute{e}t} \), to a log structure on the Zariski site. However, \( (X_{\acute{e}t}, M) \) may fail to descend to a unique log structure on the whole of \( X_{\text{Zar}} \). Our present aim is to show that, at least under a few more assumptions on \( M \), we may find a blow up \( (X'_{\acute{e}t}, M') \to (X_{\acute{e}t}, M) \) such that \( (X'_{\acute{e}t}, M') \) descends to a log structure on \( X'_{\text{Zar}} \). To begin with, for every \( \lambda \in \Lambda \) let

\[
T_\lambda := (\text{Spec}(P_\lambda))^\sharp \quad \text{and} \quad S_\lambda := \text{Spec} \mathbb{Z}[P_\lambda].
\]

Also, let \( S_\lambda := (\text{Spec}(\mathbb{Z}, P_\lambda), T_\lambda, \psi_{P_\lambda}) \) be the object of \( \mathcal{K} \) attached to \( P_\lambda \), as in example 12.6.5(i). From the isomorphism

\[
(U_{\lambda, \text{Zar}}, \tilde{u}_\lambda M_{U_\lambda}) \cong U_\lambda \times_{S_\lambda} \text{Spec}(\mathbb{Z}, P_\lambda)
\]
we deduce an object
\[ U_\lambda := U_\lambda \times S_\lambda \subseteq (U_{\lambda, \text{Zar}}, \tilde{u}_s M_{[U_\lambda]}, T_\lambda, \psi_\lambda). \]

Suppose now that \( M \) is a fs log structure; then we may choose for each \( \lambda \) a fine and saturated
monoid (lemma \[ 12.1.18 \)(iii)). Next, suppose that \( X \) is quasi-compact; in this case we may
assume that \( \lambda \) is a finite set, hence \( \mathcal{S} := \{ \lambda \mid \lambda \in \Lambda \} \) is a finite set of monoids, and con-
sequently we may choose a finite sequence of integers \( c(\mathcal{S}) \) fulfilling the conditions of \( (6.6.25) \)
relative to the category \( \mathcal{S} \)-Fan. Then, for every \( \lambda \in \Lambda \) we have a well defined integral roof
\( \rho_\lambda : T_\lambda(\mathbb{Q}_+) \to \mathbb{Q}_+ \), and we denote by \( f_\lambda : T(\rho_\lambda) \to T_\lambda \) the corresponding subdivision. There
follows a cartesian morphism
\[ f_\lambda^* U_\lambda \to U_\lambda \]
whose underlying morphism of log schemes is a saturated blow up of the ideal \( \mathcal{I}_{\rho_\lambda, \tilde{u}_s M_{[U_\lambda]}} \)
(proposition \[ 6.6.13 \] and corollary \[ 12.6.18 \]). Next, for \( \lambda, \mu \in \Lambda \), set \( U_{\lambda, \mu} := U_\lambda \times U_\mu \) and let
\[ U_{\lambda, \mu} := ((U_{\lambda, \mu}, \tilde{u}_s M_{[U_{\lambda, \mu}]}, T_\lambda, \psi_{\lambda, \mu}) \]
where \( \psi_{\lambda, \mu} \) is the composition of \( \psi_\lambda \) and the projection \( U_{\lambda, \mu} \to U_\lambda \). Denote by \( (U_{\lambda, \mu}, \tilde{M}_{\lambda, \mu}) \) (resp.
\( (U_{\lambda, \mu}^\sim, \tilde{M}_{\lambda, \mu}^\sim) \)) the log scheme underlying \( f_\lambda^* U_\lambda \) (resp. \( f_\lambda^* U_{\lambda, \mu} \)). Also, for any \( \lambda, \mu, \gamma \in \Lambda \), let
\( \pi_{\lambda, \mu, \gamma} : U_{\lambda, \mu} \times U_\gamma \to U_{\lambda, \mu} \) be the natural projection.

**Lemma 12.6.49.** In the situation of \( (12.6.48) \), we have :

(i) There exists a unique isomorphism of log schemes \( g_{\lambda, \mu} : (U_{\lambda, \mu}^\sim, \tilde{M}_{\lambda, \mu}^\sim) \to (U_{\mu, \lambda}^\sim, \tilde{M}_{\mu, \lambda}^\sim) \)
fitting into a commutative diagram :

\[
\begin{array}{ccc}
(U_{\lambda, \mu}^\sim, \tilde{M}_{\lambda, \mu}^\sim) & \xrightarrow{g_{\lambda, \mu}} & (U_{\mu, \lambda}^\sim, \tilde{M}_{\mu, \lambda}^\sim) \\
\downarrow & & \downarrow \\
U_{\lambda, \mu} & \xrightarrow{\sim} & U_{\mu, \lambda}
\end{array}
\]

whose vertical arrows are the saturated blow up morphisms.

(ii) There exist natural isomorphisms of \( \mathcal{O}_{U_{\lambda, \mu}} \)-modules

\[ \omega_{\lambda, \mu} : g_{\lambda, \mu}^* \mathcal{O}_{U_{\lambda, \mu}}(1) \xrightarrow{\sim} \mathcal{O}_{U_{\mu, \lambda}}(1) \]

such that \( (\pi_{\mu, \gamma, \lambda}^*, \omega_{\lambda, \mu}) \circ (\pi_{\lambda, \mu, \gamma}^*, \omega_{\mu, \lambda}) = \pi_{\lambda, \mu, \gamma}^* \omega_{\mu, \lambda} \) for every \( \lambda, \mu, \gamma \in \Lambda \).

**Proof.** (i): By the universal property of the saturated blow up, it suffices to show that :

\[ (12.6.50) \quad \mathcal{I}_{\rho_\lambda, \tilde{u}_s M_{[U_{\lambda, \mu}]}} = \mathcal{I}_{\rho_\mu, \tilde{u}_s M_{[U_{\mu, \lambda}]}} \quad \text{on} \quad U_{\lambda, \mu} = U_{\mu, \lambda}. \]

The assertion is local on \( U_{\lambda, \mu} \), hence let \( x \in U_{\lambda, \mu} \) be any point; we get an isomorphism of
\( \tilde{u}_s M_{[x]} \)-monoids :

\[ \mathcal{O}_{T_\lambda, \psi_{\lambda, \mu}(x)} \xrightarrow{\sim} \mathcal{O}_{T_\mu, \psi_{\mu, \lambda}(x)} \]

whence an isomorphism of fans \( U(\psi_{\lambda, \mu}(x)) \xrightarrow{\sim} U(\psi_{\mu, \lambda}(x)) \) (notation of \( (6.5.16) \)). Therefore, the
subset \( U(x) := \psi_{\lambda, \mu}^{-1} U(\psi_{\lambda, \mu}(x)) \cap \psi_{\mu, \lambda}^{-1} U(\psi_{\mu, \lambda}(x)) \) is an open neighborhood of \( x \) in \( U_{\lambda, \mu} \), and both
\( \psi_{\lambda, \mu} \) and \( \psi_{\mu, \lambda} \) factor through the same morphism of monoidal spaces :

\[ \psi(x) : (U(x), (\tilde{u}_s M_{[x]})) \to F(x) := (\text{Spec} \tilde{u}_s M_{[x]})^\sharp \]

and open immersions \( F(x) \to T_\lambda \) and \( F(x) \to T_\mu \). It then follows from \( (6.6.25) \) that the
preimage of \( \mathcal{I}_{\rho_\lambda} \) on \( F(x) \) agrees with the preimage of \( \mathcal{I}_{\rho_\mu} \), whence the contention.

(ii): By inspecting the definitions, it is easily seen that the epimorphism \( (10.6.24) \) identifies naturally \( \mathcal{O}_{U_{\lambda, \mu}^\sim}(1) \) to the ideal \( \mathcal{I}_{\rho_\mu, \mathcal{O}_{U_{\lambda, \mu}^\sim}} \) of \( \mathcal{O}_{U_{\lambda, \mu}^\sim} \) generated by the image of \( \mathcal{I}_{\rho_\lambda, \tilde{u}_s M_{[U_{\lambda, \mu}]}} \). Hence
the assertion follows again from \( (12.6.50) \).
12.6.51. Lemma[12.6.49] implies that

\[(U^\sim_{\lambda}, \vartheta_{U^\sim_{\lambda}}(1)), (g_{\mu}, \omega_{\mu}) \mid \lambda, \mu \in \Lambda)\]

is a descent datum – relative to the faithfully flat and quasi-compact morphism \(\coprod_{\lambda \in \Lambda} U_{\lambda} \to X\) – for the fibred category of schemes endowed with an ample invertible sheaf. According to [65], Exp.VIII, Prop.7.8, such a datum is effective, hence it yields a projective morphism \(\pi : X^\sim \to X\) together with an ample invertible sheaf \(\mathcal{O}_{X^\sim}(1)\) on \(X^\sim\), with isomorphisms \(g_\lambda : X^\sim \times_X U_{\lambda} \overset{\sim}{\to} U^\sim_{\lambda}\) of \(U_{\lambda}\)-schemes and \(\pi^\sim_{\lambda} \mathcal{O}_{X^\sim}(1) \overset{\sim}{\to} g_\lambda^* \mathcal{O}_{U^\sim_{\lambda}}(1)\) of invertible modules.

Then the datum \((\tilde{u}^* M^\sim_{\lambda}, \tilde{u}^* \log g_{\mu}) \mid \lambda, \mu \in \Lambda)\) likewise determines a unique sheaf of monoids \(\tilde{M}^\sim\) on \(X^\sim_{\et}\), and the structure maps of the log structures \(M^\sim\) glue to a well defined morphism of sheaves of monoids \(\tilde{M}^\sim \to \mathcal{O}_{X^\sim_{\et}}\), so that \((X^\sim_{\et}, \tilde{M}^\sim)\) is a log scheme, and the projection \(\pi\) extends to a morphism of log schemes \((\pi, \log \pi) : (X^\sim_{\et}, \tilde{M}^\sim) \to (X_{\et}, M)\).

**Proposition 12.6.52.** In the situation of [12.6.51], the counit of adjunction

\[\tilde{u}^* u_* (X^\sim_{\et}, \tilde{M}^\sim) \to (X^\sim_{\et}, M^\sim)\]

is an isomorphism.

**Proof.** (This is the counit of the adjoint pair \((\tilde{u}^*, u_*)\) of \((12.1.6)\), relating the categories of log structures on \(X^\sim_{\zar}\) and \(X^\sim_{\et}\).) Recall that there exist natural epimorphisms \((\mathcal{O}^{\sharp \oplus}_{\rho_{\lambda}})_{T(\rho_{\lambda})} \to \mathcal{O}_{T(\rho_{\lambda})}, Q\) (see (6.6.27)), which induce epimorphisms of \(U^\sim_{\lambda,zar}\)-monoids

\[\vartheta_\lambda : (\mathcal{O}^{\sharp \oplus}_{\rho_{\lambda}})_{U^\sim_{\lambda,zar}} \to (\tilde{M}^\sim_{\lambda})_Q\]

for every \(\lambda \in \Lambda\).

The compatibility with open immersions expressed by (6.6.28) implies that the system of maps \((\tilde{u}^* \vartheta_\lambda \mid \lambda \in \Lambda)\) glues to a well defined epimorphism of \(X^\sim_{\et}\)-monoids:

\[\vartheta : (\mathcal{O}^{\sharp \oplus}_{\rho_{\lambda}})_{X^\sim_{\et}} \to (M^\sim)^2_Q\]

In view of lemma 4.9.27(ii), it follows that the counit of adjunction:

\[\tilde{u}^* u_* (M^\sim)^2_Q \to (M^\sim)^2_Q\]

is an isomorphism. By applying again lemma 4.9.27(ii) to the monomorphism \((M^\sim)^2_Q \to (M^\sim)^2_Q\), we deduce that also the counit

\[\tilde{u}^* u_* (M^\sim)^2_Q \to (M^\sim)^2_Q\]

is an isomorphism. Then the assertion follows from proposition [12.2.3](ii). \(\square\)

**Corollary 12.6.53.** Let \((X_{\et}, M)\) be a quasi-compact regular log scheme. Then there exists a smooth morphism of log schemes \((X_{\et}', M') \to (X_{\et}, M)\) whose underlying morphism of schemes is proper and birational, and such that \(X'\) is a regular scheme. More precisely, \(f\) restricts to an isomorphism \((X'_{\et}, M')_{tr} \to (X_{\et}, M)_{tr}\) on the trivial loci.

**Proof.** Given such \((X_{\et}, M)\), we construct first the morphism \(\pi : (X^\sim_{\et}, M^\sim) \to (X_{\et}, M)\) as in (12.6.51). Since \(\pi \times_X \mathbf{1}_{U_{\lambda}}\) is proper for every \(\lambda \in \Lambda\), if follows that \(\pi\) is proper ([49], Ch.IV, Prop.2.7.1)]. Likewise, notice that each morphism \(U^\sim_{\lambda} \to U_{\lambda}\) induces an isomorphism \((U^\sim_{\lambda}, M^\sim_{\lambda})_{tr} \overset{\sim}{\to} (U_{\lambda}, \tilde{u}_* M_{U_{\lambda}})_{tr}\) (remark [12.6.17]). It follows easily that \(\pi\) restricts an isomorphism on the trivial loci. Hence, we may replace \((X_{\et}, M)\) by \((X^\sim_{\et}, \tilde{M}^\sim)\). Then, by corollary (12.3.2)(ii) and proposition (12.6.52), we are further reduced to showing that there exists a proper morphism \(\pi' : (X^\sim_{\zar}, M') \to u_* (X^\sim_{\et}, M^\sim)\) with \(X'\) regular, restricting to an isomorphism on the trivial loci. However, in light of lemma (12.5.21) (and again, proposition (12.6.52), the sought \(\pi'\) is provided by the more precise theorem [12.6.32]. \(\square\)
Lemma 12.7.1. In the situation of (12.7), for every point \( s \in S \), the fibre \( f^{-1}(s) \) is either empty, or else it is pure-dimensional, of dimension

\[
\dim f^{-1}(s) = \dim Q - \dim P = \text{rk}_Z \text{Coker } \lambda^{gp}.
\]

Proof. To begin with, notice that \( \lambda^{-1}Q^\times = P^\times \), whence the second stated identity, in view of corollary 6.4.10(i). To prove the first stated identity, we easily reduce to the case where \( R \) is a field. Notice that the image of \( f \) is an open subset \( U \subset S \) (Ch.IV, Th.2.4.6)), especially \( U \) (resp. \( S' \)) is pure-dimensional of dimension \( \text{rk}_Z P^{gp} \) (resp. \( \text{rk}_Z Q^{gp} \)) by claim 11.6.36(ii). Hence, fix any closed point \( s \in S \), and set \( X := f^{-1}(s) \). From Ch.IV, Cor.6.1.2 we deduce that, for every closed point \( s' \in X \), the Krull dimension of \( \mathcal{O}_{X,s} \) equals \( r := \text{rk}_Z \text{Coker } \lambda^{gp} \). More precisely, say that \( Z \subset X \) is any irreducible component; we may find a closed point \( s' \in Z \) which does not lie on any other irreducible component of \( X \), and then the foregoing implies that the dimension of \( Z \) equals \( r \), as stated.

Next, let \( s \in U \) be any point, and denote \( K \) the residue field of \( \mathcal{O}_{U,s} \), and \( \pi : R[P] \to K \) the natural map. Let \( y \in \text{Spec } K[P] \) be the \( K \)-rational closed point such that \( a(y) = \pi(a) \) for every \( a \in P \); then the image of \( y \) in \( S \) equals \( s \), and if we let \( f_K := \text{Spec } K[\lambda] \), we have an isomorphism of \( K \)-schemes \( f_K^{-1}(y) \sim f^{-1}(s) \). The foregoing shows that \( f_K^{-1}(y) \) is pure-dimensional of dimension \( r \), hence the same holds for \( f^{-1}(s) \).

Now, let us fix \( s \in S \), such that \( f^{-1}(s) \neq \emptyset \), and suppose that \( \psi_P(s) = m_P \) is the closed point of \( T_P \). For every \( q \in \varphi^{-1}(m_P) \), the closure \( \overline{\{q\}} \) of \( \{q\} \) in \( T_Q \) is the image of the natural map \( \text{Spec } Q/q \to T_Q \). We deduce natural isomorphisms of schemes:

\[
S_0 := \psi_P^{-1}\{m_P\} \sim \text{Spec } R(P/m_P) \quad S'_q := \psi_Q^{-1}\{q\} \sim \text{Spec } R(Q/q)
\]

under which, the restriction \( f_q : S'_q \to S_0 \) of \( f \) is identified with \( \text{Spec } R(\lambda_q) \), where \( \lambda_q : P/m_P \to Q/q \) is induced by \( \lambda \). The latter is an integral and injective morphism as well (corollary 6.1.52). Explicitly, set \( F := Q \setminus q \), and let \( \lambda_F : P^\times \to F \) be the restriction of \( \lambda \); then \( \lambda_q = (\lambda_F)_{\circ} \), and lemma 12.7.1 yields the identity:

\[
\dim f_q^{-1}(s) = \dim Q/q = \dim Q - \text{ht } q.
\]

Also, notice that \( T_Q \) is a finite set under the current assumptions (lemma 6.1.21(iii)), and clearly

\[
f^{-1}(s) = \bigcup_{q \in \text{Max}(\varphi^{-1}m_P)} f_q^{-1}(s)
\]

where, for a topological space \( T \), we denote by \( \text{Max}(T) \) the set of maximal points of \( T \). Therefore, for every irreducible component \( Z \) of \( f^{-1}(s) \) there must exist \( q \in \text{Max}(\varphi^{-1}m_P) \) such that \( Z \subset f_q^{-1}(s) \), and especially,

\[
\dim f^{-1}(s) = \dim f_q^{-1}(s).
\]

Conversely, we claim that (12.7.3) holds for every \( q \in \text{Max}(\varphi^{-1}m_P) \). Indeed, suppose that \( \dim f_q^{-1}(s) < \dim f^{-1}(s) \) for one such \( q \), and let \( Z \) be an irreducible component of \( f_q^{-1}(s) \); let also \( Z' \) be an irreducible component of \( f^{-1}(s) \) containing \( Z \). By the foregoing, there exists \( q' \in \text{Max}(\varphi^{-1}m_P) \) with \( Z' \subset f_{q'}^{-1}(s) \). Set \( q'' := q \cup q' \); then clearly \( q'' \in \varphi^{-1}(m_P) \), and

\[
\overline{\{q''\}} = \overline{\{q\}} \cap \overline{\{q'\}}.
\]
Especially, \( Z \subset f_q^{-1}(s) \); however, it follows from (12.7.2) that \( \dim f_q^{-1}(s) < \dim f_q^{-1}(s) \) (since \( \text{ht } q < \text{ht } q'' \)); but this is absurd, since \( \dim Z = \dim f_q^{-1}(s) \) (lemma 12.7.1). The same counting argument also shows that every maximal point of \( f^{-1}(s) \) gets mapped necessarily to a maximal point of \( \varphi^{-1}(m_P) \); in other words, we have shown that \( \psi_Q \) restricts to a surjective map:

\[
\text{Max}(f^{-1}(s)) \to \text{Max}(\varphi^{-1}(m_P)).
\]

More precisely, let \( s' \in f^{-1}(s) \) be a point such that \( \psi_Q(s') = m_Q \), the closed point of \( T_Q \). Then clearly \( s' \in f_q^{-1}(s) \) for every \( q \in \text{Max}(\varphi^{-1}(m_P)) \), and it follows that the foregoing surjection restricts further to a surjective map:

\[
(12.7.4) \quad f_q^{-1}(s) \to \text{Max}(\varphi^{-1}(m_P)).
\]

On the other hand, since \( \log \psi_Q \) is an isomorphism, we have

\[
(Q^\log_{\mathfrak{p}} S)_{s'} = \mathcal{O}_{T_Q, q} = Q^\mathfrak{p}_q \quad \text{for every } s' \in \psi_Q^{-1}(q)
\]

(where \( s' \) denotes any \( \tau \)-point of \( S' \) localized at \( s' \)); explicitly, if \( F = Q \setminus q \), then \( Q^\mathfrak{p}_q = Q/F \); likewise, we get \( (P^\log S_{\mathfrak{p}})_q = P/\varphi^{-1}F \). Taking into account (12.7.2), we deduce:

\[
\dim f^{-1}(f(s')) - \dim f_q^{-1}(f(s')) = \dim Coker(\log f)_{s'}^{\mathfrak{p}} \quad \text{for every } s' \in \psi_Q^{-1}(q).
\]

Thus, for every \( n \in \mathbb{N} \), let

\[
U_n := \{ s' \in S' \mid \dim Coker(\log f)_{s'}^{\mathfrak{p}} = n \}.
\]

The foregoing implies that for every \( s \in S \), the subset \( U_0 \cap f^{-1}(s) \) is open and dense in \( f^{-1}(s) \), and \( U_n \cap f^{-1}(s) \) is either empty, or else it is a subset of pure codimension \( n \) in \( f^{-1}(s) \).

12.7.5. In the situation of (12.7), suppose moreover that \( \log f \) is saturated; notice that this condition holds if and only if \( \log \varphi \) is saturated, if and only if the same holds for \( \lambda \) (lemma 6.2.12(ii)). Then, corollary 6.2.32(ii) says that \( Coker(\log f^1)^{\mathfrak{p}}_{\varphi} \) is torsion-free for every \( s' \in S' \); especially, \( Coker(\log f^1)^{\mathfrak{p}}_{\varphi} \) vanishes for every \( s' \in U_0 \). Then corollary 6.2.32(i) implies that \( \log f^\mathfrak{p}_{\varphi} \) is an isomorphism for every \( s' \in U_0 \), in which case the same holds for \( \log f_{\varphi} \) (lemma 12.1.4); in other words, \( U_0 \) is the strict locus of \( f \) (see definition 12.2.7(ii)).

**Lemma 12.7.6.** Let \( K \) be an algebraically closed field of characteristic \( p \), and \( \chi : P \to (K, \cdot) \) a local morphism of monoids. Let also \( \lambda : P \to Q \) be as in (12.7.5). We have:

(i) The \( K \)-algebra \( Q \otimes_P K \) is Cohen-Macaulay.

(ii) If moreover, either \( p = 0 \), or else the order of the torsion subgroup of \( \Gamma := \text{Coker} \lambda^{\mathfrak{p}} \) is not divisible by \( p \), then \( Q \otimes_P K \) is reduced (i.e. its nilradical is trivial).

**Proof.** (i): Since \( \chi \) is a local morphism, we have \( \chi^{-1}(0) = m_P \), and \( \chi \) is determined by its restriction \( P^\times \to K^\times \), which is a homomorphism of abelian groups. Notice that \( K^\times \) is divisible, hence it is injective in the category of abelian groups; since the unit of adjunction \( P \to P^{\text{sat}} \) is local (lemma 6.2.9(iii)), it follows that \( \chi \) extends to a local morphism \( \chi' : P^{\text{sat}} \to K \). Notice that \( Q \otimes_P K = Q^{\text{sat}} \otimes_{P^{\text{sat}}} K \) (lemma 6.2.12(iv)), hence we may replace \( P \) by \( P^{\text{sat}} \) and \( Q \) by \( Q^{\text{sat}} \), which allows us to assume from start that \( Q \) is saturated. In this case, by theorem 11.6.34(i), both \( K[P] \) and \( K[Q] \) are Cohen-Macaulay; since \( K[\lambda] \) is flat, theorem 10.4.38 and [49, Ch.IV, Cor.6.1.2] imply that \( Q \otimes_P K \) is Cohen-Macaulay as well.

(ii): Let \( Q = \bigoplus_{\gamma \in \Gamma} Q_\gamma \) be the \( \lambda \)-grading of \( Q \) (see remark 6.2.5(iii)). Under the current assumptions, \( \lambda \) is exact (lemma 6.2.30(ii)), consequently \( Q_0 = P \) (remark 6.2.5(iv)). Moreover, \( Q_{\gamma} \) is a finitely generated \( P \)-module, for every \( \gamma \in \Gamma \) (corollary 6.4.3), hence either \( Q_{\gamma} = \emptyset \), or else \( Q_{\gamma} \) is a free \( P \)-module of rank one, say generated by an element \( u_{\gamma} \) (remark 6.2.5(iv)). Furthermore, \( Q_{\gamma}^k = Q_{\gamma k} \) for every integer \( k > 0 \) and every \( \gamma \in \Gamma \) (proposition 6.2.31). Thus, whenever \( Q_{\gamma} \neq \emptyset \), the element \( u_{\gamma} \otimes 1 \) is a basis of the \( K \)-vector space \( Q_{\gamma} \otimes_P K \), and \( (u_{\gamma} \otimes 1)^k \) is
a basis of $Q_{k_7} \otimes P K$, for every $k > 0$; especially, $u_7 \otimes 1$ is not nilpotent. In view of proposition 7.6.12 ii), the contention follows.

12.7.7. Let $f : (X, M) \to (Y, N)$ be a smooth and log flat morphism of fine log schemes. For every $n \in \mathbb{N}$, let $U(f, n) \subset X$ be the subset of all $x \in X$ such that $\text{rk}_\mathcal{O}(\log f^*Z)^\text{gp} = n$, for any $\tau$-point $\tau$ localized at $x$. By lemma 12.2.21 (iii), $U(f, n)$ is a locally closed subset (resp. an open subset) of $X$, for every $n > 0$ (resp. for $n = 0$).

**Theorem 12.7.8.** In the situation of (12.7.7), we have:

(i) $f$ is a flat morphism of schemes.

(ii) For all $y \in Y$, every connected component of $f^{-1}(y)$, is pure dimensional, and $f^{-1}(y) \cap U_n$ is either empty, or else it has pure codimension $n$ in $f^{-1}(y)$, for every $n \in \mathbb{N}$.

(iii) Moreover, if $f$ is saturated, we have:

(a) The strict locus $\text{Str}(f)$ of $f$ is open in $X$, and $\text{Str}(f) \cap f^{-1}(y)$ is a dense subset of $f^{-1}(y)$, for every $y \in Y$.

(b) $f^{-1}(y)$ is geometrically reduced and Cohen-Macaulay, for every $y \in Y$.

(c) $\text{Coker}(\log f^*Z)^\text{gp}$ is a free abelian group of finite rank, for every $\tau$-point $\tau$ of $X$.

**Proof.** Let $\xi$ be any $\tau$-point of $X$; according to corollary 12.1.35 there exist a neighborhood $V$ of $\xi$, and a fine chart $P_V \to \mathbb{N}_V$, such that $P^\text{gp}$ is a free abelian group of finite rank, and the induced morphism of monoids $P \to \mathcal{O}_Y,\xi$ is local.

By lemma 12.1.14, 49, Ch.IV, Th.2.4.6, Prop.2.5.1 and 51, Ch.IV, Prop.17.5.7, it suffices to prove the theorem for the morphism $f \times_Y V : (X, M) \times_Y V \to (V, N)_V$. Hence we may assume from start that $N$ admits a fine chart $\beta : P_V \to N$, such that $P^\text{gp}$ is torsion-free and the induced map $P \to \mathcal{O}_Y,\xi$ is local.

By theorem 12.3.37 remark 12.1.23 (i), 49, Ch.IV, Th.2.4.6 and 51, Ch.IV, Prop.17.5.7 (and again lemma 12.1.14) we may further assume that $f$ admits a fine chart $(\beta, \omega_Q : Q_X \to M, \lambda)$, such that $\lambda$ is injective, the torsion subgroup of $\text{Coker} \lambda^\text{gp}$ is a finite group whose order is invertible in $\mathcal{O}_X$, and the induced morphism of schemes $X \to Y \times_{\text{Spec} \mathbb{Z}[Q]} \text{Spec} \mathbb{Z}[P]$ is étale. Moreover, by theorem 12.1.37 (iii), we may assume − after replacing $Q$ by a localization, and $X$ by a neighborhood of $\xi$ in $X_\tau$ − that the morphism $\lambda : P \to Q$ is integral (resp. saturated, if $f$ is saturated), and the morphism $Q \to \mathcal{O}_X,\xi$ induced by $\omega_{P,\xi}$ is local, so $\lambda$ is local as well.

In this case, the same sort of reduction as in the foregoing shows that, in order to prove (i) and (ii), it suffices to consider a morphism $f$ as in (12.7), for which these assertions have already been established. Likewise, in order to show (iii), it suffices to consider a morphism $f$ as in (12.7.5). For such a morphism, assertions (iii.a) and (iii.c) are already known, and (iii.b) is an immediate consequence of lemma 12.7.6.

**Theorem 12.7.8** (iii) admits the following partial converse:

**Proposition 12.7.9.** Let $f : (X, M) \to (Y, N)$ be a smooth and log flat morphism of fs log schemes, such that $f^{-1}(y)$ is geometrically reduced, for every $y \in Y$. Then $f$ is saturated.

**Proof.** Fix a $\tau$-point $\xi$ of $X$; the assertion can be checked on stalks, hence we may assume that $N$ admits a fine and saturated chart $\beta : P_V \to N$ (lemma 12.1.18 (iii)), such that the induced morphism $\alpha_P : P \to \mathcal{O}_{Y, f(\xi)}$ is local (claim 12.1.31). Then, by corollary 12.3.42, we may find an étale morphism $g : U \to X$ and a $\tau$-point $\xi' \in U$ with $f(\xi') = \xi$, such that the induced morphism of log schemes $f_U : (U, g^*M) \to (Y, N)$ admits a fine and saturated chart $(\beta, \omega_Q : Q_U \to g^*M, \lambda)$, where $\lambda$ is injective, and the induced ring homomorphism (12.7.10) $Q \otimes_P \mathcal{O}_{Y, f(\xi)} \to \mathcal{O}_{U, \xi'}$ is étale. By 51, Ch.IV, Prop.17.5.7, the fibres of $f_U$ are still geometrically reduced, hence we are reduced to the case where $U = X$ and $\xi = \xi'$. Furthermore, after replacing $Q$ by
a localization, and \(X\) by a neighborhood of \(\xi\), we may assume that the map \(\alpha_Q : Q \to \mathcal{O}_{X,\xi}\) induced by \(\omega_{Q,\xi}\) is local and \(\lambda\) is integral (theorem \([12.1.37](\text{iii})\) and lemma \([6.2.9](\text{ii})\)). Lastly, let \(K\) be the residue field of \(\mathcal{O}_{Y,f(\xi)}\); our assumption on \(f^{-1}(y)\) means that the ring \(A := \mathcal{O}_{X,\xi} \otimes_{\mathcal{O}_{Y,f(\xi)}} K\) is reduced.

We shall apply the criterion of proposition \([6.2.31]\). Thus, let \(Q = \bigoplus_{\gamma \in \Gamma} Q_{\gamma}\) be the \(\lambda\)-grading of \(Q\) and notice as well that \(\lambda\) is a local morphism (since the same holds for \(\alpha_P\) and \(\alpha_Q\)), therefore it is exact (lemma \([6.2.30](\text{ii})\)); consequently \(Q_0 = P\) (remark \([6.2.5](\text{v})\)). Moreover, \(Q_{\gamma}\) is a finitely generated \(P\)-module, for every \(\gamma \in \Gamma\) (corollary \([6.4.3]\)), hence either \(Q_{\gamma} = \emptyset\), or else \(Q_{\gamma}\) is a free \(P\)-module of rank one.

We have to prove that \(Q^k_{\gamma} = Q_{k\gamma}\) for every integer \(k > 0\) and every \(\gamma \in \Gamma\). In case \(Q_{\gamma} = \emptyset\), this is the assertion that \(Q_{k\gamma} = \emptyset\) as well. However, since \(Q\) is saturated, the same holds for \(\Gamma' := (\lambda P)^{-1} Q / (\lambda P)^{\text{gp}}\) (lemma \([6.2.9](\text{i,ii})\)), so it suffices to remark that \(\Gamma' \subset \Gamma\) is precisely the submonoid consisting of all those \(\gamma \in \Gamma\) such that \(Q_{\gamma} \neq \emptyset\).

Therefore, fix a generator \(u_{\gamma}\) for every \(P\)-module \(Q_{\gamma} \neq \emptyset\), and by way of contradiction, suppose that there exist \(\gamma \in \Gamma\)' and \(k > 0\) such that \(u_{\gamma}^k\) does not generate the \(P\)-module \(Q_{k\gamma}\); this means that there exists \(a \in m_P\) such that \(u_{\gamma}^k = a \cdot u_{k\gamma}\). Now, notice that the induced morphism of monoids \(\beta : P \to K\) is local, especially \(\beta(a) = 0\), therefore \((u_{\gamma} \otimes 1)^k = 0\) in the \(K\)-algebra \(Q \otimes_P K\). Denote by \(I \subset Q \otimes_P K\) the annihilator of \(u_{\gamma} \otimes 1\), and notice that, since \([12.7.10]\) is flat, \(IA\) is the annihilator of the image \(u'\) of \(u_{\gamma} \otimes 1\) in \(A\).

On the other hand, it is easily seen that \(I\) is the graded ideal generated by \((u_{\mu} \otimes 1 \mid \mu \in \Gamma')\) where \(\Gamma' \subset \Gamma\) is the subset of all \(\mu\) such that \(u_{\gamma} \cdot u_{\mu}\) is not a generator of the \(P\)-module \(Q_{\gamma + \mu}\). Clearly \(u_{\mu} \notin Q^x\) for every \(\mu \in \Gamma\)', therefore the image of \(u_{\mu} \otimes 1\) in \(A\) lies in the maximal ideal. Therefore \(IA \neq A\), i.e., \(u'\) is a non-zero nilpotent element, a contradiction.

**12.7.11.** Let \((X, M)\) be any log scheme, and \(\overline{x}\) any geometric point, localized at a point \(x \in X\). Suppose that \(y \in X\) is a generalization of \(x\), and \(\overline{y}\) a geometric point localized at \(y\); then, arguing as in \([4.9.23]\), we may extend uniquely any strict specialization morphism \(X(\overline{y}) \to X(\overline{x})\) to a morphism of log schemes \((X(\overline{y}), M(\overline{y})) \to (X(\overline{x}), M(\overline{x}))\) fitting into a commutative diagram

\[
\begin{array}{ccc}
(X(\overline{y}), M(\overline{y})) & \to & (X(y), M(y)) \\
\downarrow & & \downarrow \\
(X(\overline{x}), M(\overline{x})) & \to & (X(x), M(x))
\end{array}
\]

whose right vertical arrow is induced by the natural isomorphism

\[
(X(y), M(y)) \to (X(x), M(x)) \times_{X(x)} X(y).
\]

A simple inspection shows that the induced morphism

\[
\Gamma(X(\overline{x}), M(\overline{x}))^\sharp \to \Gamma(X(\overline{y}), M(\overline{y}))^\sharp
\]

is naturally identified with the morphism \(M^\sharp_{\overline{x}} \to M^\sharp_{\overline{y}}\) obtained from the specialization map \(\overline{x} \to \overline{y}\).

**12.7.12.** Let \(g : (X, M) \to (Y, N)\) be a morphism of log schemes, \(\overline{x}\) any geometric point of \(X\), and set \(\overline{y} := g(\overline{x})\). The log structures \(M \to \mathcal{O}_X\) and \(N \to \mathcal{O}_Y\), and the map \(\log g_{\overline{x}}\) induce a commutative diagram of continuous maps

\[
\begin{array}{ccc}
X(\overline{x}) & \xrightarrow{g_{\overline{x}}} & Y(\overline{y}) \\
\psi_{\overline{x}} \downarrow & & \downarrow \psi_{\overline{y}} \\
\text{Spec } M_{\overline{x}} & \xrightarrow{\psi_{\overline{x}}} & \text{Spec } N_{\overline{y}}
\end{array}
\]
Proposition 12.7.14. In the situation of (12.7.12), suppose that $g$ is a smooth morphism of fine log schemes, and moreover:

(a) either $g$ is a saturated morphism
(b) or $(X, M)$ is a fs log scheme.

Then the following holds:

(i) The map $\psi_\tau$ restricts to a bijection:

$$\text{Max}(g_\tau^{-1}(\overline{y})) \sim \text{Max}(\psi_\tau^{-1}(t_\tau)).$$

(ii) For every irreducible component $Z$ of $g_\tau^{-1}(\overline{y})$, set

$$(Z, M(Z)) := (X(\overline{x}), M(\overline{x})) \times_{X(\overline{\tau})} Z.$$

Then the $\kappa(\overline{y})$-log scheme $(Z, M(Z))$ is geometrically pointed regular. (Notation of example 12.1.24 and remark 12.5.8(ii).)

Proof. By corollary 12.1.35, there exist a neighborhood $U \rightarrow Y$ of $\overline{y}$, and a fine chart $\beta : P_U \rightarrow N_U$ such that $\beta_\tau$ is a local morphism, and $P^{\text{red}}$ is torsion-free. Now, let $g_\tau := (g_\tau, \log g_\tau) : (X(\overline{x}), M(\overline{x})) \rightarrow (Y(\overline{y}), N(\overline{y}))$ be the morphism of log schemes induced by $g$ (notation of 12.7.11); by theorem 12.3.37, we may find a fine chart for $g_\tau$ of the type $(g_\tau(\beta, \omega, \lambda : P \rightarrow Q)$, where $\lambda$ is injective, and the order of the torsion subgroup of $\text{Coker} \lambda^{\text{red}}$ is invertible in $\mathcal{O}_{X, x}$. Moreover, set $R := \mathcal{O}_{Y(\overline{y}), \overline{y}}$; then the induced map $X(\overline{x}) \rightarrow \text{Spec} Q \otimes_P R$ is ind-etale, and – after replacing $Q$ by some localization – we may assume that $\omega_\tau : Q \rightarrow \mathcal{O}_{X(\overline{\tau})}$ is local (claim 12.1.31), hence the same holds for $\lambda$. Furthermore, under assumption (a) (resp. (b)), we may also suppose that $Q$ is saturated, by lemmata 6.2.9(ii) and 12.1.12(ii) (resp. that $\lambda$ is saturated, by theorem 12.1.37(iii)).

Let us now define $f : S' \rightarrow S$ as in (12.7); notice that $\omega_\tau$ induces a closed immersion $Y(\overline{y}) \rightarrow S$, and we have a natural identification of $Y(\overline{y})$-schemes:

$$\text{Spec} Q \otimes_P R = Y(\overline{y}) \times_S S'.$$

Denote by $\overline{s}$ the image of $\overline{y}$ in $S$, and $\overline{s}'$ the image of $\overline{x}$ in $Y(\overline{y}) \times_S S' \subset S'$; there follows an isomorphism of $Y(\overline{y})$-schemes:

$$X(\overline{x}) \sim Y(\overline{y}) \times_S S'(\overline{s}')$$

(51 Ch.IV, Prop.18.8.10]). Moreover, our chart induces isomorphisms:

$$\text{Spec} M_\tau \sim T_Q \quad \text{Spec} N_\tau \sim T_P$$

which identify $\phi_\tau$ to the map $\phi : T_Q \rightarrow T_P$ of (12.7). In view of these identifications, we see that (12.7.13) is the restriction to the closed subset $X(\overline{x})$, of the analogous diagram:

$$\begin{array}{ccc}
S'(\overline{s}') & \xrightarrow{f_{\overline{s}'}^{-1}} & S(\overline{s}) \\
\downarrow \psi & & \downarrow \psi_\tau \\
T_Q & \xrightarrow{\phi} & T_P.
\end{array}$$

We may thus assume that $X = S'$, $Y = S$ and $g = f$. Moreover, let $s$ (resp. $s'$) be the support of $\overline{s}$ (resp. of $\overline{s}'$); the morphism $\tau : S'(\overline{s}') \rightarrow S'(s')$ is flat, hence it restricts to a surjection

$$\text{Max}(f_{\overline{s}'}^{-1}s) \rightarrow \text{Max}(f_{s'}^{-1}s).$$

In order to prove (i), it suffices then to show that the map $\text{Max}(f_{\overline{s}'}^{-1}s) \rightarrow \text{Max}(\phi^{-1}m_P)$, defined as the composition of the foregoing map and the surjection (12.7.4), is injective. This boils
down to the assertion that, for every $q \in \text{Max}(\varphi^{-1}m_p)$ the point $s'$ lies on a unique irreducible component of the fibre $\pi^{-1}(f_{q,s})$. However, let $\beta : P \to \kappa(s)$ be the composition of the chart $P \to R$ and the projection $R \to \kappa(s)$; then $f_{q^{-1}}(s) = \text{Spec } Q/q \otimes_P \kappa(s)$. Since $\pi$ is ind-étale, the assertion will follow from [51, Ch.IV, Prop.17.5.7] and corollary [12.5.13] together with:

**Claim 12.7.15.** The log scheme $W_q := \text{Spec } \mathbb{Z}[Q/q] \times_{\text{Spec } \mathbb{Z}[P]} \text{Spec } \kappa(s)$ is geometrically pointed regular.

**Proof of the claim.** To ease notation, set $F := Q \setminus q$; by assumption $\lambda^{-1}F = P^\times$, so that

$$W_q = (W_q')_o \quad \text{where} \quad W_q' := \text{Spec } \mathbb{Z}[F] \times_{\text{Spec } \mathbb{Z}[P]} \text{Spec } \kappa(s)$$

(notation of [12.2.13]); notice that the log structures of $\text{Spec } \mathbb{Z}[P^\times]$ and $\text{Spec } \kappa(s)$ are trivial.

Moreover, let $\lambda_F : P^\times \to F$ be the restriction of $\lambda$; then $\lambda_F^\text{gp}$ is injective, and

$$\text{Coker } \lambda_F^\text{gp} \subset \text{Coker } \lambda^\text{gp}$$

(corollary 6.2.33(ii)), hence the order of the torsion subgroup of $\text{Coker } \lambda_F^\text{gp}$ is invertible in $\mathcal{O}_{S,s}$. Moreover, if $\lambda$ is saturated, then the same holds for $\lambda_F$ (corollary 6.2.33(ii)), and it is easily seen that if $Q$ is saturated, the same holds for $F$. Consequently, the morphism $\text{Spec } \mathbb{Z}[\lambda_F]$ is smooth (proposition 12.3.34). The same then holds for the morphism $W_q' \to \text{Spec } \kappa(s)$ obtained after base change of $\text{Spec } \mathbb{Z}[\lambda_F]$ along the morphism $h : \text{Spec } \mathbb{Z}[P] \to \text{Spec } \kappa(s)$ induced by $\beta$ (proposition 12.3.24(ii)).

Now we notice that under either of the assumptions (a) or (b), $W_q'$ is a fs log scheme. Indeed, under assumption (b), this follows by remarking that $\text{Spec } \kappa(s)$ is trivially a fs log scheme, and $\text{Spec } \mathbb{Z}[\lambda_F]$ is saturated. Under assumption (a), $\text{Spec } \mathbb{Z}[F]$ is a fs log scheme, and it suffices to observe that $h$ is a strict morphism. Lastly, since the morphism $W_q' \to \text{Spec } \kappa(s)$ is obviously saturated, we apply corollary [12.5.29] to conclude.

(ii): In light of the foregoing, we see that, for any irreducible component $Z$ of $g_{\pi^{-1}}(\overline{y})$, there exists a unique $q(Z) \in \text{Max}(\varphi^{-1}m_p)$ such that $Z$ is isomorphic to the strict henselization of $f_{q(Z)}^{-1}(s)$, at the geometric point $\pi'$. Notice now that the log structure of $W_{q(Z)}$ is reduced, by virtue of claim [12.7.15] and proposition [12.5.38]; then, a simple inspection of the definitions shows that $(Z, M(Z)_{\text{red}})$ is isomorphic to the strict henselization $W_{q(Z)}(\pi')$. Invoking again claim 12.7.15 we deduce the contention. \hfill \Box

**12.7.16.** In the situation of [12.7.12], suppose that $Y$ is a normal scheme, and $(Y, N)_{\text{tr}}$ is a dense subset of $Y$. Let $\overline{y}$ be a geometric point of $Y(\overline{y})$, localized at the generic point $\eta$, and

$$(U_q \mid q \in \text{Spec } M_{\pi})$$

the logarithmic stratification of $(X(\overline{y}), M(\overline{y}))$ (see [12.5.35]). Notice that $\psi_{\pi}(g^{-1}(\eta))$ lies in the preimage $\Sigma \subset \text{Spec } M_{\pi}$ of the maximal point $\emptyset$ of $\text{Spec } N_{\overline{y}}$; therefore, $g_{\pi^{-1}}(\eta)$ is the union of the subsets $U_q \times_Y |\eta|$, for all $q \in \Sigma$.

**Proposition 12.7.17.** In the situation of [12.7.16], suppose that $g$ is a smooth morphism of fine log schemes. Then the following holds:

(i) $X$ is a normal scheme.

(ii) The scheme $g_{\pi^{-1}}(\overline{z})$ is normal and irreducible.

(iii) For every $q \in \Sigma$, the $\kappa(\eta)$-scheme $U_q \times_Y |\eta|$ is non-empty, geometrically normal and geometrically irreducible, of pure dimension $\dim g_{\pi^{-1}}(\eta) - \text{ht } q$.

(iv) Especially, set $W := (X(\overline{y}) \setminus U_{\emptyset}) \times_Y |\overline{y}|$; then $\psi_{\pi}$ induces a bijection:

$$\text{Max}(W) \xrightarrow{\sim} \{ q \in \Sigma \mid \text{ht } q = 1 \}.$$ 

(v) For every $w \in \text{Max}(W)$, the stalk $\mathcal{O}_{g_{\pi^{-1}}(\overline{y}), w}$ is a discrete valuation ring.
Proof. Set \( R := \mathcal{O}_{Y(\eta), \pi} \); arguing as in the proof of proposition 12.7.14, we may find:

- a local, flat and saturated morphism \( \lambda : P \to Q \) of fine monoids, such that the order of the torsion subgroup of \( \text{Coker} \lambda^{\text{gp}} \) is invertible in \( R \);
- local morphisms of monoids \( P \to R, Q \to \mathcal{O}_{X(\eta), \pi} \) which are charts for the log structures deduced from \( N \) and respectively \( M \), and such that the induced morphism of \( Y(\eta) \)-schemes \( X(\pi) \to \text{Spec} \, Q \otimes_P R \) is ind-étale.

By [51] Ch.IV, Prop.17.5.7, we may then assume that \((X, M)\) (resp. \((Y, N)\)) is the scheme \( \text{Spec} \, Q \otimes_P R \) (resp. \( \text{Spec} \, R \)), endowed with the log structure deduced from the natural map \( Q \to Q \otimes_P R \) (resp. the chart \( P \to R \)), and \( g \) is the natural projection. Suppose first that \( R \) is excellent, and let \( R' \) be the normalization of \( R \) in a finite extension \( K' \) of \( \text{Frac}(R) \); then \( R' \) is also strictly local and noetherian, and if \( \eta' \) denotes the closed point of \( Y' := \text{Spec} \, R' \), then the residue field extension \( \kappa(\eta) \subset \kappa(\eta') \) is purely inseparable. Set

\[
(X', M') := (X, M) \times_Y Y' \quad \text{and} \quad (Y', N') := (Y, N) \times_Y Y'.
\]

and let \( g' : (X', M') \to (Y', N') \) be the induced morphism of log schemes; it follows especially that the restriction \( g'^{-1}(\eta') \to g^{-1}(\eta) \) is a homeomorphism on the underlying topological spaces. Hence, there is a geometric point \( \pi' \) of \( X' \), unique up to isomorphism, whose image in \( X \) agrees with \( \pi \), and we easily deduce an isomorphism of \( Y \)-schemes ([51] Ch.IV, Prop.18.8.10(i))

\[
(12.7.18) \quad X'(\pi') \cong X(\pi) \times_Y Y'.
\]

Let \( \eta' \) be the generic point of \( Y' \); by assumption, \( N' \) is trivial in a Zariski neighborhood of \( \eta' \), hence \( (X', N') \times_Y \eta' \) is a fs log schemes (since \( g \) is saturated), and then the same log scheme is also regular (theorem 12.5.28), therefore \( g'^{-1}(\eta') \) is a normal scheme (corollary 12.5.13).

On the other hand, \( R' \) is a Krull domain ([103] Th.33.10), and \( g' \) is flat with reduced fibres (theorem 12.7.8(iii,b)), so \( X' \) is a noetherian normal scheme (lemma 9.8.2), consequently the same holds for \( X'(\pi') \) ([51] Ch.IV, Prop.18.8.12(i)); especially, the latter is irreducible, so the same holds for \( X'(\pi) \times_Y \eta' \). In view of (12.7.18), it follows that \( X'(\pi) \times_Y \eta' \) is also normal and irreducible.

Since \( K' \) is arbitrary, this completes the proof of (i) and (ii), in this case.

Next, if \( R \) is any normal ring, we may write \( R \) as the union of a filtered family \( (R_i \mid i \in I) \) of excellent normal local subrings ([49] Ch.IV, (7.8.3)(ii,vi)). For each \( i \in I \), denote by \( \overline{\eta}_i \) the image of \( \eta \) in \( \text{Spec} \, R_i \); then the strict henselization \( R_i^{\text{sh}} \) of \( R_i \) at \( \overline{\eta}_i \) is also a subring of \( R \), so we may replace \( R_i \) by \( R_i^{\text{sh}} \), which allows to assume that each \( R_i \) is strictly local, normal and noetherian ([51] Ch.IV, Prop.18.8.8(iv), Prop.18.8.12(i)). Up to replacing \( I \) by a cofinal subset, we may assume that the image of \( P \) lies in \( R_i \), for every \( i \in I \). For each \( i \in I \), set \( X_i := \text{Spec} \, Q \otimes_P R_i, Y_i := \text{Spec} \, R_i \), and endow \( X_i \) (resp. \( Y_i \)) with the log structure \( M_i \) (resp. \( N_i \)) deduced from the natural map \( Q \to Q \otimes_P R_i \). There follows a system of morphisms of log schemes \( g_i : (X_i, M_i) \to (Y_i, N_i) \) for every \( i \in I \), whose limit is the morphism \( g \). Moreover, since \((Y_i, N_i)_i\) is dense in \( Y \), the image of \( P \) lies in \( \bigcap_i R_i \setminus \{0\} \), hence it lies in \( R_i \setminus \{0\} \) for every \( i \in I \), and the latter means that \((Y_i, N_i)_i\) is dense in \( Y_i \), for every \( i \in I \). Let \( \overline{\eta}_i \) (resp. \( \pi_i \)) be the image of \( \eta \) (resp. of \( \pi \)) in \( Y_i \) (resp. \( X_i \)); moreover, for each \( i \in I \), let \( x_i \in X_i \) be the support of \( \pi_i \). By the previous case, we know that \( g_i^{-1}(\overline{\eta}_i) \) is normal and irreducible. However, \( X \) (resp. \( g^{-1}(\eta) \)) is the limit of the system of schemes \( (X_i \mid i \in I) \) (resp. \( (g_i^{-1}(\eta_i) \mid i \in I) \)), so (i) and (ii) follow. (Notice that the colimit of a filtered system of integral (resp. normal) domains, is an integral (resp. normal) domain : exercise for the reader.)

(iii): For every \( q \in \text{Spec} \, Q = \text{Spec} \, M_{\pi, \pi}, \) set \( X_q := \text{Spec} \, Q/q \otimes_P R \); since the chart \( Q \to \mathcal{O}_{X(\pi), \pi} \) is local, it is clear that \( x \in X_q \) for every such \( q \), and:

\[
X_q(\pi) = \bigcup_{p \in \text{Spec} \, Q/q} U_p.
\]
If \( \varphi(q) = \emptyset \), the induced map \( P \to Q/q \) is still flat (corollary 6.1.52), hence the projection \( X_q(\overline{q}) \to Y \) is a flat morphism of schemes, especially \( g_{X_q}^{-1}(\eta) \cap X_q(\overline{q}) \neq \emptyset \). Furthermore, the subset \( X_q(\overline{q}) \) is pure-dimensional, of codimension \( \operatorname{ht} q \) in \( g_{X_q}^{-1}(\eta) \), by (12.7.2) and [49, Ch.IV, Cor.6.1.4]. It follows that \( U_q \) is a dense open subset of \( X_q(\overline{q}) \). To conclude, it remains only to show that each \( X_q(\overline{q}) \) is geometrically normal and geometrically irreducible; however, let \( j_q : X_q \to X \) be the closed immersion; the induced morphism of log schemes \( g_q : (X_q, j_q^* M) \to (Y, N) \) is still smooth, hence the assertion follows from (ii).

(iv) is a straightforward consequence of (iii).

(v) Notice that \( A := \mathcal{O}_{X_q}^{-1}(\overline{q}, w) \) is ind-étale over the noetherian ring \( Q \otimes P \kappa(\overline{q}) \), hence its strict henselization is noetherian, and then \( A \) itself is noetherian ([51, Ch.IV, Prop.18.8.8(iv)]).

Since \( X \) is normal, and \( w \) is a point of height one in \( g_{X_q}^{-1}(\overline{q}) \), we conclude that \( A \) is a discrete valuation ring.

13. Étale coverings of schemes and log schemes

13.1. Acyclic morphisms of schemes. For any scheme \( X \), we shall denote by:

\[
\text{Cov}(X)
\]

the category whose objects are the finite étale morphisms \( E \to X \); the morphisms \( (E \to X) \to (E' \to X) \) are the \( X \)-morphisms of schemes \( E \to E' \). By faithfully flat descent, \( \text{Cov}(X) \) is naturally equivalent to the subcategory of \( X_{\text{ét}} \) consisting of all locally constant constructible sheaves. If \( f : X \to Y \) is any morphism of schemes, and \( \varphi : E \to Y \) is an object \( \text{Cov}(Y) \), then \( f^* \varphi := \varphi \times_Y X : E \times_Y X \to X \) is an object of \( \text{Cov}(X) \); more precisely, we have a fibration:

\[
(13.1.1) \quad \text{Cov} \to \text{Sch}
\]

over the category of schemes, whose fibre, over any scheme \( X \), is the category \( \text{Cov}(X) \).

**Lemma 13.1.2.** Let \( f \) be a morphism of schemes, and suppose that either one of the following conditions holds:

(a) \( f \) is integral and surjective.
(b) \( f \) is faithfully flat.
(c) \( f \) is proper and surjective.

Then \( f \) is of universal 2-descent for the fibred category \( (13.1.1) \).

**Proof.** This is [8, Exp.VIII, Th.9.4].

**Lemma 13.1.3.** In the situation of definition [10.5.42] let \( U \subset X \) be any open subset with \( Y \subset U \). If \( \text{Lef}(X, Y) \) holds, the closed immersion \( j : Y \to U \) induces a fully faithful functor

\[
\text{j}^* : \text{Cov}(U) \to \text{Cov}(Y).
\]

**Proof.** Let \( \text{Cov}(X) \) be the full subcategory of \( \mathcal{O}_X \text{-Alg}_{\text{aff}} \) consisting of all finite étale \( \mathcal{O}_X \)-algebras (notation of lemma [10.5.43(ii)]); the category \( \text{Cov}(U) \) is a full subcategory of \( \mathcal{O}_U \text{-Alg}_{\text{aff}} \), so lemma (10.5.43 ii) already implies that the functor \( \text{Cov}(U) \to \text{Cov}(X) \) is fully faithful, hence we are reduced to showing that the functor:

\[
\text{Cov}(X) \to \text{Cov}(Y) \quad \mathcal{O} \mapsto \text{Spec} \mathcal{O} \otimes_{\mathcal{O}_X} \mathcal{O}_Y
\]

is fully faithful. To this aim, let \( \mathcal{I} \subset \mathcal{O}_X \) be the ideal defining the closed immersion \( Y \subset X \); consider the direct system of schemes

\[
(Y_n := \text{Spec} \mathcal{O}_X / \mathcal{I}^{n+1} | n \in \mathbb{N})
\]

and let \( \text{Cov}(Y_n) \) be the category consisting of all direct systems \( (E_n | n \in \mathbb{N}) \) of schemes, such that \( E_n \) is finite étale over \( Y_n \), and such that the transition maps \( E_n \to E_{n+1} \) induce
isomorphisms $E_n \xrightarrow{\sim} E_{n+1} \times_{Y_{n+1}} Y_n$ for every $n \in \mathbb{N}$. The morphisms in $\text{Cov}(Y)$ are the morphisms of direct systems of schemes. We have a natural fully faithful functor:

$$\text{Cov}(X) \to \text{Cov}(Y) \quad \mathcal{A} \mapsto (\text{Spec } \mathcal{O} / \mathcal{I}^{n+1} \mathcal{A} | n \in \mathbb{N})$$

([44], Ch.I, Cor.10.6.10(ii)). Finally, the functor $\text{Cov}(Y) \to \text{Cov}(Y)$ given by the rule:

$$(E_n | n \in \mathbb{N}) \to E_0$$

is an equivalence, by [51], Ch.IV, Th.18.1.2. The claim follows. □

13.1.4. Consider now a cofiltered family $\mathcal{A} := (S_{\lambda} | \lambda \in \Lambda)$ of affine schemes. Denote by $S$ the limit of $\mathcal{A}$, and suppose moreover that $\Lambda$ admits a final element $0 \in \Lambda$. Let $f_0 : X_0 \to S_0$ be a finitely presented morphism of schemes, and set:

$$X_{\lambda} := X_0 \times_{S_0} S_{\lambda} \quad f_{\lambda} := f_0 \times_{S_0} S_{\lambda} : X_{\lambda} \to S_{\lambda} \quad \text{for every } \lambda \in \Lambda.$$  

Set as well $X := X_0 \times_{S_0} S$ and $f := f_0 \times_{S_0} S : X \to S$. For every $\lambda \in \Lambda$, let $p_{\lambda} : S \to S_{\lambda}$ (resp. $p'_{\lambda} : X \to X_{\lambda}$) be the natural morphism. The functors $p'_{\lambda} : \text{Cov}(X_{\lambda}) \to \text{Cov}(X)$ define a pseudo-cocone in the 2-category $\text{Cat}$, whence a functor:

$$(13.1.5) \quad 2\text{-colim}_{\lambda \in \Lambda} \text{Cov}(X_{\lambda}) \to \text{Cov}(X).$$

Lemma 13.1.6. In the situation of (13.1.4), the functor (13.1.5) is an equivalence.

Proof. It is a rephrasing of [50], Ch.IV, Th.8.8.2, Th.8.10.5 and [51], Ch.IV, Prop.17.7.8(ii). □

Lemma 13.1.7. Let $X$ be a scheme, $j : U \to X$ an open immersion with dense image, and $f : X' \to X$ an integral surjective and radical morphism. The following holds:

(i) The morphism $f$ induces an equivalence of sites

$$f^* : X'_{\text{et}} \to X_{\text{et}}$$

and the functor $f^* : \text{Cov}(X) \to \text{Cov}(X')$ is an equivalence.

(ii) The functor $j^* : \text{Cov}(X) \to \text{Cov}(U)$ is faithful.

(iii) Suppose that $X$ is reduced and normal, and moreover:

(a) either $X$ has finitely many maximal points

(b) or else, $j$ is a quasi-compact open immersion.

Then $j^*$ is fully faithful, and its essential image consists of all the objects $\varphi$ of $\text{Cov}(U)$ such that $\varphi \times_X (X(\overline{\tau})$ lies in the essential image of the pull-back functor:

$$\text{Cov}(X(\overline{\tau})) \to \text{Cov}(X(\overline{\tau}) \times_X U)$$

for every geometric point $\overline{\tau}$ of $X$. (Notation of definition [4], 9.17(ii).)

(iv) Furthermore, if $X$ is locally noetherian and regular, and $X \setminus U$ has codimension $\geq 2$ in $X$, then $j^*$ is an equivalence.

Proof. (i) follows from [8], Exp.VIII, Th.1.1.

(ii): Indeed, let $\varphi : E \to X$ and $\varphi' : E' \to X$ be any two finite étale morphisms, and $f, g : E \to E'$ two morphisms of $X$-schemes such that $f \times_X U = g \times_X U$; let $\Delta_{E'} : E' \to E' \times_X E'$ be the open and closed diagonal immersion. $(f, g) : E \to E' \times_X E'$ the morphism deduced from $f$ and $g$, and set $D := (f, g)^{-1} \Delta_{E'}$. Then $D$ is the largest open subset of $E'$ such that $f|_D = g|_{D'}$; on the other hand, by assumption $\varphi^{-1} U \subset D$, and since $\varphi$ is an open map, $\varphi^{-1} U$ is dense in $E$. Lastly, $D$ is also a closed subset of $E$, so $D = E$, whence the claim.

(iii): Choose a covering $X = \bigcup_{i \in I} V_i$ consisting of affine open subsets, let

$$X' := \prod_{i \in I} V_i \quad X'' := X' \times_X X'$$

and denote by $g : X' \to X$ the induced morphism; set also $j^i := j \times_X V_i$ for every $i \in I$. By lemma [13.1.2], $g$ is of universal 2-descent for the fibred category $\text{Cov}$. On the other hand, the induced open immersion $j'' : U \times_X X'' \to X''$ has dense image, hence the corresponding
functor $j''$ is faithful, by (ii). By corollary \[3.4.30\](ii), the full faithfulness of $j^*$ follows from the full faithfulness of the pull-back functor $j''^*$ corresponding to the open immersion $j' := j \times_X X'$. The latter holds if and only if the same holds for all the pull-back functors $j_{1i}''$. Hence, we may replace $X$ by $V$, and assume from start that $X$ is affine, say $X = \text{Spec} A$. Let $E \to X$ and $E' \to X$ be two objects of Cov($X$), and $h : E \times_X U \to E' \times_X U$ a morphism, and write $E = \text{Spec} B$, $E' = \text{Spec} B'$ for finite étale $A$-algebras $B$ and $B'$; we have to check that $h$ extends to a morphism $E \to E'$.

- To this aim, consider first the case where $X$ has finitely many maximal points $\eta_1, \ldots, \eta_s$. Under the current assumptions, $A$ is the product of $s$ domains, and its total ring of fractions $\text{Frac} A$ is the product of fields $\kappa(\eta_1) \times \cdots \times \kappa(\eta_s)$. The restrictions $h_{\eta_i} := h \times_U X(\eta_i) : E(\eta_i) \to E'(\eta_i)$ induce a map of $\text{Frac} A$-algebras

$$h^\circ_{\eta_i} := \prod_{i=1}^s h^\circ_{\eta_i} : B' \otimes_A \text{Frac} A \to B \otimes_A \text{Frac} A.$$ 

On the other hand, by \[551\] Ch.IV, Prop.17.5.7, $B$ (resp. $B'$) is the normalization of $A$ in $B \otimes_A \text{Frac} A$ (resp. in $B' \otimes_A \text{Frac} A$). It follows that $h^\circ_{\eta_i}$ restricts to a map $B' \to B$, and the corresponding morphism $E \to E'$ is necessarily an extension of $h$. This shows that $j''$ is fully faithful in this case.

- Next, suppose that assumption (b) holds, and set $\mathcal{E} := B^\sim$, $\mathcal{E}' := B'^\sim$; then $\mathcal{E}$ and $\mathcal{E}'$ are étale $\mathcal{O}_X$-algebras and locally free $\mathcal{O}_X$-modules of finite type, and $h$ corresponds to a morphism $h^i : \mathcal{E} \to \mathcal{E}'$. Under the current assumptions, $j_* \mathcal{O}_U$ is a quasi-coherent $\mathcal{O}_X$-algebra, and $\mathcal{O}_{X,x}$ is integrally closed in $(j_* \mathcal{O}_U)_x$, for every $x \in X$ (\[59\] Prop.8.2.31(i)). Likewise, $j_* j^* \mathcal{E} = \mathcal{E} \otimes_{\mathcal{O}_X} j_* \mathcal{O}_U$, so $\mathcal{E}'_x$ is the integral closure of $\mathcal{O}_{X,x}$ in $(j_* j^* \mathcal{E})_x$, for every $x \in X$. Lastly, $\mathcal{E}'_x$ is integral over $\mathcal{O}_{X,x}$, so the map $(j_* j^* \mathcal{E})_x : (j_* j^* \mathcal{E})_x \to (j_* j^* \mathcal{E})_x$ restricts to a map $\mathcal{E}'_x \to \mathcal{E}'_x$, and the assertion follows.

To proceed, we make the following general remark.

**Claim 13.1.8.** Let $Z$ be a scheme, $V_0 \subset Z$ an open subset, and $\varphi : E \to V_0$ an object of Cov($V_0$). Suppose that, for every open subset $V \subset Z$ containing $V_0$, the pull-back functor $j_V^* : \text{Cov}(V) \to \text{Cov}(V_0)$ is fully faithful. Let $\mathcal{F}$ be the family consisting of all the data $(V, \psi, \alpha)$ where $V \subset X$ is any open subset with $V_0 \subset V$, $\psi : E_V \to V$ is a finite étale morphism, and $\alpha : \psi^{-1} V_0 \xrightarrow{\sim} E$ is an isomorphism of $V_0$-schemes. $\mathcal{F}$ is preordered (see example 1.1.6(iii)) by the relation such that $(V, \psi, \alpha) \geq (V', \psi', \alpha')$ if and only if $V' \subset V$ and there is an isomorphism $\beta : \psi^{-1} V' \xrightarrow{\sim} E_{V'}$ of $V'$-schemes, such that $\alpha' \circ j_V^*(\beta) = \alpha$. Then the partially ordered quotient $\mathcal{F}'$ of $\mathcal{F}$ admits a supremum (see example 1.1.16).

**Proof of the claim.** It is easily seen that, whereas $\mathcal{F}$ is not small in our universe $U$, the quotient $\mathcal{F}'$ is essentially small, i.e. there is a small subset of $\mathcal{F}$ mapping bijectively onto $\mathcal{F}'$ (verification left to the reader). Using Zorn’s lemma, it is easily seen that every element of $\mathcal{F}'$ can be dominated by a maximal element, and it remains to show that any two maximal elements $(V, \psi, \alpha)$ and $(V', \psi', \alpha')$ of $\mathcal{F}$ are isomorphic; to see this, set $V'' := V \cap V'$: by assumption, the isomorphism $\alpha' \circ j_V^*(\beta) : \psi^{-1} V_0 \xrightarrow{\sim} \psi'^{-1} V_0$ extends to an isomorphism of $V''$-schemes $\psi^{-1} V'' \xrightarrow{\sim} \psi'^{-1} V''$, using which one can glue $E_V$ and $E_{V'}$ to obtain a datum $(V \cup V', \psi'', \alpha'')$ which is larger than both our maximal elements, hence it is isomorphic to both. \[\diamondsuit\]

**Claim 13.1.9.** In the situation of claim \[13.1.8\], suppose that $Z$ is reduced and normal, $V_0$ is dense in $Z$, and either one of the assumptions (a) or (b) of (ii) hold for $Z$ and the open immersion $V_0 \to Z$. Let $(V_{\text{max}}, \psi, \alpha)$ be a supremum for $\mathcal{F}$, and $\overline{z}$ a geometric point of $Z$, such that $\varphi \times_Z Z(\overline{z})$ extends to a finite étale covering of $Z(\overline{z})$; then the support of $\overline{z}$ lies in $V_{\text{max}}$.

**Proof of the claim.** By lemma \[13.1.6\] there exist an étale neighborhood $g : Y \to Z$ of $\overline{z}$, with $Y$ affine, a finite étale morphism $\varphi_Y : E_Y \to Y$, and an isomorphism $h : \varphi \times_V V_0 \simeq \varphi_Y \times_Z V_0$. \[\square\]
We have a natural essentially commutative diagram:

\[
\begin{array}{ccc}
\text{Cov}(gY) & \xrightarrow{\alpha} & \text{Desc}(\text{Cov}, g) \\
\downarrow & & \downarrow \\
\text{Cov}(V_0 \cap gY) & \xrightarrow{\beta} & \text{Desc}(\text{Cov}, g \times_Z V_0) \\
\end{array}
\]

where \(\alpha\) and \(\beta\) are equivalences, by lemma 13.1.2. Moreover, let \(Y' := Y \times_Z Y\) and \(Y'' := Y' \times_Z Y\); it is easily seen that is assumption (a) (resp. (b)) of (ii) holds for \(Z\) and \(V_0\), the same holds for \(Y'\) and \(Y' \times_Z V_0\), and also for \(Y''\) and \(Y'' \times_Z V_0\). By the foregoing, it follows that the functors

\[
\text{Cov}(Y') \to \text{Cov}(Y' \times_Z V_0) \quad \text{and} \quad \text{Cov}(Y'') \to \text{Cov}(Y'' \times_Z V_0)
\]

are fully faithful, hence the right square subdiagram is 2-cartesian (corollary 3.4.30(iii)). Thus, the datum \((\varphi \times_Z gY, \varphi_Y, h)\) determines an object \(\varphi'\) of \(\text{Cov}(gY)\), together with an isomorphism \(\varphi' \times_Z V_0 \cong \varphi \times_Z gY\), which we may use to glue \(\varphi\) and \(\varphi'\) to a single object \(\varphi''\) of \(\text{Cov}(V_0 \cup gY)\).

The claim follows. \(\Box\)

The foregoing shows that the assumptions of claim 13.1.8 are fulfilled, with \(Z := X, V_0 := U\) and any object \(\varphi\) of \(\text{Cov}(U)\), hence there exists a largest open subset \(U_{\text{max}} \subset X\) over which \(\varphi\) extends. However, claim 13.1.9 shows that \(U_{\text{max}} = X\), so the proof of (iii) is complete.

(iv): In view of (iii) and [51] Ch.IV, Cor.18.8.13, we are reduced to the case where \(X\) is a regular local scheme, and it suffices to show that \(j^*\) is essentially surjective. We argue by induction on the dimension \(n\) of \(X \setminus U\). If \(n = 0\), then \(X \setminus U\) is the closed point, in which case it suffices to invoke the Zariski-Nagata purity theorem ([68] Exp.X, Th.3.4(i))). Suppose \(n > 0\) and that the assertion is already known for smaller dimensions. Let \(\varphi\) be a given finite étale covering of \(U\), and \(x\) a maximal point of \(X \setminus U\); then \(X(x) \setminus U = \{x\}\), so \(\varphi_{U \cap X(x)}\) extends to a finite étale morphism \(\varphi_x\) over \(X(x)\). In turns, \(\varphi_x\) extends to an affine open neighborhood \(V \subset X\) of \(X\), and up to shrinking \(V\), this extension \(\varphi'\) agrees with \(\varphi\) on \(U \cap V\), by lemma 13.1.6. Hence we can glue \(\varphi\) and \(\varphi'\), and replace \(U\) by \(U \cup V\). Repeating the procedure for every maximal point of \(X \setminus U\), we reduce the dimension of \(X \setminus U\); then we conclude by the inductive assumption.

\[\square\]

**Definition 13.1.10.** Let \(f : X \to S\) be a morphism of schemes, \(\pi\) a geometric point of \(X\) localized at \(x \in X\); and set \(s := f(x), \pi := f(\pi)\). Let also \(n \in \mathbb{N}\) be any integer, and \(\mathbb{L} \subset \mathbb{N}\) any non-empty set of prime numbers.

(i) Denote by \(f_\pi : X(\pi) \to S(\pi)\) the morphism of strictly local schemes induced by \(f\). We say that \(f\) is locally \((-1)\)-acyclic at the point \(x\), if the scheme \(f_\pi^{-1}(\xi)\) is non-empty for every strict geometric point \(\xi\) of \(S(\pi)\) (see definition 4.9.17(i)).

(ii) We say that \(f\) is locally 0-acyclic at the point \(x\), if the scheme \(f_\pi^{-1}(\xi)\) is non-empty and connected for every strict geometric point \(\xi\) of \(S(\pi)\).

(iii) We say that a group \(G\) is a finite \(\mathbb{L}\)-group if \(G\) is finite and all the primes dividing the order of \(G\) lie in \(\mathbb{L}\). We say that \(G\) is an \(\mathbb{L}\)-group if it is a filtered union of finite \(\mathbb{L}\)-groups.

(iv) We say that \(f\) is locally 1-aspherical for \(\mathbb{L}\) at the point \(x\), if we have:

\[H^1(f_\pi^{-1}(\xi)_\text{et}, G) = \{1\}\]

for every strict geometric point \(\xi\) of \(S(\pi)\), and every \(\mathbb{L}\)-group \(G\) (where 1 denotes the trivial \(G\)-torsor).

(v) We say that \(f\) is locally \((-1)\)-acyclic (resp. locally 0-acyclic, resp. locally 1-aspherical for \(\mathbb{L}\)) if \(f\) is locally \((-1)\)-acyclic (resp. locally 0-acyclic, resp. locally 1-aspherical for \(\mathbb{L}\)) at every point of \(X\).
(vi) We say that \( f \) is \((-1)-acyclic\) (resp. \(0\)-acyclic) if the unit of adjunction: \( \mathcal{F} \to f_*f^*\mathcal{F} \) is a monomorphism (resp. an isomorphism) for every sheaf \( \mathcal{F} \) on \( S_{\text{ét}} \).

See section 4.1 for generalities about \( G \)-torsors for a group object \( G \) on a topos \( T \). Here we shall be mainly concerned with the case where \( T \) is the étale topos \( X_{\text{ét}} \) of a scheme \( X \), and \( G \) is representable by a group scheme, finite and étale over \( X \). In this case, using faithfully flat descent one can show that any \( G \)-torsor is representable by a principal \( G \)-homogeneous space, i.e. a finite, surjective, étale morphism \( E \to X \) with a \( G \)-action \( G \to \text{Aut}_X(E) \) such that the induced morphism of \( X \)-schemes

\[
G \times E \to E \times_X E
\]

is an isomorphism.

13.1.11. If \( G_X \) is the constant \( X_{\text{ét}} \)-group arising from a finite group \( G \) and \( X \) is non-empty and connected, right \( G_X \)-torsors are also understood as \( G \)-valued characters of the étale fundamental group of \( X \). Indeed, let \( \xi \) be a geometric point of \( X \); recall (65 \text{ Exp.V, §7}) that \( \pi := \pi_1(X_{\text{ét}}, \xi) \) is defined as the automorphism group of the fibre functor

\[
F_\xi : \text{Cov}(X) \to \text{Set} \quad (E \xrightarrow{f} X) \mapsto f^{-1}\xi.
\]

We endow \( \pi \) with its natural profinite topology, as in (3.5.7), so that \( F_\xi \) can be viewed as an equivalence of categories

\[
F_\xi : \text{Cov}(X) \to \pi\text{-Set}.
\]

Lemma 13.1.12. In the situation of (13.1.11), there exists a natural bijection of pointed sets:

\[
H^1(X_{\text{ét}}, G_X) \sim H^1_{\text{cont}}(\pi, G)
\]

from the pointed set of right \( G_X \)-torsors, to the first non-abelian continuous cohomology group of \( P \) with coefficients in \( G \) (see (3.5.1)).

Proof. Let \( f : E \to X \) be a right \( G_X \)-torsor, and fix a geometric point \( s \in F_\xi(E) \); given any \( \sigma \in \pi \), there exists a unique \( g_{s,\sigma} \in G \) such that

\[
s \cdot g_{s,\sigma} = \sigma_E(s).
\]

Any \( g \in G \) determines a \( X \)-automorphism \( g_E : E \to E \), and by definition, the automorphism \( F_\xi(g_E) \) on \( F_\xi(E) \) commutes with the left action of any element \( \tau \in \pi \); however \( F_\xi(g_E) \) is just the right action of \( g \) on \( F_\xi(E) \), hence we may compute:

\[
s \cdot g_{s,\sigma} \cdot g_{s,\sigma'} = \left(\tau_E(s)\right) \cdot g_{s,\sigma} \cdot \tau_E(s \cdot g_{s,\sigma}) = \tau_E(s \cdot g_{s,\sigma}) = \tau_E \cdot \sigma_E(s)
\]

so the rule \( \sigma \mapsto g_{s,\sigma} \) defines a group homomorphism \( \rho_{s,f} : \pi \to G \) which is clearly continuous. We claim that the conjugacy class of \( \rho_{s,f} \) does not depend on the choice of \( s \). Indeed, if \( s' \in F_\xi(E) \) is another choice, there exists a (unique) element \( h \in G \) such that \( h(s) = s' \); arguing as in the foregoing we see that \( \sigma_E \) commutes with the right action of \( h \) on \( F_\xi(E) \). In other words, \( \sigma_E(s) = h^{-1} \circ \sigma_E(s') \), so that \( g_{s',\sigma} = h \circ g_{s,\sigma} \circ h^{-1} \).

Therefore, denote by \( \rho_f \) the conjugacy class of \( \rho_{s,f} \); we claim that \( \rho_f \) depends only on the isomorphism class of \( G_X \)-torsor \( E \). Indeed, any isomorphism \( t : E \xrightarrow{\sim} E' \) of right \( G_X \)-torsors induces a bijection \( F_\xi(t) : F_\xi(E) \xrightarrow{\sim} F_\xi(E') \), equivariant for the action of \( G \), and for any \( \sigma \in \pi \) we have \( F_\xi(t) \circ \sigma_E = \sigma_{E'} \circ F_\xi(t) \), whence the assertion.

Conversely, given a continuous group homomorphism \( \rho : \pi \to G \), let us endow \( G \) with the induced left \( \pi \)-action, and right \( G \)-action. Then \( G \) is an object of \( \pi\text{-Set} \), to which there corresponds a finite étale morphism \( E_{\rho} \to X \), with an isomorphism \( E_{\rho} \times_X |\xi| \to G \) of sets with left \( \pi \)-action. Since the right action of \( G \) is \( \pi \)-equivariant, we have a corresponding \( G \)-action by \( X \)-automorphisms on \( E_{\rho} \), so \( E_{\rho} \) is \( G \)-torsor, and its image under the map of the lemma is clearly the conjugacy class of \( \rho \).
Finally, in order to show that the map of the lemma is injective, it suffices to prove that, for any right $G_X$-torsor $(f : E \to X, \varphi : E \times G \to E)$ and any $s \in F_\xi(E)$, there exists an isomorphism of right $G_X$-torsors $E_{\rho_{s,f}} \xrightarrow{\sim} E$. However, $s$ and $\rho_{s,f}$ determine an identification of sets with left $\pi$-action:

$$G \xrightarrow{\sim} F_\xi(E)$$

whence an isomorphism $t : E_{\rho_{s,f}} \xrightarrow{\sim} E$ in Cov$(X)$. Moreover, (13.1.13) also identifies the right $G$-action on $F_\xi(E)$ to the natural right $G$-action on $G$; the latter is $\pi$-equivariant, hence it induces a right $G$-action $\varphi' : E \times G \to E$, such that $t$ is $G$-equivariant. To conclude, it suffices to show that $\varphi = \varphi'$. In view of [51, Ch.IV, Cor.17.4.8], the latter assertion can be checked on the stalks over the geometric point $\xi$, where it holds by construction. \hfill\qed

**Remark 13.1.14.** (i) In the situation of (13.1.11), let $E \to X$ be any right $G_X$-torsor, and $\rho_E : \pi \to G$ the corresponding representation. Then the proof of lemma [13.1.12] shows that the left $\pi$-action on $F_\xi(E)$ is isomorphic to the left $\pi$-action on $G$ induced by $\rho_E$; especially, $\rho_E$ is surjective if and only if $\pi$ acts transitively on $F_\xi(E)$, if and only if the scheme $E$ is connected (since a decomposition of $E$ into connected components corresponds to a decomposition of $F_\xi(E)$ into orbits for the $\pi$-action).

(ii) Let $\varphi : G' \to G$ be a homomorphism of finite groups, and $H^1_{\text{cont}}(\pi, \varphi) : H^1_{\text{cont}}(\pi, G') \to H^1_{\text{cont}}(\pi, G)$ the induced map. Denote by $r$ (resp. $l$) the right (resp. left) translation action of $G$ on itself. Let also $E' \to X$ be a principal $G'$-homogeneous space, given by a map $\rho : G' \to \text{Aut}_X(E')$, and denote by $c' \in H^1_{\text{cont}}(\pi, G')$ the class of $E'$. Then the class $c := H^1_{\text{cont}}(\pi, \varphi)(c')$ can be described geometrically as follows. The scheme $E' \times G$ admits an obvious right $G$-action, induced by $r$. Moreover, it admits as well a right $G'$-action: namely, to any element $g \in G'$, we assign the $X$-automorphism $\rho_g \times l_{\varphi(g^{-1})} : E' \times G \xrightarrow{\sim} E' \times G$. Set $E := (E \times G)/G'$; it is easily seen that $E$ is a principal $G$-homogeneous space, and its class is precisely $c$ (the detailed verification shall be left as an exercise for the reader).

(iii) Consider a commutative diagram of schemes

$$
\begin{array}{ccc}
E' & \xrightarrow{g} & E \\
\downarrow{f'} & & \downarrow{f} \\
X & \xrightarrow{f} & E
\end{array}
$$

where $f$ (resp. $f'$) is a $G$-torsor (resp. a $G'$-torsor) for a given finite group $G$ (resp. $G'$). Denote by $\rho : G \to \text{Aut}_X(E)$ and $\rho' : G' \to \text{Aut}_X(E')$ the respective actions. We have:

(a) Suppose that there exists a group homomorphism $\varphi : G' \to G$, such that $\rho \circ \varphi = g \circ \rho'$. Then $g$ induces a $G'$-equivariant map $F_\xi(E') \to \text{Res}(\varphi)F_\xi(E)$ whence an isomorphism $(E' \times G)/G' \xrightarrow{\sim} G$ of $G$-torsors. Hence, let $c$ (resp. $c'$) denote any representative of the equivalence class of $E$ (resp. $E'$) in $H^1_{\text{cont}}(\pi, G)$ (resp. $H^1_{\text{cont}}(\pi, G')$); in view of (ii), it follows that $H^1(\pi, \varphi)(c') = c$.

In other words, the induced diagram of continuous group homomorphisms

$$
\begin{array}{ccc}
\pi_1(X_{\text{ét}}, \xi) & \xrightarrow{\varphi} & G' \\
\downarrow{c} & & \downarrow{c} \\
G & \xrightarrow{\varphi} & G
\end{array}
$$
commutes, up to composition with an inner automorphism of $G$. (Details left to the reader.)

(b) If $E$ is connected, a group homomorphism $\varphi : G \to G'$ fulfilling the condition of (a) exists and is unique up to composition with an inner automorphism of $G$. Indeed, fix any $e' \in F_2(E')$ and let $e := f(e')$; if $g' \in G'$, define $\varphi(g')$ as the unique $g \in G$ such that $f(e' \cdot g') = e \cdot g$; also, in view of (i) we may pick $\sigma_{g'} \in \pi_1(X, \xi)$ such that $\sigma_{g'} \cdot e = e' \cdot g'$, and notice that $\sigma_{g'} \cdot e = e \cdot \varphi(g')$ for every $g' \in G'$. Now, if $h' \in G'$ is any other element, we may compute:

$$f(e' \cdot g' h') = f(\sigma_{g'} \cdot e' \cdot h') = \sigma_{g'} \cdot f(e' \cdot h') = \sigma_{g'} \cdot e \cdot \varphi(h') = e \cdot \varphi(g') \cdot \varphi(h')$$

whence $\varphi(g' h') = \varphi(g') \cdot \varphi(h')$, as required.

Lemma 13.1.15. Let $f : X \to Y$ be a morphism of schemes, $\mathcal{F}$, $\mathcal{G}$ two sheaves on $Y_{\acute{e}t}$. Then:

(i) If $\mathcal{F}$ is locally constant and constructible, the natural map:

$$\vartheta_f : f^* \mathcal{H}om_{Y_{\acute{e}t}}(\mathcal{F}, \mathcal{G}) \to \mathcal{H}om_{X_{\acute{e}t}}(f^*\mathcal{F}, f^*\mathcal{G})$$

is an isomorphism.

(ii) If $f$ is 0-acyclic, it induces a fully faithful functor

$$f^* : \text{Cov}(Y) \to \text{Cov}(X) : (E \to Y) \mapsto (E \times_Y X \to X).$$

Proof. (i): Suppose we have a cartesian diagram of schemes:

$$\begin{array}{ccc}
X' & \xrightarrow{g'} & X \\
\downarrow f' & & \downarrow f \\
Y' & \xrightarrow{g} & Y
\end{array}$$

Then, according to (4.8.2), we have a natural isomorphism:

$$\vartheta_{g'} \circ g'^* \vartheta_f \Rightarrow \vartheta_f \circ f^* \vartheta_g$$

(an invertible 2-cell, in the terminology of (2.1)). Now, if $g$ and therefore $g'$ is a covering morphism, $\vartheta_g$ and $\vartheta_{g'}$ are isomorphisms, and $g'^* \vartheta_f$ is an isomorphism if and only if the same holds for $\vartheta_f$. Summing up, in this case $\vartheta_f$ is an isomorphism if and only if the same holds for $\vartheta_f$. Thus, we may choose $g$ such that $g^*$ is a constant sheaf, and after replacing $f$ by $f'$, we may assume that $\mathcal{F} = \mathcal{F}_1 = Y$ is the constant sheaf associated with a finite set $S$. Since the functors

$$\mathcal{H}om_{Y_{\acute{e}t}}(-, \mathcal{G}) : (Y_{\acute{e}t})^\circ \to Y_{\acute{e}t}$$

and

$$f^* : Y_{\acute{e}t} \to X_{\acute{e}t}$$

are left exact, we may further reduce to the case where $S = \{1\}$ is the set with one element, in which case $\mathcal{F} = 1_Y$ is the final object of $Y_{\acute{e}t}$, and $f^* \mathcal{F} = 1_X$ is the final object of $X_{\acute{e}t}$. Moreover, we have a natural identification:

$$\mathcal{H}om_{Y_{\acute{e}t}}(1_Y, \mathcal{G}) \cong \mathcal{G} : \sigma \mapsto \sigma(1)$$

and likewise for $\mathcal{H}om_{X_{\acute{e}t}}(1_Y, f^* \mathcal{G})$. Using the foregoing characterization, it is easily checked that, under these identifications, $\vartheta_f$ is the identity map of $f^* \mathcal{G}$, whence the claim.

(ii): It has already been remarked that $\text{Cov}(Y)$ is equivalent to the category of locally constant constructible sheaves on $Y_{\acute{e}t}$, and likewise for $\text{Cov}(X)$. Let $E$ and $F$ be two objects of $\text{Cov}(Y)$; we have natural bijections:

$$\text{Hom}_{\text{Cov}(X)}(f^* E, f^* F) \cong \Gamma(X, \mathcal{H}om_{X_{\acute{e}t}}(f^* E, f^* F))$$

$$\cong \Gamma(Y, f_* f^* \mathcal{H}om_{Y_{\acute{e}t}}(E, F))$$

by (i)

$$\cong \Gamma(Y, \mathcal{H}om_{Y_{\acute{e}t}}(E, F))$$

since $f$ is 0-acyclic

$$\cong \text{Hom}_{\text{Cov}(Y)}(E, F)$$
as stated. □

**Lemma 13.1.16.** Let \( f : X \to S \) be a quasi-compact morphism of schemes, and suppose that:

(a) \( f \) is locally \((-1\)-acyclic).

(b) For every strict geometric point \( \xi \) of \( S \), the induced morphism \( f_\xi : f^{-1}(\xi) \to |\xi| \) is \( 0 \)-acyclic (i.e. \( f \) has non-empty geometrically connected fibres).

Then \( f \) is \( 0 \)-acyclic.

**Proof.** Let \( \mathcal{F} \) be a sheaf on \( S_{\text{et}} \). For every strict geometric point \( \xi \) of \( S \), we have a commutative diagram:

\[
\begin{array}{ccc}
\mathcal{F}_\xi & \xrightarrow{\varepsilon_\xi} & (f_*f^*\mathcal{F})_\xi \\
\alpha & & \downarrow \\
\Gamma(|\xi|, \xi^*\mathcal{F}) & \xrightarrow{f^*_{\xi}} & \Gamma((f^{-1}(\xi), f^*_{\xi} \circ \xi^*\mathcal{F})
\end{array}
\]

where \( \varepsilon : \mathcal{F} \to f_*f^*\mathcal{F} \) is the unit of adjunction. The map \( \alpha \) is an isomorphism, and the same holds for \( f^*_{\xi} \), since \( f_{\xi} \) is \( 0 \)-acyclic. Hence \( \varepsilon_{\xi} \) is injective, which shows already that \( f \) is \((-1\)-acyclic). It remains to show that \( \varepsilon_{\xi} \) is surjective. Hence, let \( t \in (f_*f^*\mathcal{F})_\xi \) be any section. From (13.1.17) we see that there exists a section \( t' \in \mathcal{F}_\xi \) such that the images of \( t \) and \( \varepsilon_{\xi}(t') \) agree on \( \Gamma((f^{-1}(\xi), f^*_{\xi} \circ \xi^*\mathcal{F}) \). We may find an étale neighborhood \( g : U \to S \) of \( \xi \), such that \( t' \) (resp. \( t \)) extends to a section \( t'' \in \mathcal{F}(U) \) (resp. \( t_U \in \Gamma(X \times_S U, f^*\mathcal{F}) \)). Let \( X_U := X \times_S U \), so \( f_U := f \times_S U : X_U \to U \), and for every geometric point \( \overline{\tau} \) of \( X_U \), denote by \( f^*_{\overline{\tau}} : \mathcal{F}_{f_U(\overline{\tau})} \to f_U^\tau \) the natural isomorphism (4.9.22). We set

\[
V := \{ x \in X_U \mid t_U \varepsilon = f^*_{\overline{\tau}}(t'_{U,(\overline{\tau})}) \}
\]

where \( \overline{\tau} \) is any geometric point of \( X \) localized at \( x \), and \( t_U \varepsilon \in f^*\mathcal{F} \) (resp. \( t'_{U,(\overline{\tau})} \in \mathcal{F}_{f_U(\overline{\tau})} \)) denotes the image of \( t_U \) (resp. \( t'_{U,(\overline{\tau})} \)). Clearly \( V \) is an open subset of \( X_U \), and we have:

**Claim 13.1.18.** (i) \( V = f_U^{-1}f_U(V) \).

(ii) \( f_U(V) \subset U \) is an open subset.

**Proof of the claim.** (i): Given a point \( u \in U \), choose a strict geometric point \( \overline{\tau} \) localized at \( u \), and set \( \overline{\tau} := g(\overline{\tau}) \); abuse of notation, the morphism \( f_{\overline{\tau}} : f^{-1}(\overline{\tau}) \to |\overline{\tau}| \) is \( 0 \)-acyclic, hence the image of \( t_U \) in \( \Gamma((f^{-1}(\overline{\tau}), f^*_{\overline{\tau}} \circ \xi^*\mathcal{F}) \) is of the form \( f^*_{\overline{\tau}}t'' \), for some \( t'' \in \mathcal{F}_{\overline{\tau}} \). It follows that \( V \cap f_U^{-1}(u) \) is either the whole of \( f_U^{-1}(u) \) or the empty set, according to whether \( t'' \) agrees or not with the image of \( t'' \) in \( \mathcal{F}_{\overline{\tau}} = g^*\mathcal{F}_{\overline{\tau}} \).

(ii): The subset \( X \setminus V \) is closed, especially pro-constructible; since \( f \) is quasi-compact, we deduce that \( f_U(X \setminus V) \) is a pro-constructible subset of \( U \) (corollary 8.1.47). It then follows from (i) that \( f_U(V) \) is ind-constructible, hence we are reduced to showing that \( f_U(V) \) is closed under generalizations (proposition [8.1.44](ii))). To this aim, since \( V \) is open, it suffices to show that \( f_U \) is generizing, i.e. that the induced maps \( X_U(x) \to U(u) \) are surjective, for every \( u \in U \) and every \( x \in f_U^{-1}(u) \). However, choose a geometric point \( \overline{\tau} \) localized at \( x \), and let \( \overline{\pi} := f_U(\overline{\tau}) \); since the natural maps \( X_U(\overline{\tau}) \to X_U(x) \) and \( U(\overline{\pi}) \to U(\overline{\tau}) \) are surjective, it suffices to show that the same holds for the map \( f_{\overline{\pi}} : X_U(\overline{\pi}) \to U(\overline{\pi}) \). The image of \( \overline{\pi} \) (resp. \( \overline{\tau} \)) in \( X \) (resp. \( S \)) is a geometric point which we denote by the same name; since the natural maps \( X_U(\overline{\pi}) \to X(\overline{\pi}) \) and \( U(\overline{\pi}) \to S(\overline{\pi}) \) are isomorphisms, we are reduced to showing that \( f_{\overline{\pi}} : X(\overline{\pi}) \to S(\overline{\pi}) \) is surjective, which holds, since \( f \) is locally \((-1\)-acyclic).

Set \( W := f_U(V) \); in view of claim 13.1.18, \( W \) is an étale neighborhood of \( \xi \), and the natural map \( \mathcal{F}(W) \to f^*\mathcal{F}(U) \) sends the restriction \( t_{U,W} \) of \( t_U \) to the restriction \( t_{U,V} \) of \( t_U \), whence the claim. □

13.1.19. Consider now a cartesian diagram of schemes:

\[
\begin{array}{ccc}
X' & \xrightarrow{g'} & X \\
\downarrow{f'} & & \downarrow{f} \\
S' & \xrightarrow{g} & S
\end{array}
\]

(13.1.20)

where \( g \) is a local morphism of strictly local schemes, and denote by \( s \) (resp. by \( s' \)) the closed point of \( S \) (resp. of \( S' \)). Let \( x' \in f'^{-1}(s') \) be any point, \( \pi' \) a geometric point of \( X' \) localized at \( x' \), and set \( x := g'(x') \), \( \pi := g'(\pi') \). Then \( g' \) induces a morphism of \( S' \)-schemes:

\[
X'(\pi') \to X(\pi) \times_S S'.
\]

(13.1.21)

Lemma 13.1.22. In the situation of (13.1.19), suppose that \( g \) is an integral morphism. Then:

(i) The induced morphism \( f'^{-1}(s') \to f^{-1}(s) \) induces a homeomorphism on the underlying topological spaces.

(ii) \( (13.1.21) \) is an isomorphism.

Proof. If \( g \) is integral, \( \kappa(s') \) is a purely inseparable algebraic extension of \( \kappa(s) \), hence the morphism \( T' := \text{Spec} \, \kappa(s') \to T := \text{Spec} \, \kappa(s) \) is radicial, and the same holds for the induced morphisms:

\[
f'^{-1}(s') \xrightarrow{\sim} f^{-1}(s) \times_T T' \to f^{-1}(s) \quad f_x^{-1}(s) \times_T T' \to f_x^{-1}(s)
\]

([44] Ch.I, Prop.3.5.7(ii)). Especially (i) holds, and therefore the natural map \( X'(x') \to X(x) \times_S S' \) is an isomorphism; we see as well that \( f_x^{-1}(s) \times_T T' \) is a local scheme. Then the assertion follows from [51] Ch.IV, Rem.18.8.11].

Proposition 13.1.23. Let \( f : X \to S \) and \( g : S' \to S \) be morphisms of schemes, with \( g \) quasi-finite, and set \( X' := X \times_S S' \). Suppose that \( f \) is locally \((-1)\)-acyclic (resp. locally 0-acyclic); then the same holds for \( f' := f \times_S S' : X' \to S' \).

Proof. Let \( \pi' \) be any geometric point of \( S' \), and set \( \pi := g(\pi') \). Denote by \( s \in S \) (resp. \( s' \in S' \)) the support of \( \pi \) (resp. \( \pi' \)); then \( f \) is locally \((-1)\)-acyclic at the points of \( f^{-1}(s) \), if and only if \( f_x := f \times_S S(\pi) : X \times_S S(\pi) \to S(\pi) \) enjoys the same property at the points of \( f_x^{-1}(s) \). Likewise, \( f' \) is locally \((-1)\)-acyclic (resp. locally 0-acyclic) at the points of \( f'^{-1}(s') \), if and only if \( f'_x : X' \times_{S'} S'((\pi')) \to S'(\pi') \) enjoys the same property at the points of \( f'_x^{-1}(\pi') \). Hence, we may replace \( g \) by \( g_{\text{st}} : S'(\pi') \to S(\pi) \), and \( f \) by the induced morphism \( X \times_S S(\pi) \to S(\pi) \), which allows to assume that \( g \) is finite ([51] Ch.IV, Th.18.5.11]), hence integral. Let \( \xi' \) (resp. \( \pi' \)) be any strict geometric point of \( S' \) (resp. of \( f'^{-1}(s') \)), and let \( \xi := g(\xi')_{\text{st}} \), (resp. let \( \pi \) be the image of \( \pi' \) in \( X \)); we have natural morphisms:

\[
f'^{-1}(\xi') \xrightarrow{\alpha} X(\pi) \times_S \xi' \xrightarrow{\beta} f_x^{-1}(\xi)
\]

However, \( \alpha \) is an isomorphism, by lemma (13.1.22(ii)), and \( \beta \) is a radicial morphism, since the field extension \( \kappa(\xi) \subset \kappa(\xi') \) is purely inseparable ([44] Ch.I, Prop.3.5.7(ii)). The claim follows.

Lemma 13.1.24. (i) Let \( S \) be a strictly local scheme, \( s \in S \) the closed point, \( f : X \to S \) a morphism of schemes, \( \pi \) (resp. \( \xi \)) a strict geometric point of \( f^{-1}(s) \) (resp. of \( S \)). We may find:

(a) A cartesian diagram (13.1.20), with \( S' \) strictly local, irreducible and normal.
(b) A strict geometric point \( \pi' \) of \( f'^{-1}(s') \) with \( g(\pi')_{\text{st}} = \pi \).
(c) A strict geometric point \( \xi' \) of \( S' \) localized at the generic point of \( S' \), with \( g(\xi')_{\text{st}} = \xi \), and such that (13.1.21) induces an isomorphism:

\[
f'^{-1}(\xi') \xrightarrow{\sim} f_x^{-1}(\xi).
\]

(13.1.25)
(ii) Moreover, if \( S \) is noetherian, we may find \( S' \) as in (i), such that \( \mathcal{O}_S(S) \) is a Krull domain.

**Proof.** (i): Denote by \( Z \subset S \) the closure of the image of \( \xi \), endow \( Z \) with its reduced subscheme structure, set \( Y := X \times_S Z \subset X \), and let \( h_T : Y(\overline{\pi}) \rightarrow Z \) be the natural morphism. Then \( Z \) is a strictly local scheme ([51] Ch.IV, Prop.18.5.6(ii)). Moreover, the closed immersion \( Y \rightarrow X \) induces an isomorphism of \( Z \)-schemes : \( Y(\overline{\pi}) \overset{\sim}{\rightarrow} X(\overline{\pi}) \times_S Z \) (lemma [13.1.22](ii)). By construction, \( \xi \) factors through a strict geometric point \( \xi' \) of \( Z \), and we deduce an isomorphism : \( h_T^{-1}(\xi') \overset{\sim}{\rightarrow} f_T^{-1}(\xi) \) of \( Z \)-schemes. Thus, we may replace \( (S, X, \xi) \) by \((Z, Y, \xi')\), and assume that \( S \) is the spectrum of a strictly local domain, and \( \xi \) is localized at the generic point of \( S \). Say that \( S = \text{Spec} \ A \), and denote by \( A' \) the normalization of \( A \) in its field of fractions \( F \). Then \( A' \) is the union of a filtered family \((A_{\lambda} \mid \lambda \in \Lambda)\) of finite \( A \)-subalgebras of \( F \); since \( A \) is henselian, each \( A_{\lambda} \) is a product of henselian local rings, hence it is a local henselian ring, so the same holds for \( A' \). Moreover, the residue field \( \kappa(s') \) of \( A' \) is an algebraic extension of the residue field \( \kappa(s) \) of \( A \), which is separably closed, hence \( \kappa(s') \) is separably closed, i.e. \( A' \) is strictly henselian, so we may fulfill condition (a) by taking \( S' := \text{Spec} \ A' \). Condition (b) holds as well, due to lemma [13.1.22](ii). Finally, it is clear that \( \xi \) lifts to a unique strict geometric point \( \xi' \) of \( S' \), and it follows from lemma [13.1.22](ii) that \((13.1.25)\) is an isomorphism, as required.

(ii): A direct inspection of the proof of (i) reveals that if \( S \) is noetherian, the scheme \( S' \) exhibited is the spectrum of the normalization of a noetherian domain; the assertion then follows from [103 Th.33.10]. \( \square \)

13.1.26. In the situation of \((13.1.4)\), let \( x \in X \) be any point, and \( s := f(x) \). Let also \( \xi \) be a strict geometric point of \( S \). We deduce a compatible system of points \( \lambda := p_{a}(x) \in X_{\lambda} \), whence a cofiltered system of local schemes

\[
\mathcal{R} := (X_{\lambda}(x_{\lambda}) \mid \lambda \in \Lambda).
\]

Moreover, we get a compatible system of strict geometric points \( \xi_{\lambda} := p_{\lambda}(\xi)^{\text{at}} \mid \lambda \in \Lambda \), with :

\[
\xi \overset{\sim}{\rightarrow} \lim_{\lambda \in \Lambda} \xi_{\lambda}.
\]

Choose a geometric point \( \overline{\pi} \) of \( X \) localized at \( x \), and set likewise \( \overline{\pi}_{\lambda} := p'_{\lambda}(\overline{\pi}); \) then \( \mathcal{R} \) lifts to a system \( \mathcal{R}^{\text{sh}} := (X_{\lambda}(\overline{\pi}_{\lambda}) \mid \lambda \in \Lambda) \), whose limit is naturally isomorphic to \( X(\overline{\pi}) \) ([51] Ch.IV, Prop.18.8.18(ii))). Furthermore, \( \mathcal{R}^{\text{sh}} \) induces a natural isomorphism of \( \kappa(\xi) \)-schemes :

\[
(13.1.27) \quad f_{\overline{\pi}}^{-1}(\xi) \overset{\sim}{\rightarrow} \lim_{\lambda \in \Lambda} f_{\overline{\pi}_{\lambda}}^{-1}(\xi_{\lambda})
\]

where, as usual, \( f_{\overline{\pi}} : X(\overline{\pi}) \rightarrow S \) (resp. \( f_{\lambda,\overline{\pi}} : X_{\lambda}(\overline{\pi}_{\lambda}) \rightarrow S_{\lambda} \)) is deduced from \( f \) (resp. from \( f_{\lambda} \)). These remarks, together with the following lemma [13.1.28] and the previous lemma [13.1.24] will allow in many cases, to reduce the study of the fibres of \( f_{\overline{\pi}} \), to the case where the base \( S \) is strictly local, excellent and normal.

**Lemma 13.1.28.** Let \( S \) be a strictly local normal scheme. Then there exists a cofiltered family \( \mathcal{S} := (S_{\lambda} \mid \lambda \in \Lambda) \) consisting of strictly local normal excellent schemes, such that :

(a) \( S \) is isomorphic to the limit of \( \mathcal{S} \).

(b) The natural morphism \( S \rightarrow S_{\lambda} \) is dominant for every \( \lambda \in \Lambda \).

**Proof.** Say that \( S = \text{Spec} \ A \), and write \( A \) as the union of a filtered family \( \mathcal{A} := (A_{\lambda} \mid \lambda \in \Lambda) \) of excellent noetherian local subrings, which we may assume to be normal, by [49] Ch.IV, (7.8.3)(ii),(vi)]. Proceeding as in \((13.1.26)\), we choose a compatible family of geometric points \( \overline{\pi}_{\lambda} \) localized at the closed points of \( \text{Spec} A_{\lambda} \), for every \( \lambda \in \Lambda \); using these geometric points, we lift \( \mathcal{A} \) to a filtered family \( (A_{\lambda}^{\text{sh}} \mid \lambda \in \Lambda) \) of strict henselizations, whose colimit is naturally isomorphic to \( A \). Moreover, each \( A_{\lambda}^{\text{sh}} \) is noetherian, normal and excellent ([51] Ch.IV, Prop.18.8.8(iv), Prop.18.8.12(ii)] and proposition [9.7.19](ii)). Let \( \eta \) be the generic point of \( S \),
We obtain a compatible system of strict geometric points $\eta|_\lambda$ for every $\lambda \in \Lambda$. The cofiltered system $(S_\lambda \mid \lambda \in \Lambda)$ fulfills condition (a). Moreover, by construction, the image of $\eta|_\lambda$ in $\Spec A_\lambda$ is the generic point $\eta|_\lambda$; then $\eta|_\lambda$ is the generic point of $S_\lambda$, since the latter is the only point of $S_\lambda$ lying over $\eta|_\lambda$. Hence (b) holds as well.

**Proposition 13.1.29.** Let $f : X \to S$ be a flat morphism of schemes. We have:

(i) $f$ is locally $(-1)$-acyclic.

(ii) Suppose moreover that $f$ has geometrically reduced fibres, and:

(a) either $f$ is locally finitely presented,

(b) or else, $S$ is locally noetherian.

Then $f$ is locally $0$-acyclic.

**Proof.** Let $x \in X$ be any point, set $s := f(x)$, choose a geometric point $\overline{s}$ of $X$ localized at $x$, set $\overline{s} := f(\overline{s})$, and let $\xi$ be any geometric point of $S(\overline{s})$.

(i): If $f$ is flat, the induced morphism $f_\overline{s} : X(\overline{s}) \to S(\overline{s})$ is faithfully flat; especially, $f_\overline{s}$ is surjective (100 Th.7.3(i)).

(ii): Set $X' := X \times_S S(\overline{s})$. The natural morphism $X(\overline{s}) \to X$ factors uniquely through a morphism of $S(\overline{s})$-schemes $j : X(\overline{s}) \to X'$, and if we denote by $\overline{x}'$ the image in $X'$ of $\overline{x}$, then $j$ induces an isomorphism of $S(\overline{s})$-schemes $X(\overline{s}) \cong X'$. Hence, $f$ is locally $0$-acyclic at the point $x$, if and only if the induced morphism $X' \to S(\overline{s})$ is locally $0$-acyclic at the support $x'$ of $\overline{x}$, so we may replace $S$ by $S(\overline{s})$, and assume that $S$ is strictly local, when (a) holds, and even strictly local and noetherian, when (b) holds. We have to show that $f_\overline{s}^{-1}(\xi)$ is connected, and by lemma 13.1.24, we are further reduced to the case where $S = S(\overline{s}) = \Spec A$ is strictly local and normal, $\xi$ is localized at the generic point of $S$, and:

(a') either $f$ is finitely presented,

(b') or else, $A$ is a (not necessarily noetherian) Krull domain.

**Claim 13.1.30.** In case (b') holds, $f_\overline{s}^{-1}(\xi)$ is connected.

**Proof of the claim.** Let $F$ be the field of fractions of $A$; the field $\kappa(\xi)$ is algebraic over $F$, hence it suffices to show that $X(\overline{s}) \times_S \Spec K$ is connected for every finite field extension $F \subset K$ (50 Ch.IV, Prop.8.4.1(ii))). Let $A_K$ be the normalization of $A$ in $K$; then $A_K$ is again a Krull domain (28 Ch.VII, §11, n.8, Prop.12)), and $B := \mathcal{O}_{X,x}^\text{sh} \otimes_A A_K$ is a flat $A_K$-algebra. Notice that the geometric fibres of the induced morphism $f_{\overline{s},K} : \Spec B \to \Spec A_K$ are cofiltered limits of schemes that are étale over the fibres of $f$; since the fibres of $f$ are geometrically reduced, it follows that the same holds for the fibres of $f_{\overline{s},K}$. Hence $B$ is integrally closed in $B \otimes_A F$ (lemma 9.8.2); especially these two rings have the same idempotents, whence the contention.\[\heartsuit\]

Finally, suppose that (a') holds. By lemma 13.1.28, the scheme $S$ is the limit of a cofiltered family $(S_\lambda \mid \lambda \in \Lambda)$ of strictly local excellent and normal schemes, such that the natural morphisms $p_\lambda : S \to S_\lambda$ are dominant. By claim 9.8.4, there exists $\lambda \in \Lambda$ and a flat morphism of schemes $f_\lambda : X_\lambda \to S_\lambda$ with geometrically reduced fibres, with an isomorphism of $S$-schemes $S \times_{S_\lambda} X_\lambda \to X$; then, for every $\mu \in \Lambda$ with $\mu \geq \lambda$, set $X_\mu := S_\mu \times_{S_\lambda} X_\lambda$ and $f_\mu := S_\mu \times_{S_\lambda} f_\lambda : X_\mu \to S_\mu$. After replacing $\Lambda$ by a cofinal subset, we may assume that $f_\lambda$ is defined for every $\lambda \in \Lambda$. For every such $\lambda$, let $x_\lambda \in X_\lambda$ be the image of $x$. Arguing as in (13.1.26), we obtain a compatible system of strict geometric points $\xi_\lambda$ of $S_\lambda$ (resp. $\overline{\xi}_\lambda$ of $X_\lambda$), such that $p_\lambda(\xi)$ factors through $\xi_\lambda$; whence an isomorphism (13.1.27). Thus, $f_\lambda(\xi)$ is reduced if and only if $f_\lambda^{-1}(\xi)$ is reduced for every sufficiently large $\lambda \in \Lambda$ (50 Ch.IV, Prop.8.7.2)).

Furthermore, since $p_\lambda$ is dominant, $\xi_\lambda$ is localized at the generic point of $S_\lambda$, for every $\lambda \in \Lambda$. Thus, we are reduced to the case where $S = S(\overline{s})$ is the spectrum of a strictly local noetherian normal domain $A$, and $\xi$ is localized at the generic point of $S$; since such $A$ is a Krull domain (100 Th.12.4(i)), this is covered by claim 13.1.30.\[\heartsuit\]
Example 13.1.31. (i) Let $A$ be an excellent local ring, and $A^\wedge$ the completion of $A$. Then the natural morphism:

$$f : \text{Spec } A^\wedge \to \text{Spec } A$$

is locally 0-acyclic. Indeed, this follows from proposition [13.1.29](ii) (and from the excellence assumption, which includes the geometric regularity of the formal fibres of $A$).

(ii) Suppose additionally, that $A$ is strictly local. Then $f$ is 0-acyclic. To see this, we apply the criterion of lemma [13.1.16]: indeed, since $f$ is flat, it is $(-1)$-acyclic (proposition [13.1.29](i)); it remains to show that $f$ has geometrically connected fibres, and since $A^\wedge$ is strictly local ([51 Ch.IV, Prop.18.5.14]), this is the same as showing that $f$ is locally 0-acyclic at the closed point of $\text{Spec } A^\wedge$, which has already been remarked in (i).

(iii) More generally, $f$ is 0-acyclic whenever $A$ is excellent and henselian. Indeed, in this case the argument of (ii) again reduces to showing that $f$ has geometrically connected fibres. However, consider the natural commutative diagram:

$$\begin{array}{ccc}
\text{Spec } (A^\wedge)^{\text{sh}} & \longrightarrow & \text{Spec } A^\wedge \\
\downarrow f^{\text{sh}} & & \downarrow f \\
\text{Spec } A^{\text{sh}} & \longrightarrow & \text{Spec } A.
\end{array}$$

(13.1.32)

Since $A$ is henselian, $A^{\text{sh}}$ is the colimit of a filtered family of finite étale and local $A$-algebras. Since $A$ and $A^\wedge$ have the same residue field, it follows easily that $A^\wedge \otimes_A A^{\text{sh}}$ is the colimit of a filtered family of finite étale and local $A^\wedge$-algebras, hence it is strictly henselian, and therefore [13.1.32] is cartesian, especially the geometric fibres of $f$ are connected if and only if the same holds for the geometric fibres of $f^{\text{sh}}$, and the latter are reduced (even regular), since $A$ is excellent. Hence, we come down to showing that $f^{\text{sh}}$ is locally 0-acyclic at the closed point of $\text{Spec } (A^\wedge)^{\text{sh}}$, which holds again by proposition [13.1.29](ii).

For future use, we point out the following

Proposition 13.1.33. Let $g : X \to Y$ be a flat morphism of excellent noetherian schemes, with $X$ strictly local, and $Y$ normal. Let $U \subset X$ be an open subset, and $Z \subset Y$ a closed subscheme. Suppose that:

(i) $g^{-1}(z) \subset U$ for every maximal point $z$ of $Z$.

(ii) $U \cap g^{-1}(z)$ is a dense open subset of $g^{-1}(z)$, for every $z \in Z$.

(iii) The fibres $g^{-1}(z)$ are reduced, for every $z \in Z$.

Then the induced functor $\text{Cov}(U) \to \text{Cov}(U \times_Y Z)$ is fully faithful.

Proof. Indeed, say that $X = \text{Spec } B$, $Y = \text{Spec } A$, $Z = V(I)$ for some ideal $I \subset A$, and denote by $B^\wedge$ the $m_B$-adic completion of the local ring $B$ (where $m_B \subset B$ denotes the maximal ideal). Let also $f : \text{Spec } B^\wedge \to Y$ be the induced morphism, and $U^\wedge \subset \text{Spec } B^\wedge$ the preimage of $U$. In light of example [13.1.31](ii) and lemma [13.1.15](ii), it suffices to show that the induced functor $\text{Cov}(U^\wedge) \to \text{Cov}(U^\wedge \times_Y Z)$ is fully faithful. In view of lemma [13.1.3] we are further reduced to checking that conditions (a)–(c) of proposition [10.5.46] hold for the induced ring homomorphism $\varphi : A \to B^\wedge$, the open subset $U^\wedge$, and the ideal $I$. However, by example [10.5.41] we have $\text{Ass}_A(I, A) = \text{Max}(Z)$, hence (c) follows trivially from our assumption (i). Next, since $B^\wedge$ is a faithfully flat $B$-algebra, assumption (ii) implies that $U^\wedge \cap f^{-1}(z)$ is a dense open subset of $f^{-1}(z)$, for every $z \in Z$. Moreover, since $B$ is excellent, the natural morphism $\text{Spec } B^\wedge \to X$ is regular, so the same holds for the induced morphism $f^{-1}(z) \to g^{-1}(z)$, and then our assumption (iii) implies – together with [100 Th.32.3(i)] – that $f^{-1}(z)$ is reduced, for every $z \in Z$, whence condition (b). Lastly, we check condition (a), i.e. we show that $B^\wedge$ is $I$-adically complete. Indeed, let $C$ be the $I$-adic completion of $B^\wedge$; the natural map $B^\wedge \to C$ is injective, and it admits a left inverse, constructed as follows. Let $g := (a_n \mid n \in \mathbb{N})$ be a given
sequence of elements of $B^\wedge$, which is Cauchy for the $I$-adic topology; then $\varphi$ is also Cauchy for the $m_B$-adic topology, and it is easily seen that the limit $l$ of $\varphi$ in the $m_B$-adic topology depends only on the class $[\varphi]$ of $\varphi$ in $C$, so we get a well defined ring homomorphism $\lambda : C \to B^\wedge$ by the rule : $[\varphi] \mapsto l$, and clearly $\lambda$ is the sought left inverse. It remains to check that $\lambda$ is injective; thus, suppose that $l = 0$, and that $[\varphi] \neq 0$; this means that there exists $N \in \mathbb{N}$ such that $a_n \notin I^N$, for every $n \in \mathbb{N}$. Now, the induced sequence $(\pi_n | n \in \mathbb{N})$ of elements of $(B^\wedge)^{/I^N}$ is stationary, and on the other hand, it converges $m_B$-adically to 0; therefore $\pi_n = 0$ for every sufficiently large $n \in \mathbb{N}$, a contradiction. \hfill $\square$

13.1.34. Let $A$ be a noetherian normal ring, and endow the $A$-algebra $A[[t]]$ with its $t$-adic topology. Let

$$\varphi : X := \text{Spf} \ A[[t]] \to X := \text{Spec} \ A[[t]]$$

$$\pi : X \to S := \text{Spec} \ A \quad i : S \to X$$

be respectively the natural morphism of locally ringed spaces, the natural projection, and the closed immersion determined by the ring homomorphism $A[[t]] \to A$ given by the rule : $f(t) \mapsto f(0)$, for every $f(t) \in A[[t]]$. Let also $U_0 \subset \text{Spec} \ A$ be an open subset, $U := \pi^{-1}U_0$ and $U \setminus = \varphi^{-1}U$. Finally, denote by $\mathcal{E}$ a locally free $\mathcal{O}_U$-module of finite rank, and set $\mathcal{E}^\wedge := \varphi_*^t \mathcal{E}$, which is a locally free $\mathcal{O}_U$-module of finite rank.

**Lemma 13.1.35.** In the situation of (13.1.34), suppose that $S \setminus U_0$ has codimension $\geq 2$ in $S$. Then:

(i) The natural map

$$\Gamma(U, \mathcal{E}) \to \Gamma(U, \mathcal{E}^\wedge)$$

is an isomorphism of $A[[t]]$-modules.

(ii) The restriction $i_{|U_0} : U_0 \to U$ of $i$ induces an equivalence :

$$i_{|U_0}^* : \text{Cov}(U) \to \text{Cov}(U_0) \quad (E \to U) \mapsto (E \times_U U_0 \to U_0).$$

**Proof.** (i): To begin with, set $Z := S \setminus U_0$; since the morphism $\pi$ is flat, hence generizing ([100 Th.9.5]), the closed subset $X \setminus U = \pi^{-1}Z$ has codimension $\geq 2$ in $X$. Since $A$ and $A[[t]]$ are both normal, we deduce :

(13.1.36) $\text{depth}_{X \setminus U} \mathcal{O}_X \geq 2 \quad \text{depth}_Z \mathcal{O}_S \geq 2$

(theorem[10.4.21] and [100 Th.23.8]); therefore (corollary[10.4.23]) :

(13.1.37) $\Gamma(U, \mathcal{O}_X) = \Gamma(X, \mathcal{O}_X) = A[[t]].$

Next, the short exact sequences of $\mathcal{O}_X$-modules :

$$0 \to i_* \mathcal{O}_S \to \mathcal{O}_X/t^{n+1} \mathcal{O}_X \to \mathcal{O}_X/t^n \mathcal{O}_X \to 0$$

for every $n \in \mathbb{N}$ induce exact sequences

(13.1.38) $R^j i_* \Gamma_i \mathcal{O}_S \to R^j \Gamma_i \mathcal{O}_X/t^{n+1} \mathcal{O}_X \to R^j \Gamma_i \mathcal{O}_X/t^n \mathcal{O}_X$

for every $n, j \in \mathbb{N}$. Then (13.1.36) and (13.1.38) yield inductively :

$$\text{depth}_Z \mathcal{O}_X/t^n \mathcal{O}_X \geq 2$$

for every $n \in \mathbb{N}$ and again corollary[10.4.23] implies :

(13.1.39) $\Gamma(U, \mathcal{O}_X/t^n \mathcal{O}_X) = A[[t]/t^n A[[t]]$ for every $n \in \mathbb{N}$.

Since $U$ is quasi-compact, we may find a left exact sequence $P := (0 \to \mathcal{E} \to \mathcal{O}_U^{\oplus m} \to \mathcal{O}_U^{\oplus n})$ of $\mathcal{O}_U$-modules (corollary[10.3.26]). Since $\varphi$ is a flat morphism of locally ringed spaces, the sequence $\varphi_* P$ is still left exact. Since the global section functors are left exact, we are then reduced to the case where $\mathcal{E} = \mathcal{O}_U$. Then we may write :

$$\mathcal{E}^\wedge = \mathcal{O}_U = \lim_{n \in \mathbb{N}} \mathcal{O}_U/t^n \mathcal{O}_U$$
where, for each \( n \in \mathbb{N} \), we regard \( \mathcal{O}_U/t^n\mathcal{O}_U \) as a sheaf of (pseudo-discrete) rings on \( U = V(\ell) \subset U \). The functor \( \Gamma(U, -) \) is a right adjoint, hence commutes with limits, and we deduce an isomorphism :

\[
\Gamma(U, \mathcal{E}^\wedge) \xrightarrow{\sim} \lim_{n \in \mathbb{N}} \Gamma(U, \mathcal{O}_U/t^n\mathcal{O}_U).
\]

(This is even a homeomorphism, provided we view the target as a limit of rings with the discrete topology.) Taking \((13.1.39)\) into account, we obtain \( \Gamma(U, \mathcal{E}^\wedge) = A[[t]] \) which, together with \((13.1.37)\), implies the contention.

(ii): Notice that (i) and lemma \((10.5.44)\) imply that \( \text{Ldet}(U, i(U_0)) \) holds (see definition \((10.5.42)\)). Since the pull-back functor \( \pi^*_U : \text{Cov}(U_0) \to \text{Cov}(U) \) is a right quasi-inverse to \( i^*_U \), the latter is essentially surjective. The full faithfulness is a special case of lemma \((13.1.3)\). \( \square \)

13.2. Local asphericity of smooth morphisms of schemes. Let \( S \) be a strictly local scheme, \( s \in S \) the closed point, \( f : X \to S \) a smooth morphism, \( \pi \) any geometric point of \( f^{-1}(s) \), and denote by \( f_\pi : X(\pi) \to S \) the induced morphism of strictly local schemes. For any open subset \( U \subset S \) we have a base change functor :

\[
f_\pi^* : \text{Cov}(U) \to \text{Cov}(f_\pi^{-1}U) \quad (E \to U) \mapsto (E \times_U f_\pi^{-1}U).
\]

**Theorem 13.2.2.** In the situation of \((13.2)\), we have :

(i) The functor \((13.2.1)\) is fully faithful.

(ii) Suppose moreover that \( S \) is excellent and normal, and that \( S \setminus U \) has codimension \( \geq 2 \) in \( S \). Then \((13.2.1)\) is an equivalence of categories.

**Proof.** (i): In view of lemma \((13.1.15)\), it suffices to show that \( f_\pi \) is 0-acyclic (since in that case, the same will obviously hold also for its restriction \( f_\pi^{-1}U \to U \)). To begin with, \( f_\pi \) is locally \((-1)\)-acyclic, by proposition \((13.1.29)\)(i), hence it remains only to show that \( f \) is locally \(-1\)-acyclic at the point \( x \) (lemma \((13.1.16)\)). The latter assertion follows from proposition \((13.1.29)\)(ii) and \([51]\) Ch.IV, Th.17.5.1).

(ii): In light of (i), it suffices to show that \((13.2.1)\) is essentially surjective, under the assumptions of (ii). We argue by induction on the relative dimension \( n \) of \( f \). Let \( x \in X \) be the support of \( \pi \). We may find an open neighborhood \( U \subset X \) of \( x \), and an étale morphism of \( S \)-schemes \( \varphi : U \to \mathbb{A}^n_S \) (\([51]\) Ch.IV, Cor.17.11.4)). Let \( \pi : \pi \mapsto \pi(\pi) \); there follows an isomorphism of \( S \)-schemes :

\[
X(\pi) \xrightarrow{\sim} \mathbb{A}^n_S(\pi),
\]

hence we may assume from start that \( X = \mathbb{A}^n_S \), and \( f \) is the natural projection. Especially, the theorem holds for \( n = 0 \). Suppose then, that \( n > 0 \), and that the theorem is already known when the relative dimension is \( < n \). Write \( f = h \circ g \), where

\[
g : X \simeq \mathbb{A}^{n-1}_S \times_S \mathbb{A}^1_S \to \mathbb{A}^1_S \quad \text{and} \quad h : \mathbb{A}^1_S \to S
\]

are the natural projections; set \( \pi_1 := g(\pi) \), and \( U_1 := h^{-1}_\pi(U) \), (where \( h^{-1}_\pi : S_1 := \mathbb{A}^1_S(\pi_1) \to S \) is the morphism induced by \( h \)). We have \( S_1 \setminus U_1 = h^{-1}(S(\pi)) \), and since flat maps are generalizing (\([100]\) Th.9.5) we easily see that the codimension of \( S_1 \setminus U_1 \) in \( S_1 \) equals the codimension of \( S \setminus U \) in \( S \). From our inductive assumption, we deduce that the base change functor \( \text{Cov}(U_1) \to \text{Cov}(U) \) is essentially surjective, and hence it suffices to show that the same holds for the functor \( \text{Cov}(U) \to \text{Cov}(U_1) \). Thus, we are reduced to the case where \( X = \mathbb{A}^n_S \), Suppose now, that \( E \to f^{-1}U \) is a finite étale morphism; we can write \( f_\pi \) as the limit of a cofiltered family of smooth morphisms \( (f_\lambda : Y_\lambda \to S \mid \lambda \in \Lambda) \), where each \( Y_\lambda \) is an affine étale \( \mathbb{A}^n_S \)-scheme. Then \( f_\pi^{-1}U \) is the limit of the family \( (Y_\lambda \times_S U \mid \lambda \in \Lambda) \). By \([50]\) Ch.IV, Th.8.8.2(ii), Th.8.10.5 and \([51]\) Ch.IV, Prop.17.7.8, we may find a \( \lambda \in \Lambda \), a finite étale morphism \( E_\lambda \to Y_\lambda \times_S U \) and an isomorphism of \( f_\pi^{-1}U \)-schemes :

\[
E_\lambda \times_{Y_\lambda} \mathbb{A}^1_S(\pi) \xrightarrow{\sim} E.
\]

Denote by \( y \in Y_\lambda \) the image of the closed point of \( \mathbb{A}^1_S(\pi) \), and by \( \overline{\gamma} \) the geometric point of \( Y_\lambda \) obtained as the image of \( \overline{\pi} \) (the latter is viewed naturally as a geometric point of \( \mathbb{A}^1_S(\pi) \)); by construction, \( y \) lies in the closed fibre \( Y_0 := Y_\lambda \times_S \text{Spec } \kappa(s) \), which is an étale \( \mathbb{A}^1_{\kappa(s)} \)-scheme, and we may therefore find
a specialization \( z \in Y_0 \) of \( y \), with \( z \) a closed point. Pick a geometric point \( \overline{z} \) of \( Y_0 \) localized at \( z \), and a strict specialization map \( \Lambda(\overline{z}) \to \Lambda(\overline{y}) \) as in (4.9.23); there follows a commutative diagram:

\[
\begin{array}{c}
\Lambda_S^1(\overline{z}) \\ ^\cong \Lambda_Y(\overline{y}) \\
\downarrow \\
\Lambda_Y(y) \\
\downarrow \\
\Lambda_Y(z).
\end{array}
\]

The finite étale covering \( E_\Lambda \times_{Y_\Lambda} Y_\Lambda(y) \to Y_\Lambda(y) \times_S U \) lies in the essential image of the functor

\[
\text{Cov}(Y_\Lambda(z) \times_S U) \to \text{Cov}(Y_\Lambda(y) \times_S U) \\
C \mapsto C \times_{Y_\Lambda(z)} Y_\Lambda(y).
\]

It follows that \( E \to f^{-1}_\pi U \) lies in the essential image of the functor

\[
\text{Cov}(f^{-1}_\pi U) \to \text{Cov}(f^{-1}_\pi U) \\
C \mapsto C \times_{Y(\overline{y})} Y(\overline{y}) \cong C \times_{Y(\overline{\pi})} \Lambda_S^1(\overline{\pi})
\]

and therefore it suffices to show that the pull-back functor \( \text{Cov}(U) \to \text{Cov}(f^{-1}_\pi U) \) is essentially surjective. In other words, we may replace \( x \) by \( z \), and assume throughout that \( x \) is a closed point of \( \Lambda_S^1 \).

**Claim 13.2.3.** Under the current assumptions, we may find a strictly local normal scheme \( T \), with closed point \( t \), a finite surjective morphism \( g : T \to S \), and a finite morphism of \( \text{Spec} \kappa(s) \)-schemes:

\[\text{Spec} \kappa(t) \to \text{Spec} \kappa(x).\]

**Proof of the claim.** Since \( \kappa(x) \) is a finite extension of \( \kappa(s) \), it is generated by finitely many algebraic elements \( u_1, \ldots, u_n \), and an easy induction allows to assume that \( n = 1 \). In this case, one constructs first a scheme \( T' \) by taking any lifting of the minimal polynomial of \( u \): for the details, see e.g. [46, Ch.0, (10.3.12.)], which shows that the resulting \( T \) is local, finite and flat over \( S \), so \( T' \) maps surjectively onto \( S \). Next, we may replace \( T' \) by its maximal reduced subscheme, which is still strictly local and finite over \( S \). Next, since \( S \) is excellent, the normalization \((T')^\nu \) of \( T' \) is finite over \( S \) ([59, Ch.IV, Scholie 7.8.3(vi)]); let \( T \) be any irreducible component of \((T')^\nu \); by [51, Ch.IV, Prop.18.8.10], \( T \) fulfills all the sought conditions. 

Choose \( g : T \to S \) as in claim [13.2.3] since the residue field extension \( \kappa(s) \to \kappa(t) \) is algebraic and purely inseparable, there exists a unique point \( x' \in \Lambda_S^1(\overline{\pi}) \times_S T \) lying over \( t \), and we may find a unique strict geometric point \( \overline{x'} \) of \( \Lambda_S^1(\overline{\pi}) \times_S T \) localized at \( x' \), and lying over \( \overline{\pi} \). In view of [51, Ch.IV, Prop.18.8.10], there follows a natural isomorphism of \( T \)-schemes:

\[
\Lambda_S^1(\overline{\pi}) \times_S T \cong \Lambda_T^1(\overline{\pi}).
\]

Denote by \( f_{\overline{\pi}} := f_{\pi} \times_S T : \Lambda_T^1(\overline{\pi}) \to T \) the natural projection, and set \( U_T := g^{-1}U \); since the morphism \( g : T \to S \) is generizing ([100, Th.9.4(ii)]), it is easily seen that \( T \setminus U_T \) has codimension \( \geq 2 \) in \( T \).

Let \( F : \text{Cov} \to \text{Sch} \) be the fibred category [13.1.1]. We have a natural essentially commutative diagram of categories:

\[
\begin{array}{ccc}
\text{Cov}(U) & \longrightarrow & \text{Desc}(F, g \times_S U) \\
\downarrow & & \downarrow \delta \\
\text{Cov}(f_{\pi}^{-1}U) & \longrightarrow & \text{Desc}(F, g \times_S f_{\pi}^{-1}U)
\end{array}
\]

where, for any morphism of schemes \( h \), we have denoted by \( \text{Desc}(F, h) \) the category of descent data for the fibred category \( F \), relative to the morphism \( h \).

According to lemma [13.1.2], the morphism \( g \) is of universal 2-descent for the fibred category \( F \), so the horizontal arrows in (13.2.4) are equivalences. Hence, the theorem will follow, once we know that \( \delta \) is essentially surjective. However, we have:
Claim 13.2.5. (i) Set $U'_T := U_T \times_S T$ and $U''_T := U'_T \times_S T$. The pull-back functors:

$$\Cov(U'_T) \to \Cov(A^1_T(\pi') \times_T U'_T) \quad \Cov(U''_T) \to \Cov(A^1_T(\pi') \times_T U''_T)$$

are fully faithful.

(ii) Suppose that the pull-back functor

$$\Cov(U_T) \to \Cov(f^{-1}_* U_T)$$

is essentially surjective. Then the same holds for the functor $\delta$.

Proof of the claim. (i): Let $\pi'$ be any geometric point of $X' := A^1_T \times_S T \times_S T$ whose strict image in $A^1_T$ is $\pi'$, and let $\pi''$ be the image of $\pi'$ in $X' := A^1_T \times_S T$; by lemma [13.1.22](ii), the natural morphisms:

$$X'(\pi') \to A^1_T(\pi') \times_S T \quad X''(\pi'') \to A^1_T(\pi') \times_S T \times_S T$$

are isomorphisms (notice that $T \times_S T$ is also strictly local). Then the claim follows from assertion (i) of the theorem, applied to the projections $X' \to T \times_S T$ and $X'' \to T \times_S T \times_S T$.

(ii): Recall that an object of $\Desc(F, g \times_S f^{-1}_* U)$ consists of a finite étale morphism $E'_T \to f^{-1}_* U_T$ and a $X'$-isomorphism $\beta' : E'_T \times_S T \iso T \times_S E'_T$ fulfilling a cocycle condition on $\times_S T \times_S T$. By assumption, $E'_T$ descends to a finite étale morphism $E' \to U_T$; then (i) implies that $\beta'$ descends to a $U_T$-isomorphism $\beta : E_T \times_S T \iso T \times_S E_T$, and the cocycle identity for $\beta'$ descends to a cocycle identity for $\beta$. 

In view of claim [13.2.5], we may replace $(S, U, x)$ by $(T, U_T, x')$, and therefore assume that $x$ is a $\kappa(s)$-rational point of $A^1_{\kappa(s)}$. In this case, any choice of coordinate $t$ on $A^1_{\kappa}$ yields a section $\sigma_T : S \to A^1_{\kappa}(\pi)$ of the natural projection, such that $\sigma_T(s) = x$. To conclude the proof of the theorem, it suffices to show that the pull-back functor:

$$\Cov(f^{-1}_* U) \xrightarrow{\sigma_T} \Cov(U)$$

is fully faithful.

Say that $S = \Spec A$; then the scheme $A^1_{\kappa}(\pi)$ is the spectrum of $A\{t\}$, the henselization of $A[t]$ along the ideal $m\{t\}$ generated by $t$ and the maximal ideal $m$ of $A$. Let $A^\wedge$ (resp. $A\{t\}^\wedge$) be the $m$-adic (resp. $m\{t\}$-adic) completion of $A$ (resp. of $A\{t\}$), and notice the natural isomorphism:

$$A\{t\}^\wedge / tA\{t\}^\wedge \iso A^\wedge$$

(indeed, it is easy to check that $A\{t\}^\wedge \iso A^\wedge[[t]]$), whence a natural diagram of schemes:

$$\begin{array}{ccc}
X^\wedge := \Spec A\{t\}^\wedge & \xrightarrow{g'} & \Spec A\{t\} \\
\pi \downarrow \sigma \downarrow \downarrow f_T \downarrow \sigma_T & & \downarrow f_T \\
S^\wedge := \Spec A^\wedge & \xrightarrow{g} & \Spec A
\end{array}$$

(whence a natural diagram of schemes:

$$\begin{array}{ccc}
X^\wedge := \Spec A\{t\}^\wedge & \xrightarrow{g'} & \Spec A\{t\} \\
\pi \downarrow \sigma \downarrow \downarrow f_T \downarrow \sigma_T & & \downarrow f_T \\
S^\wedge := \Spec A^\wedge & \xrightarrow{g} & \Spec A
\end{array}$$

(where $\pi$ is the natural projection) whose horizontal arrows commute with both the downward arrows and the upward ones. Set $U^\wedge := g^{-1} U$; by example [13.1.31](ii) and lemma [13.1.15](ii), the pull-back functors

$$g^* : \Cov(U) \to \Cov(U^\wedge) \quad g'^* : \Cov(f^{-1}_* U) \to \Cov(\pi^{-1} U^\wedge)$$

are fully faithful. Consequently, we are easily reduced to showing that the pull-back functor:

$$\Cov(\pi^{-1} U^\wedge) \xrightarrow{\sigma_T} \Cov(U^\wedge)$$

is an equivalence. The latter holds by lemma [13.1.35](ii). \qed
Example 13.2.6. As an application of theorem [13.2.2], suppose that $K \subset E$ is an extension of separably closed fields, $V_K$ a geometrically normal and strictly local $K$-scheme, $U \subset V_K$ an open subset, and $\xi$ a geometric point of $V_E := V_K \times_K E$, whose image in $V_K$ is supported on the closed point. Then the induced functor

$$\text{Cov}(U) \rightarrow \text{Cov}(U \times_{V_K} V_E(\xi))$$

is fully faithful, and it is an equivalence in case $V_K \setminus U$ has codimension $\geq 2$ in $V_K$.

Indeed, let $K^a$ (resp. $E^a$) be an algebraic closure of $K$ (resp. $E$), and choose a homomorphism $K^a \rightarrow E^a$ extending the inclusion of $K$ into $E$. Then both $V_{K^a} := V_K \times_K K^a$ and $V_{E^a}(\xi) := V_E(\xi) \times_E E^a$ are still normal and strictly local (lemma [13.1.22(ii)]), and the induced functors

$$\text{Cov}(U) \rightarrow \text{Cov}(U \times_{V_K} V_{K^a}) \quad \text{Cov}(U \times_{V_K} V_E(\xi)) \rightarrow \text{Cov}(U \times_{V_K} V_{E^a}(\xi))$$

are equivalences (lemma [13.1.7(i)]). It then suffices to show that the induced functor

$$\text{Cov}(U \times_{V_K} V_{K^a}) \rightarrow \text{Cov}(U \times_{V_K} V_{E^a}(\xi))$$

has the asserted properties. Hence, we may replace $K$ by $K^a$ and $E$ by $E^a$, and assume from start that $K \subset E$ is an extension of algebraically closed fields. In this case, $E$ can be written as the colimit of a filtered family $(R_\lambda | \lambda \in \Lambda)$ of smooth $K$-algebras; correspondingly, $V_E$ is the limit of a cofiltered system $(V_\lambda | \lambda \in \Lambda)$ of smooth $V_K$-schemes, and – by lemma [13.1.6] – the induced functor

$$\text{Cov}(U \times_{V_K} V_E(\xi))$$

is the 2-colimit of the system of categories

$$\text{Cov}(U \times_{V_K} V_\lambda(\xi_\lambda)) \quad (\lambda \in \Lambda)$$

(where, for each $\lambda \in \Lambda$, we denote by $\xi_\lambda$ the image of $\xi$ in $V_\lambda$). Now the contention follows directly from theorem [13.2.2].

Theorem 13.2.7. Let $f : X \rightarrow S$ be a smooth morphism of schemes, $\mathbb{L} \subset \mathbb{N}$ be a set of primes, and suppose that all the elements of $\mathbb{L}$ are invertible in $\mathcal{O}_S$. Then $f$ is 1-aspherical for $\mathbb{L}$.

Proof. Let $\pi$ be any geometric point of $X$, $\pi := f(\pi)$, and $\overline{\eta}$ a strict geometric point of $S(\overline{\pi})$. To ease notation, set $T := X(\overline{\pi})$, let $f_\pi : T \rightarrow S$ be the natural map, and $T_\pi := f_\pi^{-1}(\overline{\eta})$; we have to show that $H^1(T_\pi, G) = \{1\}$ for every $\mathbb{L}$-group $G$. Arguing as in the proof of proposition [13.1.29], we reduce to the case where $S = S(\overline{\pi})$. Then, by lemma [13.1.14], we can further assume that $S$ is normal and $\overline{\eta}$ is localized at the generic point $\eta$ of $S$. By lemma [13.1.28], $S$ is the limit of a cofiltered system $(S_\lambda | \lambda \in \Lambda)$ of strictly local, normal and excellent schemes, and as usual, after replacing $\lambda$ by a cofinal subset, we may assume that $f$ (resp. $\overline{\eta}$) descends to a compatible system of morphisms $(f_\lambda : X_\lambda \rightarrow S_\lambda | \lambda \in \Lambda)$, (resp. of strict geometric points $\overline{\eta}_\lambda$ localized at the generic point of $S_\lambda$). By [51] Ch.IV, Prop.17.7.8(ii)), there exists $\lambda \in \Lambda$ such that $f_\mu$ is smooth for every $\mu \geq \lambda$. Then, in view of [8] Exp.VII, Rem.5.14 and the isomorphism (13.1.27), we may replace $f$ by $f_\lambda$, and $\overline{\eta}$ by $\overline{\eta}_\lambda$, and assume from start that $S$ is strictly local, normal and excellent, and $G$ is a finite $\mathbb{L}$-group.

Let $\varphi : E_\overline{\pi} \rightarrow T_\overline{\pi}$ be a principal $G$-homogeneous space; we come down to showing that $E_\overline{\pi}$ has a section $T_\overline{\pi} \rightarrow E_\overline{\pi}$. By [51] Ch.IV, Prop.17.7.8(ii)) and [50] Ch.IV, Th.8.8.2(ii), Th.8.10.5), we may find a finite separable extension $\kappa(\eta) \subset L$, and a principal $G$-homogeneous space such that

$$\varphi_L : E_L \rightarrow T_L := T \times_S \text{Spec} L \quad \rho_L : G \rightarrow \text{Aut}_{T_L}(E_L)$$

such that

$$\varphi = \varphi_L \times_{\text{Spec} L} \text{Spec} \kappa(\overline{\eta}) \quad \rho = \rho_L \times_{\text{Spec} L} \text{Spec} \kappa(\overline{\eta}).$$

Say that $S = \text{Spec} A$, denote by $A_L$ the normalization of $A$ in $L$, and set $S_L := \text{Spec} A_L$. Then $S_L$ is again normal and excellent ([49] Ch.IV, (7.8.3)(ii),(vi)), and the residue field of $A_L$ is an algebraic extension of the residue field of $A$, hence it is separably closed, so $S_L$ is strictly local as well. Thus, we may replace $S$ by $S_L$, and assume that $E_\overline{\pi}$ descends to a principal
G-homogeneous space $E_\eta \to T_\eta := f_\eta^{-1}(\eta)$ on $T_\eta$. Next, we may write $\eta$ as the limit of the filtered system of affine open subsets of $S$, so that – by the same arguments – we find an affine open subset $U \subset S$ and a principal $G$-homogeneous space $E_U \to T_U := f_\eta^{-1}U$, with a $G$-equivariant isomorphism of $T_\eta$-schemes: $E_U \times_{T_U} T_\eta \sim E_\eta$. Denote by $D_1, \ldots, D_n$ the irreducible components of $S \setminus U$ which have codimension one in $S$, and for every $i \leq n$, set $D'_i := f_\eta^{-1}D_i$. Let also $\eta_T$ be the generic point of $T$.

Claim 13.2.9. For given $i \leq n$, let $y$ be the generic point of $D_i$, and $z$ a maximal point of $D'_i$. We have:

(i) $T$ and $E_U$ are normal schemes, and $T(y)$ is regular.
(ii) $D'_i$ is a closed subset of pure codimension one in $T$.
(iii) Let $m_y$ (resp. $m_z$) be the maximal ideal of $\mathcal{O}_{S,y}$ (resp. of $\mathcal{O}_{T,z}$); then $m_y \cdot \mathcal{O}_{T,z} = m_z$.
(iv) Let $t \in A$ be any element such that $t \cdot \mathcal{O}_{S,y} = m_y$. Then there exist an integer $m > 0$ such that $(m, \text{char } \mathbb{F}(s)) = 1$, a finite étale covering

$$E_y \to T(y)[t^{1/m}] := T(y) \times_S \text{Spec } A[T]/(T^m - t)$$

and an isomorphism of $T(y)[t^{1/m}] \times_T T_U$-schemes:

$$E_y \times_T T_U \sim E_U \times_T T(y)[t^{1/m}]$$

Proof of the claim. (i): Since $S$ is normal by assumption, the assertion for $T$ and $E_U$ follows from [51 Ch.IV, Prop.17.5.7, Prop.18.8.12(ii)]. Next, set $W := X(y)$; since $\mathcal{O}_{S,y}$ is a discrete valuation ring, $W$ is a regular scheme ([51 Ch.IV, Prop.17.5.8(iii)]). For any $w \in T(y) \subset W$, the natural map $\mathcal{O}_{T,y},w \to W(w)^{\text{sh}}$ is faithfully flat, and $W(w)^{\text{sh}}$ is regular ([51 Ch.IV, Cor.18.8.13]), therefore $\mathcal{O}_{T,y},w$ is regular, by [48 Ch.0, Prop.17.3.3(i)].

(ii): Say that $p \subset A$ is the prime ideal of height one such that $V(p) = D_i$; to ease notation, let also $B := \mathcal{O}_{S,y}^{\text{sh}}$. Let $\{q_1, \ldots, q_k\} \subset \text{Spec } B$ be the set of maximal points of $D'_i$. Using the fact that flat morphisms are generizing ([100 Th.9.5]), one verifies easily that $A \cap q_j = p$ for every $j \leq k$. Fix $j \leq k$, and set $q := q_j$. Since $A$ is normal, $A_p$ is a discrete valuation ring, hence $pA \cap A_p$ is a principal ideal, say generated by $t \in A_p$; therefore $qB_q$ is the minimal prime ideal of $B_q$ containing $t$, so $qB_q$ has height at most one, by Krull's Hauptidealsatz ([100 Th.13.5]). However, a second application of [100 Th.9.5] shows that the height of $q$ in $B$ cannot be lower than one, hence $q$ has height one, which is the contention.

(iii): From (i) and (ii) we see that $\mathcal{O}_{S,y}^{\text{sh}}$ and $\mathcal{O}_{T,z}$ are discrete valuation rings; then the assertion follows easily from [51 Ch.IV, Th.17.5.1].

(iv): To begin with, since $T(y)$ is regular, it decomposes as a disjoint union of connected components, in natural bijection with the set of maximal points of $D'_i$. Let $Z \subset T(y)$ be the connected open subscheme containing $z$; it suffices to show that there exists a finite étale covering:

$$E_Z \to Z[t^{1/m}] := Z \times_{T(y)} T(y)[t^{1/m}]$$

with an isomorphism of $Z[t^{1/m}] \times_T T_U$-schemes: $E_Z \times_T T_U \sim E_U \times_T Z[t^{1/m}]$. By (iii) we have $t \cdot \mathcal{O}_{T,z} = m_z$. Notice that $T(z) \times_T T_U = T(\eta_T)$, and $E_{\eta_T} := E_U \times_T T(z)$ is a disjoint union of spectra of finite separable extensions $L_1, \ldots, L_k$ of $\mathbb{F}(\eta_T)$. Moreover, $E_{\eta_T}$ is a principal $G$-homogeneous space over $T(\eta_T)$, i.e. every $L_j$ is a Galois extension of $\mathbb{F}(\eta_T)$, with Galois group $G_j := \text{Gal}(L_j/\mathbb{F}(\eta_T)) \subset G$. Since $G$ is an $\mathbb{L}$-group, the same holds for $G_j$, hence $E_U \times_T Z$ is tamely ramified along the divisor $\{z\}$ (the topological closure of $\{z\} \subset Z$), and the assertion follows from Abhyankar's lemma [63 Exp.XIII, Prop.5.2].

Claim 13.2.9. There exist:

(a) a finite dominant morphism $S' \to S$, such that both $S'$ and $T' := T \times_S S'$ are strictly local and normal;
(b) an open subset $U' \subset S'$, such that $S' \setminus U'$ has codimension $\geq 2$ in $S'$;
(c) a finite étale morphism $E' \to T_{U'} := T \times_S U'$, with an isomorphism of $T_{U'}$-schemes:

$$E' \times_T T_\eta \simeq E_\eta \times_T T_{U'}.$$  

**Proof of the claim.** For every $i \leq n$, let $y_i$ be the maximal point of $D_i$, and choose $t_i \in A$ whose image in $\mathcal{O}_{S,y_i}$ generates the maximal ideal. Choose also $m_i \in \mathbb{N}$ with $(m_i, \text{char } \kappa(s)) = 1$ and such that there exists a finite étale covering $E_i \to T(y_i)[t_i^{1/m_i}]$ extending the étale covering $E_U \times_T T(y_i)[t_i^{1/m_i}]$ (claim 13.2.8(ii,d)). Let $S'$ be the normalization of $\text{Spec } A[t_1^{1/m_1}, \ldots, t_s^{1/m_s}]$. Then $S'$ is finite over $S$, hence it is excellent ([49, Ch.IV, Proposition 17.5.7], strictly local (cp. the proof of lemma [13.1.24]). Set $E'_\eta := E_\eta \times_S S'$, $T' := T \times_S S'$; since the geometric fibres of $f_\tau$ are connected (proposition 13.1.29(ii)), the same holds for the geometric fibres of the induced morphism $T' \to S'$, therefore $T'$ is connected, and then it is also strictly local, by the usual arguments. Notice also that $T'$ is the limit of a cofiltered family of smooth $S'$-schemes, hence it is reduced and normal ([51, Ch.IV, Proposition 17.5.7]). Say that $E'_\eta = \text{Spec } C$, $T = \text{Spec } B$, $T' = \text{Spec } B'$, and let $C'$ be the integral closure of $B'$ in $C$. Notice that $C \otimes_B \kappa(\eta_T)$ is a finite product of finite separable extensions of the field $B' \otimes_B \kappa(\eta_T)$, and consequently the natural morphism $\varphi' : E_{T'} := \text{Spec } C' \to T'$ is finite ([100, §33, Lemma 1]). Define:

$$U' := \{ y \in S' | \varphi' \times_S S'(y) : E_{T'}(y) \to T'(y) \text{ is étale} \}.$$  

Let now $y \in U'$ any point; then $S'(y)$ is the limit of the cofiltered family $(U_\lambda | \lambda \in \Lambda)$ of affine open neighborhoods of $y$ in $S'$, and $\varphi' \times_S S'(y)$ the limit of the system of morphisms $(\varphi'_\lambda := \varphi' \times_S U_\lambda | \lambda \in \Lambda)$; we may then find $\lambda \in \Lambda$ such that $\varphi'_\lambda$ is étale ([51, Ch.IV, Proposition 17.7.8(ii))], hence $U_\lambda \subset U'$, which shows that $U'$ is open. Furthermore, from ([51, Ch.IV, Proposition 17.5.7] it follows that $E_U \times_T T'$ is normal, whence an isomorphism of $T'$-schemes:

$$E_{T'} \times_S U \simeq E_U \times_T T'$$  

(cp. the proof of lemma [13.1.7](iii)) especially, $U \times_S S' \subset U'$. Likewise, by construction we have natural morphisms: $T'(y_i) \to T(y_i)[t_i^{1/m_i}]$, and using the fact that all the schemes in view are normal we deduce isomorphisms of $T'(y_i)$-schemes:

$$E_{T'}(y_i) \simeq E_i \times_{T(y_i)[t_i^{1/m_i}]} T'(y_i).$$  

Thus, $U'$ contains all the points of $S'$ of codimension $\leq 1$, since the image in $S$ of any such point lies in $U \cup \{ y_1, \ldots, y_n \}$. The morphism $E' := E_{T'} \times_S U' \to T_{U'}$ fulfills conditions (a)-(c). \hfill \Box

Now, choose $S' \to S$, $U' \subset S'$, and $E' \to T_{U'}$ as in claim 13.2.9, since the corresponding $T'$ is local, there exists a unique point $x' \in X'$ := $X \times_S S'$ lying over $x$; pick a geometric point $\overline{x}'$ of $X'$ localized at $x'$, and lying over $\overline{x}$; it then follows from ([51, Ch.IV, Proposition 18.8.10]) that the natural morphism $X'(\overline{x}') \to T'$ is an isomorphism. In such situation, theorem 13.2.2 says that there exists a finite étale covering $E \to U'$ with an isomorphism of $T_{U'}$-schemes: $E \times_{U'} T_{U'} \simeq E'$, whence an isomorphism of $T_\eta$-schemes:

$$E_\eta \simeq E(\eta) \times_{\text{Spec } \kappa(\eta)} T_\eta.$$  

Since $\kappa(\eta)$ is separably closed, the étale morphism $E(\eta) \to \text{Spec } \kappa(\eta)$ admits a section, hence the same holds for $\varphi$, as claimed. \hfill \Box

13.2.10. Let $f : X \to S$ be a morphism of schemes, and $j : U \subset X$ an open immersion such that $U_\eta := U \cap f^{-1}(\eta) \neq \emptyset$ for every $\eta \in S_{\text{max}}$, where $S_{\text{max}} \subset S$ denotes the subset of all
maximal points of $S$. We deduce a natural essentially commutative diagram of functors:

$$
\begin{array}{ccc}
\mathcal{D}(S, f, U) & \xrightarrow{\eta} & \mathcal{D}(U) \\
\Pi_{\eta \in S_{\text{max}}} \mathcal{D}(f^{-1}\eta) & \xrightarrow{\Pi_{\eta \in S_{\text{max}}} \eta \in X(U)} & \Pi_{\eta \in S_{\text{max}}} \mathcal{D}(U_{\eta}) \\
\end{array}
$$

where $j_\eta : U_\eta \to f^{-1}(\eta)$ is the restriction of $j$ and $\iota_\eta : f^{-1}(\eta) \to X$ is the natural immersion. Let us say that $U \subset X$ is fibrewise dense, if $f^{-1}(s) \cap U$ is dense in $f^{-1}(s)$, for every $s \in S$. Then we have:

**Theorem 13.2.11.** In the situation of (13.2.10), suppose that $f$ is smooth, and $U$ is fibrewise dense. The following holds:

(i) The restriction functor $j^*$ is fully faithful.
(ii) The diagram $\mathcal{D}(S, f, U)$ is 2-cartesian.
(iii) If furthermore, $f^{-1}S_{\text{max}} \subset U$, then $j^*$ is an equivalence.

**Proof.** Assertion (ii) means that the functors $j^*$ and $\iota^*_\eta$ induce an equivalence $(j, \iota^*_\eta)^*$ from $\mathcal{D}(X)$ to the category $\mathcal{C}(X, U)$ of data

$$
E := (\varphi, (\psi_\eta, \alpha_\eta \mid \eta \in S_{\text{max}}))
$$

where $\varphi$ (resp. $\psi_\eta$) is an object of $\mathcal{D}(U)$ (resp. of $\mathcal{D}(f^{-1}\eta)$, for every $\eta \in S_{\text{max}}$), and $\alpha_\eta : \varphi \times_U \text{Spec } k(\eta) \to \psi_\eta \times_{f^{-1}\eta} U_\eta$ is an isomorphism of $U$-schemes, for every $\eta \in S_{\text{max}}$ (see example 3.2.12(ii)). On the basis of this description, it is easily seen that (i),(ii)$\Rightarrow$(iii). Furthermore, we remark :

**Claim 13.2.13.** (i) If $j^*$ is fully faithful, then the same holds for $(j, \iota^*_\eta)^*$.

(ii) For every open subset $U'' \subset X$ containing $U$, suppose that:

(a) The pull-back functor $\mathcal{D}(U'') \to \mathcal{D}(U)$ is fully faithful.
(b) If $f^{-1}S_{\text{max}} \subset U'$, the pull-back functor $\mathcal{D}(X) \to \mathcal{D}(U'')$ is an equivalence.

Then assertion (ii) holds.

**Proof of the claim.** (i): Since $f^{-1}\eta$ is a normal (even regular) scheme ([51, Ch.IV, Prop.17.5.7]), the pull-back functors $\iota^*_\eta$ are fully faithful (lemma 13.1.7(iii)); the assertion is an immediate consequence.

(ii): In light of (i), it remains only to check that $(j, \iota^*_\eta)^*$ is essentially surjective. Thus, let $\varphi : E \to U$ be a finite étale morphism, such that $\iota^*_\eta \varphi$ extends to a finite étale morphism $\varphi'_{\eta} : E'_\eta \to f^{-1}(\eta)$, for every maximal point $\eta \in S$. By claim 13.1.8, there is a largest open subset $U_{\text{max}}$ containing $U$, over which $\varphi$ extends to a finite étale morphism $\varphi_{\text{max}}$. To conclude, we have to show that $U_{\text{max}} = X$. However, for any maximal point $\eta$, let $i_\eta : f^{-1}(\eta) \to X(\eta)$ be the natural closed immersion. By lemma 13.1.7(i), $i^*_\eta$ is an equivalence, hence we may find a finite étale morphism $\varphi'_{\eta} : E'(\eta) \to X(\eta)$ such that $i_\eta \varphi'_{\eta} \simeq \varphi'_{\eta}$. By the same token, we also see that $E'(\eta) \times_{X(\eta)} U(\eta)$ is $U(\eta)$-isomorphic to $E \times_U U(\eta)$.

Next, $S(\eta)$ is the limit of the filtered system $V$ of all open subsets $V \subset S$ with $\eta \in V$, hence lemma 13.1.6 ensures that we may find $V \in \mathcal{V}$ and an object $\varphi'_V : E'_V \to f^{-1}V$ of $\mathcal{D}(f^{-1}V)$ such that $\varphi'_V \times_V S(\eta) \simeq \varphi'_V(\eta)$, and after shrinking $V$, we may also assume (again by lemma 13.1.6) that $E'_V \times_U U$ is $U$-isomorphic to $E \times_S V$. Hence we may glue $E'$ and $E$ along the common intersection, to deduce a finite étale morphism $E' \to U' := U \cup f^{-1}V$ that extends $\varphi$. It follows that $f^{-1}(\eta) \subset f^{-1}V \subset U_{\text{max}}$. Since $\eta$ is arbitrary, (b) implies that the pull-back functor $\mathcal{D}(X) \to \mathcal{D}(U_{\text{max}})$ is an equivalence, especially $\varphi$ lies in the essential image of $j^*$, as claimed. \hfill $\diamond$
Claim 13.2.14. (i) Suppose that $S$ is noetherian and normal, and $X$ is separated. Then (i) holds.

(ii) If furthermore, $S$ is also excellent, then (ii) holds as well.

Proof of the claim. (i): Under the assumptions of the claim, $X$ is normal and noetherian ([51 Ch.IV, Prop.17.5.7]), so (i) follows from lemma [13.1.7](iii), which also says – more generally – that assumption (a) of claim [13.2.13] holds in this case, hence in order to show (ii) it suffices to check that assumption (b) of claim [13.2.13] holds whenever $U \cup f^{-1}S_{\text{max}} \subset U' \subset X$, especially $X \setminus U'$ has codimension $\geq 2$ in $X$. Suppose first that $S$ is regular; then the same holds for $X$ ([51 Ch.IV, Prop.17.5.8]), and the contention follows from lemma [13.1.7](iv).

In the general case, let $S_{\text{reg}} \subset S$ be the regular locus, which is open since $S$ is excellent, and contains all the points of codimension $\leq 1$, by Serre’s normality criterion ([49 Ch.IV, Th.5.8.6]). Consider the restriction $f^{-1}S_{\text{reg}} \to S_{\text{reg}}$ of $f$, and the fibrewise dense open immersion $j_{\text{reg}} : U' \cap f^{-1}S_{\text{reg}} \subset f^{-1}S_{\text{reg}}$, by the foregoing, the functor $j^*_{\text{reg}}$ is an equivalence, hence we are easily reduced to showing that the functor $\text{Cov}(X) \to \text{Cov}(U' \cup f^{-1}S_{\text{reg}})$ is an equivalence, i.e., we may assume that $V := f^{-1}S_{\text{reg}} \subset U'$. Moreover, since the full faithfulness of $j^*$ is already known, we only need to show that any finite étale morphism $\varphi : E \to U'$ extends to an object of $\text{Cov}(X)$. To this aim, by lemma [13.1.7](iii), it suffices to prove that $\varphi \times_{U'} (X(\xi) \times_X U')$ extends to an object of $\text{Cov}(X(\xi))$, for every geometric point $\xi$ of $X$. Let $\bar{\xi} := f(\xi)$, and denote by $s \in S$ the support of $\bar{\xi}$; by assumption, we may find a geometric point $\xi$ of $f^{-1}(s)$, whose support lies in $U' \cap f^{-1}(s)$, and a strict specialization morphism $X(\xi) \to X(\bar{\xi})$. There follows an essentially commutative diagram:

\[
\begin{array}{ccc}
\text{Cov}(X(\bar{\xi})) & \xrightarrow{\rho} & \text{Cov}(X(\bar{\xi}) \times_X V) \\
\delta & & \gamma \\
\text{Cov}(X(\xi)) & \xrightarrow{\tau} & \text{Cov}(X(\xi) \times_X V)
\end{array}
\]

where $\alpha$ and $\beta$ are both equivalences, by theorem [13.2.2](ii); hence $\gamma$ is an equivalence as well. Moreover, both $\text{Cov}(X(\bar{\xi}))$ and $\text{Cov}(X(\xi))$ are equivalent to the category of finite sets, and $\delta$ is obviously an equivalence. By construction, $\gamma(\varphi \times_{U'} (X(\xi) \times_X V))$ lies in the essential image of $\tau$, hence $\varphi \times_{U'} (X(\xi) \times_X V)$ lies in the essential image of $\rho$, so say it is isomorphic to $\rho(\varphi')$ for some object $\varphi'$ of $\text{Cov}(X(\bar{\xi}))$. Using (i) and ([51 Ch.IV, Prop.18.8.12]) one checks easily that $\varphi' \times_X U' \simeq \varphi \times_{U'} (X(\xi) \times_X U')$, whence the contention. \hfill \diamondsuit

Claim 13.2.15. Let $m \in \mathbb{N}$ be any integer. Assertions (i) and (ii) hold if $S$ and $X$ are affine schemes of finite type over $\text{Spec} \mathbb{Z}$, the fibres of $f$ have pure dimension $m$, and furthermore:

(13.2.16) \hspace{1cm} \dim f^{-1}(s) \setminus U < m \quad \text{for every } s \in S.

Proof of the claim. Indeed, in this situation, $S$ admits finitely many maximal points, hence the normalization morphism $S^\nu \to S$ is integral and surjective. Set:

$S_2 := S^\nu \times_S S^\nu \quad U_1 := U \times_S S^\nu \quad U_2 := U \times_S S_2.$

Let $\beta : X_1 := X \times_S S^\nu \to X$, $f_1 : X_1 \to S^\nu$ and $j_2 : U_2 \to X_2 := X \times_S S_2$ be the induced morphisms; clearly $f_1^{-1}(s')$ has pure dimension $m$ for every $s' \in S^\nu$, and from (13.2.16) we deduce that $\dim f_1^{-1}(s') \setminus U_1 < m$, especially, $U_1$ is dense in every fibre of $f_1$; by the same token, $U_2$ is dense in $X_2$. Then $j_2^*$ is faithful (lemma [13.1.7](ii)), and lemma [13.1.2] and corollary [3.4.30](ii) imply that $j^*$ is fully faithful, provided the same holds for the functor $j_2^* : \text{Cov}(X_1) \to \text{Cov}(U_1)$. In other words, in order to prove assertion (i), we may replace $(f, U)$ by $(f_1, U_1)$, which allows to assume that $S$ is an affine normal scheme, and then it suffices to invoke claim [13.2.14] to conclude.

Concerning assertion (ii): by the foregoing, we already know that $j^*$ is fully faithful, so the same holds for $(j, \iota_\bullet)^*$ (claim [13.2.13](i)). To show that $(j, \iota_\bullet)^*$ is essentially surjective, let $E$
be an object as in (13.2.12) of the category \( \mathcal{C}(X, U) \); the normalization morphism induces a bijection \( S'_{\text{max}} \overset{\sim}{\to} S_{\text{max}} : \eta' \mapsto \eta \), and clearly \( \kappa(\eta') = \kappa(\eta) \) for every \( \eta \in S_{\text{max}} \), whence a datum

\[
E' := (\varphi_1 := \varphi \times_U U_1, (\psi_\eta, \alpha_\eta : \eta' \in S'_{\text{max}}))
\]

of the analogous category \( \mathcal{C}(X_1, U_1) \); by claim 13.2.14(ii), we may find \( \varphi' \in \text{Ob}(\text{Cov}(X_1)) \) and an isomorphism \( \alpha : \varphi' \times_{X_1} U_1 \overset{\sim}{\to} \varphi_1 \). Let \( U_3 := U_2 \times_U U_1 \), and denote by \( j_3 : U_3 \rightarrow X_3 := X_2 \times_X X_1 \) the open immersion; by the foregoing, we know already that both \( j_2^* \) and \( j_3^* \) are fully faithful; then corollary 3.4.30(iii) says that the natural essentially commutative diagram:

\[
\begin{array}{ccc}
\text{Desc}(\text{Cov}, \beta) & \longrightarrow & \text{Desc}(\text{Cov}, \beta \times_X U) \\
\downarrow & & \downarrow \\
\text{Cov}(X_1) & \longrightarrow & \text{Cov}(U_1)
\end{array}
\]

is 2-cartesian. Thus, let \( \rho : \text{Cov}(U) \rightarrow \text{Desc}(\text{Cov}, \beta \times_X U) \) be the functor defined in (3.4.22); it follows that the datum \( (\varphi', \rho(\varphi), \alpha) \) comes from a descent datum \( (\varphi'_1, \omega) \) in \( \text{Desc}(\text{Cov}, \beta) \). By lemma 13.1.2, the latter descends to an object \( \varphi' \) of \( \text{Cov}(X) \), and by construction we have \((j_* \varphi')' = E\), as required. \( \Box \)

Next, we consider assertions (i) and (ii) in case where both \( X \) and \( S \) are affine. We may find an affine open covering \( X = V_0 \cup \cdots \cup V_n \) such that the fibres of \( f_i : V_i \rightarrow fV_i \) are of pure dimension \( i \), for every \( i = 0, \ldots, n \) (51, Ch.IV, Prop.17.10.2). For \( i = 0, \ldots, n \), let \( j_i : V_i \cap U \rightarrow V_i \) be the induced open immersion; we have natural equivalences of categories:

\[
\text{Cov}(X) \overset{\sim}{\to} \prod_{i=0}^n \text{Cov}(V_i) \quad \text{Cov}(U) \overset{\sim}{\longrightarrow} \prod_{i=0}^n \text{Cov}(V_i \cap U)
\]

which induce a natural identification: \( j^* = j_0^* \times \cdots \times j_n^* \). It follows \( j^* \) is fully faithful if and only if the same holds for every \( j_i^* \), and moreover \( \mathcal{D}(S, f, U) \) decomposes as a product of \( n \) diagrams \( \mathcal{D}(S, f|_{V_i}, U \cap V_i) \). Hence we may replace \( f \) by \( f|_{V_i} \), for any \( m \leq n \), after which we may also assume that all the fibres \( f \) have the same pure dimension \( m \). In that case, notice that the assumption on \( U \) is equivalent to (13.2.16). Next, say that \( X = \text{Spec} \Lambda \), and let \( I \subset \Lambda \) be an ideal such that \( V(I) = X \setminus U \); we may write \( I \) as the union of the filtered family \( (I_\lambda : \lambda \in \Lambda) \) of its finitely generated subideals. Set \( U_\lambda := X \setminus V(\lambda) \) for every \( \lambda \in \Lambda \); it follows that \( U = \bigcup_{\lambda \in \Lambda} U_\lambda \). For every \( \lambda \in \Lambda \), set

\[ Z_\lambda := \{ s \in S \mid \dim f^{-1}(s) \setminus U_\lambda < m \}. \]

Claim 13.2.17. (i) \( Z_\lambda \) is a constructible subset of \( S \), for every \( \lambda \in \Lambda \).

(ii) We have \( Z_\lambda \subset Z_\mu \) whenever \( \mu \geq \lambda \), and moreover \( S = \bigcup_{\lambda \in \Lambda} Z_\lambda \).

Proof of the claim. (i): Let \( V_\lambda := \{ x \in X \mid \dim_x f^{-1}(f(x)) \setminus U_\lambda = m \} \); according to [50, Ch.IV, Prop.9.9.1], every \( V_\lambda \) is a constructible subset of \( X \), hence \( f(V_\lambda) \) is a constructible subset of \( S \) (48, Ch.IV, Th.1.8.4)), so the same holds for \( Z_\lambda = S \setminus f(V_\lambda) \).

(ii): Let \( \mu, \lambda \in \Lambda \), such that \( \mu \geq \lambda \); then it is clear that \( f^{-1}(s) \setminus U_\lambda \subset f^{-1}(s) \setminus U_\mu \) for every \( s \in S \); using (13.2.16), the claim follows easily. \( \Box \)

Claim 13.2.17 and [48, Ch.IV, Cor.1.9.9] imply that \( Z_\lambda = S \) for every sufficiently large \( \lambda \in \Lambda \). Hence, after replacing \( \Lambda \) by a cofinal subset, we may assume that all the open subsets
$U_\lambda$ are fibrewise dense. We have a natural essentially commutative diagram:

\[
\begin{array}{ccc}
\text{Cov}(U) & \longrightarrow & 2\text{-}\lim_{\lambda \in \Lambda} \text{Cov}(U_\lambda) \\
\downarrow & & \downarrow \\
\prod_{\eta \in S_{\text{max}}} \text{Cov}(U_\eta) & \longrightarrow & \prod_{\eta \in S_{\text{max}}} 2\text{-}\lim_{\lambda \in \Lambda} \text{Cov}(f^{-1}(\eta) \cap U_\lambda)
\end{array}
\]

whose horizontal arrows are equivalences (notation of definition 2.5.1(i)); it follows formally that $j^*$ is fully faithful, provided the same holds for all the pull-back functors $\text{Cov}(X) \to \text{Cov}(U_\lambda)$, and likewise, $\mathcal{D}(S, f, U)$ is 2-cartesian, provided the same holds for all the diagrams $\mathcal{D}(S, f, U_\lambda)$. Hence, we may replace $U$ by $U_\lambda$, and assume that $U$ is constructible, and (13.2.16) still holds.

Next, we may write $S$ as the limit of a cofiltered family $(S_\lambda \mid \lambda \in \Lambda)$ of affine schemes of finite type over $\text{Spec} \mathbb{Z}$, and $f$ as the limit of a cofiltered family $f_\bullet := (f_\lambda : X_\lambda \to S_\lambda \mid \lambda \in \Lambda)$ of affine finitely presented morphisms, such that:

- The natural morphism $g_\lambda : S \to S_\lambda$ is dominant for every $\lambda \in \Lambda$.
- $f_\lambda$ is smooth for every $\lambda \in \Lambda$ (31 Ch.IV, Prop.17.7.8(ii)), and $f_\mu = f_\lambda \times_{S_\lambda} S_\mu$ whenever $\mu \geq \lambda$.

Furthermore, we may find $\lambda \in \Lambda$ such that $U = U_\lambda \times_{S_\lambda} S$ (50 Ch.IV, Cor.8.2.11), so that $j$ is the limit of the cofiltered system of open immersions ($j_\mu : U_\mu := U_\lambda \times_{S_\lambda} S_\mu \to X_\lambda \mid \mu \geq \lambda$), and after replacing $\Lambda$ by a cofinal subset, we may assume that $j_\mu$ is defined for every $\mu \in \Lambda$. For every $\lambda \in \Lambda$ and $n \in \mathbb{N}$, let $X_{\lambda,m} \subset X_\lambda$ be the open and closed subset consisting of all $x \in X_\lambda$ such that $\dim_x f^{-1} f(x) = n$; clearly $f_\bullet$ restricts to a cofiltered family $f_{\bullet,m} := (f_\lambda|_{X_{\lambda,m}} : X_{\lambda,m} \to S_\lambda \mid \lambda \in \Lambda)$, whose limit is again $f$. Hence we may replace $X_\lambda$ by $X_{\lambda,m}$, and assume that the fibres of $f_\lambda$ have pure dimension $m$, for every $\lambda \in \Lambda$. For every $\lambda \in \Lambda$, let:

$$Z'_\lambda := \{ s \in S_\lambda \mid \dim f_\lambda^{-1}(s) \setminus U_\lambda = m \}.$$

and endow $Z'_\lambda$ with its constructible topology $\mathcal{H}_\lambda$; since $Z'_\lambda$ is a constructible subset of $S_\lambda$ (50 Ch.IV, Prop.9.9.1), $(Z'_\lambda, \mathcal{H}_\lambda)$ is a compact topological space, and due to (13.2.16), we have:

$$\lim_{\lambda \in \Lambda} Z'_\lambda = \emptyset.$$

Then 54 Ch.I, §9, n.6, Prop.8 implies that $Z'_\lambda = \emptyset$ for every sufficiently large $\lambda \in \Lambda$. Set:

$$\text{Cov}(X_\bullet) := 2\text{-}\text{colim}_{\mu \geq \lambda} \text{Cov}(X_\mu) \quad \text{Cov}(U_\bullet) := 2\text{-}\text{colim}_{\mu \geq \lambda} \text{Cov}(U_\mu).$$

(See definition 2.5.1(ii).) There follows an essentially commutative diagram of categories:

\[
\begin{array}{ccc}
\text{Cov}(X) & \longrightarrow & \text{Cov}(X_\bullet) \\
j^* \uparrow & & j^*_\bullet \downarrow \\
\text{Cov}(U) & \longrightarrow & \text{Cov}(U_\bullet)
\end{array}
\]

where $j^*_\bullet$ is the 2-colimit of the system of pull-back functors $j^*_\mu : \text{Cov}(X_\mu) \to \text{Cov}(U_\mu)$. In light of lemma 13.1.6 the horizontal arrows of (13.2.18) are equivalences, so $j^*_\bullet$ will be fully faithful, provided the same holds for the functors $j^*_\mu$, for every large enough $\mu \in \Lambda$.

Hence, in order to prove assertion (i) when $X$ and $S$ are affine, we may assume that $S$ is of finite type over $\text{Spec} \mathbb{Z}$, the fibres of $f$ have pure dimension $m$, and (13.2.16) holds, which is the case covered by claim 13.2.15.

Concerning assertion (ii), since the morphism $g_\mu$ is dominant, for every $\eta' \in (S_\mu)_{\text{max}}$ we may find $\eta \in S_{\text{max}}$ such that $g_\mu(\eta) = \eta'$. Denote by:

$$h : f^{-1}\eta \to f^{-1} \eta' \quad \text{and} \quad j^*_\mu : (U_\mu)_{\eta'} := U_\mu \cap f^{-1}\eta' \to f^{-1}\eta'.$$
the natural morphisms. With this notation, we have the following:

**Claim 13.2.19.** The induced essentially commutative diagram:

\[
\begin{array}{ccc}
\text{Cov}(f^{-1}_\mu \eta') & \xrightarrow{j^*_\mu} & \text{Cov}((U_\mu)_{\eta'}) \\
\downarrow h^* & & \downarrow h^*_U \\
\text{Cov}(f^{-1}_\eta) & \xrightarrow{j^{*}_\eta} & \text{Cov}(U_\eta)
\end{array}
\]

is 2-cartesian.

**Proof of the claim.** The pair \((h^*, j^*_\mu)\) induces a functor \((h, j^*_\mu)^*\) from \(\text{Cov}(f^{-1}_\mu \eta')\) to the category of data of the form \((\varphi, \varphi', \alpha)\), where \(\varphi'\) (resp. \(\varphi\)) is a finite étale covering of \((U_\mu)_{\eta'}\) (resp. of \(f^{-1}_\eta\)), \(\alpha : \varphi \times_{f^{-1}_\eta} U_\eta \xrightarrow{\sim} \varphi' \times_{\eta'} \eta\) is an isomorphism in \(\text{Cov}(U_\eta)\), and the contention is that \((h, j^*_\mu)^*\) is an equivalence. The full faithfulness of the functors \(j^*_\mu\) and \(j^*_\eta\) (lemma [13.1.7(iii)]) easily implies the full faithfulness of \((h, j^*_\mu)^*\). To prove that \((h, j^*_\mu)^*\) is essentially surjective, amounts to showing that if \(\varphi' : E' \to (U_\mu)_{\eta'}\) is a finite étale morphism and

\[
\varphi'' := \varphi' \times_{\eta'} \eta : E'' := E' \times_{\eta'} \eta \to U_\eta
\]

extends to a finite étale morphism \(\varphi : E \to f^{-1}_\eta\), then \(\varphi'\) extends to a finite étale covering of \(f^{-1}_\mu \eta'\). Now, let \(L\) be the maximal purely inseparable extension of \(\kappa(\eta')\) contained in \(\kappa(\eta)\).

Since the induced morphism \(\eta'' := \text{Spec } L \to \text{Spec } \kappa(\eta')\) is radicial, the base change functors

\[
\text{Cov}(f^{-1}_\mu \eta') \to \text{Cov}((f^{-1}_\mu \eta') \times_{\eta'} \eta'') \quad \text{Cov}((U_\mu)_{\eta'}) \to \text{Cov}((U_\mu)_{\eta'} \times_{\eta'} \eta'')
\]

are equivalences (lemma [13.1.7](i)). Thus, we may replace \(\eta'\) by \(\eta''\), and assume that the field extension \(\kappa(\eta') \subset \kappa(\eta)\) is separable, hence the induced morphism \(\text{Spec } \kappa(\eta') \to \text{Spec } \kappa(\eta)\) is regular ([28, Ch.VIII, §7, no.3, Cor.1]), and then the same holds for the morphism \(h\) ([49, Ch.IV, Prop.6.8.3(iii)]). Given \(\varphi'\) as above, set \(A := (j^*_\mu \circ \varphi')_* \mathcal{O}_E\); then \(A\) is a quasi-coherent \(\mathcal{O}_{f^{-1}_\eta}\)-algebra, and we may define the quasi-coherent \(\mathcal{O}_{f^{-1}_\eta}\)-algebra \(B\) as the integral closure of \(\mathcal{O}_{f^{-1}_\eta}\) in \(h^* A\). By [49, Ch.IV, Prop.6.14.1], \(h^* B\) is the integral closure of \(\mathcal{O}_{f^{-1}_\eta}\) in \(h^* A\).

By [49, Ch.IV, Prop.6.14.1], \(h^* B\) is the integral closure of \(\mathcal{O}_{f^{-1}_\eta}\) in \(h^* A\). By [51, Ch.IV, Prop.17.5.7], it then follows that \(h^* B = \varphi^\bullet \mathcal{O}_E\), therefore \(B\) is a finite étale \(\mathcal{O}_{f^{-1}_\eta}\)-algebra ([51, Ch.IV, Prop.17.7.3(ii)] and [49, Ch.IV, Prop.2.7.1]). The claim follows.

By the foregoing, we already know that \(j^*_\mu\) is essentially surjective, hence the same holds for \((j, \iota_\bullet)^*\) (claim [13.2.13](i)). To show that \((j, \iota_\bullet)^*\) is essentially surjective, consider any \(E'\) as in ([13.2.12]): we may find \(\mu \in \Lambda\), and a finite étale morphism \(\varphi' : E' \to U_\mu\) such that \(\varphi = \varphi' \times_{U_\mu} U\), whence objects \(\varphi'_{\eta'} := \varphi' \times_{U_\mu} (U_\mu)_{\eta'}\) in \(\text{Cov}((U_\mu)_{\eta'})\), for every \(\eta' \in (S_{\mu})_{\text{max}}\). By construction, we have \(\varphi'_{\eta'} \times_{\eta'} \eta \simeq \psi_{\eta'} \times_{\eta'} \eta\) for every \(\eta' \in (S_{\mu})_{\text{max}}\) and every \(\eta \in S_{\max}\) such that \(g_{\mu}(\eta) = \eta'\). Then claim [13.2.19] shows that, for every \(\eta' \in (S_{\mu})_{\text{max}}\) there exists an object \(\psi'_{\eta'}\) of \(\text{Cov}(f^{-1}_\mu \eta')\) with isomorphisms:

\[
\psi'_{\eta'} \times_{f^{-1}_\eta} f^{-1}_\eta \eta' \simeq \psi_{\eta'} \quad \alpha_{\eta'} : \psi'_{\eta'} \times_{f^{-1}_\eta} f^{-1}_\eta (U_\mu)_{\eta'} \xrightarrow{\sim} \varphi'_{\eta'}.
\]

Therefore, the datum \(E_{\mu} := (\varphi', (\psi'_{\eta'}, \alpha_{\eta'}) \mid \eta' \in (S_{\mu})_{\text{max}})\) is an object of the 2-limit of the diagram of categories

\[
\text{Cov}(U_\mu) \xleftarrow{j^*_\mu} \text{Cov}(X_\mu) \xrightarrow{\prod_{\eta' \in (S_{\mu})_{\text{max}}} j^{*}_{\eta'}} \prod_{\eta' \in (S_{\mu})_{\text{max}}} \text{Cov}(f^{-1}_\mu \eta')
\]

(where \(\iota_{\eta'} : f^{-1}_\mu \eta' \to X_\mu\) is the natural immersion, for every \(\eta' \in (S_{\mu})_{\text{max}}\)). By claim [13.2.15] the datum \(E_{\mu}\) comes from an object \(\varphi_{\mu}\) of \(\text{Cov}(X_\mu)\). Let \(\varphi''\) be the image of \(\varphi_{f'}\) in \(\text{Cov}(X)\); by construction we have \((j, \iota_\bullet)^* \varphi'' = E\), as required.
This conclude the proof of (i) and (ii), in case \( X \) and \( S \) are affine. To deal with the general case, let \( X = \bigcup_{i \in I} V_i \) be a covering consisting of affine open subschemes, and for every \( i \in I \), let \( fV_i = \bigcup_{\lambda \in \Lambda_i} S_{i\lambda} \) be an affine open covering of the open subscheme \( fV_i \subset S \); set also \( V_{i\lambda} := V_i \cap f^{-1}S_{i\lambda} \) for every \( i \in I \) and \( \lambda \in \Lambda_i \). The restrictions \( f|_{V_{i\lambda}} : V_{i\lambda} \to S_{i\lambda} \) are smooth morphisms; moreover, the image of the open immersion
\[
j_{i\lambda} := j_{U \cap V_{i\lambda}} : U \cap V_{i\lambda} \to V_{i\lambda}
\]
is dense in every fibre of \( f|_{V_i} \). The induced morphism
\[
\beta : X' := \prod_{i \in I} \prod_{\lambda \in \Lambda_i} V_{i\lambda} \to X
\]
is faithfully flat, hence of universal 2-descent for (13.1.1); moreover, it is easily seen that \( X'' := X' \times_X X' \) is separated, and \( j'' := j \times_X X'' \) is a dense open immersion, hence \( j'' \) is faithful (lemma 13.1.7(ii)). Then, by corollary 3.4.30(ii), \( j'' \) is fully faithful, provided the pull-back functor \( \text{Cov}(X') \to \text{Cov}(X' \times_X U) \) is fully faithful, i.e. provided the same holds for the functors \( j^*_{i\lambda} : \text{Cov}(V_{i\lambda}) \to \text{Cov}(V_{i\lambda} \cap U) \). However, each \( V_{i\lambda} \) is affine ([44, Ch.I, Prop.5.5.10]), hence assertion (i) is already known for the morphisms \( f|_{V_{i\lambda}} \) and the open subsets \( U \cap V_{i\lambda}; \) this concludes the proof of (i).

To show (ii), we use the criterion of claim 13.2.13(ii) : indeed, assumption (a) is already known, hence we are reduced to showing that assertion (iii) holds. To this aim, we consider again the morphism \( \beta \) of (13.2.20), and denote by \( f'' : X'' \to S \) the induced morphism. Clearly \( f'' \) is smooth, and \( j'' \) is an open immersion, such that \( f''^{-1}(s) \times_X U \) is dense in \( f''^{-1}(s) \), for every \( s \in S \); then assertion (i) implies that \( j'' \) is fully faithful. Moreover it is easily seen that \( X''' := X'' \times_X X'' \) is separated, and \( j \times_X X''' \) is a dense open immersion, hence \( j''' \) is faithful (lemma 13.1.7(ii)), and therefore corollary 3.4.30(ii) reduces to showing that the pull-back functor \( \text{Cov}(X') \to \text{Cov}(X' \times_X U) \) is an equivalence, or – what is the same – that this holds for the pull-back functors \( j^*_{i\lambda} \), which is already known.

13.2.21. We consider now the local counterpart of theorem 13.2.11. Namely, suppose that \( f : X \to S \) is a smooth morphism, let \( \overline{\xi} \) be any geometric point of \( X \), set \( \overline{\xi} := f(\overline{\xi}) \), and let \( s \in S \) be the support of \( \overline{\xi} \). Then \( \overline{\xi} \) induces the morphism \( f_{\overline{\xi}} : X(\overline{\xi}) \to S(\overline{\xi}) \), and for every open immersion \( j : U \to X(\overline{\xi}) \), we may then consider the diagram \( \mathcal{D}(S(\overline{\xi}), f_{\overline{\xi}}, U) \) as in (13.2.10). Notice as well that, for every geometric point \( \xi \) of \( S \), the fibre \( f_{\overline{\xi}}^{-1}(\xi) \) is normal, since it is a cofiltered limit of smooth \( \vert \xi \vert \)-schemes; on the other hand, \( f_{\overline{\xi}}^{-1}(\xi) \) is also connected, by proposition 13.1.29(ii), hence \( f_{\overline{\xi}} \) has geometrically irreducible fibres.

**Theorem 13.2.22.** In the situation of (13.2.21), suppose that \( U \) contains the generic point of \( f_{\overline{\xi}}^{-1}(s) \). Then:

(i) \( j^* : \text{Cov}(X(\overline{\xi})) \to \text{Cov}(U) \) is fully faithful.

(ii) The diagram \( \mathcal{D}(S(\overline{\xi}), f_{\overline{\xi}}, U) \) is 2-cartesian.

**Proof.** (i): To begin with, since \( f_{\overline{\xi}} \) is generizing ([100, Th.9.5]), and \( S \) is local, every fibre of \( f_{\overline{\xi}} \) has a point that specializes to the generic point \( \eta_s \) of \( f_{\overline{\xi}}^{-1}(s) \); since the fibres are irreducible, it follows that the generic point of every fibre specializes to \( \eta_s \). Therefore \( U \) is fibrewise dense in \( X(\overline{\xi}) \), and moreover it is connected. Now, the category \( \text{Cov}(X) \) is equivalent to the category of finite sets, hence every object in the essential image of \( j^* \) is (isomorphic to) a finite disjoint union of copies of \( U \); since \( U \) is connected, the morphisms of \( U \)-schemes between two such objects \( E \) and \( E' \) are in natural bijection with the set-theoretic mappings \( \pi_0(E) \to \pi_0(E') \) of their sets of connected components, whence the assertion.

(ii): Let us write \( U \) as the union of a filtered family \( (U_{\lambda} \mid \lambda \in \Lambda) \) of constructible open subsets of \( X(\overline{\xi}) \); up to replacing \( \Lambda \) by a cofinal subset, we may assume that \( \eta_s \in U_{\lambda} \) for every \( \lambda \in \Lambda \).
Arguing as in the proof of theorem \[13.2.11\] we see that $\mathcal{D}(S(\pi), f_\pi, U)$ is the 2-limit of the system of diagrams $\mathcal{D}(S(\pi), f_\pi, U_\lambda)$, hence it suffices to show the assertion with $U = U_\lambda$, for every $\lambda \in \Lambda$, which allows to assume that $U$ is quasi-compact. Next, arguing as in the proof of proposition \[13.1.29\] we are reduced to the case where $S = S(\pi)$. We may write $X(\pi)$ as the limit of a cofiltered system $(X_\lambda \mid \lambda \in \Lambda)$ of affine schemes, étale over $X$, and for $\lambda \in \Lambda$ large enough, we may find an open subset $U_\lambda \subset X_\lambda$ such that $U = U_\lambda \times_X X(\pi)$ (\[50\] Ch.IV, Cor.8.2.11)). For every $\mu \geq \lambda$, set $U_\mu := U_\lambda \times_X X_\mu$, and denote by $f_\mu : X_\mu \to S$ the natural morphism. Suppose first that $S$ is irreducible; then, from lemma \[13.1.6\] it is easily seen that $\mathcal{D}(S, f_\pi, U)$ is the 2-colimit of the system of diagrams $\mathcal{D}(S, f_\mu, U_\mu)$, so the assertion follows from theorem \[13.2.11\](ii) (more generally, this argument works whenever $S_{\text{max}}$ is a finite set, since filtered 2-colimits of categories commute with finite products).

In the general case, let $\varphi : E \to U$ be a finite étale morphism, and suppose that $\varphi_\eta := \varphi \times_X X(\pi) f_\pi^{-1}(\eta)$ extends to an object $\psi_\eta$ of $\text{Cov}(f_\pi^{-1} \eta)$, for every $\eta \in S_{\text{max}}$. The assertion boils down to showing that $\varphi$ extends to an object $\varphi'$ of $\text{Cov}(X(\pi))$. To this aim, for every $\eta \in S_{\text{max}}$, let $Z_\eta \to S$ be the closed immersion of the topological closure of $\eta$ in $S$ (which we endow with its reduced scheme structure); set also $Y_\eta := X \times_S Z_\eta$. Then $Z_\eta$ is a strictly local scheme ([51, Ch.IV, Prop.18.5.6(ii)]), and $\pi$ factors through the closed immersion $Y \to X$, which induces an isomorphism of $Z$-schemes:

$$Y_\eta(\pi) \xrightarrow{\sim} X(\pi) \times_S Z_\eta$$

(lemma \[13.1.22\](ii)). By the foregoing case, $\varphi \times_S Z_\eta$ extends to an object $\overline{\psi}_\eta$ of $\text{Cov}(Y_\eta(\pi))$. However, $Z_\eta$ is the limit of the cofiltered system $(Z_{\eta,i} \mid i \in I(\eta))$ consisting of the constructible closed subschemes of $S$ that contain $Z_\eta$. By lemma \[13.1.6\] it follows that we may find $i \in I(\eta)$ and an object $\overline{\psi}_{\eta,i}$ of $\text{Cov}(X(\pi) \times_S Z_{\eta,i})$ whose image in $\text{Cov}(Y_\eta(\pi))$ is isomorphic to $\overline{\psi}_\eta$, and if $i$ is large enough, $\overline{\psi}_{\eta,i} \times_X U$ agrees with $\varphi \times_S Z_{\eta,i}$ in $\text{Cov}(U \times_S Z_{\eta,i})$. For each $\eta, \eta' \in S_{\text{max}}$, choose $i \in I(\eta), i' \in I(\eta')$ with these properties, and to ease notation, set:

$$X'_\eta := X \times_S Z_{\eta,i} \quad X''_{\eta,\eta'} := X'_\eta \times_S Z_{\eta',\eta'} \quad \varphi'_\eta := \overline{\psi}_{\eta,i}$$

and denote by $\alpha_\eta : \varphi'_\eta \times_X X(\pi) U \xrightarrow{\sim} \varphi \times_S Z_{\eta,i}$ the given isomorphism. As in the foregoing, we notice that $\pi$ factors through $X'_\eta$, and the closed immersion $X'_\eta \to X$ induces an isomorphism $X'_\eta(\pi) \xrightarrow{\sim} X(\pi) \times_S Z_{\eta,i}$ of $Z_{\eta,i}$-schemes. According to [48, Ch.IV, Cor.1.9.9], we may then find a finite subset $T \subset S_{\text{max}}$ such that the induced morphism:

$$\beta : X_1 := \prod_{\eta \in T} X'_\eta(\pi) \to X(\pi)$$

is surjective. Set $X_2 := X_1 \times_X X(\pi) X_2$ and $X_3 := X_2 \times_X X(\pi) X_1$; notice that $X_2$ is the disjoint union of schemes of the form $X(\pi) \times_S Z_{\eta,i} \times_S Z_{\eta',\eta}$, for $\eta, \eta' \in T$, and again, the latter is naturally isomorphic to $X''_{\eta,\eta'}(\pi)$, for a unique lifting of the geometric point $\pi$ to a geometric point of $X''_{\eta,\eta'}$. Similar considerations can be repeated for $X_3$, and in light of (i), we deduce that the pull-back functors:

$$\text{Cov}(X_i \times_X X(\pi) U) \to \text{Cov}(X_i) \quad i = 1, 2, 3$$

are fully faithful, in which case corollary \[3.4.30\](iii) says that the essentially commutative diagram of categories:

$$\text{Desc}(\text{Cov}, \beta) \longrightarrow \text{Desc}(\text{Cov}, \beta \times_X X(\pi) U)$$

$$\prod_{\eta \in T} \text{Cov}(X'_\eta(\pi)) \longrightarrow \prod_{\eta \in T} \text{Cov}(X'_\eta(\pi) \times_X X(\pi))$$
is 2-cartesian. Let \( \rho : \text{Cov}(U) \to \text{Desc}(\text{Cov}(\beta \times _X \ U)) \) be the functor defined in \((3.4.22)\); it follows that the datum \((((\varphi_\eta', \alpha_\eta) \mid \eta \in T), \rho(\varphi))\) comes from a descent datum \((\varphi'_1, \omega)\) in \(\text{Desc}(\text{Cov}(\beta))\). By lemma \((13.1.2)\), the latter descends to an object \(\varphi'\) of \(\text{Cov}(X(X))\), and by construction we have \(j^*\varphi' = \varphi\), as required. \qed

13.3. Étale coverings of log schemes. We resume the general notation of \((12.2.1)\), especially, we choose implicitly \(\tau\) to be either the Zariski or étale topology, and we shall omit further mention of this choice, unless the omission might be a source of ambiguities.

13.3.1. Let \(Y := ((Y, \tau), T, \psi)\) be an object of \(\mathcal{K}_{\text{int}}\) (see \((12.6.10)\) : especially \(\tau = \text{Zar}\) here), \(\varphi : T'' \to T\) an integral proper subdivision of the fan \(T\) (definition \(6.5.22\)(ii),(iii)), and suppose that both \(T\) and \(T''\) are locally fine and saturated. Set \(((Y', \tau'), T', \psi') := \varphi^*Y\) (proposition \((12.6.14)\)(iii)), and let \(f : Y'' \to Y\) be the morphism of schemes underlying the cartesian morphism \(\varphi^*Y \to Y\).

**Proposition 13.3.2.** In the situation of \((13.3.1)\), the following holds :

(i) For every geometric point \(\xi\) of \(Y\), the fibre \(f^{-1}(\xi)\) is non-empty and connected.

(ii) The functor \(f^* : \text{Cov}(Y) \to \text{Cov}(Y'')\) is an equivalence.

**Proof.** (i): The assertion is local on \(Y\), hence we may assume that \(T = (\text{Spec } P)^{\sharp}\) for a fine, sharp and saturated monoid \(P\). In this case, we may find a subdivision \(\varphi' : T'' \to T'\) such that both \(\varphi'\) and \(\varphi \circ \varphi'\) are compositions of saturated blow up of ideals generated by at most two elements of \(P\) (example \((6.6.15)\)(iii)). We are reduced to showing the assertion for the morphisms \(\varphi'\) and \(\varphi \circ \varphi'\), after which, we may further assume that \(\varphi\) is the saturated blow up of an ideal generated by two elements of \(\Gamma(T, \mathcal{O}_T)\), in which case the assertion follows from the more precise theorem \((12.4.51)\).

(ii): First, we claim that the assertion is local on the Zariski topology of \(Y\). Indeed, let \(Y = \bigcup_{i \in I} U_i\) be a Zariski open covering, and set \(U_{ij} := U_i \cap U_j\) for every \(i, j \in I\); according to corollary \((3.4.30)\)(ii) and lemma \((13.1.2)\), it suffices to prove the contention for the objects \((U_i \times _Y (Y, \tau), T, \psi|_{U_i})\) and \((U_{ij} \times _Y (Y, \tau), T, \psi|_{U_{ij}})\), and the morphism \(\varphi\). Hence, we may again suppose that \(T = \text{Spec } P\), for a monoid \(P\) as in (i).

Arguing as in the proof of (i), we may next reduce to the case where \(\varphi\) is the saturated blow up of an ideal generated by two elements of \(\Gamma(T, \mathcal{O}_T)\). Now, the morphism of schemes \(f\) induces a morphism of topoi \(Y'_{\text{ét}} \to Y_{\text{ét}}\) which we denote again by \(f\); then, assertion (i) and the proper base change theorem \([9\text{ Exp.XII, Th.5.1(i) }]\) imply that the unit of adjunction \(\mathcal{F} \to f_*f^*\mathcal{F}\) is an isomorphism for every sheaf \(\mathcal{F}\) on \(Y\), so \(f^*\) is fully faithful (proposition \((1.1.20)\)(iii)) Next, if \(\varphi : E' \to Y'\) is a finite étale covering, \(Y'\) decomposes into a disjoint union of open and closed subsets \(Y' = Y'_0 \cup \cdots \cup Y'_k\), such that \((\varphi_*\mathcal{O}_E)|_{Y'_j}\) is locally free of rank \(r\), for every \(r = 0, \ldots, k\). Set \(Y'_r := \{\varphi(Y'_j)\} \text{ for } r = 0, \ldots, k\); since the fibers of \(f\) are connected, we see that \(Y'_r = f^{-1}Y'_r\) for every such \(r\). Moreover, since \(f\) is a closed map and the topology of \(Y\) is induced from that of \(Y'\) via \(f\), we see that \(Y'_r\) is a closed subset of \(Y\) for \(r = 0, \ldots, k\), so \(Y = Y'_0 \cup \cdots \cup Y'_k\) is a partition of \(Y\) by open and closed subsets. After replacing \(Y\) by \(Y_r\), we may then assume that \(\varphi_*\mathcal{O}_E\) is locally free of rank \(r\), and notice that the isomorphism classes of étale coverings of this type are classified by the pointed set \(H^1(Y'_{\text{ét}}, S_{r,Y})\), where \(S_r\) is the symmetric group on \(r\) elements. Thus, it suffices to show that the induced map:

\[
H^1(Y'_{\text{ét}}, S_{r,Y}) \to H^1(Y'_{\text{ét}}, S_{r,Y'})
\]

is a bijection. However, theorem \((4.9.9)\) yields the exact sequence of pointed sets:

\[
\{1\} \to H^1(Y'_{\text{ét}}, f_*S_{r,Y}) \xrightarrow{\omega} H^1(Y'_{\text{ét}}, S_{r,Y'}) \to H^0(Y'_{\text{ét}}, f^*S_{r,Y'})
\]

On the other hand, assertion (i) and the proper base change theorem \([9\text{ Exp.XII, Th.5.1(i) }]\) imply that the unit of adjunction \(S_{r,Y} \to f_*f^*S_{r,Y} = f_*S_{r,Y'}\) is an isomorphism, hence \(\omega\) is
Proof. By corollary 12.1.36(i) and theorem 12.1.37(ii), we may find a neighborhood $U \rightarrow Y$ of $\xi$ in $Y$, and a finite chart $(\omega_P, \omega_Q, \vartheta)$ for the restriction $f|_U : (U, N|_U) \rightarrow (X, M)$ of $f$. This follows easily from (i), (ii) and example 12.6.5(ii), that $f$ is of Kummer type for every $\tau$-point of $Y$. It then follows easily from (i), (ii) and example 12.6.5(ii), that $f$ is of Kummer type. In the same vein, we have the following:

Definition 13.3.4. (i) Let $\varphi : T \rightarrow S$ be a morphism of fans. We say that $\varphi$ is of Kummer type, if the map $(\log \varphi)_\xi : \Theta_{S, \varphi(t)} \rightarrow \Theta_{T,t}$ is of Kummer type, for every $t \in T$ (see definition 6.4.56).

(ii) Let $f : (Y, N) \rightarrow (X, M)$ be a morphism of log schemes.

(a) We say that $f$ is of Kummer type, if for every $\tau$-point $\xi$ of $Y$, the morphism of monoids $(\log f)_\xi : f^*M_{\xi} \rightarrow N_{\xi}$ is of Kummer type.

(b) A Kummer chart for $f$ is the datum of charts

$$\omega_P : P_Y \rightarrow N \quad \omega_Q : Q_X \rightarrow M$$

and a morphism of monoids $\vartheta : Q \rightarrow P$ such that $(\omega_P, \omega_Q, \vartheta)$ is a chart for $f$ (see definition 12.1.17(iii)), and $\vartheta$ is of Kummer type.

Remark 13.3.5. (i) Let $f : P \rightarrow Q$ be a morphism of monoids of Kummer type, with $P$ integral and saturated. It follows easily from lemma 6.4.57(iii,v), that the induced morphism of fans $(\Spec f)^\sharp : (\Spec Q)^\sharp \rightarrow (\Spec P)^\sharp$ is of Kummer type.

(ii) In the situation of definition 13.3.4(ii), it is easily seen that $f$ is of Kummer type, if and only if the morphism of $\tau$-monoids $f^*M_{\xi} \rightarrow N_{\xi}$ deduced from $\log f$, is of Kummer type for every $\tau$-point $\xi$ of $Y$.

(iii) In the situation of definition 13.3.4(ii), suppose that the chart $(\omega_P, \omega_Q, \vartheta)$ is of Kummer type, and $Q$ is integral and saturated. It then follows easily from (i), (ii) and example 12.6.5(ii), that $f$ is of Kummer type.

Lemma 13.3.6. Let $f : (Y, N) \rightarrow (X, M)$ be a morphism of log schemes with coherent log structures, $\xi$ a $\tau$-point of $Y$, and suppose that:

(a) $M_{f(\xi)}$ is fine and saturated.

(b) The morphism $(\log f)_\xi : M_{f(\xi)} \rightarrow N_{\xi}$ is of Kummer type.

Then there exists a (Zariski) open neighborhood $U$ of $\xi$ in $Y$, such that the restriction $f|_U : (U, N|_U) \rightarrow (X, M)$ of $f$ is of Kummer type.

Proof. By corollary 12.1.36(i) and theorem 12.1.37(ii), we may find a neighborhood $U' \rightarrow Y$ of $\xi$ in $Y$, and a finite chart $(\omega_P, \omega_Q, \vartheta)$ for the restriction $f|_{U'}$, with $Q$ finite and saturated. Set

$$S_P := \omega_P^{-1}N_{\xi'} \quad S_Q := \omega_Q^{-1}f(\xi)_{\xi} \quad P' := S_P^{-1}P \quad Q' := S_Q^{-1}Q.$$ 

According to claim 12.1.31(iii) we may find neighborhoods $U'' \rightarrow U'$ of $\xi$ in $Y$, and $V \rightarrow X$ of $f(\xi)$ in $X$, such that the charts $\omega_{P|_{U''}}$ and $\omega_{Q|V}$ extend to charts

$$\omega_P' : P'_{U''} \rightarrow N_{U''} \quad \omega_Q' : Q'_V \rightarrow M_{|V}.$$
Clearly \( \vartheta \) extends as well to a unique morphism \( \vartheta' : Q' \to P' \), and after shrinking \( U'' \) we may assume that the restriction \( f_{U''} : (U'', N_{U''}) \to (X, M) \) factors through a morphism \( f' : (U'', N_{U''}) \to (V, M'_V) \), in which case it is easily seen that the datum \( (\omega_{P'}, \omega_{Q'}, \vartheta') \) is a chart for \( f' \). Notice as well that \( Q' \) is still fine and saturated (lemma \[6.2.9](i)), and by claim \[12.1.31](iv) the maps \( \omega_{P'} \) and \( \omega_{Q'} \) induce isomorphisms:

\[
P'' \xrightarrow{\sim} N^2_{\xi} \quad Q'' \xrightarrow{\sim} M^2_{f(\xi)}
\]

Our assumption (b) then implies that the map \( Q'' \to P'' \) deduced from \( \vartheta' \) is of Kummer type, and then the morphism of fans \( \Spec \vartheta' : \Spec P' \to \Spec Q' \) is of Kummer type as well (remark \[13.3.5](i)). However, let

\[
\varpi_{P'} : (U'', N^2_{U''}) \to (\Spec P')^2 \quad \varpi_{Q'} : (V, M^2_V) \to (\Spec Q')^2
\]

be the morphisms of monoidal spaces deduced from \( \omega_{P'} \) and \( \omega_{Q'} \); we obtain a morphism

\[
(f', \Spec \vartheta') : (U'', N^2_{U''}, (\Spec P')^2, \varpi_{P'}) \to (V, M^2_V, (\Spec Q')^2, \varpi_{Q'})
\]

in the category \( \mathcal{K} \) of \( \{12.6.2\} \), which – in view of remark \[13.3.5\](ii) – shows that \( f' \) is of Kummer type. This already concludes the proof in case \( \tau = \text{Zar} \), and for \( \tau = \text{ét} \) it suffices to remark that the image of \( U'' \) in \( Y \) is a Zariski open neighborhood \( U \) of \( \xi \), such that the restriction \( f_{U'} \) is of Kummer type.

We shall use the following criterion:

**Proposition 13.3.7.** Let \( k \) be a field, \( f : P \to Q \) an injective morphism of fine monoids, with \( P \) sharp. Suppose that the scheme \( \Spec k(Q/m_PQ) \) admits an irreducible component of Krull dimension 0. We have:

(i) \( f \) is of Kummer type, and \( k(Q/m_PQ) \) is a finite \( k \)-algebra.

(ii) If moreover, \( Q^\times \) is a torsion-free abelian group, then \( Q \) is sharp, and \( k(Q/m_PQ) \) is a local \( k \)-algebra with \( k \) as residue field.

**Proof.** Notice that the assumption means especially that \( Q/m_PQ \neq \{1\} \), so \( f \) is a local morphism. Set \( I := \text{rad}(m_PQ) \) (notation of definition \[6.1.8\](ii)), and let \( p_1, \ldots, p_n \subset Q \) be the minimal prime ideals containing \( I \); then \( I = p_1 \cap \cdots \cap p_n \), by lemma \[6.1.16\]. Clearly the natural closed immersion \( \Spec k(Q/I) \to \Spec k(Q/m_PQ) \) is a homeomorphism; on the other hand, say that \( q \subset k(Q/I) \) is a prime ideal containing \( I \); then \( q \cap Q \) is a prime ideal of \( Q \) containing \( I \), hence \( p_i \subset q \) for some \( i \leq n \), i.e. \( \Spec k(Q/I) \) is the union of its closed subsets \( \Spec k(Q/p_iQ) \), for \( i = 1, \ldots, n \). The Krull dimension of each irreducible component of \( \Spec k(Q/p_iQ) = \Spec k[Q/p_i] \) equals

\[
\text{rk}_k(Q/p_i) + \dim Q/p_i = \text{rk}_kQ^\times + d - \text{ht}(p_i)
\]

where \( d := \dim Q \) (claim \[11.6.36\](ii) and corollary \[6.4.10\](i, ii)). Our assumption then implies that \( Q^\times \) is a finite group, and \( \text{ht}(p_i) = d \), i.e. \( p_i = m_Q \), for at least an index \( i \leq n \), and therefore \( I = m_Q \). Furthermore, since \( m_Q \) is finitely generated, we have \( m^n_Q \subset m_PQ \) for a sufficiently large integer \( n > 0 \), and then it follows easily that \( k(Q/m_PQ) \) is a finite \( k \)-algebra. If \( Q^\times \) is torsion-free, then we also deduce that \( Q \) is sharp, and moreover the maximal ideal of \( k(Q/m_PQ) \) generated by \( m_Q \) is nilpotent, hence the latter \( k \)-algebra is local.

Let now \( q \subset Q \) be any prime ideal, and pick \( x \in m_Q \setminus q \); the foregoing implies that there exists an integer \( r > 0 \) such that \( x^r = f(p_q)q \) for some \( p_q \in m_P \) and \( q \subset Q \), hence \( f(p_q) \notin q \), and \( f(p_q) \) is not invertible in \( Q \), since \( f \) is local. If now \( q \) has height \( d - 1 \), it follows that \( f(p_q) \) is a generator of \( (Q/q)_{\mathbb{R}} \), which is an extremal ray of the polyhedral cone \( Q_{\mathbb{R}} \), and every such extremal ray is of this form (proposition \[6.4.7\]); furthermore, the latter cone is strictly convex, since \( Q^\times \) is finite. Hence the set \( S := \{ f(p_q) : \text{ht}(q) = d - 1 \} \) is a system of generators of
the polyhedral cone $Q_\mathbb{R}$ (see (6.3.15)). Let $Q' \subset Q$ be the submonoid generated by $S$; then $S_Q = S_\mathbb{R} \cap Q_\mathbb{Q} = Q_\mathbb{Q}$ (proposition 6.3.22 iii), i.e. $f$ is of Kummer type.

13.3.8. Let $f : (\text{Y}_\text{Zar}, N) \to (X_\text{Zar}, M)$ be a morphism of log schemes with Zariski log structures; it follows easily from the isomorphism (12.1.9) and remark 13.3.5 (ii) that $f$ is of Kummer type if and only if $\tilde{u}^* f : (X_\text{ét}, \tilde{u}^* M) \to (\text{Y}_\text{ét}, \tilde{u}^* N)$ is a morphism of Kummer type between schemes with étale log structures (notation of (6.3.20)). Since $s$ is an integral and saturated chart $\text{Y}_\text{Zar}$, and denote by $\text{s.Kum}(X_\text{Zar}, M)$ (resp. $\text{s.Kum}(X_\text{ét}, \tilde{u}^* M)$) the full subcategory of $\text{sat.log}/(X_\text{Zar}, M)$ (resp. of $\text{sat.log}/(X_\text{ét}, \tilde{u}^* M)$) whose objects are all the morphisms of Kummer type. In view of the foregoing (and of lemma 12.1.18 (i)), we see that $\tilde{u}^*$ restricts to a functor :

(s. Kum\((X_\text{Zar}, M)\) \to \text{s.Kum}(X_\text{ét}, \tilde{u}^* M).

\textbf{Lemma 13.3.10.} The functor (13.3.9) is an equivalence.

\textbf{Proof.} By virtue of proposition 12.2.3 (ii) we know already that (13.3.9) is fully faithful, hence we only need to show its essential surjectivity. Thus, let $f : (\text{Y}_\text{ét}, N) \to (X_\text{ét}, \tilde{u}^* M)$ be a morphism of Kummer type. By remark 13.3.5 (ii), we know that $\log f$ induces an isomorphism

\[ \tilde{u}^* f^* M^\sharp_Q \cong f^* \tilde{u}^* M^\sharp_Q \cong N^\sharp_Q \]

(note of (6.3.20)). Since $\mathcal{N}$ is integral and saturated, the natural map $N^\sharp \to N^\sharp_Q$ is a monomorphism, so that the counit of adjunction $\tilde{u}^* \mathcal{N}^\sharp \to N^\sharp$ is an isomorphism (lemma 4.9.27 (ii)), and then the same holds for the counit of adjunction $\tilde{u}^* \mathcal{N}^\sharp \to N^\sharp$ (proposition 12.2.3 (iii)).

\textbf{Proposition 13.3.11.} Let $f : (Y, N) \to (X, M)$ be a morphism of fs log schemes. The following conditions are equivalent:

(a) Every geometric point of $X$ admits an étale neighborhood $U \to X$ such that $Y_U := U \times_X Y$ decomposes as a disjoint union $Y_U = \bigcup_{i=1}^n Y_i$ of open and closed subschemes (for some $n \in \mathbb{N}$), and we have :

(i) Each restriction $Y_i \times_Y (Y, N) \to U \times_X (X, M)$ of $f \times_X 1_U$ admits a fine, saturated Kummer chart $(\omega_{P_i}, \omega_{Q_i}, \vartheta_i)$ such that $P_i$ and $Q_i$ are sharp, and the order of $\text{Coker} \vartheta_i^{\text{rep}}$ is invertible in $\text{O}_U$.

(ii) The induced morphism of $U$-schemes $Y_i \to U \times_{\text{Spec} \mathbb{Z}[P_i]} \text{Spec} \mathbb{Z}[Q_i]$ is an isomorphism, for every $i = 1, \ldots, n$.

(b) $f$ is étale, and the morphism of schemes underlying $f$ is finite.

\textbf{Proof.} (a) $\Rightarrow$ (b): Indeed, it is easily seen that the morphism $\text{Spec} \mathbb{Z}[\vartheta_i]$ is finite, hence the same holds for the restriction $Y_i \to U$ of $f$, in view of (a.ii), and then the same holds for $f \times_X 1_U$, so finally $f$ is finite on the underlying schemes ([49, Ch.IV, Prop.2.7.1]), and it is étale by the criterion of theorem 12.3.37.

(b) $\Rightarrow$ (a): Arguing as in the proof of theorem 12.3.37 we may reduce to the case where $\tau = \text{ét}$. Suppose first that both $X$ and $Y$ are strictly local. In this case, $M$ admits a fine and saturated chart $\omega_P : P_X \to M$, sharp at the closed point (corollary 12.1.36 (i)). Moreover, $f$ admits a chart $(\omega_P, \omega_Q : Q_Y \to N, \vartheta : P \to Q)$, for some fine monoid $Q$ such that $Q^\times$ is torsion-free; also $\vartheta$ is injective, the induced morphism of $X$-schemes

\[ g : Y \to X' := X \times_{\text{Spec} \mathbb{Z}[P]} \text{Spec} \mathbb{Z}[Q] \]

is étale, and the order of $\text{Coker} \vartheta^{\text{rep}}$ is invertible in $\text{O}_X$ (corollary 12.3.42). Since $f$ is finite, $g$ is also closed ([45, Ch.II, Prop.6.1.10]), hence its image $Z$ is an open and closed local subscheme, finite over $X$. Let $k$ be the residue field of the closed point of $X$; it follows that $X' \times_X \text{Spec} k \simeq \text{Spec} k[Q/m_P Q]$ admits an irreducible component of Krull dimension zero
(namely, the intersection of \( Z \) with the fibre of \( X' \) over the closed point of \( X \)), in which case the criterion of proposition 13.3.7(ii) ensures that \( \vartheta \) is of Kummer type and \( Q \) is sharp, hence \( X' \) is finite over \( X \), and moreover \( X' \times_X \text{Spec} k \) is a local scheme with \( k \) as residue field. Since \( X \) is strictly henselian, it follows that \( X' \) itself is strictly local, and therefore \( g \) is an isomorphism, so the proposition is proved in this case.

Let now \( X \) be a general scheme, and \( \xi \) a geometric point of \( X \); denote by \( X(\xi) \) the strict henselization of \( X \) at the point \( \xi \), and set \( Y(\xi) := X(\xi) \times_X Y \). Since \( f \) is finite, \( Y(\xi) \) decomposes as the disjoint union of finitely many open and closed strictly local subschemes \( Y_1(\xi), \ldots, Y_n(\xi) \). Then we may find an étale neighborhood \( U \to X \) of \( \xi \), and open and closed subschemes \( Y_1, \ldots, Y_n \) of \( X \times_X U \), with isomorphisms of \( X(\xi) \)-schemes \( Y_i(\xi) \to Y_i \times_U X(\xi) \), for every \( i = 1, \ldots, n \) (50 Ch.IV, Cor.8.3.12). We may then replace \( X \) by \( U \), and we reduce to proving the proposition for each of the restrictions \( Y_i \to U \) of \( f \times_X 1_U \); hence we may assume that \( Y(\xi) \) is strictly local. By the foregoing case, we may find a chart
\[
(13.3.12) \quad P_{X(\xi)} \to M(\xi) \quad Q_{Y(\xi)} \to N(\xi) \quad \vartheta : P \to Q
\]
of \( f \times_X 1_{X(\xi)} \), with \( \vartheta \) of Kummer type, such that \( P \) and \( Q \) are sharp, the order \( d \) of \( \text{Coker} \vartheta_{\text{red}} \) is invertible in \( \mathcal{O}_{X(\xi)} \), and the induced morphism of \( X(\xi) \)-schemes \( X(\xi) \times_{\text{Spec} \mathbb{Z}[P]} \text{Spec} \mathbb{Z}[Q] \) is an isomorphism. By corollary 12.2.34 we may find an étale neighborhood \( U \to X \) of \( \xi \) such that (13.3.12) extends to a chart for \( f \times_X 1_U \). After shrinking \( U \), we may assume that \( d \) is invertible in \( \mathcal{O}_U \). Lastly, by further shrinking of \( U \), we may ensure that the induced morphism of \( U \)-schemes \( U \times_X Y \to U \times_{\text{Spec} \mathbb{Z}[P]} \text{Spec} \mathbb{Z}[Q] \) is an isomorphism (50 Ch.IV, Cor.8.8.2.4).

**Definition 13.3.13.** Let \( f : (Y, N) \to (X, M) \) be a morphism of fs log schemes. We say that \( f \) is an étale covering of \((X, M)\), if \( f \) fulfills the equivalent conditions (a) and (b) of proposition 13.3.11. We denote by \( \text{Cov}(X, M) \) the full subcategory of the category of \((X, M)\)-schemes, whose objects are the étale coverings of \((X, M)\).

**Remark 13.3.14.** (i) Notice that all morphisms in \( \text{Cov}(X, M) \) are étale coverings, in light of corollary 12.2.25(ii).

(ii) Moreover, \( \text{Cov}(X, M) \) is a Galois category (see 65 Exp.V, Déf.5.1), and if \( \xi \) is any geometric point of \((X, M)_x\), we obtain a fibre functor for this category, by the rule \( f \mapsto f^{-1}(\xi) \), for every étale covering \( f \) of \((X, M)_x\). (Details left to the reader.) We shall denote by \( \pi_1((X, M)_{\text{ét}}, \xi) \) the corresponding fundamental group.

**Example 13.3.15.** Let \( (f, \log f) : (Y, N) \to (X, M) \) be an étale covering of a regular log scheme \((X, M)\), and suppose that \( X \) is strictly local of dimension 1 and \( Y \) is connected (hence strictly local as well). Let \( x \in X \) (resp. \( y \in Y \)) be the closed point; it follows that \( \mathcal{O}_{X,x} \) is a strictly henselian discrete valuation ring (corollary 12.5.13). The same holds for \( \mathcal{O}_{Y,y} \) in view of theorem 12.5.28 and 51 Ch.IV, Prop.18.5.10. In case \( \dim M_x = 0 \), the log structures \( M \) and \( N \) are trivial, so \( f : Y \to X \) is an étale morphism of schemes. Otherwise we have \( \dim M_x = 1 = \dim N_y \) (lemma 6.4.57(i)), and then \( M_x^y \simeq N \simeq N_y^x \) (theorem 6.4.16(ii)); also, the choice of a chart for \( f \) as in proposition 13.3.11 induces an isomorphism
\[
\mathcal{O}_{X,x} \otimes_{M_x} N_y^x \simeq \mathcal{O}_{Y,y}
\]
where the map \( M_x^y \to N_y^x \) is the \( N \)-Frobenius map of \( N \), where \( N > 0 \) is an integer invertible in \( \mathcal{O}_{X,x} \). Moreover, notice that the image of the maximal ideal of \( M_x \) generates the maximal ideal of \( \mathcal{O}_{X,x} \) (and likewise for the image of \( N_y \) in \( \mathcal{O}_{Y,y} \)), so the structure map of \( \mathcal{O}_{X,x} \) induces an
isomorphism $M_x^i \rightarrow \Gamma_+$, onto the submonoid of the value group $(\Gamma, \leq)$ of $\mathcal{O}_{X,x}$ consisting of all elements $\leq 1$ (and likewise for $N_x^i$). In other words, $\mathcal{O}_{Y,y}$ is obtained from $\mathcal{O}_{X,x}$ by adding the $N$-th root of a uniformizer. It then follows that the ring homomorphism $\mathcal{O}_{X,x} \rightarrow \mathcal{O}_{Y,y}$ is an algebraic tamely ramified extension of discrete valuation rings (see e.g. [59], Cor.6.2.14).

**Definition 13.3.16.** Let $X$ be a normal scheme, and $Z \rightarrow X$ a closed immersion such that:

(a) $Z$ is a union of irreducible closed subsets of codimension one in $X$.

(b) For every maximal point $z \in Z$, the stalk $\mathcal{O}_{X,z}$ is a discrete valuation ring.

Set $U := X \setminus Z$, let $f : U' \rightarrow U$ be an étale covering, and $g : X' \rightarrow X$ the normalization of $X$ in $U'$. Notice that $g^{-1}Z$ is a union of irreducible closed subsets of codimension one in $X'$ (by the going down theorem [100], Th.9.4(ii)).

(i) We say that $f$ is *tamely ramified along $Z$* if, for every geometric point $\xi \in X'$ localized at a maximal point of $g^{-1}Z$, the induced finite extension

$$\mathcal{O}_{X,g(\xi)}^{\text{sh}} \rightarrow \mathcal{O}_{X',\xi}^{\text{sh}}$$

of strictly henselian discrete valuation rings ([51], Ch.IV, Cor.18.8.13), is tamely ramified. Recall that the latter condition means the following: let $\Gamma_{g(\xi)} \rightarrow \Gamma_{\xi}$ be the map of value groups induced by the above extension; then the *ramification index of $f$ at $\xi$*

$$e_{\xi}(f) := (\Gamma_{\xi} : \Gamma_{f(\xi)})$$

is invertible in the residue field $\kappa(\xi)$, and $g$ induces an isomorphism $\kappa(f(\xi)) \cong \kappa(\xi)$.

(ii) Suppose that $f$ is tamely ramified along $Z$, and that the set of maximal points of $Z$ is finite. Then the *ramification index of $f$ along $Z$* is the least common multiple $e_{Z}(f)$ of the ramification indices $e_{\xi}(f)$, where $\xi$ ranges over the set of all geometric points of $X'$ supported at a maximal point of $g^{-1}Z$.

(iii) We denote by $\text{Tame}(X,U)$ the full subcategory of $\text{Cov}(U)$ whose objects are the étale coverings of $U$ that are tamely ramified along $Z$.

**Lemma 13.3.17.** Let $\varphi : X' \rightarrow X$ be a dominant morphism of normal schemes, $Z \subset X$ a closed subset, and set $Z' := \varphi^{-1}Z$. Suppose that:

(a) The closed immersions $Z \rightarrow X$ and $Z' \rightarrow X'$ satisfy conditions (a) and (b) of definition 13.3.16.

(b) $\varphi$ restricts to a map $\text{Max} Z' \rightarrow \text{Max} Z$ on the subsets of maximal points of $Z$ and $Z'$.

We have:

(i) $\varphi^* : \text{Cov}(U) \rightarrow \text{Cov}(U')$ restricts to a functor

$$\text{Tame}(X,U) \rightarrow \text{Tame}(X',U').$$

(ii) Suppose that $\text{Max} Z$ and $\text{Max} Z'$ are finite sets. Then, for any object $f : V \rightarrow U$ of $\text{Tame}(X,U)$, the index $e_{Z}(\varphi^* f)$ divides $e_{Z}(f)$.

(iii) Suppose that $X$ is regular, and let $j : U \rightarrow X$ be the open immersion. Then the essential image of the pull-back functor $j^* : \text{Cov}(X) \rightarrow \text{Tame}(X,U)$ consists of the objects $f : V \rightarrow U$ such that $e_{Z}(f) = 1$.

**Proof.** Let $V \rightarrow U$ be an object of $\text{Tame}(X,U)$, and denote by $g : W \rightarrow X$ (resp. $g' : W' \rightarrow X'$) the normalization of $X$ in $V$ (resp. of $X'$ in $V \times_U U'$). Let $w'$ be a geometric point of $W'$ localized at a maximal point of $g'^{-1}Z'$, and denote by $w$ (resp. $x'$, resp. $x$) the image of $w'$ in $W$ (resp. in $X'$, resp. in $X$); in order to check (i) and (ii), we have to show that the ramification index of $g'$ at the geometric point $w'$ is invertible in $\kappa(w')$, and the residue field extension $\kappa(x') \subset \kappa(w')$ is trivial. To this aim, in view of [51], Ch.IV, Prop.17.5.7, we may replace $X'$ by $X'(x')$, $X$ by $X(x)$, $W$ by $W(w)$, and assume from start that $X$, $X'$ and $W$ are strictly local, say $X = \text{Spec} \ A$, $X' = \text{Spec} \ B$ and $C = \text{Spec} \ W$ for some strictly henselian local.
rings $A, B, C$. In this case, $D := B \otimes_A C$ is a direct product of finite and local $B$-algebras, and $x'$ is localized at a closed point of $X'$, so $w'$ is localized at a closed point of $W'$, therefore $\partial_{W', w'}$ is a direct factor of $D$, and $\kappa(\omega)$ is a quotient of $\kappa(x') \otimes_{\kappa(x)} \kappa(w)$; but we have $\kappa(w) = \kappa(x)$ by assumption, so this already yields $\kappa(w') = \kappa(x')$. Moreover, by construction, $\partial_{W', w'} \otimes_A \text{Frac} A$ is a finite separable extension of $\text{Frac} B$, and the diagram

$$
\text{Frac} A \longrightarrow \text{Frac} C
\bigg\downarrow
\text{Frac} B \longrightarrow \text{Frac} \partial_{W', w'}
$$

is cocartesian (in the category of fields). Since $V$ is tamely ramified along $Z$, the top horizontal arrow of (13.3.18) is a finite (abelian) extension whose degree $e_w$ is invertible in $\kappa(x)$ ([59 Cor.6.2.14]); it follows that the bottom horizontal arrows is a Galois extension as well, and its degree divides $e_w$, as required.

(iii): Let $f : V \to U$ be an object of $\text{Tame}(X, U)$. By claim [13.1.8], there exists a largest open subset $U_{\text{max}} \subset X$ containing $U$, and such that $f$ is the restriction of an étale covering $f_{\text{max}} : V' \to U_{\text{max}}$ now, if $e_Z(f) = 1$, every point of codimension one of $X \setminus U$ lies in $U_{\text{max}}$, by claim [13.1.9]. Hence $X \setminus U$ has codimension $\geq 2$ in $X$, in which case lemma [13.1.7(iv) implies that $X = U_{\text{max}}$, as required. \qed

**Remark 13.3.19.** The assumptions (a) and (b) of lemma [13.3.17] are fulfilled, notably, when $f$ is finite and dominant, or when $f$ is flat ([100 Th.9.4(iii), Th.9.5]).

13.3.20. Let now $\underline{X} := (X_i \mid i \in I)$ be a cofiltered system of normal schemes, such that, for every morphism $\varphi : i \to j$ in the indexing category $I$, the corresponding transition morphism $f_{\varphi} : X_i \to X_j$ is dominant and affine. Suppose also, that for every $i \in I$, there exists a closed immersion $Z_i \to X_i$, fulfilling conditions (a) and (b) of definition [13.3.16] such that $\text{Max} Z_i$ is a finite set, and for every morphism $\varphi : i \to j$ of $I$, we have:

- $Z_i = f_{\varphi}^{-1} Z_j$.
- The corresponding morphism $f_{\varphi}$ restricts to a map $\text{Max} Z_i \to \text{Max} Z_j$.

Let also $X$ be the limit of $\underline{X}$, and $Z$ the limit of the system $(Z_i \mid i \in I)$, and suppose furthermore that the closed immersion $Z \to X$ fulfills as well conditions (a) and (b) of definition [13.3.16].

**Proposition 13.3.21.** In the situation of [13.3.20], we have:

(i) The induced morphism $\pi_i : X \to X_i$ restricts to a map

$$\text{Max} Z \to \text{Max} Z_i \quad \text{for every } i \in I.$$

(ii) The morphisms $\pi_i$ induce an equivalence of categories:

$$2\text{-colim}_{I} \text{Tame}(X_i, X_i \setminus Z_i) \to \text{Tame}(X, X \setminus Z).$$

**Proof.** (i): More precisely, we shall prove that there is a natural homeomorphism:

$$\text{Max} Z \xrightarrow{\sim} \lim_{i \in I} \text{Max} Z_i.$$

(Notice the each $\text{Max} Z_i$ is a discrete finite set, hence this will show that $\text{Max} Z$ is a profinite topological space.) Indeed, suppose that $z := (z_i \mid i \in I)$ is a maximal point of $Z$. For every $i \in I$, let $T_i \subset \text{Max} Z_i$ be the subset of maximal generizations of $z_i$ in $Z_i$. It is easily seen that $f_{\varphi}^{-1} T_i \subset T_j$ for every morphism $\varphi : i \to j$ in $I$. Clearly $T_i$ is a finite non-empty set for every $i \in I$, hence the limit $T$ of the cofiltered system $(T_i \mid i \in I)$ is non-empty. However, any point of $T$ is a generalization of $z$ in $Z$, hence it must coincide with $z$. The assertion follows easily.

(ii): To begin with, lemma [13.3.17(i)] shows that, for every morphism $\varphi : i \to j$ in $I$, the transition morphism $f_{\varphi}$ induces a pull-back functor $\text{Tame}(X_j, X_j \setminus Z_j) \to \text{Tame}(X_i, X_i \setminus Z_i)$,
so the 2-colimit in (ii) is well-defined, and combining (i) with lemma 13.3.17(i) we obtain indeed a well-defined functor from this 2-colimit to $\mathbb{T}ame(X, X \setminus Z)$.

The full faithfulness of the functor of (ii) follows from lemma 13.1.6 Next, let $g : V \to X \setminus Z$ be an object of $\mathbb{T}ame(X, X \setminus Z)$; invoking again lemma 13.1.6 we may descend $g$ to an étale covering $g_j : V_j \to X_j \setminus Z_j$, for some $j \in I$; after replacing $I$ by $I/j$, we may assume that $j$ is the final object of $I$ and we may define $g_i := f^*_i(g_j)$ for every $i : j \to j$ in $I$. To conclude the proof, it suffices to show that there exists $i \in I$ such that $g_i$ is tamely ramified along $Z_i$.

Now, let $\bar{g}_i : \bar{V}_i \to V_i$ be the normalization of $X_i$ in $V_i \times X_i$, for every $i \in I$, and $\bar{g} : \bar{V} \to X$ the normalization of $X$ in $V$. Given a geometric point $\bar{v}$ localized at a maximal point of $\bar{g}^{-1}Z$, let $\bar{v}_i$ (resp. $\bar{z}_i$) be the image of $\bar{v}$ in $\bar{V}_i$ (resp. in $Z_i$), for every $i \in I$. Let also $\bar{z}$ be the image of $\bar{v}$ in $Z$. Then

$$\mathcal{O}^{sh}_{\bar{V}, \bar{v}} = \lim_{i \in I} \mathcal{O}^{sh}_{X_i, \bar{v}_i}, \quad \mathcal{O}^{sh}_{V, \bar{v}} = \lim_{i \in I} \mathcal{O}^{sh}_{V_i, \bar{z}_i}. \tag{31 \text{ Ch.IV, Prop.18.8.18(ii))},}$$

and it follows easily that there exists $i \in I$ such that the finite extension $\mathcal{O}^{sh}_{X_i, \bar{v}_i} \to \mathcal{O}^{sh}_{V_i, \bar{z}_i}$ is already tamely ramified. Since only finitely many points of $V_i$ lie over the support of $Z$, and since $I$ is cofiltered, it follows that there exists $i \in I$ such that the induced morphism $\bar{V}_i \times X_i, X_i(\bar{z}_i) \to X_i(\bar{v}_i)$ is already tamely ramified. However, notice that $\pi^{-1}_i(z_i)$ is open in $\text{Max} Z$, for every $i \in I$, and $z_i \in \text{Max} Z_i$. Therefore, we may find a finite subset $I_0 \subset I$, and for every $i \in I_0$ a subset $T_i \subset \text{Max} Z_i$, such that:

- $\text{Max} Z = \bigcup_{i \in I_0} \pi^{-1}_i(T_i)$.
- For every geometric point $z_i$ localized in $T_i$, the morphism $\bar{V}_i \times X_i, X_i(z_i) \to X_i(z_i)$ is tamely ramified.

Since $I$ is cofiltered, we may find $k \in I$ with morphisms $\varphi_i : k \to i$ for every $i \in I_0$; after replacing $T_i$ by $f_i^{-1}(T_i)$ for every $i \in I_0$, we may then assume that $I_0 = \{k\}$, so that $\text{Max} Z = \pi^{-1}_k(T_k)$. It follows that $\text{Max} Z_i = f_i^{-1}T_k$ for some $i \in I$ and some $\varphi : i \to k$. Then it is clear that $g_i$ is tamely ramified along $Z_i$, as required. \hfill \Box

13.3.22. Let $X$ be a scheme, $U \subset X$ a connected open subset, $\xi$ any geometric point of $U$, and $N > 0$ an integer which is invertible in $\mathcal{O}_U$; then the $N$-Frobenius map $\mathcal{N}$ of $\mathcal{O}^\times_U$ gives a Kummer exact sequence of abelian sheaves on $X_{\text{ét}}^\circ$:

$$0 \to \mathcal{N}_{\mu_{N, U}} \to \mathcal{O}^\times_U \overset{N}{\longrightarrow} \mathcal{O}^\times_U \to 0$$

(where $\mu_{N, U}$ is the $N$-torsion subsheaf of $\mathcal{O}^\times_U$; see [9 Exp.IX, 3.2])]. Suppose now that $\mu_{N, U}$ is a constant sheaf on $U_{\text{ét}}$; this means especially that $\mu_N := (\mu_{N, U})_{\xi}$ is a cyclic group of order $N$. Indeed, $\mu_N$ certainly contains such a subgroup (since $N$ is invertible in $\mathcal{O}_U$), so denote by $\zeta$ one of its generators; then every $u \in \mu_N$ satisfies the identity $0 = u_N - 1 = \prod_{i=1}^N (u - \zeta_i)$, and each factor $u_i$ of this decomposition vanishes on a closed subset $U_i$ of $U(\xi)$; clearly $U_i \cap U_j = \emptyset$ for $i \neq j$, so we get a decomposition of $U(\xi)$ as a disjoint union of open and closed subsets $U(\xi) = U_1 \cup \cdots \cup U_N$ such that $u = \zeta_i$ on $U_i$, for every $i \leq N$; since $U(\xi)$ is connected, it follows that $U(\xi) = U_i$ for some $i$, i.e. $\zeta$ generates $\mu_N$. There follows a natural map:

$$\partial_N : \Gamma(U_{\text{ét}}, \mathcal{O}^\times_U) \to H^1(U_{\text{ét}}, \mu_{N, U}) \cong \text{Hom}_{\text{cont}}(\pi_1(U_{\text{ét}}, \xi), \mu_N)$$

(lemma 13.1.12). Recall the geometric interpretation of $\partial_N : a$ given $u \in \mathcal{O}^\times_U(\xi)$ is viewed as a morphism of schemes $\xi : U \to \mathbb{G}_m$, where $\mathbb{G}_m := \text{Spec } \mathbb{Z}[\mathbb{Z}]$ is the standard multiplicative group scheme; we let $U'$ be the fibre product in the cartesian diagram of schemes:

$$(13.3.23)$$

\[
\begin{array}{ccc}
U' & \longrightarrow & \mathbb{G}_m \\
\downarrow & & \downarrow \\
U & \longrightarrow & \text{Spec } \mathbb{Z}[\mathbb{Z}]
\end{array}
\]
Then \( \varphi_n \) is a torsor under the \( U_\text{et}^* \)-group \( \mu_{N,U} \), and to such torsor, lemma [13.1.12] attaches a well defined continuous group homomorphism as required.

If \( M > 0 \) is any integer dividing \( N \), a simple inspection yields a commutative morphism diagram:

\[
\begin{array}{ccc}
\Gamma(U_\text{et}, O_X) & \xrightarrow{\partial_N} & \text{Hom}_{\text{cont}}(\pi_1(U_\text{et}, \xi), \mu_N) \\
\downarrow \partial_M & & \downarrow \pi_{N,M} \\
\text{Hom}_{\text{cont}}(\pi_1(U_\text{et}, \xi), \mu_M) & & \\
\end{array}
\]

(13.3.24)

where \( \pi_{N,M} \) is induced by the map \( \mu_N \to \mu_M \) given by the rule \( x \mapsto x^{N/M} \) for every \( x \in \mu_N \).

13.3.25. Let now \( X \) be a strictly local scheme, \( x \) the closed point of \( X \), and denote by \( p \) the characteristic exponent of the residue field \( \kappa(x) \) (so \( p \) is either 1 or a positive prime integer). Let also \( \beta : M \to O_X \) be a log structure on \( X_\text{et} \), take \( U := (X, M)_\text{tr} \), suppose that \( U \neq \emptyset \), and fix a geometric point \( \xi \) of \( U \); for every integer \( N > 0 \) with \( (N, p) = 1 \), we get a morphism of monoids:

\[
M_x \xrightarrow{\beta} \Gamma(U_\text{et}, O_X) \xrightarrow{\partial_N} \text{Hom}_{\text{cont}}(\pi_1(U_\text{et}, \xi), \mu_N)
\]

(13.3.26)

whose kernel contains \( M_x^N \), the image of the \( N \)-Frobenius endomorphism of \( M_x \). Notice that the \( N \)-Frobenius map of \( O_{X,x} \) is surjective: indeed, since the residue field \( \kappa(x) \) is separably closed, and \( (N, p) = 1 \), all polynomials in \( \kappa(x)[T] \) of the form \( T^N - u \) (for \( u \neq 0 \)) split as a product of distinct monic polynomials of degree 1; since \( O_{X,x} \) is henselian, the same holds for all polynomials in \( O_{X,x}[T] \) of the form \( T^N - u \), with \( u \in O_{X,x}^\times \). It follows that (13.3.26) factors through a natural map:

\[
M_x^{\text{gp}} \to \text{Hom}_{\text{cont}}(\pi_1(U_\text{et}, \xi), \mu_N)
\]

which is the same as a group homomorphism:

\[
M_x^{\text{gp}} \times \pi_1(U_\text{et}, \xi) \to \mu_N.
\]

(13.3.27)

In view of the commutative diagram (13.3.24), it is easily seen that the pairings (13.3.27), for \( N \) ranging over all the positive integers with \( (N, p) = 1 \), assemble into a single pairing:

\[
M_x^{\text{gp}} \times \pi_1((X, M)_{\text{tr}, \text{et}}, \xi) \to \prod_{\ell \neq p} \mathbb{Z}_\ell(1)
\]

(13.3.28)

(where \( \ell \) ranges over the prime numbers different from \( p \), and \( \mathbb{Z}_\ell(1) := \lim_{n \in \mathbb{N}} \mu_{\ell^n} \)). The latter is the same as a group homomorphism:

13.3.29. Let \( f : (X, M) \to (Y, N) \) be a morphism of log schemes, such that both \( X \) and \( Y \) are strictly local, and \( f \) maps the closed point \( x \) of \( X \) to the closed point \( y \) of \( Y \). Then \( f \) restricts to a morphism of schemes \( f_{\text{tr}} : (X, M)_{\text{tr}} \to (Y, N)_{\text{tr}} \) (remark [12.2.8(i)]). Fix again a geometric point \( \xi \) of \( (X, M)_{\text{tr}} \); we get a diagram of group homomorphisms:

\[
\begin{array}{ccc}
\pi_1((X, M)_{\text{tr}, \text{et}}, \xi) & \xrightarrow{\pi_1(f_{\text{tr}}, \xi)} & \pi_1((Y, N)_{\text{tr}, \text{et}}, f(\xi)) \\
\downarrow N_{y}^{\text{gp}} \otimes \mathbb{Z} \prod_{\ell \neq p} \mathbb{Z}_\ell(1) & & \downarrow M_{x}^{\text{gp}} \otimes \mathbb{Z} \prod_{\ell \neq p} \mathbb{Z}_\ell(1) \\
\end{array}
\]

whose vertical arrows (resp. bottom horizontal arrow) are the maps (13.3.28) (resp. is induced by \( (\log f_x)^{\text{gp}} \)), and by inspecting the constructions, it is easily seen that this diagram commutes.
13.3.30. Suppose now that \((X, M)\) as in \((13.3.25)\) is a fs log scheme, so that \(P := M^\sharp\) is fine and saturated; in this case, we wish to give a second construction of the pairing \((13.3.27)\).

- Namely, for every integer \(N > 0\) set \(S_P := \text{Spec} \mathbb{Z}[P]\) and consider the finite morphism of schemes \(g_N : S_P \to S_P\) induced by the \(N\)-Frobenius endomorphism of \(P\). Notice that \(S_P\) contains the dense open subset \(U_P := \text{Spec} \mathbb{Z}[1/N, \mathbb{P}^{\text{gp}}]\), and it is easily seen that the restriction \(g_N|_{U_P} : U_P \to U_P\) of \(g_N\) is an étale morphism. Let \(\tau \in U_P\) be any geometric point; then \(\tau\) corresponds to a ring homomorphism \(\mathbb{Z}[1/N, \mathbb{P}^{\text{gp}}] \to \kappa := \kappa(\tau)\), which is the \(\mathbb{Z}\)-algebra \(\mathbb{P}^{\text{gp}}\). Notice that every \(\chi \) is not separably closed, and \(N\) is invertible in \(\kappa\). Let \(C_N\) be the cokernel of the \(\mathbb{N}\)-Frobenius endomorphism of \(\mathbb{P}^{\text{gp}}\); there follows a short exact sequence of finite abelian groups:

\[
0 \to \text{Hom}_{\mathbb{Z}}(C_N, \kappa) \to \text{Hom}_{\mathbb{Z}}(\mathbb{P}^{\text{gp}}, \kappa) \xrightarrow{\pi_1} \text{Hom}_{\mathbb{Z}}(\mathbb{P}^{\text{gp}}, \kappa) \to 0.
\]

Especially, we see that the fibre \(g_N^{-1}(\tau)\) is naturally a torsor under the group \(\text{Hom}_{\mathbb{Z}}(C_N, \kappa) = \text{Hom}_{\mathbb{Z}}(\mathbb{P}^{\text{gp}}, \mu_N(\kappa))\), where \(\mu_N(\kappa) \subseteq \kappa\) is the \(\mathbb{N}\)-torsion subgroup. Hence \(g_N|_{U_P}\) is an étale Galois covering of \(U_P\), whose Galois group is naturally isomorphic to \(\text{Hom}_{\mathbb{Z}}(\mathbb{P}^{\text{gp}}, \mu_N(\kappa))\); therefore, \(g_N|_{U_P}\) is classified by a well defined continuous representation:

\[
\pi_1(U_P, \tau) \to \text{Hom}_{\mathbb{Z}}(\mathbb{P}^{\text{gp}}, \mu_N(\kappa))
\]

(lemma \[13.1.12\].) The corresponding action of \(\text{Hom}_{\mathbb{Z}}(\mathbb{P}^{\text{gp}}, \mu_N(\kappa))\) on \(U_P\) can be extracted from the construction: namely, let \(\chi : \mathbb{P}^{\text{gp}} \to \mu_N(\kappa)\) be a given character; by definition, the action of \(\chi\) sends the geometric point \(\tau\) to the geometric point \(\tau'\) whose character \(\chi_{\tau'} : \mathbb{P}^{\text{gp}} \to \kappa^\times\) is given by the rule \(x \mapsto \chi(x) \cdot \chi_x\) for every \(x \in \mathbb{P}^{\text{gp}}\). Consider the automorphism \(\rho_\chi\) of the \(\mathbb{Z}\)-algebra \(\mathbb{P}^{\text{gp}}\) given by the rule \(x \mapsto \chi(x) \cdot x\) for every \(x \in \mathbb{P}^{\text{gp}}\), and notice that \(\rho(\tau) = \tau'\); since the fibre functors are faithful on étale coverings, we conclude that \(\rho\) acts as \(\text{Spec} \rho_\chi\) on \(U_P\).

- Moreover, if \(\lambda : Q \to P\) is any morphism of fine and saturated monoids, clearly we have a commutative diagram

\[
\begin{array}{ccc}
U_P & \xrightarrow{\text{Spec} \mathbb{Z}[\lambda]|_{U_P}} & U_Q \\
g_N|_{U_P} \downarrow & & \downarrow g_N|_{U_Q} \\
U_P & \xrightarrow{\text{Spec} \mathbb{Z}[\lambda]|_{U_P}} & U_Q
\end{array}
\]

whence, by remark \[13.1.14\] iii.a), a well defined group homomorphism

\[
(13.3.32) \quad \text{Hom}_{\mathbb{Z}}(\mathbb{P}^{\text{gp}}, \mu_N) \to \text{Hom}_{\mathbb{Z}}(\mathbb{Q}^{\text{gp}}, \mu_N)
\]

that makes commute the induced diagram:

\[
\begin{array}{ccc}
\text{Hom}_{\mathbb{Z}}(\mathbb{P}^{\text{gp}}, \mu_N) & \to & \text{Hom}_{\mathbb{Z}}(\mathbb{Q}^{\text{gp}}, \mu_N) \\
\pi_1(U_P, \xi) \downarrow & & \downarrow \\
\pi_1(U_Q, \xi') & & \text{Hom}_{\mathbb{Z}}(\mathbb{P}^{\text{gp}}, \mu_N) \to \text{Hom}_{\mathbb{Z}}(\mathbb{Q}^{\text{gp}}, \mu_N)
\end{array}
\]

whose vertical arrows are the maps \((13.3.31)\). By inspecting the constructions, it is easily seen that \((13.3.32)\) is just the map \(\text{Hom}_{\mathbb{Z}}(\mathbb{Q}^{\text{gp}}, \mu_N)\).

- Next, by corollary \[12.1.36\] ii) the projection \(M_x \to P\) admits a splitting

\[
\alpha : P \to M_x
\]

(which defines a sharp chart for \(M\)); if \(N\) is invertible in \(\mathcal{O}_X\), this splitting induces a morphism of schemes \(X \to S_P\), which restricts to a morphism \(U \to U_P\). If we let \(\tau\) be the image of \(\xi\), we
deduce a continuous group homomorphism \( \pi_1(U_{\text{ét}}, \xi) \to \pi_1(U_{P, \text{ét}}, \tau) \) ([65 Exp.V, §7]), whose composition with \((13.3.31)\) yields a continuous map:
\[
\pi_1(U_{\text{ét}}, \xi) \to \text{Hom}_Z(P^{gp}, \mu_N(\kappa)).
\]

We claim that the pairing \( P^{gp} \times \pi_1(U_{\text{ét}}, \xi) \to \mu_N(\kappa) \) arising from \((13.3.33)\) agrees with \((13.3.27)\), under the natural identification \( \mu_N(\kappa) \to \mu_N \). Indeed, for given \( s \in P \), let \( j_s : Z \to P^{gp} \) be the map such that \( j_s(n) := s^n \) for every \( n \in \mathbb{Z} \); by composing \((13.3.33)\) with \( \text{Hom}_Z(j_s, \mu_N(\kappa)) \), we obtain a map \( \pi_1(U_{\text{ét}}, \xi) \to \text{Hom}_Z(\mathbb{Z}, \mu_N(\kappa)) \to \mu_N(\kappa) \); in view of the foregoing, it is easily seen that the corresponding \( \mu_N(\kappa) \)-torsor is precisely \( \varphi_{\alpha(s)} \), in the notation of \((13.3.25)\), whence the contention.

**Proposition 13.3.34.** In the situation of \((13.3.33)\), suppose that \((X, M)\) is a regular log scheme. Then \((13.3.28)\) is a surjection.

**Proof.** From the discussion of \((13.3.30)\), we are reduced to showing that the morphism \((13.3.33)\) is surjective, for every \( N > 0 \) such that \((N, p) = 1\). The latter comes down to showing that the corresponding torsor \( g_{N|U_{P, \text{ét}}} : U_{P, \text{ét}} \to U \) is connected (remark \(13.1.14(i)\)). However, the map \( \alpha : P \to M_\nu \) induces a morphism of log schemes \( \psi : (X, M) \to \text{Spec}(\mathbb{Z}, P) \) (see \((12.2.13)\)); we remark the following:

**Claim 13.3.35.** Slightly more generally, for any Kummer morphism \( \nu : P \to Q \) of monoids, with \( Q \) fine, sharp and saturated, define \((X_\nu, M_\nu)\) as the fibre product in the cartesian diagram:
\[
\begin{array}{ccc}
(X_\nu, M_\nu) & \longrightarrow & \text{Spec}(\mathbb{Z}, Q) \\
\downarrow f_\nu & & \downarrow \text{Spec}(\mathbb{Z}, \nu) \\
(X, M) & \psi \rightarrow & \text{Spec}(\mathbb{Z}, P)
\end{array}
\]

Then \((X_\nu, M_\nu)\) is regular, and \(X_\nu\) is strictly local.

**Proof of the claim.** By lemma \(12.5.24\), \((X_\nu, M_\nu)\) is regular at every point of the closed fibre \(X_\nu \times_X \text{Spec} \kappa(x)\), and since \( f_\nu\) is a finite morphism, every point of \(X_\nu\) specializes to a point of the closed fibre, therefore \((X_\nu, M_\nu)\) is regular (theorem \(12.5.31\)). Moreover, \(X_\nu\) is connected, provided the same holds for the closed fibre; in turn, this follows immediately from proposition \(13.3.7(ii)\). Then \(X_\nu\) is strictly local, by [51 Ch.IV, Prop.18.5.10].

From claim \(13.3.35\) we see that \(X_\nu\) is normal (corollary \(12.5.13\)) for every such \(\nu\), especially this holds for the \(N\)-Frobenius endomorphism of \(P\), in which case \(U'\) is an open subset of \(X_\nu\); since the latter is connected, the same then holds for \(U'\).

**Example 13.3.37.** (i) In the situation of example \(12.6.20\), let \(X \to S\) be any morphism of schemes, set \(X := X \times_S S_\kappa\); denote by \((X, M)\) the log scheme underlying \(X\); and define \((X_\nu, M_\nu)\) as the fibre product in the cartesian diagram of log schemes:
\[
\begin{array}{ccc}
(X_\nu, M_\nu) & \pi_\nu & \text{Spec}(R, P) \\
\downarrow X_\nu & & \downarrow \text{Spec}(R, k_\nu) \\
(X, M) & \pi & \text{Spec}(R, P)
\end{array}
\]

where \(\pi\) is the natural projection. Set as well
\[
X_\nu := ((X_\nu, M_\nu), T_P, \psi_P \circ \pi_\nu).
\]
which is an object of $\mathcal{K}_{\text{int}}$; by proposition 12.6.14(iii), diagram (6.5.28) (with $T := T_P$) underlies a commutative diagram in $\mathcal{K}_{\text{int}}$:

$$
\begin{array}{ccc}
\varphi^* X_{(k)} & \longrightarrow & X_{(k)} \\
\downarrow \quad g_X & & \downarrow (k_X, k_{TP}) \\
\varphi^* X & \longrightarrow & X
\end{array}
$$

whose horizontal arrows are cartesian. Clearly this diagram is isomorphic to $X \times_S (12.6.21)$; we deduce that the morphism $g_X$ of log schemes underlying $g_X$ is finite, and of Kummer type; by proposition 13.3.11, $g_X$ is even an étale covering, if $k$ is invertible in $O_X$.

(ii) Suppose furthermore, that $((X, M))$ is regular; by claim 13.3.35 it follows that $((X(k), M(k)))$ is regular as well, and then the same holds for the log schemes $((X \varphi^*, M))$ and $(Y, N)$ underlying respectively $\varphi^* X$ and $\varphi^* X_{(k)}$ (proposition 12.6.14(v) and theorem 12.5.28). Let now $y \in Y$ be a point of height one in $Y$, lying in the closed subset $Y \setminus (Y, N)_{\text{tr}}$, and set $x := g_X(y)$; arguing as in example 13.3.15 we see that $N^1_Y$ and $M^1_{\varphi, x}$ are both isomorphic to $\mathbb{N}$, and the induced map $\partial_{X, \varphi, x} \rightarrow \partial_{Y, y}$ is an extension of discrete valuation rings, whose corresponding extension of valued fields is finite. Denote by $\Gamma_x \rightarrow \Gamma_y$ the associated extension of value groups; in view of (12.6.22) we see that the ramification index $(\Gamma^e_y : \Gamma^e_x)$ equals $k$.

13.3.38. Resume the situation of (13.3.30). Every (finite) discrete quotient map

$$
\rho : M^{gp^V} \otimes \mathbb{Z} \prod_{\ell \neq p} \mathbb{Z}(1) \rightarrow G
$$

corresponds, via composition with (13.3.28), to a $G_U$-torsor, which can be explicitly constructed as follows. Set $P := M^1_U$, pick a splitting $\alpha$ as in (13.3.30), choose an integer $N > 0$ large enough, so that $(N, p) = 1$, and $\rho$ factors through a group homomorphism

$$
\overline{\rho} : \text{Hom}(P^{gp}, \mu_N(k)) \rightarrow G
$$

and set $H := \text{Ker} \overline{\rho}$. Now, via (13.3.28), the quotient $G' := \text{Hom}(P^{gp}, \mu_N(k))$ corresponds to the $G'_U$-torsor on $U$ obtained from $g_N : U_P \rightarrow U_P$ via pull-back along the morphism $U \rightarrow U_P$ given by the chart $\alpha$ (notation of (13.3.30)). According to remark 13.1.14(ii), the sought $G_U$ is therefore isomorphic to the one obtained from the quotient $g'_N : U_P/H \rightarrow U_P$, via pull-back along the same morphism. To exhibit such quotient, consider the exact sequence:

$$
0 \rightarrow \text{Hom}(G, \kappa^\times) \rightarrow P^{gp} \otimes \mathbb{Z}/N\mathbb{Z} \rightarrow \text{Hom}(H, \kappa^\times) \rightarrow 0.
$$

Define $Q^{gp} \subset P^{gp}$ as the kernel of the induced map $P^{gp} \rightarrow \text{Hom}(H, \kappa^\times)$, and set $Q := Q^{gp} \cap P$. By construction, the $N$-Frobenius endomorphism of $P$ factors through an injective map $\nu : P \rightarrow Q$ and the inclusion map $j : Q \rightarrow P$, so $g_N$ factors as a composition:

$$
U_P \rightarrow U_Q \overset{h}{\rightarrow} U_P.
$$
The maps on geometric points $U_P(\kappa) \to U_Q(\kappa) \to U_P(\kappa)$ induced by $g_N$ and $h$ correspond to $j^{\text{gp}*}$ and respectively $\nu^{\text{gp}*}$ in the resulting commutative diagram

$$
\begin{array}{c}
\begin{array}{ccc}
0 & \longrightarrow & H \\
& \text{Hom}_\mathbb{Z}(P^{\text{gp}}, \mu_N(\kappa)) & \longrightarrow \\
& G & \longrightarrow & 0 \\
& \downarrow & \downarrow & \downarrow \\
0 & \longrightarrow & \text{Hom}_\mathbb{Z}(P^{\text{gp}}, \kappa^\times) \\
& \longrightarrow & \text{Hom}_\mathbb{Z}(Q^{\text{gp}}, \kappa^\times) \\
& \downarrow & \downarrow & \downarrow \\
& 0 & \longrightarrow & \text{Hom}_\mathbb{Z}(P^{\text{gp}}, \kappa^\times) \\
& & & \downarrow \\
& & & 0
\end{array}
\end{array}
$$

whose rows and column are exact. Hence, let $\tau$ and $\chi_\tau : P^{\text{gp}} \to \kappa^\times$ be as in (13.3.30); the fibre $h^{-1}(\tau)$ corresponds to the set of all characters $\chi_\tau' : Q^{\text{gp}} \to \kappa^\times$ whose restriction $\chi_\tau' \circ \nu^{\text{gp}}$ to $P^{\text{gp}}$ agrees with $\chi_\tau$. Then, with the notation of (13.3.36), we conclude that the restriction $(f_\nu)_\text{tr} : (X_\nu, M_\nu)_\text{tr} \to U$ is the sought $G_U$-torsor. Notice as well that $f_\nu$ is an étale covering of $(X, M)$.

- Here is another handier description of the same submonoid $Q$ of $P$. Notice that $\rho$ is the same as a group homomorphism

$$
\rho^\dagger : P^{\text{gp}V} \to \text{Hom}_\mathbb{Z}(\prod_{t \not\equiv p} \mathbb{Z}_t(1), G)
$$

and let $L := \ker \rho^\dagger$. Fix a generator $\zeta_N$ of $\mu_N(\kappa)$; by definition

$$
Q^{\text{gp}} = \{ x \in P^{\text{gp}} \mid t(x) \otimes \xi = 0 \text{ for all } t \in P^{\text{gp}V} \text{ and } \xi \in \mu_N \text{ such that } \overline{p}(t \otimes \xi) = 0 \} = \{ x \in P^{\text{gp}} \mid t(x) \otimes \zeta_N = 0 \text{ for all } t \in P^{\text{gp}V} \text{ such that } \overline{p}(t \otimes \zeta_N) = 0 \} = \{ x \in P^{\text{gp}} \mid t(x) \in \mathbb{N}Z \text{ for all } t \in L \}.
$$

On the other hand, notice that the $N$-Frobenius of $P^{\text{gp}V}$ factors through a map $\beta : P^{\text{gp}V} \to L$ and the inclusion map $i : L \to P^{\text{gp}V}$, and $\beta \circ i$ is the $N$-Frobenius map of $L$. Let $\omega : P^{\text{gp}} \to (P^{\text{gp}V})^\vee$ be the natural isomorphism. We may then write

$$
Q^{\text{gp}} = \{ x \in P^{\text{gp}} \mid \omega(x)(t) \in \mathbb{N}Z \text{ for all } t \in L \} = \{ x \in P^{\text{gp}} \mid \omega(x) \circ i \in N \cdot L^\vee = \iota^\vee \circ \beta^\vee(L^\vee) \} = \omega^{-1}(\text{Im } \beta^\vee).
$$

In other words, $\omega$ induces a natural isomorphism $Q^{\text{gp}} \iso L^\vee$, that identifies $\beta^\vee$ with the map $j^{\text{gp}} : Q^{\text{gp}} \to P^{\text{gp}}$, and then necessarily also the map $\iota^\vee$ with $\nu$. Now, the image of $Q$ inside $L^\vee$ can be recovered just as $L^\vee \cap P^{\text{gp}V}_Q$ (the intersection here takes place in $L^\vee_Q$, which contains $(P^{\text{gp}V})^\vee$, via the injective map $\iota^\vee$; details left to the reader).

13.3.39. Our chief supply of tamely ramified coverings comes from the following source. Let $f : (Y, N) \to (X, M)$ be an étale morphism of log schemes, whose underlying morphism of schemes is finite, and suppose that $(X, M)$ is regular. Then $(Y, N)$ is regular, and both $X$ and $Y$ are normal schemes (theorem 12.5.28 and corollary 12.5.13). Moreover, lemma 6.4.57 ii) and proposition 13.3.11 imply that $(Y, N)_\text{tr} = f^{-1}(X, M)_\text{tr}$, hence the restriction of $f$

$$
f_{\text{tr}} : (Y, N)_\text{tr} \to (X, M)_\text{tr}
$$
is a finite étale morphism of schemes (corollary 12.3.27(i)). Furthermore, it follows easily from corollary 12.5.20(i) that the closed subset $X \setminus (X, \mathcal{M})_{tr}$ is a union of irreducible closed subsets of codimension 1 in $X$ (and the union is locally finite on the Zariski topology of $X$); the same holds also for $Y \setminus (Y, \mathcal{N})_{tr}$, especially $Y$ is the normalization of $(Y, \mathcal{N})_{tr}$ over $X$. Finally, example 13.3.15 implies that $f_{tr}$ is tamely ramified along $X \setminus (X, \mathcal{M})_{tr}$. It is then clear that the rule $f \mapsto f_{tr}$ defines a functor:

$$F_{(X, \mathcal{M})} : \text{Cov}(X, \mathcal{M}) \to \text{Tame}(X, (X, \mathcal{M})_{tr}).$$

It follows easily from remark 12.5.40 that $F_{(X, \mathcal{M})}$ is fully faithful; therefore, any choice of a geometric point $\xi$ of $(X, \mathcal{M})_{tr}$ determines a surjective group homomorphism:

$$\pi_1((X, \mathcal{M})_{tr, \text{ét}}, \xi) \to \pi_1((X, \mathcal{M})_{\text{ét}}, \xi)$$

(65, Exp.V, Prop.6.9)).

**Proposition 13.3.41.** In the situation of (13.3.25), suppose that $(X, \mathcal{M})$ is a regular log scheme. Then the map (13.3.28) factors through (13.3.40), and induces an isomorphism:

$$(13.3.42) \pi_1((X, \mathcal{M})_{\text{ét}}, \xi) \xrightarrow{\sim} M_{\text{gp}}^{\text{FV}} \otimes_{\mathbb{Q}} \prod_{\ell \neq p} \mathbb{Z}_{\ell}(1).$$

**Proof.** The discussion of (13.3.28) shows that (13.3.28) factors through (13.3.40), and proposition 13.3.34 implies that (13.3.42) is surjective. Next, let $f : (Y, \mathcal{N}) \to (X, \mathcal{M})$ be an étale covering; according to proposition 13.3.11, $f$ admits a Kummer chart $(\omega_\tau, \omega_\sigma, \psi)$ with $Q$ finite, sharp and saturated, such that the order $k$ of $\text{Coker} \, \psi^{\text{gp}}$ is invertible in $O_Y$. Moreover, the induced morphism of $X$-schemes $Y \to X \times_{\text{Spec} \, \mathbb{Z}[P]} \text{Spec} \, \mathbb{Z}[Q]$ is an isomorphism. With this notation, denote by $G$ the cokernel of the induced group homomorphism $\text{Hom}_{\text{Z}}(\psi^{\text{gp}}, k_{P_{\text{tr}}})$; there follows a map $\rho : P_{\text{gp}} \otimes_{\mathbb{Z}} \prod_{\ell \neq p} \mathbb{Z}_{\ell}(1) \to G$, and by inspecting the construction, one may check that the corresponding $G_U$-torsor, constructed as in (13.3.38), is isomorphic to $f \times_X \mathbb{1}_U$ (details left to the reader). This shows the injectivity of (13.3.42), and completes the proof of the proposition.

The following result is the logarithmic version of the classical Abhyankar’s lemma.

**Theorem 13.3.43.** The functor $F_{(X, \mathcal{M})}$ is an equivalence.

**Proof.** First we show how to reduce to the case where $\tau = \text{ét}$.

**Claim 13.3.44.** Let $(X_{\text{Zar}}, \mathcal{M})$ be a regular log structure on the Zariski site of $X$, and suppose that the theorem holds for $u^*(X_{\text{Zar}}, \mathcal{M})$. Then the theorem holds for $(X_{\text{Zar}}, \mathcal{M})$ as well.

**Proof of the claim.** Let $g : V \to (X_{\text{Zar}}, \mathcal{M})_{tr}$ be an étale covering whose normalization over $X$ is tamely ramified along $X \setminus (X_{\text{Zar}}, \mathcal{M})_{tr}$. By assumption, there exists an étale covering $f : (Y_{\text{ét}}, \mathcal{N}) \to \tilde{u}^*(X_{\text{Zar}}, \mathcal{M})$ such that $f_{tr} = g$; by lemma 13.3.10, we may then find a morphism of log schemes of Kummer type $f_{\text{Zar}} : \tilde{u}_{\text{Zar}}^*(Y_{\text{ét}}, \mathcal{N}) \to (X_{\text{Zar}}, \mathcal{M})$ such that $\tilde{u}^* f_{\text{Zar}} = f$, therefore $f_{\text{Zar}}$ is an étale covering of $(X_{\text{Zar}}, \mathcal{M})$ (corollary 12.3.27(iii)), and clearly $(f_{\text{Zar}})_{tr} = g$, so the functor $F_{(X_{\text{Zar}}, \mathcal{M})}$ is essentially surjective. Full faithfulness for the same functor is derived formally from the full faithfulness of the functor $F_{u^*}(X_{\text{Zar}}, \mathcal{M})$, and of the functor (13.3.9): details left to the reader.

Henceforth we assume that $\tau = \text{ét}$.

**Claim 13.3.45.** Let $g : V \to (X, \mathcal{M})_{tr}$ be an object of $\text{Tame}(X, (X, \mathcal{M})_{tr})$. Then $g$ lies in the essential image of $F_{(X, \mathcal{M})}$ if (and only if) there exists an étale covering $(U_\lambda \to X \mid \lambda \in \Lambda)$ of $X$, such that, for every $\lambda \in \Lambda$, the étale covering $g \times_X U_\lambda$ lies in the essential image of $F_{(U_\lambda, \mathcal{M})_{tr}}$.
Proof of the claim. We have to exhibit a finite étale covering \( f : (Y, N) \to (X, M) \) such that \( f\tau = g \). However, given such \( f \), theorem 12.5.28 and corollary 12.5.13 imply that \( Y \) is the normalization of \( V \) over \( X \), and proposition 12.5.38 says that \( N = j_*\mathcal{O}_Y^\times \cap \mathcal{O}_Y \), where \( j : V \to Y \) is the open immersion; then \( \log f : f^\ast M \to N \) is completely determined by \( f \), hence by \( g \). Thus, we come down to showing that :

(i) \( N := j_*\mathcal{O}_Y^\times \cap \mathcal{O}_Y \) is a regular log structure on the normalization \( Y \) of \( V \) over \( X \).

(ii) The unique morphism \( f : (Y, N) \to (X, M) \) is an étale covering.

However, [100, §33, Lemma 1] implies that \( Y \) is finite over \( X \). To show (ii), it then suffices to prove that each restriction \( f_\lambda : f \times_X 1_U \) is étale (proposition 12.3.24(iii)). Likewise, (i) holds, provided the restriction \( N|_{\lambda Y} \) is a regular log structure on \( Y_\lambda := Y \times_X U_\lambda \), for every \( \lambda \in \Lambda \). Let \( j_\lambda : V_\lambda := V \times_X U_\lambda \to Y_\lambda \) be the induced open immersion. It is clear that \( N|_{\lambda Y} = j_\lambda^*\mathcal{O}_Y^\times \cap \mathcal{O}_{Y_\lambda} \), and \( Y_\lambda \) is the normalization of \( V_\lambda \) over \( U_\lambda \) ([51, Ch.IV, Prop.17.5.7]); moreover, \((U_\lambda, M|_{U_\lambda})\) is again regular, so our assumption implies that \((Y_\lambda, N|_{\lambda Y})\) is the unique regular log structure on \( Y_\lambda \) whose trivial locus is \( V_\lambda \), and that \( f_\lambda \) is indeed étale.

Claim 13.3.46. If \( F_{(X, M)(\xi)} \) is essentially surjective for every geometric point \( \xi \) of \( X \), the same holds for \( F_{(X, M)} \).

Proof of the claim. Indeed, let \( g : V \to (X, M)_{\text{tr}} \) be an object of \( \text{Tame}(X, (X, M)_{\text{tr}}) \), and \( \xi \) any geometric point of \( X \). By claim 13.3.45 it suffices to find an étale neighborhood \( U \to X \) of \( \xi \) such that \( g \times_X 1_U \) lies in the essential image of \( F_{(U, M|_U)} \). Denote by \( Y \) the normalization of \( X \) in \( V \), which is a finite \( \text{X}-\text{scheme} \) ([100, §33, Lemma 1]). The scheme \( Y(\xi) := Y \times_X X(\xi) \) decomposes as a finite disjoint union of strictly local open and closed subspaces \( Y_1(\xi), \ldots, Y_n(\xi) \), and we may find an étale neighborhood \( U \to X \) of \( \xi \), and a decomposition of \( Y \times_X U \) by open and closed subspaces \( Y_1, \ldots, Y_n \), with isomorphisms of \( X(\xi)-\text{schemes} \) \( Y_i(\xi) \simeq Y_i \times_X X(\xi) \) for every \( i = 1, \ldots, n \) ([50, Ch.IV, Cor.8.3.12]). We are then reduced to showing that all the restrictions \( Y_i \to U \) lie in the essential image of \( F_{(U, M|_U)} \).

Thus, we may replace \( X \) by \( U \), and \( Y \) by any \( Y_i \), after which we may assume that \( Y(\xi) \) is strictly local. Proposition 12.5.16 and theorem 12.5.31 imply that \((X(\xi), M(\xi))\) is a regular log scheme. Clearly \( g_\xi := g \times_X 1_{X(\xi)} \) is an object of \( \text{Tame}(X(\xi), (X(\xi), M(\xi))_{\text{tr}}) \), so by assumption there exists a finite étale covering \( h : (Z, N) \to (X(\xi), M(\xi)) \) such that \( h_{\text{tr}} = g_\xi \).

By theorem 12.5.28 and corollary 12.5.13 we know that \( Z \) is a normal scheme, and we deduce that \( Z = Y(\xi) \) ([51, Ch.IV, Prop.17.5.7]).

According to proposition 13.3.11 the morphism \( h \) admits a fine and saturated Kummer chart \((\omega_p, \omega_Q, \vartheta : P \to Q)\), such that the order \( d \) of \( \text{Coker} \vartheta^{\text{sp}} \) is invertible in \( \mathcal{O}_{X(\xi)} \), and such that the induced map \( Y(\xi) \to X(\xi) \times_{\text{Spec } P} \text{Spec } Q \) is an isomorphism. By proposition 12.2.28 there exist an étale neighborhood \( U \to X \) of \( \xi \) and a coherent log structure \( N' \) on \( Y' := Y \times_X U \) with an isomorphism \( Y(\xi) \times_{Y'} (Y', N') \simeq (Y(\xi), N) \). Moreover, let \( h' : Y' \to U \) be the projection; after shrinking \( U \), the map \( \log h \) descends to a morphism of log structures \( h'^* \mathcal{M}|_U \to N' \), whence a morphism \((h', \log h') : (Y', N') \to (U, M|_U)\) of log schemes, such that \( h' \times_U 1_{X(\xi)} = h \). After further shrinking \( U \), we may also assume that \( h' \) admits a Kummer chart \((\omega'_p, \omega'_Q, \vartheta')\) (corollary 12.2.34), that \( d \) is invertible in \( \mathcal{O}_U \), and that the induced morphism \( Y' \to U \times_{\text{Spec } P} \text{Spec } Q \) is an isomorphism ([50, Ch.IV, Cor.8.8.24]). Then \( h' \) is an étale covering, by proposition 13.3.11 and by construction, \( F_{(U, M|_U)}(h') = g \times_X 1_U \), as desired.

Claim 13.3.47. Assume that \( X \) is strictly local, denote by \( x \) the closed point of \( X \), set \( U := (X, M)_{\text{tr}} \), and \( P := M|_U \). Let \( h : V \to U \) be any connected non-empty étale covering, tamely ramified along \( X \setminus U \); then \( h \) lies in the essential image of \( F_{(X, M)} \), provided there exist a fine, sharp and saturated monoid \( Q \), and a morphism \( \nu : P \to Q \) of Kummer type, such that

\[
h_\nu := h \times_X X_\nu : V \times_X X_\nu \to U \times_X X_\nu
\]
admits a section (notation of [13.3.36]).

Proof of the claim. Suppose first that the order of \( \text{Coker } \nu^\text{gp} \) is invertible in \( \mathcal{O}_X \); in this case, \( f_\nu \) is an étale covering of log schemes (proposition [13.3.11]), hence \( (f_\nu)_M \) is an étale covering of the scheme \( U \). Then, by composing a section of \( h_{\nu^*} \) with the projection \( V \times_X \chi_{\nu^*} \to V \) we deduce a morphism \( U \times_X \chi_{\nu^*} \to V \) of étale coverings of \( U \). Such morphism shall be open and closed, hence surjective, since \( V \) is connected; hence the \( \pi_1(U, \xi) \)-set \( h^{-1}(\xi) \) will be a quotient of \( f_\nu^{-1}(\xi) \), on which \( \pi_1(U, \xi) \) acts through [13.3.28], as required. Next, for a general morphism \( \nu \) of Kummer type, let \( L \subset Q^{\nu^\text{gp}} \) be the largest subgroup such that \( \nu^\text{gp}(\mathcal{O}_X^\nu) \subset L \), and \( (L : P^\nu) \) is invertible in \( \mathcal{O}_X \). Set \( Q' := L \cap Q \), and notice that \( Q' \cap L = L \). Indeed, every element of \( L \) can be written in the form \( x = b^{-1}a \), for some \( a, b \in Q \); then choose \( n > 0 \) such that \( b^n \in \nu P \), write \( x = b^{-n} \cdot (b^{n-1}a) \) and remark that \( b^{-n}, b^{n-1}a \in Q' \). The morphism \( \nu \) factors as the composition of \( \nu' : P \to Q' \) and \( \psi : Q' \to Q \), and therefore \( f_\nu \) factors through a morphism \( f_\psi : \chi_{\nu^*} \to \chi_{\nu'}. \)

In view of the previous case, we are reduced to showing that the morphism \( h_{\nu^*} \) already admits a section, hence we may replace \( (X, M) \) by \( (X, M', M') \) (which is still regular and strictly local, by claim [13.3.35], \( h \) by \( h_{\nu^*} \), and \( \nu \) by \( \psi \), after which we may assume that the order of \( \text{Coker } \nu^\text{gp} \) is \( p^m \) for some integer \( m > 0 \), where \( p \) is the characteristic of the residue field \( \kappa(x) \), and then we need to show that \( h \) already admits a section.

Next, say again claim [13.3.35] and an easy induction, we may likewise reduce to the case where \( m = 1 \). Say that \( X = \text{Spec } A \), and suppose first that \( A \) is a \( \mathbb{F}_p \)-algebra (where \( \mathbb{F}_p \) is the finite field with \( p \) elements), so that \( X_{\nu^*} = \text{Spec } A \otimes_{\mathbb{F}_p} \mathbb{F}_p[Q] \); it is easily seen that the ring homomorphism \( \mathbb{F}_p[\nu] : \mathbb{F}_p[P] \to \mathbb{F}_p[Q] \) is invertible up to \( \Phi \), in the sense of [59, Def.3.5.8(i)]. Especially, \( \text{Spec } \mathbb{F}_p[\nu] \) is integral, surjective and radicial, hence the same holds for \( f_\nu \), and therefore the morphism of sites:

\[
f_{\nu^*} : X_{\text{ét}} \to X_{\nu^*, \text{ét}}
\]

is an equivalence of categories (lemma [13.1.7(i)]). It follows that in this case, \( h \) admits a section if and only if the same holds for \( h_{\nu^*} \).

Next, suppose that the field of fractions \( K \) of \( A \) has characteristic zero; we may write \( X_{\nu^*} \times_X \text{Spec } K = \text{Spec } K_{\nu^*} \) and \( V \times_X \text{Spec } K = \text{Spec } E \) for two field extensions \( K_{\nu^*} \) and \( E \) of \( K \), such that \( [K_{\nu^*} : K] = p \), and the section of \( h_{\nu^*} \) yields a map \( E \to K_{\nu^*} \) of \( K \)-algebras. Therefore we have either \( E = K \) (in which case \( V = U \), and then we are done), or else \( E = K_{\nu^*} \), in which case \( V = (X_{\nu^*}, M_{\nu^*})_U \), since both these schemes are normal and finite over \( U \).

Hence, let us assume that \( V = (X_{\nu^*}, M_{\nu^*}) \), and pick any point \( \eta \in X \) of codimension one, whose residue field \( \kappa(\eta) \) has characteristic \( p \). Then \( X_{\nu^*} \times_X X(\eta) = \text{Spec } B \), where \( B := \mathcal{O}_{X, \eta} \otimes_{\mathbb{Z}[P]} \mathbb{Z}[Q] \), and \( \overline{B} := B \otimes_{\mathbb{Z}[K]} \mathbb{Z}[Q] \). Since the map \( \mathbb{F}_p[P] \to \mathbb{F}_p[Q] \) is invertible up to \( \Phi \), we easily deduce that \( \overline{B} \) is local, and its residue field is a purely inseparable extension of \( \kappa(\eta) \), say of degree \( d \). Therefore \( f_{\nu^{-1}} \eta \) consists of a single point \( \eta' \), and \( \mathcal{O}_{X, \nu^*} \simeq B \) is a normal and finite \( \mathcal{O}_{X, \nu} \)-algebra, hence it is a discrete valuation ring. Let \( e \) denote the ramification index of the extension \( \mathcal{O}_{X, \eta} \to \mathcal{O}_{X, \eta'} \); then \( ed = p \) ([28, Ch.VI, §8, n.5, Cor.1]). Suppose that \( e = p \); in view of [59, Lemma 6.2.5], the ramification index of the induced extension of strict henselizations \( \mathcal{O}_{X, \eta}^{\text{sh}} \to \mathcal{O}_{X, \eta'}^{\text{sh}} \) is still equal to \( p \), which is impossible, since \( h \) is tamely ramified along \( X \setminus U \). In case \( e = 1 \), we must have \( d = p \), and since the residue field \( \kappa(\eta)^{\flat} \) of \( \mathcal{O}_{X, \eta}^{\text{sh}} \) is a separable closure of \( \kappa(\eta) \), it follows easily that the residue field of \( \mathcal{O}_{X, \eta'}^{\text{sh}} \) must be a purely inseparable extension of \( \kappa(\eta)^{\flat} \) of degree \( p \), which again contradicts the tameness of \( h \).

Claim 13.3.48. If \( (X, M) = (X', M')_2 \), then \( F_{(X, M)} \) is essentially surjective (notation of definition [12.2.7(i)]).

Proof of the claim. By claim [13.3.46] we may assume that \( X \) is strictly henselian. In this case, let \( U, P \) and \( h : V \to U \) be as in claim [13.3.47]. By assumption \( d := \dim P \leq 2 \), and we have
to show that $h \times_X X_\nu$ admits a section, for a suitable Kummer morphism $\nu : P \to Q$ (notation of (13.3.36)). If $d = 0$, then $P = \{1\}$, in which case $U = X$ is strictly local, so its fundamental group is trivial, and there is nothing to prove. In case $d = 1$, then $P \simeq \mathbb{N}$ (theorem 6.4.16(ii)), in which case $X$ is a regular scheme (corollary 12.5.19), and $X \setminus U$ is a regular divisor (remark 12.5.15) and then the assertion follows from the classical Abhyankar’s lemma (65 Exp.XIII, Prop.5.2]). For $d = 2$, we may find $e_1, e_2 \in P$, and an integer $N > 0$ such that

$$Ne_1 + Ne_2 \subset P \subset P' := N\frac{e_1}{N} \oplus N\frac{e_2}{N}$$

(see example 6.4.17(i)). Especially, the inclusion $\nu : P \to P'$ is a morphism of Kummer type. Since a composition of morphisms of Kummer type is obviously of Kummer type, claims 13.3.47 and 13.3.35 imply that we may replace $(X, M)$ by $(X_\nu, M_\nu)$ and $h$ by $h_\nu$ (notation of (13.3.36)), after which we may assume that $P$ is isomorphic to $\mathbb{N}^{\oplus 2}$. In this case, $X$ is again regular and $X \setminus U$ is a strict normal crossings divisor, so the assertion follows again from [65 Exp.XIII, Prop.5.2].

Claim 13.3.49. In the situation of (13.3.1), suppose that $(Y, N)$ is regular. Then the functor $f^*_\text{tr} : \text{Cov}(Y, N)_\text{tr} \to \text{Cov}(Y', N')_\text{tr}$ restricts to an equivalence:

(13.3.50)

Proof of the claim. Arguing as in the proof of proposition 13.3.2, we may reduce to the case where $\varphi : T' \to T$ is the saturated blow up of an ideal generated by two elements of $\Gamma(T, \mathcal{O}_T)$.

Notice that $(f, \log f)$ is an étale morphism (proposition 12.6.14(iii)), and it restricts to an isomorphism $f^*_\text{tr} : (Y', N')_\text{tr} \to (Y, N)_\text{tr}$ (remark 12.6.17). Especially, $(Y', N')$ is regular, and $f^*_\text{tr}$ is trivially an equivalence from the étale coverings of $(Y, N)_\text{tr}$ to those of $(Y', N')_\text{tr}$.

Let $g : V \to (Y, N)_\text{tr}$ be an object of $\text{Tame}(Y, (Y, N)_\text{tr})$. By claim 13.3.48 and lemma 12.5.21, the functor $F_{(Y, N)}$ is essentially surjective, and then the same holds for $F_{(Y', N')}$, in view of claim 13.3.44; hence we may find an étale covering $(W, Q) \to (Y, N)_\text{tr}$, and an isomorphism $V \to (Y, N)_\text{tr} \times_Y W$ of $(Y, N)_\text{tr}$-schemes. On the other hand, example 6.5.56(ii) shows that $\varphi$ restricts to a morphism $T_1 \to T_2$ (notation of 6.5.16), consequently $f$ restricts to a morphism $(Y', N')_1 \to (Y, N)_2$. There follows a well defined étale covering:

$$((Y', N')_1 \times (Y, N)_2)(W, Q) \to (Y', N')_1 \times_{Y'} (Y', N').$$

whose image under $F_{(Y', N')}$ is $f^*_\text{tr}(g)$. However, $(Y', N')_1$ contains all the points of height one of $Y' \setminus (Y', N')_\text{tr}$ (corollary 12.5.20(i)), hence $f^*_\text{tr}(g)$ is tamely ramified along $Y' \setminus (Y', N')_\text{tr}$ (see (13.3.39)). This shows that (13.3.50) is well defined, and clearly this functor is fully faithful, since the same holds for $f^*_\text{tr}$. 

Suppose again that $(X, M)$ is strictly henselian, define $P$, $U$ and $h : V \to U$ as in claim 13.3.47 and set $T_P := (\text{Spec } P)^\sharp$; it is easily seen that the counit of adjunction

$$\tilde{u}^* \tilde{u}_*(X, M) \to (X, M)$$

is an isomorphism (cp. (12.6.48)), hence $\tilde{u}_*(X, M)$ is regular (lemma 12.5.21). Let

$$X := (\tilde{u}_*(X, M), T_P, \pi_X)$$

be the object of $\mathcal{X}$ arising from $\tilde{u}_*(X, M)$, as in (12.6.7); by theorem 12.6.32 (and its proof), we may find an integral proper simplicial subdivision $\varphi : F \to T_P$, such that the morphism of schemes underlying $(f, \varphi) : \varphi^* X \to X$ is a resolution of singularities for $X$. Let $k$ be the ramification index of the covering $h$; we define $(X(k), M(k)), (X(\varphi), M(\varphi)), (Y, N), g_X$ and $k_X$ as in example 13.3.37: this makes sense, since, in the current situation, $X$ is isomorphic to $X \times S \tilde{S}$ (where $\tilde{S}$ is defined as in example 12.6.5(i)). Moreover, by the same token, the morphism of schemes $Y \to X(k)$ is a resolution of singularities.
Set as well $U_\varphi := (X_\varphi, M_\varphi)_{tr}$ and $U(k) := (X(k), M(k))_{tr}$; by claim \[13.3.49\] and lemma \[13.3.17(i)\], we have an essentially commutative diagram of functors:

$$
\begin{array}{ccc}
\text{Tame}(X, U) & \xrightarrow{f_{tr}^*} & \text{Tame}(X_\varphi, U_\varphi) \\
\downarrow^{k_X^*} & & \downarrow^{g_X^*} \\
\text{Tame}(X(k), U(k)) & \longrightarrow & \text{Tame}(Y, (Y, N)_{tr})
\end{array}
$$

whose horizontal arrows are equivalences. In light of claim \[13.3.47\], we are reduced to showing that $k_X^*(h)$ admits a section. Set $h_\varphi := f_{tr}^*(h)$; then it suffices to show that $g_X^*(h_\varphi)$ admits a section, and notice that the ramification index of $h_\varphi$ along $X_\varphi \setminus U_\varphi$ divides $k$ (lemma \[13.3.17(ii)\]).

Let $\overline{Y} \to X_\varphi$ be the normalization of $h_\varphi$ over $X_\varphi$, and $w$ a geometric point of $\overline{V} \times X_\varphi Y$ whose support has height one; denote by $y$ (resp. $v$, resp. $x$) the image of $w$ in $Y$ (resp. in $\overline{V}$, resp. in $X_\varphi$), and suppose that the support of $x$ lies in $U_\varphi$. Denote by $K_{sh}(x)$ the field of fractions of the strict henselization $O_{X,x}^{sh}$ of $O_{X,x}$, and define likewise $K_{sh}(w)$, $K_{sh}(y)$ and $K_{sh}(v)$. There follows a commutative diagram of inclusions of valued fields:

$$
\begin{array}{ccc}
K_{sh}(x) & \longrightarrow & K_{sh}(y) \\
\downarrow & & \downarrow \\
K_{sh}(v) & \longrightarrow & K_{sh}(w)
\end{array}
$$

which is cocartesian in the category of fields \(i.e.\) $K_{sh}(w)$ is the compositum of $K_{sh}(y)$ and $K_{sh}(v)$; cp. the proof of lemma \[13.3.17(ii)\]). By the foregoing, the ramification index of $O_{\overline{V},v}^{sh}$ over $O_{X_\varphi,x}^{sh}$ divides $k$; on the other hand, example \[13.3.37(ii)\] shows that the ramification index of $O_{\overline{Y},y}^{sh}$ over $O_{X_\varphi,x}^{sh}$ equals $k$. It then follows \(e.g.\) from \[59, Claim 6.2.15\]) that $K_{sh}(v) \subset K_{sh}(y)$, and therefore $K_{sh}(w) = K_{sh}(y)$; this shows that the ramification index of $g_X^*(h_\varphi)$ along $Y \setminus (Y, N)_{tr}$ equals 1, therefore $g_X^*(h_\varphi)$ is the restriction of an étale covering $\overline{h}$ of $Y$ (lemma \[13.3.17(iii)\]). By proposition \[13.3.2(ii)\], $\overline{h}$ is the pull-back of an étale covering of $X(k)$. Since $X(k)$ is strictly local (claim \[13.3.35\]), it follows that $\overline{h}$ admits a section, hence the same holds for $g_X^*(h_\varphi)$, as required.

**Remark 13.3.51.** A proof of theorem \[13.3.43\] similar to the one given here can be found in \[101, §2.3\].

13.3.52. As an application of theorem \[13.3.43\], we shall determine the fundamental group of the “punctured” scheme obtained by removing the closed point from a strictly local regular log scheme $(X, M)$ (with non-trivial log structure) of dimension $\geq 2$. Indeed, let $x \in X$ be the closed point, and set $r := \dim M_x$. Also, let $\overline{y}$ be any geometric point of $X$, localized at a point $y \in U := X \setminus \{x\}$, and $\xi$ a geometric point of $X$ localized at the maximal point. Let $p$ (resp. $p'$) denote the characteristic exponent of $\kappa(x)$ (resp. of $\kappa(y)$). Pick any lifting of $\xi$ to a geometric point $\xi_y$ of $X(\overline{y})$; since $(X(\overline{y}), M(\overline{y}))$ is regular (theorem \[12.5.31\]), according to proposition \[13.3.41\] the vertical arrows of the commutative diagram in \[13.3.29\] factor through the surjections \[13.3.40\], and we get a commutative diagram of group homomorphisms:

$$
\begin{array}{ccc}
\pi_1((X(\overline{y}), M(\overline{y}))_{et}, \xi_y) & \xrightarrow{\varphi_y} & \pi_1((X, M)_{et}, \xi) \\
\downarrow & & \downarrow \\
M_y^{gp'} \otimes_{\mathbb{Z}} \prod_{\ell \neq p'} \mathbb{Z}_\ell(1) & \longrightarrow & M_x^{gp'} \otimes_{\mathbb{Z}} \prod_{\ell \neq p} \mathbb{Z}_\ell(1)
\end{array}
$$

whose vertical arrows are the isomorphisms \[13.3.42\], and whose top (resp. bottom) horizontal arrow is induced by the natural morphism $X(\overline{y}) \to X$ (resp. by the specialization map $M_x \to$...
\[ M_\eta \]. Now, by corollary \[ \text{[12.5.13]} \], \text{the scheme } U \text{ is connected and normal, hence the restriction functor } \text{Cov}(U) \to \text{Tame}(X,(X,M)_r) \text{ is fully faithful (lemma [13.1.7(iii)]); by [65 Exp.V, Prop.6.9] and theorem \[ 13.3.43 \], it follows that the induced group homomorphism}

\[ \pi_1((X,M)_{\text{et}},\xi) \to \pi_1(U_{\text{et}},\xi) \]

is surjective (see \[ 13.3.39 \]). Clearly, the image of \( \varphi_y \) lies in the kernel of \( 13.3.53 \). Especially:

\[ (U,M)(U),r \neq \emptyset \Rightarrow \pi_1(U_{\text{et}},\xi) = \{1\} \]

since, for any geometric point \( \overline{y} \) of \((X,M)_r\), the specialization map \( M_x \to M_\overline{y} \) is an isomorphism (notation of definition \[ 12.2.7(i) \]). Thus, suppose that \((X,M)_r = \{x\}\), set \( P := M_\overline{y} \), and denote by \( \psi : X \to \text{Spec} P \) the natural continuous map; we have \( M_\overline{y} = P_\psi(y) \), and if we let \( F_y := P \setminus \psi(y) \), we get a short exact sequence of free abelian groups of finite rank:

\[ 0 \to F_y^{\text{gp}} \to M_x^{\text{gp}} \to M_\overline{y}^{\text{gp}} \to 0. \]

It is easily seen that \( \psi \) is surjective; hence, for any \( p \in \text{Spec} P \) of height \( r - 1 \), pick \( y \in \psi^{-1}(p) \). With this choice, we have \( F_y^{\text{gp}} = \mathbb{Z} \); considering \( 13.3.54 \), we deduce that \( \pi_1(U_{\text{et}},\xi) \) is a quotient of \( \widehat{\mathbb{Z}}(1) := \prod_{\ell \neq \mathfrak{p}} \mathbb{Z}_\ell(1) \). More precisely, let \((\text{Spec} P)_{r - 1}\) be the set of prime ideals of \( P \) of height \( r - 1 \); then we have:

\[ \text{Theorem 13.3.55. If } (X,M)_r = \{x\}, \text{ we have a natural identification:} \]

\[ \sum_{p \in (\text{Spec} P)_{r-1}} P_p^{\text{gp}} \otimes_\mathbb{Z} \widehat{\mathbb{Z}}(1) \cong \pi_1(U_{\text{et}},\xi) \]

and these two abelian groups are cyclic of finite order prime to \( p \).

\[ \text{Proof.} \] The foregoing discussion already yields a natural surjective map as stated; it remains only to check the injectivity, and to verify that the source is a cyclic finite group.

However, since \( d \geq 2 \), and \( (X,M)_r = \{x\} \), corollary \[ 12.5.20(i) \] implies that \( r \geq 2 \), in which case \((\text{Spec} P)_{r-1}\) must contain at least two distinct elements, say \( p \) and \( q \). Let \( F := P \setminus p \); the image \( H \) of \( (P_q)^{\text{gp}} \) in \( F_{\text{gp}} \) is clearly a non-trivial subgroup, hence \( F_{\text{gp}}/H \) is a cyclic finite group, and then the same holds for the source of \[ 13.3.56 \].

Next, it follows easily from lemma \[ 13.1.7(iii) \] that \[ 13.3.53 \] identifies \( \pi_1(U_{\text{et}},\xi) \) with the quotient of \( \pi_1((X,M)_{\text{et}},\xi) \) by the sum of the images of the maps \( \varphi_y \), for \( y \) ranging over all the points of \( U \). However, it is clear that the same sum is already spanned by the sum of the images of the \( \varphi_y \) such that \( y \in (X,M)_{r-1} \); whence the theorem.

\[ \square \]

\[ \text{Example 13.3.57.} \] Let \( P \subset \mathbb{N}^{\theta^2} \) be the submonoid of all pairs \((a,b)\) such that \( a + b \in 2\mathbb{N} \). Clearly \( P \) is fine and saturated of dimension \( 2 \). Let \( K \) be any field; the \( K \)-scheme \( X := \text{Spec} K[P] \) is the singular quadric in \( \mathbb{A}_K^2 \) cut by the equation \( XY - Z^2 = 0 \). It is easily seen that \( \text{Spec}(K,P)_{\theta^2} \) consists of a single point \( x \) (the vertex of the cone); let \( \overline{x} \) be a geometric point of \( X \) localized at \( x \), and \( U \subset X(\overline{x}) \) the complement of the closed point. Then \( U \) is a normal \( K \)-scheme of dimension \( 1 \), and we have a natural isomorphism

\[ \pi_1(U,\xi) \cong \mathbb{Z}/2\mathbb{Z}. \]

Indeed, a simple inspection shows that \( P \) admits exactly two prime ideals of height one, namely \( p := P \setminus (2\mathbb{N} \cup \{0\}) \) and \( q := P \setminus (\{0\} \cup 2\mathbb{N}) \). Then, \( P_p = \{(a,b) \in \mathbb{Z} \otimes \mathbb{N} \mid a + b \in 2\mathbb{N}\} \), and similarly \( P_q \) is a submonoid of \( \mathbb{N} \otimes \mathbb{Z} \). The quotients \( P_p^{\text{gp}} \) and \( P_q^{\text{gp}} \) are both isomorphic to \( \mathbb{N} \), and are both generated by the class of \((1,1)\). Let \( \varphi : P_p^{\text{gp}} \to \mathbb{Z} \) be a map of monoids; then the image of \( \varphi \) in \( P_{\text{gp}}^{\text{gp}} \) is the unique map of monoids \( P \to \mathbb{Z} \) given by the rule: \((2,0) \mapsto 0, (1,1) \mapsto \varphi(1,1), (0,0) \mapsto 2\varphi(1,1) \). Likewise, a map \( \psi : P_q^{\text{gp}} \to \mathbb{Z} \) gets sent to the morphism \( P \to \mathbb{Z} \) such that \((2,0) \mapsto 2\psi(1,1), (1,1) \mapsto \psi(1,1), (0,2) \mapsto 0 \). We see therefore that
(P^1)^{gpv} + (P)^{gpv} is a subgroup of index two in \(P^{gpv}\), and the contention follows from theorem \[13.3.55\].

13.4. Local acyclicity of smooth morphisms of log schemes. In this section we consider a smooth and saturated morphism \(f : (X, M) \to (Y, N)\) of fine log schemes. We fix a geometric point \(x\) of \(X\), localized at a point \(x,\) and let \(\overline{y} := f(x)\). We shall suppose as well that \(Y\) is strictly local and normal, that \((Y, N)_{tr}\) is a dense open subset of \(Y\), and that \(\overline{y}\) is localized at the closed point \(y\) of \(Y\). Let \(\overline{y}\) be a geometric point of \(Y\), localized at the generic point \(\eta\); to ease notation, set :

\[
U := f^{-1}(y), \quad U_{tr} := (X, M(x))_{tr} \cap U, \quad \overline{U} := U \times_{\eta} |\eta|, \quad \overline{U}_{tr} := U_{tr} \times_{\eta} |\eta|
\]

and notice that \(U_{tr}\) is a dense open subset of \(U\), by virtue of proposition [12.7.17(ii,iv)]. Choose a geometric point \(\xi\) of \(\overline{U}_{tr}\), and let \(\xi'\) be the image of \(\xi\) in \(U_{tr}\). There follows a short exact sequence of topological groups :

\[
1 \to \pi_1(\overline{U}_{tr, et}, \xi) \to \pi_1(U_{tr, et}, \xi') \xrightarrow{\alpha} \pi_1(\eta_{et}, \eta) \to 1.
\]

On the other hand, let \(p\) be the characteristic exponent of \(\kappa := \kappa(\overline{y})\); for every integer \(e\) such that \((e, p) = 1\), the discussion of (13.3.25) yields a commutative diagram :

\[
\begin{array}{ccc}
\mathcal{N}_{\overline{y}} & \xrightarrow{\log f_{\overline{y}}} & \kappa(\eta)^\times \\
\downarrow & & \downarrow \\
\mathcal{M}_{\overline{y}} & \xrightarrow{\Gamma(U_{tr}, \mathcal{O}_U^e)} & \text{Hom}_{cont}(\pi_1(\eta_{et}, \eta), \mu_e(\kappa))
\end{array}
\]

such that the composition of the two top (resp. bottom) horizontal arrows factors through \(\mathcal{N}_{\overline{y}}\) (resp. \(\mathcal{M}_{\overline{y}}\)). There follows a system of natural group homomorphisms :

\[
\text{Coker}(\log f_{\overline{y}})^{gp} \to \text{Hom}_{cont}(\pi_1(\overline{U}_{tr, et}, \xi), \mu_e(\kappa)) \quad \text{where } (e, p) = 1
\]

which assemble into a group homomorphism :

\[
\pi_1(\overline{U}_{tr, et}, \xi) \to \text{Coker}(\log f_{\overline{y}})^{gp} \otimes_{\mathbb{Z}} \prod_{\ell \neq p} \mathbb{Z}(1).
\]

13.4.4. We wish to give a second description of the map (13.4.5), analogous to the discussion in (13.3.30). To this aim, let \(R\) be a ring; for any monoid \(P\), and any integer \(e > 0\), denote by \(e_P : P \to P\) the \(e\)-Frobenius map of \(P\). Let \(\lambda : P \to Q\) be a local morphism of finitely generated monoids. For any integer \(e > 0\), we get a commutative diagram of monoids :

\[
\begin{array}{ccc}
P & \xrightarrow{e_P} & P \\
\downarrow{\lambda} & & \downarrow{\lambda} \\
Q & \xrightarrow{\mu'} & Q' \\
\downarrow{e_Q|P} & & \downarrow{e_Q} \\
Q & \xrightarrow{e_Q} & Q
\end{array}
\]

whose square subdiagram is cocartesian, and such that \(e_Q|P \circ \mu' = e_Q\). The latter induces a commutative diagram of log schemes :

\[
\begin{array}{ccc}
\text{Spec}(R, Q) & \xrightarrow{g_{Q|P}} & \text{Spec}(R, Q') \\
\downarrow{g} & & \downarrow{g'} \\
\text{Spec}(R, P) & \xrightarrow{g_P} & \text{Spec}(R, P)
\end{array}
\]
whose square subdiagram is cartesian, and such that \( g_Q := g' \circ g_{Q|P} \) is the morphism induced by \( e_Q \). Also, by example [2.6.5] we have a commutative diagram of monoidal spaces:

\[
\begin{array}{ccc}
\Spec(R, Q) & \xrightarrow{g_{Q|P}} & \Spec(R, Q') \\
\downarrow{\psi_Q} & & \downarrow{\psi_{Q'}} \\
T_Q & \xrightarrow{\varphi} & T_{Q'}
\end{array} \xrightarrow{g_e} \begin{array}{c}
\Spec(R, P)
\end{array}
\]

(where \( \varphi := (\Spec e_{Q|P})^\sharp \)) which determines morphisms in the category \( \mathcal{X} \):

\[
(\Spec(R, Q), T_Q, \psi_Q) \to (\Spec(R, Q'), T_{Q'}, \psi_{Q'}) \to (\Spec(R, P), T_P, \psi_P).
\]

13.4.6. Now, suppose that the closed point \( m_Q \) of \( T_Q \) lies in the strict locus of \( (\Spec \lambda)^2 \) (which just means that \( \lambda^2 \) is an isomorphism). Notice that the functor \( M \mapsto M^2 \) commutes with colimits (since it is a left adjoint); taking into account lemma [6.1.13], we deduce that the square subdiagram of (13.4.5) \( (\lambda)^2 \) is still cocartesian, and therefore \( e_{Q|P}^\sharp \) is an isomorphism, so the same holds for \( \varphi \).

More generally, let \( q \in \Spec Q \) be any prime ideal in the strict locus of \( (\Spec \lambda)^2 \); set \( p := \lambda^{-1}q, \tau := \varphi(q) \), and recall that \( T_{Qq} := \Spec Q_q \) is naturally an open subset of \( T_Q \) (see (6.5.16)). A simple inspection shows that the restriction \( T_{Qq} \to T_{Q\tau} \) of \( \varphi \) is naturally identified with the morphism of affine fans \( (\Spec e_{Qq|P})^2 \). Since \( q \) is the closed point of \( T_{Qq} \), the foregoing shows that \( T_{Qq} \) lies in the strict locus of \( \varphi \); in other words, \( \Str(\varphi) \) is an open subset of \( T_Q \), and we have

\[
\text{(13.4.7)} \quad \Str((\Spec \lambda)^2) \subset \Str(\varphi).
\]

Moreover, recall that \( \Spec e_Q : T_Q \to T_Q \) is the identity on the underlying topological space (see example [6.5.10](i)), and by construction it factors through \( \varphi \), so the latter is injective on the underlying topological spaces. Especially, \( \Str(\varphi) = \varphi^{-1}(\Str(\varphi)) \), and therefore

\[
\text{(13.4.8)} \quad \Str(g_{Q|P}) = \psi_Q^{-1}(\Str(\varphi)) = g_{Q|P}^{-1}(\psi_{Q'}^{-1}\varphi(\Str(\varphi))).
\]

Hence, set \( g := \Spec(R, \lambda) \); from (13.4.7) and (12.6.3) we obtain:

\[
\Str(g) \subset \Str(g_{Q|P})
\]

and together with (13.4.8) we deduce that:

- \( \Str(g_{Q|P}) \) is an open subset of \( \Spec R[Q] \).
- \( \psi_Q^{-1}\varphi(\Str(\varphi)) \) is a locally closed subscheme of \( \Spec R[Q'] \).
- The restriction \( \Str(g) \to \psi_Q^{-1}\varphi(\Str(\varphi)) \) of \( g_{Q|P} \) is a finite morphism.

Lastly, suppose that \( e \) is invertible in \( R \); in this case, the morphisms \( g_P \) and \( g_Q \) are étale (proposition [12.3.34]), so the same holds for \( g_{Q|P} \) (corollary [12.3.25](iii)). From corollary [12.3.27](i) we deduce that the restriction \( \Str(g) \to \psi_Q^{-1}\varphi(\Str(\varphi)) \) of \( g_{Q|P} \) is a (finite) étale covering.

13.4.9. In the situation of (13.4.4), suppose additionally, that \( R \) is a \( \mathbb{Z}[1/e, \mu_e] \)-algebra (where \( \mu_e \) is the \( e \)-torsion subgroup of \( \mathbb{C}^\times \)), \( P \) and \( Q \) are fine monoids, and \( \lambda \) is integral, so that \( Q' \) is also fine. Set

\[
G_P := \Hom_{\mathbb{Z}}(P^{\gp}, \mu_e) \quad G_Q := \Hom_{\mathbb{Z}}(Q^{\gp}, \mu_e) \quad G_{Q|P} := \Hom_{\mathbb{Z}}(\Coker \lambda^{\gp}, \mu_e).
\]
Notice that the trivial locus $\Spec(R, P)_{tr}$ is the open subset $\Spec R[\mathfrak{p}^\gp]$, and likewise for $\Spec(R, Q)_{tr}$ and $\Spec(R, Q')_{tr}$, therefore, \((13.4.5)\) induces a cartesian diagram of schemes

\[
\begin{array}{ccc}
\Spec(R, Q')_{tr} & \xrightarrow{g'_{tr}} & \Spec(R, Q)_{tr} \\
\downarrow g_{e, tr} & & \downarrow g_{tr} \\
\Spec(R, P)_{tr} & \xrightarrow{g_{P, tr}} & \Spec(R, P)_{tr}.
\end{array}
\]

Fix a geometric point $\tau'_Q$ of $\Spec(R, Q')_{tr}$, and let $\tau_Q := g'(\tau'_Q)$, $\tau_P := g(\tau_Q)$, $\tau'_P := g_e(\tau'_Q)$. It was shown in \((13.3.30)\) that $g_{P, tr}^{-1}(\tau_P)$ is a $G_P$-torsor, so $g_{P, tr}$ is a Galois étale covering, corresponding to a continuous representation \((13.3.31)\) into $G_P$. Hence $g_{P, tr}^{-1}(\tau_Q)$ is a $G_P$-torsor, and $g'_{tr}$ is a Galois étale covering, whose corresponding representation of $\pi_1(\Spec(R, Q)_{tr, \et}, \tau_Q)$ is obtained by composing \((13.3.31)\) with the natural continuous group homomorphism $\pi_1(\Spec(R, Q)_{tr, \et}, \tau_Q) \rightarrow \pi_1(\Spec(R, P)_{tr, \et}, \tau_P)$.

By the same token, $g_{Q, tr}^{-1}(\tau_Q)$ is a $G_Q$-torsor, so also $g_{Q, tr}$ is a Galois étale covering, and a simple inspection shows that the surjection $g_{Q, tr}^{-1}(\tau_Q) \rightarrow g_{P, tr}^{-1}(\tau_Q)$

induced by $g_{Q, P}$ is $G_Q$-equivariant, for the $G_Q$-action on the target obtained from the map $\Hom_Z(\lambda^{\gp}, \mu_e) : G_Q \rightarrow G_P$.

The situation is summarized by the commutative diagram of continuous group homomorphisms

\[
\begin{array}{ccc}
\pi_1(\Spec(R, Q')_{tr, \et}, \tau'_Q) & \xrightarrow{\pi_1(g_{e, tr}, \tau'_Q)} & \pi_1(\Spec(R, Q)_{tr, \et}, \tau_Q) \\
\downarrow \pi_1(g_{e, tr}, \tau'_Q) & & \downarrow \pi_1(g_{tr}, \tau_Q) \\
\pi_1(\Spec(R, P)_{tr, \et}, \tau'_P) & \xrightarrow{\pi_1(g_{P, tr}, \tau_Q)} & \pi_1(\Spec(R, P)_{tr, \et}, \tau_P) \\
& & \downarrow \Hom_Z(\lambda^{\gp}, \mu_e) \\
& & G_P
\end{array}
\]

whose horizontal right-most arrows are the maps \((13.3.31)\). Consequently, $g_{Q, P}^{-1}(\tau'_Q)$ is a $G_{Q, P}$-torsor, and $g_{Q, P, tr}$ is a Galois étale covering, classified by a continuous group homomorphism $\pi_1(\Spec(R, Q)_{tr, \et}, \tau_Q) \rightarrow \pi_1(\Spec(R, P)_{tr, \et}, \tau_P)$.

13.4.11. Let us return to the situation of \((13.4)\), and assume additionally, that both $(X, M)$ and $(Y, N)$ are fs log schemes. Take $R := \mathcal{O}_Y$ in \((13.4.4)\); by corollary \((12.3.42)\) and theorem \((12.1.37)\)(iii), we may assume that there exist

- a local and saturated morphism $\lambda : P \rightarrow Q$ of fine and saturated monoids, such that $P$ is sharp, $Q^\times$ is a free abelian group of finite type, say of rank $r$, and $\Ass_Z \Coker \lambda^{\gp}$ does not contain the characteristic exponent of $\kappa(\overline{y})$;
- a morphism of schemes $\pi : Y \rightarrow \Spec R[P]$, which is a section of the projection $\Spec R[P] \rightarrow Y$, such that $$(Y, N) = Y \times_{\Spec R[P]} \Spec(R, P) \quad (X, M) = Y \times_{\Spec R[P]} \Spec(R, Q)$$

and $f$ is obtained by base change from the morphism $g := \Spec(R, \lambda)$. Moreover, the induced chart $Q_X \rightarrow M$ shall be local at the geometric point $\overline{x}$.

By claim \((12.1.39)\) we may further assume that the projection $Q \rightarrow Q^\times$ admits a section $\sigma : Q^\times \rightarrow Q$, such that $\lambda(P)$ lies in the image of $\sigma$. In this case, $g$ factors through the morphism $\Spec(R, P) \rightarrow \Spec(R, Q^\times)$ induced by $\lambda^\times$, and $\sigma$ induces an isomorphism of log schemes

$$\Spec(R, Q) = \mathcal{G}^{\gp}_{m, Y} \times_Y \Spec(R, Q^\times)$$
(where $G_{m,Y}^\oplus$ denotes the standard torus of rank $r$ over $Y$). In this situation, $X$ is smooth over $Y \times_{\Spec R[P]} \Spec R[Q^e]$, and more precisely

\begin{equation}
(13.4.12) \quad (X, M) = G_{m,Y}^\oplus \times_{\Spec R[P]} \Spec(R, Q^e).
\end{equation}

Summing up, after replacing $Q$ by $Q^e$, we may assume that $Q$ is also sharp, and \((13.4.12)\) holds with $\Spec(R, Q)$ instead of $\Spec(R, Q^e)$. Moreover, the image of $x$ in $T_Q$ is the closed point $m_Q$.

Let $e > 0$ be an integer which is invertible in $R$; by inspecting the definition, it is easily seen that there exists a finite separable extension $K_e$ of $\kappa(\eta) = \Frac(R)$, such that the normalization $Y_e$ of $Y$ in $\Spec K_e$ fits into a commutative diagram of schemes:

\[
\begin{array}{ccc}
Y_e & \longrightarrow & Y \\
\pi_e & \downarrow & \pi \\
\Spec R[P] & \longrightarrow & \Spec R[P]
\end{array}
\]

(whose top horizontal arrow is the obvious morphism); namely, $\pi$ is defined by some morphism of monoids $\beta : P \rightarrow R$, and one takes for $K_e$ any subfield of $\kappa(\eta)$ containing $\kappa(\eta)$ and the $e$-th roots of the elements of $\beta(P)$. Set $(Y_e, N_e) := Y_e \times_{\Spec R[P]} \Spec(R, P)$, and define log schemes $(X_e, M_e), (X'_e, M'_e)$ so that the two square subdiagrams of the diagram of log schemes

\[
\begin{array}{ccc}
(X'_e, M'_e) & \xrightarrow{h_e} & (X_e, M_e) \\
\downarrow & & \downarrow \\
\Spec(R, Q) & \xrightarrow{g_{Q,P}} & \Spec(R, P)
\end{array}
\]

are cartesian (here $\pi'_e$ is the composition of $\pi_e$ and the projection $G_{m,Y}^\oplus \times_Y Y_e \rightarrow Y_e$), whence a commutative diagram:

\begin{equation}
(13.4.13)
\begin{array}{ccc}
(X'_e, M'_e) & \xrightarrow{h_e} & (X_e, M_e) \\
\downarrow & & \downarrow \\
(Y_e, N_e) & \xrightarrow{f_e} & (Y_e, N_e).
\end{array}
\end{equation}

Notice that both $f_e$ and $f'_e$ are smooth and saturated morphisms of fine log schemes. Also, by construction $Y_e$ is strictly local, and $(Y_e, N_e)_X$ is a dense subset of $Y_e$. In other words, $f_e$ and $f'_e$ are still of the type considered in \((13.4)\). Moreover, $h_e$ is étale, since the same holds for $g_{Q,P}$, and the discussion in \((13.4.6)\) shows that the restriction

$$Str(f'_e) \rightarrow X_e$$

is an étale morphism of schemes. Furthermore, the discussion in \((13.4.9)\) shows that

$$h_{e,\tr} : (X'_e, M'_e)_X \rightarrow (X_e, M_e)_X$$

is a Galois étale covering.

13.4.14. More precisely, notice that $\lambda^e = \log f^e_{\tr}$; combining with \((13.4.10)\), we deduce a continuous group homomorphism:

\begin{equation}
(13.4.15) \quad \Ker \pi_1(f_{e,\tr}, \xi'_e) \rightarrow \Hom_{\mathbb{Z}}(\Coker f^e_{\tr}^{\mathbb{G}_m}, \mu_e(\kappa))
\end{equation}

where $\xi'_e$ is the image in $X_e$ of the geometric point $\xi$. The geometric point $\xi_e$ lifts uniquely to a geometric point $\xi'_e$ of $Y_e$, localized at the closed point $y_e$, and the pair $(\xi, \xi'_e)$ determines a unique geometric point $\xi_e$ such that $f_e(\xi_e) = \xi'_e$. Also, since the field extension $\kappa(y) \rightarrow \kappa(y_e)$ is purely
inseparable, it is easily seen that the induced map \( f_{\pi}^{-1}(\eta_e) \to f^{-1}(y) \) is a homeomorphism; there follows an isomorphism of \( X(\pi) \)-schemes ([51] Ch.IV, Prop.18.8.10)]:

\[
X_e(\pi_e) \xrightarrow{\sim} X(\pi) \times_Y Y_e.
\]

Let \( \eta_e \) be the generic point of \( Y_e \); by construction, \( \eta \) lifts to a geometric point \( \eta_e \) of \( Y_e \), localized at \( \eta_e \), and we have continuous group homomorphisms:

\[
(13.4.16) \quad \pi_1(U_{tr}, \xi) \xrightarrow{\sim} \text{Ker} (\pi_1(U_{e, tr}, \xi_e) \to \pi_1(\eta_e, |\eta_e|)) \to \text{Ker} \pi_1(f_{e, tr}, \xi_e).
\]

The composition of \((13.4.15)\) and \((13.4.16)\) is a continuous group homomorphism

\[
(13.4.17) \quad \pi_1(U_{tr}, \xi) \to \text{Hom}_Z(\text{Coker} (\log f)^{gp}_{\pi}, \mu_e(\kappa))
\]

whence, finally, a pairing

\[
\text{Coker} (\log f)^{gp}_{\pi} \times \pi_1(U_{tr}, \xi) \to \mu_e(\kappa).
\]

We claim that this pairing agrees with the one deduced from \((13.4.2)\). Indeed, by tracing back through the constructions, we see that \((13.4.17)\) is the homomorphism arising from the Galois covering of \( U_{tr} \), which is obtained from \( g_{Q,P} \), after base change along the composition

\[
U_{tr} \to X_e \to \text{Spec } R[Q'].
\]

On the other hand, the discussion of \((13.3.30)\) shows that the homomorphism \( \pi_1(U_{tr, \acute{e}}, \xi') \to G_Q \) arising from the bottom row of \((13.4.1)\), classifies the Galois covering \( C \to U_{tr} \), obtained from \( g_Q \), by base change along the same map. By the same token, the top row of \((13.4.1)\) corresponds to the \( G_P \)-Galois covering \( C' \to \vert \eta \vert \) obtained by base change of \( g_P \) along the composition \( |\eta| \to Y \to S_P \). The map \( \log f_p \) induces a morphism of schemes \( C \to C' \times_{|\eta|} U_{tr} \), and \((13.4.2)\) corresponds to the \( G_{Q,P} \)-torsor obtained from a fibre of this morphism. Evidently, this torsor is isomorphic to \( g^{-1}_{Q,P}(\tau_q') \), whence the contention.

13.4.18. In the situation of \((13.4)\), recall that there is a natural bijection between the set of maximal points of \( f_{\pi}^{-1}(\overline{y}) \), and the set \( \Sigma \) of maximal points of the closed fibre of the induced map

\[
(13.4.19) \quad \text{Spec } M_{\pi} \to \text{Spec } N_{\overline{y}}
\]

(proposition [12.7.14]). For every \( q \in \Sigma \), denote by \( \eta_q \) the corresponding maximal point of \( f_{\pi}^{-1}(\overline{y}) \), choose a geometric point \( \eta_q \) localized at \( \eta_q \), and let \( X(\eta_q) \) be the strict henselization of \( X(\pi) \) at \( \eta_q \). Also, set

\[
U_q := U \times_{X(\pi)} X(\eta_q) \quad U_q := U_q \times_{|\eta|} |\eta|
\]

and notice that \( U_q \) is an irreducible normal scheme. Notice as well that \( f \) induces a strict morphism \( (X(\eta_q), M(\eta_q)) \to (Y, N) \) (theorem [12.7.8](iii.a)), and therefore the log structure of \( U_q \times_{X(\eta_q)} X(\eta_q) \) is trivial.

Recall that \( Z := U_\acute{e} \setminus U_{tr} \) is a finite union of irreducible closed subsets of codimension one in \( U_\acute{e} \), and \( \partial_{tr,z} \) is a discrete valuation ring, for each maximal point \( z \in Z \) (proposition [12.7.17](iv,v)); especially, the category \( \text{Tame}(U, U_{tr}) \) is well defined (definition [13.3.16](iii)).

We denote

\[
\text{Tame}(f, \pi)
\]

the full subcategory of \( \text{Tame}(U, U_{tr}) \) consisting of all the coverings \( C \to U_{tr} \) such that, for every \( q \in \Sigma \), the induced covering

\[
C \times_{U_{tr}} U_q \to U_q
\]

is trivial (i.e. \( C \times_{U_{tr}} U_q \) is a disjoint union of copies of \( U_q \)). It is easily seen that \( \text{Tame}(f, \pi) \) is a Galois category (see [65] Exp.V, Df.5.1]), and we obtain a fibre functor for this category,
by restriction of the usual fibre functor $\varphi \mapsto \varphi^{-1}(\xi)$ defined on all étale coverings $\varphi$ of $\mathcal{U}_{\text{tr}}$; we denote by $\pi_1(\mathcal{U}_{\text{tr}}/Y_{\text{et}}, \xi)$ the corresponding fundamental group. According to [65 Exp.V, Prop.6.9], the fully faithful inclusion $\text{Tame}(f, \pi) \to \text{Cov}(\mathcal{U}_{\text{tr}})$ induces a continuous surjective group homomorphism

$$\pi_1(\mathcal{U}_{\text{tr}}, \xi) \to \pi_1(\mathcal{U}_{\text{tr}}/Y_{\text{et}}, \xi).$$

**Proposition 13.4.21.** The map $(13.4.3)$ factors through $(13.4.20)$, and the induced group homomorphism:

$$\pi_1(\mathcal{U}_{\text{tr}}/Y_{\text{et}}, \xi) \to \text{Coker } (\log f^g_{\pi})^\vee \otimes_{\mathbb{Z}} \prod_{\ell \neq p} \mathbb{Z}_\ell(1).$$

is surjective.

**Proof.** Let $\sigma_Y : Y \to Y^{qf}$ be the natural morphism of schemes exhibited in remark $12.2.36$ iv), and set

$$(Y, N^i) := Y \times_{Y^{qf}} (Y, N)^{qf} \quad (X, M') := (Y, N') \times (Y, X, M).$$

Since $f$ is saturated, both $(X, M')$ and $(Y, N')$ are fs log schemes (see remark $12.2.36$ i)); also, the morphism of schemes underlying the induced morphism of log schemes $f^i : (X, M') \to (Y, N')$, agrees with that underlying $f$. Moreover, by construction we have $N^i_{\text{ad}} = (N_{\text{ad}}^i)^{\text{sat}}$ for every geometric point $\varpi$ of $Y$, especially $(Y, N')_{\text{tr}} = (Y, N)^{\text{tr}}$; Likewise, $M^i_{\text{ad}} = (M_{\text{ad}}^i)^{\text{sat}}$ (lemma $6.2.12$ iii, iv), therefore $\text{Str}(f^i) = \text{Str}(f)$, and especially, $(X, M')_{\text{tr}} = (X, M)^{\text{tr}}$. Furthermore, notice that the natural map

$$\text{Coker } (\log f^g_{\pi})^\vee \to \text{Coker } (\log f^i_{\pi})^\vee$$

is surjective, and its kernel is a quotient of $(M_{\text{ad}}^i)^{\vee}/M_{\text{ad}}^i$, especially it is a torsion subgroup. However, the cokernel of $(\log f^g_{\pi})$ equals the cokernel of $(\log f^i_{\pi})$, hence it is torsion-free (corollary $6.2.32$ ii)), so $(13.4.23)$ is an isomorphism. Thus, we may replace $N$ (resp. $M$) by $N'$ (resp. $M'$), and assume from start that $f$ is a smooth, saturated morphism of fs log schemes.

In this case, in light of the discussion of $(13.4.14)$, it suffices to prove that $(13.4.17)$ is a surjection, and that it factors through $\pi_1(\mathcal{U}_{\text{tr}}/Y_{\text{et}}, \xi)$. To prove the surjectivity comes down to showing that $\mathcal{U}_{\text{tr}} \times_{\mathcal{U}} X_e'$ is a connected scheme. However, let $x_e$ be the support of $\mathcal{U}_{\text{et}}$, and notice that $\psi_P \circ \pi_e(y_e) = m_P$, the closed point of $T_P$. Since $x$ maps to the closed point of $T_Q$, we deduce easily that the image of $x_e$ in $T_{Q'}$ is the closed point $m_{Q'}$, i.e. $x_e$ lies in the closed subscheme $X_e \times_{S_{Q'}} \text{Spec } \mathbb{Q}'/m_{Q'}$. Notice as well that $e_{Q'/P}$ is of Kummer type (see definition $6.4.56$); by proposition $13.3.7$ ii), it follows that there exists a unique geometric point $\mathcal{P}'_e$ of $X_e'$ lying over $\mathcal{P}_e$, whence an isomorphism of $X_e(\mathcal{P}_e')$-schemes

$$(13.4.23) \quad X_e'_{(\mathcal{P}'_e)} \cong X_e' \times_{X_e} X_e(\mathcal{P}_e).$$

Hence $\mathcal{U}_{\text{tr}} \times_{\mathcal{U}} X_e'$ is an open subset of $|\eta_{\mathcal{U}}| \times_{\mathcal{U}} X_e'_{(\mathcal{P}_e)}$, and the latter is an irreducible scheme, by proposition $12.7.17$ ii). We also deduce that the induced morphism

$$h_{e, \mathcal{U}} : (X_e'_{(\mathcal{P}_e)}, (M_e')_{(\mathcal{P}_e)}) \to (X_e(\mathcal{P}_e), (M_e)(\mathcal{P}_e))$$

is a finite étale covering of log schemes. From the discussion in $(13.4.11)$, we see that the restriction of $h_{e, \mathcal{U}}$

$$\text{Str}(h_{e, \mathcal{U}}) \to X_e(\mathcal{P}_e)$$

is an étale morphism, and $\text{Str}(h_{e, \mathcal{U}})$ contains the strict locus of the induced morphism

$$f_{e, \mathcal{U}}' : (X_e'_{(\mathcal{P}_e)}, (M_e')_{(\mathcal{P}_e)}) \to (Y_e, N_e).$$

Since the field extension $\kappa(\mathcal{P}) \to \kappa(\mathcal{P}_e)$ is purely inseparable, $\eta_{\mathcal{U}}$ lifts uniquely to a geometric point $\eta_{e, \mathcal{U}} \in X_e(\mathcal{P}_e)$, and as usual we deduce that the strict henselization $X_e(\eta_{\mathcal{U}})$ of $X_e(\mathcal{P}_e)$ at $\eta_{e, \mathcal{U}}$ is isomorphic, as an $X_e(\mathcal{P}_e)$-scheme, to $X_e(\mathcal{P}_e) \times_{X(\mathcal{P})} X(\eta_{\mathcal{U}})$. Moreover, if $\eta_{e, \mathcal{U}}$ is the
Say that $Y = \text{Spec } R$; for every algebraic field extension $K$ of $\kappa(\eta) = \text{Frac}(R)$, let $R_K$ be the normalization of $R$ in $K$, set $|\eta_K| := \text{Spec } K$ and

$$Y_K := \text{Spec } R_K \quad (Y_K, N_K) := (Y_K, \eta_K) \quad (X_K, M_K) := (Y_K \times_Y X, M)$$

Moreover, let $f_K : (X_K, M_K) \to (Y_K, N_K)$ be the induced morphism, and $\eta_{K, q}$ any geometric point localized at the closed point $y_K$ of the strictly local scheme $Y_K$; since the extension $\kappa(\eta) \to \kappa(\eta_K)$ is purely inseparable, there exists a unique geometric point $\pi_K$ of $X_K$ lifting $\pi$, and we have an isomorphism of $(X(\pi), M(\pi))$-schemes:

$$(X_K(\pi_K), M_K(\pi_K)) \to X_K \times_Y (X(\pi), M(\pi)) = Y_K \times_Y (X(\pi), M(\pi)).$$

Clearly the morphism $f_K$ is again of the type considered in (13.4.18); especially, the maximal points of $f_K^{-1}(\pi_K)$ are in natural bijection with the elements of $\Sigma$, and it is natural to denote

$$U_K := U \times_Y |\eta_K| \quad U_{K, tr} := U \times_Y |\eta_K| \quad U_{K, q} := U \times_X (\eta_q) \times \eta_{K, q}$$

for every $q \in \Sigma$. Then, let $\eta_{K, q}$ be the unique geometric point of $f_K^{-1}(\pi_K)$ lying over $\eta_q$, and $\eta_{K, q}$ the support of $\eta_{K, q}$; as usual, we have

$$X_K(\eta_{K, q}) = X(\eta_q) \times_Y Y_K$$

hence the above notation is consistent with the one introduced for the original morphism $f$. Furthermore, if $z$ is any maximal point of $U \setminus U_{tr}$, the image $\pi_K$ of $z$ in $U_K$ is a maximal point of $U_K \setminus U_{K, tr}$, and since the induced map $\partial_{U_K, z} \to \partial_{U_{tr}, z}$ is faithfully flat, proposition (12.7.17 iv,v) easily implies that $\partial_{U_K, z}$ is a discrete valuation ring. We may then denote

$$\text{Tame}(f, \pi, K)$$

the full subcategory of $\text{Tame}(U_K, U_{K, tr})$, consisting of those objects $C \to U_{K, tr}$, such that the induced covering $C \times_{U_{K, tr}} U_{K, q} \to U_{K, q}$ is trivial, for every $q \in \Sigma$. We have a natural functor

$$(13.4.26) \quad \text{colim}_{K} \text{Tame}(f, \pi, K) \to \text{Tame}(f, \pi)$$

where the 2-colimit ranges over the filtered family of all finite separable extensions $K$ of $\kappa(\eta)$.

**Lemma 13.4.27.** The functor (13.4.26) is an equivalence.

**Proof.** Let $\overline{\eta} : \overline{C} \to \overline{U}_{tr}$ be an object of the category $\text{Tame}(f, \pi)$. According to [51] Ch.IV, Prop.17.7.8(ii) and [50] Ch.IV, Prop.8.10.5, we may find a finite extension $K$ of $\kappa(\eta)$, such that $\overline{\eta}$ descends to a finite étale morphism

$$h_K : C_K \to U_{K, tr}.$$ 

Let $C_K'$ (resp. $\overline{C}'$) denote the normalization of $C_K$ (resp. of $\overline{C}$) over $U_K$ (resp. over $\overline{U}$). Since the morphism $|\eta| \to |\eta_K|$ is ind-étale, we have $\overline{C}' = C_K' \times_{|\eta_K|} |\eta|$ ([51] Ch.IV, Prop.17.5.7]), and it follows easily that $C_K$ is tamely ramified along the divisor $U_K \setminus U_{K, tr}$. From (13.4.25) we get a natural isomorphism:

$$U_{q, \eta} \to U_{K, q} \times_{|\eta_K|} |\eta|.$$ 

Thus, after replacing $K$ by a larger finite separable extension of $\kappa(\eta)$, we may assume that the induced morphism $C_K \times_{U_{K, tr}} U_{K, q} \to U_{K, q}$ is a trivial étale covering, for every $q \in \Sigma$.

This shows that (13.4.26) is essentially surjective; likewise one shows the full faithfulness: the details shall be left to the reader.

\[\square\]
13.4.28. In the situation of \([13.4.24]\), let \(K\) be an algebraic extension of \(\kappa(\eta)\), and
\[ h : C \to U_{K,\text{tr}} \]
y any object of \(\text{Tame}(U_K, U_{K,\text{tr}})\), and denote by \(C'\) the normalization of \(X_K(\pi_K)\) in \(C\). We claim that there exists a largest non-empty open subset
\[ E(h) \subset X_K(\pi_K) \]
such that the restriction \(h^{-1}E(h) \to E(h)\) of \(h\) is étale. Indeed, in any case, \(h\) restricts to an étale morphism on a dense open subset containing \(U_{K,\text{tr}}\), and there exists a largest open subset \(E' \subset C'\) such that \(h|_{E'}\) is étale (claim \([13.1.8]\) and lemma \([13.1.7]\)(iii)). Then it is easily seen that \(E(h) := X_K(\pi_K) \setminus h(C\setminus E')\) will do.

Lemma 13.4.29. With the notation of \([13.4.28]\), the category \(\text{Tame}(f, \pi, K)\) is the full subcategory of \(\text{Tame}(U_K, U_{K,\text{tr}})\) consisting of those objects \(h : C \to U_{K,\text{tr}}\) such that \(E(h)\) contains the maximal points of \(X_K(\pi_K)\times_{Y_K}[y_K]\).

Proof. In view of claim \([13.1.9]\) this characterization is a rephrasing of the definition of the category \(\text{Tame}(f, \pi, K)\).

13.4.30. Keep the notation of \([13.4.28]\), and suppose that \(h\) is an object of \(\text{Tame}(f, \pi, K)\). Fix \(q \in \Sigma\); then lemma \([13.4.29]\) says that \(\eta_{K,q} \in E(h)\). Thus, we obtain a functor
\[ \text{Tame}(f, \pi, K) \to \text{Cov}(\eta_{K,q}) : C \mapsto C' \times_{X_K(\pi_K)} \eta_{K,q} \]
However, the natural morphism \(\eta_{K,q} \to \eta_q\) is radicial, hence it induces an equivalence
\[ \text{Cov}(\eta_q) \sim \text{Cov}(\eta_{K,q}) \]
(lemma \([13.1.7]\)(i)). Combining these functors in the special special case where \(K := \kappa(\eta)\), we get a functor
\[ \text{Tame}(f, \pi) \to \text{Cov}(\eta_q) : (C \to U_{\text{tr}}) \mapsto (C|q \to |\eta_q|) \]
Now, the rule \(\varphi \mapsto \varphi^{-1}(\eta_q)\) yields a fibre functor for the Galois category \(\text{Cov}(\eta_q)\); by composition with \([13.4.31]\), we deduce a fibre functor for \(\text{Tame}(f, \pi)\), whose group of automorphisms we denote \(\pi_1(U_{\text{tr}}/Y_{\text{et}}, \eta_q)\). Also, set \(F(q) := M_\pi \setminus q\), and notice that the structure map \(M_\pi \to \mathcal{O}_{X(\pi),\pi}\) induces a group homomorphism
\[ F(q)^{\text{gp}} \to \kappa(\eta)^\times. \]

Lemma 13.4.33. With the notation of \([13.4.30]\), we have:

(i) The natural map \(\text{Coker}(\log f_\pi) \to F(q)\) induces a commutative diagram of groups
\[ \begin{array}{ccc}
\pi_1(|\eta_q|_{\text{et}}, \eta_q) & \xrightarrow{\alpha} & \pi_1(U_{\text{et}}/Y_{\text{et}}, \eta_q) \\
F(q)^{\text{gp}} \otimes_{\mathbb{Z}} \prod_{\ell \neq p} \mathbb{Z}_\ell(1) & \xrightarrow{\gamma} & \text{Coker}(\log f_\pi)^{\text{gp}} \otimes_{\mathbb{Z}} \prod_{\ell \neq p} \mathbb{Z}_\ell(1) \\
\end{array} \]
where \(\beta\) is \([13.4.22]\), and \(\alpha\) is deduced from \([13.4.32]\), as in the discussion of \([13.3.25]\).

(ii) \(\alpha\) is surjective, and \(\gamma\) is an isomorphism.

Proof. (i): The proof amounts to unwinding the definitions, and shall be left as an exercise for the reader. Notice that the second arrow on the top row is only well-defined up to inner automorphisms, but since the groups on the bottom row are abelian, the ambiguity does not affect the statement.

(ii): Notice that \(\log f_\pi\) restricts to a map of monoids \(\mathcal{O}_{Y_{\text{et}}}^{\times} \to F(q)\), which induces an isomorphism \(\text{Coker}(\log f)^\times \sim F(q)^\times\); we deduce that \(\gamma\) is an isomorphism. Next, let \(Z\) be the...
topological closure of $\eta_\ell$ in $X(\pi)$, and endow $Z$ with its reduced subscheme structure; set also $(Z, M(Z)) := Z \times_{X(\pi)} (X, M)$. The map $\alpha$ factors as a composition

$$\pi_1([\eta_\ell]|_\ell, \eta_\ell) \to \pi_1((Z, M(Z))_{tr, \etale}, \eta_\ell) \to F(q)^{et} \otimes_Z \prod_{\ell \neq p} Z[1]$$

where the first map is surjective, by lemma [13.1.7(ii)]. Lastly, notice that $M(Z)_{red, \etale} = F(q)_\ell^*$ by propositions [13.3.41] and [12.7.14(ii)], it follows that the second map is surjective as well, so the proof of (ii) is complete.

13.4.34. In the situation of (12.3.44), suppose that $Y_i$ is a strictly local normal scheme for every $i \in I$, and the transition morphisms $Y_j \to Y_i$ are local and dominant, for every morphism $i \to j$ in $I$. Let $\pi$ be a geometric point of $X$, and denote by $\pi_i$ the image of $\pi$ in $X_i$, for every $i \in I$. Suppose that the image $\overline{\eta}$ of $\pi$ in $Y$ is localized at the closed point. Also, let $\overline{\eta}_i$ be a strict geometric point of $Y_i$ localized at the generic point $\eta_i$, and denote by $\overline{\eta}_i$ (resp. $\overline{\eta}_i$) the strict image of $\overline{\eta}$ (resp. $\overline{\eta}$) in $Y_i$ (see definition 4.9.17(v)).

**Lemma 13.4.35.** In the situation of (13.4.34), suppose that $(g, \log g) : (X, M) \to (Y, N)$ is a smooth and saturated morphism of fine log schemes. Then there exist $i \in I$, and a smooth and saturated morphism $(g_i, \log g_i) : (X_i, M_i) \to (Y_i, N_i)$ of fine log schemes, such that $\log g = \pi_i^* \log g_i$.

**Proof.** By corollary [12.3.45] we can descend $(g, \log g)$ to a smooth morphism $(g_i, \log g_i)$ of fine log schemes, and after replacing $I$ by $I/i$, we may assume that $i = 0$. Then the contention follows from corollary [12.2.34(ii)].

13.4.36. Keep the situation of (13.4.34), and suppose that $(g_0, \log g_0) : (X_0, M_0) \to (Y_0, N_0)$ is a smooth and saturated morphism of fine log schemes; set

$$(X_i, M_i) := X_i \times_{X_0} (X_0, M_0) \quad (Y_i, N_i) := Y_i \times_{Y_0} (Y_0, N_0)$$

and denote $(g_i, \log g_i) : (X_i, M_i) \to (Y_i, N_i)$ the induced morphism of log schemes, for every $i \in I$. Also, let $(g, \log g) : (X, M) \to (Y, N)$ be the limit of the system of morphisms $((g_i, \log g_i) \mid i \in I)$. These are morphisms of the type considered in (13.4), so we may define $U_i := g_i^{-1}(\eta)$, and introduce likewise the schemes $U_i, U_i$ and $\overline{U}_i, \overline{U}_i$ as in (13.4). Moreover, set $Z_i := U_i \setminus U_i$ for every $i \in I$; clearly $Z_i = Z_j \times_{X_i(\pi_j)} X_i(\pi_i)$ for every morphism $i \to j$ in $I$. Also, each $Z_i$ is a finite union of irreducible subsets of codimension one, and for every $i \to j$ in $I$, the transition morphisms $X_i \to X_j$ restrict to maps

$$\text{Max } Z_i \to \text{Max } Z_j \quad \text{Max } X_i(\pi_i) \times_{Y_i} [\overline{\eta}_i] \to \text{Max } X_j(\pi_j) \times_{Y_j} [\overline{\eta}_j]$$

Combining proposition [13.3.21(ii)] and lemma [13.4.29] we deduce a fully faithful functor

$$(13.4.37) \quad 2\text{-colim}_{i \in I} \text{Tame}(g_i, \pi_i) \to \text{Tame}(g, \pi)$$

**Lemma 13.4.38.** The functor (13.4.37) is an equivalence.

**Proof.** It remains only to show the essential surjectivity. Hence, let $h$ be a given object of $\text{Tame}(g, \pi)$; by proposition [13.3.21(ii)], we know that there exists $j \in I$ such that $h$ descends to an étale covering $h_j : V_j \to \overline{U}_{j, \etale}$, tamely ramified along $Z_j$, and after replacing $I$ by $I/j$, we may assume that $j$ is the final object of $I$, and define $h_i := \overline{U}_{i, \etale} \times_{\overline{U}_{j, \etale}} h_j$ for every $i \to j$ in $I$. Now, let $E' \subset E(h_j)$ be a constructible open subset containing the maximal points of $X(\pi) \times_Y [\overline{\eta}]$. For every $i \in I$, let $\overline{Y}_i$ be the normalization of $Y_i$ in $\text{Spec } \kappa(\overline{\eta}_i)$, and set $X_i := X_i(\pi_i) \times_{Y_i} \overline{Y}_i$; according to [50, Ch.IV, Th.8.3.11], there exists $i \in I$ such that $E'$ descends to a constructible open subset $E'_i \subset X_i$, and then necessarily $E'_i$ contains all the maximal points of $X_i(\pi_i) \times_{Y_i} [\overline{\eta}_i]$. As usual, we may assume that $i$ is the final object, so $E'_i$ is defined for every
\[ \pi_1(U_{tr,\xi}, \xi) \xrightarrow{\alpha} \mathcal{M}_{tr}^{gp} \otimes \prod_{\ell \neq p} \mathbb{Z}_\ell(1) \]

whose top horizontal arrow is \((13.4.3)\), and whose right vertical arrow is deduced from the projection \(\mathcal{M}_{tr}^{gp} \to \text{Coker}(\log f_{\pi}^{gp})\). Lastly, proposition \([13.3.41]\) shows that the natural action of \(\pi_1(U_{tr,\xi}, \xi')\) on \(h^{-1}(\xi')\) factors through \(\alpha\), so the claim follows. \(\Box\)

Next, suppose that \(Y\) is an arbitrary normal, strictly local scheme. The discussion in \([13.4.14]\) implies that, in order to prove the theorem, it suffices to find an integer \(e > 0\), a \((X, M)\)-scheme \((X'_e, M'_e)\) as in \([13.4.11]\), and a geometric point \(x'_e\) of \(X'_e\) lying over \(\bar{x}\), such that \(h \times X(\pi) \times X'_e(\bar{x}_e)\) is a trivial covering. To this aim, we write \(Y\) as the limit of a cofiltered system \((Y_i \mid i \in I)\) of strictly local excellent and normal schemes (lemma \([13.1.28]\), and we denote by \(\eta_i\) the generic point of \(Y_i\), for every \(i \in I\). By lemma \([13.4.35]\) we may then descend \((f, \log f)\) to a smooth and saturated morphism \((f_i, \log f_i) : (X_i, M_i) \to (Y_i, N_i)\), for some \(i \in I\), and as usual, we may assume that \(i\) is the final object of \(I\). Let \(\pi_i\) be the image of \(\pi\) in \(X_i\); by lemmata \([13.4.38]\) and \([13.4.27]\) the object \(h_i\) of \(\text{Tame}(f_i, \pi_i, K)\) descends to an object \(h_{i,e}\) of \(\text{Tame}(f_i, \bar{x}_i, K)\), for some \(i \in I\), and some finite separable extension \(K\) of \(K(\eta_i)\). It suffices therefore to find \(e > 0\), a \((X_i, M_i)\)-scheme \((X'_i, M'_i, e)\), and a geometric point \(x'_i, e\) of \(X'_i, e\) lying...
over \( \pi \), such that \( h_i \times_{X_i(\pi)} X_i'_{\pi}(\pi_{i,\pi}) \) is a trivial covering. In other words, we may replace throughout \( Y \) by \( Y_{i,K} \), and assume from start that \( Y \) is excellent, and \( \overline{h} \) descends to an object \( h : C \to U_{tr} \) of \( \text{Tame}(f, \pi, \kappa(\eta)) \).

- By [45, Ch.II, Prop.7.1.7] (see also remark [12.5.34]) we may find a discrete valuation ring \( V \) and a local injective morphism \( R \to V \) inducing an isomorphism on the respective fields of fractions. Let \( V^{sh} \) be the strict henselization of \( V \) (at a geometric point whose support is the closed point), and set

\[
Y := \text{Spec} V^{sh} \quad (Y, N) := Y \times_Y (Y, N) \quad (X, M) := Y \times_Y (X, M).
\]

Also, let \( f : (X, M) \to (Y, N) \) be the induced morphism. Denote by \( y \) a geometric point localized at the closed point \( y \) of \( Y \); also, pick any geometric point \( x \) of \( X \), whose image in \( X \) is \( \pi \); the induced morphism

\[
(13.4.41) \quad \left( X(x), M(x) \right) \to \left( X(\pi), M(\pi) \right)
\]

restricts to a flat morphism \( f^{-1}_x(y) \to f^{-1}_x(y) \) and from proposition [12.7.14] we see that the latter induces a bijection between the sets of maximal points of the two fibres. On the other hand, let \( \eta \) denote a geometric point localized at the generic point \( \eta \) of \( Y \); then \( (13.4.41) \) restricts to an ind-étale morphism \( f^{-1}_x(\eta) \to f^{-1}_x(\eta) \). Hence, set

\[
U_{tr} := (X(\pi), M(\pi))_{tr} \times_Y |1(\eta)|.
\]

From lemma [13.4.29] it follows easily that the covering \( C \times_{U_{tr}} U_{tr} \to U_{tr} \) is an object of \( \text{Tame}(f, x, \kappa(\eta)) \).

For any integer \( e > 0 \) invertible in \( R \), pick a \((Y, N)\)-scheme \((Y_e, N_e)\) as in (13.4.11), so that we may define the étale morphism \((X'_e, M'_e) \to (X_e, M_e)\) of \((Y_e, N_e)\)-schemes as in (13.4.13). Notice that the morphism \((X'_e, M'_e) \to (X_e, N_e)\) is again of the type considered in (13.4), and there exists, up to isomorphism, a unique geometric point \( x'_e \) of \( X'_e \) lifting \( \pi \); moreover, for any geometric point \( y_e \) supported at \( y_e \), the induced map

\[
\text{Spec} M'_{\pi, x'_e} \to \text{Spec} N_{\pi, y_e}
\]

is naturally identified with (13.4.19). Likewise, pick a \((Y, N)\)-scheme \((Y_e, N_e)\) in the same fashion, and denote by \( \eta_e \) (resp. \( \eta_{\pi,e} \)) the generic point of \( Y_e \) (resp. of \( y_e \)), and by \( y_e \in Y_e \) (resp. \( y_e \in Y_e \)) the closed point. We may choose \( y_e \) so that \( \kappa(\eta_{\pi,e}) \) contains \( \kappa(\eta_e) \), in which case we have a strict morphism

\[
(Y_e, N_e) \to (Y_e, N_e)
\]

of log schemes, and we may set \((X'_e, M'_e) := Y_e \times_{Y_e} (X'_e, M'_e)\). Again, there exists, up to isomorphism, a unique geometric point \( x'_e \) of \( X'_e \) lifting \( \pi \), and by claim [13.4.40] we may assume that both \( e \) and \( \kappa(\eta_{\pi,e}) \) have been chosen large enough, so that the base change

\[
h \times_{X(\pi)} X'_e(\pi_{x'_e})
\]

shall be a trivial étale covering. Hence, we may replace \( Y \) by \( Y_{e_i} \), \( Y \) by \( Y_e \), \( X \) by \( X'_e \), and \( h \) by \( h \times_{X(\pi)} X'_e(\pi_{x'_e}) \), and assume from start that \( C \times_{U_{tr}} U_{tr} \) is a trivial covering of \( U_{tr} \). The theorem will follow, once we show that – in this case – \( h \) is a trivial étale covering.

Let \( C' \) (resp. \( C \)) be the normalization of \( X(\pi) \) in \( C \) (resp. of \( X(\pi) \) in \( C \times_{U_{tr}} U_{tr} \)), and define \( E(h) \) as in (13.4.28). Then \( C' \) is a trivial étale covering of \( X(\pi) \), and since \( X(\pi) \) is excellent, the induced morphism \( h' : C' \to X(\pi) \) is finite.

**Claim 13.4.42.** For every maximal point \( \eta_q \) of \( f^{-1}_x(\pi) \), the induced covering \( C|_{\eta_q} \to |1(\eta)| \) is trivial (notation of (13.4.31)).

**Proof of the claim.** Let \( Z_q \) denote the topological closure of \( \{\eta_q\} \) in \( X(\pi) \), and endow \( Z_q \) with its reduced subscheme structure; then \( E_q := E(h) \cap Z_q \) is non-empty (lemma [13.4.29], and
geometrically normal (proposition 12.7.14(ii) and corollary 12.5.13). Also, (13.4.41) induces an isomorphism of $\kappa(y)$-schemes

$$E_q \times_{X(\pi)} X(\pi) \xrightarrow{\sim} E_q \times_{\kappa(y)} \kappa(y).$$

Moreover, $Z_q$ is strictly local, and $Z_q \times_{X(\pi)} X(\pi)$ is the strict henselization of $Z_q \times_{\kappa(y)} \kappa(y)$ at the point $x$. Furthermore, the morphism $h'' := h' \times_{X(\pi)} E_q$ is an étale covering of $E_q$, and $h'' \times_{\kappa(y)} \kappa(y)$ is naturally identified with the restriction of $C$ to the subscheme $E_q \times_{X(\pi)} X(\pi)$ (51 Ch.IV, Prop.17.5.7)), hence it is a trivial covering. By example 13.2.6 it follows that $h''$ is trivial as well. Since $C|_{\eta_q}$ is the restriction of $h''$ to $|\eta_q|$, the claim follows.

\[\Box\]

Claim 13.4.43. $X(\pi) \times_Y |\eta| \subset E(h)$.

Proof of the claim. Notice first that $(X, M) \times_Y |\eta|$ is a regular log scheme (corollary 12.5.29).

For any geometric point $\xi$ of $X(\pi)$, denote by $(X(\xi), M(\xi))$ the strict henselization of $(X(\pi), M(\pi))$ at $\xi$, and set $C'(\xi) := C' \times_{X(\pi)} X(\xi)$. Now, suppose that the support of $\xi$ lies in the stratum $U_q \times_Y |\eta|$, and let $\xi_q$ be a geometric point localized at the generic point of $U_q$. By assumption, $C'(\xi)$ is a finite $X(\xi)$-scheme, tamely ramified along the non-trivial locus of $(X(\xi), M(\xi))$. Likewise, $C'(\xi_q)$ is tamely ramified along the non-trivial locus of $(X(\xi_q), M(\xi_q))$. Pick any strict specialization map $(X(\xi_q), M(\xi_q)) \to (X(\xi), M(\xi))$ (see 12.7.11); it induces a functor

$$\text{Cov}(X(\xi), M(\xi)) \to \text{Cov}(X(\xi_q), M(\xi_q))$$

and theorem 13.3.43 implies that $C'(\xi)$ is an object of the source of (13.4.44), which is mapped, under this functor, to the object $C'(\xi_q)$. By proposition 13.3.41, for any geometric point $\xi$ of $X(\pi) \times_Y |\eta|$, the category $\text{Cov}(X(\xi), M(\xi))$ is equivalent to the category of finite sets with a continuous action of $(M_{\xi})^{gp} \otimes \mathbb{Z} \prod_{\pi} Z_{\pi}(1)$. On the other hand, clearly $M(\pi)^{gp}$ restricts to a constant sheaf of monoids on $(U_q)_{\tau}$. In view of 13.3.52, we deduce that (13.4.44) is an equivalence; lastly, we have seen that the induced morphism $C'(\xi_q) \to X(\xi_q)$ is étale, i.e. is a trivial covering, therefore the same holds for the morphism $C'(\xi) \to X(\xi)$, and consequently the support of $\xi$ lies in $E(h)$ (claim 13.1.9). Since $\xi$ is arbitrary, the assertion follows.

\[\Box\]

Claim 13.4.45. There exists a non-empty open subset $U_Y \subset Y$ such that $X(\pi) \times_Y U_Y \subset E(h)$.

Proof of the claim. Since $X(\pi)$ is a noetherian scheme, $E(h)$ is a constructible open subset, hence $Z := X(\pi) \setminus E(h)$ is a constructible closed subset of $X(\pi)$. The subset $f_p(Z)$ is pro-constructible (48 Ch.IV, Prop.1.9.5(vii)) and does not contain $\eta$ (by claim 13.4.43), hence neither does its topological closure $W$ (48 Ch.IV, Th.1.10.1). It is easily seen that $U_Y := Y \setminus W$ will do.

\[\Box\]

Claim 13.4.46. Let $U_Y$ be as in claim 13.4.45. We have:

(i) There exists an irreducible closed subset $Z$ of $Y$ of dimension one, such that $Z \cap (Y, N)_{tr} \cap U_Y \neq \emptyset$.

(ii) For any $Z$ as in (i), the induced functor $\text{Cov}(E(h)) \to \text{Cov}(Z \times_Y E(h))$ is fully faithful.

Proof of the claim. (i): More generally, let $(A, m)$ be any local noetherian domain of Krull dimension $d \geq 1$, and $W \subset \text{Spec} A$ a proper closed subset; we show that there exists an irreducible closed subset $Z \subset \text{Spec} A$ of dimension one, not contained in $W$. To this aim, we may assume that $W = \text{Spec} A/fA$ for some $f \in m \setminus \{0\}$; let $n$ be any maximal ideal of $A[f^{-1}]$, ...
and \( p := A \cap n \). Since \( A/p[f^{-1}] \) is a field, \([48] \text{ Ch.0, Cor.16.3.3}\) implies that \( Z := \text{Spec } A/p \) will do.

(ii): It suffices to check that conditions (i)–(iii) of proposition \( \text{13.1.33} \) hold for \( Z \) and the open subset \( E(h) \). However, condition (i) is immediate, since the generic point \( \eta_Z \) of \( Z \) lies in \( U_Y \). Likewise, condition (ii) holds trivially for the fibre over the point \( \eta_Z \), so it suffices to consider the fibre over the closed point \( y \) of \( Z \), in which case the assertion is just lemma \( \text{13.4.29} \).

Lastly, condition (iii) follows directly from theorem \( \text{12.7.8} \) (iii) and \([51] \text{ Ch.IV, Prop.18.8.10, 18.8.12} \).

Let \( Z \) be as in claim \( \text{13.4.46} \) (i), and endow \( Z \) with its reduced subscheme structure. Let also \( Z' \) be the normalization of \( Z \); then both \( Z \) and \( Z' \) are strictly local, and the morphism \( Z' \to Z \) is radicial and surjective, hence the induced functor

\[
\text{Cov}(Z \times_Y E(h)) \to \text{Cov}(Z' \times_Y E(h))
\]

is an equivalence (lemma \( \text{13.1.7} \) (i)). Taking into account claim \( \text{13.4.46} \) we are thus reduced to showing that the morphism

\[
(Z' \times_Y E(h)) \times_{X(\pi)} C' \to Z' \times_Y E(h)
\]

is a trivial étale covering. However, let \( \eta_{Z'} \) be the generic point of \( Z' \), and set

\[
(Z', N') := Z' \times_Y (Y, N) \quad (X', M') := Z' \times_Y (X, M).
\]

The open subset \( (Z', N')_{\text{tr}} \) is dense in \( Z' \), by virtue of claim \( \text{13.4.46} \) (i), so the induced morphism \( f' : (X', M') \to (Z', N') \) is still of the type considered in \( \text{13.4} \), the geometric point \( \pi \) lifts uniquely (up to isomorphism) to a geometric point \( \pi' \) of \( X' \), and \( h \times_Y Z' \) is an object of \( \text{Tame}(f', \pi', \kappa(\eta_{Z'})) \) (lemma \( \text{13.3.17} \) (i)). Hence, we may replace from start \( (X, M) \) by \( (X', M') \), \( (Y, N) \) by \( (Z', N') \), and \( h \) by \( h \times_Y Z' \); after which, we may assume that \( Y \) is noetherian and of dimension one. Moreover, taking into account claim \( \text{13.4.42} \), we may assume that the induced covering \( C|_{\eta_h} \to |\eta_h| \) is trivial, for every maximal point \( \eta_h \) of \( f^{-1}_\pi(Y) \), and it remains to show that \( h \) is trivial under these assumptions.

To this aim, we look at the corresponding commutative diagram of groups, provided by lemma \( \text{13.4.33} \) (i) : with the notation of \textit{loc.cit.}, we see that in the current situation, \( \beta \) is an isomorphism as well, by claim \( \text{13.4.40} \) therefore lemma \( \text{13.4.33} \) (ii) says that the group homomorphism \( \pi_1(|\eta_h|_{\text{ét}}, \eta_h) \to \pi_1(U_{tr}/Y_{\text{ét}}, \xi) \) is surjective, for any maximal point \( \eta_h \) of \( f^{-1}_\pi(Y) \).

From this, we deduce that \( \overline{h} \) is a trivial covering, and therefore there exists an étale covering \( C_Y \to |\eta| \) with an isomorphism \( C \iso C_Y \times_{|\eta|} U_{\text{tr}} \) (\([65] \text{ Exp.IX, Th.6.1}\) ). Denote by \( C^\eta_Y \) the normalization of \( Y \) in \( C_Y \). Also, set \( E' := E(h) \subset \text{Str}(f'_{\text{ét}}) \). In light of theorem \( \text{12.7.8} \) (iii) and lemma \( \text{13.4.29} \) it is easily seen that the restriction \( E' \to Y \) of \( f'_{\text{ét}} \) is surjective; the latter is also a smooth morphism of schemes (corollary \( \text{12.3.27} \) (ii)). It follows that \( C^\eta_Y \times_X E' \) is the normalization of \( E' \) in \( C \) (\([51] \text{ Ch.IV, Prop.17.5.7}\) ), especially, it is an étale covering of \( E' \). We then deduce that \( C^\eta_Y \) is already a (trivial) étale covering of \( Y \) (\([51] \text{ Ch.IV, Prop.17.7.1} \) (ii)), and then clearly \( h \) must be a trivial covering as well.

\textbf{Remark 13.4.47.} Theorem \( \text{13.4.39} \) is the local acyclicity result that gives the name to this section. However, the title is admittedly not self-explanatory, and its full justification would require the introduction of a more advanced theory of the \textit{log-étale site}, that lies beyond the bounds of this treatise. In rough terms, we can try to describe the situation as follows. In lieu of the standard strict henselization, one should consider a suitable notion of strict \textit{log henselization} for points of the \textit{log-étale topoi} associated with log schemes. Then, for \( f : X \to Y \) as in \( \text{13.4} \) with saturated log structures on both \( X \) and \( Y \), and log-étale points \( \overline{x} \) of \( X \) with image \( \overline{y} \) in \( Y \), one should look, not at our \( f_{\text{ét}} \), but rather at the induced morphism \( f_{\text{ét}} \) of strict log henselizations (of \( X \) at \( \overline{x} \) and of \( Y \) at \( \overline{y} \)). The (suitably defined) \textit{log geometric fibres} of \( f_{\text{ét}} \) will be the \textit{log Milnor fibres} of \( f \) at the log-étale point \( \overline{x} \), and one can state for such fibres an acyclicity result : namely,
the prime-to-$p$ quotients of their (again, suitably defined) log fundamental groups vanish. The proof proceeds by reduction to our theorem [13.4.39] which, with hindsight, is seen to supply the essential geometric information encoded in the more sophisticated log-étale language.

14. THE ALMOST PURITY TOOLBOX

The sections of this rather heterogeneous chapter are each devoted to a different subject, and are linked to each other only very loosely, if they are at all. They have been lumped here together, because they each contribute a distinct self-contained little theory, that will find application in one step or other of the proof of the almost purity theorem or of its applications in chapter [17]. The exception is section [14.8]: it studies a class of rings more general than the measurable algebras introduced in section [14.5]: the results of section [14.8] will not be used elsewhere in this treatise, but they might be interesting for other purposes.

Section 14.4 develops the yoga of almost pure pairs (see definition [14.4.1](i)); the relevance to the almost purity theorem is clear, since the latter establishes the almost purity of certain pairs $(X, Z)$ consisting of a scheme $X$ and a closed subscheme $Z \subset X$. This section provides the means to perform various kinds of reductions in the proof of the almost purity theorem, allowing to replace the given pair $(X, Z)$ by more tractable ones.

Section 14.5 introduces measurable (and more generally, ind-measurable) $K^+$-algebras, for $K^+$ a fixed valuation ring of rank one: see definitions [14.5.3](ii) and [14.5.64]. For modules over a measurable algebra, one can define a well-behaved real-valued normalized length. This length function is non-negative, and additive for short exact sequences of modules. Moreover, the length of an almost zero module vanishes (for the standard almost structure associated with $K^+$). Conversely, under some suitable assumptions, a module of normalized length zero will be almost zero.

Lastly, section 14.6 studies some questions concerning the formation of quotients of affine almost schemes under a finite group action.

14.1. Non-flat almost structures. This section contains some material that complements the generalities of [59, §2.4, §2.5]: indeed, whereas many of the preliminaries in loc.cit. make no assumptions on the basic setup $(V, \mathfrak{m})$ that underlies the whole discussion, for the more advanced results it is usually required that $\mathfrak{m} := \mathfrak{m} \otimes V \mathfrak{m}$ is a flat $V$-module. We shall show how, with more work, one can remove this condition (or at least, weaken it significantly) and still recover most of the useful almost ring theory of [59]. This extension shall be applied in a later section, in order to state and prove the most general case of almost purity.

14.1.1. We begin with a simple observation, that completes the discussion of [59, §2.1.6].

Proposition 14.1.2. Let $V$ be a reduced ring, and consider ideals $\mathfrak{m}, J_1, \ldots, J_k \subset V$ such that:

(a) $\mathfrak{m}$ is a filtered union of principal ideals.

(b) $J_1 \otimes_V \cdots \otimes_V J_k$ is a flat $V$-module.

Then the following holds:

(i) The natural map $\mathfrak{m} \otimes_V \mathfrak{m} \to \mathfrak{m}^2$ is an isomorphism.

(ii) If the set $\text{Min} V$ of minimal prime ideals of $V$ is a quasi-compact subset of $\text{Spec} V$, then the natural map $J_1 \otimes_V \cdots \otimes_V J_k \to J_1 \cdots J_k$ is an isomorphism.

Proof. (i): We are easily reduced to checking the following. For every $x \in V$, the natural map $\mu : Vx \otimes_V Vx \to Vx^2$ is an isomorphism. Now, $I_n := \text{Ann}_V(x^n)$ for $n = 1, 2$, and notice that $I_1 \subset I_2$; the map $\mu$ is naturally identified with the map

$$V/I_1 \otimes_V V/I_1 \to V/I_2, \quad \overline{a} \otimes \overline{b} \mapsto \overline{ab}. $$
The latter is the composition of the natural isomorphism $V/I_1 \otimes_V V/I_1 \sim V/I_1$ and the projection $V/I_1 \to V/I_2$, so we are reduced to checking that $I_1 = I_2$. But if $x^2y = 0$ for some $y \in V$, then $(xy)^2 = 0$, hence $xy = 0$, since $V$ is reduced, and so $y \in I_1$, whence the contention.

(ii): Set $L := J_1 \otimes_V \cdots \otimes_V J_k$ and $J := J_1 \cdots J_k$; the natural map $\varphi : L \to J$ is surjective, so it remains to check that it is injective, under the assumptions of (ii). However, notice that, for every $p \in Y := \text{Min } V$, the localization $V_p$ is a field, since $V$ is reduced; it follows easily that $\varphi_p : L_p \to J_p$ is an isomorphism for every such $p$. We are then reduced to checking that the natural map $\psi_L : L \to \prod_{p \in \text{Min } V} L_p$ is injective. However, endow $Y$ with the topology induced by $X := \text{Spec } V$ via the inclusion map $i : Y \to X$, and denote by $L^\sim$ the quasi-coherent $O_X$-module arising from $L$. Then $\psi_L$ is a composition of maps

$$L \xrightarrow{\psi_L} \Gamma(Y, i^* L^\sim) \xrightarrow{\psi_p^\sim} \prod_{p \in Y} L_p = \prod_{p \in Y} L_p$$

and $\psi_p^\sim$ is obviously injective. Thus, it remains to show that $\psi_L$ is injective. But, by Lazard’s theorem [95, Ch.1, Th.1.2], $L$ is the colimit of a filtered system $(F_\lambda \mid \lambda \in \Lambda)$ of free $V$-modules of finite rank, so $L^\sim$ is the colimit of the induced filtered system $(F^{\sim}_\lambda \mid \lambda \in \Lambda)$ of quasi-coherent $O_X$-modules. By lemma [10.1.7](i), we are then reduced to checking that the natural map $F_\lambda \to \Gamma(Y, i^* F^{\sim}_\lambda)$ is injective for every $\lambda \in \Lambda$. For the latter, it suffices to check that the natural map $\psi_V : V \to \Gamma(Y, i^* O_X)$ is injective; but the composition of $\psi_V$ with the natural map $\Gamma(Y, i^* O_X) \to \prod_{p \in Y} O_{X,p} = \prod_{p \in Y} V_p$ is injective, since $V$ is reduced, whence the claim. □

**Remark 14.1.3.** As a corollary, we see that if $(V, m)$ is a basic setup (in the sense of [59, §2.1.1]), such that $V$ is a reduced ring, then the natural map $\widetilde{m} \to m$ is an isomorphism, provided that either (a) $m$ is a filtered union of principal ideal, or else (b) $\widetilde{m}$ is a flat $V$-module, and $\text{Min } V$ is a quasi-compact subset of $\text{Spec } V$.

14.1.4. Let now $(V, m)$ be any basic setup in the sense of [59, §2.1.1], and $R$ any $V$-algebra. For every interval $I \subset \mathbb{N}$, we have a localization functor

$$C^I (R\text{-Mod}) \to C^I (R^a\text{-Mod}) \quad K^\bullet \mapsto K^\bullet_a$$

from complexes of $R$-modules, to complexes of $R^a$-modules, which is obviously exact, hence it induces a derived localization functor:

$$D^I (R\text{-Mod}) \to D^I (R^a\text{-Mod}).$$

The functor (14.1.5) admits a left (resp. right) adjoint

$$C^I (R^a\text{-Mod}) \to C^I (R\text{-Mod}) \quad K^\bullet \mapsto K^\bullet_\ast \quad (\text{resp. } K^\bullet \mapsto K^\bullet_\ast)$$

defined by applying termwise to $K^\bullet$ the functor $M \mapsto M_\ast$ (resp. $M \mapsto M_\ast$) for $R^a$-modules given by [59, §2.2.10, §2.2.21]. However, if $\widetilde{m}$ is not flat, the functor $M \mapsto M_\ast$ is obviously not exact, and the localization functor $R\text{-Mod} \to R^a\text{-Mod}$ does not send injectives to injectives (cp. [59, Cor.2.2.24]). This makes it trickier to deal with constructions in the derived category; for instance, if $\widetilde{m}$ is flat, we get a left adjoint to (14.1.6), simply by deriving trivially the exact functor $M \mapsto M_\ast$. This fails in the general case, but we shall see later that a suitable derived version of the construction of $M_\ast$ is still available.

14.1.8. For any interval $I \subset \mathbb{N}$, let $\Sigma_I$ be the multiplicative set of morphisms $\varphi$ in $D^I (R\text{-Mod})$ such that $\varphi^a$ is an isomorphism in $D^I (R^a\text{-Mod})$; arguing as in the proof of [125, Prop.10.4.4], one sees that $\Sigma_I$ is right locally small, hence the localized category $\Sigma_I^{-1} D^I (R\text{-Mod})$ has small Hom-sets (proposition [1.6.16](ii)) which are independent (up to natural isomorphism) of the choice of universe. Obviously the derived localization functor factors through a natural functor

$$\Sigma_I^{-1} D^I (R\text{-Mod}) \to D^I (R^a\text{-Mod}).$$
Lemma 14.1.10. (i) For every interval $I$, the functor $\Sigma_I^{-1}D^i(R\text{-Mod})$ is an equivalence.

(ii) For every $K^\bullet, L^\bullet \in \text{Ob}(D^i(R\text{-Mod}))$ the induced $R^a$-linear morphism

$$\text{Hom}_{D^i(R\text{-Mod})}(K^\bullet, L^\bullet)^a \to \text{Hom}_{D^i(R^a\text{-Mod})}(K^{\ast a}, L^{\ast a})^a$$

is an isomorphism.

Proof. (i): A proof is sketched in [59, §2.4.9], in case $m$ is flat, but in fact this assumption is superfluous. Indeed, since the unit of adjunction $M \to M^a$ is an isomorphism ([59 Prop.2.2.23(ii)]), it is clear that the functor $K^\bullet \mapsto K^\bullet$ of (14.1.7) descends to a functor (14.1.11)

$$D^i(R^a\text{-Mod}) \to \Sigma_I^{-1}D^i(R\text{-Mod})$$

such that the composition (14.1.9) $\circ$ (14.1.11) is naturally isomorphic to the identity automorphism of $D^i(R^a\text{-Mod})$. Likewise, a simple inspection shows that (14.1.11) $\circ$ (14.1.9) is naturally isomorphic to the identity of $\Sigma_I^{-1}D^i(R\text{-Mod})$, whence the contention.

(ii): The $R$-module $\text{Hom}_{\Sigma_I^{-1}D^i(R\text{-Mod})}(K^\bullet, L^\bullet)$ is calculated as the colimit of the system of $R$-modules $(\text{Hom}_{D^i(R\text{-Mod})}(K^\bullet, L^\bullet)\mid \varphi^\bullet : K^\bullet \to K^\bullet)$, where $\varphi^\bullet$ ranges over the elements of $\Sigma_I$ with target $K^\bullet$. For such a morphism $\varphi^\bullet$, we have $m \cdot H^i(Cone \varphi^\bullet) = 0$ for every $i \in \mathbb{Z}$.

Claim 14.1.12. Let $C^\bullet$ be any object of $D^i(R\text{-Mod})$ such that $(H^iC^\bullet)^a = 0$ for every $i \in \mathbb{Z}$. Then $\text{Hom}_{D^i(R\text{-Mod})}(C^\bullet, L^\bullet)^a = 0$ for every $L^\bullet \in \text{Ob}(D^i(R\text{-Mod}))$.

Proof of the claim. Set $H_{n,k} := \text{Hom}_{D^i(R\text{-Mod})}(C^\bullet, (\tau^{\geq -n}L^\bullet)[k])$ for every $n, k \in \mathbb{N}$; the natural morphism $L^\bullet \to \lim_{n \in \mathbb{N}} \tau^{\geq -n}L^\bullet$ is an isomorphism in $\mathbb{C}(R\text{-Mod})$, so we have a short exact sequence

$$0 \to \lim_{n \in \mathbb{N}} H_{n,-1} \to \text{Hom}_{D^i(R\text{-Mod})}(C^\bullet, L^\bullet) \to \lim_{n \in \mathbb{N}} H_{n,0} \to 0$$

(proposition 7.3.43(iii)). Hence, it suffices to check that $H_{n,0}^a = H_{n,-1}^a = 0$ for every $n \in \mathbb{N}$, and we are reduced to the case where $L^\bullet$ is bounded below.

Likewise, set $H_n^\prime := \text{Hom}_{D^i(R\text{-Mod})}(\tau^{\leq n}C^\bullet, L^\bullet)$ for every $n \in \mathbb{Z}$; since the natural morphism $\text{colim}_{n \in \mathbb{N}} \tau^{\leq n}C^\bullet \to C^\bullet$ is an isomorphism in $\mathbb{C}(R\text{-Mod})$, we have an isomorphism

$$\text{Hom}_{D^i(R\text{-Mod})}(C^\bullet, L^\bullet) \cong \lim_{n \in \mathbb{N}} H_n^\prime$$

(proposition 7.3.43(ii)), so we may assume that $C^\bullet$ is a bounded above complex. In this situation, say that $L^\bullet \in \text{Ob}(D^{\geq 0}(R\text{-Mod}))$ and $C^\bullet \in \text{Ob}(D^{\leq b}(R\text{-Mod}))$ for some $a, b \in \mathbb{Z}$; we may assume that $a \leq b$, and we show, by induction on $n$, that $(H_n^\prime)^a = 0$ for every $n \geq a - 1$.

The claim will follow for $n = b$. Indeed, notice that

$$H_r^\prime = \text{Hom}_{D^i(R\text{-Mod})}(\tau^{\leq r}C^\bullet, \tau^{\leq r}L^\bullet)$$

for every $r \in \mathbb{Z}$

by virtue of remark 7.3.14(iv), so the assertion is clear for $n = a - 1$. Next, suppose that the assertion is already known for every integer $< n$; from the short exact complexes $0 \to \tau^{\leq n-1}C^\bullet \to \tau^{\leq n}C^\bullet \to (H_nC^\bullet)[-n] \to 0$ we deduce the exact sequence

$$\text{Hom}_{D^i(R\text{-Mod})}((H_nC^\bullet)[-n], L^\bullet) \to H_n^\prime \to H_{n-1}^\prime$$

(remark 7.3.33). But since $m \cdot H^aC^\bullet = 0$, the first term in this exact sequence is annihilated by $m$, and the same holds for the third term, by inductive assumption; then it holds for the middle term as well, as required.

By claim 14.1.12 we have $\text{Hom}_{D^i(R\text{-Mod})}(\text{Cone} \varphi^\bullet, L^\bullet)^a = 0$; by considering the long exact $\text{Hom}_{D^i(R\text{-Mod})}(-, L^\bullet)$-sequence associated with the distinguished triangle $K^\bullet \to K^\bullet \to \text{Cone} \varphi^\bullet$, we deduce an $R^a$-linear isomorphism

$$\text{Hom}_{D^i(R\text{-Mod})}(\varphi^\bullet, L^\bullet)^a : \text{Hom}_{D^i(R\text{-Mod})}(K^\bullet, L^\bullet)^a \cong \text{Hom}_{D^i(R\text{-Mod})}(K^\bullet, L^\bullet)^a$$

(see remark 7.3.33). In light of (i), the assertion follows straightforwardly.
14.1.13. We sketch a few generalities on derived tensor products, that will be applied to construct useful objects in various derived categories. Recall first that the tensor product $- \otimes_R -$ on $R$-modules descends to a bifunctor $- \otimes_{R_0} -$ ([59], §2.2.6, §2.2.12), and if $M$ is a flat $R$-module, then $M^a$ is a flat $R^a$-module ([59], Lemma 2.4.7). It follows that the category $R^a$-$\text{Mod}$ has enough flat objects, so every bounded above complex of $R^a$-modules admits a bounded above flat resolution. Now, given bounded above complexes $K^\bullet$, $L^\bullet$ of $R^a$-modules, set

$$K^\bullet \otimes^{L}_{R^a} L^\bullet := (K^\bullet \otimes^{L}_R L^\bullet)^a$$

which is a well defined object of $D(R^a$-$\text{Mod})$.

- We claim that this rule yields a well defined functor

$$- \otimes^{L}_{R^a} : D^{-}(R^a$-$\text{Mod}) \times D^{-}(R^a$-$\text{Mod}) \to D^{-}(R^a$-$\text{Mod}).$$

Indeed, suppose $\varphi^\bullet : K^\bullet \to K'^\bullet$ is a morphism in $C(R^a$-$\text{Mod})$, inducing an isomorphism in $D(R^a$-$\text{Mod})$, and set $C^\bullet := \text{Cone}(\varphi^\bullet)$; clearly, $C^a\bullet = 0$ in $D(R^a$-$\text{Mod})$. Now, pick any flat bounded above resolution $P^\bullet \to K^\bullet$, so that $K^\bullet_i \otimes R P^\bullet$ computes $K^\bullet_i \otimes_R L^\bullet_i$, for $i = 1, 2$. We get natural isomorphism:

$$\text{Cone}(\varphi^\bullet \otimes_{R^a} L^\bullet) \sim (C^\bullet \otimes_{R} P^\bullet)^a \sim C^a\bullet \otimes_{R^a} P^a\bullet = 0,$$

so the derived tensor product depends only on the image of $K^\bullet$ in $D^{-}(R^a$-$\text{Mod})$; likewise for the argument $L^\bullet$, whence the contention.

- Next, suppose that $P^\bullet \to K^\bullet$ is a bounded above resolution, with $P^\bullet$ a complex of flat $R^a$-modules; we claim that there is a natural isomorphism in $D(R^a$-$\text{Mod})$

$$K^\bullet \otimes^{L}_{R^a} L^\bullet \sim P^\bullet \otimes_{R^a} L^\bullet.$$  

Indeed, pick any bounded above flat resolution $Q^\bullet \to L^\bullet$; we have natural isomorphisms

$$K^\bullet \otimes^{L}_{R^a} L^\bullet \sim (K^\bullet \otimes_{R} Q^\bullet)^a \sim K^\bullet \otimes_{R^a} Q^\bullet a \sim P^\bullet \otimes_{R^a} Q^\bullet a$$

in $D(R^a$-$\text{Mod})$, where the last holds, since $Q^\bullet a$ is a complex of flat $R^a$-modules. Finally, the induced map

$$P^\bullet \otimes_{R^a} Q^\bullet a \to P^\bullet \otimes_{R^a} L^\bullet$$

is also an isomorphism in $D(R^a$-$\text{Mod})$, since $P^\bullet$ is a complex of flat $R^a$-modules, so the claim follows.

- Notice that, for any $K^\bullet \in \text{Ob}(D^{-}(R$-$\text{Mod}))$ and any flat resolution $P^\bullet \to K^\bullet$, the induced morphism $P^\bullet a \to K^\bullet a$ is a flat resolution; it follows that, for any $L^\bullet \in \text{Ob}(D(R$-$\text{Mod}))$ we get a natural isomorphism

$$(14.1.14) \quad (K^\bullet \otimes^{L}_{R} L^\bullet)^a \sim K^\bullet a \otimes_{R^a} L^\bullet a \quad \text{in } D(R^a$-$\text{Mod}).$$

**Remark 14.1.15.** Clearly, for the derived tensor products of $R^a$-modules, one has the same commutativity and associativity isomorphisms as the ones detailed in remark 7.3.37(i) for usual modules, as well as the vanishing properties of lemma 7.3.40(ii).

We are now ready to return to the question of the existence of adjoints to derived localization. The key point is the following:

**Lemma 14.1.16.** In the situation of (14.1.14), let $K^\bullet$ be any complex of $R$-modules, $i \in \mathbb{Z}$ any integer and suppose that :

(a) $K^\bullet \in \text{Ob}(D^{\leq i}(R$-$\text{Mod}))$

(b) $K^\bullet a \in \text{Ob}(D^{\leq i-1}(R^a$-$\text{Mod})).$

Then $m \otimes_V K^\bullet \in \text{Ob}(D^{\leq i-1}(R$-$\text{Mod})).$
Proof. We apply the standard spectral sequence

\[ E^2_{pq} := \text{Tor}^V_p(m, H^qK^*) \Rightarrow H^{q-p}(m \otimes_V K^*). \]

Indeed, (a) says that \( H^qK^* = 0 \) for every \( q > i \), and (b) says that \( (H^qK^*)^a = 0 \), and therefore \( m_V \otimes_V H^iK^* = 0 \) ([59 Rem.2.1.4(i)]). In either case, we conclude that \( E^2_{pq} = 0 \) whenever \( q-p \geq i \), whence the lemma.

14.1.17. Now, let us define inductively:

\[ \mathcal{M}^i_0 := V[0] \quad \text{and} \quad \mathcal{M}^i_{i+1} := m \otimes_V \mathcal{M}^i_i \quad \text{for every} \quad i \in \mathbb{N}. \]

A simple induction shows that \( \mathcal{M}^i_i \in D^{\leq 0}(V\text{-Mod}) \) for every \( i \in \mathbb{N} \), so all these derived tensor products are well defined in \( D^{\leq 0}(V\text{-Mod}) \). Moreover, from the short exact sequence of \( V \)-modules

\[ \Sigma : 0 \rightarrow m \rightarrow V \rightarrow V/m \rightarrow 0 \]

we obtain a distinguished triangle

\[ \mathcal{M}^i_i \otimes_V \Sigma : \mathcal{M}^i_{i+1} \rightarrow \mathcal{M}^i_i \rightarrow \mathcal{M}^i_i \otimes_V (V/m) \rightarrow \mathcal{M}^i_{i+1}[1] \quad \text{for every} \quad i \in \mathbb{N}. \]

Especially, we get an inverse system of morphisms in \( D^{\leq 0}(V\text{-Mod}) \):

\[ \cdots \rightarrow \mathcal{M}^i_{i+1} \rightarrow \mathcal{M}^i_i \rightarrow \mathcal{M}^i_i \otimes_V (V/m) \rightarrow \cdots \rightarrow \mathcal{M}^i_0 := V[0]. \]

Also, from (14.1.14) we deduce natural isomorphisms in \( D^{\leq 0}(V^a\text{-Mod}) \):

(14.1.18) \( \mathcal{M}^i_i \simeq V^a[0] \quad \text{for every} \quad i \in \mathbb{N} \)

and under these identifications, the morphism \( \pi^a \) corresponds to the identity automorphism of \( V^a[0] \) (details left to the reader). Furthermore, we deduce the following derived version of [59 Rem.2.1.4(ii)]:

**Proposition 14.1.19.** Let \( a, b \in \mathbb{Z} \) be any integers with \( a \leq b \). We have:

(i) For every \( K^* \in \text{Ob}(D^{[a,b]}(R\text{-Mod})) \), the following conditions are equivalent:

(a) \( K^* \simeq 0 \) in \( D^{[a,b]}(R^a\text{-Mod}) \).

(b) \( \tau \geq a(\mathcal{M}^i_{b-a+1} \otimes_V K^*) \simeq 0 \) in \( D^{[a,b]}(R\text{-Mod}) \).

(ii) For every morphism \( \varphi^* : K^* \rightarrow L^* \) in \( D^{\leq b}(R\text{-Mod}) \), the following conditions are equivalent:

(a) \( \varphi^a \) is an isomorphism in \( D^{[a,b]}(R^a\text{-Mod}) \).

(b) \( \tau \geq a(\mathcal{M}^i_{b-a+2} \otimes_V \varphi^*) \) is an isomorphism in \( D^{[a,b]}(R\text{-Mod}) \).

**Proof.** (i): From (14.1.18), it is easily seen that (b)\( \Rightarrow \) (a). The other direction follows straightforwardly from lemma 14.1.16 via an easy descending induction on \( b \).

(ii): Again, the direction (b)\( \Rightarrow \) (a) is immediate from (14.1.18). For the other direction, denote by \( C^* \) the cone of \( \varphi^* \); then \( C^* \in \text{Ob}(D^{[a-1,b]}(R\text{-Mod})) \), and \( C^a \simeq 0 \) in \( D^{[a-1,b]}(R^a\text{-Mod}) \). From (i) we deduce that \( \tau \geq a-1(\mathcal{M}^i_{b-a+2} \otimes_V C^*) \simeq 0 \) in \( D^{[a-1,b]}(R\text{-Mod}) \). Since the derived tensor product is a triangulated functor, the assertion follows easily: details left to the reader.

**Corollary 14.1.20.** With the notation of (14.1.17), the morphism

\[ \tau \geq 2-i \mathcal{M}^i_{i+1} \rightarrow \tau \geq 2-i \mathcal{M}^i_i \]

is an isomorphism in \( D^{[2-i,0]}(V\text{-Mod}) \) for every integer \( i \geq 2 \).
Proof. By construction, we have a natural isomorphism:

\[
\text{Cone}(\tau^{2-i} \pi^\ast) \cong \tau^{1-i} (\mathcal{M}_\ast \otimes_V (V/\mathfrak{m})) \quad \text{in } D^{[-i,0]}(V\text{-Mod})
\]

in light of which, the assertion is an immediate consequence of proposition 14.1.19(i). \[\square\]

**Proposition 14.1.21.** In the situation of (14.1.4), we have:

(i) The localization functor \(D^+(R\text{-Mod}) \to D^+(R^a\text{-Mod})\) admits the right adjoint:

\[
D^+(R^a\text{-Mod}) \to D^+(R\text{-Mod}) : \quad K^\ast \mapsto K^\ast[a] := R\text{Hom}_{R^a}^\ast (R^a[0], K^\ast).
\]

(ii) Let \(a, b, i \in \mathbb{Z}\) be any three integers with \(b \geq a\) and \(i \geq b - a + 2\). The localization functor \(D^{[a,b]}(R\text{-Mod}) \to D^{[a,b]}(R^a\text{-Mod})\) admits the left adjoint:

\[
D^{[a,b]}(R^a\text{-Mod}) \to D^{[a,b]}(R\text{-Mod}) : \quad K^\ast \mapsto K^\ast[a] := \tau^{\geq a} (\mathcal{M}_\ast \otimes_V K^\ast[a]).
\]

and the right adjoint

\[
D^{[a,b]}(R^a\text{-Mod}) \to D^{[a,b]}(R\text{-Mod}) : \quad K^\ast \mapsto \tau^{\leq b} K^\ast[a].
\]

(iii) For every \(K^\ast \in \text{Ob}(D^+(R^a\text{-Mod}))\) (resp. \(L^\ast \in \text{Ob}(D^{[a,b]}(R^a\text{-Mod}))\)) the counit of adjunction is an isomorphism

\[
(K^\ast[a])^\ast \cong K^\ast \quad \text{(resp. } (\tau^{\leq b} L^\ast[a])^\ast \cong L^\ast)\).
\]

(iv) For every \(L^\ast \in \text{Ob}(D^{[a,b]}(R^a\text{-Mod}))\), the unit of adjunction is an isomorphism

\[
L^\ast \to (L^\ast[a])^\ast.
\]

**Proof.** (i): This is analogous to lemma 10.1.16(iii). Recall the construction: we know that the category \(R^a\text{-Mod}\) admits enough injectives ([59, 2.2.18]), hence (14.1.22) can be represented by \(I^\ast\), where \(K^\ast \cong I^\ast\) is any injective resolution of \(K^\ast\), and \(I^\ast\) is obtained by applying termwise to \(I^\ast\) the functor \(M \mapsto M_\ast\) of [59, §2.2.10]. Indeed, taking into account [59, Cor.2.2.19] we get natural isomorphisms:

\[
\text{Hom}_{D^+(R\text{-Mod})}(L^\ast, I^\ast) \cong H^0 \text{Hom}_R^\ast (L^\ast, I^\ast)
\]

\[
\cong H^0 \text{Hom}_{R^a}^\ast (L^\ast[a], I^\ast)
\]

\[
\cong \text{Hom}_{D(R^a\text{-Mod})}(L^\ast[a], I^\ast)
\]

\[
\cong \text{Hom}_{D(R\text{-Mod})}(L^\ast[a], K^\ast)
\]

for every bounded below complex \(L^\ast\) of \(R\)-modules.

(iii) follows by direct inspection of the definitions, taking into account that, for every \(R^a\)-module \(M\), the counit of adjunction \((M_\ast)^a \to M\) is an isomorphism ([59, Prop.2.2.14(iii)]): details left to the reader.

(ii): We consider first the assertion concerning the right adjoint: let \(K^\ast \in D^{[a,b]}(R^a\text{-Mod})\); we may find an injective resolution \(K^\ast \cong I^\ast\) such that \(I^j = 0\) for every \(j < a\), in which case \(I^\ast \in D^{\geq a}(R\text{-Mod})\), and \(\tau^{\leq b} I^\ast\) represents \(\tau^{\leq b} K^\ast[a]\) in \(D^{[a,b]}(R\text{-Mod})\). Then, in view of (i), the assertion is reduced to remark 7.3.14(iv). For the left adjoint, let us set

\[
\omega L^\ast := \tau^{\geq a} (\mathcal{M}_\ast \otimes_V L^\ast) \quad \text{for every } L^\ast \in \text{Ob}(D^{[a,b]}(R\text{-Mod})).
\]

Then \(\omega L^\ast\) is naturally an object of \(D^{[a,b]}(R\text{-Mod})\), as explained in remark 7.3.37(ii), and likewise for \(K^\ast[a]\) if \(K^\ast\) is any object of \(D^{[a,b]}(R^a\text{-Mod})\). We begin with the following:

**Claim 14.1.23.** Let \(K^\ast, L^\ast \in \text{Ob}(D^{[a,b]}(R\text{-Mod}))\) be any two objects. Then the natural map

\[
\text{Hom}_{D^{[a,b]}(R\text{-Mod})}(\omega K^\ast, L^\ast) \to \text{Hom}_{D^{[a,b]}(R^a\text{-Mod})}(K^\ast[a], L^\ast[a])
\]

is an isomorphism.
Proof of the claim. Arguing as in [59, §2.2.2], and taking into account lemma [14.1.10](i), we reduce to showing that for any \( K^\bullet \in D^{[a,b]}(R\text{-Mod}) \), the natural morphism

\[ \varphi_{K^\bullet} : \omega K^\bullet \to K^\bullet \]

is initial in the full subcategory of \( D^{[a,b]}(R\text{-Mod})/K^\bullet \) whose objects are the morphisms \( \psi : L^\bullet \to K^\bullet \) that lie in \( \Sigma_{[a,b]} \). However, say that \( \alpha, \beta \) are such that \( \alpha \neq \beta \). Let \( \varphi \) be any such \( \psi \). We have a commutative diagram in \( D^{[a,b]}(R\text{-Mod}) \):

\[
\begin{array}{ccc}
\omega L^\bullet & \xrightarrow{\varphi_{L^\bullet}} & L^\bullet \\
\downarrow & & \downarrow \\
\omega K^\bullet & \xrightarrow{\varphi_{K^\bullet}} & K^\bullet \\
\end{array}
\]

whose left vertical arrow is an isomorphism, by proposition [14.1.19](ii). There follows a morphism \( \varphi_{K^\bullet} \to \psi \), and we have to check that this is the unique morphism from \( \varphi_{K^\bullet} \) to \( \psi \). However, say that \( \alpha, \beta : \varphi_{K^\bullet} \to \psi \) are two such morphisms; then their difference is a morphism \( \gamma := \alpha - \beta : \omega K^\bullet \to L^\bullet \) such that \( \psi \circ \gamma = 0 \), so \( \gamma \) factors through a morphism \( \tau \) : \( \omega K^\bullet \to \text{Cone} \psi[-1] \). Set \( C^\bullet := \tau^{=k}\text{Cone} \psi[-1] \); then \( C^\bullet \in D^{[a,b]}(R\text{-Mod}) \), and according to remark [7.3.14](iv), \( \tau \) lifts uniquely to a morphism \( \omega K^\bullet \to C^\bullet \) that we denote again \( \tau \). We deduce a commutative diagram

\[
\begin{array}{ccc}
\omega \circ \omega K^\bullet & \xrightarrow{\varphi_{\omega K^\bullet}} & \omega C^\bullet \\
\downarrow \varphi_{\omega K^\bullet} & & \downarrow \varphi_{C^\bullet} \\
\omega K^\bullet & \xrightarrow{\tau} & C^\bullet \\
\end{array}
\]

Now, by construction \( C^{\ast a} = 0 \), therefore \( \omega C^\bullet = 0 \) (proposition [14.1.19](i)); on the other hand, \( \varphi_{\omega K^\bullet} \) is an isomorphism, by proposition [14.1.19](ii). We conclude that \( \tau = 0 \), whence \( \alpha = \beta \), as sought.

Assertion (ii.a) is an immediate consequence of (iii) and claim [14.1.23] from this, also (iv) is immediate : details left to the reader. \( \square \)

Remark 14.1.24. Let \( a, b, i \in \mathbb{Z} \) be any three integers such that \( a \leq b \) and \( i \geq b - a + 2 \). From propositions [14.1.21](ii.a,iii) and [14.1.19](ii) we deduce a natural isomorphism

\[ \tau^{=a} (\mathcal{M_i}^L \otimes_V K^\bullet) \xrightarrow{\sim} (K^{\ast a})_{[i]} \quad \text{for every} \quad K^\bullet \in \text{Ob}(D^{[a,b]}(R\text{-Mod})) \]

(details left to the reader), which allows to compute \( (K^{\ast a})_{[i]} \) purely in terms of \( K^\bullet \) and operations within \( D(R\text{-Mod}) \). It turns out that an analogous isomorphism is available also for \( K_{[\ast]} : \) this is contained in the following

Lemma 14.1.25. Let \( a, b, i \in \mathbb{N} \) be any integers such that \( a \leq b \) and \( i \geq b - a + 2 \). For every \( K^\bullet \in \text{Ob}(D^{[a,b]}(R\text{-Mod})) \), we have a natural isomorphism:

\[ \tau^{\leq b} \text{RHom}_V^\bullet (\mathcal{M_i}^L, K^\bullet) \xrightarrow{\sim} \tau^{\leq b} K_{[\ast]}^a. \]

Proof. Theorem [10.1.18](ii) yields a natural isomorphism

\[ \text{RHom}_V^\bullet (\mathcal{M_i}^L, K^\bullet) \xrightarrow{\sim} \text{RHom}_R^\bullet (\mathcal{M_i}^L \otimes_V R[0], K^\bullet). \]

To compute the right-hand side, we may fix an injective resolution \( K^\bullet \xrightarrow{\sim} I^\bullet \); the complex \( I^{\ast a} \) is not necessarily injective, but we can find an injective resolution \( \varphi : I^{\ast a} \xrightarrow{\sim} J^\bullet \) (in the category of bounded below complexes of \( R^\ast \)-modules). In view of [14.1.14] and [14.1.18], the morphism \( \varphi \) induces a natural transformation

\[ \psi : \text{RHom}_R^\bullet (\mathcal{M_i}^L \otimes_V R[0], K^\bullet) \to \text{RHom}_R^\bullet (R^{[a][\ast]}, K^{\ast a}) = (K^{\ast a})_{[\ast]} \]
and it suffices to show that, for every $j \leq b$, the map
\[ H^j \psi : \text{Hom}_{D(R, \text{Mod})}(\mathfrak{M}_i \overset{L}{\otimes}_V R[0], K^*[j]) \to \text{Hom}_{D(R^n, \text{Mod})}(R^n[0], K^{*a}[j]) \]
is an isomorphism. However, by remark 7.3.14(iv), the latter is the same as a map
\[ (14.1.26) \quad \text{Hom}_{D(R, \text{Mod})}(\mathfrak{M}_i \overset{L}{\otimes}_V R[0], \tau^{-c} K^*[j]) \to \text{Hom}_{D(R^n, \text{Mod})}(R^n[0], \tau^{-c} K^{*a}[j]) \]
and a direct inspection shows that (14.1.26) agrees with the map arising in claim 14.1.23, for every $j \leq b$. Especially, for every such $j$, the map (14.1.26) is an isomorphism, as sought. $\square$

**Proposition 14.1.27.** Let $a, b, c \in \mathbb{Z}$ be any three integers such that $a \leq b$, and $K^*, L^*$ any two objects of $D^{[a,b]}(R, \text{Mod})$. Suppose that

(a) $\text{Hom}_{D(R, \text{Mod})}(K^*, X[-j]) = 0$ for all $j \in [c, b]$ and all $R$-modules $X$ with $X^a = 0$.

(b) $\text{Hom}_{D(R, \text{Mod})}(X[-j], L^*) = 0$ for all $j \in [a, c]$ and all $R$-modules $Y$ with $Y^a = 0$.

Then the natural map
\[ (14.1.28) \quad \text{Hom}_{D(R, \text{Mod})}(K^*, L^*) \to \text{Hom}_{D(R^n, \text{Mod})}(K^{*a}, L^{*a}) \]
is an isomorphism.

**Proof.** We start out with the following observation:

**Claim 14.1.29.** Consider the following conditions:

(a') $\text{Hom}_{D(R, \text{Mod})}(K^*, X^*) = 0$ for every $X^* \in \text{Ob}(D^{[c,b]}(R, \text{Mod}))$ such that $X^a = 0$.

(b') $\text{Hom}_{D(R, \text{Mod})}(Y^*, L^*) = 0$ for every $Y^* \in \text{Ob}(D^{[a,c]}(R, \text{Mod}))$ such that $Y^a = 0$.

Then (a)$\iff$(a') and (b)$\iff$(b').

**Proof of the claim.** Obviously (a')$\Rightarrow$(a). For the converse, one argues by decreasing induction on $c \leq b$. Indeed, the case $c = b$ is immediate. Then, suppose that the sought equivalence has already been established for some $d \leq b$; if $X^* \in D^{d-1,b]}(R, \text{Mod})$ and $X^a = 0$, and if we know that (a) holds with $c := d - 1$, we set $H^* := H^*X^*[-c]$, and consider the distinguished triangle
\[ H^* \to X^* \to \tau^{-c} X^* \to H^*[1]. \]

By inductive assumption, we have $\text{Hom}_{D(R, \text{Mod})}(K^*, \tau^{-c} X^*) = 0$, and (a) says that
\[ \text{Hom}_{D(R, \text{Mod})}(K^*, H^*) = 0. \]

It then follows that $\text{Hom}_{D(R, \text{Mod})}(K^*, X^*) = 0$, which shows that the equivalence holds for $c$.

The proof of the equivalence (b)$\iff$(b') is wholly analogous. $\diamond$

Fix an integer $i \geq b - a + 2$, and set
\[ C^* := \text{Cone}((\pi_{i}^* \circ \cdots \circ \pi_{i}^* : \mathfrak{M}_i \to V[0]) \]
(note of (14.1.17)); notice that $C^* \in D^{c-1}(R, \text{Mod})$, and $C^*a = 0$. By virtue of condition (b), claim 14.1.29 and remark 7.3.14(iv), it follows that:
\[ R^i \text{Hom}_{R}^*(C^*, L^*) = \text{Hom}_{D(R, \text{Mod})}(\tau^{\geq a}(C^*[-j]), L^*) = 0 \quad \text{for every } j < c \]
In other words, $D^* := R\text{Hom}_{R}^*(C^*, L^*) \in D^{c}(R, \text{Mod})$, and clearly $D^{*a} = 0$; also notice the induced distinguished triangle
\[ \Sigma : D^* \to L^* \to R\text{Hom}_{R}^*(\mathfrak{M}_i^*, L^*) \to D^*[-1]. \]
Now, condition (a), claim 14.1.29 and remark 7.3.14(iv) imply that
\[ \text{Hom}_{D(R, \text{Mod})}(K^*, D^*[j]) = \text{Hom}_{D(R, \text{Mod})}(K^*, \tau^{\geq b} D^*[j]) = 0 \quad \text{for every } j \leq 0 \]
whence, by considering the distinguished triangle $R\text{Hom}_{\omega}^* (K^*, \Sigma)$, natural isomorphisms
\[
\text{Hom}_{\mathcal{D}(R\text{-Mod})}(K^*, L^*) \sim \text{Hom}_{\mathcal{D}(R\text{-Mod})}(K^*, R\text{Hom}_{\omega}^* \otimes_V K^*)
\]
\[
\sim \text{Hom}_{\mathcal{D}(R\text{-Mod})}(\mathcal{M}_R^* \otimes_V K^*, L^*) \quad (\text{by } \text{[125, Th.10.8.7]})
\]
\[
\sim \text{Hom}_{\mathcal{D}(R\text{-Mod})}(\tau^{-a} \mathcal{M}_R^* \otimes_V K^*, L^*) \quad (\text{by remark } \text{[7.3.14 iv]})
\]
\[
\sim \text{Hom}_{\mathcal{D}(R\text{-Mod})}(K^{*a}, L^{*a}) \quad (\text{by claim } \text{[14.1.23]})
\]
whose composition, after a simple inspection, is seen to agree with the map $\text{(14.1.28)}$. □

**Remark 14.1.30.** (i) For every interval $I \subset \mathbb{N}$, denote by
\[
\Phi_I : \mathcal{D}^I(R/mR\text{-Mod}) \rightarrow \mathcal{D}^I(R\text{-Mod})
\]
the forgetful functor. It follows easily from lemma $\text{[10.1.16 iii] and remark } \text{[7.3.14 iv]}$, that, for every interval $[a,b]$, the functor $\Phi_{[a,b]}$ admits the right adjoint
\[
\mathcal{D}^{[a,b]}(R\text{-Mod}) \rightarrow \mathcal{D}^{[a,b]}(R/mR\text{-Mod}) \quad K^* \mapsto \Psi_{[a,b]}(K^*) := \tau^{-b} R\text{Hom}_{\omega}^*(R/mR[0], K^*).
\]

(ii) Likewise, theorem $\text{[10.1.16] and remark } \text{[7.3.14 iv]}$ imply that $\Phi_{[a,b]}$ admits the left adjoint
\[
\mathcal{D}^{[a,b]}(R\text{-Mod}) \rightarrow \mathcal{D}^{[a,b]}(R/mR\text{-Mod}) \quad K^* \mapsto \psi_{[a,b]}(K^*) := \tau^{-a}(K^* \otimes_R R/mR[0]).
\]

(iii) Consider as well the following two conditions :

(a”) $\text{Hom}_{\mathcal{D}(R\text{-Mod})}(K^*, \Phi_{[c,b]} X^*) = 0$ for every $X^* \in \text{Ob}(\mathcal{D}^{[c,b]}(R/mR\text{-Mod})).$

(b”) $\text{Hom}_{\mathcal{D}(R\text{-Mod})}(\Phi_{[a,c]} Y^*, L^*) = 0$ for every $Y^* \in \text{Ob}(\mathcal{D}^{[a,c]}(R/mR\text{-Mod})).$

Then, arguing as in the proof of claim $\text{[14.1.29] it is easily seen that condition (a) of proposition } \text{[14.1.27] is equivalent to (a”), and condition (b) is equivalent to (b”).}

**Proposition 14.1.31.** Let $a, b \in \mathbb{Z}$ be any two integers such that $a \leq b$. For every object $K^*$ of $\mathcal{D}^{[a,b]}(R\text{-Mod})$, the following conditions are equivalent :

(a) $K^*$ lies in the essential image of the left adjoint functor $X^* \mapsto X^*_{[1]}$.

(b) $K^* \otimes_R R/mR[0] \in \text{Ob}(\mathcal{D}^{<a-1}(R/mR\text{-Mod})).$

**Proof.** We start out with the following :

**Claim 14.1.32.** We may assume that $V = R$.

**Proof of the claim.** Clearly condition (b) does not depend on the underlying ring $V$. It suffices then to remark that condition (a) depends only on the basic setup $(R, mR)$ (as opposed to the original basic setup $(V, m)$). Indeed, notice that there is a natural equivalence
\[
\Omega : R^a\text{-Mod} \sim (R, mR)^a\text{-Mod}
\]
(where $R^a$ denotes, as in the foregoing, the image of $R$ in the category of $(V, m)$-algebras), and the induced equivalence of the respective derived categories fits into an essentially commutative diagram
\[
\begin{array}{ccc}
\mathcal{D}(R\text{-Mod}) & \xrightarrow{D(\Omega)} & \mathcal{D}((R, mR)^a\text{-Mod}) \\
\mathcal{D}(R^a\text{-Mod}) & \xrightarrow{D(\Omega)} & \mathcal{D}((R, mR)^a\text{-Mod})
\end{array}
\]
whose downward arrows are the forgetful functors. Especially, the left (resp. right) adjoints of these two forgetful functors share the same essential images.

Henceforth, we assume that $V = R$ (and therefore, $m = mR$). Fix an integer $i \geq b - a + 2$, set $L^* := \tau^{a-1}(\mathcal{M}_R^* \otimes_V K^*)$, and notice first that, taking into account proposition $\text{[14.1.21 iv] and remark } \text{[14.1.24] condition (a) is equivalent to :}
(c) The morphism \( \pi^* \circ \cdots \circ \pi_{i-1}^* : \mathcal{M}_i \rightarrow V[0] \) induces an isomorphism \( \tau^{\geq a} L^* \rightarrow K^* \).

(c)⇒(b): Indeed, set \( H := H^{a-1} L^* \); if (c) holds, we have a distinguished triangle
\[
H[a - 1] \rightarrow L^* \rightarrow K^* \rightarrow H[a]
\]
whence a distinguished triangle in \( D(V/m-\text{Mod}) \)
\[
(14.1.33) \quad H[a - 1] \otimes_V V/m[0] \rightarrow L^* \otimes_V V/m[0] \rightarrow K^* \otimes_V V/m[0] \rightarrow H[a] \otimes_V V/m[0].
\]
However, we have natural isomorphisms
\[
\tau^{\geq a-1}(L^* \otimes_V V/m[0]) \overset{\sim}{\rightarrow} \tau^{\geq a-1}((\mathcal{M}^i \otimes V K^*) \otimes_V V/m[0]) \quad \text{(by lemma 7.3.40(ii))}
\]
\[
\tau^{\geq a-1}((\mathcal{M}^i \otimes V K^*) \otimes_V V/m[0]) \overset{\sim}{\rightarrow} \tau^{\geq a-1}(\mathcal{M}^i \otimes_V (K^* \otimes V V/m[0])) \quad \text{(by remark 7.3.37(i))}
\]
\[
\tau^{\geq a-1}(\mathcal{M}^i \otimes_V (K^* \otimes V V/m[0])) \overset{\sim}{\rightarrow} 0 \quad \text{(by lemma 7.3.40(ii))}
\]
whence (b), after considering the distinguished triangle \( \tau^{\geq a-1}(14.1.33) \).

(b)⇒(a): We remark

\textbf{Claim 14.1.34.} Condition (b) is equivalent to condition (a’’) of remark 14.1.30(iii), with \( c := a - 1 \).

\textbf{Proof of the claim.} Indeed, (b) holds if and only if \( \Psi^i_{[a-1,b]} K^* = 0 \) in \( D^{[a,b]}(R/mR-\text{Mod}) \) (notation of remark 14.1.30(ii)). If the latter condition holds, then clearly \( (a'') \) holds with \( c := a - 1 \). Conversely, if \( (a'') \) holds for this value of \( c \), then \( \text{Hom}_{D(R/mR-\text{Mod})}(\Psi^i_{[a-1,b]} K^*, X^*) = 0 \) for every \( X^* \in D^{[a-1,b]}(R/mR-\text{Mod}) \); especially, the identity automorphism of \( \Psi^i_{[a-1,b]} K^* \) factors through 0, so \( \Psi^i_{[a-1,b]} K^* \) vanishes.

From claim 14.1.34 and remark 14.1.30(iii) we deduce that if (b) holds, condition (a) of proposition 14.1.27 holds for \( c := a - 1 \), and condition (b) of the same proposition holds trivially for this value of \( c \), for every \( L^* \in D^{[a,b]}(R-\text{Mod}) \). We conclude that the natural map
\[
\text{Hom}_{D(R-\text{Mod})}(K^*, L^*) \rightarrow \text{Hom}_{D(R-\text{Mod})}(K^{\geq a}, L^{\geq a}) \overset{\sim}{\rightarrow} \text{Hom}_{D(R-\text{Mod})}(K^{\geq a}, L^*)
\]
is an isomorphism, for every \( L^* \in D^{[a,b]}(R-\text{Mod}) \), whence (a). \( \square \)

\textbf{Proposition 14.1.35.} Let \( a, b \in \mathbb{Z} \) be any two integers such that \( a \leq b \). For every \( L^* \in \text{Ob}(D^{[a,b]}(R-\text{Mod})) \), the following conditions are equivalent:

(a) \( L^* \) lies in the essential image of the right adjoint functor \( X^* \mapsto \tau^{\leq b} X^* \).

(b) \( R\text{Hom}^a(L^*, L^*) \in \text{Ob}(D^{\geq b+1}(R/mR-\text{Mod})) \).

\textbf{Proof.} By the same argument as in the proof of claim 14.1.32, we reduce to the case where \( V = R \). Next, fix \( i \in \mathbb{N} \) such that \( i \geq b - a + 2 \), define
\[
K^* := R\text{Hom}^i (\mathcal{M}_i^L, L^*) \quad Q_i := \mathcal{M}_i^L \otimes_V V/m[0]
\]
and notice that
\[
(14.1.36) \quad \tau^{\geq a-b-1} Q_i = 0 \quad \text{in } D^{[a-b-1,0]}(V/m-\text{Mod})
\]
due to proposition 14.1.19(i). Moreover, in view of proposition 14.1.21(iii) and lemma 14.1.25 condition (a) is equivalent to:

(c) The morphism \( \pi^* \circ \cdots \circ \pi_{i-1}^* : \mathcal{M}_i \rightarrow V[0] \) induces an isomorphism \( L^* \overset{\sim}{\rightarrow} \tau^{\leq b} K^* \).
(c)⇒(b): We argue as in the proof of proposition 14.1.31, namely, set $H := H^{b+1}K^\bullet$; if (c) holds, we obtain a distinguished triangle

\[(14.1.37) \quad H[-b-2] \rightarrow L^\bullet \rightarrow \tau^{\leq b+1}K^\bullet \rightarrow H[-b-1]\]

and by considering the induced distinguished triangle $\tau^{\leq b+1}R\text{Hom}^\bullet_V(V/m[0],(14.1.37))$, we reduce to observing that

\[
\tau^{\leq b+1}R\text{Hom}^\bullet_V(V/m[0],\tau^{\leq b+1}K^\bullet) \sim \tau^{\leq b+1}R\text{Hom}^\bullet_V(V/m[0],K^\bullet) \sim \tau^{\leq b+1}R\text{Hom}^\bullet_V(\tau^{\geq a-b-1}q^\bullet, L^\bullet) \sim 0
\]

(by lemma 7.3.40).

(b)⇒(a): Again, we proceed as in the proof of the corresponding assertion in proposition 14.1.31, namely, arguing as in the proof of claim 14.1.34, we see that condition (b) is equivalent to condition (b") of remark 14.1.30(iii), with $c := b+1$. Hence, if (b) holds, condition (b) of proposition 14.1.27 holds for $c := b+1$, and notice that condition (a) of loc.cit. holds trivially for this value of $c$, for every $K^\bullet \in D^{[c,b]}(R\text{-Mod})$. We conclude that the natural map

\[
\text{Hom}_{D(R\text{-Mod})}(K^\bullet, L^\bullet) \rightarrow \text{Hom}_{D(R\text{-Mod})}(K^{\bullet^*}, L^{\bullet^*}) \sim \text{Hom}_{D(R\text{-Mod})}(K^\bullet, \tau^{\leq b}L^{\bullet^*})
\]

is an isomorphism, for every $K^\bullet \in D^{[c,b]}(R\text{-Mod})$, whence (a).

14.1.38. Let $A$ be any $V^a$-algebra; recall that the localization functor $V^a\text{-Alg} \rightarrow V^a\text{-Alg}$ admits a left adjoint $R \rightarrow R_!$, whose restriction to the subcategory of $A_!$-algebras yields a left adjoint for the localization functor $A_!\text{-Alg} \rightarrow A_!\text{-Alg}$ (59, Prop.2.2.29). In [59], we have studied the deformation theory of $A$-algebras by means of this left adjoint, under the assumption that $\mathfrak{m}$ is $V$-flat; here we wish to show that the same can be repeated in the current setting, if one appeals instead to the results of the foregoing paragraphs. To begin with, we remark:

**Proposition 14.1.39.** Let $A \rightarrow B$ be a morphism of $V^a$-algebras, $N$ a $B_!$-module. We have:

(i) If the unit of adjunction $N \rightarrow N^a$ is injective, the natural map

\[(14.1.40) \quad \text{Exal}_{A_!}(B_!, N) \rightarrow \text{Exal}_A(B, N^a)
\]

is a bijection (notation of [59] §2.5.7).

(ii) If $N^a = 0$, then $\text{Exal}_{A_!}(B_!, N) = 0$.

**Proof.** (i): Consider any square-zero extension of $A$-algebras

\[
\Sigma : 0 \rightarrow N^a \rightarrow E \xrightarrow{\varphi} B \rightarrow 0.
\]

There follows a square-zero extension of $A_!$-algebras

\[
\Sigma_!! : 0 \rightarrow N_!^a / \text{Ker} \varphi_! \rightarrow E_! \rightarrow B_! \rightarrow 0
\]

Under the stated assumption, the counit of adjunction $N_!^a \rightarrow N$ factors uniquely through a $B$-linear map $g_\varphi : N_!^a / \text{Ker} \varphi_! \rightarrow N$; then $g_\varphi \ast \Sigma_!!$ (defined as in [59], §2.5.5) yields an element of $\text{Exal}_{A_!}(B_!, N)$ whose image under (14.1.40) equals the class of $\Sigma$. Conversely, if

\[
\Omega : 0 \rightarrow N \rightarrow F \xrightarrow{\psi} B_! \rightarrow 0
\]

is a square-zero extension of $A_!$-algebras, then by adjunction we get a natural map

\[
\Omega_!!^a \rightarrow \Omega
\]

which in turns, by simple inspection, induces an isomorphism $g_{\psi^a} \ast \Omega_!!^a \sim \Omega$ in the category of square-zero $A_!$-algebra extensions of $B_!$ (details left to the reader). The assertion follows.
(ii): Suppose \( N^a = 0 \), and let \( \Omega \) be as in the foregoing; it follows that \( \psi^a : F^a \to B \) is an isomorphism of \( A \)-algebras. By adjunction, the morphism \((\psi^a)^{-1}\) corresponds to a map of \( A \)-algebras \( \varphi : B \to E \), and it is easily seen that \( \psi \circ \varphi \) is the identity automorphism of \( B \), whence the assertion. \( \square \)

**Definition 14.1.41.** Let \( f : A \to B \) be a morphism of \( V^a \)-algebras. We set

\[
\mathbb{L}^a_{B/A} := (\mathbb{L}_{B/A})^a
\]

which is a simplicial complex of \( B \)-modules that we call the almost cotangent complex of \( f \).

**Remark 14.1.42.** (i) In case \( \tilde{m} \) is a flat \( V \)-module, we have introduced in [59, Def.2.5.20] a simplicial \( B \)-module \( \mathbb{L}_{B/A} \). Notice that the notation of *loc.cit.* agrees with the current one: indeed, [59, Prop.8.1.7(ii)] shows that complex \((\mathbb{L}^a_{B/A})^a\) obtained by applying the derived localization functor to \( \mathbb{L}_{B/A} \) is naturally isomorphic (in \( D(s.B\text{-Mod}) \)) to the complex of definition 14.1.41

(ii) Depending on the context, we will want to regard \( \mathbb{L}_{B/A} \) either as a simplicial object, or as a cochain complex, via the Dold-Kan isomorphism ([125, Th.8.4.1]). The resulting slight notational ambiguity should not be a source of confusion.

**Theorem 14.1.43.** In the situation of definition 14.1.41 let \( N \) be any \( B \)-module. Then there are natural isomorphisms

\[
\begin{align*}
\text{Der}_A(B, N) & \cong \text{Ext}^0_B(\mathbb{L}^a_{B/A}, N) \\
\text{Exal}_A(B, N) & \cong \text{Ext}^1_B(\mathbb{L}^a_{B/A}, N).
\end{align*}
\]

(*Notation of [59, Def.2.5.22(i)]; so, here we view \( \mathbb{L}^a_{B/A} \) as an object of \( D^{<0}(B\text{-Mod}) \).)

**Proof.** The first isomorphism follows easily from [82, II.1.2.4.2] and the natural isomorphism

\[
\Omega_{B/A} \cong (\Omega_{B/A})^a
\]

proved in [59, Lemma 2.5.29] (the proof in *loc.cit.* does not use the assumption that \( \tilde{m} \) is \( V \)-flat).

Clearly we have

\[
\text{Hom}_{D(B_{\text{ht}-\text{Mod}})}(Y[0], N^a_*) = 0 \quad \text{for every } B_{\text{ht}}\text{-module } Y \text{ such that } Y^a = 0.
\]

On the other hand, we have:

**Claim 14.1.46.** \( \text{Hom}_{D(B_{\text{ht}-\text{Mod}})}(\mathbb{L}^a_{B/A}, X^*) = 0 \) for every \( X^* \in \text{Ob}(D^{[0,1]}(B_{\text{ht}-\text{Mod}})) \) such that \( X_*^a = 0 \).

**Proof of the claim.** For every \( X^* \in \text{Ob}(D^{[0,1]}(B_{\text{ht}-\text{Mod}})) \) we have a distinguished triangle

\[
H^0X^*[0] \to X^* \to H^1X^*[-1] \to (H^0X^*)[1]
\]

which reduces to considering the cases where \( X^* = M[j] \) for some almost zero \( B_{\text{ht}} \)-module \( M \), and \( j = 0, -1 \). The case where \( j = -1 \) follows from [82, III.1.2.3] and proposition 14.1.39(ii). The case where \( j = 0 \) follows easily from [82, II.1.2.4.2] and (14.1.44) \( \diamond \)

Now, (14.1.45) says that \( L^* := N^a_*[0] \) fulfills condition (b) of proposition 14.1.27, and claim 14.1.46 says that \( K^* := \mathbb{L}^a_{B/A} \) fulfills condition (a), so the natural map

\[
\text{Ext}^1_{B_{\text{ht}}}(\mathbb{L}^a_{B/A}, N^a_*) \to \text{Ext}^1_{B}(\mathbb{L}^a_{B/A}, N)
\]

is an isomorphism. Taking into account proposition 14.1.39(i) and [82, III.1.2.3], the theorem follows. \( \square \)
14.1.47. For the further study the almost cotangent complex, we shall need some preliminaries concerning the derived functors of certain non-additive functors. This material generalizes the results of [59 §8.1], that were obtained under the assumption that \( m \) is \( V \)-flat.

**Lemma 14.1.48.** Let \( (V, m) \) be any basic setup, \( R \) a simplicial \( V \)-algebra, \( n \in \mathbb{N} \) an integer, \( M \) and \( N \) two \( R \)-modules such that \( H_iM = H_iN = 0 \) for every \( i \geq n \). The following holds:

(i) If \( M^a = 0 \) in \( D(R^a\text{-Mod}) \), then \( a \cdot 1_M = 0 \) in \( D(R\text{-Mod}) \), for every \( a \in m \).

(ii) If \( \varphi : M \rightarrow N \) is a morphism of \( R \)-modules such that \( \varphi^a \) is an isomorphism in \( D(R^a\text{-Mod}) \), then for every \( a \in m \) we may find a morphism \( \psi : N \rightarrow M \) in \( D(R\text{-Mod}) \), such that \( \psi \circ \varphi = a \cdot 1_M \) and \( \varphi \circ \psi = a \cdot 1_N \) in \( D(R^a\text{-Mod}) \).

**Proof.** (i): For every \( R \)-module \( X \), set (notation of remark [7.10.21 iii])

\[
\tau^{\leq -1}X := \sigma \circ \omega X
\]

According to [82 I.3.2.1.9(ii)], there exists a natural sequence of morphisms

\[
(14.1.49) \quad \tau^{\leq -1}X \rightarrow X \rightarrow s.H_0(X) \rightarrow \sigma(\tau^{\leq -1}X)
\]

whose induced sequence of normalized complexes is a distinguished triangle in \( D(V\text{-Mod}) \) (i.e. a distinguished triangle of \( D(R\text{-Mod}) \), in the terminology of [82 I.3.2.4], and in view of [82 1.3.2.2.5]). Let now \( n \) and \( M \) be as in the lemma; we argue by induction on \( n \). The case where \( n = 0 \) is trivial, so suppose that \( n > 0 \), and that the assertion has been proven for all almost zero \( R \)-modules \( N \) such that \( H_iN = 0 \) for every \( i \geq n - 1 \). Especially, for \( N := \tau^{\leq -1}P = s.H_0(M) \) we have \( a \cdot 1_{\omega N} = 0 \) and \( a \cdot 1_P = 0 \) in \( D(R\text{-Mod}) \), for every \( a \in m \). Since the adjunction \( \sigma \circ \omega N \rightarrow N \) is an isomorphism in \( D(R\text{-Mod}) \) ([82 I.3.2.1.10]), we deduce that

\[
\text{Hom}_{D(R\text{-Mod})}(M, N)^a = 0 = \text{Hom}_{D(R\text{-Mod})}(M, P)^a
\]

whence \( \text{End}_{D(R\text{-Mod})}(M)^a = 0 \), by virtue of (14.1.49) (with \( X := M \)) and [82 I.3.2.2.10]. The assertion follows.

(ii): Set \( C := \text{Cone} \varphi \); according to [82 I.3.2.2], we have a distinguished triangle

\[
(14.1.50) \quad M \xrightarrow{\varphi} N \rightarrow C \rightarrow \sigma M
\]

whence – by [82 I.3.2.2.10] – an exact sequence of \( V \)-modules

\[
\text{Hom}_{D(R\text{-Mod})}(N, M) \xrightarrow{\alpha} \text{End}_{D(R\text{-Mod})}(N) \xrightarrow{\beta} \text{Hom}_{D(R\text{-Mod})}(N, C).
\]

Now, let us write \( a = \sum_{i=1}^n a_ib_i \) for some \( a_1, b_1, \ldots, a_n, b_n \in m \); the assumption on \( \varphi \) implies that \( C^a = 0 \) in \( D(R^a\text{-Mod}) \); therefore (i) yields \( \beta(a_i \cdot 1_N) = a_i \cdot \beta(1_N) = 0 \), so there exists a morphism \( \psi_i : N \rightarrow M \) in \( D(R\text{-Mod}) \) such that \( \alpha(\psi_i) = a_i \cdot 1_N \), i.e. \( \varphi \circ \psi_i = a_i \cdot 1_N \) for every \( i = 1, \ldots, n \). Likewise, by considering the long exact sequence \( \text{Ext}^n_{R^a}(\bigotimes_{i=1}^n(M_i \otimes_R N_i), M) \) provided by [82 I.3.2.2.10] we find, for every \( i = 1, \ldots, n \), a morphism \( \psi_i' : N \rightarrow M \) such that \( \psi_i' \circ \varphi = b_i \cdot 1_M \). Thus,

\[
a_i \cdot \psi_i' = \psi_i' \circ \varphi \circ \psi_i = b_i \cdot \psi_i \quad \text{for every } i = 1, \ldots, n
\]

and a simple computation shows that \( \psi := \sum_{i=1}^n b_i \cdot \psi_i \) will do.

**Remark 14.1.51.** Before considering non-additive functors, let us see how to define derived tensor products in \( D(R^a\text{-Mod}) \), for any simplicial \( V \)-algebra \( R \). We proceed as in (14.1.13) : for given \( R^a \)-modules \( M, N \), set

\[
M \otimes_{R^a} N := (M \otimes_{R^a} N_i)^a.
\]

(i) We claim that this rule yields a well defined functor

\[
- \otimes_{R^a} - : D(R^a\text{-Mod}) \times D(R^a\text{-Mod}) \rightarrow D(R^a\text{-Mod}).
\]
Indeed, say that \( \varphi : M \to M' \) is a quasi-isomorphism of \( R^a \)-modules, and set \( C := \text{Cone}(\varphi_1) \). We need to check that \( (\varphi_1 \otimes_R N)^a \) is a quasi-isomorphism, for any \( R \)-module \( N \); in light of remark 7.10.21(iv), it then suffices to show that \( (C \otimes_R N)^a = 0 \); but the latter \( R^a \)-module may be computed as
\[
(C \otimes_R \perp^R N)^a = C^a \otimes_{R^a} (\perp^R N)^a
\]
whence the claim, since \( C^a = 0 \) in \( R^a \text{-Mod} \).

(ii) Next, suppose that \( M \) is a flat \( R^a \)-module; then we claim that the natural morphism of \( R^a \)-modules
\[
M \otimes_{R^a} N \to M \otimes_{R^a} N
\]
is a quasi-isomorphism, for every \( R^a \)-module \( N \). Indeed, by Eilenberg-Zilber’s theorem 7.4.49, the assertion comes down to checking that the augmented simplicial \( R^a \)-module
\[
(M_i \otimes_R \perp^R N_i)^a \to M \otimes_{R^a} N
\]
is aspherical. But for every \( k \in \mathbb{N} \), the \( k \)-th column of the latter is isomorphic to the augmented \( R^a \)-module
\[
M[k] \otimes_{R^a[k]} (\perp^R[k] N_i[k])^a \to M[k] \otimes_{R^a[k]} N[k]
\]
which is aspherical, since \( M[k] \) is a flat \( R^a[k] \)-module, whence the assertion.

(iii) Just as in (14.1.13), the foregoing immediately implies yields a natural isomorphism
\[
(M \otimes_{R^a} N)^a \sim (M^a \otimes_{R^a} N^a) \quad \text{in } D(R^a \text{-Mod})
\]
for any two \( R \)-modules \( M \) and \( N \) (details left to the reader).

(iv) Furthermore, we get suspension and loop functors \( \sigma \) and \( \omega \) for \( R^a \)-modules, by the rule :
\[
\sigma M := (\sigma M_i)^a \quad \text{and} \quad \omega M := (\omega M_i)^a \quad \text{for every } R^a \text{-module } M
\]
from which it follows that \( \sigma \) is left adjoint to \( \omega \). Then, it is clear that the assertions of remark 7.10.21(iii) hold as well for these functors.

(v) Likewise, we define the cone of a morphism \( \varphi : M \to N \) of \( R^a \)-modules, by the rule
\[
\text{Cone } \varphi := (\text{Cone } \varphi_1)^a
\]
and then the assertion of remark 7.10.21(iv) holds also for morphisms of \( R^a \)-modules.

(vi) In view of (iv) and (v), it is then easy to check that also lemma 7.10.22 holds verbatim for \( A := V \), and any two \( R^a \)-modules \( X, Y \).

**Remark 14.1.52.** (i) In the same vein, we may define derived tensor products of \( R^a \)-algebras, for any simplicial \( V \)-algebra \( R \). Namely, if \( S \) and \( S' \) are any two \( R^a \)-algebras, we set
\[
S \otimes_{R^a} S' := (S_i \otimes_{R^a} S'_i)^a
\]
(see (14.1.38)), where \( \otimes_{R^a} \) denotes the derived tensor product for \( R \)-algebras, defined in example 7.10.15. In view of remarks 7.10.21(ii) and 14.1.51(i), it is easily seen that this rule defines a functor
\[
\otimes_{R^a} : D(R^a \text{-Alg}) \times D(R^a \text{-Alg}) \to D(R^a \text{-Alg})
\]
and moreover, the formation of these tensor products commutes with the forgetful functor \( D(R^a \text{-Alg}) \to D(R^a \text{-Mod}) \).

(ii) Moreover, they are computed by arbitrary flat resolutions : if \( S \) (or \( S' \)) is a flat \( R^a \)-algebras, then the natural morphism
\[
S \otimes_{R^a} S' \to S \otimes_{R^a} S'
\]
is an isomorphism in \( D(R^a \text{-Alg}) \).
Proof. Let $\phi$, it is easily seen that, for every $a \in M$, where $\phi$ is admitted a set of generators of cardinality $\omega(M)$ elements; then there exists a cardinality $\omega$ of $\phi(M)$, such that $\phi(\phi')$ is an isomorphism as well (details left to the reader).

Remark 14.1.54. Let $(V, \omega)$ be a basic setup, $A$ a $V$-algebra, $d \in \mathbb{N}$, and $T : A\text{-Mod} \to A\text{-Mod}$ a $V$-homogeneous functor of degree $d$. Suppose that either $d \leq 1$ or else $m$ fulfills condition (B) of [59, §2.1.6].

(i) Let also $\varphi : M \to N$ be a homomorphism of $A$-modules such that $\varphi^a : M^a \to N^a$ is an isomorphism (for the almost structure given by $(V, \omega)$); arguing as in the proof of lemma 14.1.48(ii), it is easily seen that, for every $a \in m$ there exists a $B$-linear map $\psi : N \to M$ such that $\varphi \circ \psi = a \cdot 1_N$ and $\psi \circ \varphi = a \cdot 1_M$. Then, the $V$-homogeneity property of $T$ implies that $(T\varphi)^a$ is an isomorphism as well (details left to the reader).

(ii) Hence, $T$ induces a well defined functor

$$T : A^a\text{-Mod} \to A^a\text{-Mod}$$

$$M^a \mapsto (TM)^a \quad (\varphi^a : M^a \to N^a) \mapsto (T\varphi)^a.$$ 

For every cardinality $c$, let $\mathcal{M}_c(A^a)$ be the set of isomorphism classes of $A^a$-modules which admit a set of generators of cardinality $\leq c$. We endow $\mathcal{M}_c(A^a)$ with the uniform structure as in [59, Def.2.3.1(i)]. Let $\omega$ be an infinite cardinality, such that $m$ is generated by at most $\omega$ elements; then there exists a cardinality $\omega' \geq \omega$ such that the isomorphism class of $T^a_M$ lies in $\mathcal{M}_{\omega'}(A^a)$, for every $A^a$-module $M$ whose isomorphism class lies in $\mathcal{M}_\omega(A^a)$; thus, $T^a$ induces a map

$$\mathcal{M}_\omega(T^a) : \mathcal{M}_\omega(A^a) \to \mathcal{M}_{\omega'}(A^a) \quad N \mapsto T^a N.$$ 

Lemma 14.1.55. Let $(V, \omega)$ be a basic setup, $A$ a $V$-algebra, $I, J \subset A$ two ideals, and $\varphi : M' \to M$ a morphism of $A^a$-modules with $I \cdot \operatorname{Ker} \varphi = J \cdot \operatorname{Coker} \varphi = 0$. Then there exists an $A^a$-linear morphism $\lambda : I \otimes_A J \otimes_A M \to M'$ with

$$\varphi \circ \lambda = \mu_{1,I,J} \varphi A 1_M \quad \text{and} \quad \lambda \circ (I \otimes_A J \otimes_A \varphi) = \mu_{1,I,J} \varphi A 1_M,$$

where $\mu_{1,I,J} : I \otimes_A J \to A$ is the multiplication law: $a \otimes b \mapsto ab$ for every $a \in I$ and $b \in J$.

Proof. Let $M^a \xrightarrow{\varphi} \lambda M_0 := \operatorname{Im} \varphi \xrightarrow{\psi_a} M$ be the natural factorization of $\varphi$; then for every $a \in I$ and $b \in J$ we have $A^a$-linear morphisms $\psi_a : M_0 \to M'$ and $\mu_b : M_0 \to M$ such that $\psi_a \circ \varphi = a \cdot 1_{M'}$ and $i \circ \mu_b = b \cdot 1_M$.

Let us check that $\overline{\varphi} \circ \psi_a = a \cdot 1_M$; since $\overline{\varphi}$ is an epimorphism, it suffices to show that $\overline{\varphi} \circ \psi_a \circ \overline{\varphi} = (a \cdot 1_M) \circ \overline{\varphi}$, which is clear. Likewise, let us check that $\mu_b \circ i = b \cdot 1_M$; since $i$ is a monomorphism, it suffices to show that $i \circ \mu_b \circ i = i \circ b \cdot 1_M$, which is clear. For every $a \in I$ and $b \in J$ set $\lambda_{a,b} := \psi_a \circ \mu_b : M \to M'$; we deduce that

$$\varphi \circ \lambda_{a,b} = i \circ \overline{\varphi} \circ \psi_a \circ \mu_b = i \circ (a \cdot 1_{M_0}) \circ \mu_b = i \circ \mu_b \circ (a \cdot 1_M) = ab \cdot 1_M$$

and a similar computation yields $\lambda_{a,b} \circ \varphi = ab \cdot 1_{M'}$. Thus, we obtain a map

$$I \times J \times M \to M' \quad (a, b, x) \mapsto \lambda_{a,b}(x).$$
A simple inspection shows that this map is $A$-trilinear, hence it factors uniquely through an $A$-linear map $\lambda : I \otimes_A J \otimes_A M \to M'$, and the foregoing easily implies that $\lambda$ fulfills the required identities.

\textbf{Proposition 14.1.56.} In the situation of remark 14.1.54 the following holds:

(i) If $T$ commutes with filtered colimits, and for every free $A$-module $L$ of finite rank, $(TL)^a$ is a flat $A^a$-module (resp. is the zero $A^a$-module), then for every flat $A^a$-module $M$, the $A^a$-module $T^a M$ is flat (resp. is the zero $A^a$-module).

(ii) If for every free $A$-module $L$ of finite rank (resp. for every free $A$-module $L$), $(TL)^a$ is an almost projective $A^a$-module, then for every almost projective and almost finitely generated $A^a$-module $M$ (resp. for every almost projective $A^a$-module $M$), the $A^a$-module $T^a M$ is almost projective.

(iii) The map $\mathcal{M}_{\omega,\omega}(T^a)$ of remark 14.1.54 (ii) is uniformly continuous.

\textbf{Proof.} (i): Say that $M = N^a$ for an $A$-module $N$, and let $\mathcal{F}$ be the category whose objects are the pairs $(C, \varphi)$, where $C$ is a finitely presented $A$-module and $\varphi : C \to N$ is an $A$-linear map; the morphisms $\psi : (C, \varphi) \to (C', \varphi')$ in $\mathcal{F}$ are the $A$-linear maps $\psi : C \to C'$ such that $\varphi' \circ \psi = \varphi$, with the obvious composition law. We have a functor $F : \mathcal{F} \to A\text{-Mod}$ given by the rule $(C, \varphi) \mapsto C$. It is easily seen that $\mathcal{F}$ is filtered, and $\beta$ is a universal co-cone: the details are left to the reader. Since $T$ commutes with filtered colimits, $TN$ is isomorphic to the colimit of the functor $T \circ F : \mathcal{F} \to A\text{-Mod}$, and $T \circ \beta : T \circ F \Rightarrow e_{TN}$ is again a universal co-cone. We need to show that $m\text{Tor}^A_1TN, X) = 0$ for every $A$-module $X$ (resp. that $mTN = 0$), and by the foregoing it then suffices to check that for every $(C, \varphi) \in \text{Ob}(\mathcal{F})$, the induced map $(C, \varphi) \mapsto C$ is almost zero (resp. that $T\varphi$ is almost zero). However, since $N^a$ is a flat $A^a$-module, \cite[Lemma 2.4.17]{59} implies that for every $a \in m$ there exists a free $A$-module $L$ of finite rank and $A$-linear maps $\varphi' : C \to L, \varphi'' : L \to M$ with $a \cdot \varphi = \varphi'' \circ \varphi'$. Hence $a^d \cdot T\varphi = T(\varphi'') \circ T(\varphi')$, and therefore $a^d \cdot \lambda^a = 0$, since by assumption $(TL)^a$ is a flat $A^a$-module (resp. and therefore $a^d \cdot (T\varphi')^a = 0$, since $(TL)^a = 0$); the contention follows, since we have either $d \leq 1$, or else $m$ fulfills condition (B).

(ii): Suppose first that for every free $A$-module $L$ of finite rank, $(TL)^a$ is almost projective, and let $M$ be an almost projective and almost finitely generated $A$-module. According to \cite[2.4.15]{59}, for every $a \in m$ there exists a free $A$-module $L$ of finite rank and $A^a$-linear morphisms $\varphi' : M \to L^a, \varphi'' : L^a \to M$ such that $a \cdot 1_M = \varphi'' \circ \varphi'$. We deduce that $a^d \cdot \operatorname{Ext}^1_A(1_{TM}, X)^a = \operatorname{Ext}^1_A(T\varphi', X)^a \circ \operatorname{Ext}^1_A(T\varphi'', X)^a = 0$ for every $A$-module $X$, since $\operatorname{Ext}^1_A(TL, X)^a = 0$ by assumption (and by \cite[Rem.2.4.12(ii)]{59}). The contention follows, again because either $d \leq 1$ or else $m$ fulfills condition (B). One argues similarly in case $M$ is almost projective and $(TL)^a$ is almost projective for every free $A$-module $L$; the details shall be left to the reader.

(iii): Let $m_0 \subset m$ be a subideal of finite type, and $\varphi : M' \to M$ a morphism of $A^a$-module with $m_0 \operatorname{Ker} \varphi = m_0 \operatorname{Coker} \varphi = 0$. Denote by $m^{(2d)}_0 \subset m_0$ the subideal generated by the system $(a^d | a \in m_0^\alpha)$. By lemma 14.1.55, for every $a \in m_0^\alpha$ there exists a morphism $\lambda : M \to M'$ of $A^a$-modules with $\varphi \circ \lambda = a \cdot 1_M$ and $\lambda \circ \varphi = a \cdot 1_M$; therefore $T^a(\varphi) \circ T^a(\lambda) = a^d \cdot 1_{T^a M}$ and $T^a(\lambda) \circ T^a(\varphi) = a^d \cdot 1_{T^a M'}$. 

which implies that $m^{(2d)}_n \cdot \Ker T^n(\varphi) = m^{(2d)}_n \cdot \Coker T^n(\varphi) = 0$, whence the assertion, since we either have $d \leq 1$ or $m$ fulfills condition (B).

**Example 14.1.57.** Let $(V, m)$ be a basic setup such that $m$ satisfies condition (B); let $A$ be a $V$-algebra, and $P$ any $A$-module. According to [31, Ch. X, §9, n.3], for every integer $n > 0$ we have a complex of $A$-modules

$$\Sigma_A^n(P) : 0 \to A^n_P \to \cdots \to (A^j_P) \otimes_A (\Sym_{A}^{n-j} P) \to \cdots \to \Sym_{A}^n P = 0$$

which is functorial for morphisms of $A$-modules, and is acyclic if $P$ is a flat $A$-module ([31, Ch. X, §9, n.3, Prop. 3]). Clearly, for every $j \in \mathbb{N}$ the functor

$$T^j : A\text{-Mod} \to A\text{-Mod} \quad P \mapsto H^j(\Sigma_A^\bullet(P))$$

fulfills the conditions of (14.1.58) (with $d := n$) and $T^nP = 0$ if $P$ is a flat $A$-module. By proposition 14.1.56(i), we deduce that the induced complex of $A^n$-modules $\Sigma_A^n(P)^n$ is acyclic, if $P^n$ is a flat $A^n$-module. With this observation, all the results of [59, §4.3, §4.4] extend now verbatim to the case where $m$ fulfills condition (B) (whereas the proofs in loc. cit. used the stronger condition that $m$ is a flat $V$-module: the details shall be left to the reader).

**14.1.58.** Let $\pi : V\text{-Alg, Mod} \to V\text{-Alg}$ be the functor such that $\pi(A, M) := A$ and $\pi(f, \varphi) := f$ for every object $(A, M)$ and every morphism $(f, \varphi)$ of $V\text{-Alg, Mod}$. We consider a functor

$$T : V\text{-Alg, Mod} \to V\text{-Alg, Mod} \quad \text{such that } \pi \circ T = \pi.$$ 

Let also be $R$ a simplicial $V$-algebra, $d \in \mathbb{N}$ and suppose that:

- $T$ is $V$-homogeneous of degree $d$, i.e. for every $V$-algebra $A$, the restriction of $T$
  $$T_A : A\text{-Mod} \to A\text{-Mod}$$
  is $V$-homogeneous of degree $d$.
- $T_A$ commutes with filtered colimits (cp. (7.10.16)) for every $V$-algebra $A$.
- Either $d \leq 1$ or else the ideal $m \cdot H_0(R)$ of $H_0(R)$ satisfies condition (B) of [59, §2.1.6].

**Remark 14.1.59.** (i) As detailed in (7.10.16), the functor $T$ induces a functor

$$T_R : R\text{-Mod} \to R\text{-Mod} \quad (M[n] \mid n \in \mathbb{N}) \mapsto (T_R[n]M[n] \mid n \in \mathbb{N}).$$

(ii) Let $T$ and $T'$ be two functors as in (14.1.58), $V$-homogeneous of degrees respectively $d$ and $d'$; then we get the functor $V$-homogeneous of degree $d + d'$

$$T \otimes T' : V\text{-Alg, Mod} \to V\text{-Alg, Mod} \quad (A, M) \mapsto (A, T_AM \otimes_A T'_A M)$$

and it is easily seen that $(T \otimes T')_A$ commutes with filtered colimits, for every $V$-algebra $A$.

(iii) Likewise, if $f : T \to T'$ is a natural transformation of functors fulfilling the conditions of (14.1.58), for the same degree $d$; then the same holds for the functors $\Ker f$ and $\Coker f$.

(iv) In the situation of (14.1.58), let $f : H_0(R) \to B$ be any morphism of $V$-algebras. If condition (B) holds for $m \cdot H_0(R)$, it holds also also for $mB$; then remark 14.1.54(ii) implies that $T_B$ induces a functor $T_B^\bullet := T_B^\bullet : B^\bullet\text{-Mod} \to B^\bullet\text{-Mod}$. Especially, the above holds with $B := R[p]$, for any $p \in \mathbb{N}$, and $f$ the natural map given by the degeneracies of the simplicial $V$-algebra $R$. It is then clear that $T_R$ induces a well defined functor

$$T_{R^B} : R^n\text{-Mod} \to R^n\text{-Mod}.$$ 

The following result shows that, in this situation, the construction of left derived functors descends likewise to $R^n\text{-modules}$. 

**Theorem 14.1.60.** In the situation of (14.1.58), the following holds:
(i) Let \( \varphi : M \to N \) be a morphism of \( R \)-modules, and \( n \in \mathbb{N} \) an integer such that \( H_i(\varphi)^a : (H_iM)^a \to (H_iN)^a \) is an isomorphism of \( V^a \)-modules, for every \( i \leq n \). Then
\[
H_i(\text{LT}\varphi)^a : H_i(\text{LT}M)^a \to H_i(\text{LT}N)^a
\]
is an isomorphism of \( V^a \)-modules, for every \( i \leq n \).

(ii) Especially, the functor \( T_R \) induces a well defined left derived functor
\[
\text{LT}_R^a : \mathcal{D}(\mathcal{R}^a \text{-Mod}) \to \mathcal{D}(\mathcal{R}^a \text{-Mod}).
\]

Proof. Clearly (ii) follows from (i).

(i): In light of corollary 14.1.24(i), we may replace \( M \) and \( N \) by respectively \( \cosk_n M \) and \( \cosk_n N \), after which, we may assume that \( H_iM = H_iN = 0 \) for every \( i > n \), so \( \varphi^a \) is an isomorphism in \( \mathcal{D}(\mathcal{R}^a \text{-Mod}) \). Next, by proposition 14.1.18 we may replace \( M \) and \( N \) by their respective standard free resolutions, in which case we are reduced to checking that the induced map \( (T_R\varphi)^a \) is an isomorphism in \( \mathcal{D}(\mathcal{R}^a \text{-Mod}) \). Since \( T \) is homogeneous and (B) holds for \( m \cdot H_0(R) \), the latter assertion follows straightforwardly from lemma 14.1.48(ii). \( \square \)

14.1.61. Next, we wish to decide how much of the foregoing theory can be salvaged, when we drop condition (B). We will concentrate on the functors that are relevant to the later study of the cotangent complex. Thus, henceforth, for every integer \( d \in \mathbb{N} \), we shall denote by \( T^d \) one of the three standard functors
\[
\text{Sym}^d, \Lambda^d, \Gamma^d : \mathcal{V-Alg.} \text{-Mod} \to \mathcal{V-Alg.} \text{-Mod}
\]
(namely, the symmetric and exterior \( d \)-th power functors, and the \( d \)-th divided power functor). Notice that the functor \( T^d \) fulfills the conditions of (14.1.58), for every \( d \in \mathbb{N} \). Moreover, in all three cases we have natural identifications :
\[
(14.1.62) \quad T^1 \cong 1_{\mathcal{V-Alg.}\text{-Mod}}.
\]

In general, we can no longer expect that \( T^d \) descends to almost modules; indeed, consider the following :

Example 14.1.63. Let \((V, m)\) be as in (14.1.61), and \( p \in \mathbb{N} \) any prime integer. The Frobenius map \( \Phi_R : R/pR \to R/pR \) for \( V \)-algebras \( R \), can be seen as a homogeneous polynomial law of degree \( p \) on the \( V \)-module \( V/pV \). Denote by \( m^{(p)} \subset V \) the ideal generated by \((x^p \mid x \in m)\). Clearly \( \Phi \) descends to a polynomial law
\[
\overline{\Phi} : V/(pV + m) \to W_p := V/(pV + m^{(p)})
\]
which is still homogeneous of degree \( p \), so it factors through a unique \( V \)-linear map
\[
\Gamma^p_A(V/(pV + m)) \to W_p.
\]
The latter is surjective, since its image contains the class of the unit element of \( V \). Now, the proof of [59, Prop.2.1.7(ii)] shows that – if (B) does not hold for \( m \) – there exists some prime \( p \) such that \( pV + m^{(p)} \) does not contain \( m \), therefore \( W^A_p \neq 0 \). This shows that the functor
\[
\mathcal{V-Mod} \to \mathcal{V^a-Mod} \quad M \mapsto (\Gamma^p_A M)^a
\]
does not factor through \( \mathcal{V^a-Mod} \).

However, we will see that example 14.1.63 is, in a sense, the worst that can happen.

Lemma 14.1.64. In the situation of (14.1.61), we have :

(i) There are natural transformations
\[
T^{i+j} \to T^i \otimes T^j \to T^{i+j} \quad \text{for every } i, j \in \mathbb{N}
\]
whose composition equals \( \binom{i+j}{i} \cdot 1_{T^{i+j}} \). (Notation of remark 14.1.59(ii).)
(ii) For every simplicial $\ast$-algebra $R$, the maps of (i) induce natural transformations

$$LT_R^{i+j} \to LT_R^i \otimes_R LT_R^j \to LT_R^{i+j}$$

for every $i, j \in \mathbb{N}$ whose composition equals $(i+j) \cdot 1_{LT_R^{i+j}}$.

Proof. (i): For $T = \Lambda$, the sought morphism $\Lambda^{i+j} \to \Lambda^i \otimes \Lambda^j$ is the one denoted $\Delta_{i,j}$ in [59, §4.3.20], and the morphism $\Lambda^i \otimes \Lambda^j \to \Lambda^{i+j}$ is given by the rule: $x \otimes y \mapsto x \wedge y$, for every $(A, M) \in \text{Ob}(\text{V-Alg.Mod})$, every $x \in \Lambda^i_A M$ and every $y \in \Lambda^j_A M$. The sought identity follows easily from the explicit formula given in [59, (4.3.21)]: details left to the reader.

For $T = \text{Sym}$, the natural transformation $\text{Sym}^{i+j} \to \text{Sym}^i \otimes \text{Sym}^j$ is given by a similar formula; namely, for every object $(A, M)$ of $\text{V-Alg.Mod}$, every sequence of elements $x_1, \ldots, x_{i+j} \in M$, and every subset $I \subset \{1, \ldots, i + j\}$, set $x_I := \prod_{k \in I} x_k \in \text{Sym}^i_A M$ (where the multiplication is formed in the graded ring $\text{Sym}^i_A M$); one checks easily that the rule

$$x_1 \cdot \cdots \cdot x_{i+j} \mapsto \sum_{I,j} x_I \otimes x_J$$

defines a well defined $A$-linear map on $\text{Sym}^{i+j}_A M$ (where the sum ranges over all the partitions $(I,J)$ of $\{1, \ldots, i+j\}$ such that the cardinality of $I$ equals $i$). Then one defines a map $\text{Sym}^{i}_A M \otimes_A \text{Sym}^{j}_A M \to \text{Sym}^{i+j}_A M$ by the rule: $u \otimes v \mapsto u \cdot v$ for every $u \in \text{Sym}^i_A M$ and $v \in \text{Sym}^j_A M$. Again, the sought identity is verified by direct computation.

If $T = \Gamma$, then for every object $(A, M)$ of $\text{V-Alg.Mod}$ we define a homogeneous polynomial law $M \leadsto \Gamma^i_A M \otimes_A \Gamma^j_A M$ of degree $i + j$, by the rule: $x \mapsto x^{[i]} \otimes x^{[j]}$ for every $A$-algebra $B$, and every $x \in B \otimes_A M$. This law yields a transformation $\Gamma^{i+j} \to \Gamma^i \otimes \Gamma^j$ as sought. Next, the multiplication of the graded ring functor $\Gamma^\ast$ gives a transformation $\Gamma^i \otimes \Gamma^j \to \Gamma^{i+j}$. The composition of these two transformations is characterized as the unique transformation $\psi$ of $\Gamma^{i+j}$ such that $\psi(x^{[i+j]})(x^{[i]} \cdot x^{[j]})$ for every object $(A, M)$ of $\text{V-Alg.Mod}$, and every $x \in M$. Then, by corollary 9.5.56, we must have $\psi(x,A,M) = (i+j)1_M$, as required.

(ii): Recall that the three functors $\Lambda$, $\Gamma$ and $\text{Sym}$ transform free $\ast$-modules into free $\ast$-modules, for every $\ast$-algebra $A$. Therefore, the sought natural transformation is none else than the map

$$LT_R^{i+j}(\underline{1}_M) \to LT_R^i(\underline{1}_M) \otimes_R LT_R^j(\underline{1}_M) \to LT_R^{i+j}(\underline{1}_M)$$
given by (i), for any $R$-module $M$. \hfill \square

Proposition 14.1.65. In the situation of (14.1.61), let $p \in \mathbb{N}$ be a prime integer, $R$ a simplicial $V \otimes_{\mathbb{Z}} \mathbb{Z}_p(\ast)$-algebra, $M$ an $\ast$-module such that $M^a = 0$ in $D(R^a_{\ast}\text{-Mod})$. Then

$$(LT_R^d M)^a = 0 \quad \text{in} \quad D(R^a_{\ast}\text{-Mod}), \quad \text{for each} \quad d \in \mathbb{N} \quad \text{such that} \quad (p, d) = 1.$$ \hfill \square

Proof. In light of corollary 7.10.29(i), we may replace $M$ by $\cosk_{\ast} M$, in which case lemma 14.1.48(i) implies that $a \cdot 1_M = 0$ for every $a \in m$. Now, we apply lemma 14.1.64(ii) with $i = 1$ and $j = d = 1$ (notice that $j \geq 0$, since $d > 0$); in view of (14.1.62), there result natural transformations

$$LT^d_R M \to M \otimes_R LT^{d-1}_R M \to LT^d_R M$$

whose composition is $d \cdot 1_{LT^d_R M}$. Since the image of $d$ is invertible in $R$, it follows easily that $a \cdot 1_{LT^d_R M} = 0$ for every $a \in m$, whence the assertion. \hfill \square

Theorem 14.1.66. Let $d, n, p \in \mathbb{N}$ be any three integers, with $d > 0$ and $p$ a prime. Let also $R$ be a simplicial $V \otimes_{\mathbb{Z}} \mathbb{Z}_p(\ast)$-algebra, $M$ an $\ast$-module, and suppose that

(a) $H_i M = 0$ for every $i < n$.

(b) $M^a = 0$ in $D(R^a_{\ast}\text{-Mod})$.

Then we have:

(i) \( H_i(L\Gamma^d_R M)^a = 0 \) for every \( i < n \).
(ii) \( H_i(L\Lambda^d_R M)^a = 0 \) for every \( i < n + p - 1 \).
(iii) \( H_i(L\text{Sym}^d_R M)^a = 0 \) for every \( i < n + 2(p - 1) \).

**Proof.** (i) is just a special case of corollary [7.10.24](ii), and for \( d < p \), assertions (ii) and (iii) follow from the more general proposition [14.1.65] hence we may assume that \( d \geq p \). For every \( j = 0, \ldots, d \), set

\[
F^j := \Gamma^j \otimes \Lambda^{d-j} \quad G^j := \Lambda^j \otimes \text{Sym}^{d-j}.
\]

By remark [14.1.59](ii), these functors are homogeneous of degree \( d \), and fulfill the conditions of [14.1.58]. Moreover, since \( \Gamma, \Lambda \) and \( \text{Sym} \) transform free modules into free modules, we have natural isomorphisms of functors:

\[
(14.1.67) \quad LF^j_R \cong L\Gamma^j_R \otimes_R \Lambda^{d-j}_R \quad LG^j_R \cong \Lambda^j_R \otimes_R \text{Sym}^{d-j}_R \quad \text{for every } j = 0, \ldots, d
\]

(details left to the reader).

(ii): According to [82, I.4.3.1.7], there is a natural complex of functors:

\[
(14.1.68) \quad 0 \to F^d_R \xrightarrow{\partial_{d-1}} F^{d-1}_R \to \cdots \to F^1_R \xrightarrow{\partial_0} F^0_R \to 0
\]

which is exact on flat \( R \)-modules. Set \( Z_p := \text{Ker} \partial_{p-1} \); due to remark [14.1.59](iii) we may consider the derived functor \( LZ_p \), and from corollary [7.10.24](ii) and assumption (a), we get

\[
(14.1.69) \quad H_i(LZ_p M) = 0 \quad \text{for every } i < n.
\]

The evaluation of \((14.1.68)\) on \((\bigwedge^\bullet M)^\Delta\) gives an exact sequence of \( R \)-modules:

\[
0 \to LZ_p M \to LF_{R}^{p-1} M \to \cdots \to LF_{R}^1 M \to LF_{R}^0 M \to 0.
\]

Notice as well, that

\[
(14.1.70) \quad (LF^j_R M)^a = 0 \quad \text{in } D(R^a\text{-Mod}) \text{ for } j = 1, \ldots, p - 1
\]

in view of \((14.1.67)\), remark [14.1.51](iii), and proposition [14.1.65]. The assertion now follows from \((14.1.69)\) and claim [7.10.40].

(iii): According to [82, I.4.3.1.7], there is a natural complex of functors:

\[
\Sigma : 0 \to G^d_R \xrightarrow{\partial_{d-1}} G^{d-1}_R \to \cdots \to G^1_R \xrightarrow{\partial_0} G^0_R \to 0.
\]

Set \( Z'_p := \text{Ker} \partial_{p-1} \); due to remark [14.1.59](iii) we may consider the derived functor \( LZ'_p \), and since \( \Sigma \) is exact on flat \( R \)-modules, we obtain two exact sequences of \( R \)-modules:

\[
\Sigma' : 0 \to LG^d_R M \to LG^{d-1}_R M \to \cdots \to LG^1_R M \to LG^0_R M \to 0
\]

\[
\Sigma'' : 0 \to LZ'_p M \to LG^p_R M \to \cdots \to LG^1_R M \to LG^0_R M \to 0.
\]

On the one hand, in light of (ii), remark [14.1.51](iii,vi) and \((14.1.67)\), we see that

\[
\text{cosk}_{n+p-1}(LG^d_R M)^a = 0 \quad \text{in } D(R^a\text{-Mod}) \text{ for every } j = 1, \ldots, d.
\]

By applying claim [7.10.40] to the exact sequence \( \text{cosk}_{n+p-1}\Sigma'^a \), we deduce that \( H_i(LZ'_p M)^a = 0 \) for every \( i < n + p - 1 \). On the other hand, \((14.1.67)\) and proposition [14.1.65] imply that

\[
(LG^j_R M)^a = 0 \quad \text{in } D(R^a\text{-Mod}) \text{ for } j = 1, \ldots, p - 1
\]

so the assertion follows, after applying claim [7.10.40] to the exact sequence \( \Sigma'' \). □
14.1.71. Let now \( \varphi : R \to S \) be any morphism of simplicial \( V^a \)-algebras; pick any resolution \( \rho : P \to S \) with \( P \) a flat \( R \)-algebra, and consider the composition

\[
S \otimes_R P \xrightarrow{S \otimes_R \rho} S \otimes_R S \xrightarrow{\mu_S} S
\]

where \( \mu_S \) is the multiplication law of \( S \). Then (14.1.72) represents a morphism

\[
\Delta(\varphi) : S \otimes_R S \to S \quad \text{in } D(R\text{-Alg})
\]

which is independent (up to unique isomorphism) of the choice of \( P \). Notice that if \( \varphi \) is an isomorphism in \( D(s.V^a\text{-Alg}) \), then the same holds for \( \varphi \otimes_R \varphi : R \to S \otimes_R S \); also, we have

\[
\varphi = \Delta(\varphi) \circ (\varphi \otimes_R \varphi) \quad \text{in } D(s.V^a\text{-Alg}).
\]

More generally, set \( C := \text{Cone } \varphi \); then, by considering the section \( S \otimes_R \varphi \) of \( \Delta(\varphi) \), we get a natural decomposition

\[
S \otimes_R S \xrightarrow{\Delta} S \otimes (S \otimes_R C) \quad \text{in } D(R\text{-Mod})
\]

which identifies \( \Delta(\varphi) \) with the natural projection, whence a natural isomorphism

\[
\text{Cone } \Delta(\varphi) \xrightarrow{\sim} \sigma S \otimes_R C.
\]

Thus, say that \( C = \sigma^k C' \) in \( D(R\text{-Mod}) \), for some \( R \)-module \( C' \) with \( H_0 C' \neq 0 \); there follows a distinguished triangle in \( D(R\text{-Mod}) \)

\[
\sigma^k C' \to \sigma^k S \otimes_R C' \to \sigma^{2k} C' \otimes_R C' \to \sigma^{k+1} C'.
\]

Especially, if \( k \geq 2 \), then \( H_k C = H_k(\sigma \otimes_R C) \), and we see that, in this case, \( \text{Cone } \Delta(\varphi) = \sigma^{k+1} C'' \) in \( D(R\text{-Mod}) \), for some \( C'' \) such that \( H_0 C'' \neq 0 \). However, it is clear from (14.1.73) that \( \text{Cone } \Delta^2(\varphi) = \sigma^2 C'' \) for some object \( C'' \) of \( D(R\text{-Mod}) \). We conclude that if \( \Delta^n(\varphi) \) is an isomorphism in \( D(R\text{-Mod}) \) for some \( n \geq 2 \), then the same holds already for \( \Delta^2(\varphi) \).

Definition 14.1.74. In the situation of (14.1.71), we say that \( \varphi \) is a weakly étale morphism, if \( \Delta^2(\varphi) \) is an isomorphism in \( D(R\text{-Alg}) \).

14.1.75. Let \( \varphi : R' \to R \) be any morphism of simplicial \( V^a \)-algebras, and \( S, T \) two \( R \)-algebras. Since the standard resolution \( F_R(S) := F_{R_n}(S_n)^n \) of example 7.10.15 is clearly functorial in both \( R \) and \( S \), we have a natural map

\[
F_R(S)^\Delta \to F_R(S)^\Delta
\]

of simplicial \( R' \)-algebras, whence a natural morphism

\[
(14.1.76) \quad S \otimes_{R'} T \to F_R(S)^\Delta \otimes_{R'} T \to S \otimes_R T.
\]

Lemma 14.1.77. In the situation of (14.1.75), suppose that \( \varphi \) is a quasi-isomorphism. Then the same holds for (14.1.76).

Proof. Let \( \psi : F_{R'}(S)^\Delta \otimes_{R'} R \to F_{R'}(S)^\Delta \) be the natural morphism; by construction, (14.1.76) factors as the composition of \( \psi \otimes_R 1_T \) and the natural isomorphism

\[
F_{R'}(S)^\Delta \otimes_{R'} T \xrightarrow{\sim} (F_{R'}(S)^\Delta \otimes_{R'} R) \otimes_R T.
\]

Since both \( F_{R'}(S)^\Delta \otimes_{R'} R \) and \( F_{R'}(S)^\Delta \) are flat \( R \)-algebras, remark 14.1.52(ii) then reduces to checking that \( \psi \) is a quasi-isomorphism. Since the natural maps \( \beta : F_R(S)^\Delta \to S \) and \( \alpha : F_R(S)^\Delta \to F_R(\Delta) \otimes_R R \) are quasi-isomorphisms, it suffices to show that the composition \( \beta \circ \psi \circ \alpha \) is a quasi-isomorphism. But the latter is none else than the standard resolution \( F_{R'}(S) \to S \), whence the lemma.
**Proposition 14.1.78.** Let \( \varphi : R \to S \) and \( \varphi' : R' \to S' \) be two morphisms of simplicial \( V \)-algebras, and suppose we have a commutative diagram in \( D(R \text{-Alg}) \)

\[
\begin{array}{ccc}
R & \xrightarrow{\varphi} & S \\
\psi \downarrow & & \downarrow \psi' \\
R' & \xrightarrow{\varphi'} & S'
\end{array}
\]  

(14.1.79)

where \( \psi \) and \( \psi' \) are isomorphisms (in \( D(R \text{-Alg}) \)). Then \( \varphi'^a \) is weakly étale if and only if the same holds for \( \varphi'^a \).

**Proof.** Denote by \( \text{Hot}(V \text{-Alg}) \) the homotopy category of simplicial \( V \)-algebras, and recall that the multiplicative system of quasi-isomorphisms in \( \text{Hot}(V \text{-Alg}) \) admits a right calculus of fractions (\[82\] I.3.1.8(ii)). We begin with the following special case:

**Claim 14.1.80.** Suppose that \( \psi \) and \( \psi' \) are also morphisms of simplicial \( V \)-algebras, and that (14.1.79) commutes in the category \( \text{Hot}(V \text{-Alg}) \). Then the proposition holds.

**Proof of the claim.** Indeed, in this situation it follows easily from lemma [14.1.77] that \( \varphi'^a \) (resp. \( \varphi'^a \)) is weakly étale if and only if the same holds for \( \psi'^a \circ \varphi'^a \) (resp. for \( \varphi'^a \circ \psi'^a \)), so we are reduced to the case where \( R = R', S = S' \), and \( \varphi, \varphi' : R \to S \) are two homotopic morphisms of simplicial \( V \)-algebras. In this case, there exist morphisms of simplicial \( V \)-algebras \( \varphi'' : R \to S'' \) and \( d_0, d_1 : S'' \to S \), such that \( d_0 \circ d_1 \) are quasi-isomorphisms, and \( \varphi = d_0 \circ \varphi'' \), \( \varphi' = d_1 \circ \varphi'' \) (see \[82\] I.2.3.2)). Then the claim follows by applying repeatedly lemma 14.1.77.

Next, there exist a simplicial \( V \)-algebra \( S'' \) and morphisms \( \beta : S'' \to S \) and \( \gamma : S'' \to S' \) of simplicial \( V \)-algebras, such that both \( \beta \) and \( \gamma \) are quasi-isomorphisms, and \( \psi' = \gamma \circ \beta^{-1} \) in \( D(s.V \text{-Alg}) \). Moreover, there exist morphisms \( \varphi'' : R'' \to S'' \) and \( \psi'' : R'' \to R \) such that \( \psi'' \) is a quasi-isomorphism, and the resulting diagram

\[
\begin{array}{ccc}
R'' & \xrightarrow{\varphi''} & S'' \\
\psi'' \downarrow & & \downarrow \psi'' \\
R & \xrightarrow{\varphi} & S
\end{array}
\]

commutes in \( \text{Hot}(V \text{-Alg}) \). By claim 14.1.80 we may then replace \( \varphi \) by \( \varphi'' \) and \( \psi' \) by \( \beta \), after which we may assume that \( \psi' \) is a morphism of simplicial \( V \)-algebras.

Likewise, we may find morphisms \( \beta' : R'' \to R \) and \( \gamma' : R'' \to R' \) of simplicial \( V \)-algebras that are quasi-isomorphisms, and such that \( \psi = \gamma' \circ \beta'^{-1} \) in \( D(s.V \text{-Alg}) \); again by lemma 14.1.77 we see that \( \varphi'^a \) is weakly étale if and only if the same holds for \( \varphi'^a \circ \beta'^a \), so we may replace \( \varphi \) by \( \varphi \circ \beta \), \( \psi' \) by \( \psi \circ \gamma \), and assume from start that also \( \psi \) is a map of simplicial \( V \)-algebras.

In this situation, by applying once again lemma 14.1.77 we see that \( \varphi'^a \) (resp. \( \varphi'^a \)) is weakly étale if and only if the same holds for \( \psi'^a \circ \varphi'^a \) (resp. for \( \varphi'^a \circ \psi'^a \)). Therefore, we may assume from start that \( R = R', S = S' \), and \( \varphi, \varphi' : R \to S \) are two maps of simplicial \( V \)-algebras that represent the same morphism in \( D(s.V \text{-Alg}) \). In this case, we may find a morphism \( \vartheta : R'' \to R \) of simplicial \( V \)-algebras, such that \( \vartheta \) is a quasi-isomorphism, and \( \varphi \circ \vartheta, \varphi' \circ \vartheta : R'' \to S \) are homotopic maps; then the assertion follows from claim 14.1.80 (and again, from lemma 14.1.77; details left to the reader).

**Corollary 14.1.81.** Let \( \varphi : R \to S \) and \( \psi : S \to T \) be any two morphisms of simplicial \( V^a \)-algebras. We have:

1. If \( \varphi \) and \( \psi \) are weakly étale, the same holds for \( \psi \circ \varphi \).
2. If \( \varphi \) and \( \psi \circ \varphi \) are weakly étale, the same holds for \( \psi \).
(iii) If \( \varphi \) is weakly étale, and \( R \rightarrow R' \) is any morphism of simplicial \( V^a \)-algebras, then 
\[
\varphi' := R' \otimes_R \varphi \text{ is weakly étale.}
\]
(iv) \( \varphi \) is weakly étale if and only if the same holds for \( \Delta(\varphi) \).

**Proof.** (iv) is immediate from the discussion of \([14.1.71]\).

(iii): Endow \( S' := R' \otimes_R S \) with the \( R' \)-algebra structure deduced from its left tensor factor; then the assertion is an immediate consequence of the following more general

**Claim 14.1.82.** There exists a commutative diagram in \( D(R'-\text{Alg}) \)

\[
\begin{array}{ccc}
S' \otimes_{R'} S' & \rightarrow & R' \otimes_R (S \otimes_R S) \\
\Delta(\varphi') & \downarrow & \downarrow R' \otimes_R \Delta(\varphi) \\
S' & \rightarrow & R' \otimes_R (S \otimes_R S)
\end{array}
\]

whose horizontal arrow is an isomorphism.

**Proof of the claim.** Pick any resolution \( \rho : P \rightarrow S \) with \( P \) a flat \( R \)-algebra; then \( R' \otimes_R P \) represents \( R' \otimes_R S \), and we have a natural isomorphism of \( R' \)-algebras

\[
(R' \otimes_R P) \otimes_{R'} (R' \otimes_R P) \cong R' \otimes_R (P \otimes_R P).
\]

In view of remark \([7.10.21](i)\), the source of this map represents \( S' \otimes_{R'} S' \), and the target represents \( R' \otimes_R (S \otimes_R S) \). Under these identifications, the morphism \( R' \otimes_R \Delta(\varphi) \) becomes the map 
\[
1_{R' \otimes R}(\mu_{S \otimes (\rho \otimes_R \rho)}) \text{ (notation of } [14.1.71])
\]
whereas \( \Delta(\varphi') \) is represented by the multiplication map \( \mu_{R' \otimes_R P} = 1_{R' \otimes_R P} \mu_{\rho} \) of \( R' \otimes_R P \). The claim follows straightforwardly.

(i): Pick a resolution \( P \rightarrow S!! \) with \( P \) a flat \( R!! \)-algebra, and a resolution \( Q \rightarrow T!! \) with \( Q \) a flat \( P \)-algebra; in light of proposition \([14.1.78] \) it suffices to show that the resulting morphism \( R \rightarrow Q^a \) is weakly étale, so we may replace \( S \) by \( P^a \) and \( T \) by \( Q^a \), and assume from start that both \( \varphi \) and \( \psi \) are flat morphisms. Due to (iv), it then suffices to check that \( \Delta(\psi \circ \varphi) : T \otimes R T \rightarrow T \) is weakly étale; however, the latter can be factored as the composition

\[
(14.1.83) \quad T \otimes R T \rightarrow T \otimes_S (S \otimes_R S) \otimes_S T \xrightarrow{T \otimes_S \Delta(\varphi) \otimes_S T} T \otimes_S T \xrightarrow{\Delta(\psi)} T
\]

and by (iv) the maps \( \Delta(\psi) \) and \( \Delta(\varphi) \) are weakly étale, so the same holds for \( T \otimes_S \Delta(\varphi) \otimes_S T \), in view of (iii). We may therefore replace \( \psi \) by \( \Delta(\psi) \) and \( \varphi \) by \( T \otimes_S \Delta(\varphi) \otimes_S T \), after which, we may assume that \( \Delta(\psi) \) is an isomorphism in \( D(s.A-\text{Alg}) \). In this case, the factorization \( \Delta(\psi \circ \varphi) \) makes it clear that \( \Delta(\psi \circ \varphi) \) is weakly étale, as stated.

(ii): Set \( S' := S \otimes_R S \) and \( T' := S \otimes_R T \); we may factor \( \psi \) as the composition

\[
S \xrightarrow{S \otimes_R (\psi \circ \varphi)} T' \xrightarrow{T' \otimes_S \Delta(\varphi)} T
\]

so the assertion follows from (i), (iii) and (iv). \( \square \)

**Theorem 14.1.84.** Let \( \varphi : R \rightarrow S \) be a morphism of simplicial \( V \)-algebras, \( c, p \in \mathbb{N} \) two integers, with \( p \) a prime, and suppose that \( \varphi^a \) is weakly étale. We have :

(i) If the ideal \( m \cdot H_0(S) \) of \( H_0(S) \) satisfies condition (B) of \([59] \[2.1.6]\), then 
\[
\mathbb{L}^a_{S/R} = 0 \quad \text{in } D(S^a.\text{-Mod}).
\]

(ii) If \( S \) is a \( \mathbb{Z}(p) \)-algebra and \( H_i\mathbb{L}_{S/R} = 0 \) for every \( i < c \), then 
\[
H_i\mathbb{L}_{S/R} = 0 \quad \text{for every } i < c + 2p - 1.
\]

**Proof.** We begin with the following :
Claim 14.1.85. We may assume that both \(\Delta(\varphi^a)\) and \(H_0(\varphi)\) are isomorphisms.

Proof of the claim. To ease notation, set \(S' := S \otimes_R S\), and consider the sequence of morphisms

\[
(14.1.86) \quad S \xrightarrow{1_S \otimes \varphi} S' \xrightarrow{\mu_S} S
\]

where \(\mu_S\) is the composition of the multiplication map \(S \otimes_R S \to S\) and the natural map \(S' \to S \otimes_R S\); the transitivity triangle (\([82, \text{III.2.1.2}]\)) relative to \((14.1.86)\) yields a natural isomorphism

\[
\mathbb{L}_{S'/S} \sim \sigma S \otimes_{S'} \mathbb{L}_{S'/S} \sim \sigma S \otimes_{S'} (S' \otimes_S \mathbb{L}_{S/R}) \quad \text{in } \mathbf{D}(\mathbf{S-Mod})
\]

where the last isomorphism follows from the base change theorem of \([82, \text{III.2.1.1}]\). Thus, \(\mathbb{L}_{S'/S} \simeq \sigma \mathbb{L}_{S/R}\) in \(\mathbf{D}(\mathbf{S-Mod})\), so assertion (i) (resp. (ii)) holds for \(\varphi\), provided it holds for \(\Delta(\varphi)\), and then the claim follows from corollary \([14.1.81]\) iv).

Henceforth, we assume that both \(\Delta(\varphi^a)\) and \(H_0(\varphi)\) are isomorphisms. Let \(P \to S\) be a resolution, with \(P\) an \(R\)-algebra, such that \(P[n]\) is a free \(R[n]\)-algebra for every \(n \in \mathbb{N}\); set \(P' := S \otimes_R P\), and recall that there are natural isomorphisms

\[
\mathbb{L}_{S/R} \sim S \otimes_P \Omega^1_{P/R} \sim S \otimes_P \Omega^1_{P'/S}
\]

where \(\Omega^1_{P/R}\) denotes the flat simplicial \(P\)-module such that \(\Omega^1_{P/R}[n] := \Omega_{P[n]/R[n]}\) (and likewise for \(\Omega^1_{P'/S}\)), with faces and degeneracies deduced from those of \(P\) and \(R\) (resp. those of \(P'\) and \(S\)), in the obvious way. In other words, set

\[
J := \ker(\mu_S : P' \to S)
\]

(with \(\mu_S\) as in the proof of claim \([14.1.85]\)); then \(\mathbb{L}_{S/R} \simeq J/J^2\) in \(\mathbf{D}(\mathbf{S-Mod})\), and notice that

\[
(14.1.87) \quad J^a = 0 \quad \text{in } \mathbf{D}(\mathbf{S^n-Mod})
\]

since \(\Delta(\varphi^a)\) is an isomorphism.

Claim 14.1.88. \(J\) is a quasi-regular ideal, and \(H_0 J = 0\).

Proof of the claim. Since \(H_0(\varphi)\) is an isomorphism, it is clear that \(H_0 J = 0\). Next, for every \(n \in \mathbb{N}\), the \(S[n]\)-algebra \(P[n]\) is free, hence we reduce to showing the following. Let \(B\) be any ring, \(C := B[X_i \mid i \in I]\) any free \(B\)-algebra (for any set \(I\)), and \(f : C \to B\) any morphism of \(B\)-algebras; then \(\ker f\) is a quasi-regular ideal of \(C\). However, for every \(i \in I\), set \(b_i := f(X_i)\), and let \(g : C \sim C\) be the isomorphism of \(B\)-algebras such that \(g(X_i) = X_i - a_i\) for every \(i \in I\); clearly \(\ker f\) is a quasi-regular ideal if and only if the same holds for \(g^{-1}\ker f\). But the latter is the ideal \((X_i \mid i \in I)\), so the assertion follows from remark \([7.10.34]\) iii).

(i): We need to show that \(H_n(J/J^2)^a = 0\) for every \(n \in \mathbb{N}\), and we shall argue by induction on \(n\). The assertion for \(n = 0\) is clear from \((14.1.87)\), in view of the exact sequence

\[
H_n J \to H_n(J/J^2) \to H_{n-1} J^2 \quad \text{for every } n \in \mathbb{N}.
\]

Hence, suppose that \(n > 0\), and the assertion is already known for every degree \(< n\). The same exact sequence reduces to checking that \(H_{n-1}(J^2)^a = 0\). Now, from claim \([14.1.88]\) and theorem \([7.10.38]\) we know that \(H_{n-1}(J^n) = 0\). Therefore, by an easy induction, we are further reduced to showing that \(H_{n-1}(J^i/J^{i+1})^a = 0\) for every \(i = 2, \ldots, n - 1\). However, on the one hand, proposition \([7.10.35]\) ii.a) says that the natural map

\[
\text{LSym}_S^i(J/J^2) \to J^i/J^{i+1}
\]

is an isomorphism in \(\mathbf{D}(\mathbf{S-Mod})\), for every \(i \in \mathbb{N}\); on the other hand, the inductive assumption and theorem \([14.1.60]\) (i) imply that \(H_j(\text{LSym}_S^i J/J^2)^a = 0\) for every \(j \leq n\), whence the contention.
(ii): We show, by induction on \( n \), that \( H_n(J/J^2)^a = 0 \) for every \( n < c + 2p - 1 \). Arguing as in the foregoing, we may assume that \( c + 2p - 1 > n > 0 \), and the sought vanishing is already known in degrees \( n < n \), in which case we reduce to checking that \( H_{n-1}(L\text{Sym}_S^i J/J^2)^a = 0 \) for every \( i = 2, \ldots, n - 1 \). Set \( M := \cosk_n(s.\text{trunc}_n J/J^2) \); then \( H_j M = 0 \) for every \( j < c \), and the inductive assumption implies that \( M^a = 0 \) in \( \text{D}(\text{S}^a\text{-Mod}) \), so \( H_{n-1}(L\text{Sym}_S^i M)^a = 0 \), by theorem 14.1.66(iii). Lasty, by corollary 7.10.24(i), we see that
\[
H_{n-1}(L\text{Sym}_S^i M) = H_{n-1}(L\text{Sym}_S^i J/J^2)
\]
whence the contention. \( \square \)

**Remark 14.1.89.** Let \( A \to B \) be any morphism of simplicial rings such that the multiplication map \( \mu_B : B \otimes_A B \to B \) induces an isomorphism \( H_0(\mu_B) : H_0(B) \otimes H_0(A) \to H_0(B) \). Pick a resolution \( \varphi : P \to B \) such that \( P[n] \) is a free \( A[n] \)-algebra for every \( n \in \mathbb{N} \), and set \( P' := B \otimes_A P, J := \ker(\mu_B \circ (B \otimes_A \varphi) : P' \to B) \). The assumption on \( B \) implies that \( H_0 J = 0 \). On the other hand, arguing as in the proof of claim 14.1.88 we see that \( J \) is a quasi-
regular ideal. Taking into account proposition 7.10.35(ii) the spectral sequence associated with the \( J \)-adic filtration of \( P' \) can be written as
\[
E_{p,q}^2 := H_{p+q}(L\text{Sym}_B^q(\mathbb{L}_{B/A})) \Rightarrow \text{Tor}_{p+q}^A(B, B).
\]
Though the \( J \)-adic filtration is not finite, using proposition 7.2.18(i) and theorem 7.10.38 one sees that this spectral sequence is convergent, and the filtration on its abutment is finite. We will not use this result.

**Corollary 14.1.90.** Let \( \varphi : A \to B \) be a morphism of \( V^a \)-algebras, \( p \in \mathbb{N} \) a prime integer, and suppose that
(a) \( V \) is a \( \mathbb{Z}_{(p)} \)-algebra
(b) the induced morphism \( s.\varphi : s.A \to s.B \) of simplicial \( V^a \)-algebras is weakly étale.
Then \( H_i \mathbb{L}_{B/A}^a = 0 \) for every \( i \leq 2p \).

**Proof.** Notice that condition (a) implies that \( B \) is a \( \mathbb{Z}_{(p)} \)-algebra; letting \( c := 0 \) in theorem 14.1.84(ii), we deduce that \( H_i \mathbb{L}_{B/A}^a = 0 \) for \( i = 0, 1 \). But in view of claim 14.1.46 the latter implies that \( H_i \mathbb{L}_{B_n/A_n}^a = 0 \) for \( i = 0, 1 \). So, actually the morphism \( \varphi \) fulfills the conditions of theorem 14.1.84(ii), with \( c = 2 \), whence the assertion. \( \square \)

**Remark 14.1.91.** As an application we can now generalize the deformation theory for almost rings in 59 §3.2] to the case of an arbitrary basic setup \((V, m)\). Indeed, 59 Lemmata 3.2.1 and 3.26, Prop.3.2.9 and Cor.3.2.11 hold verbatim for any such basic setup, with the same proof: the only difference is that instead of invoking 59 §3.2] we must appeal to our theorem 14.1.43 in the explanation of 59 §3.2.7]. Next, let \( A \to B \) be any weakly étale morphism of \( V^a \)-algebras; for every prime integer \( p \), let \( V(p) := \mathbb{Z}_{(p)} \otimes \mathbb{Z} V \), and denote
\[
\delta_p : (V, m)^a\text{-Alg} \to (V(p), mV(p))^a\text{-Alg} \quad C \mapsto \mathbb{Z}_{(p)} \otimes_{\mathbb{Z}} C
\]
the natural functor; with this notation, it is easily seen that
\[
\mathbb{Z}_{(p)} \otimes_{\mathbb{Z}} B_{\text{et}} = (\delta_p B)_{\text{et}}
\]
(details left to the reader), and in view of 82 II.2.2.1] we deduce a natural isomorphism
\[
\mathbb{Z}_{(p)} \otimes_{\mathbb{Z}} \mathbb{L}_{B_n/A_n} \sim \mathbb{L}((\delta_p B)_{\text{et}})/(\delta_p A)_{\text{et}}.
\]
Corollary 14.1.90 then easily implies that \( H_i \mathbb{L}_{B/A}^a = 0 \) for every \( i \leq 4 \). Combining with the results just quoted from 59, we see that the whole of 59 Th.3.2.18 still holds under the current assumptions. In the same vein, we may complement as follows the descent results of 59 §3.4]:
Corollary 14.1.92. Consider a cartesian diagram of $V^a$-algebras

\begin{align*}
\begin{array}{ccc}
A_0 & \longrightarrow & A_1 \\
\downarrow & & \downarrow \\
A_2 & \longrightarrow & A_3
\end{array}
\end{align*}

such that the morphism $A_1 \to A_3$ is an epimorphism on the underlying $V^a$-modules. Then the resulting morphism $A_0 \to A_1 \times A_2$ is of universal effective descent for the fibred categories $w.\Et$ of weakly étale morphisms and $\Et$ of étale morphisms.

Proof. Arguing as in the proof of [59, Prop.3.4.33], and using [59, Cor.3.4.22], we see that the morphism $A_0 \to A_1 \times A_2$ is of effective descent for the fibred categories $w.\Et$ and $\Et$. Next, consider any morphism $A_0 \to B_0$ of $V^a$-algebras, and set $B_i := B_0 \otimes_{A_0} A_i$ for $i = 1, 2, 3$. The resulting diagram $0 \to B_0 \to B_1 \times B_2 \to B_3 \to 0$, which shows that $f$ is an epimorphism. Newt, for any $B$-module $M$ we show more generally that

$$\text{Ann}_B(M \otimes_{A_0} A_1) \cdot \text{Ann}_B(M \otimes_{A_0} A_2) \subset \text{Ann}_B(M).$$

Letting $M := B$, it will then follow easily that $(\ker f)^2 = 0$. Now, let $x,y \in B$ be two almost elements such that $x \cdot (M \otimes_{A_0} A_1) = 0$ and $y \cdot (M \otimes_{A_0} A_2) = 0$, and let also $I := \ker (A_1 \to A_3) = \ker (A_0 \to A_2)$; since $M \otimes_{A_0} A_2 = M/I M$, we deduce that $y M \subset I M$, and on the other hand the natural morphism of $A_0$-modules $M \otimes_{A_0} A_1 \otimes_{A_1} I \to M \otimes_{A_0} I \to I M$ is an epimorphism, so that $x \cdot I M = 0$, and the assertion follows.

Now, by the foregoing we known already that the induced morphism $B_1' \to B_1 \times B_2$ is of effective descent for $w.\Et$ and $\Et$. But claim 14.1.93 together with remark 14.1.91 implies that the base change functors

$$B_0 \cdot w.\Et \to B_0' \cdot w.\Et \quad \text{and} \quad B_0 \cdot \Et \to B_0' \cdot \Et$$

are equivalences of categories; thus, also the induced morphism $B_0 \to B_1 \times B_2$ is of effective descent, as required. \qed

14.1.94. We conclude this section with a few words on the cohomology of sheaves of almost modules. Namely, let $(V, m)$ again be an arbitrary basic setup, which we view as a basic setup relative to the one-point topos $\{ \text{pt} \}$, in the sense of [59, §3.3]. Let $(X, \mathcal{O}_X)$ be a ringed topos, $m_X \subset \mathcal{O}_X$ an ideal, such that $(\mathcal{O}_X, m_X)$ is a basic setup relative to the topos $X$, and suppose also that we are given a morphism of ringed topoi:

$$\pi : (X, \mathcal{O}_X) \to (\{ \text{pt} \}, V) \quad \text{such that} \quad (\pi^* m) \cdot \mathcal{O}_X \subset m_X.$$  

We deduce a natural morphism:

$$R\pi_* : D^+((\mathcal{O}_X, m_X)^a\text{-Mod}) \to D^+((V, m)^a\text{-Mod})$$

which can be constructed as usual, by taking injective resolutions. In case $m$ is a flat $V$-module, this is the same as setting

$$R\pi_* (K^•) := (R\pi_* K^•)^a.$$
Using [59, Cor.2.2.24] one may verify that the two definitions coincide: the details shall be left to the reader. In many cases, both statements and proofs of results concerning the cohomology of $\mathcal{O}_X$-modules carry over verbatim to $\mathcal{O}^a_\mathfrak{a}$-modules. One sets, as customary:

$$H^\bullet(X, K^\bullet) := H^\bullet R\pi_* K^\bullet$$

for every object $K^\bullet$ of $D^+((\mathcal{O}_X, \mathfrak{m}_X)^a$-$\text{Mod})$.

**14.1.95.** As an illustration, we consider the following situation. Suppose that:

- $f : A \to A'$ is a map of $V$-algebras, and set:
  $$\varphi := \text{Spec } f : X' := \text{Spec } A' \to X := \text{Spec } A.$$
- $t \in A$ is an element which is regular both in $A$ and in $A'$, and such that the induced map $A/tA \to A'/tA'$ is an isomorphism.
- $U \subset X$ is any open subset containing $D(t) := \{ p \in X \mid t \notin p \}$, and set $U' := \varphi^{-1}U$.
- $\mathcal{F}$ is a quasi-coherent $\mathcal{O}^a_\mathfrak{a}$-module, and set $\mathcal{F}' := \varphi^a_{U'} \mathcal{F}$, which is a quasi-coherent $\mathcal{O}^a_\mathfrak{a}$-module.

Then we have natural morphisms of $A^a$-modules:

$$H^q(U, \mathcal{F}) \to H^q(U', \mathcal{F}') \quad \text{for every } q \in \mathbb{N}. \quad (14.1.96)$$

**Lemma 14.1.97.** In the situation of (14.1.95), suppose moreover that $t$ is $\mathcal{F}$-regular. Then (14.1.96) is an isomorphism for every $q > 0$, and induces an isomorphism of $A^a$-modules:

$$H^0(U, \mathcal{F}) \otimes_A A' \to H^0(U', \mathcal{F}'). \quad (14.1.98)$$

**Proof.** To ease notation, we shall write $\varphi$ instead of $\varphi_{|U'}$. To start out, we remark:

**Claim 14.1.98.** (i) $\text{Tor}_1^{\mathcal{O}^a_\mathfrak{a}}(\mathcal{F}, \mathcal{O}^a_\mathfrak{a}/t \mathcal{O}^a_\mathfrak{a}) = 0$ and $\text{Tor}_1^{\mathcal{O}^a_\mathfrak{a}}(H^0(U, \mathcal{F}), A/tA) = 0$.

(ii) The $\mathcal{O}^a_\mathfrak{a}$-module $\varphi_* \mathcal{F}' = \mathcal{F} \otimes_{\mathcal{O}^a_\mathfrak{a}} \varphi_* \mathcal{O}^a_\mathfrak{a}$ (resp. the $A^a$-module $H^0(U, \mathcal{F}) \otimes_{A^a} A^a$) is $t$-torsion-free.

**Proof of the claim.** (i): Since $t$ is regular on $\mathcal{O}_U$, we have a short exact sequence: $\mathcal{E} := (0 \to \mathcal{O}^a_\mathfrak{a} \to \mathcal{O}^a_\mathfrak{a} \to \mathcal{O}^a_\mathfrak{a}/t \mathcal{O}^a_\mathfrak{a} \to 0)$, and since $t$ is regular on $\mathcal{F}$, the sequence $\mathcal{E} \otimes_{\mathcal{O}^a_\mathfrak{a}} \mathcal{F}$ is still exact; the vanishing of $\text{Tor}_1^{\mathcal{O}^a_\mathfrak{a}}(\mathcal{F}, \mathcal{O}^a_\mathfrak{a}/t \mathcal{O}^a_\mathfrak{a})$ is an easy consequence. For the second stated vanishing one argues similarly, using the exact sequence $0 \to A \to A \to A/tA \to 0$.

(ii): Under the current assumptions, the natural map $\mathcal{O}_U/t \mathcal{O}_U \to \varphi_*(\mathcal{O}_U/t \mathcal{O}_U)$ is an isomorphism, whence a short exact sequence: $\mathcal{E}' := (0 \to \varphi_* \mathcal{O}^a_\mathfrak{a} \to \varphi_* \mathcal{O}^a_\mathfrak{a} \to \mathcal{O}^a_\mathfrak{a}/t \mathcal{O}^a_\mathfrak{a} \to 0)$. In view of (i), the sequence $\mathcal{E}' \otimes_{\mathcal{O}^a_\mathfrak{a}} \mathcal{F}$ is still exact, so $\mathcal{F} \otimes_{\mathcal{O}^a_\mathfrak{a}} \varphi_* \mathcal{O}^a_\mathfrak{a}$ is $t$-torsion-free. An analogous argument works as well for $H^0(U, \mathcal{F}) \otimes_{A^a} A^a$. \hfill \Box

**Claim 14.1.99.** For every $n > 0$, the map $A/t^nA \to A'/t^nA'$ induced by $f$ is an isomorphism.

**Proof of the claim.** Indeed, since $t$ is regular on both $A$ and $A'$, and $A/tA \to A'/tA'$, the map of graded rings $\oplus_{n \in \mathbb{N}} A/n^A A' \to \oplus_{n \in \mathbb{N}} A'/n^{A'} A'$ is bijective. Then the claim follows from [28, Ch.III, §2, n.8, Cor.3]. \hfill \Box

Let $j : D(t) \to U$ be the natural open immersion, and set:

$$\mathcal{F}[-1] := j_* j^* \mathcal{F} \simeq \mathcal{F} \otimes_{\mathcal{O}^a_\mathfrak{a}} j_* \mathcal{O}^a_{D(t)}.$$ 

Notice the natural isomorphisms:

$$j_* j^* \varphi_* \mathcal{F}' \simeq (\mathcal{F} \otimes_{\mathcal{O}^a_\mathfrak{a}} \varphi_* \mathcal{O}^a_\mathfrak{a}) \otimes_{\mathcal{O}^a_\mathfrak{a}} j_* \mathcal{O}^a_{D(t)} \simeq \mathcal{F}[-1] \otimes_{\mathcal{O}^a_\mathfrak{a}} \varphi_* \mathcal{O}^a_\mathfrak{a}. \quad (14.1.100)$$

Since $t$ is $\mathcal{F}$-regular, the natural map $\mathcal{F} \to \mathcal{F}[-1]$ is a monomorphism, and the same holds for the corresponding map $\varphi_* \mathcal{F}' \to j_* j^* \varphi_* \mathcal{F}'$, in view of claim [14.1.98(ii)]. Moreover, $\mathcal{F} := \mathcal{F}[-1]/\mathcal{F}$ can be written as the increasing union of its subsheaves $\text{Ann}_G(t^n)$ (for all $n \in \mathbb{N}$);
hence claim 14.1.99 implies that the natural map $\mathcal{G} \to \mathcal{G} \otimes_{\varphi^*} \mathcal{G}_{\mathcal{U}, t}$ is an isomorphism. There follows a ladder of short exact sequences:

$$
\begin{array}{ccccccccc}
0 & \to & \mathcal{G} & \to & \mathcal{G}[t^{-1}] & \to & \mathcal{G} & \to & 0 \\
\downarrow & & \downarrow & & \downarrow & & \downarrow & & \\
0 & \to & \varphi_*, \mathcal{G}' & \to & \mathcal{G}[t^{-1}] \otimes_{\varphi^*} \mathcal{G}_{\mathcal{U}, t} & \to & \mathcal{G} & \to & 0.
\end{array}
$$

(14.1.101)

On the other hand, since $j$ is an affine morphism, we may compute:

$$
H^q(U, \mathcal{F}[t^{-1}]) \simeq H^q(U, Rj_*j^* \mathcal{F}) \simeq H^q(D(t), j^* \mathcal{F}) \simeq 0 \quad \text{for every } q > 0.
$$

Likewise, from (14.1.100) we get:

$$
H^q(U, \mathcal{F}[t^{-1}] \otimes_{\varphi^*} \mathcal{G}_{\mathcal{U}, t}) \simeq 0 \quad \text{for every } q > 0.
$$

Thus, in the commutative diagram:

$$
\begin{array}{ccc}
H^{q-1}(U, \mathcal{G}) & \xrightarrow{\partial} & H^q(U, \mathcal{F}) \\
\downarrow & & \downarrow \\
H^q(U, \mathcal{F}) & \xrightarrow{\sim} & H^q(U', \mathcal{F}')
\end{array}
$$

the boundary maps $\partial$ and $\partial'$ are isomorphisms whenever $q > 1$, and the right vertical arrow is (14.1.96), so the assertion follows already for every $q > 1$. To deal with the remaining cases with $q = 0$ or 1, we look at the ladder of exact cohomology sequences:

$$
\begin{array}{ccccccccc}
0 & \to & H^0(U, \mathcal{F}) & \to & H^0(D(t), \mathcal{F}) & \to & H^0(U, \mathcal{G}) & \to & H^1(U, \mathcal{F}) & \to & 0 \\
\downarrow & & \downarrow & & \downarrow & & \downarrow & & \downarrow & & \\
0 & \to & H^0(U', \mathcal{F}') & \to & H^0(D(t), \mathcal{F}) \otimes_{A^\alpha} A^\alpha & \to & H^0(U, \mathcal{G}) & \to & H^1(U', \mathcal{F}') & \to & 0
\end{array}
$$

deduced from (14.1.101). On the one hand, we remark that the natural inclusion $\text{Im } \beta \subset \text{Im } \beta'$ factors as a composition

$$
\text{Im } \beta \xrightarrow{\iota} M := A^\alpha \otimes_{A^\alpha} \text{Im } \beta \xrightarrow{\pi} \text{Im } \beta'
$$

where $\iota$ is given by the rule: $x \mapsto 1 \otimes x$, for all $x \in A^\alpha$, and $\pi$ is an epimorphism.

On the other hand, the image of $\beta$ is isomorphic to $N := \text{Coker } \alpha$, and the latter is the increasing union of its submodules $\text{Ann}_N(t^n)$ (for all $n \in \mathbb{N}$). Again from claim 14.1.99 we deduce that $M = \text{Im } \beta$, hence $\text{Im } \beta' = \text{Im } \beta$, which shows that (14.1.96) is an isomorphism also for $q = 1$. By the same token, $\text{Ker}(\alpha \otimes_{A^\alpha} 1_{A^\alpha})$ is the increasing union of its $t^n$-torsion submodules (for all $n \in \mathbb{N}$), since it is a quotient of $\text{Tor}_1^{A^\alpha}(\text{Im } \beta, A^\alpha)$; hence $\text{Ker}(\alpha \otimes_{A^\alpha} 1_{A^\alpha}) = 0$, in view of claim 14.1.98(ii). This easily implies the last assertion for $q = 0$. \hfill \square

14.2. **Inverse systems of almost modules.** The considerations of this section expand upon [59, §2.3.14, §2.4.1, Lemmata 2.3.15, 2.4.2 and 2.4.13].

14.2.1. Let $V$ be a ring, $(m_\lambda \mid \lambda \in \Lambda)$ a filtered system of ideals of $V$ such that $m_\lambda^2 = m_\lambda$ for every $\lambda$, and set $m := \bigcup_{\lambda \in \Lambda} m_\lambda$. Then $(V, m)$ and $(V, m_\lambda)$ for every $\lambda \in \Lambda$ are basic setups, and we have an obvious compatible system of localization functors:

$$
\begin{array}{ccc}
(V, m)^{a}\text{-Mod} & \xrightarrow{\pi_\lambda} & (V, m_\lambda)^{a}\text{-Mod} \\
\downarrow & & \downarrow \\
(V, m_\mu)^{a}\text{-Mod} & \xrightarrow{\pi_\lambda \mu} & (V, m_\lambda)^{a}\text{-Mod}
\end{array}
$$

(14.2.2) for every $\lambda \geq \mu$ in $\Lambda$. 
Proposition 14.2.3. (i) The compatible system \((14.2.2)\) induces an equivalence of categories
\[
\omega : (V, m)^a-\text{Mod} \xrightarrow{\sim} \text{2-lim}_{\lambda \in \Lambda} (V, m)^a-\text{Mod}.
\]

(ii) If \(m_\lambda\) fulfills condition (B) of \([59] \S 2.1.6\) for every \(\lambda \in \Lambda\), then the same holds for \(m\).

Proof. (ii) is obvious. To show (i), we construct a quasi-inverse \(\tau\) for \(\omega\) as follows. Recall that an object of the above 2-limit is a datum \((M_*, f_*):= ((M_\lambda : \lambda \in \Lambda), (f_{\lambda \mu} : \pi_{\lambda \mu}(M_\lambda) \xrightarrow{\sim} M_\mu : \lambda \geq \mu))\) consisting of \((V, m)^a\)-modules \(M_\lambda\) for every \(\lambda \in \Lambda\), and isomorphisms \(f_{\lambda \mu}\) of \((V, m)^a\)-modules, for every \(\lambda \geq \mu\) in \(\Lambda\). Such a datum is required moreover to satisfy the compatibility condition:
\[
f_{\lambda \mu} \circ a_{\mu \nu}(f_{\lambda \mu}) = f_{\lambda \nu}
\]
whenever \(\lambda \geq \mu \geq \nu\).

However, the discussion of \([59] \S 2.2.2\) allows to describe such a datum more concretely as follows. Choose, for every \(\lambda \in \Lambda\) a \(V\)-module \(M'_\lambda\) whose image in \((V, m)^a\)-\text{Mod} represents \(M_\lambda\); the isomorphism \(f_{\lambda \mu}\) corresponds then to a unique \(V\)-linear isomorphism
\[
f'_{\lambda \mu} : \tilde{m}_\mu \otimes_V M'_\lambda \xrightarrow{\sim} \tilde{m}_\mu \otimes_V M'_\mu\]
whenever \(\lambda \geq \mu\) (with \(\tilde{m}_\lambda := m_\lambda \otimes_V m_\lambda\) for every \(\lambda \in \Lambda\) such that
\[
(14.2.4)\quad f'_{\lambda \mu} \circ (\tilde{m}_\nu \otimes_V f'_{\lambda \mu}) = \tilde{m}_\nu \otimes_V f'_{\lambda \nu}\]
whenever \(\lambda \geq \mu \geq \nu\). Set \(M'_\lambda := \tilde{m}_\lambda \otimes_V M'_\lambda\); by composing the inverse of \(f'_{\lambda \mu}\) with the natural map \(\tilde{m}_\mu \otimes_V M'_\lambda \to M_\lambda\), we obtain a well defined \(V\)-linear map
\[
f''_{\lambda \mu} : M_\mu \to M_\lambda\]
whenever \(\lambda \geq \mu\) and in light of \((14.2.4)\) we deduce easily that \(f''_{\lambda \mu} = f''_{\mu \nu} \circ f''_{\lambda \mu}\) whenever \(\lambda \geq \mu \geq \nu\) (details left to the reader). We now let
\[
\tau(M_*, f_*) := (\text{colim}_{\lambda \in \Lambda} M_\lambda)^a \in \text{Ob}((V, m)^a-\text{Mod}).
\]

If \((N_*, g_*)\) is another object of the above 2-limit of categories, a morphism \((M_*, f_*) \to (N_*, g_*)\) is the datum of a system of morphisms \(h_\lambda : M_\lambda \to N_\lambda\) fulfilling obvious compatibility conditions with respect to the isomorphisms \(f_*\) and \(g_*\). After choosing representative \(V\)-modules \(N'_\lambda\) for each \(N_\lambda\), the morphism \(h_\lambda\) corresponds to a unique \(V\)-linear map \(h'_\lambda : M_\lambda \to N'_\lambda\) for every \(\lambda \in \Lambda\). It is then clear that the resulting system \(h'_*\) yields a natural transformation \(M'_* \to N'_*\) of direct systems indexed by \(\Lambda\), whence a well defined morphism of \((V, m)^a\)-modules
\[
\tau(h_*) := (\text{colim}_{\lambda \in \Lambda} h'_\lambda)^a : \tau(M_*, f_*) \to \tau(N_*, g_*).\]

This completes the construction of our functor \(\tau\). It is easily seen that the definition of \(\tau\) is independent of all choices, up to a canonical isomorphism of functors. Especially, if \((M_*, f_*) = \omega(M^a)\) for some \(V\)-module \(M\), we may assume that \(M'_\lambda\) has been chosen equal to \(M\), and \(f''_{\lambda \mu} = \tilde{m}_\lambda \otimes_V 1_M\) for every \(\lambda, \mu \in \Lambda\) with \(\lambda \geq \mu\). With these choices, we get a natural isomorphism \(\tau \circ \omega(M^a) \xrightarrow{\sim} M^a\) for every \((V, m)^a\)-module \(M^a\). Next, for any given datum \((M_*, f_*)\) as in the foregoing, set \((P_*, t_*) := \omega \circ \tau(M_*, f_*)\); for every \(\mu \in \Lambda\), the subset \(\Lambda(\mu) := \{\lambda \in \Lambda : \lambda \geq \mu\}\) is cofinal in \(\Lambda\), hence \(P_\mu\) is naturally isomorphic to
\[
(\text{colim}_{\lambda \in \Lambda(\mu)} M_\lambda)^a \cong \text{colim}_{\lambda \in \Lambda(\mu)} (M_\lambda)^a \cong \text{colim}_{\lambda \in \Lambda(\mu)} \pi_{\lambda \mu}(M_\lambda)
\]
where the transition morphisms in the latter colimit are given by the isomorphisms \(f_{\lambda \mu}\), i.e. is naturally isomorphic to \(M_\mu\). Lastly, under this identification, it is easily seen that the morphism \(t_{\lambda \mu}\) corresponds to \(f_{\lambda \mu}\) whenever \(\lambda \geq \mu\) in \(\Lambda\) (details left to the reader); summing up, we have obtained a natural isomorphism \(\omega \circ \tau(M_*, f_*) \xrightarrow{\sim} (M_*, f_*)\), and the proof is concluded. \(\square\)
Corollary 14.2.5. With the notation of (14.2.1), for every \((V, m)^a\)-module \(M\) and every \(\lambda \in \Lambda\), denote by \(M_{\lambda}\) the image of \(M\) in \((V, m_{\lambda})^a\)-Mod. Let \(A\) be a \((V, m)^a\)-algebra, \(M\) an \(A\)-module, \(B\) an \(A\)-algebra, and \(r \in \mathbb{N}\). Then the following holds:

(i) We have natural isomorphisms of \(V\)-modules:
\[
\colim_{\lambda \in \Lambda} M_{\lambda} \cong M \quad M_{\lambda} \cong \lim_{\lambda \in \Lambda} M_{\lambda}. 
\]

(ii) The system of localization functors \(A\)-Alg \(\rightarrow\) \(A_{\lambda}\)-Alg induces a natural equivalence
\[
A\text{-Alg} \cong 2\text{-lim}_{\lambda \in \Lambda} A_{\lambda}\text{-Alg}.
\]

(iii) The \(A\)-module \(M\) is flat (resp. faithfully flat, resp. almost projective, resp. almost finitely generated, resp. almost finitely presented) if and only if the same holds for the \(A_{\lambda}\)-module \(M_{\lambda}\), for every \(\lambda \in \Lambda\).

(iv) Suppose that \(m_{\lambda}\) fulfills condition (B) for every \(\lambda \in \Lambda\). Then the \(A\)-module \(M\) is almost projective of almost finite rank (resp. of finite rank \(\leq r\)) if and only if the same holds for the \(A_{\lambda}\)-module \(M_{\lambda}\), for every \(\lambda \in \Lambda\).

(v) The \(A\)-algebra \(B\) is flat (resp. faithfully flat, resp. weakly unramified, resp. weakly étale, resp. unramified, resp. étale) if and only if the same holds for the \(A_{\lambda}\)-algebra \(B_{\lambda}\), for every \(\lambda \in \Lambda\).

Proof. (i): The assertion for \(M_{\lambda}\) is clear. For the assertion concerning \(M_{\lambda}\), it suffices to notice that for any two \((V, m)^a\)-modules \(M\) and \(N\), proposition (14.2.3) implies that the natural map
\[
\text{Hom}_{(V, m)^a\text{-Mod}}(M, N) \rightarrow \lim_{\lambda \in \Lambda} \text{Hom}_{(V, m_{\lambda})^a\text{-Mod}}(M_{\lambda}, N_{\lambda})
\]
is an isomorphism of \(V\)-modules.

(ii),(iii): Clearly the functors \(\pi_{\lambda}\) and \(\pi_{\lambda_{\mu}}\) of (14.2.1) are all compatible with tensor products and with the \(\text{alHom}\) functors; moreover, for every \(\lambda \in \Lambda\), every short exact sequence of \((V, m_{\lambda})^a\)-modules is isomorphic to \(\Sigma^n\), for some short exact sequence \(\Sigma\) of \(V\)-modules (and likewise for short exact sequences of \((V, m)^a\)-modules: details left to the reader). In view of proposition (14.2.3) (i), assertion (ii) follows straightforwardly, and taking into account the isomorphism (14.2.6), we also deduce that the \(A\)-module \(M\) is flat (resp. almost projective) if and only if the same holds for the \(A_{\lambda}\)-module \(M_{\lambda}\), for every \(\lambda \in \Lambda\).

Next, if every \(M_{\lambda}\) is a faithfully flat \(A_{\lambda}\)-module, and \(X\) is an \(A\)-module with \(M \otimes_A X = 0\), it follows that \(M_{\lambda} \otimes_{A_{\lambda}} X_{\lambda} = 0\) for every \(\lambda \in \Lambda\), whence \(X_{\lambda} = 0\) for every such \(\lambda\), and hence \(X = 0\), by proposition (14.2.3) (i). Conversely, if \(M\) is faithfully flat and \(\lambda \in \Lambda\), consider any \(A\)-module \(X\) such that \(M_{\lambda} \otimes_{A_{\lambda}} X_{\lambda} = 0\); then \((M \otimes_A X)_{\lambda} = 0\), i.e. \(m_{\lambda} \otimes (M_{\lambda} \otimes_{A_{\lambda}} X_{\lambda}) = 0\), so that \(M \otimes_A (m_{\lambda} \otimes_X X) = 0\). By assumption, this implies that \(m_{\lambda} \otimes_X X = 0\), and therefore \(X_{\lambda} = 0\); this shows that \(M_{\lambda}\) is faithfully flat.

Next, say that \(A = R^a\) and \(M = N^a\) for some \(V\)-algebra \(R\) and some \(R\)-module \(N\); suppose that each \(M_{\lambda}\) is almost finitely generated (resp. almost finitely presented), and let \(m_0 \subset m\) be any finitely generated subideal. We then find \(\lambda \in \Lambda\) such that \(m_0 \subset m_{\lambda}\), and by applying [59] Cor.2.3.13 to the \(A_{\lambda}\)-module \(M_{\lambda}\) we find a finitely generated (resp. finitely presented) \(R\)-module \(N'\) and an \(R\)-linear map \(N' \rightarrow N\) whose kernel and cokernel are annihilated by \(m_0\). Then, by applying [59] Cor.2.3.13 to the \(A\)-module \(M\), we deduce the assertion.

(iv): If every \(M_{\lambda}\) is almost projective of almost finite rank, we already know that \(M\) is almost projective, and it remains only to check that \(M\) is of almost finite rank. To this aim, let \(\varepsilon \in m\) be any element, choose \(\lambda \in \Lambda\) such that \(\varepsilon \in m_{\lambda}^2\), and write \(\varepsilon = \sum_{i=1}^n \varepsilon_i \varepsilon_i'\) for some \(n \in \mathbb{N}\) and \(\varepsilon_i, \varepsilon_i' \in m_{\lambda}\); if \(M_{\lambda}\) is of almost finite rank, we may then find \(j \in \mathbb{N}\) such that \(\varepsilon_i \cdot A_{\lambda}^j M_{\lambda} = 0\) for \(i = 1, \ldots, n\), in which case it follows easily that \(\varepsilon_i \varepsilon_i' \cdot A_{\lambda}^j M = 0\) for every \(i = 1, \ldots, n\) (details left to the reader), whence the assertion. One argues likewise in case each \(M_{\lambda}\) has rank \(\leq r\); the details shall be left to the reader.
(v) follows immediately from (i), (ii) and (iii). □

Remark 14.2.7. (i) Let $V$ be a ring, $m, m' \subset V$ two ideals such that $(V, m)$ and $(V, m')$ are both basic setups, and let $m^n := m \cdot m'$; set as usual $\tilde{m} := m \otimes_V m$, and define likewise the $V$-modules $\tilde{m}$ and $\tilde{m}''$. It is easily seen that $(V, m^n)$ is a basic setup as well. Moreover, we claim that there exists a natural isomorphism of $V$-modules:

\[
\tilde{m} \otimes_V \tilde{m} \cong \tilde{m}''
\]

Indeed, let $\mu : m \otimes_V m' \rightarrow m^n$ be the multiplication map; we know already that $\text{Ker} \mu$ is annihilated by both $m$ and $m'$, hence $m^n \otimes_V \mu : m^n \otimes_V m \otimes_V m' \rightarrow \tilde{m}''$ is an isomorphism, and likewise for $\mu \otimes_V m \otimes_V m' : \tilde{m} \otimes_V \tilde{m} \rightarrow m^n \otimes_V \tilde{m}$, so the same holds for their composition, which is $\tilde{m} \otimes_V \tilde{m} \cong \tilde{m}''$.

(ii) Let $M$ be any $V$-module; denote by $(M, m)^a \in \text{Ob}((V, m)^a\text{-Mod})$ the image of $M$, and define likewise $(M, m')^a \in \text{Ob}((V, m')^a\text{-Mod})$ and $(M, m'')^a \in \text{Ob}((V, m'')^a\text{-Mod})$. We deduce from (i) natural $V$-linear identifications:

\[
(M, m^n)^a \twoheadrightarrow (M, m^n)^a \twoheadrightarrow (M, m^n)^a \twoheadrightarrow (M, m^n)^a
\]

14.2.9. Let $V$ be any ring; a $V$-linear abelian category is the datum of an abelian category $\mathcal{A}$ together with a $V$-module structure on $\text{Hom}_\mathcal{A}(A, B)$ for every $A, B \in \text{Ob}(\mathcal{A})$, such that the composition law of $\mathcal{A}$ is a $V$-bilinear map

\[
\text{Hom}_\mathcal{A}(A, B) \times \text{Hom}_\mathcal{A}(B, C) \rightarrow \text{Hom}_\mathcal{A}(A, C)
\]

We say that a functor $F : \mathcal{A} \rightarrow \mathcal{A}'$ between $V$-linear abelian categories is $V$-linear if the map

\[
\text{Hom}_\mathcal{A}(A, B) \rightarrow \text{Hom}_{\mathcal{A}'}(FA, FB)
\]

is $V$-linear, for every $A, B \in \text{Ob}(\mathcal{A})$.

Remark 14.2.10. Let $V$ be a ring, and $\mathcal{A}, \mathcal{A}'$ two $V$-linear abelian categories.

(i) For every $x \in V$ and $A \in \text{Ob}(\mathcal{A})$ we define the subobject $xA := \text{Im} x \cdot 1_A \subset A$. Moreover, if $J \subset V$ is an ideal generated by a finite system $x_1, \ldots, x_n \in V$, we let $JA := \sum_{i=1}^n x_i A \subset A$. Let us check that the subobject $JA$ does not depend on the choice of a finite system of generators for $J$; it suffices to show that for every $a \in J$ we have $aA \subset JA$; to this aim, say that $a = \sum_{i=1}^n a_i x_i$ for certain $a_1, \ldots, a_n \in V$, and for every $i = 1, \ldots, n$ denote by $A \twoheadrightarrow A^{\oplus n}$ $\overset{p_i}{\twoheadrightarrow}$ $A$ the inclusion into the i-th direct summand and the projection onto the i-th direct factor of $A^{\oplus n}$. Set $\varphi := \sum_{i=1}^n x_i \cdot p_i$ and $\psi := \sum_{i=1}^n a_i \cdot e_i$; it is easily seen that $\text{Im} \varphi = JA$ and the $V$-bilinearity of the composition law implies that $\varphi \circ \psi = a \cdot 1_A$. Since $\text{Im} \varphi \circ \psi \subset \text{Im} \varphi$, the assertion follows.

(ii) Recall that the opposite $\mathcal{A}^{\circ}$ of the abelian category $\mathcal{A}$ is abelian; moreover, $\mathcal{A}^{\circ}$ inherits from $\mathcal{A}$ an obvious $V$-linear structure: the reader may spell out the details. Likewise, if $F : \mathcal{A} \rightarrow \mathcal{A}'$ any $V$-linear functor, then $F^{\circ} : \mathcal{A}^{\circ} \rightarrow \mathcal{A}'^{\circ}$ is again $V$-linear.

(iii) Obviously, for every $V$-algebra $A$, the category $A\text{-Mod}$ is naturally a $V$-linear abelian category. If $(V, m)$ is any basic setup, and $A$ any $(V, m)^a$-algebra, then also $A\text{-Mod}$ is a $V$-linear abelian category.

(iv) Let $J \subset V$ be any ideal, and $A \in \text{Ob}(\mathcal{A})$ any object. We say that $JA = 0$ if $xA = 0$ for every $x \in J$; notice that if $J$ is finitely generated, this notation agrees with that of (i). We say that $\mathcal{A}$ is $J$-torsion-free if there are no non-zero objects $A$ of $\mathcal{A}$ with $JA = 0$. For instance, if $(V, m)$ is any basic setup, and $A$ any $(V, m)^a$-algebra, then $A\text{-Mod}$ is $m$-torsion-free. Clearly, if $\mathcal{A}$ is $J$-torsion-free, the same holds for $\mathcal{A}^{\circ}$, for its natural $V$-linear structure.

(v) Let $f : A \rightarrow B$ be any morphism of $\mathcal{A}$, and $J, J' \subset V$ two ideals such that $J \cdot \text{Ker} f = J' \cdot \text{Coker} f = 0$ (notation of (iv)). Then for every $a \in J$ and $b \in J'$ there exists a morphism

\[
g : B \rightarrow A \text{ such that } f \circ g = ab \cdot 1_B \text{ and } g \circ f = ab \cdot 1_A.
\]
Indeed, write \( f = e \circ p \), where \( A \xrightarrow{p} \text{Im } f \xrightarrow{\text{ess zero}} B \) are the natural morphisms. Since \( J \cdot \text{Ker } p = J \cdot \text{Ker } f = 0 \), the endomorphism \( a \cdot 1_A \) factors through \( p \) and a morphism \( g_1 : \text{Im } f \to A \). Likewise, since \( J' \cdot \text{Coker } e = J' \cdot \text{Coker } f = 0 \), the endomorphism \( b \cdot 1_B \) factors through \( e \) and a morphism \( g_2 : B \to \text{Im } f \). Then \( g := g_1 \circ g_2 \) fulfills the stated conditions.

(vi) In the situation of (v), let \( F : \mathcal{A} \to \mathcal{A}' \) be a \( V \)-linear functor; we get \( Ff \circ Fg = ab \cdot 1_{FB} \) and \( Fg \circ Ff = ab \cdot 1_{FA} \). It follows easily that \( JJ' \cdot \text{Ker } Ff = JJ' \cdot \text{Coker } Ff = 0 \).

**Definition 14.2.11.** Let \((V, m)\) be a basic setup, \( \mathcal{A} \) a \( V \)-linear abelian category, \( I \) a small category, and consider a functor

\[
M \circ : I \to \mathcal{A} \quad i \mapsto M_i \quad (j \xrightarrow{\varphi} i) \mapsto (M_i \xrightarrow{M_{\varphi}} M_j).
\]

(i) We say that \( M \circ \) is essentially zero, if for every \( i \in \text{Ob}(I) \) there exists a morphism \( \varphi : j \to i \) in \( I \) with \( M_\varphi = 0 \).

(ii) We say that \( M \circ \) is almost essentially zero, if for every \( i \in \text{Ob}(I) \) and every subideal \( m_0 \subset m \) of finite type there exists a morphism \( \varphi : j \to i \) in \( I \) with \( m_0 \cdot M_\varphi = 0 \). We denote

\[
\text{Fun}(I, \mathcal{A})_{\text{ess zero}}
\]

the full subcategory of \( \text{Fun}(I, \mathcal{A}) \) whose objects are the almost essentially zero functors.

(iii) We say that \( M \circ \) is almost essentially constant, if there exist \( L \in \text{Ob}(\mathcal{A}) \) and a cone \( \pi_\circ : c_L \Rightarrow M \circ \) inducing almost essentially zero functors

\[
\text{Ker } \pi_\circ : I \to \text{A-Mod} \quad \text{and} \quad \text{Coker } \pi_\circ : I \to \text{A-Mod}.
\]

(iv) We say that \( M \circ \) has the almost Mittag-Leffler property if for every \( i \in \text{Ob}(I) \) and every subideal \( m_0 \subset m \) of finite type there exists a morphism \( j \xrightarrow{\varphi} i \) in \( I \) with:

\[
m_0 \cdot \text{Im } M_\varphi \subset \text{Im } M_{\varphi \circ \psi} \quad \text{for every morphism } \psi : k \to j \text{ in } I.
\]

(v) We say that \( M \circ \) is a Cauchy functor, if for every subideal \( m_0 \subset m \) of finite type there exists \( i \in \text{Ob}(I) \) with \( m_0 \cdot \text{Ker } M_\varphi = m_0 \cdot \text{Coker } M_\varphi = 0 \) for every morphism \( \varphi : j \to i \) of \( I \).

We say that \( M \circ \) is null, if it is both a Cauchy functor and almost essentially zero.

(vi) Let \( P(M \circ) \) be either one of the conditions: “\( M \circ \) is essentially zero”, “\( M \circ \) is almost essentially zero”, “\( M \circ \) is almost essentially constant”, “\( M \circ \) has the almost Mittag-Leffler property”, “\( M \circ \) is a Cauchy functor” or “\( M \circ \) is null”. We say that \( M \circ \) has the dual \( P \) property if \( P(M \circ) \) holds, for the opposite functor \( M^\circ : I^\circ \to \mathcal{A}^\circ \) (see remark [14.2.10(ii)]).

**Remark 14.2.12.** (i) In the situation of definition 14.2.11 for every \( M \in \text{Ob}(\mathcal{A}) \) and every subideal \( m_0 \subset m \) of finite type, set \( M[m_0] := \bigcap_{x \in m_0} \text{Ker } x \cdot 1_M \). Notice that \( M \circ \) is almost essentially zero if and only if the following holds. For every such \( m_0 \), the induced functor

\[
M / \text{Ker } M \circ : I \to \mathcal{A} \quad i \mapsto M_i / \text{Ker } M_i \circ [m_0]
\]

is essentially zero.

(ii) Suppose that \( I \) is cofiltered and \( \mathcal{A} \) is complete, and let us set:

\[
M^\Delta_i := \bigcap_{\varphi : j \to i} \text{Im } M_\varphi \quad \text{for every } i \in \text{Ob}(I).
\]

We claim that \( M_\psi \) restricts to a morphism in \( \mathcal{A} \)

\[
M^\Delta_\psi : M^\Delta_i \to M^\Delta_i \quad \text{for every morphism } \psi : i' \to i \text{ in } I.
\]

Indeed, it suffices to check that \( M_\psi(M^\Delta_i) \subset \text{Im } M_\varphi \) for every morphism \( \varphi : j \to i \) in \( I \). However, since \( I \) is cofiltered, for every such \( \varphi \) there exist \( k \in \text{Ob}(I) \) and morphisms \( \varphi' : k \to i' \) and \( \psi' : k \to j \) such that \( \varphi \circ \varphi' = \psi \circ \varphi' \). It follows that \( M_\psi(M^\Delta_i) \subset M_\psi(\text{Im } \varphi') = M_\varphi(\text{Im } \psi') \) whence the contention. Next, let \( \tau_\circ : c_L \Rightarrow M \circ \) be any cone; notice that

\[
(14.2.13) \quad \text{Im } \tau_i \subset M^\Delta_i \quad \text{for every } i \in \text{Ob}(I).
\]
On the other hand, a direct inspection of the definitions shows that
\[(M_* / M_*^\triangle)_{i} = 0 \quad \text{for every } i \in \text{Ob}(I).\]
Hence, (14.2.13) implies that every cone \(c_{\ell} \Rightarrow M_* / M_*^\triangle\) is the zero morphism, so we must have \(\lim_i M_* / M_*^\triangle = 0\), and since \(\lim_i\) is a left exact functor (because it is a right adjoint: see (1.3)) we conclude that the inclusion \(\overset{\rightarrow}{\lim}_i M_*\) induces an isomorphism:

\[\lim_i M_*^\triangle \xrightarrow{\sim} \lim_i M_*\]

(iii) In the situation of (ii), let \(A\) be any \((V, m)^a\)-algebra, and take \(\mathcal{A} := A\text{-Mod}\) (see remark [14.2.10](ii)); notice then that \(M_*\) has the almost Mittag-Leffler property if and only if the following holds. For every \(i \in \text{Ob}(I)\), the induced system \(M_* / i := (\text{Im} M_{\varphi} | \varphi : j \rightarrow i)\) of submodules of \(M_*\) is a Cauchy net of the uniform space \(\mathcal{J}_A(M_i)\) defined as in [59] Def.2.3.1]. In this case, by [59] Lemma 2.3.5], the Cauchy sequence \(M_* / i\) admits a unique limit in \(\mathcal{J}_A(M_i)\), and by direct inspection we see that this limit is \(M_*^\triangle\), since for every subideal \(m_0 \subset m\) of finite type there exists a morphism \(\varphi : j \rightarrow i\) in \(I\) such that \(m_0 \cdot \text{Im} M_{\varphi} \subset M_*^\triangle\).

(iv) Notice that \(M_* : I \rightarrow \mathcal{A}\) is a Cauchy functor if and only if the following holds. For every subideal \(m_0 \subset m\) of finite type there exists \(i \in \text{Ob}(I)\) such that for every pair of morphisms \(k \xrightarrow{\psi} j \xrightarrow{\varphi} i\) of \(I\), we have \(m_0 \cdot \text{Ker} M_{\psi} = m_0 \cdot \text{Coker} M_{\varphi} = 0\). Indeed, the latter condition clearly implies that \(M_*\) is a Cauchy functor; conversely, suppose that \(M_*\) is a Cauchy functor, and let \(m_0 \subset m_1 \subset m\) be subideals of finite type with \(m_0 \subset m_1^2\); by assumption, we may find \(i \in \text{Ob}(I)\) such that, for every \(\varphi\) and \(\psi\) as in the foregoing, \(m_1\) annihilates all but the first and the fourth terms in the induced exact sequence:

\[0 \rightarrow \text{Ker} M_{\psi} \rightarrow \text{Ker} M_{\varphi \circ \psi} \rightarrow \text{Ker} M_{\varphi} \rightarrow \text{Coker} M_{\psi} \rightarrow \text{Coker} M_{\varphi \circ \psi} \rightarrow \text{Coker} M_{\varphi} \rightarrow 0.\]

It follows easily that \(m_1 \cdot \text{Ker} M_{\psi} = m_0 \cdot \text{Coker} M_{\varphi}\), as required. Notice also that every Cauchy functor has the almost Mittag-Leffler property: the details shall be left to the reader.

(v) Suppose again that \(I\) is cofiltered. In view of (iv), we deduce that a functor \(M_* : I \rightarrow \mathcal{A}\) is null if and only if the following holds. For every subideal \(m_0 \subset m\) of finite type there exists \(i \in \text{Ob}(I)\) such that \(m_0 M_j = 0\) for every morphism \(\varphi : j \rightarrow i\) of \(I\); the details shall be left to the reader. It follows easily that the full subcategory of \(\text{Fun}(I, \mathcal{A})\) whose objects are the null functors, is a Serre subcategory: again, we leave the details to the reader.

Lemma 14.2.14. In the situation of definition [14.2.11] the following holds:

(i) The category \(\text{Fun}(I, \mathcal{A})_{a,\text{ess},0}\) is a Serre subcategory of \(\text{Fun}(I, \mathcal{A})\). Hence

\[\mathcal{L}(I, \mathcal{A}) := \text{Fun}(I, \mathcal{A}) / \text{Fun}(I, \mathcal{A})_{a,\text{ess},0}\]

is an abelian category whose objects are the functors \(I \rightarrow \mathcal{A}\).

(ii) If \(\mathcal{A}\) is \(m\)-torsion-free (see remark [14.2.10]iv), then for every almost essentially zero functor \(M_* : I \rightarrow A\text{-Mod}\), we have \(\lim_i M_* = 0\).

(iii) Suppose that \(I\) is cofiltered, and \(\mathcal{A}\) is complete and \(m\)-torsion-free. Then the functor

\[\lim : \text{Fun}(I, \mathcal{A}) \rightarrow \mathcal{A}\]

(see (1.3)) factors through the localization \(\text{Fun}(I, \mathcal{A}) \rightarrow \mathcal{L}(I, \mathcal{A})\) and a functor

\[\mathcal{L}(I, \mathcal{A}) \rightarrow \mathcal{A} \quad M_* \mapsto \lim_i M_*\]

Proof. (i): Consider a short exact sequence of functors from \(I\) to \(A\text{-Mod}\):

\[(14.2.15) \quad 0 \rightarrow M'_* \xrightarrow{f} M_* \xrightarrow{\theta} M''_* \rightarrow 0.\]

It is easily seen that if \(M_*\) is almost essentially zero, the same holds for \(M'_*\) and \(M''_*\). Conversely, suppose that \(M'_*\) and \(M''_*\) are almost essentially zero, and let \(i \in \text{Ob}(I)\), and \(m_0 \subset m\) a finitely
generated subideal. By assumption there exists a morphism \( \varphi : j \to i \) in \( I \) such that \( m_0 \cdot \operatorname{Im} M'_{\varphi} = 0 \), and also a morphism \( \psi : k \to j \) such that \( m_0 \cdot \operatorname{Im} M''_{\psi} = 0 \). It follows that there exists a morphism \( h : m_0 M_k \to M'_j \) such that \( f_j \circ h : m_0 M_k \to M_j \) is the restriction of \( M_{\psi} \).

Then \( M_{\psi \circ \varphi}(m_0^2 M_k) = m_0 \cdot \operatorname{Im}(M_\varphi \circ f_j \circ h) = m_0 \cdot \operatorname{Im}(f_i \circ M'_\varphi \circ h) = 0 \), which shows that \( M_\bullet \) is almost essentially zero.

(ii): Suppose first that \( M_\bullet \) is essentially zero. Let \( X \in \operatorname{Ob}(\mathcal{A}) \) be any object, and \( \tau_\bullet : c_X \Rightarrow M_\bullet \) any cone; by assumption, for every \( i \in \operatorname{Ob}(I) \) there exists a morphism \( \varphi : j \to i \) in \( I \) with \( M_{\varphi} = 0 \). Then \( \tau_i = M_\varphi \circ \tau_j = 0 \) for every such \( i \), so that \( \tau_\bullet = 0 \), whence the contention.

For a general almost essentially zero functor \( M_\bullet \), and every subideal \( m_0 \subset m \) of finite type, we have a short exact sequence of functors

\[
0 \to M_\bullet[m_0] \to M_\bullet \to M_\bullet/M_\bullet[m_0] \to 0
\]

whose right-most term is essentially zero, by remark [14.2.12(i)], so that \( \lim_I M_\bullet/M_\bullet[m_0] = 0 \) by the previous case. On the other hand, clearly \( m_0 \) annihilates \( \lim_I M_\bullet[m_0] \). The functor \( \operatorname{Lim}_I \) is left exact (since it admits a left adjoint: see [1.3]); it then follows that \( m_0 \) annihilates as well \( \lim_I M_\bullet \), and since \( m_0 \) is arbitrary and \( \mathcal{A} \) is \( m \)-torsion-free, the claim follows.

(iii): As \( \operatorname{Lim}_I \) is left exact, in the situation of (14.2.15) we see easily from (ii) that if \( M''_\varphi \) is almost essentially zero, then \( f_\bullet \) induces an isomorphism \( \lim_I M''_\bullet \cong \lim_I M_\bullet \). Thus, it remains only to check that if \( M''_\varphi \) is almost essentially zero, then \( g_\bullet \) induces an isomorphism \( g : \lim_I M''_\bullet \cong \lim_I M_\bullet \). To this aim, we suppose first that \( M_\bullet \) is the constant functor of value \( M \), and that for every subideal \( m_0 \subset m \) of finite type there exists \( i \in \operatorname{Ob}(I) \) such that \( m_0 \cdot M_i = 0 \). Then, for every morphism \( \varphi : j \to i \) in \( I \) we have as well \( m_0 \cdot M'_j = 0 \). Hence, for such \( m_0 \) and \( i \), and for every \( b \in m_0 \) and every \( \varphi : j \to i \), the endomorphism \( b \cdot 1_M : M \to M \) is the composition of \( g_j : M \to M'_j \) and a unique morphism \( h_j : M''_j \to M \) of \( \mathcal{A} \), and it is easily seen that \( g_j \circ h_j = b \cdot 1_M \). Moreover, the system of morphisms \( (g_j \mid \varphi : j \to i) \) amounts to a natural cocone \( h_\bullet : M''_\bullet \circ s_i \Rightarrow M_\bullet \circ s_i \), where \( s_i : I/i \to I \) denotes the source functor. Since \( s_i \) is final (example [1.5.8(i)]), we deduce a morphism of \( \mathcal{A} \)

\[
h : L'' := \lim_I M''_\bullet \to M = \lim_I M_\bullet.
\]

By construction, we have \( g \circ h = b \cdot 1_{L''} \) and \( h \circ g = b \cdot 1_M \). Especially, \( b \) annihilates \( \operatorname{Ker} g \) and \( \operatorname{Coker} g \), and since \( m_0 \) and \( b \) are arbitrary, the assertion follows in this case.

Lastly, let \( M'_\bullet \) be an arbitrary almost essentially zero functor, and notice that

\[
N_\varphi := f_i(\operatorname{Im} M'_\varphi) = M_\varphi(\operatorname{Ker} g_j)
\]

for every morphism \( \varphi : j \to i \) in \( I \).

Hence, for every such \( \varphi \), the morphism \( M''_\varphi \) is the composition of unique morphisms of \( \mathcal{A} \)

\[
h_\varphi : M''_j \xrightarrow{h_\varphi} Q_\varphi := M_i/N_\varphi \xrightarrow{\pi_\varphi} M''_i
\]

such that \( h_\varphi \circ g_j = \pi_\varphi \circ M_\varphi \) and \( \pi_\varphi \circ \pi_\varphi = g_i \),

where \( \pi_\varphi : M_i \to Q_i \) is the projection. For any fixed \( i \in \operatorname{Ob}(I) \), let \( c_{M_i} : I\!/i \to \mathcal{A} \) be the constant functor of value \( M_i \); we get a short exact sequence of functors

\[
0 \to N_\bullet \to c_{M_i} \xrightarrow{\pi_\bullet} Q_\bullet \to 0
\]

where \( N_\bullet, Q_\bullet : I\!/i \to \mathcal{A} \) are given by the rules \( \varphi \mapsto N_\varphi \) and respectively \( \varphi \mapsto Q_\varphi \) for every morphism \( \varphi : j \to i \) in \( I \). By construction, for every subideal \( m_0 \subset m \) of finite type there exists \( \varphi \in \operatorname{Ob}(I\!/i) \) such that \( m_0 \cdot N_\varphi = 0 \); by the foregoing case, it follows that \( \pi_\bullet \) induces an isomorphism

\[
\pi_i : M_i \xrightarrow{\sim} Q := \lim_{I\!/i} Q_\bullet.
\]
On the other hand, the system \((h_\varphi \mid \varphi \in \text{Ob}(I/i))\) amounts to a natural transformation \(h_\bullet : M'' \circ s_i \Rightarrow Q_\bullet\) (the details are left to the reader), whence an induced morphism of \(\mathcal{A}\)

\[
  h_i : L''_i := \lim_i M''_i \xrightarrow{\sim} \lim_i M''_i \circ s_i \rightarrow Q.
\]

In turn, the system \((\pi_i^{-1} \circ h_i \mid i \in \text{Ob}(I))\) amounts to a cone \(c_{L''} \Rightarrow M_\bullet\), whence an induced morphism of \(\mathcal{A}\)

\[
  h : L'' \rightarrow L := \lim_i M_i.
\]

Claim 14.2.16. \(g \circ h = 1_{L''}\).

Proof of the claim. Indeed, let also \(\tau_\bullet : c_L \Rightarrow M_\bullet\) and \(\tau''_\bullet : c_{L''} \Rightarrow M''_\bullet\) be the universal cones; it suffices to show that \(\tau''_i \circ g \circ h = \tau''_i\) for every \(i \in \text{Ob}(I)\). But we have

\[
  \tau''_i \circ g \circ h = g_i \circ \tau_i \circ h = g_i \circ \pi_i^{-1} \circ h_i = \pi_\varphi \circ \pi_i^{-1} \circ h_i
\]

for every morphism \(\varphi : j \rightarrow i\) in \(I\), and on the other hand \(\tau''_i = M''_\varphi \circ \tau''_j = \pi_\varphi \circ h_\varphi \circ \tau''_j\) so we are reduced to checking that

\[
  \pi_\varphi \circ \pi_i^{-1} \circ h_i = h_\varphi \circ \tau''_j \quad \text{for every morphism } \varphi : j \rightarrow i.
\]

Now, let \(\tau^Q_\bullet : c_Q \Rightarrow Q_\bullet\) be the universal cone; then \(\pi_\varphi \circ \pi_i^{-1} = \pi^Q_\varphi\) for every such \(\varphi\), and finally, \(\tau^Q_i \circ h_i = h_\varphi \circ \tau''_j\), as required.

From claim [14.2.16] we see that \(g\) is an epimorphism; but it is also a monomorphism, since \(\lim_I M_i' = 0\), and since the functor \(\lim_I\) is left exact. Hence \(g\) is an isomorphism, as stated. \(\Box\)

Remark 14.2.17. Keep the situation of definition [14.2.11] and suppose that \(I\) is cofiltered.

(i) Consider a short exact sequence [14.2.15] of functors \(I \rightarrow \mathcal{A}\), such that \(M'_\bullet\) and \(M''_\bullet\) are Cauchy functors. Then \(M_\bullet\) is also a Cauchy functor. Indeed, let \(m_0 \subseteq m_1 \subseteq m_2\) be two subideals of finite type with \(m_0 \subseteq m_1^2\). Since \(I\) is cofiltered, taking into account remark [14.2.12](iv), we find \(i \in \text{Ob}(I)\) such that \(m_1\) annihilates the kernel and cokernel of both \(M'_\varphi\) and \(M''_\varphi\), for every morphism \(\varphi : j \rightarrow i\); by the snake lemma, it follows easily that \(m_0 \cdot \text{Ker} M_\varphi = m_0 \cdot \text{Coker} M_\varphi = 0\) for every such \(\varphi\), whence the contention.

(ii) Moreover, if \(X_\bullet, Y_\bullet : I \rightarrow \mathcal{A}\) are Cauchy functors, and \(f_\bullet : X_\bullet \rightarrow Y_\bullet\) is any morphism of functors, then \(\text{Ker} f_\bullet, \text{Coker} f_\bullet\) and \(\text{Im} f_\bullet\) are Cauchy functors. Indeed, let us check first the assertion for \(Z_\bullet := \text{Im} f_\bullet\): since the latter is a subfunctor of \(Y_\bullet\), for every subideal \(m_0 \subseteq m\) of finite type we find \(i \in \text{Ob}(I)\) such that for every pair of morphisms \(k \xrightarrow{\sim} j \xrightarrow{\sim} i\) we have \(m_0 \cdot \text{Ker} Z_\varphi = 0\) (remark [14.2.12](iv)). Likewise, since \(Z_\bullet\) is a quotient of \(X_\bullet\), for every such \(m_0\) there exists \(i' \in \text{Ob}(I)\) such that for every pair of morphisms \(k' \xrightarrow{\sim} j' \xrightarrow{\sim} i'\) we have \(m_0 \cdot \text{Coker} Z_{\varphi'} = 0\). Since \(I\) is cofiltered, we find \(i'' \in \text{Ob}(I)\) with morphisms \(i \leftarrow i'' \rightarrow i'\), and then \(m_0\) annihilates the cokernel of \(Z_{\lambda}\), for every morphism \(\lambda : j'' \rightarrow i''\) of \(I\).

Lastly, by considering the short exact sequences of functors:

\[
  0 \rightarrow \text{Ker} f_\bullet \rightarrow X_\bullet \rightarrow Z_\bullet \rightarrow 0 \quad 0 \rightarrow Z_\bullet \rightarrow Y_\bullet \rightarrow \text{Coker} f_\bullet \rightarrow 0
\]

and combining with (i), we deduce the assertions for \(\text{Ker} f_\bullet\) and \(\text{Coker} f_\bullet\).

Proposition 14.2.18. With the notation of definition [14.2.11] and of remark [14.2.12](ii), assume that \(I\) is cofiltered, and \(\mathcal{A}\) is complete and \(m\)-torsion-free. Then we have:

(i) If \(M_\bullet : I \rightarrow \mathcal{A}\) has the almost Mittag-Leffler property, the following holds:

(a) \(M^\Delta_\bullet : M^\Delta_j \rightarrow M^\Delta_i\) is an epimorphism in \(\mathcal{A}\), for every morphism \(\varphi : j \rightarrow i\) of \(I\).

(b) The inclusions \((M^\Delta_i \rightarrow M_i \mid i \in \text{Ob}(I))\) define an isomorphism \(M^\Delta_\bullet \xrightarrow{\sim} M_\bullet\) in \(\mathcal{L}(I, \mathcal{A})\).

(ii) For every functor \(M_\bullet : I \rightarrow \mathcal{A}\) the following conditions are equivalent:

(a) \(M_\bullet\) is almost essentially constant.
(b) $M_\bullet$ is isomorphic to a constant functor, in the category $\mathcal{L}(I, \mathscr{A})$ of lemma [14.2.14](i).
(c) Every universal cone $c_L \Rightarrow M_\bullet$ is an isomorphism in the category $\mathcal{L}(I, \mathscr{A})$.
(d) $M_\bullet$ has the almost Mittag-Leffler property, and $M_\Delta$ is a Cauchy functor.

(iii) Every Cauchy functor $M_\bullet : I \to \mathscr{A}$ is almost essentially constant.

Proof. (i.a): Pick a morphism $k \xrightarrow{\psi} j$ such that $m_0 \cdot \operatorname{Im} M_\psi \subset M_j^\Delta$ (remark [14.2.12](iii)). Then

$$m_0 M_i^\Delta \subset m_0 \cdot \operatorname{Im} M_{\varphi \psi} = M_\varphi (m_0 \cdot \operatorname{Im} M_\psi) \subset M_\varphi (M_j^\Delta).$$

Since $m_0$ is arbitrary, the assertion follows.

(ii.b): For every $i \in \operatorname{Ob}(I)$, let $\beta_i : M_i^\Delta \to M_i$ be the inclusion; we need to check that the resulting functor $\operatorname{Coker} \beta_\bullet : I \to \mathscr{A}$ is almost essentially zero. Indeed, let $i \in \operatorname{Ob}(I)$ and $m_0 \subset m$ any subideal of finite type; since $M_\bullet$ has the almost Mittag-Leffler property, there exists a morphism $\varphi : j \to i$ in $I$ such that $m_0 \cdot \operatorname{Im} M_\varphi \subset M_i^\Delta$. Hence, $m_0$ annihilates the image of the induced morphism $\operatorname{Coker} \beta_i \Rightarrow \operatorname{Coker} \beta_\bullet$, whence the assertion.

(ii.a)$\Rightarrow$(ii.d): Let $L \in \operatorname{Ob}(\mathscr{A})$ with a cone $\tau : c_L \Rightarrow M_\bullet$ such that the functors $\operatorname{Ker} \tau_\bullet$ and $\operatorname{Coker} \tau_\bullet$ are almost essentially zero. This means that for every $i \in \operatorname{Ob}(I)$ and every subideal $m_0 \subset m$ of finite type, there exists a morphism $\varphi : j \to i$ such that $m_0 \cdot \operatorname{Im} M_\varphi \subset \operatorname{Im} \tau_i$. But clearly $\operatorname{Im} \tau_i \subset M_i^\Delta$, so we see that $M_\bullet$ has the almost Mittag-Leffler property. By the same token, since $m_0 M_i^\Delta \subset \operatorname{Im} M_\varphi$, we get $m_0 M_i^\Delta \subset \operatorname{Im} \tau_i$, and since $m_0$ is arbitrary, we conclude that $M_i^\Delta = \operatorname{Im} \tau_i$ for every $i \in \operatorname{Ob}(I)$. Next, by assumption, for every $i \in \operatorname{Ob}(I)$ and every subideal $m_0 \subset m$ of finite type there exists a morphism $\varphi : j \to i$ of $I$ such that $m_0 \cdot \operatorname{Ker} \tau_j = 0$. Now, let $\psi : k \to j$ be any morphism of $I$, and set $K := \tau_k^{-1}(\operatorname{Ker} M_\psi^\Delta)$; it is easily seen that $K \subset \operatorname{Ker} \tau_j$, hence $m_0 K = 0$, and finally $m_0 \cdot \operatorname{Ker} M_\psi^\Delta = 0$, since we have already established that $\tau_k : L \to M_k^\Delta$ is an epimorphism.

(ii.d)$\Rightarrow$(ii.b): In light of (ii.b), we are reduced to checking that the functor $M_\Delta$ is almost essentially constant. Thus, let $M_\Delta$ be the limit of the functor $M_\bullet$, and $\tau_\bullet : c_{M_\Delta} \Rightarrow M_\Delta$ the universal cone; let also $m_0 \subset m$ be any subideal of finite type, and pick $i \in \operatorname{Ob}(I)$ such that $m_0 \cdot \operatorname{Ker} M_\Delta^\phi = 0$ for every morphism $\varphi : j \to i$ of $I$. Recall that the source functor $s_i : I/i \to I$ is cofinal, so that $M_\Delta$ represents also the limit of $M_\bullet \circ s_i : I/i \to \mathscr{A}$. It follows easily that $\operatorname{Ker}(\tau_i : M_\Delta \to M_i^\Delta)$ represents the limit of the induced functor

$$(0 \times M_i^\Delta, M_\bullet^\Delta) \circ s_i : I \to \mathscr{A} \quad (j \xrightarrow{\varphi} i) \mapsto \operatorname{Ker} M_\varphi^\Delta = 0 \times M_i^\Delta,$$

But then it is clear that $m_0 \cdot \operatorname{Ker} \tau_i = 0$. Especially, the functor $\operatorname{Ker} \tau_\bullet : I \to \mathscr{A}$ is trivially almost essentially zero. To conclude, we show that $\tau_i$ is an epimorphism for every $i \in \operatorname{Ob}(I)$. To this aim, let $m_0 \subset m$ be any subideal of finite type; in view of (i.a), we may assume that $m_0 \cdot \operatorname{Ker} M_\Delta^\varphi = 0$ for every morphism $\varphi : j \to i$. Hence, for every $b \in m_0$ we have a unique morphism in $\mathscr{A}$

$$f_{\varphi, b} : M_i^\Delta \to M_j^\Delta \quad \text{such that} \quad M_\varphi^\Delta \circ f_{\varphi, b} = b \cdot 1_{M_j^\Delta}.$$

By inspecting the construction, it is easily seen that $M_\psi^\Delta \circ f_{\varphi \psi, b} = f_{\varphi, b}$ for every morphism $\psi : k \to j$ in $I$, hence the rule $\varphi \mapsto f_{\varphi, b}$ defines a cone $c_{M_i^\Delta} \Rightarrow M_\Delta^\bullet \circ s_i$, whence a unique morphism of $A$-modules

$$h : M_i^\Delta \to M_\Delta \quad \text{such that} \quad f_{\varphi, h} = \tau_j \circ h \text{ for every } \varphi : j \to i.$$
(ii.b)⇒(ii.a): It suffices to prove:

**Claim** 14.2.19. Let \( M_\bullet, M'_\bullet : I \to \mathcal{A} \) be two functors, \( f_\bullet : M_\bullet \Rightarrow M'_\bullet \) a natural transformation, and suppose that \( f_\bullet \) is an isomorphism in \( \mathcal{L}(I, \mathcal{A}) \). Then \( M_\bullet \) is almost essentially constant if and only if the same holds for \( M'_\bullet \).

**Proof of the claim.** Let \( L \) and \( L' \) be the limits of \( M_\bullet \) and respectively \( M'_\bullet \); denote by \( \tau_\bullet : c_L \Rightarrow M_\bullet \) and \( \tau'_\bullet : c_{L'} \Rightarrow M'_\bullet \) the respective universal cones. There exists a unique morphism \( f : L \to L' \) in \( \mathcal{A} \) that makes commute the diagram:

\[
\begin{array}{ccc}
\tau_\bullet \quad c_L & \longrightarrow & c_{L'} \\
\tau'_\bullet \downarrow & & \downarrow \\
M_\bullet & \xrightarrow{f_\bullet} & M'_\bullet
\end{array}
\]

But lemma [14.2.14](iii) implies that \( f \) is an isomorphism; as \( f_\bullet \) is an isomorphism in \( \mathcal{L}(I, \mathcal{A}) \), it follows that \( \tau_\bullet \) is an isomorphism in \( \mathcal{L}(I, \mathcal{A}) \) if and only if the same holds for \( \tau'_\bullet \).

Lastly, clearly (c)⇒(a). Suppose then that (a) holds, and let \( \tau_\bullet : c_L \Rightarrow M_\bullet \) be a universal cone; let also \( \mu_\bullet : c_X \Rightarrow M_\bullet \) be another cone that is an isomorphism in \( \mathcal{L}(I, \mathcal{A}) \). Then there exists a unique morphism \( f : X \to L \) in \( \mathcal{A} \) such that \( \tau_\bullet \circ f = \mu_\bullet \). Set \( \mu := \lim_I \mu_\bullet \) and \( \tau := \lim_I \tau_\bullet \), so that \( \tau \circ f = \mu \). Now, \( \tau \) is an isomorphism, and the same holds for \( \mu_\bullet \) by lemma [14.2.14](iii); hence \( f \) is an isomorphism, so the cone \( \mu_\bullet \) is universal, whence (c).

(iii): We know already that \( M_\bullet \) has the almost Mittag-Leffler property (remark [14.2.12](iv)); moreover, \( \ker M_{\phi}^\omega \subset \ker M_{\phi} \) for every morphism \( \phi \) of \( I \), hence \( M_\bullet \) fulfills condition (ii.c), whence the contention. \( \square \)

**Proposition 14.2.20.** Let \( \mathcal{A} \) and \( \mathcal{A}' \) be \( V \)-linear abelian categories, \( I \) a small category, \( F : \mathcal{A} \to \mathcal{A}' \) a \( V \)-linear functor, and \( M_\bullet, M'_\bullet : I \to \mathcal{A} \) two functors. The following holds:

(i) Let \( f_\bullet : M_\bullet \Rightarrow M'_\bullet \) be a natural transformation. If \( \ker f_\bullet \) and \( \coker f_\bullet \) are almost essentially zero (resp. null, resp. dual almost essentially zero, resp. dual null), then the same holds for the kernel and cokernel of \( Ff_\bullet : FM_\bullet \Rightarrow FM'_\bullet \).

(ii) If \( M_\bullet \) is a Cauchy functor, the same holds for \( FM_\bullet \).

(iii) If \( M_\bullet \) is almost essentially constant (resp. dual almost essentially constant), so is \( FM_\bullet \).

(iv) Suppose that \( F \) is right exact (resp. left exact). If \( M_\bullet \) has the almost Mittag-Leffler property (resp. the dual almost Mittag-Leffler property), then the same holds for \( FM_\bullet \).

**Proof.** (ii): The assertion follows immediately from remark [14.2.10](vi).

(i): We can write \( f_\bullet = e_\bullet \circ p_\bullet \), where \( e_\bullet : I \to \mathcal{A} \) is a monomorphism of functors, and \( p_\bullet : I \to \mathcal{A} \) is an epimorphism of functors, and then clearly it suffices to check the stated assertions for \( e_\bullet \) and \( p_\bullet \). Moreover, if the stated assertions are known for all monomorphisms of functors and all \( V \)-linear categories \( \mathcal{A} \), they follow for every epimorphism as well, by considering the opposite transformation \( f_\bullet^\vee : M_\bullet^\vee \Rightarrow M_\bullet^\vee \) and invoking remark [14.2.10](ii).

Thus, let \( f_\bullet \) be a monomorphism, \( \phi : j \to i \) any morphism in \( I \), and \( a \in V \) that annihilates the morphism \( \coker f_j \to \coker f_i \), induced by \( M_{\phi}^\omega \). The latter means that \( \text{Im}(aM_{\phi}^\omega) \subset \text{Im} f_j \); it follows that there exists a morphism \( g : M_j \to M_i \) in \( \mathcal{A} \) such that \( f_i \circ g = aM_{\phi}^\omega \), and therefore

\[
f_i \circ g \circ f_j = aM_{\phi}^\omega \circ f_j = aM_{\phi} = f_i \circ (aM_{\phi})
\]

whence \( g \circ f_j = aM_{\phi} \), since \( f_i \) is a monomorphism. The induced identities \( Ff_j \circ Fg = aFM_{\phi} \) and \( Fg \circ Ff_j = aFM_{\phi} \) imply that \( \text{Im}(aFM_{\phi}) \subset \text{Im} Ff_j \) and \( aM_{\phi}(\ker Ff_j) = 0 \). Hence, if \( \ker f_\bullet \) and \( \coker f_\bullet \) are almost essentially zero (resp. dual almost essentially zero) then the same holds for \( \ker Ff_\bullet \) and \( \coker Ff_\bullet \). Combining with (ii), we deduce that if \( \ker f_\bullet \) and \( \coker f_\bullet \) are null (resp. dual null), the same follows for \( \ker Ff_\bullet \) and \( \coker Ff_\bullet \).

(iii) is an immediate consequence of (i).
(iv) As usual, the assertion in case $F$ is left exact will follow from the assertion for the case $F$ is right exact, by considering $M_\bullet$ and $F^\circ$. Hence, suppose that $F$ is right exact and $M_\bullet$ has the almost Mittag-Leffler property. For a given subideal $m_0 \subset m$ of finite type and $i \in \text{Ob}(I)$, choose a morphism $\varphi : j \to i$ in $I$ such that for every morphism $\psi : k \to j$ of $I$ we have $m_0 \cdot \text{Ker} M_{\psi \varphi} \subset \text{Ker} M_{\varphi}$. Let $C$ be the cokernel of the morphism $\overline{M}_{\varphi \psi} : M_k \to \text{Im} M_{\varphi}$ induced by $M_{\psi \varphi}$; the assumption means that $m_0 C = 0$. Since $F$ is right exact, $FC$ is the cokernel of $F\overline{M}_{\varphi \psi} : FM_k \to F(\text{Im} M_{\varphi})$, and obviously $m_0 FC = 0$. By the same token, $M_{\varphi} : M_j \to M_i$ factors through epimorphisms $FM_j \to F(\text{Im} M_{\varphi}) \to \text{Im} FM_{\varphi}$; we conclude that the cokernel of the morphism $FM_k \to \text{Im} FM_{\varphi}$ induced by $F\overline{M}_{\varphi \psi}$ is a quotient of $FC$, and especially is annihilated by $m_0$. The assertion follows.

Remark 14.2.21. Keep the notation of definition 14.2.11 and let $M_\bullet : I \to \mathcal{A}$ be any functor.

(i) By unwinding the definitions, we find that $M_\bullet$ has the dual almost Mittag-Leffler property if and only if the following holds. For every subideal $m_0 \subset m$ of finite type, and every $i \in \text{Ob}(I)$ there exists a morphism $\varphi : i \to j$ in $I$ such that

$$m_0 \cdot \text{Ker} M_{\psi \varphi} \subset \text{Ker} M_{\varphi} \quad \text{for every morphism } \psi : j \to k \text{ in } I.$$  

(ii) The natural isomorphism $\text{Fun}(I, \mathcal{A}) \xrightarrow{\sim} \text{Fun}(I^0, \mathcal{A}^{\circ})^0$ of remark 1.1.19(i) identifies $(\text{Fun}(I^0, \mathcal{A}^{\circ})_{a,\text{ess},0})^0$ with the full subcategory of $\text{Fun}(I, \mathcal{A})$ whose objects are the dual almost essentially zero functors. Since the opposite of a Serre subcategory is a Serre subcategory, lemma 14.2.14(i) implies that the quotient

$$\mathcal{C}(I, \mathcal{A}) := \text{Fun}(I, \mathcal{A}) / (\text{Fun}(I^0, \mathcal{A}^{\circ})_{a,\text{ess},0})^0$$

is again an abelian category, whose objects are the functors $I \to \mathcal{A}$.

(iii) The rest of lemma 14.2.14 dualizes as well: first, part (ii) of the lemma implies that if $\mathcal{A}$ is m-torsion-free and $M_\bullet$ is dual almost essentially zero, then $\text{colim}_I M_\bullet = 0$. Next, if $I$ is filtered, and $\mathcal{A}$ is cocomplete and m-torsion-free, the functor $\text{Colim}_I$ of remark 1.3.3(ii) factors through the localization $\text{Fun}(I, \mathcal{A}) \to \mathcal{C}(I, \mathcal{A})$ and a functor

$$\mathcal{C}(I, \mathcal{A}) \to \mathcal{A} \quad M_\bullet \mapsto \text{colim}_I M_\bullet.$$  

(iv) Also remark 14.2.12(ii,iii) admits a valid dual: namely, suppose that $I$ is filtered and $\mathcal{A}$ is cocomplete. We set

$$M_i^\vee := \bigcup_{\varphi : i \to j} \text{Ker} M_{\varphi} \subset M_i \quad \text{for every } i \in \text{Ob}(I).$$

Then, arguing as in 14.2.12(ii) one easily checks that $M_\varphi$ restricts to a morphism

$$M_\varphi^\vee : M_i^\vee \to M_i^\varphi \quad \text{for every morphism } \psi : i \to i' \text{ in } I$$

whence an induced functor $M_\varphi^\vee : I \to \mathcal{A}$, and a direct inspection of the definitions shows that

$$(M_\varphi^\vee)^\varphi = M_\varphi^\vee.$$  

Notice moreover that every cocone $\tau : M_\bullet \Rightarrow c_L$ factors (uniquely) through the projection $\pi_\bullet : M_\bullet \to M_\bullet / M_\bullet^\vee$. Combining with (14.2.22) we deduce that

$$\text{colim}_I M_\bullet^\vee = 0$$

and furthermore, $\pi_\bullet$ induces an isomorphism in $\mathcal{A}$:

$$\text{colim}_I M_\bullet \xrightarrow{\sim} \text{colim}_I M_\bullet / M_\bullet^\vee.$$  

(v) Under the assumptions of (iv), we deduce that $M_\bullet$ has the dual almost Mittag-Leffler property if and only if for every subideal $m_0 \subset m$ of finite type and every $i \in \text{Ob}(I)$ there exists a morphism $\varphi : i \to j$ such that $m_0 \cdot M_i^\varphi \subset \text{Ker} M_{\varphi}$. In the case where $\mathcal{A} = A\text{-Mod}$ for a
given \((V, m)^\varphi\)-algebra \(A\), it follows that for every \(i \in \text{Ob}(I)\) the system \((\Ker M_\varphi \mid \varphi : i \to j)\) is a Cauchy net in the uniform space \(\mathcal{F}_A(M_i)\), and its unique limit is the \(A\)-submodule \(M_i^\varphi\).

(vi) Suppose that \(I\) is filtered, and is \(\mathcal{A}\) is cocomplete and \(m\)-torsion-free. Then :

- By dualizing proposition [14.2.18](ii), we see that the following conditions are equivalent :
  - (a) \(M_*\) is dual almost essentially constant.
  - (b) \(M_*\) is isomorphic to a constant functor, in the category \(\mathcal{E}(I, \mathcal{A})\) of remark [14.2.21](ii).
  - (c) \(M_*\) has the dual almost Mittag-Leffler property, and for every subideal \(m_0 < m\) of finite type, there exists \(i \in \text{Ob}(I)\) such that \(m_0\) annihilates the cokernel of the morphism
    \[
    M_i/M_i^\varphi \to M_j/M_j^\varphi
    \]
    induced by \(M_\varphi\), for every morphism \(\varphi : i \to j\) in \(I\) (notation of remark [14.2.21](iv)).
- Moreover, the dual of proposition [14.2.18](i) states that if \(M_*\) has the dual almost Mittag-Leffler property, then [14.2.23] is a monomorphism for every morphism \(\varphi : i \to j\) in \(I\), and the projections \((M_i \to M_i/M_i^\varphi \mid i \in \text{Ob}(I))\) define an isomorphism \(M_* \to M_*/M_*^\varphi\) in \(\mathcal{E}(I, \mathcal{A})\).

**Lemma 14.2.24.** In the situation of definition [14.2.11] let \(A\) be any \((V, m)^\varphi\)-algebra, \(M_* : \mathbb{N}^\varphi \to A\text{-Mod}\) a functor whose transition morphisms \(M_{m,n} : M_m \to M_n\) are epimorphisms for every \(m, n \in \mathbb{N}\), and set \(L := \lim_{n \in \mathbb{N}} M_n\). Then we have :

- (i) The universal cone \(\tau_* : c_L \Rightarrow M_*\) is an epimorphism of functors.
- (ii) \(\lim_{n \in \mathbb{N}} M_n = 0\).
- (iii) For every almost finitely generated (resp. almost finite projective) \(A\)-module \(N\), the cone \(N \otimes_A L \to \lim_{n \in \mathbb{N}} N \otimes_A M_n\).
- (iv) More generally, if \(N\) is an \(A\)-module and \(a \in A_*\) such that \(a \cdot 1_N\) factors as a composition of \(A\)-linear morphisms \(N \xrightarrow{\alpha} N_0 \xrightarrow{\beta} N\) with \(N_0\) almost finitely generated (resp. almost finite projective), then \(a \cdot \text{Coker} \varphi_N = 0\) (resp. \(a \cdot \text{Ker} \varphi_N = 0\)).

**Proof.** (i): Let \(M_* : \mathbb{N}^\varphi \to A_*\text{-Mod}\) be the composition of \(M_*\) with the left adjoint \((-)_*: A\text{-Mod} \to A_*\text{-Mod}\) of the localization \((-)^\varphi\). Set \(T := \lim_{n \in \mathbb{N}} M_n\), and let \(\mu_* : c_T \Rightarrow M_*\) be the universal cone; then \(L = T^\varphi\) and the natural isomorphism \(M_* \sim (M_*^\varphi)^\varphi\) identifies \(\mu_*\) with \(\mu_*^\varphi\). Thus, it suffices to check that \(\mu_*\) is an epimorphism of functors. However, the transition morphisms \((M_{m,n})_!: M_{m!} \to M_{n!}\) are surjective, so the assertion is clear.

(ii): Recall that for every functor \(M_* : \mathbb{N}^\varphi \to A\text{-Mod}\) (resp. \(N_* := \mathbb{N}^\varphi \to A_*\text{-Mod}\)) the right derived functor \(R\lim_{n \in \mathbb{N}} M_*\) (resp. \(R\lim_{n \in \mathbb{N}} N_*\)) is computed by a natural two-term complex \(\Pi(M_*)\) (resp. \(\Pi(N_*)\)) : see [125], §3.5. With this notation, we have \(\Pi(M_*) = \Pi(M_*^\varphi)\), since the localization \((-)^\varphi\) commutes with all products. However, \(\lim_{n \in \mathbb{N}} M_{m!} = 0\), since the transition morphisms \((M_{m,n})_!\) are surjective ([125], Lemma 3.5.3]). The assertion follows.

(iii): Suppose first that \(N\) is finitely generated; hence there exists \(r \in \mathbb{N}\) and a short exact sequence \(0 \to K \to A^{\varphi r} \to N \to 0\) of \(A\)-modules. For every \(n \in \mathbb{N}\), let \(C_n \subset A^{\varphi r} \otimes_A M_n\) be the image of \(K \otimes_A M_n\); we get an inverse system \((C_n \mid n \in \mathbb{N})\) whose transition morphisms are also epimorphisms (details left to the reader). By virtue of (ii), there follows an epimorphism of \(A\)-modules
\[
\lim_{n \in \mathbb{N}} A^{\varphi r} \otimes_A M_n = A^{\varphi r} \otimes_A L \overset{\psi}{\to} \lim_{n \in \mathbb{N}} N \otimes_A M_n.
\]
Lastly, it is easily seen that \(\psi\) factors through \(\varphi_N\) and the induced morphism \(A^{\varphi r} \otimes_A L \to N \otimes_A L\), whence the contention in this case. Next, consider the functor
\[
T : A_*\text{-Mod} \to A_*\text{-Mod} \quad X \mapsto (\text{Coker} \varphi_X)_a
\]
that assigns to every \(A\)-linear morphism \(f : N \to N'\) the induced map \((\text{Coker} \varphi_{N'})_a \to (\text{Coker} \varphi_{N''})_a\) of \(A_*\)-modules. It is easily seen that \(T\) is \(V\)-homogeneous of degree 1 (see
definition \([14.1.53]\), and the associated functor \(T^a : A\text{-Mod} \to A\text{-Mod}\) is given by the rule: \(N \mapsto \text{Coker } \varphi_N\) for every \(A\)-module \(N\) (notation of remark \([14.1.54]\)(ii)). By the foregoing, \(T^aN = 0\) whenever \(N\) is finitely generated; however, on the one hand, for every suitable pair of infinite cardinalities \(\omega, \omega'\) the associated map \(\mathcal{M}_{\omega, \omega'}(T^a) : \mathcal{M}_\omega(A) \to \mathcal{M}_{\omega'}(A)\) is uniformly continuous (proposition \([14.1.56]\)(iii)), and on the other hand, it is easily seen that the subset \(\{0\}\) is closed in the topology of the uniform space \(\mathcal{M}(A)\). Hence, \(T^aN = 0\) for every almost finitely generated \(A\)-module, as stated.

Next, suppose that \(N\) is almost finite projective; then for every \(a \in \mathbb{m}\) there exists \(r \in \mathbb{N}\) and \(A\)-linear morphisms \(N \xrightarrow{\Delta} A^\oplus_r \xrightarrow{\beta} N\) whose composition is \(a \cdot 1_N\) (\([59\text{, Lemma 2.4.15}]\)). There follows a commutative diagram:

\[
\begin{array}{cccccccc}
N \otimes_A L & \xrightarrow{\alpha \otimes_AL} & A^\oplus_r \otimes_A L & \xrightarrow{\beta \otimes_AL} & N \otimes_A L \\
\varphi_N & & \downarrow & & \varphi_N \\
\lim_{n \in \mathbb{N}} N \otimes_A M_n & \longrightarrow & \lim_{n \in \mathbb{N}} A^\oplus_r \otimes_A M_n & \longrightarrow & \lim_{n \in \mathbb{N}} N \otimes_A M_n
\end{array}
\]

whose central arrow is an isomorphism, and we already know that \(\varphi_N\) is an epimorphism. By a simple diagram chase we deduce that \(a \cdot \text{Ker } \varphi_N = 0\), and since \(a\) is arbitrary, we conclude that \(\varphi_N\) is an isomorphism in this case, as stated.

(iii): Suppose first that \(\mathbb{m}\) is cofiltered and consider the following conditions:

(a) The functor \(\text{Coker } \tau_\bullet\) is almost essentially zero.

(b) \(M_\bullet\) has the almost Mittag-Leffler property.

Then (a)\(\Rightarrow\)(b), and if there exists a final functor \(\mathbb{N}^\circ \to I\), then (b)\(\Rightarrow\)(a).

(ii) Suppose that is \(I\) filtered. Then \(M_\bullet\) has the dual almost Mittag-Leffler property if and only if the functor \(\text{Ker } \tau'_\bullet\) is dual almost essentially zero.

(iii) Suppose that \(I = \mathbb{N}^\circ\), where \(\mathbb{N}\) is endowed with its standard total ordering. If \(M_\bullet\) has the almost Mittag-Leffler property, then \(\lim_{n \in \mathbb{N}} M_n = 0\).

Proof. (iii): Suppose first that \(M_\bullet\) is almost essentially zero, and consider, for every finitely generated subideal \(m_0 \subset \mathbb{m}\), the short exact sequence of functors:

\[
\Sigma_\bullet : \quad 0 \to M_\bullet[m_0] \to M_\bullet \to M_\bullet/M_\bullet[m_0] \to 0
\]

whose right-most term is an essentially zero inverse system, by remark \([14.2.12]\)(i), and therefore

\[
\lim_{n \in \mathbb{N}} M_n/M_n[m_0] = \lim_{n \in \mathbb{N}} M_n/m_0 = 0.
\]

On the other hand, clearly \(m_0\) annihilates \(\lim_{n \in \mathbb{N}} M_n[m_0]\). From the long exact cohomology sequence associated with \(\Sigma_\bullet\) it follows that \(m_0\) annihilates as well \(\lim_{n \in \mathbb{N}} M_n\). Since \(m_0\) is arbitrary, the claim follows in this case.

Next, let \(M_\bullet\) be an arbitrary functor with the almost Mittag-Leffler property; for every \(m, n \in \mathbb{N}\) with \(m > n\), we let \(M_{m,n} : M_m \to M_n\) be the transition morphism. By proposition \([14.2.18]\)(i,a), the restriction \(M_{m,n}^\Delta : M_m^\Delta \to M_n^\Delta\) of \(M_{m,n}\) is an epimorphism for every such \(n\) and \(p\). Let us then consider the short exact sequence of inverse systems:

\[
\Sigma^\bullet : \quad 0 \to M^\Delta \to M_\bullet \to M_\bullet/M^\Delta \to 0.
\]
Proposition 14.2.18(i.b) implies that $M_*/M_\Delta^*$ is almost essentially zero, so $\lim_{n \in \mathbb{N}} M_n/M_\Delta^n = 0$, by the previous case; also, $\lim_{n \in \mathbb{N}} M_n^\Delta = 0$, by lemma 14.2.24(ii). The assertion follows then, by considering the long exact $R$-lim sequence associated with $\Sigma_*^\mu$.

(i.a) $\Rightarrow$ (i.b): By assumption, for every subideal $m_0 \subset m$ of finite type and every $i \in \text{Ob}(I)$ there exists a morphism $\varphi : j \to i$ in $I$ such that $m_0$ annihilates the image of the induced morphism $\text{Coker } \tau_j \to \text{Coker } \tau_i$. The latter means that $m_0 \cdot \text{Im } M_{\varphi} \subset \text{Im } \tau_i$; but clearly $\text{Im } \tau_i \subset \text{Im } M_{\varphi} \psi$ for every morphism $\psi : k \to j$ in $I$, whence the contention.

Next, suppose that there exists a final functor $\varphi : \mathbb{N}^o \to I$, and that $M_*$ has the almost Mittag-Leffler property; notice that $\tau_i$ factors through a morphism $\mu_* : L \to M_\Delta$ and the inclusion $M_i^\Delta \to M_i$, for every $i \in \text{Ob}(I)$. There follows a short exact sequence of functors:

$$\text{Coker } \mu_* \to \text{Coker } \tau_* \to M_*^\Delta \to 0.$$ By proposition 14.2.18(i.b), $M_*/M_\Delta^*$ is almost essentially zero, hence $L$ also represents the limit of $M_\Delta^*$, and $\mu_*$ is a universal cone; by lemma 14.2.24(i) it then suffices to show that $\text{Coker } \mu_* = 0$. Now, $\mu_* \cdot \lambda : c_L \Rightarrow M_\Delta \circ \lambda$ is still a universal cone (remark 1.5.5(ii,iii)). Since we also know that $M_\Delta^\psi$ is an epimorphism for every morphism $\varphi$ of $I$ (proposition 14.2.18(i.a)), we are then reduced to checking that $\mu_{\lambda(n)} : L \to M_{\lambda(n)}^\Delta$ is an epimorphism for every $n \in \mathbb{N}$. The latter follows from lemma 14.2.24(i).

(ii): Suppose that $\text{Ker } \tau_i'$ is dual almost essentially zero; this means that for every subideal $m_0 \subset m$ of finite type, and every $i \in \text{Ob}(I)$ there exists a morphism $\varphi : i \to j$ in $I$ such that $M_* (m_0 \cdot \text{Ker } \tau'_i) = 0$. But we have $\text{Ker } M_{\varphi} \varphi \subset \text{Ker } \tau'_i$ for every morphism $\psi : j \to k$ in $I$; whence $m_0 \cdot \text{Ker } M_{\varphi} \varphi \subset \text{Ker } M_{\varphi}$ for every such $\psi$. Hence $M_*$ has the dual Mittag-Leffler property, by remark 14.2.21(i). Conversely, suppose that $M_*$ has the dual Mittag-Leffler property; we know that the functor $M_\varphi$ is almost essentially zero (remark 14.2.21(vii)) hence it suffices to check that $M_\varphi = \text{Ker } \tau'_i$ for every $i \in \text{Ob}(I)$. After replacing $I$ by $i/I$, we may assume that $i$ is an initial object of $I$, whence an induced cone $\mu_* : c_M \Rightarrow M_*$, and notice that $M_i^\varphi = \text{colim}_I \text{Ker } \mu_*$. On the other hand, $\text{colim}_I \mu_* = \tau'_i$; since filtered colimits in $A$-$\text{Mod}$ are exact, the assertion follows.

14.2.26. Pontryagin duality. Recall that for every ring $R$ and every $R$-module $N$, we have a natural $R$-module structure on

$$N^\vee := \text{Hom}_Z(N, \mathbb{Q}/\mathbb{Z}).$$

Namely, for every $a \in R$ and every $\mathbb{Z}$-linear map $\varphi : N \to \mathbb{Q}/\mathbb{Z}$ we set $a \cdot \varphi := \varphi \circ (a1_N)$. Especially, $R^\vee$ is naturally an $R$-module, and there follows a natural $R$-linear isomorphism:

$$\text{Hom}_R(N, R^\vee) \xrightarrow{\sim} N^\vee$$

assigning to every $R$-linear map $\varphi : N \to R^\vee$ the $\mathbb{Z}$-linear map $\varphi' : N \to \mathbb{Q}/\mathbb{Z}$ such that $\varphi'(n) := \varphi(n)(1)$ for every $n \in N$. Its inverse assigns to every $\mathbb{Z}$-linear map $\psi : N \to \mathbb{Q}/\mathbb{Z}$ the homomorphism of $R$-modules $\psi' : N \to R^\vee$ that sends every $n \in N$ to the $\mathbb{Z}$-linear map $\psi'(n) : R \to \mathbb{Q}/\mathbb{Z}$ such that $\psi'(n)(a) := \psi(an)$ for every $a \in R$. Since $\mathbb{Q}/\mathbb{Z}$ is an injective $\mathbb{Z}$-module, there results an exact functor

$$R$-$\text{Mod} \to R$-$\text{Mod}^\vee \quad N \mapsto N^\vee.$$ Moreover, it is easily seen that the natural biduality $R$-linear map is an injection:

$$N \to N^{\vee\vee} \quad \text{for every } R$$

Let now $(V, m)$ be a basic setup, and $A$ a $(V, m)^\alpha$-algebra; we consider the associated $A$-module

$$J_A := ((A_\alpha)\vee)^\alpha$$
and from the foregoing it is easily seen that the Pontryagin duality functor

\[ (\cdot)^\vee : \text{A-Mod} \to \text{A-Mod}^\circ \quad M \mapsto M^\vee := \text{alHom}_A(M, J_A) \]

is again exact and \( V \)-linear, where \( \text{alHom}_A(-, -) \) denotes the bifunctor of almost homomorphisms defined as in \([59] \, \text{\S} 2.2.11\); indeed, we have a natural isomorphism of \( A \)-modules

\[ M^\vee \cong ((M_\ast)^\vee)\ast \quad \text{for every } A\text{-module } M \]

(details left to the reader). Moreover, it follows that the biduality morphism \( M \to M^{\vee \vee} \) is a monomorphism of \( A \)-modules; especially, \( (-)^\vee \) is a conservative functor.

**Remark 14.2.27.** (i) For every small category \( I \), we get a natural extension of Pontryagin duality to functors \( I \to \text{A-Mod} \). Namely, we have a conservative exact functor :

\[ \text{Fun}(I, \text{A-Mod})^\circ \to \text{Fun}(I^\circ, \text{A-Mod}) \quad M_\ast \mapsto M'^\vee := (\cdot)^\vee \circ M_\ast. \]

(ii) For every \( A \)-module \( M \), and every \( A \)-submodule \( N \subset M \), let \( i_N : N \to M \) the inclusion; it is easily seen that the induced map

\[ \mathcal{I}_A(M) \to \mathcal{I}_A(M') \quad N \mapsto \ker(i_N^\vee : M' \to N') \]

is uniformly continuous, for the uniform structures defined as in \([59] \, \text{Def.2.3.1(i)}\).

(iii) Then, if \( I \) is cofiltered, and \( M_\ast : I \to \text{A-Mod} \) is any functor with the almost Mittag-Leffler property, combining with remarks \([14.2.12](iii)\) and \([14.2.21](v)\) we deduce that the \( A \)-linear epimorphism \( i_{M^\Delta}^\vee : M_i^\vee \to (M_i^\Delta)^\vee \) factors through an isomorphism of \( A \)-modules

\[ M_i^\vee/(M_i^\ast)^\vee \cong (M_i^\Delta)^\vee \quad \text{for every } i \in \text{Ob}(I). \]

**Lemma 14.2.28.** With the notation of remark \([14.2.27]\) for every functor \( M_\ast : I \to \text{A-Mod} \) the following holds:

(i) \( M_\ast \) is essentially zero (resp. almost essentially zero) if and only if \( M'^\vee \) is dual essentially zero (resp. dual almost essentially zero).

(ii) Suppose that \( I \) is cofiltered. Then \( M_\ast \) is almost essentially constant (resp. has the almost Mittag-Leffler property) if and only if \( M'^\vee \) is dual almost essentially constant (resp. has the dual almost Mittag-Leffler property).

**Proof.** (i): By direct inspection we see that if \( M_\ast \) is essentially zero (resp. almost essentially zero), then \( M'^\vee \) is dual essentially zero (resp. dual almost essentially zero). Likewise, if \( M_\ast \) is dual essentially zero (resp. dual almost essentially zero), then \( M'^\vee \) is essentially zero (resp. almost essentially zero). From this, the converse assertions follow easily, since the biduality morphism \( M_\ast \to M^{\vee \vee} \) is a monomorphism.

(ii): For a given pair of morphisms \( k \xrightarrow{\psi} j \xrightarrow{\varphi} i \) of \( I \), set \( N := \text{Im}M_\varphi/\text{Im}M_{\varphi \psi} \). Since Pontryagin duality is exact and conservative, for every subideal \( m_0 \subset m \) we have :

\[ m_0N = 0 \iff m_0N' = 0 \iff m_0 \cdot \ker(\text{Im}M'^{\vee \psi} \to M'^\vee) = 0 \iff m_0 \ker M'^{\vee \psi} \subset \ker M'^\psi. \]

Taking into account remark \([14.2.21](i)\), we deduce that \( M_\ast \) has the almost Mittag-Leffler property if and only if \( M'^\vee \) has the dual almost Mittag-Leffler property.

Next, proposition \([14.2.20](ii)\) implies that if \( M_\ast \) is almost essentially constant, then \( M'^\vee \) is dual almost essentially constant. Conversely, if \( M'^\vee \) is dual almost essentially constant, then \( M'^\ast \) has the dual almost Mittag-Leffler property, and for every subideal \( m_0 \subset m \) of finite type there exists \( i \in \text{Ob}(I) \) with

\[ (14.2.29) \quad m_0 \cdot \text{Coker}(M_i^\vee/(M_i^\ast)^\vee \to M_j^\vee/(M_j^\ast)^\vee) = 0 \quad \text{for every morphism } i \xrightarrow{\varphi} j. \]
filtered colimits are exact in the category whence the contention, in light of proposition 14.2.18(ii).

there follow induced isomorphisms C

Proposition 14.2.28(ii)), and arguing as in the proof of (iv) we deduce that \( M_* \) is almost essentially constant.

Proposition 14.2.30. Let \( I \) be a small cofiltered category, and

\[ 0 \to M'_* \to M_* \to M''_* \to 0 \]

a short exact sequence of functors \( I \to A\text{-Mod} \). We have:

(i) If \( M'_* \) and \( M''_* \) are almost essentially constant (resp. have the almost Mittag-Leffler property), then the same holds for \( M_* \).

(ii) If \( M_* \) has the almost Mittag-Leffler property, the same holds for \( M''_* \).

(iii) If \( M_* \) has the almost Mittag-Leffler property and \( M''_* \) is almost essentially constant, then \( M'_* \) has the almost Mittag-Leffler property.

(iv) If \( f_* : X_* \to Y_* \) is a natural transformation between almost essentially constant functors, then \( \ker f_* \) and \( \mathrm{Coker} f_* \) are almost essentially constant.

Proof. (ii) is clear from the definitions.

(iv): By proposition 14.2.18(ii), the universal cones \( \tau^X_* : X_* \Rightarrow X_* \) and \( \tau^Y_* : X_* \Rightarrow Y_* \) are isomorphisms in \( \mathcal{L}(I,A\text{-Mod}) \). Thus, there exists a unique morphism \( f : X \to Y \) of \( A \)-modules that makes commute the diagram

\[
\begin{array}{ccc}
X_* & \xrightarrow{f_*} & Y_* \\
\downarrow{\tau^X_*} & & \downarrow{\tau^Y_*} \\
X_* & \xrightarrow{c} & Y_*
\end{array}
\]

whose vertical arrows are isomorphism in \( \mathcal{L}(I,A\text{-Mod}) \). Set \( K := \ker f \) and \( C := \mathrm{Coker} f \); there follow induced isomorphisms \( c_K \xrightarrow{\sim} \ker f_* \) and \( c_C \xrightarrow{\sim} \mathrm{Coker} f_* \) in \( \mathcal{L}(I,A\text{-Mod}) \), whence the contention, in light of proposition 14.2.18(ii).

(i): Let \( L, L' \) and \( L'' \) be the colimits of the functors \( M'_* \), \( M''_* \) and respectively \( M''_* \); since filtered colimits are exact in the category \( A\text{-Mod} \), we get a commutative diagram of functors with exact rows:

\[
\begin{array}{ccc}
0 & \to & M''_* \\
\downarrow{c_{L''}} & & \downarrow{c_L} \\
0 & \to & M'_*
\end{array}
\]

whose vertical arrows are the universal cocones. Consider first the case where \( M'_* \) and \( M''_* \) are almost essentially constant; then \( M''_* \) and \( M''_* \) are dual almost essentially constant (lemma 14.2.28(ii)), and arguing as in the proof of (iv) we deduce that the first and third vertical arrows are isomorphisms in the quotient category \( \mathcal{C}(I,A\text{-Mod}) \), hence the same holds for the middle one, by the 5-lemma. Then \( M'_* \) is dual almost essentially constant, by remark 14.2.21(vi), hence \( M_* \) is almost essentially constant, again by lemma 14.2.28(ii).

Next, if \( M'_* \) and \( M''_* \) have the almost Mittag-Leffler property, then \( M''_* \) and \( M''_* \) have the dual almost Mittag-Leffler property (lemma 14.2.28(ii)), hence the kernels of the first and third vertical arrows are dual almost essentially zero (proposition 14.2.25(ii)). Then the same holds for the kernel of the middle vertical arrow, so \( M_* \) has the dual almost Mittag-Leffler property, again by proposition 14.2.25(ii); finally, \( M_* \) has the almost Mittag-Leffler property, by lemma 14.2.28(ii).
(iii): We consider again the induced commutative ladder with exact rows. Arguing as in the
proof of (ii), we see that the kernel of the middle vertical arrow and the cokernel of the left-most
vertical arrow are both dual almost essentially zero, hence the same holds for the kernel of the
right-most vertical arrow, by the snake lemma. Then \( M' \) has the dual almost Mittag-Leffler
property, by proposition \( \text{14.2.25}(ii) \), and finally, \( M' \) has the almost Mittag-Leffler property, by
lemma \( \text{14.2.28}(ii) \). □

14.2.31. Let us now consider a basic setup \((V, m)\), a (small) cofiltered category \( I \), and a functor
\[
I \to (V, m)^\text{-Alg}.\text{Mod} \quad i \mapsto (A_i, M_i)
\]
where \((V, m)^\text{-Alg}.\text{Mod}\) is defined as in \( \text{[59 Def.2.5.22}(ii) \)). Hence, for every \( i \in \text{Ob}(I) \),
the pair \((A_i, M_i)\) consists of a \((V, m)^\text{-algebra} A_i\), and an \( A_i\)-module \( M_i\). To each morphism
\( \varphi : j \to i \) of \( I \), the functor assigns a pair \((A_\varphi, g_\varphi) : (A_j, M_j) \to (A_i, M_i)\), where \( A_\varphi : A_j \to A_i\)
is a morphism of \((V, m)^\text{-algebras}, and \( g_\varphi : A_i \otimes_A M_j \to M_i\) is an \( A_i\)-linear morphism. We
get two obvious induced functors
\[
A_* : I \to (V, m)^\text{-Alg} \quad M_* : I \to (V, m)^\text{-Mod}.
\]
Namely, for every morphism \( \varphi \) as in the foregoing we let \( M_\varphi : M_j \to M_i\) be the composition
of \( g_\varphi \) with the natural \( A_j\)-linear morphism \( M_j \to A_i \otimes_A M_j \). Set also
\[
A := \lim_i A_* \quad \text{and} \quad M := \lim_i M_\varphi.
\]
Notice that \( A_* \) (resp. \( M_* \)) can also be viewed as a functor with values in \( A\text{-Alg} \) (resp. \( A\text{-Mod} \)).

**Proposition 14.2.32.** With the notation of \( \text{[14.2.31]} \), the following holds:

(i) If \( A_* : I \to A\text{-Mod} \) has the almost Mittag-Leffler property, and \( g_\varphi \) is an epimorphism
for every morphism \( \varphi \) of \( I \), then \( M_* : I \to A\text{-Mod} \) has the almost Mittag-Leffler property.

(ii) Suppose that \( g_\varphi \) is an isomorphism for every morphism \( \varphi \) of \( I \). Then, if \( A_* : I \to A\text{-Mod} \)

is almost essentially constant (resp. is a Cauchy functor), the same holds for \( M_* \).

(iii) Moreover, under the assumptions of (i) (resp. (ii)), the natural morphism
\[
\alpha_i : A_i \otimes_A M_i^\Delta \to M_i \quad \text{(resp.} \quad \beta_i : A_i \otimes_A M \to M_i \text{)}
\]
is an epimorphism (resp. an isomorphism) for every \( i \in \text{Ob}(I) \).

(iv) Lastly, under the assumptions of (i), if there exists a final functor \( N^\varphi \to I \), then \( \beta_i \) is an
epimorphism for every \( i \in \text{Ob}(I) \).

**Proof.** We fix universal cones \( \tau_*^A : c_A \Rightarrow A_* \) and \( \tau_*^M : c_M \Rightarrow M_* \).

**Claim 14.2.33.** Assertions (ii) and (iii) hold if \( A_* \) is a Cauchy functor and \( g_\varphi \) is an isomorphism
for every morphism \( \varphi \) of \( I \).

**Proof of the claim.** Indeed, in this case for every subideal \( m_0 \subset m \) of finite type we find \( i \in \text{Ob}(I) \) such that for every morphism \( \varphi : j \to i \) we have \( m_0 \cdot \text{Ker} A_\varphi = m_0 \cdot \text{Coker} A_\varphi = 0 \). By
virtue of remark \( \text{14.2.10}(vi) \), it follows that \( m_0^2 \) annihilates the kernel and cokernel of \( A_\varphi \otimes_A M_j \),
for every such \( \varphi \). Since \( g_\varphi \) is an isomorphism, it follows that \( m_0^3 \cdot \text{Ker} M_\varphi = m_0^3 \cdot \text{Coker} M_\varphi = 0 \),
for every such \( \varphi \). This shows that \( M_* \) is a Cauchy functor.

Next, notice that \( \text{Ker} \tau_*^A \) and \( \text{Coker} \tau_*^A \) are also Cauchy functors (remark \( \text{14.2.17}(ii) \)),
and moreover they are almost essentially zero, since \( A_* \) is almost essentially constant (proposition
\( \text{14.2.18}(ii,iii) \)). Hence, \( \text{Ker} \tau_*^M \) and \( \text{Coker} \tau_*^M \) are null. The same argument shows that \( \text{Ker} \tau_*^M \)
and \( \text{Coker} \tau_*^M \) are null, since \( M_* \) is a Cauchy functor. Moreover, the kernel and cokernel of
\( \tau_*^A \otimes_A M \) are null as well, since the functor \( - \otimes_A M : A\text{-Mod} \to A\text{-Mod} \) is \( V \)-linear
(proposition \( \text{14.2.20}(i) \)). Since we have :
\[
\beta_i \circ (\tau_i^A \otimes_A M) = \tau_i^M \quad \text{for every} \ i \in \text{Ob}(I)
\]
and as the null functors form a full Serre subcategory of \( \text{Fun}(I, A\text{-Mod}) \) (remark 14.2.12(v)), it follows that also \( \text{Ker} \beta_i \) and \( \text{Coker} \beta_i \) are null functors. Now, let \( m_0 \subset m \) be a subideal of finite type, and \( i \in \text{Ob}(I) \); since \( I \) is cofiltered, we deduce that there exists a morphism \( \varphi : j \to i \) such that \( m_0 \cdot \text{Ker} \beta_j = m_0 \cdot \text{Coker} \beta_j = 0 \). Since the functor \( A_i \otimes A_j \to A_i\text{-Mod} \) is \( V \)-linear, it follows that \( m_0^2 \) annihilates the kernel and cokernel of \( A_i \otimes A_j \beta_j : A_i \otimes A M \to A_i \otimes A_j M_j \) (remark 14.2.10(vi)). But notice that
\[
\varphi \circ (A_i \otimes A_j \beta_j) = \beta_i.
\]
So finally \( m_0^2 \cdot \text{Ker} \beta_i = m_0^2 \cdot \text{Coker} \beta_i = 0 \). Since \( m_0 \) is arbitrary, we conclude that \( \beta_i \) is an isomorphism, as stated.

We can now complete the proof of (ii) and (iii), for the case where \( A_i \) is almost essentially constant, and \( g_\varphi \) is still an isomorphism for every morphism \( \varphi \) of \( I \). To this aim, set
\[
\overline{A}_\varphi := \text{Im} A_\varphi \quad \text{and} \quad \overline{M}_\varphi := A_\varphi \otimes_{A_j} M_j \quad \text{for every morphism} \quad \varphi : j \to i \text{ of } I.
\]
Let \( j \xrightarrow{\varphi} i \) and \( j' \xrightarrow{\varphi'} i' \) be two object of \( \text{Morph}(I) \), and \( (\psi, \psi') : \varphi' \to \varphi \) a morphism of \( \text{Morph}(I) \); by definition, \( \psi : j' \to j \) and \( \psi' : i' \to i \) are morphisms in \( I \) such that \( \psi' \circ \varphi' = \varphi \circ \psi \), and then it is clear that \( A_\psi \) restricts to a morphism of \( (V, m)^n \)-algebras
\[
\overline{A}_{(\psi, \psi')} : \overline{A}_{\varphi'} \to \overline{A}_\varphi.
\]
Then, \( M_\psi : M_{j'} \to M_j \) induces a \( \overline{A}_\varphi \)-linear morphism
\[
\overline{g}_{(\psi, \psi')} : \overline{A}_\varphi \otimes_{\overline{A}_{j'}} \overline{M}_{\varphi'} \xrightarrow{\sim} \overline{A}_\varphi \otimes_{A_j} M_j \to \overline{M}_\varphi
\]
and it is easily seen that the rules :
\[
\varphi \mapsto (\overline{A}_\varphi, \overline{M}_\varphi) \quad \text{and} \quad (\varphi' \xrightarrow{(\psi, \psi')} \varphi) \mapsto (\overline{A}_{(\psi, \psi')}, \overline{g}_{(\psi, \psi')})
\]
for every \( \varphi \in \text{Ob}(\text{Morph}(I)) \) and every morphism \( (\psi, \psi') \) of \( \text{Morph}(I) \), define a functor
\[
\text{Morph}(I) \to (V, m)^n \text{-Alg.Mod}
\]
whence, as in (14.2.31), two functors
\[
\overline{A}_\varphi : \text{Morph}(I) \to A\text{-Alg} \quad \overline{M}_\varphi : \text{Morph}(I) \to A\text{-Mod}
\]
and notice also that :
\[
(14.2.34) \quad \overline{A}_\varphi^\Delta = A_\varphi^\Delta \quad \text{for every morphism} \quad \varphi : j \to i \text{ in } I.
\]
Next, let \( \mathcal{I} \) be the category whose objects are the pairs \( (j \xrightarrow{\varphi} i, m_0) \) where \( \varphi \) is a morphism of \( I \) and \( m_0 \subset m \) is a subideal of finite type such that :
\[
m_0 A_\varphi \subset A_\varphi^\Delta
\]
(notation of remark 14.2.12(ii)). For every \( (\varphi, m_0), (\varphi', m'_0) \in \text{Ob}(\mathcal{I}) \), the set of morphisms \( (\varphi', m'_0) \to (\varphi, m_0) \) in \( \mathcal{I} \) is empty if \( m_0 \not\subset m'_0 \), and otherwise consists of the morphisms \( \varphi' \to \varphi \) in \( \text{Morph}(I) \). The composition law is then the same as that of \( \text{Morph}(I) \), so that the projection \( (\varphi, m_0) \mapsto \varphi \) and the rule : \( i \mapsto 1 \), for every \( i \in \text{Ob}(I) \) define functors
\[
\mathcal{I} \xrightarrow{\pi} \text{Morph}(I) \xleftarrow{\delta} I.
\]

Claim 14.2.35. The functors \( \pi \) and \( \delta \) are final.

Proof of the claim. It is easily seen that both \( \mathcal{I} \) and \( \text{Morph}(I) \) are cofiltered, so we can apply the (dual of the) criterion of lemma 15.5.7(i). Condition (a) of the lemma is trivially verified by \( \pi \). To check condition (b) for \( \pi \), consider any object \( \varphi : j \to i \) of \( \text{Morph}(I) \), any object \( (\varphi' : j' \to i', m_0) \) of \( \mathcal{I} \), and a pair of morphisms \( (\psi, \psi'), (\mu, \mu') : \varphi' \to \varphi \). Since \( I \) is cofiltered, we find morphisms \( \nu : j'' \to j' \) and \( \nu' : i'' \to i' \) in \( I \) such that \( \psi \circ \nu = \mu \circ \nu \) and
ψ′ o ψ = μ′ o ψ′. Then we also find k ∈ Ob(I) with morphisms λ : k → j" and λ′ : k → i" such that ψ′ o λ = ψ′ o λ′. Set ϕ := ψ′ o λ′; we deduce a morphism (ψ o λ, 1_{ϕ'}) : ϕ → ϕ' in Morph(I) with (ψ, ϕ') o (ψ o λ, 1_{ϕ'}) = (ψ, ϕ'). From 14.2.33 we get \( \overline{A}_ϕ^\Delta = \overline{A}_ϕ^\Delta \). By assumption we have \( m_0 \cdot \overline{A}_ϕ^\Delta \subset \overline{A}_ϕ^\Delta \), and clearly \( \overline{A}_ϕ^\Delta \subset \overline{A}_ϕ^\Delta \). Hence \( m_0 \cdot \overline{A}_ϕ^\Delta \subset \overline{A}_ϕ^\Delta \), so \( (ϕ', m_0) \in \text{Ob}(Y) \), and \( (ν o λ, 1_{ϕ'}) \) is a morphism \( (ϕ', m_0) \to (ϕ', m_0) \) in \( Y \) such that \( (ψ, ϕ') o (ν o λ, 1_{ϕ'}) = (ψ, ϕ') o (ν o λ, 1_{ϕ'}) \), as required. The verification of conditions (a) and (b) for the functor δ is easy, and shall be left to the reader. 

We consider then the induced functor:

\[ \overline{A}_ϕ \circ π : Y \to A\text{-Mod} \]

Notice that \( \text{Im} τ^A_i \subset \overline{A}_ϕ \) for every morphism \( ϕ : j \to i \) of I; we deduce a cone

\[ τ^A_i : c_A \Rightarrow \overline{A}_ϕ \quad (j \xrightarrow{ξ} i, m_0) \mapsto (τ^A_i : A \to \overline{A}_ϕ) \]

such that \( τ^A_i \circ δ = τ^A_i \). In light of claim 14.2.35 it follows that \( τ^A_i \) is a universal cone, and by the same token, the same holds for the cone \( τ^A_i \circ π : c_A \Rightarrow \overline{A}_ϕ \circ π \).

Claim 14.2.36. \( \overline{A}_ϕ \circ π \) is a Cauchy functor.

Proof of the claim. By proposition 14.2.18 the functor \( A_ϕ^\Delta : I \to A\text{-Mod} \) is Cauchy and \( A_ϕ \) has the almost Mittag-Leffler property, so \( A_ϕ^\Delta : A_j^\Delta \to A_i^\Delta \) is an epimorphism for every morphism \( ϕ : j \to i \) of I. Hence, for every subideal \( m_0 \subset m \) of finite type there exists \( i \in \text{Ob}(I) \) with \( m_0 \cdot \text{Ker} A_ϕ^\Delta = 0 \) for every such \( ϕ \), and moreover there exists \( ϕ : j \to i \) with \( m_0 \overline{A}_ϕ^\Delta \subset \overline{A}_ϕ^\Delta \). For such \( ϕ \), we have \( (ϕ, m_0) \in \text{Ob}(Y) \); now, let \( (ψ, ψ') : (ϕ' : j' \to i', m'_0) \to (ϕ, m_0) \) be any morphism in \( Y \); this means that \( m_0 \subset m'_0 \) and \( m_0 \overline{A}_ϕ^\Delta \subset \overline{A}_ϕ^\Delta = A_ϕ^\Delta \). Also, \( \overline{A}_ϕ(ψ, ψ') : \overline{A}_ϕ^\Delta \to \overline{A}_ϕ^\Delta \) is the restriction of \( A_ϕ^\Delta : A_i^\Delta \to A_i^\Delta \). Therefore

\[ m_0 \cdot \text{Ker} \overline{A}_ϕ(ψ, ψ') \subset A_ϕ^\Delta \cap \text{Ker} A_ϕ \subset \text{Ker} A_ϕ^\Delta, \]

whence \( m_0^2 \cdot \text{Ker} \overline{A}_ϕ(ψ, ψ') = 0 \). Lastly, \( \text{Coker} \overline{A}_ϕ(ψ, ψ') \) is a quotient of \( \overline{A}_ϕ^\Delta / A_ϕ(ψ, ψ')^\Delta = \overline{A}_ϕ^\Delta / A_ϕ^\Delta \), which is annihilated by \( m_0 \), so \( m_0 \cdot \text{Coker} \overline{A}_ϕ(ψ, ψ') = 0 \).

Since \( A_ϕ \) are isomorphisms for every morphism \( ϕ \) of I, a simple inspection shows that \( g_ϕ \) is an isomorphism for every morphism \( ϕ \) of Morph(I). Together with claims 14.2.36 and 14.2.33, we deduce that assertion (iii) holds for the functors \( A_ϕ \circ π \) and \( M_σ \circ π \), and moreover \( M_σ \circ π \) is a Cauchy functor.

However, let \( λ : I \to Y \) be the functor given by the rules : \( i \mapsto (1_i, 0) \) and \( ϕ \mapsto (ϕ, ϕ) \) for every \( i \in \text{Ob}(I) \) and every morphism \( ϕ \) of I. It is easily seen that \( \overline{A}_ϕ \circ π o λ = A_ϕ \) and \( M_σ \circ π o λ = M_σ \). Then assertion (ii) for \( A_ϕ \) and \( M_σ \) follows straightforwardly. Especially, the functor \( M_σ \) is isomorphic to the functor \( A_ϕ \otimes_A M \). Since the functor \( - \otimes_A M : A\text{-Mod} \to A\text{-Mod} \) is V-linear, proposition 14.2.20 (iii) implies that \( M_σ \) is almost essentially constant, and the proof of (iii) is completed, under the assumptions of (ii).

Lastly, suppose that the assumptions of (i) hold; hence \( g_ϕ \) is an epimorphism for every morphism \( ϕ \) of I, and it follows easily that the induced morphism \( A_ϕ \otimes_A \text{Im} M_ϕ \to M_i \) is an epimorphism as well, for every such \( ϕ \). On the other hand, by assumption for every \( i \in \text{Ob}(I) \) and every subideal \( m_0 \subset m \) of finite type there exists \( ϕ : j \to i \) such that \( m_0 \text{Im} M_ϕ \subset M_i^\Delta \). Hence, \( m_0 M_i \subset \text{Im} A_ϕ \). Since \( m_0 \) is arbitrary, we conclude that \( A_ϕ \) is an epimorphism.

1. For every \( i \in \text{Ob}(I) \) and every subideal \( m_0 \subset m \) there exists a morphism \( ϕ : j \to i \) such that for every morphism \( ψ : k \to j \) in I we have \( m_0 \cdot \text{Im} A_ϕ \subset \text{Im} A_ϕ \). It then follows that for every such \( m_0, ϕ \) and \( ψ \) we have

\[ m_0 \cdot \text{Im}(A_ϕ \otimes_A \delta) \subset \text{Im}(A_ϕ \otimes_A \delta). \]
Since \( g_\psi \) is an epimorphism and \( g_\psi^\otimes \circ (A_\psi \otimes A_k M_k) = M_\psi^\otimes \), we deduce:

\[
m_0 \cdot \text{Im} M_\psi = m_0 \cdot \text{Im}(M_\psi \circ g_\psi) = m_0 \cdot \text{Im}(g_\psi^\otimes \circ (A_\psi \otimes A_k M_k)) \subseteq \text{Im} M_\psi^\otimes
\]

which shows that \( M_* \) has the almost Mittag-Leffler property, as stated.

(iv): Notice that \( \tau_*^M : M \to M_i \) factors through a morphism \( \mu_* : M \to M_i^\triangle \) and the inclusion \( M_i^\triangle \to M_i \), for every \( i \in \text{Ob}(I) \). Since \( M_* / M_i^\triangle \) is almost essentially zero (proposition 14.2.18(i,b)), it follows that \( \mu_* : c_M \Rightarrow M_i^\triangle \) is a universal cone. If \( \lambda : N^a \to I \) is a final functor, the cone \( \mu_* \circ \lambda \) is still universal (remark 1.5.5(ii,iii)), and then \( \mu_{\lambda(n)} : M \to M_{\lambda(n)}^\triangle \) is an epimorphism for every \( n \in \mathbb{N} \) (lemma 14.2.24(i)). Since \( M_i^\triangle \) is an epimorphism for every \( i \in \text{Ob}(I) \) (proposition 14.2.18(i,a)), we conclude that \( \mu_* : M \to M_i^\triangle \) is an epimorphism for every \( i \in \text{Ob}(I) \). Since we already know that \( \alpha_i \) is an epimorphism, it follows that the same holds for \( \beta_i \), for every such \( i \).

\[ \square \]

14.2.37. Keep the notation of (14.2.31), and consider a second functor

\[ I \to (V, m)^a-\text{Alg. Mod} \quad i \mapsto (A'_i, N_i) \]

as well as the corresponding induced functors

\[ A'_* : I \to (V, m)^a-\text{Alg} \quad N_* : I \to (V, m)^a-\text{Mod} \]

and suppose that \( A_* = A'_* \). Let also \( N \) be the limit of \( N_* \). Then we get an induced functor

\[ I \to (V, m)^a-\text{Alg. Mod} \quad i \mapsto (A_i, M_i \otimes_{A_i} N_i) \]

and the corresponding induced functor

\[ M_* \otimes_{A_*} N_* : I \to (V, m)^a-\text{Mod} \quad i \mapsto M_i \otimes_{A_i} N_i \]

**Proposition 14.2.38.** In the situation of (14.2.31), suppose that \( A_* \), \( M_* \) and \( N_* \) are almost essentially constant functors with values in \( A-\text{Mod} \). Then the same holds for \( M_* \otimes_{A_*} N_* \), and \( M \otimes_A N \) represents the limit of \( M_* \otimes_{A_*} N_* \).

**Proof.** For every \( i \in \text{Ob}(I) \), the \( V^a \)-linear map

\[ \varphi_i : M_i \otimes_{V^a} A_i \otimes_{V^a} N_i \to M_i \otimes_{V^a} N_i, \quad x \otimes a \otimes y \mapsto ax \otimes y - x \otimes ay \]

yields a natural identification : \( \text{Coker} \varphi_i \cong M_i \otimes_{A_i} N_i \). In view of proposition 14.2.30(iv), we are then easily reduced to showing that the two functors :

\[ I \to (V, m)^a-\text{Mod} \quad i \mapsto M_i \otimes_{V^a} A_i \otimes_{V^a} N_i \quad i \mapsto M_i \otimes_{V^a} N_i \]

are both almost essentially constant, and their limits are represented by \( M \otimes_{V^a} A \otimes_{V^a} N \) and respectively \( M \otimes_{V^a} N \). Moreover, if both \( P_* := M_* \otimes_{V^a} A_* \) and \( P \otimes_{V^a} N_* \) are almost essentially constant with limits \( P := M \otimes_{V^a} A \) and respectively \( P \otimes_{V^a} N \), then \( M_* \otimes_{V^a} A_* \otimes_{V^a} N_* \) will be almost essentially constant with the sought limit. Hence, we are further reduced to showing the proposition in case \( A_* \) is the constant functor with \( A_i = V^a \) for every \( i \in \text{Ob}(I) \). Now, let \( \tau_* : c_M \Rightarrow M_* \) be the universal cone. We have right exact sequences :

\[ K_i := (\text{Ker} \tau_i) \otimes_{V^a} N_i \to \text{Ker}(\tau_i \otimes_{V^a} N_i) \to T_i \to 0 \quad \text{for every } i \in \text{Ob}(I) \]

where \( T_i \) is the cokernel of the natural morphism \( \text{Tor}_1^{V^a}(M_i, N_i) \to \text{Tor}_1^{V^a}(\text{Coker} \tau_i, N_i) \). Since, by assumption, both \( \text{Ker} \tau_* \) and \( \text{Coker} \tau_* \) are almost essentially zero, it is easily seen that the same holds for the induced functors \( K_* \) and \( T_* \), and then the same follows for the functor \( \text{Ker}(\tau_* \otimes_{V^a} N_* \) by lemma 14.2.14(i). Likewise, \( \text{Coker}(\tau_* \otimes_{V^a} N_* \) is the functor \( (\text{Coker} \tau_* \otimes_{V^a} N_* \) which is again almost essentially zero. Thus, \( M_* \otimes_{V^a} N_* \) is isomorphic to \( M \otimes_{V^a} N_* \) in the category \( \mathcal{L}(I, (V, m)^a-\text{Mod}) \). Lastly, let \( F : (V, m)^a-\text{Mod} \to (V, m)^a-\text{Mod} \) be the functor such that \( FX := M \otimes_{V^a} X \) for every \( V^a \)-module \( X \); since \( N_* \) is almost essentially constant,
the same holds for \( FN_\bullet = M \otimes_{\tau^A} N_\bullet \), and its limit is \( M \otimes_{\tau^A} N \), by proposition \[14.2.20^{(i,iii)}\], whence the assertion.

**Theorem 14.2.39.** Let \((V, m)\) be a basic setup, \( I \) a small cofiltered category, and consider an almost essentially constant functor \( A_\bullet : I \to (V, m)^a\text{-Alg} \). Denote by \( A \) the limit of \( A_\bullet \), and let \( \tau^A_s : c_A \Rightarrow A_\bullet \) be a universal cone; let also \( M \) be an \( A \)-module, \( B \) an \( A \)-algebra, \( r \in \mathbb{N} \) and \( A_\bullet \)-\( \text{Mod} : I \to \text{Cat} \), \( i \mapsto A_i \)-\( \text{Mod} \) and \( A_\bullet \)-\( \text{Alg} : I \to \text{Cat} \), \( i \mapsto A_i \)-\( \text{Alg} \) the pseudo-functors naturally induced by \( A_\bullet \). The following holds:

(i) The cone \( \tau^A_\bullet \) induces equivalences of categories

\[
A\text{-Alg} \xrightarrow{\sim} 2\lim_i A_i \text{-Alg} \quad A\text{-Mod} \xrightarrow{\sim} 2\lim_i A_i \text{-Mod}.
\]

(ii) The \( A \)-module \( M \) is almost finitely generated (resp. almost finitely presented, resp. flat, resp. faithfully flat resp. almost projective) if and only if the same holds for the \( A_i \)-module \( A_i \otimes_A M \), for every \( i \in \text{Ob}(I) \).

(iii) Suppose that \((V, m)\) fulfills condition (B) of [59] \[2.1.6\]. Then \( M \) is almost projective of almost finite rank (resp. of finite rank \( \leq r \)) if and only if the same holds for the \( A_i \)-module \( A_i \otimes_A M \), for every \( i \in \text{Ob}(I) \).

(iv) The \( A \)-algebra \( B \) is weakly unramified (resp. unramified, resp. weakly étale, resp. étale) if and only if the same holds for the \( A_i \)-algebra \( A_i \otimes_A B \), for every \( i \in \text{Ob}(I) \).

**Proof.** (i): Let \( \pi : (V, m)^a\text{-Alg}\text{-Mod} \to (V, m)^a\text{-Alg} \) be the natural projection functor. Then \( 2\lim_i A_i \text{-Mod} \) is the subcategory of \( \text{Fun}(I, (V, m)^a\text{-Alg}\text{-Mod}) \) whose objects are the functors

\[
(A_\bullet, M_\bullet) : I \to (V, m)^a\text{-Alg}\text{-Mod} \quad i \mapsto (A_i, M_i)
\]

with \( \pi \circ (A_\bullet, M_\bullet) = A_\bullet \), and such that, with the notation of [\[14.2.31\]], the morphism \( g_\varphi : A_i \otimes_A j_i \to M_i \) is an isomorphism of \( A_i \)-modules, for every morphism \( \varphi : j \to i \) in \( I \). The morphisms \( \beta_\bullet : (A_\bullet, M_\bullet) \to (A_\bullet, M'_\bullet) \) are the natural transformations such that \( \pi \ast \beta_\bullet = 1_{A_\bullet} \).

Under this identification, the functor \( (A_\bullet, A_\bullet \otimes_A -) : A\text{-Mod} \to 2\lim_i A_i \text{-Mod} \) of (i) assigns to every \( A \)-module \( M \) the functor

\[
(A_\bullet, A_\bullet \otimes_A M) : I \to (V, m)^a\text{-Alg}\text{-Mod} \quad i \mapsto (A_i, A_i \otimes_A M).
\]

Conversely, following [\[14.2.31\]], with every functor \( (A_\bullet, M_\bullet) \) as in the foregoing, we associate a functor \( M_\bullet : I \to A\text{-Mod} \), and let \( M \) be the limit of \( M_\bullet \). From proposition [\[14.2.32\] iii) we obtain a natural isomorphism

\[
(A_\bullet, A_\bullet \otimes_A M) \xrightarrow{\sim} (A_\bullet, M_\bullet).
\]

This shows that \( (A_\bullet, A_\bullet \otimes_A -) \) is essentially surjective. Next, let \( M, N \) be two \( A \)-modules; according to proposition [\[14.2.20\] i), the kernel and cokernel of \( \tau^A \otimes_A N : c_N \Rightarrow A_\bullet \otimes_A N \) are almost essentially zero, and therefore \( \tau^A \otimes_A N \) is a universal cone. There follow natural isomorphisms

\[
\text{Hom}_A(M, N) \xrightarrow{\sim} \lim_i \text{Hom}_A(M, A_\bullet \otimes_A N) \xrightarrow{\sim} \lim_i \text{Hom}_A((A_\bullet, A_\bullet \otimes_A M, A_\bullet \otimes_A N))
\]

and notice that the latter limit is naturally identified with the set of morphisms \( (A_\bullet, A_\bullet \otimes_A M) \to (A_\bullet, A_\bullet \otimes_A N) \) in \( 2\lim_i A_i \text{-Mod} \). Thus \( (A_\bullet, A_\bullet \otimes_A -) \) is an equivalence.

(ii): Suppose first that \( M_\bullet := A_i \otimes_A M \) is almost finitely generated for every \( i \in \text{Ob}(I) \). Let \( N_\bullet : \Lambda \to A\text{-Mod} \) be any functor from a small filtered category \( \Lambda \); denote by \( N \) the colimit of \( N_\bullet \), and let \( \tau^N : N_\bullet \Rightarrow c_N \) be a universal cocone. We have two \( V \)-linear functors

\[
F : A\text{-Mod} \to A\text{-Mod} \quad P \mapsto \text{colim}_A \text{alHom}_A(M, P \otimes_A N_\bullet)
\]

\[
G : A\text{-Mod} \to A\text{-Mod} \quad P \mapsto \text{alHom}_A(M, P \otimes_A N)
\]
and \( \tau_i^N \) induces a natural transformation

\[
\beta_i : F \Rightarrow G \quad P \mapsto \text{colim}_A \text{alHom}_A(M, P \otimes_A \tau_i^N) : FP \to GP
\]

and according to \([59, \text{Prop.2.3.16(i)}]\), it suffices to check that \( \beta_A \) is a monomorphism. However, we have a commutative diagram of functors:

\[
\begin{array}{ccc}
  c_{FA} & \xrightarrow{c_{\beta_A}} & c_{GA} \\
  F \star \tau_A & \Downarrow & \Downarrow G \star \tau_A \\
  F \circ A & \xrightarrow{\beta \star A} & G \circ A
\end{array}
\]

and by propositions \([14.2.18]\) ii) and \([14.2.20]\) i), the vertical arrows of the diagram are both isomorphisms in the category \( \mathcal{L}(I, A\text{-Mod}) \). We claim that \( \beta_i : F A_i \to G A_i \) is a monomorphism for every \( i \in \text{Ob}(I) \). Indeed:

\[
FA_i = \text{colim}_A \text{alHom}_A(M_i, A_i \otimes_A N_i) \quad \text{and} \quad GA_i = \text{alHom}_A(M_i, A_i \otimes_A N)
\]

and since by assumption the \( A_i \)-module \( M_i \) is almost finitely generated, the assertion follows from \([59, \text{Prop.2.3.16(ii)}]\). We deduce that \( c_{\beta_A} \) is also a monomorphism in \( \mathcal{L}(I, A\text{-Mod}) \), i.e. \( \beta_A \) is a monomorphism, as required.

One argues likewise, in case \( M_i \) is almost finitely presented for every \( i \in \text{Ob}(I) \), invoking \([59, \text{Prop.2.3.16(ii)}]\) to see that in this case \( \beta_A \) is an isomorphism for every such \( i \), whence \( \beta_A \) is an isomorphism, so that \( M \) is almost finitely presented, again by \([59, \text{Prop.2.3.16(ii)}]\).

Next, suppose that \( M_i \) is an almost projective \( A_i \)-module for every \( i \in \text{Ob}(I) \), and let \( f : N' \to N \) be an epimorphism of \( A \)-modules. We attach to the pair \((M, N)\) the \( V \)-linear functor

\[
H_{M,N} : A\text{-Mod} \to A\text{-Mod} \quad P \mapsto \text{alHom}_A(P \otimes_A M, P \otimes_A N)
\]

define likewise \( H_{M,N'} : A\text{-Mod} \to A\text{-Mod} \). The morphism \( f \) induces a natural transformation \( H_{M,f} : H_M \Rightarrow H_{M,N'} \), whence a commutative diagram of functors:

\[
\begin{array}{ccc}
  CH_{M,N}(A) & \xrightarrow{CH_{M,f}(A)} & CH_{M,N'}(A) \\
  H_{M,N} \circ A_i & \Downarrow & \Downarrow H_{M,N'} \circ A_i \\
  H_{M,N} \circ A_i & \xrightarrow{H_{M,f} \circ A_i} & H_{M,N'} \circ A_i
\end{array}
\]

whose vertical arrows are isomorphisms in \( \mathcal{L}(I, A\text{-Mod}) \), by virtue of propositions \([14.2.18]\) ii) and \([14.2.20]\) i); moreover, \( H_{M,N'} \circ \tau_i^A \) is an epimorphism for every \( i \in \text{Ob}(I) \), since \( M_i \) is an almost projective \( A_i \)-module. As in the previous case, we deduce that \( H_{M,f}(A) \) is an epimorphism of \( A \)-modules, so \( M \) is almost projective.

Suppose next that \( M_i \) is flat for every \( i \in \text{Ob}(I) \), and let \( f : N \to N' \) be a monomorphism of \( A \)-modules. Set \( N_i := A_i \otimes_A N \) and \( N'_i := A_i \otimes_A N' \) for every \( i \in \text{Ob}(I) \), and let \( \overline{N}_i := \text{Im}(A_i \otimes_A f) \subset N'_i \). Clearly the rule : \( i \mapsto \overline{N}_i \) defines a subfunctor \( \overline{\text{N}_*} \) of \( A_* \otimes_A N' \). By proposition \([14.2.20]\) i), the kernel of \( A_* \otimes_A f : A_* \otimes_A N \to A_* \otimes_A N' \) is almost essentially zero, hence the induced natural transformation \( \pi_* : A_* \otimes_A N \to \overline{\text{N}_*} \) is an isomorphism in \( \mathcal{L}(I, A\text{-Mod}) \). By the same token, the same holds for the natural transformation \( \tau_i^A \otimes_A N : c_N \Rightarrow A_i \otimes_A N \), and therefore also for the composition \( \mu_* : \pi_* \circ (\tau_i^A \otimes_A N) : c_N \Rightarrow \overline{\text{N}_*} \). We obtain therefore a commutative diagram of functors:

\[
\begin{array}{ccc}
  c_{M \otimes_A N} & \xrightarrow{c_{M \otimes_A f}} & c_{M \otimes_A N'} \\
  M \otimes_A \mu_* & \Downarrow & \Downarrow M \otimes_A \tau_i^A \otimes_A N \\
  M \otimes_A \overline{\text{N}_*} & \xrightarrow{M \otimes_A \tau_i^A \otimes_A N} & M \otimes_A A_i \otimes_A N'
\end{array}
\]
whose vertical arrows are, as usual, isomorphisms in $\mathcal{L}(I, A\text{-Mod})$. Let $j_i : N_i \to N'_i$ be the inclusion; we have natural isomorphisms $M \otimes_A N_i \xrightarrow{\sim} M_i \otimes_{A_i} N_i$ and $M \otimes_A A_i \otimes_A N'_i \xrightarrow{\sim} M_i \otimes_{A_i} N'_i$ for every $i \in \text{Ob}(I)$, that identify the bottom horizontal arrow with the morphism $M \otimes_{A_i} j_i$. The latter is a monomorphism for every $i \in \text{Ob}(I)$, since $M_i$ is a flat $A_i$-module; as usual it follows that $M \otimes_A f$ is a monomorphism as well, so $M$ is flat.

Lastly, suppose that $M_i$ is a faithfully flat $A_i$-module for every $i \in \text{Ob}(I)$; by the foregoing, we know already that $M$ is a flat $A$-module. Then, let $X$ be any $A$-module such that $M \otimes_A X = 0$; it follows that $M_i \otimes_{A_i} (A_i \otimes_A X) = 0$ for every $i \in \text{Ob}(I)$, whence $A_i \otimes_A X = 0$ for every such $i$. But by the foregoing, $X$ is the limit of the functor $A_i \otimes_A X$, whence $X = 0$; this shows that $M$ is faithfully flat.

(iii): Suppose that $M_i$ is an almost projective $A_i$-module of almost finite rank, for every $i \in \text{Ob}(I)$. By the foregoing, we know already that $M$ is an almost projective $A$-module, and it remains to check that it is of almost finite rank. To this aim, define the category $\mathcal{F}$ and the functors $\pi : \mathcal{F} \to \text{Morph}(I)$ and $\Lambda : \text{Morph}(I) \to A\text{-Alg}$ as in the proof of proposition [14.2.32]; recall that $\pi$ is final, and $\Lambda \circ \pi$ is a Cauchy functor (claims [14.2.35] and [14.2.36]). Moreover, the cone $\tau^A_i : c_A \Rightarrow \Lambda_i$, deduced from $\tau^A_i$, is universal, so the same holds for $\tau^A_i \circ \pi$. It follows that $\text{Ker}(\tau^A_i \circ \pi)$ and $\text{Coker}(\tau^A_i \circ \pi)$ are null functors (remark [14.2.17](ii)). Now, let $m_0 \subset m$ be a subideal of finite type; by the foregoing there exists $(\varphi : j \to i, m_1) \in \text{Ob}(\mathcal{F})$ such that the kernel and cokernel of $\tau^A_j : A \to \Lambda_j := \text{Im} A_j$ are both annihilated by $m_0$. On the other hand, since $M_j$ has almost finite rank, there exists $n \in \mathbb{N}$ such that $m_0 \cdot A_j^\Lambda M_j = 0$, and then we have as well $m_0 \cdot (\Lambda_j \otimes_A \Lambda_j^\Lambda M_j) = 0$. But by remark [14.2.10](vi), the kernel of

$$\tau^A_j \otimes_A \Lambda_j^\Lambda M : \Lambda_j^\Lambda M \to \Lambda_j \otimes_A \Lambda_j^\Lambda M \xrightarrow{\sim} \Lambda_j \otimes_A \Lambda_j^\Lambda M$$

is annihilated by $m_0^3$. We conclude that $m_0^3 \cdot \Lambda_j^\Lambda M = 0$, whence the contention. Lastly, if $M_i$ has rank $\leq r$ for every $i \in \text{Ob}(I)$, the same argument shows that $m \cdot m_0^2 \cdot \Lambda_i^\Lambda M = 0$ for every such $m_0$, i.e. $\Lambda_i^\Lambda M = 0$, so $M$ has rank $\leq r$.

(iv): Set $C := B \otimes_A B$, and let $\mu : C \to B$ be the multiplication law of the $A$-algebra $B$; the functor $C_\bullet := C \otimes_A A_\bullet : I \to (V, m)^{a\text{-Alg}}$ is still almost essentially constant, and $C \otimes_A \tau^A_i : c_C \Rightarrow C_\bullet$ is an isomorphism in $\mathcal{L}(I, A\text{-Mod})$ (proposition [14.2.20](i,iii)). Suppose now that $B_i := B \otimes_A A_i$ is a weakly unramified $A_i$-algebra, i.e. that the morphism $\mu \otimes_A A_i : C_\bullet \to B_i$ is flat for every $i \in \text{Ob}(I)$. By (ii), it follows that $\mu$ is flat, i.e. $B$ is a weakly unramified $A$-algebra. One argues likewise in case $B_i$ is an unramified (resp. weakly étale, resp. étale) $A_i$-algebra for every $i \in \text{Ob}(I)$.

The following notion of flatness for almost modules, relative to a given base ring will find application in section [17.5].

**Definition 14.2.40.** Let $(V, m)$ be a basic setup, $f : A \to V$ a ring homomorphism, and $M$ any $V$-module; we say that $M^a$ is flat over $A$ (resp. faithfully flat over $A$) if the functor

$$A\text{-Mod} \to (V, m)^{a\text{-Mod}} \quad N \mapsto M^a \otimes_A N := (M \otimes_A N)^a$$

is exact (resp. is exact and faithful).

**Lemma 14.2.41.** In the situation of definition [14.2.40], let $g : V \to B$ be a ring homomorphism, and $N$ a $B$-module. The following holds:

(i) If the $V^a$-module $B^a$ is faithfully flat over $A$, the map $g \circ f : A \to B$ is injective.

(ii) $M^a$ is faithfully flat over $A$ if and only if it is flat over $A$ and $(M/nM)^a \neq 0$ for every maximal ideal $n \subset A$.

(iii) If the $V^a$-module $B^a$ is flat (resp. faithfully flat) over $A$, and $N^a$ is a flat (resp. faithfully flat) $B^a$-module, then $N^a$ is flat (resp. faithfully flat) over $A$. 

**Proof.** (i): Set $I := \ker (g \circ f)$; by assumption, the inclusion map $I \to A$ induces a monomorphism $(I \otimes_A B)^a \to B^a$ of $V^a$-modules, i.e. the natural morphism $(I \otimes_A B)^a \to (IB)^a = 0$ is an isomorphism of $V^a$-modules. By assumption, the latter implies that $I = 0$.

Assertions (ii) and (iii) shall be left to the reader. \qed

14.2.42. In the situation of definition [14.2.40] suppose that $A$ is noetherian, let $I \subset A$ be a given ideal, and set $A_n := A/I^n$, $V_n := V/I^nV$, for every $n \in \mathbb{N}$. Consider an inverse system $M_n := (M_n, \varphi_n | n \in \mathbb{N})$, where $M_n$ is a $V_n$-module such that $M_n^a$ is flat over $A_n$, and $\varphi_n : M_{n+1} \to M_n$ is a $V_n$-linear map, such that the induced inverse system of $V^a$-modules $M^a := (M_n^a, \varphi_n^a | n \in \mathbb{N})$ has the almost Mittag-Leffler property (see definition [14.2.11]iv)). Let also $M$ be the limit of $M_n$ (in the category $V$-$\text{Mod}$).

**Proposition 14.2.43.** With the notation of (14.2.42), the following holds:

(i) $M^a$ is flat over $A$.

(ii) Every $A$-module $N$ of finite type induces an isomorphism of $V^a$-modules

\[ (N \otimes_A M)^a \cong \lim_{n \in \mathbb{N}} (N \otimes_A M_n)^a. \]

*Proof.* (ii): Let $(F_n, d_n) \to N$ be a resolution of $N$ by free $A$-modules of finite rank (hence the differential $d_i : F_i \to F_{i-1}$ is an $A$-linear map, for every $i > 0$, and $d_0 : F_0 \to N$ is an $A$-linear surjection). There follows, for every $n \in \mathbb{N}$, exact sequences of $A$-modules:

\[ 0 \to \text{Tor}_1^A(N, M_n) \to \text{Coker}(d_2) \otimes_A M_n \xrightarrow{d_1,n} F_0 \otimes_A M_n \to N \otimes_A M_n \to 0 \]

\[ 0 \to \text{Im}(d_2 \otimes A M_n) \to F_1 \otimes A M_n \to \text{Coker}(d_2) \otimes A M_n \to 0 \]

where $d_1,n$ is induced by $d_1 \otimes A M_n$, for every such $n$. Since $M_n^a$ is flat over $A_n$, we have a natural isomorphism of $V^a$-modules:

\[ \text{Tor}_1^A(N, M_n)^a \cong (\text{Tor}_1^A(N, A_n) \otimes A M_n)^a \quad \text{for every } n \in \mathbb{N}. \]

**Claim 14.2.44.** (i) The inverse system $(\text{Tor}_1^A(N, A_n) | n \in \mathbb{N})$ is essentially zero.

(ii) Consider an exact sequence of inverse systems of $V^a$-modules:

\[ K_{3,n} : (K_{3,n} | n \in \mathbb{N}) \xrightarrow{\varphi_{3,n}} (K_{2,n} | n \in \mathbb{N}) \xrightarrow{\varphi_{2,n}} (K_{1,n} | n \in \mathbb{N}) \xrightarrow{\varphi_{1,n}} (K_{0,n} | n \in \mathbb{N}) \to 0 \]

such that $K_{3,n}$ is almost essentially zero, and $K_{2,n}$ has the almost Mittag-Leffler property. Then $K_{3,n}$ induces a short exact sequence of $V^a$-modules:

\[ 0 \to \lim_{n \in \mathbb{N}} K_{2,n} \to \lim_{n \in \mathbb{N}} K_{1,n} \to \lim_{n \in \mathbb{N}} K_{0,n} \to 0. \]

**Proof of the claim.** (i): Let $K := \ker(d_0 : F_0 \to N)$; we have a natural identification:

\[ \text{Tor}_1^A(N, A_n) \cong (K \cap I^n F)/(I^n K) \quad \text{for every } n \in \mathbb{N} \]

and by the Artin-Rees lemma there exists $c \in \mathbb{N}$ such that $K \cap I^{n+c} F_0 \subset I^n K$ for every $n \in \mathbb{N}$, whence the assertion.

(ii): Set $J_n := \text{Im} \varphi_{2,n}$ for every $n \in \mathbb{N}$; we get induced exact sequences of inverse systems:

\[ K_{3,n} \to K_{2,n} \to J_n \to 0 \quad 0 \to J_n \to K_{2,n} \to K_{1,n} \to 0 \]

whence, by lemma [14.2.14]iii), an isomorphism of $V^a$-modules:

\[ \lim_{n \in \mathbb{N}} K_{2,n} \cong \lim_{n \in \mathbb{N}} J_n \]

and notice that $J_n$ has the almost Mittag-Leffler property, as the same holds for $K_{2,n}$ (proposition [14.2.30]ii); then, proposition [14.2.25]iii) yields a short exact sequence of $V^a$-modules:

\[ 0 \to \lim_{n \in \mathbb{N}} J_n \to \lim_{n \in \mathbb{N}} K_{1,n} \to \lim_{n \in \mathbb{N}} K_{0,n} \to 0 \]
whence the assertion.

From claim \[14.2.44\] (i) we deduce easily that the inverse system \((\text{Tor}_1^A(N, M_n)^a \mid n \in \mathbb{N})\) is also essentially zero. On the other hand, since \(M\) has the almost Mittag-Leffler property, the same holds for the inverse system of \(V^a\)-modules \((\text{Coker} \ d_2 \otimes_A M_n)^a\); likewise, with proposition \[14.2.30\] (ii) one checks that the inverse system \((\text{Im}(d_2 \otimes_A M_n)^a \mid n \in \mathbb{N})\) has the almost Mittag-Leffler property; then, claim \[14.2.44\] (ii) yields short exact sequences of \(V^a\)-modules:

\[
0 \to \lim_{n \in \mathbb{N}} (\text{Coker} \ d_2 \otimes_A M_n)^a \to \lim_{n \in \mathbb{N}} (F_0 \otimes_A M_n)^a \to \lim_{n \in \mathbb{N}} (N \otimes_A M_n)^a \to 0
\]

\[
0 \to \lim_{n \in \mathbb{N}} \text{Im}(d_2 \otimes_A M_n)^a \to \lim_{n \in \mathbb{N}} (F_1 \otimes_A M_n)^a \to \lim_{n \in \mathbb{N}} (\text{Coker} \ d_2 \otimes_A M_n)^a \to 0.
\]

Lastly, since \(F_1\) is a free \(A\)-module of finite type, clearly we have a natural identification

\[
\lim_{n \in \mathbb{N}} (F_i \otimes_A M_n)^a \xrightarrow{n} (F_i \otimes_A M)^a
\]

for every \(i \in \mathbb{N}\).

Summing up, we get a right exact sequence of \(V^a\)-modules

\[
(F_1 \otimes_A M)^a \xrightarrow{d_1 \otimes_A M} (F_0 \otimes_A M)^a \to \lim_{n \in \mathbb{N}} (N \otimes_A M_n)^a \to 0
\]

whence the contention.

(i): We need to check that every \(A\)-linear injection \(f : N \to N'\) of \(A\)-modules of finite type induces a monomorphism \((f \otimes_A M)^a\). However, for every \(n \in \mathbb{N}\) we have an exact sequence:

\[
\text{Tor}_1^A(\text{Coker} \ f, M_n) \to N \otimes_A M_n \xrightarrow{f \otimes_A M} N' \otimes_A M_n \to \text{Coker} \ f_n \otimes_A M_n \to 0
\]

and arguing as in the proof of (i) we see that the inverse system \((\text{Tor}_1^A(\text{Coker} \ f, M_n)^a \mid n \in \mathbb{N})\) is essentially zero, and the inverse system \((N \otimes_A M_n \mid n \in \mathbb{N})\) has the almost Mittag-Leffler property, therefore claim \[14.2.44\] (ii) implies that the inverse system \(((f \otimes_A M_n)^a \mid n \in \mathbb{N})\) induces a monomorphism \(\lim_{n \in \mathbb{N}} (N \otimes_A M_n)^a \to \lim_{n \in \mathbb{N}} (N' \otimes_A M_n)^a\). By (i), the latter is naturally identified with \((f \otimes_A M)^a\), whence the assertion. 

\[\square\]

For future reference, let us also point out the following almost analogue of proposition 8.2.13 (i, v):

**Lemma 14.2.45.** Let \((V, m)\) be a basic setup, \(f : M' \to M\) a morphism of \(V^a\)-modules, and \(\mathcal{T}\) a linear topology on \(M\). Endow \(M'\) (resp. \(M'' := \text{Coker} \ f\) with the linear topology \(\mathcal{T}'\) (resp. \(\mathcal{T}''\)) induced by \(\mathcal{T}\) via \(f\) (resp. via the projection \(\pi : M \to M''\)). We have:

(i) \(f\) induces a short exact sequence of the respective separated completions:

\[
0 \to (M', \mathcal{T}')^\wedge \xrightarrow{f^\wedge} (M, \mathcal{T})^\wedge \xrightarrow{\pi^\wedge} (M'', \mathcal{T}'')^\wedge.
\]

(ii) If \(\mathcal{T}\) has a countable fundamental system of open submodules, \(\pi^\wedge\) is an epimorphism.

**Proof.** (i): See [50, §5.3] for generalities concerning linear topologies on \(V^a\)-modules. By definition, \(\mathcal{T}\) is determined by a cofiltered family \((M_\lambda \mid \lambda \in \Lambda)\) of \(V^a\)-submodules of \(M\), and \(\mathcal{T}'\) and \(\mathcal{T}''\) are likewise given by the families \((M'_\lambda := f^{-1}M_\lambda \mid \lambda \in \Lambda)\) and \((M''_\lambda := \pi(M_\lambda)) \mid \lambda \in \Lambda\). We need to check that \(f\) induces an exact sequence of \(V^a\)-modules:

\[
0 \to \lim_{\lambda \in \Lambda} M'/M'_\lambda \to \lim_{\lambda \in \Lambda} M/M_\lambda \to \lim_{\lambda \in \Lambda} M''/M''_\lambda.
\]

To this aim, it suffices to show that the induced sequence of \(V\)-modules:

\[
0 \to \lim_{\lambda \in \Lambda}(M'/M'_\lambda)_\ast \to \lim_{\lambda \in \Lambda}(M/M_\lambda)_\ast \to \lim_{\lambda \in \Lambda}(M''/M''_\lambda)_\ast
\]

is exact. However, \(f\) induces a short exact sequence of \(V^a\)-modules:

\[
0 \to M'/M'_\lambda \to M/M_\lambda \to M''/M''_\lambda \to 0 \quad \text{for every } \lambda \in \Lambda.
\]
whence a corresponding short exact sequence of $V$-modules

$$0 \to (M'/M'_\lambda)_* \to (M/M_\lambda)_* \to (M''/M''_\lambda)_* \quad \text{for every } \lambda \in \Lambda.$$  

The assertion follows immediately.

(ii): Under the stated assumptions, we may suppose that $\Lambda = \mathbb{N}^\circ$; then the assertion follows from proposition \cite[14.2.25]{[59]} iii). \hfill \Box

14.3. Quasi-coherent sheaves of almost modules and almost rings. Throughout this section, we fix a basic setup $(V, m)$ (see \cite[§2.1.1]{59}) and we set $S := \text{Spec } V$; for every $S$-scheme $X$ we may consider the sheaf $\mathcal{O}_X^\alpha$ of almost algebras on $X$, and we refer to \cite[§5.5]{59} for the definition of quasi-coherent $\mathcal{O}_X^\alpha$-modules and algebras. However, whereas in \cite{59}, it was assumed that $\bar{m} := m \otimes_V m$ is a flat $V$-module, in this section the basic setup can be arbitrary, except where it is explicitly said otherwise. This of course requires some care when quoting from \cite{59}; however, it turns out that – thanks to the work done in section 14.1 – most of the results in \cite{59} do extend verbatim to the case of a general setup. The main exception is the theory of the finite and almost finite rank of almost projective modules, that relies on the existence of a well behaved exterior power functor, which is available only if the basic setup satisfies some minimal conditions (see \cite[14.1.6]{59}). In any case, whenever we need to import some theorem from \cite{59}, we shall comment on its range of validity.

Definition 14.3.1. Let $X$ be an $S$-scheme, $\mathfrak{A}$ a quasi-coherent $\mathcal{O}_X^\alpha$-algebra, and $\mathcal{F}$ an $\mathfrak{A}$-module which is quasi-coherent as an $\mathcal{O}_X^\alpha$-module.

(i) $\mathcal{F}$ is said to be an $\mathfrak{A}$-module of almost finite type (resp. of almost finite presentation, resp flat, resp faithfully flat) if, for every affine open subset $U \subset X$, the $\mathfrak{A}(U)$-module $\mathcal{F}(U)$ is almost finitely generated (resp. almost finitely presented, resp. flat, resp. faithfully flat).

(ii) $\mathcal{F}$ is said to be an almost coherent $\mathfrak{A}$-module if it is an $\mathfrak{A}$-module of almost finite type, and for every open subset $U \subset X$, every quasi-coherent $\mathfrak{A}(U)$-submodule of $\mathcal{F}|_U$ of almost finite type, is almost finitely presented.

(iii) We say that $\mathcal{F}$ is a torsion-free $\mathcal{O}_X^\alpha$-module if we have $\ker b \cdot 1 \mathcal{F}(U) = 0$, for every affine open subset $U \subset X$ and every regular element $b \in \mathcal{O}_X(U)$.

(iv) Suppose that $m$ satisfies condition (B) of \cite[§2.1.6]{59}. Then we say that $\mathcal{F}$ is an $\mathfrak{A}$-module of almost finite rank (resp. of finite rank) if, for every affine open subset $U \subset X$, the $\mathfrak{A}(U)$-module $\mathcal{F}(U)$ is almost finitely generated projective of almost finite (resp. finite) rank.

Remark 14.3.2. In the situation of definition 14.3.1:

(i) We denote by

$$\mathfrak{End}_{\mathfrak{A}}(\mathcal{F})$$

the $\mathcal{O}_X$-module of $\mathfrak{A}$-linear endomorphisms of $\mathcal{F}$, defined by the rule: $U \mapsto \mathfrak{End}_{\mathfrak{A}(U)}(\mathcal{F}(U))$ for every open subset $U \subset X$. It is easily seen that $\mathfrak{End}_{\mathfrak{A}}(\mathcal{F})^a$ is an $\mathfrak{A}$-module.

(ii) Suppose that $\mathcal{F}$ is a flat and almost finitely presented $\mathfrak{A}$-module. Then there exists a trace morphism

$$\text{tr}_{\mathfrak{A}/\mathfrak{A}} : \mathfrak{End}_{\mathfrak{A}}(\mathcal{F}) \to \mathfrak{A}$$

that, on every affine open subset $U \subset X$, induces the trace morphism $\text{tr}_{\mathfrak{A}(U)/\mathfrak{A}(U)}$ of the almost finitely generated projective $\mathfrak{A}(U)$-module $\mathcal{F}(U)$ (details left to the reader; see \cite[§4.1]{59}), which does not depend on any assumption on the basic setup).

14.3.3. Let $f : Y \to X$ be any morphism of $V$-schemes. The usual functor $f^*$ for quasi-coherent $\mathcal{O}_X$-modules admits a variant for quasi-coherent $\mathcal{O}_X^\alpha$-modules; namely, we define

$$f^* : \mathcal{O}_X^\alpha\text{-Mod}_{\text{qcoh}} \to \mathcal{O}_Y^\alpha\text{-Mod}_{\text{qcoh}} \quad \mathcal{F} \mapsto (f^* \mathcal{F})^a.$$  

If $f$ is also quasi-compact and quasi-separated, we have as well a direct image functor

$$f_* : \mathcal{O}_Y^\alpha\text{-Mod}_{\text{qcoh}} \to \mathcal{O}_X^\alpha\text{-Mod}_{\text{qcoh}} \quad \mathcal{F} \mapsto (f_* \mathcal{F})^a.$$
Moreover, if $\mathcal{F}$ (resp. $\mathcal{G}$) is any quasi-coherent $\mathcal{O}_X$-module (resp. $\mathcal{O}_Y$-module), it is easily seen that the natural morphism

$$f^*(\mathcal{F}^a) \to (f^*\mathcal{F})^a \quad \text{resp.} \quad f_*(\mathcal{F}^a) \to (f_*\mathcal{F})^a$$

is an isomorphism. It follows that, if $Z \subset X$ is any constructible closed subset, there is a well defined functor of sections with support in $Z$:

$$\Gamma_Z: \mathcal{O}_X\text{-}\text{Mod}_{\text{qcoh}} \to \mathcal{O}_X\text{-}\text{Mod}_{\text{qcoh}} \quad \mathcal{F} \mapsto (\Gamma_Z\mathcal{F})^a$$

(see (10.4.16)) and again, for every quasi-coherent $\mathcal{O}_X$-module $\mathcal{F}$, the natural map

$$\Gamma_Z(\mathcal{F}^a) \to (\Gamma_Z\mathcal{F})^a$$

is an isomorphism (details left to the reader).

**Lemma 14.3.4.** Suppose that $\mathfrak{m}$ fulfills condition (B), and let $X$ be a reduced $S$-scheme, $\mathcal{F}$ a flat quasi-coherent $\mathcal{O}_X^a$-module of almost finite type. We have:

(i) If $X$ is reduced and $\mathcal{F}$ is an $\mathcal{O}_X^a$-module of almost finite presentation, then $\mathcal{F}$ is an $\mathcal{O}_X^a$-module of almost finite rank.

(ii) If $X$ is integral, then $\mathcal{F}$ is an $\mathcal{O}_X^a$-module of finite rank.

**Proof.** (i): We may assume that $X$ is affine, say $X = \text{Spec} R$ for a reduced $V$-algebra $R$, and $\mathcal{F} = P^\sim$ for a flat and almost finitely presented $R^a$-module $P$. Then $P$ is almost projective ([59], Prop.2.4.18(ii)), and we need to check that it has almost finite rank. Thus, let $\varepsilon \in \mathfrak{m}$ be any element and set $R' := R[\varepsilon^{-1}]$; then $P' := R' \otimes_R P$ is a projective $R'$-module of finite rank, so there exists $n \in \mathbb{N}$ such that $R' \otimes_R \Lambda^n_R P = \Lambda^n_{R'} P' = 0$. Since $\Lambda^n_R P$ is also almost finitely presented (see [59], §4.3.1), we deduce easily that there exists $N \in \mathbb{N}$ such that $\varepsilon^n \cdot \Lambda^n_R P = 0$, and since moreover $\Lambda^n_R P$ is a flat $R^a$-module and $R$ is reduced, we have

$$\text{Ann}_{\Lambda^n_R P}(\varepsilon^N) = \text{Ann}_{R}(\varepsilon^N) \cdot \Lambda^n_R P = \text{Ann}_{R}(\varepsilon) \cdot \Lambda^n_R P$$

i.e. $\varepsilon \cdot \Lambda^n_R P = 0$, whence the contention.

(ii): Let $\eta$ be the generic point of $X$; if $\kappa(\eta)^a = 0$, we have $\mathcal{O}_X^a = 0$ as well, and there is nothing to show. If $\kappa(\eta)^a \neq 0$, the almost structure on $\kappa(\eta)$ is the trivial one (the “classical limit” case of [59], Ex.2.1.2(ii)); in this case, clearly $\mathcal{F}_\eta$ is a free $\kappa(\eta)^a$-module of finite rank, and let $r$ be this rank. From [59], Prop.2.4.19], it follows easily that $\mathcal{F}$ is almost finitely presented. Moreover, the exterior powers of $\mathcal{F}$ are still flat $\mathcal{O}_X^a$-modules; then the $r$-th exterior power vanishes, since it vanishes at the generic point of $X$. \[\square\]

**Lemma 14.3.5.** Let $f: Y \to X$ a faithfully flat and quasi-compact morphism of $S$-schemes, $\mathcal{A}$ a quasi-coherent $\mathcal{O}_X^a$-algebra, $\mathcal{F}$ a quasi-coherent $\mathcal{A}$-module, and $r \in \mathbb{N}$. Then:

(i) The $\mathcal{A}$-module $\mathcal{F}$ is of almost finite type (resp. of almost finite presentation, resp. flat, resp. faithfully flat) if and only if the same holds for the $f^*\mathcal{A}$-module $f^*\mathcal{F}$.

(ii) Suppose that $\mathfrak{m}$ fulfills condition (B). Then the $\mathcal{A}$-module $\mathcal{F}$ is of almost finite rank (resp. of finite rank $\leq r$) if and only if the same holds for the $f^*\mathcal{A}$-module $f^*\mathcal{F}$.

(iii) If the $f^*\mathcal{A}$-module $f^*\mathcal{F}$ is almost coherent, then the same holds for the $\mathcal{A}$-module $\mathcal{F}$.

**Proof.** The assertions are local on $X$, so we may assume that $X$ is affine; then $Y$ admits a finite covering $(U_i \mid i \in I)$ consisting of affine open subsets, and we may further reduce to the case where $Y$ is the disjoint union of the schemes $U_i$, so $Y$ is affine as well.

(i): For the conditions “almost finite type”, “almost finite presentation”, and “flat”, the assertion follows from [59], Rem.3.2.26(ii), which holds for any basic setup. It remains to check that if $A \to B$ is a faithfully flat map of $V$-algebras, and $M$ is any $A$-module, such that $(B \otimes_A M)^a$ is a faithfully flat $B^a$-module, then $M^a$ is a faithfully flat $A^a$-module. To this aim, let $X$ be any $A$-module such that $(M \otimes_A X)^a = 0$; then $(B \otimes_A X)^a \otimes_{B^a} (B \otimes_A X)^a = 0$, and therefore
(B ⊗_A X)^a = 0, i.e. m ⊗_V B ⊗_A X = 0, whence m ⊗_V X = 0, i.e. X^a = 0. Since we know already that M^a is a flat A^a-module, the contention follows.

(ii): It suffices to apply [59, Rem.3.2.26(iii)], and recall that exterior powers commute with any base changes : the details shall be left to the reader.

(iii) follows easily from (i).

Lemma 14.3.6. Let X be any S-scheme.

(i) The full subcategory O^X-S-Mod_{acoh} of O^X-S-Mod_{qcoh} consisting of all almost coherent modules is abelian and closed under extensions. (More precisely, the embedding O^X-S-Mod_{acoh} → O^X-S-Mod_{qcoh} is an exact functor.)

(ii) If X is a coherent scheme, then every quasi-coherent O^X-module of almost finite presentation is almost coherent.

Proof. Both assertions are local on X, hence we may assume that X is affine, say X = Spec R.

(i): Let f : M → N be a morphism of almost coherent R^a-modules. It is clear that Coker f is again almost coherent. Moreover, f(M) ⊂ N is almost finitely generated, hence almost finitely presented; then by [59, Lemma 2.3.18], Ker f is almost finitely generated, and so it is almost coherent as well. Similarly, using [59, Lemma 2.3.18] one sees that O^X-S-Mod_{acoh} is closed under extensions.

(ii): Let M be an almost finitely presented R^a-module; according to [59, Cor.2.3.13], for every finitely generated ideal m_0 ⊂ m there exist a finitely presented R-module N and an R-linear map ϕ : N → M, whose kernel and cokernel are annihilated by m_0. Likewise, if M' ⊂ M is an almost finitely generated R^a-submodule, we may find finitely many almost elements x_1, ..., x_n ∈ M' that generate an R-module containing m_0 M'. Let a_1, ..., a_k be a finite system of generators for m_0; for each i ≤ k and j ≤ n we may find y_ij ∈ N such that ϕ(y_ij) = a_ix_i. Denote by N the R-submodule of N generated by (y_ij | i ≤ k, j ≤ n). Then ϕ restricts to an R-linear map N' → M' whose kernel is annihilated by m_0, and whose cokernel is annihilated by m_0^2. Since R is coherent, N' is finitely presented, and since m_0 is arbitrary, we conclude that M' is almost finitely presented, as stated.

Lemma 14.3.7. Let X be an S-scheme, ϕ : A → B a morphism of quasi-coherent O^X-algebras, and B_λ := (B_λ | λ ∈ Λ) a filtered system of quasi-coherent and faithfully flat A-algebras. We have:

(i) ϕ is faithfully flat if and only if ϕ is injective and Coker ϕ is a flat A-module.

(ii) The colimit of B_λ is a faithfully flat A-algebra.

Proof. It is easily seen that (i)⇒(ii). In order to show (i), we may assume that X is affine, in which case ϕ is the morphism of quasi-coherent O^X-algebras arising from a morphism f : A → B of O_X(X)^a-algebras. Now, let M be any A-module; if f is injective, the short exact sequence of A-modules 0 → A → B → Coker f → 0 induces a long exact sequence

0 → Tor^A(B, M) → Tor^A(Coker f, M) → M ⊗_A M → Coker f ⊗_A M → 0.

Then, if Coker f is a flat A-module, we deduce that f ⊗_A M is injective and Tor^A(B, M) = 0 for every A-module M, so B is a faithfully flat A-algebra. Conversely, if the latter holds, then f and f ⊗_M A are both injective, hence the foregoing short exact sequence shows that Tor^A(Coker f, M) = 0 for every A-module M, so that Coker f is a flat A-module. 

Definition 14.3.8. Let X be an S-scheme, and A a quasi-coherent O^X-algebra.

(i) We say that a quasi-coherent A-algebra B is almost finite (resp. weakly unramified, resp. weakly étale, resp. unramified, resp. étale) if, for every affine open subset U ⊂ X, the A(U)-algebra B(U) is almost finite (resp. weakly unramified, resp. weakly étale, resp. unramified, resp. étale).
(ii) We define the \( \mathcal{O}_X \)-algebra \( \mathcal{A}_U \) by the short exact sequence:

\[
\overline{m} \otimes_V \mathcal{O}_X \to \mathcal{O}_X \oplus \mathcal{A}_U \to \mathcal{A}_U \to 0
\]

analogous to \([59, \S 2.2.25]\). This agrees with the definition of \([59, \S 3.3.2]\), corresponding to the basic setup \((\mathcal{O}_X, m, \mathcal{O}_X)\) relative to the Zariski topos of \(X\); in general, this is not the same as forming the algebra \( \mathcal{A}_!! \) relative to the basic setup \((V, m)\). The reason why we prefer the foregoing version of \( \mathcal{A}_U \), is explained by the following lemma \([14.3.9]\).

**Lemma 14.3.9.** Let \( X \) be an \( S \)-scheme, \( \mathcal{A} \) a quasi-coherent \( \mathcal{O}_X^\natural \)-algebra. Then \( \mathcal{A}_U \) is a quasi-coherent \( \mathcal{O}_X \)-algebra, and if \( \mathcal{A} \) is almost finite, then \( \mathcal{A}_U \) is an integral \( \mathcal{O}_X \)-algebra.

**Proof.** First, \( \mathcal{A}_U \) is a quasi-coherent \( \mathcal{O}_X \)-module \((\mathcal{O}_X, m, \mathcal{O}_X)\), hence the same holds for \( \mathcal{A}_U \). It remains to show that if \( \mathcal{A} \) is almost finite, then \( \mathcal{A}_U \) is an integral \( \mathcal{O}_X \)-algebra for every affine open subset \( U \subset X \). Since \( \mathcal{A}_U \) is an integral \( \mathcal{O}_X \)-algebra, we need only show that every element of \( m \mathcal{A}_U \) is integral over \( \mathcal{O}_X(U) \). However, by adjunction we get a map:

\[
\mathcal{A}_U \to \mathcal{O}_X(U)_* + m \mathcal{A}_U
\]

whose kernel is annihilated by \( m \) and according to \([59, \text{Lemma } 5.1.13(i)]\), \( \mathcal{A}_U \) is integral over \( \mathcal{O}_X(U)_* \). Let \( \alpha \in m \mathcal{A}_U \) be any element, and \( \bar{\alpha} \) its image in \( m \mathcal{A}_U \); we can then find \( b_0, \ldots, b_n \in \mathcal{O}_X(U)_* \) such that \( \bar{\alpha} = \sum b_i \bar{m}^i = 0 \) in \( \mathcal{A}_U \). It follows that \( (\varepsilon \alpha)^{n+1} + \sum_{i=0}^{n} \varepsilon^{n+1} b_i (\varepsilon \alpha)^i = 0 \) in \( \mathcal{A}_U \), for every \( \varepsilon \in m \). Since \( e^{n+1} b_i \) lies in the image of \( \mathcal{O}_X(U) \) for every \( i \leq n \), the claim follows easily. \( \square \)

**Remark 14.3.10.** With the notation of definition \([14.3.8]\) we have:

(i) \( \mathcal{B} \) is an unramified \( \mathcal{A} \)-algebra if and only if, for every affine open subset \( U \subset X \), there exists an idempotent element \( e_{\mathcal{B}(U)/\mathcal{A}(U)} \in (\mathcal{B} \otimes_{\mathcal{A}} \mathcal{B})(U)_* \), uniquely characterized by the following conditions:

(a) \( \mu_{\mathcal{B}/\mathcal{A}}(e_{\mathcal{B}(U)/\mathcal{A}(U)}) = 1 \), where \( \mu_{\mathcal{B}/\mathcal{A}} : \mathcal{B} \otimes_{\mathcal{A}} \mathcal{B} \to \mathcal{B} \) is the multiplication morphism of the \( \mathcal{A} \)-algebra \( \mathcal{B} \).

(b) \( e_{\mathcal{B}(U)/\mathcal{A}(U)} \cdot \ker \mu_{\mathcal{B}/\mathcal{A}}(U) = 0 \)

\([59, \text{Lemma } 3.1.4] \). It is easily seen that, on \( U' \subset U \), the element \( e_{\mathcal{B}(U)/\mathcal{A}(U)} \) restricts to \( e_{\mathcal{B}(U')/\mathcal{A}(U')} \); hence, the system \( e_{\mathcal{B}(U)/\mathcal{A}(U)} \mid U \subset X \), determines a global section

\[
e_{\mathcal{B}/\mathcal{A}} \in \Gamma(X, \mathcal{B} \otimes_{\mathcal{A}} \mathcal{B})_*
\]

which we call the diagonal idempotent of the \( \mathcal{A} \)-algebra \( \mathcal{B} \) (see \([59, \S 5.5.4]\)).

(ii) In the situation of (i), let \( \mathcal{A} \to \mathcal{A}' \) be any morphism of quasi-coherent \( \mathcal{O}_X^\natural \)-algebras, and set \( \mathcal{B} := \mathcal{A}' \otimes_{\mathcal{A}} \mathcal{B} \). Then the induced morphism \( \mathcal{A}' \to \mathcal{B} \) is unramified, and in view of the characterization provided by (i), it is easily seen that \( e_{\mathcal{B}/\mathcal{A}} \) is the image in \( \mathcal{B} \otimes_{\mathcal{A}} \mathcal{B} \) of \( e_{\mathcal{B}/\mathcal{A}'} \).

(iii) If \( \mathcal{B} \) is a flat and almost finitely presented \( \mathcal{A} \)-algebra, there exists a trace form

\[
t_{\mathcal{B}/\mathcal{A}} : \mathcal{B} \otimes_{\mathcal{A}} \mathcal{B} \to \mathcal{A}
\]

that, on each open affine subset \( U \subset X \), induces the trace form \( t_{\mathcal{B}(U)/\mathcal{A}(U)} \) of \([59, \S 4.1.12] \) (details left to the reader).

(iv) Suppose that \( \mathcal{B} \) is a flat, unramified and almost finitely presented \( \mathcal{A} \)-algebra. Then the diagonal idempotent and the trace form of \( \mathcal{B} \) are related by the identity

\[
t_{\mathcal{B}/\mathcal{A}}(e_{\mathcal{B}/\mathcal{A}} \cdot (1 \otimes b)) = b = t_{\mathcal{B}/\mathcal{A}}(e_{\mathcal{B}/\mathcal{A}} \cdot (b \otimes 1))
\]

for every affine open subset \( U \subset X \) and every \( b \in \mathcal{B}(U)_* \) \([59, \text{Rem. } 4.1.17] \).
Definition 14.3.11. (i) Let $X$ be an $S$-scheme. For a monomorphism $B \subset \mathcal{A}$ of quasi-coherent $O_X$-algebras, the integral closure $\text{i.c.}(B, \mathcal{A})$ of $B$ in $\mathcal{A}$ is a quasi-coherent $O_X$-algebra. For a monomorphism $\mathcal{A} \to B$ of $O_X$-algebras, the integral closure of $\mathcal{A}$ in $B$ is
\[
i \text{i.c.}(\mathcal{A}, B) := \text{i.c.}(\mathcal{A}, B_{\mathcal{A}})^a
\]
(see also [59, Lemma 8.2.28]). In view of lemma 14.3.9, this is a well defined quasi-coherent $O_X$-algebra. It is characterized as the unique $\mathcal{A}$-subalgebra of $B$ such that :
\[
i \text{i.c.}(\mathcal{A}, B)(U) = \text{i.c.}(\mathcal{A}(U), B(U))
\]
for every affine open subset $U \subset X$ (notation of [59, Def.8.2.27]). We say that $\mathcal{A}$ is integrally closed in $B$, if $\mathcal{A} = \text{i.c.}(\mathcal{A}, B)$.

(ii) Likewise, the weak normalization $\mathcal{C}$ and the $\pi$-integral closure $\mathcal{D}$ of the image of $\mathcal{A}_{\mathcal{A}}$ in $B_{\mathcal{A}}$ are quasi-coherent $O_X$-algebras (see (9.8.27)); then we define the weak normalization (resp. the $\pi$-integral closure) of $\mathcal{A}$ in $B$ as the quasi-coherent $O_X$-algebra $B^a$ (resp. $B^\pi$).

Remark 14.3.12. (i) In the notation of definition 14.3.11 if $B'$ is the integral closure of $B$ in $\mathcal{A}$, then $B'^a$ is the integral closure of $B^a$ in $\mathcal{A}^a$. Indeed, we may assume that $X$ is affine, in which case the assertion follows from [59, Lemma 8.2.28].

(ii) It follows that $\mathcal{B}$ is an integral $\mathcal{A}$-algebra if and only if $\mathcal{B}_{\mathcal{A}}$ is an integral $\mathcal{A}_{\mathcal{A}}$-algebra. Indeed, suppose that $\mathcal{B}$ is an integral $\mathcal{A}$-algebra, so that $\mathcal{B} = \text{i.c.}(\mathcal{A}_{\mathcal{A}}, \mathcal{B}_{\mathcal{A}})^a$, whence by adjunction, a morphism of $\mathcal{A}_{\mathcal{A}}$-algebras $\mathcal{B}_{\mathcal{A}} \to \text{i.c.}(\mathcal{A}_{\mathcal{A}}, \mathcal{B}_{\mathcal{A}})$, which must be the identity map.

(iii) Also, if $B'^a$ is the weak normalization of $B$ in $\mathcal{A}$, then it follows easily from proposition 9.8.29(i,ii) that $B'^{\pi a}$ is the weak normalization of $B^a$ in $\mathcal{A}^a$ : the details are left to the reader.

Proposition 14.3.13. Suppose that the ideal $m$ fulfills condition (B) of [59, §2.1.6]. Let $X$ be a quasi-compact $S$-scheme, $\mathcal{A}$ a quasi-coherent $O_X$-algebra, and $B$ a flat $\mathcal{A}$-algebra that is almost finitely presented as an $\mathcal{A}$-module. Then $B(\mathcal{A})$ is an integral $\mathcal{A}(\mathcal{A}(X))$-algebra.

Proof. For every $b \in B(\mathcal{A}(X))$, and every $i \in \mathbb{N}$, set :
\[
i c_i(b) := \text{tr}_{\Lambda_{\mathcal{A}}^i B/(\mathcal{A})}((\Lambda_{\mathcal{A}}^i(b1_B))) \in \mathcal{A}(\mathcal{A}(X))
\]
(see remark 14.3.2(ii)). In view of [59, Lemma 8.2.28], it suffices to show

Claim 14.3.14. For every $b \in B(\mathcal{A}(X))$, and $a \in m$, there exists $n \in \mathbb{N}$ such that :

(i) $c_i(ab) = 0$ for every $i > n$.

(ii) $\sum_{i=0}^{n} (-ab)^{i+1} \cdot c_{n-i}(ab) = 0$.

Proof of the claim. Since $X$ admits a finite affine covering, and since the trace morphism commutes with arbitrary base changes, we are easily reduced to the case where $X$ is affine. In this case, set $\mathcal{A} := \mathcal{A}(\mathcal{A}(X))$ and $B := B(\mathcal{A}(X))$; then $B$ is an almost finitely generated projective $\mathcal{A}$-algebra, and there exists $n \in \mathbb{N}$ such that $a1_B$ factors through $A$-linear maps $u : B \to A_{\mathcal{A}}^a$ and $v : A_{\mathcal{A}}^a \to B$ ([59, Lemma 2.4.15]). Thus, $ab1_B = v \circ (u \circ b1_B)$, and we get :
\[
i c_i(ab) = \text{tr}_{\Lambda_{\mathcal{A}}^i A_{\mathcal{A}}^a/(\mathcal{A})}((\Lambda_{\mathcal{A}}^i(u \circ b1_B \circ v))) \quad \text{for every } i \in \mathbb{N}
\]
([59, Lemma 4.1.2(ii)]), from which (i) already follows. By the same token, we also obtain :
\[
i \chi := \sum_{i=0}^{n} (-u \circ b1_B \circ v)^i \cdot c_{n-i}(ab) = 0
\]
([59, Prop.4.4.30]). However, the left-hand side of the identity of (ii) is none else than $(-1) \cdot v \circ \chi \circ (u \circ b1_B)$; whence the claim.

The following lemma generalizes [59, Cor. 4.4.31].
Lemma 14.3.15. Let \( A \) be a \( V^n \)-algebra, \( B \subset A \) a \( V^n \)-subalgebra, \( P \) an almost finitely generated projective \( A \)-module, and \( \varphi \) an \( A \)-linear endomorphism of \( P \). Suppose that:

(a) \( B \) is integrally closed in \( A \).
(b) \( \varphi \) is integral over \( B \).

Then we have:

(i) \( \text{tr}_{P/A}(\varphi) \in B_a \).
(ii) If \( m \) fulfills condition (B) of [59] §2.1.6, then \( \det(1_P + T\varphi) \in B_a[[T]] \).

Proof. For the meaning of assumption (b), see the proof of [59] Cor. 4.4.31.

(i): For every \( \varepsilon \in m \) we may find a free \( A \)-module \( L \) of finite rank, and \( A \)-linear morphisms \( u : P \rightarrow L, v : L \rightarrow P \) such that \( v \circ u = \varepsilon 1_P \) ([59] Lemma 2.4.15]). It follows that

\[
\text{tr}_{L/A}(u \circ \varphi \circ v) = \text{tr}_{P/A}(\varphi \circ v \circ u) = \varepsilon \cdot \text{tr}_{P/A}(\varphi)
\]

([59], Lemma 4.1.2]).

(ii): Recall that the polynomial \( T^n + \sum_{j=0}^{n-1} b_j T^j \in B_a[T] \) annihilates \( \varphi \); it is easily seen that \( T^n + \sum_{j=0}^{n-1} b_j \varepsilon^{j-1} T^j \) annihilates \( u \circ \varphi \circ v \), so the latter is integral over \( B \), as well, and therefore its trace lies in \( B_a \) ([59] Cor.4.4.31 and Rem.8.2.30(i)). Summing up, we have shown that \( \varepsilon \cdot \text{tr}_{P/A}(\varphi) \in B_a \) for every \( \varepsilon \in m \), whence the contention.

Claim 14.3.16. Let \( Q \) be another almost finitely generated projective \( A \)-module, \( \psi \) be an endomorphism of \( P \) that is also integral over \( B_a \). Then the endomorphism \( \varphi \otimes_A \psi \) of \( P \otimes_A Q \) is integral over \( B_a \).

Proof of the claim. The tensor product defines a map of unital associative \( B_a \)-algebras

\[
\text{End}_A(P) \otimes_{B_a} \text{End}_A(Q) \rightarrow \text{End}_A(P \otimes_A Q).
\]

By assumption, the subalgebra \( B_a[\varphi] \subset \text{End}_A(P) \) is finite over \( B_a \), and similarly for \( B_a[\psi] \subset \text{End}_A(Q) \). Hence, the same holds for the image of \( B_a[\varphi] \otimes_{B_a} B_a[\psi] \) in \( \text{End}_A(P \otimes_A Q) \), whence the claim.

It follows easily from claim [14.3.16] that the endomorphism \( \Lambda^i_A \varphi \) of \( \Lambda^i_A P \) is integral over \( B_a \). Hence, we may replace \( P \) by \( \Lambda^i_A P \), and reduce to showing that the trace of \( \varphi \) lies in \( B_a \), which is known, by (i).

Lemma 14.3.17. Let \( A \) be a \( V^n \)-algebra, \( I \subset \text{rad}(A) \) a tight ideal (see [59] Def.5.1.5]), and \( P \) a flat and almost finitely generated \( A \)-module. Let also \( r \in \mathbb{N} \). We have:

(i) If \( P/IP \) is a faithfully flat \( A \)-module, then \( P \) is a faithfully flat \( A \)-module.
(ii) If \( m \) fulfills condition (B), and \( P \) is an almost projective \( A \)-module such that \( P/IP \) is an \( A/I \)-module of almost finite rank (resp. of finite rank \( \leq r \)), then \( P \) is an \( A \)-module of almost finite rank (resp. of finite rank \( \leq r \)).

Proof. (i): It suffices to show that for every almost finitely generated \( A \)-module \( M \neq 0 \), we have \( M \otimes_A P \neq 0 \). To this aim, it suffices to check that \( M \otimes_A P/IP \neq 0 \); since \( M \otimes_A P/IP = (M \otimes_A A/I) \otimes_{A/I} P/IP \), and since by assumption \( P/IP \) is a faithfully flat \( A/I \)-module, we are further reduced to showing that \( M \otimes_A A/I \neq 0 \); the latter follows from [59] Lemma 5.1.7].

(ii): Suppose first that \( P/IP \) is of finite rank \( \leq r \), so that \( \Lambda^{r}_{A/I}(P/IP) = 0 \). Hence \( (\Lambda^{r}_{A})(P) \otimes_{A} P/IP = 0 \), and then [59] Lemma 5.1.7] yields \( \Lambda^{r}_{A} P = 0 \), as sought. In the more general case where \( P/IP \) has almost finite rank, pick \( n \in \mathbb{N} \) and a finitely generated subideal \( m_0 \subset m \), such that \( I^n \subset m_0 \). Let also \( m_1 \subset m \) be any finitely generated subideal such that \( m_0 \subset m_1 \). By assumption, there exists \( i \in \mathbb{N} \) such that \( m_1 \Lambda^{i}_{A/I}(P/IP) = 0 \), i.e. \( m_1 \Lambda^{i}_{A} P \subset I \Lambda^{i}_{A} P \). Therefore

\[
m_0 \Lambda^{i}_{A} P \subset m_1^{i+1} \Lambda^{i}_{A} P \subset I^{n+1} \Lambda^{i}_{A} P \subset m_0 I \Lambda^{i}_{A} P.
\]
whence \( m_0 A^i P = 0 \), by [59, Lemma 5.1.7]. Since \( m_0 \) is arbitrary, we deduce that \( P \) has almost finite rank, as claimed.

\[ \]

**Lemma 14.3.18.** Let \( A \rightarrow B \) be a morphism of \( V^a \)-algebras which is a monomorphism on the underlying \( V^a \)-modules, \( P \) an almost finitely generated and almost projective \( A \)-module, and \( r \in \mathbb{N} \). Suppose as well that \( m \) fulfills condition \((B)\); the following holds:

(i) \( P \) is an \( A \)-module of almost finite rank (resp. of finite rank \( \leq r \)) if and only if the same holds for the \( B \)-module \( B \otimes_A P \).

(ii) Suppose that \( P \) has almost finite rank. Then \( P \) is a faithfully flat \( A \)-module if and only if the same holds for the \( B \)-module \( B \otimes_A P \).

**Proof.**

(i): According to proposition [14.1.56](i), the \( A \)-module \( A^i P \) is flat for every \( i \in \mathbb{N} \); hence the natural \( A \)-linear morphism

\[
A^i P \rightarrow B \otimes_A A^i P \xrightarrow{\sim} A^i(B \otimes_A P)
\]

is a monomorphism for every \( i \in \mathbb{N} \); the assertion follows straightforwardly.

(ii): According to [59, Th.4.3.28] (which holds whenever \( m \) fulfills condition \((B)\)) we have \( V^a \)-algebras \( A_0, A' \) and an isomorphism of \( V^a \)-algebras \( A \xrightarrow{\sim} A_0 \times A' \) such that \( A_0 \otimes_A P = 0 \) and \( A' \otimes_A P \) is a faithfully flat \( A' \)-module. Suppose now that \( B \otimes_A P \) is a faithfully flat \( B \)-module; since \((B \otimes_A A_0) \otimes_B (B \otimes_A P) \cong B \otimes_A A_0 \otimes_A P = 0 \), it follows that \( B \otimes_A A_0 = 0 \). On the other hand, the induced \( A \)-linear morphism \( A_0 \rightarrow B \otimes_A A_0 \) is a monomorphism, since \( A_0 \) is a flat \( A \)-module; hence, \( A_0 = 0 \), and consequently \( P = A' \otimes_A P \) is faithfully flat. \( \square \)

**Lemma 14.3.19.** Let \( j : U \rightarrow X \) be an open quasi-compact immersion of \( S \)-schemes, \( \mathcal{B} \) a quasi-coherent \( \mathcal{O}_U^a \)-algebra, \( \mathcal{A} \) a quasi-coherent \( \mathcal{O}_X^a \)-algebra, and \( j^* \mathcal{A} \rightarrow \mathcal{B} \) an étale morphism. Then the induced morphism

\[
\mathcal{A} \rightarrow j_* j^* \mathcal{A} \rightarrow j_* \mathcal{B}
\]

is flat if and only if it is étale.

**Proof.** We may assume that \( j_* \mathcal{B} \) is a flat \( \mathcal{A} \)-algebra, and it suffices to show that \( j_* \mathcal{B} \) admits a diagonal idempotent as in remark [14.3.10](i). To this aim, let us remark more generally:

**Claim 14.3.20.** Let \( f : Y \rightarrow X \) be a quasi-compact and quasi-separated morphism, \( \mathcal{F} \) a flat quasi-coherent \( \mathcal{A} \)-module, and \( \mathcal{G} \) an \( f^* \mathcal{A} \)-module, quasi-coherent as an \( \mathcal{O}_Y^a \)-module. Then the natural map

\[
\mathcal{F} \otimes_{\mathcal{A}} f_* \mathcal{G} \rightarrow f_* (f^* \mathcal{F} \otimes_{f^* \mathcal{A}} \mathcal{G})
\]

is an isomorphism.

**Proof of the claim.** This is proved just as for \( \mathcal{O}_X \)-modules. Namely, one reduces easily to the case where \( X \) is affine, and one needs to check that the natural map

\[
\mathcal{F}(X) \otimes_{\mathcal{A}(X)} \mathcal{G}(Y) \rightarrow (f^* \mathcal{F} \otimes_{f^* \mathcal{A}} \mathcal{G})(Y)
\]

is an isomorphism. However, by assumption \( Y \) can be covered by finitely many affine open subsets \( U_1, \ldots, U_n \), and the intersection \( U_{ij} := U_i \cap U_j \) can be covered by finitely many affine open subsets \( U_{ij1}, \ldots, U_{ijn} \), for every \( i, j = 1, \ldots, n \). Since \( f^* \mathcal{F}, \mathcal{G} \) and \( f^* \mathcal{A} \) are quasi-coherent \( \mathcal{O}_Y^a \)-modules, the natural maps

\[
\mathcal{F}(X) \otimes_{\mathcal{A}(X)} \mathcal{G}(U_i) \rightarrow (f^* \mathcal{F} \otimes_{f^* \mathcal{A}} \mathcal{G})(U_i)
\]

\[
\mathcal{F}(X) \otimes_{\mathcal{A}(X)} \mathcal{G}(U_{ijk}) \rightarrow (f^* \mathcal{F} \otimes_{f^* \mathcal{A}} \mathcal{G})(U_{ijk})
\]

are isomorphisms.
are isomorphisms, for every $i, j, k = 1, \ldots, n$. Then we get:

\[
(f^* \mathcal{F} \otimes_{\mathcal{A}} \mathcal{G})(Y) = \text{Ker}(\prod_{i=1}^{n} \mathcal{F}(X) \otimes_{\mathcal{A}(X)} \mathcal{G}(U_i) \longrightarrow \prod_{i,j,k=1}^{n} \mathcal{F}(X) \otimes_{\mathcal{A}(X)} \mathcal{G}(U_{ijk}))
\]

\[
= \mathcal{F}(X) \otimes_{\mathcal{A}(X)} \text{Ker}(\prod_{i=1}^{n} \mathcal{G}(U_i) \longrightarrow \prod_{i,j,k=1}^{n} \mathcal{G}(U_{ijk}))
\]

(since $\mathcal{F}(X)$ is a flat $\mathcal{A}(X)$-module) whence the claim.

Now, set $\mathcal{B} := \mathcal{B} \otimes_{j^* \mathcal{A}} \mathcal{B}$; since $j$ is quasi-compact and $j_* \mathcal{B}$ is a flat $\mathcal{A}$-algebra, claim [14.3.20] implies that the natural morphism:

\[
j_* \mathcal{B} \otimes_{\mathcal{A}} j_* \mathcal{B} \rightarrow j_* \mathcal{B}
\]

is an isomorphism. Especially, the diagonal idempotent of $\mathcal{B}$ extends to a global section of $j_* \mathcal{B} \otimes_{\mathcal{A}} j_* \mathcal{B}$, and the assertion follows. \[\square\]

The criterion of lemma [14.3.19] has limited usefulness, since it is not usually known a priori that $j_* \mathcal{B}$ is a flat $\mathcal{A}$-algebra. In several situations, one can however apply the following variant.

**Proposition 14.3.21.** Let $X$ be an $S$-scheme, $j : U \rightarrow X$ a quasi-compact open immersion, $\mathcal{A} \rightarrow \mathcal{B}$ a morphism of quasi-coherent $O_X^S$-algebras, and suppose that:

(a) The units of adjunction $\mathcal{A} \rightarrow j_* j^* \mathcal{A}$ and $\mathcal{B} \rightarrow j_* j^* \mathcal{B}$ are monomorphisms.
(b) $\mathcal{A}$ is integrally closed in $j_* j^* \mathcal{A}$, and $\mathcal{B}$ is an integral $\mathcal{A}$-algebra.
(c) $j^* \mathcal{B}$ is a locally quasi-coherent $j^* \mathcal{A}$-algebra and an almost finitely presented $j^* \mathcal{A}$-module.
(d) The diagonal idempotent $e_{j^* \mathcal{A}/j^* \mathcal{A}}$ is a global section of the subalgebra

\[
\text{Im}(\mathcal{B} \otimes_{\mathcal{A}} \mathcal{B} \rightarrow j_* j^* (\mathcal{B} \otimes_{\mathcal{A}} \mathcal{B})).
\]

Then $\mathcal{B}$ is an étale $\mathcal{A}$-algebra and an almost finitely presented $\mathcal{A}$-module.

**Proof.** We may assume that $X$ is affine. Under our assumptions, the restriction map $\mathcal{A}(X)_* \rightarrow \mathcal{A}(U)_*$ is injective, and its image is integrally closed in $\mathcal{A}(U)_*$ ([59, Rem.8.2.30]); moreover, $\mathcal{B}(X)_!!$ is an integral $\mathcal{A}(X)_!!$-algebra (remark [14.3.12].ii)). In view of lemma [14.3.15](i), we deduce a commutative diagram

\[
\begin{array}{ccc}
\mathcal{B} \otimes_{\mathcal{A}} \mathcal{B} & \overset{t}{\longrightarrow} & \mathcal{A} \\
\downarrow & & \downarrow \\
\mathcal{j_* j^* (\mathcal{B} \otimes_{\mathcal{A}} \mathcal{B})} & \overset{j_* (t j^* \mathcal{A}/j^* \mathcal{A})}{\longrightarrow} & j_* j^* \mathcal{A}
\end{array}
\]

whose vertical arrows are the units of adjunctions, and where $t$ is a uniquely determined $\mathcal{A}$-bilinear form. Then we are reduced to showing:

**Claim 14.3.23.** Let $j : U \rightarrow X$ be as in the proposition, and $\mathcal{A} \rightarrow \mathcal{B}$ a morphism of quasi-coherent $O_X^S$-algebras fulfilling conditions (a), (c), (d) of the proposition, and such that there exists a bilinear form $t$ making commute diagram [14.3.22] Then $\mathcal{B}$ is an étale $\mathcal{A}$-algebra and an almost finitely presented $\mathcal{A}$-module.

**Proof of the claim.** The proof proceeds by a familiar argument (see e.g. the proof of [59, Claim 3.5.33]). Namely, for a given $\epsilon \in \mathfrak{m}$, we can write

\[
\epsilon \cdot e_{j^* \mathcal{A}/j^* \mathcal{A}} = \sum_{j=1}^{m} a_j \otimes b_j \quad \text{where} \quad a_j, b_j \in \mathcal{B}(X)_* \quad \text{for every} \quad j = 1, \ldots, m.
\]

In light of remark [14.3.10](iv), we deduce

\[
\epsilon \cdot a = \sum_{j=1}^{m} t(a \otimes a_j) \cdot b_j \quad \text{for every} \quad a \in \mathcal{B}(X)_*.
\]
Indeed, the identity holds after restriction to $U$, and assumption (a) implies that the restriction map $\mathcal{B}(X)_s \to \mathcal{B}(U)_s$ is injective. We may then define $\mathcal{A}$-linear maps: $\mathcal{A} \xrightarrow{\varphi} \mathcal{A}^\oplus m \xrightarrow{\psi} \mathcal{A}$ by the rules:

$$\varphi(a) := (t(a \otimes a_1), \ldots, t(a \otimes a_m)) \quad \psi(s_1, \ldots, s_m) := \sum_{j=1}^m s_j b_j$$

for every open subset $U \subset X$, every $a \in \mathcal{B}(U)_s$, and every $s_1, \ldots, s_m \in \mathcal{A}(U)_s$. Thus we have $\psi \circ \varphi = \varepsilon 1_{\mathcal{A}}$, and since $\varepsilon$ is arbitrary, this already proves that $\mathcal{B}$ is an $\mathcal{A}$-module of almost finite type, so we may apply [59, Lemma 2.4.15 and Prop.2.4.18(i)] to deduce that $\mathcal{B}$ is a flat and almost finitely presented $\mathcal{A}$-module. Now, assumption (a) and claim [14.3.20] imply that the horizontal arrows of the induced diagram

$$\begin{align*}
\mathcal{B} \otimes_{\mathcal{A}} \mathcal{B} &\xrightarrow{\mu_{\mathcal{B}/\mathcal{A}}} j_* j^*(\mathcal{B} \otimes_{\mathcal{A}} \mathcal{B}) \\
&\cong j_*\mu_{\mathcal{B}/\mathcal{A}} \\
j_* \mathcal{B} &\xrightarrow{j_* j^* \mu_{\mathcal{B}/\mathcal{A}}} j_* j^* \mathcal{B}
\end{align*}$$

are monomorphisms. From the characterization of remark [14.3.10](i), it follows easily that the section $\varepsilon j_{\mathcal{B}/\mathcal{A}}$ is the diagonal idempotent for the morphism $\mathcal{A} \to \mathcal{B}$, so $\mathcal{B}$ is an unramified $\mathcal{A}$-algebra, and the proof is concluded.

**Corollary 14.3.24.** Let $X$ be an $S$-scheme, $j : U \to X$ a quasi-compact open immersion, $\mathcal{A} \to \mathcal{B}$ a morphism of quasi-coherent $\mathcal{O}_X^n$-algebras, and suppose that:

(a) $\mathcal{B}$ is an étale $\mathcal{A}$-algebra and an almost finitely presented $\mathcal{A}$-module.

(b) The diagonal idempotent $\varepsilon_{\mathcal{B}/\mathcal{A}}$ is a global section of the subalgebra $\text{Im}(\varphi(\mathcal{B}) \otimes_{\mathcal{A}} j_* j^*(\mathcal{B} \otimes_{\mathcal{A}} \mathcal{B})).$

Then $j_* \mathcal{B}$ is an étale $j_* \mathcal{A}$-algebra and an almost finitely presented $j_* \mathcal{A}$-module.

**Proof.** Indeed, the induced morphism $j_* \mathcal{A} \to j_* \mathcal{B}$ fulfills conditions (a), (c) and (d) of proposition [14.3.21] and diagram [14.3.22] trivially commutes with $t := j_* (t_{\mathcal{B}/\mathcal{A}})$, so the corollary follow from claim [14.3.23].

Using lemma [14.3.15] we can also relax one assumption in [59, Prop.8.2.31(i)]; namely, we have the following:

**Proposition 14.3.25.** Let $A \subset B$ be a pair of $V^n$-algebras, such that $A = \text{i.c.}(A, B)$. Then, for every étale almost finite projective $A$-algebra $A_1$ we have $A_1 = \text{i.c.}(A_1, A_1 \otimes_A B)$.

**Proof.** Set $B_1 := A_1 \otimes_A B$, and suppose that $x \in B_1$, is integral over $A_1$. Let $e \in (A_1 \otimes_A A_1)_s$ be the diagonal idempotent of the unramified $A$-algebra $A_1$; for given $\varepsilon_1, \varepsilon_2, \varepsilon_3 \in m$ we write $\varepsilon_1 \cdot e = \sum_{i=1}^k c_i \otimes d_i$ for some $c_i, d_i \in A_1$. According to remark [14.3.10](iv) and [59, Prop.4.1.8(ii)], we have $\sum_{i=1}^k c_i \cdot \text{Tr}_{B_1/B}(x d_i) = \varepsilon \cdot x$. On the other hand, $\varepsilon_2 \cdot x$ and $\varepsilon_3 \cdot d_i$ are integral over $A_1$ (by [59, Lemma 5.1.13(i)], which holds for arbitrary basic setups); then lemma [14.3.15](i) implies that $\text{Tr}_{B_1/B}(\varepsilon_2 \varepsilon_3 \cdot x d_i) \in A_s$ for every $i = 1, \ldots, k$. Hence $\varepsilon_1 \varepsilon_2 \varepsilon_3 \cdot x \in A_1$, and since $\varepsilon_1, \varepsilon_2, \varepsilon_3$ are arbitrary, the assertion follows.

**Lemma 14.3.26.** Let $X$ be an $S$-scheme, $\mathcal{A}$ a quasi-coherent $\mathcal{O}_X^n$-algebra. We have:

(i) Let $f : Y \to X$ a faithfully flat and quasi-compact morphism. Then $\mathcal{A}$ is an étale (resp. weakly étale, resp. weakly unramified) $\mathcal{O}_X^n$-algebra if and only if $f^* \mathcal{A}$ is an étale (resp. weakly étale, resp. weakly unramified) $\mathcal{O}_Y^n$-algebra.

(ii) Suppose that $X$ is integral and $\mathcal{A}$ is a weakly étale $\mathcal{O}_X^n$-algebra. Let $\eta \in X$ be the generic point; then $\mathcal{A}$ is an étale $\mathcal{O}_X^n$-algebra if and only if $\mathcal{A}_\eta$ is an étale $\mathcal{O}_{X,\eta}^n$-algebra.
(iii) Suppose that \( X \) is normal and irreducible, and \( \mathcal{A} \) is integral, torsion-free and unramified over \( \mathcal{O}_X^n \). Then \( \mathcal{A} \) is étale over \( \mathcal{O}_X^n \), and almost finitely presented as an \( \mathcal{O}_X^n \)-module.

(iv) Let \( j : X \to Y \) be an open quasi-compact immersion of \( S \)-schemes, with \( Y \) normal and irreducible, and such that \( j_* \mathcal{O}_X = \mathcal{O}_Y \), and suppose that \( \mathcal{A} \) is integral and torsion-free over \( \mathcal{O}_X^n \). Then \( j_* \mathcal{A} \) is an integral \( \mathcal{O}_Y^n \)-algebra.

**Proof.** (i): Arguing as in the proof of lemma 14.3.5 one reduces easily to the case where \( X \) and \( Y \) are affine, in which case the assertion follows from [59, §3.4.1].

(ii): Let \( U \subset X \) be any affine open subset; by assumption \( \mathcal{A} \) is flat over the almost ring \( B := \mathcal{A}(U) \otimes_{\mathcal{O}_X(U)} \mathcal{A}(U) \), and \( \mathcal{A}(U) \otimes_{\mathcal{O}_X(U)} \kappa(\eta)^n \) is almost projective over \( B \otimes_{\mathcal{O}_X(U)} \kappa(\eta)^n \). Then the assertion follows from [59, Prop.2.4.19].

(iii): Let \( \eta \in X \) be the generic point. We begin with the following:

**Claim 14.3.27.** Suppose that \( V = m \) (the “classical limit” case of [59, Ex.2.1.2(ii)]), and let \( f : A \to B \) be a local homomorphism of local rings. Then:

(i) \( f^a \) is weakly étale if and only if \( f \) extends to an isomorphism of strict henselizations \( A^{sh} \to B^{sh} \).

(ii) Especially, if \( A \) is a field and \( f^a \) is weakly étale, then \( B \) is a separable algebraic extension of \( A \).

**Proof of the claim.** (i): In the classical limit case, a weakly étale morphism is the same as an “absolutely flat” map as defined in [107]; then the assertion is none else than [107, Th.5.2].

(ii): If \( A \) is a field, \( A^{sh} \) is a separable closure of \( A \); hence (i) implies that \( B \) is a subring of \( A^{sh} \), hence it is a subfield of \( A^{sh} \).\(\square\)

**Claim 14.3.28.** Suppose that \( V = m \). Let \( A \) be a field and \( f : A \to B \) a ring homomorphism such that \( f^a \) is weakly étale. Then:

(i) Every finitely generated \( A \)-subalgebra of \( B \) is finite étale over \( A \) (that is, in the usual sense of [51, Ch.IV, §17]).

(ii) \( f^a \) is étale if and only if \( f \) is étale (in the usual sense of [51]).

**Proof of the claim.** (i): From claim 14.3.27 (ii) we see that \( B \) is reduced of Krull dimension \( \leq 0 \), and all its residue fields are separable algebraic extensions of \( A \). We consider first the case of a monogenic extension \( C := A[b] \subset B \). For every prime ideal \( p \subset B \), let \( b_p \) be the image of \( b \) in \( B_p \); then for every such \( p \) we may find an irreducible separable monic polynomial \( P_p(T) \in A[T] \) with \( P_p(b_p) = 0 \). This identity persists in an open neighborhood \( U_p \subset \text{Spec } B \) of \( p \), and finitely many such \( U_p \) suffice to cover \( \text{Spec } B \). Thus, we find finitely many \( P_p(T), \ldots, P_p(T) \) such that \( \prod_{i=1}^k P_p(b) = 0 \) holds in \( B \), and after omitting repetitions, we may assume that all these polynomials are distinct. Since \( C \) is a quotient of the separable \( A \)-algebra \( A[T]/(\prod_{i=1}^k P_p(T)) \), the claim follows in this case. In the general case, we may write \( C = A[b_1, \ldots, b_n] \) for certain \( b_1, \ldots, b_n \in B \). Then \( \text{Spec } C \) is a reduced closed subscheme of \( \text{Spec } A[b_1] \times_{\text{Spec } A} \cdots \times_{\text{Spec } A} \text{Spec } A[b_n] \); by the foregoing, the latter is étale over \( \text{Spec } A \); hence the same holds for \( \text{Spec } C \).

(ii): We may assume that \( f^a \) is étale, and we have to show that \( f \) is étale, i.e. that \( B \) is a finitely generated \( A \)-module. Hence, let \( e_{B/A} \in B \otimes_A B \) be the diagonal idempotent (see remark 14.3.10(ii)); we choose a finitely generated \( A \)-subalgebra \( C \subset B \) such that \( e_{B/A} \) is the image of an element \( e' \in C \otimes_A C \). Notice that \( 1 - e' \) lies in the kernel of the multiplication map \( \mu_{C/A} : C \otimes_A C \to C \). By (i), the morphism \( A \to C' \) is étale, hence it admits as well a diagonal idempotent \( e_{C/A} \in C \otimes_A C' \); on the other hand, [59, Lemma 3.1.2(v)] says that \( B' \) is étale over \( C' \), especially \( B \) is a flat \( C \)-algebra, hence the natural map \( C \otimes_A C' \to B \otimes_A B \) is injective. Since \( 1 - e_{C/A} \) lies in the kernel of the multiplication map \( \mu_{B/A} : B \otimes_A B \to B \), we have:

\[
e_{B/A}(1 - e_{C/A}) = 0 = e_{C/A}(1 - e') = e_{C/A}(1 - e_{B/A})\]
from which it follows easily that $e_{B/A} = e_{C/A}$. Moreover, the induced morphism $\text{Spec } B \to \text{Spec } C$ has dense image, so it must be surjective, since $\text{Spec } C$ is a discrete finite set; therefore $B$ is even a faithfully flat $C$-algebra. Let $J := \text{Ker}(B \otimes_A B \to B \otimes_C B)$; then $J$ is the ideal generated by all elements of the form $1 \otimes c - c \otimes 1$, where $c \in C$; clearly this is the same as the extension of the ideal $I_{C/A} := \text{Ker}(\mu_{C/A})$. However, $I_{C/A}$ is generated by the idempotent $1 - e_{C/A}$ (§9 Cor.3.1.9), consequently $J$ is generated by $1 - e_{B/A}$, i.e. $J = \text{Ker}(\mu_{B/A})$. So finally, the multiplication map $\mu_{B/C} : B \otimes_C B \to B$ is an isomorphism, whose inverse is the map $B \to B \otimes_C B : b \mapsto b \otimes 1$. The latter is of the form $j \otimes_C 1_B$, where $j : C \to B$ is the natural inclusion map. By faithfully flat descent we conclude that $C = B$, whence the claim.

Next, we remark that $\mathcal{A}_{\eta}$ is a finitely presented $\mathcal{O}_{X,\eta}$-module. Indeed, since $K := \mathcal{O}_{X,\eta}$ is a field, we have either $mK = 0$, in which case the category of $K$-modules is trivial and there is nothing to show, or else $mK = K$. So we may assume that we are in the “classical limit” case, and then the assertion follows from claim [14.3.28(ii)].

Now, set $\mathcal{B} := \mathcal{A} \otimes_{\mathcal{O}_X} \mathcal{A}$, and let $j : X(\eta) \to X$ be the natural morphism; since $X$ is normal and $\mathcal{A}$ is torsion-free, the units of adjunction $\mathcal{O}_{X,\eta}^\vee \to j_*j^*\mathcal{O}_{X(\eta)}$ and $\mathcal{A} \to j_*j^*\mathcal{A}$ are monomorphisms. Since $\mathcal{A}$ is unramified over $\mathcal{O}_{X,\eta}^\vee$, the diagonal idempotent of $j_*j^*\mathcal{A}$ lies in the image of the restriction map $\mathcal{O}(X)_\eta \to \mathcal{B}_\eta$. In view of these observations, an easy inspection shows that the proof of proposition [14.3.21] carries over verbatim to the current situation, and yields assertion (iii).

(iv): Let $\mathcal{I} \subset \mathcal{A}_{\eta}$ be the maximal torsion $\mathcal{O}_{X,\eta}$-subsheaf, and set $\mathcal{B} := \mathcal{A}_{\eta}/\mathcal{I}$. Then $\mathcal{B}$ is an integral, torsion-free $\mathcal{O}_{X,\eta}$-algebra, by remark [14.3.12(ii)], and $\mathcal{B}^a \simeq \mathcal{A}$, hence $(j_*\mathcal{B})^a \simeq j_*\mathcal{A}$. Let $\eta \in Y$ be the generic point; in light of remark [14.3.12(ii)], it then suffices to show:

Claim 14.3.29. Under the assumptions of (v), let $\mathcal{B}$ be an integral quasi-coherent and torsion-free $\mathcal{O}_{X}$-algebra. Then $j_*\mathcal{B}$ is an integral $\mathcal{O}_{Y}$-algebra.

Proof of the claim. Let us write $\mathcal{R}_{\eta}$ as the filtered union of the family $(\mathcal{R}_\lambda : \lambda \in \Lambda)$ of its finite $\mathcal{O}_{Y,\eta}$-subalgebras, and for every $\lambda \in \Lambda$, let $\mathcal{R}_\lambda \subset \mathcal{R}$ be the quasi-coherent $\mathcal{O}_{X,\eta}$-subalgebra such that $\mathcal{R}_\lambda(V) = \mathcal{R}_\lambda \cap \mathcal{R}(V)$ for every non-empty open subset $V \subset X$. Then $\mathcal{R}$ is the filtered colimit of the family $(\mathcal{R}_\lambda : \lambda \in \Lambda)$, and clearly it suffices to show the claim for every $\mathcal{R}_\lambda$. We thus may assume from start that $\mathcal{R}_{\eta}$ is a finite $\mathcal{O}_{Y,\eta}$-algebra. Let $\mathcal{R}'$ be the integral closure of $\mathcal{R}$, i.e. the quasi-coherent $\mathcal{O}_{X,\eta}$-algebra such that $\mathcal{R}'(V)$ is the integral closure of $\mathcal{R}(V)$ in $\mathcal{R}_{\eta}$, for every non-empty affine open subset $V \subset X$. Clearly it suffices to show that $j_*\mathcal{R}'$ is integral, hence we may replace $\mathcal{R}$ by $\mathcal{R}'$ and assume from start that $\mathcal{R}$ is integrally closed. In this case, for every non-empty open subset $V \subset X$ the restriction map $\mathcal{R}(V) \to \mathcal{R}_\eta(V)$ induces a bijection between the idempotents of $\mathcal{R}(V)$ and those of $\mathcal{R}_\eta$. Especially, $\mathcal{R}(X)$ admits finitely many idempotents, and moreover we have a natural decomposition $\mathcal{R} = \mathcal{R}_1 \times \cdots \times \mathcal{R}_k$, as a product of $\mathcal{O}_{X}$-algebras, such that $\mathcal{R}_\eta$ is a field for every $i \leq k$. It then suffices to show the claim for every $j_*\mathcal{R}_i$, and then we may assume throughout that $\mathcal{R}_{\eta}$ is a field. Up to replacing $\mathcal{R}$ by its normalization in a finite extension of $\mathcal{R}_{\eta}$, we may even assume that $\mathcal{R}_{\eta}$ is a finite normal extension of $\mathcal{O}_{Y,\eta}$. Hence, let $V \subset Y$ be any non-empty affine open subset, and $a \in \mathcal{R}(X \cap V)$ any element. Let $P(T)$ be the minimal polynomial of $a$ over the field $\mathcal{O}_{Y,\eta}$, we have to show that the coefficients of $P(T)$ lie in $\mathcal{O}_\eta(V) = \mathcal{O}_X(X \cap V)$, and since $Y$ is normal, it suffices to prove that these coefficients are integral over $\mathcal{O}_X(W)$, for every non-empty affine open subset $W \subset X \cap V$. However, since $\mathcal{R}_{\eta}$ is normal over $\mathcal{O}_{Y,\eta}$, such coefficients can be written as some elementary symmetric polynomials of the conjugates of $a$ in $\mathcal{R}_{\eta}$. Hence, we come down to showing that the conjugates of $a$ are still integral over $\mathcal{O}_X(W)$. The latter assertion is clear: indeed, if $Q(T) \in \mathcal{O}_X(W)[T]$ is a monic polynomial with $Q(a) = 0$, then we have also $Q(a') = 0$ for every conjugate $a'$ of $a$. \qed
Proposition 14.3.30. Let \( X \) be a quasi-compact and quasi-separated \( S \)-scheme, \( j : U \to X \) a quasi-compact open immersion, and \( \mathcal{A} \) a quasi-coherent \( \mathcal{O}_U^a \)-module, almost finitely presented as an \( \mathcal{O}_U^a \)-module. Then for every finitely generated subideal \( m_0 \subset m \), there exist a quasi-coherent \( \mathcal{O}_X \)-algebra \( \mathcal{B} \), finitely presented as an \( \mathcal{O}_X \)-module, and a morphism \( \mathcal{B} \mid U \to \mathcal{A} \) of \( \mathcal{O}_X^a \)-algebras, whose kernel and cokernel are annihilated by \( m_0 \).

Proof. Set \( \mathcal{C} := \text{i.c.}(\mathcal{O}_X^a, j_*\mathcal{A}) \); then \( \mathcal{C} \) is a quasi-coherent \( \mathcal{O}_X^a \)-algebra, and \( \mathcal{C} \mid U = \mathcal{A} \), by lemma 14.3.9. According to proposition 10.3.29 we may write \( \mathcal{C} \mid U \) as the colimit of a filtered family \( (\mathcal{F}_i) \mid i \in I \) of finitely presented quasi-coherent \( \mathcal{O}_X \)-modules. Pick a finitely generated subideal \( m_1 \subset m \) such that \( m_0 \subset m_1 \); for every affine open subset \( U' \subset U \), we may find \( i \in I \) such that \( m_1 \cdot \mathcal{A}_i(U') \subset \text{Im}(\mathcal{F}_i(U') \to \mathcal{A}_i(U')) \), and since \( U \) is quasi-compact, finitely many such open subsets cover \( U \); hence, we may find \( i \in I \) such that \( m_1 \cdot \mathcal{A}_i \subset \text{Im}(\mathcal{F}_i(U) \to \mathcal{A}_i) \); we set \( \mathcal{F} := \mathcal{F}_i \), and let \( \varphi : \mathcal{F} := \text{Sym}_{\mathcal{O}_X} \mathcal{F} \to \mathcal{C} \mid U \) be the induced morphism of quasi-coherent \( \mathcal{O}_X \)-algebras. Notice that \( \mathcal{F} \) is finitely presented as an \( \mathcal{O}_X \)-algebra. Using again proposition 10.3.29 (or [44, Ch.I, Cor.9.4.9]) we may write \( \ker \varphi \) as the colimit of a filtered family \( (\mathcal{K}_\lambda) \mid \lambda \in \Lambda \) of quasi-coherent \( \mathcal{O}_X \)-submodules of finite type. Fix a finite covering \( (U'_i \mid i \in I) \) of \( X \) consisting of affine open subsets, and for every \( i \in I \), let \( f_{i,1}, \ldots, f_{i,n(i)} \) be a finite set of generators of \( \mathcal{F}(U'_i) \); we may find monic polynomials \( P_{i,j}(T), \ldots, P_{i,n(i)}(T) \) with coefficients in \( \mathcal{O}_X(U'_i) \) such that \( P_{i,j}(f_{i,j}) = 0 \in \mathcal{C}(U'_i) \) for every \( i \in I \) and every \( j \leq n(i) \). Let \( \lambda \in \Lambda \) be chosen large enough, so that \( P_{i,j}(f_{i,j}) \in \mathcal{K}_\lambda(U'_i) \) for every \( i \in I \) and every \( j \leq n(i) \). Let also \( \mathcal{K}_\lambda' \subset \mathcal{F} \) be the ideal generated by \( \mathcal{K}_\lambda \); then \( \mathcal{K}' \mid U \) is an integral \( \mathcal{O}_X \)-algebra of finite presentation, hence it is finitely presented as an \( \mathcal{O}_X \)-module, in view of claim 9.1.33. Clearly \( \varphi \mid U \) descends to a map \( \varphi' : \mathcal{K}' \mid U \to \mathcal{A} \mid U \), whose cokernel is annihilated by \( m_1 \), and by [59, Claim 2.3.12 and the proof of Cor.2.3.13] we may find, for every affine open subset \( U' \subset U \), a finitely generated \( \mathcal{O}_X \)-submodule \( K_{U'} \subset \ker((\mathcal{K}' \mid U')) \) such that \( m_1 \cdot \ker \varphi' \subset K_{U'} \). Another invocation of proposition 10.3.29 ensures the existence of a quasi-coherent \( \mathcal{O}_X \)-submodule of finite type \( \mathcal{J} \subset \ker \varphi \) such that \( K_{U'} \subset \mathcal{J}(U') \) for all the \( U' \) of a finite covering of \( U \); the \( \mathcal{O}_X \)-algebra \( \mathcal{B} := \mathcal{J}/\mathcal{J} \cdot \mathcal{J}' \) fulfills the required conditions.

14.3.31. Let \( (X_i \mid i \in I) \) be a cofiltered system of quasi-compact and quasi-separated \( S \)-schemes, with affine transition morphisms \( h_{ij} : X_j \to X_i \), for every morphism \( \varphi : j \to i \) in \( I \). Let also \( U_i \subset X_i \) be a quasi-compact open subset, for every \( i \in I \), such that \( U_j = h_{ij}^{-1}U_i \) for every \( \varphi : j \to i \) in \( I \). Set

\[
X := \varprojlim_{i \in I} X_i \quad U := \varprojlim_{i \in I} U_i,
\]

and denote by \( h_i : U \to X_i \) the natural morphism, for every \( i \in I \).

Corollary 14.3.32. In the situation of (14.3.31), let \( \mathcal{A} \) be any flat almost finitely presented \( \mathcal{O}_U^a \)-algebra. Then, for every finitely generated subideal \( m_0 \subset m \) there exist \( i \in I \), a quasi-coherent \( \mathcal{O}_X \)-algebra \( \mathcal{B} \), finitely presented as an \( \mathcal{O}_X \)-module, and a morphism \( \mathcal{B} \mid U \to \mathcal{A} \) of \( \mathcal{O}_X \)-algebras, such that :

(a) \( \ker f \) and \( \text{coker} f \) are annihilated by \( m_0 \).

(b) For every \( x \in U_i \) and every \( b \in m_0 \), the map \( b \cdot 1_{\mathcal{O}^a} : \mathcal{B}_x \to \mathcal{B}_x \) factors through a free \( \mathcal{O}_{U_i,x} \)-module.

Proof. From [50, Ch.IV, Th.8.3.11] it is easily seen that \( X \) is a quasi-compact and quasi-separated \( S \)-scheme, and \( U \) is a quasi-compact open subset of \( X \). Pick a finitely generated subideal \( m_1 \) such that \( m_0 \subset m_1 \); according to proposition 14.3.30, we may find a quasi-coherent \( \mathcal{O}_X \)-algebra \( \mathcal{B} \), finitely presented as an \( \mathcal{O}_X \)-module, and a morphism \( g : \mathcal{B} \mid U \to \mathcal{A} \) of \( \mathcal{O}_U^a \)-algebras whose kernel and cokernel are annihilated by \( m_1 \). By standard arguments we deduce

\[
\text{(14.3.33)} \quad m_1^2 \cdot \text{Tor}_1^{\mathcal{O}_X} (M, \mathcal{B}(U')) = 0
\]
for every affine open subset \( U' \subset U \) and every \( \mathcal{O}_X(U') \)-module \( M \). Now, let us remark, quite generally:

**Claim 14.3.34.** Let \( A \) be any ring, \( M \) and \( N \) any two \( A \)-modules, \( \varphi : M \to N \) any \( A \)-linear map, and \( M^\lor := \text{Hom}_A(M, A) \). Then \( \varphi \) factors through a free \( A \)-module of finite rank if and only if it lies in the image of the natural map

\[
(14.3.35) \quad M^\lor \otimes_A N \to \text{Hom}_A(M, N).
\]

**Proof of the claim.** Suppose first that \( \varphi \) factors as the composition of \( A \)-linear maps \( \psi : M \to A^{\oplus n} \) and \( \psi' : A^{\oplus n} \to N \), for some \( n \in \mathbb{N} \). For every \( i = 1, \ldots, n \), let \( p_i : A^{\oplus n} \to A \) (resp. \( e_i : A \to A^{\oplus n} \)) be the natural epimorphism (resp. monomorphism), and set \( \psi_i := p_i \circ \psi', \psi'_i := \psi' \circ e_i \). Then \( \varphi = \sum_{i=1}^n \psi'_i \circ \psi_i \) and each summand \( \psi'_i \circ \psi_i \) lies in the image of \((14.3.35)\). Conversely, if \( \varphi \) lies in the image of \((14.3.35)\), we have \( \varphi = \sum_{i=1}^n \psi'_i \circ \psi_i \), for some \( \psi_1, \ldots, \psi_n \in M^\lor \) and \( \psi'_1, \ldots, \psi'_n \in \text{Hom}_A(A, N) = N \), and we may define \( \psi := \sum_{i=1}^n e_i \circ \psi_i, \psi'_i := \sum_{i=1}^n \psi'_i \circ \psi_i \). Then \( \varphi = \psi' \circ \psi \). \( \square \)

Now, pick a finite covering \((U'_i, \lambda) \mid \lambda \in \Lambda \) of \( U_i \), consisting of affine open subsets, and a finite system \( b_1, \ldots, b_k \) of generators of \( m_\lambda^2 \), and set \( U'_\lambda := h^{-1}U'_i, \lambda \) for every \( \lambda \in \Lambda \); from claim \[14.3.34\] and \([59, \text{Lemma 2.4.17}]\) we deduce that for every \( \lambda \in \Lambda \) and every \( j = 1, \ldots, k \) there exists \( n(\lambda, j) \in \mathbb{N} \) such that \( b_j \cdot (1_{U'}^\lor)_{U'_\lambda} \) factors through \( \mathcal{O}_{U'_\lambda}^{\oplus n(\lambda, j)} \). Next, by virtue of \([50, \text{Ch.IV, Th.8.5.2}]\) we may assume that \( \mathcal{R} \) descends to a \( \mathcal{O}_X \)-algebra \( \mathcal{R} \), finitely presented as an \( \mathcal{O}_X \)-module, and such that \( b_j \cdot (1_{U'}^\lor)_{U'_\lambda} \) factors through \( \mathcal{O}_{U'_\lambda}^{\oplus n(\lambda, j)} \) for every \( j = 1, \ldots, k \) and every \( \lambda \in \Lambda \). It follows easily that

\[
m_\lambda^2 \cdot \text{Tor}^1_{\mathcal{O}_X(U'_\lambda)}(M, \mathcal{R}(U'_\lambda)) = 0
\]

for every \( \lambda \in \Lambda \) and every \( \mathcal{O}_X(U'_\lambda) \)-module \( M \). Then, again \([59, \text{Lemma 2.4.17}]\) and claim \[14.3.34\] imply that condition (b) holds for \( \mathcal{R} \), and by construction we also get condition (a). \( \square \)

**14.4. Almost pure pairs.** Throughout this section, we keep the notation of \((14.3)\), and we assume that \( m \) fulfills condition (B).

**Definition 14.4.1.** Let \( X \) be an \( S \)-scheme, \( Z \subset X \) a closed subscheme such that \( U := X \setminus Z \) is a dense subset of \( X \), and denote by \( j : U \to X \) the open immersion.

(i) We say that the pair \((X, Z)\) is almost pure relative to \((V, m)\) (or just almost pure, when the underlying basic setup is clear from the context) if the restriction functor

\[
(14.4.2) \quad \mathcal{O}_X^a \setminus \text{Ét}_af \to \mathcal{O}^a_U \setminus \text{Ét}_af : \mathcal{A} \mapsto \mathcal{A}_U
\]

from the category of étale \( \mathcal{O}_X^a \)-algebras of almost finite rank, to the category of étale \( \mathcal{O}^a_U \)-algebras of almost finite rank, is an equivalence.

(ii) We say that the pair \((X, Z)\) is normal if \( Z \) is a constructible subset of \( X \), and the natural map \( \mathcal{O}_X^a \to j_* \mathcal{O}^a_U \) is a monomorphism, whose image is integral closed in \( j_* \mathcal{O}^a_U \).

**Remark 14.4.3.** Let \((X, Z)\) be a pair as in definition \[14.4.1\] where \( Z \) is a constructible subset of \( X \), and set \( U := X \setminus Z \).

(i) Consider the following conditions:

(a) \( \mathcal{O}_{X,z} \) is a normal domain, for every \( z \in Z \).

(b) the natural map \( \mathcal{O}_X \to j_* \mathcal{O}_U \) is a monomorphism, and \( \mathcal{O}_X = \text{i.c.}(\mathcal{O}_{X,z} j_* \mathcal{O}_U) \).

(c) The pair \((X, Z)\) is normal.

Then (a) \( \Rightarrow \) (b), since \( (j_* \mathcal{O}_U)_z = \mathcal{O}_{X(z)}(U \cap X(z)) \) for every \( z \in Z \). Also, (b) \( \Rightarrow \) (c), by virtue of \([59, \text{Lemma 8.2.28}]\).

(ii) Let \( \mathcal{A} \) be a quasi-coherent \( \mathcal{O}_X^a \)-algebra. Then \( j_* \mathcal{A} \) is a quasi-coherent \( \mathcal{O}_X \)-algebra \([44, \text{Ch.I, Prop.9.4.2(i)}]\) and lemma \[14.3.9\], hence the integral closure \( \mathcal{A}^\lor \) of the image of \( \mathcal{O}_X^a \) in \( \mathcal{O}_X \) is...
Proof. 

(i) Let $(X, Z)$ be any normal pair, and $U \subset X$ any open subset. Directly from the definition, we see that $(U, Z \cap U)$ is still a normal pair.

Lemma 14.4.4. Let $(X, Z)$ be a normal pair as in definition 14.4.1(ii), and set $U := X \setminus Z$. Let $\mathcal{A}$ be an étale $\mathcal{O}_X^a$-algebra whose underlying $\mathcal{O}_X^a$-module is almost finitely presented (resp. is of finite rank). The following conditions are equivalent:

(a) The normalization $\mathcal{A}^{\nu}$ of $\mathcal{A}$ over $X$ (see remark 14.4.3(ii)) is a weakly unramified $\mathcal{O}_X^a$-algebra.

(b) $\mathcal{A}^{\nu}$ is an étale $\mathcal{O}_X^a$-algebra, and an almost finitely presented $\mathcal{O}_X^a$-module (resp. and an $\mathcal{O}_X^a$-module of finite rank).

Proof. Obviously (b)$\Rightarrow$(a), hence suppose that (a) holds, and let $\mathcal{B} := \mathcal{A}^{\nu} \otimes_{\mathcal{O}_X^a} \mathcal{A}^{\nu}$. We may assume that $X$ is affine, and we set

$$A := \mathcal{A}^{\nu}(X) \quad B := \mathcal{B}(X).$$

By assumption, the multiplication morphism $\mu : \mathcal{B} \rightarrow \mathcal{A}^{\nu}$ is flat, especially $A$ is a flat $B$-module. Let also $B'$ be the image of $B$ in $\mathcal{B}(U)$; clearly $\mu(X) : B \rightarrow A$ factors through an epimorphism $\mu' : B' \rightarrow A$, therefore $A = A \otimes_B B'$, so $A$ is also a flat $B'$-module. Pick a finite covering $U = U_1 \cup \cdots \cup U_k$ consisting of affine open subsets of $U$. The induced morphism

$$B' \rightarrow \mathcal{B}(U_1) \times \cdots \times \mathcal{B}(U_k)$$

is a monomorphism. On the other hand, notice that $A \otimes_{B'} \mathcal{B}(U_1) = \mathcal{A}(U_1)$ is an almost finitely presented $\mathcal{B}(U_1)$-module. It follows that $A$ is an almost finitely generated projective $B'$-module ([59], Prop. 2.4.18 and 2.4.19), and therefore the kernel of $\mu'$ is generated by an idempotent $e \in B'_0$ ([59], Rem. 3.1.8). A simple inspection shows that $e$ is necessarily the diagonal idempotent of the unramified $\mathcal{O}_X^a$-algebra $\mathcal{A}$. Then all the assumptions of proposition 14.3.21 are fulfilled, so $\mathcal{A}^{\nu}$ is an étale $\mathcal{O}_X^a$-algebra, and an almost finitely presented $\mathcal{O}_X^a$-module.

Lastly, suppose that $\mathcal{A}$ is an $\mathcal{O}_X^a$-module of finite rank, and pick $r \in \mathbb{N}$ such that, for every $i = 1, \ldots, k$, the $r$-th exterior power of the $\mathcal{O}_X^a(U_i)$-module $\mathcal{A}(U_i)$ vanishes. Since the induced morphism $\mathcal{O}_X^a \rightarrow \mathcal{O}_X^a(U_1) \times \cdots \times \mathcal{O}_X^a(U_k)$ is a monomorphism, and $A$ is a flat $\mathcal{O}_X^a$-module, we deduce that the $r$-th exterior power of $A$ vanishes as well. Especially, $\mathcal{A}^{\nu}$ is an $\mathcal{O}_X^a$-module of finite rank.

Lemma 14.4.5. Let $(X, Z)$ be a normal pair, $j : X \setminus Z \rightarrow X$ the open immersion, $\mathcal{B}$ any étale almost finitely presented $\mathcal{O}_X^a$-algebra, and $Z' \subset Z$ any constructible closed subset. We have:

(i) The natural map $\mathcal{B} \rightarrow j_* j^* \mathcal{B}$ factors through an isomorphism $\mathcal{B} \xrightarrow{\sim} (j^* \mathcal{B})^\nu$.

(ii) The restriction functor (14.4.2) is fully faithful.

(iii) The pair $(X, Z')$ is normal.

(iv) If the pair $(X, Z)$ is almost pure, the same holds for $(X, Z')$.

Proof. (i): Set $U := X \setminus Z$ and $\mathcal{A} := \mathcal{B}|_U$; the natural map $\mathcal{B} \rightarrow j_* \mathcal{A}$ factors through a morphism $\varphi : \mathcal{B} \rightarrow \mathcal{A}^{\nu}$ of $\mathcal{O}_X^a$-algebras (lemma 14.3.9 and remark 14.3.12(ii)). Fix $z \in Z$, and set $R := \mathcal{O}_{X,z}^a$, $R' := (j_* \mathcal{O}_{X,z})_z$. It follows that the stalk $\mathcal{B}_z$ is an étale $R'$-algebra. Notice that $(j_* \mathcal{A})_z = R' \otimes_R \mathcal{B}_z$, therefore $\varphi$ is a monomorphism. Moreover, since $\mathcal{B}$ is also an almost finitely presented $\mathcal{O}_X^a$-module, we have

$$\mathcal{B}_z = \text{i.c.}(\mathcal{B}_z, R' \otimes_R \mathcal{B}_z) \quad \mathcal{A}^{\nu}_z = \text{i.c.}(R, R' \otimes_R \mathcal{B}_z)$$

(proposition 14.3.25). On the other hand, $\mathcal{B}_z$ is an integral $R'$-algebra, therefore $\mathcal{B}_z = \mathcal{A}^{\nu}_z$, and since $z$ is arbitrary, we conclude that $\varphi$ is an isomorphism, as asserted.
(ii): Let $\mathcal{B}_1$ and $\mathcal{B}_2$ be two étale almost finitely presented $\mathcal{O}_X^a$-algebra, set $\mathcal{A}_i := \mathcal{B}_{iU}$ for $i = 1, 2$, and let $\psi : \mathcal{A}_1 \rightarrow \mathcal{A}_2$ be any morphism of $\mathcal{O}_X^a$-algebras; by (i), $\psi$ extends uniquely to a morphism $\psi^\nu : \mathcal{B}_1 \rightarrow \mathcal{B}_2$ of $\mathcal{O}_X^a$-algebras, whence the contention.

(iii): Set $U' := X \setminus Z'$ and let $j' : U' \rightarrow X$ be the open immersion; the natural morphism $\mathcal{O}_{X}^a \rightarrow j_{!}\mathcal{O}_{U'}$, factors through the morphism $\mathcal{O}_{X}^a \rightarrow j'_!\mathcal{O}_{U'}$, so the latter is a monomorphism. In order to show that $(X, Z')$ is normal, it then suffices to check that the image of $\mathcal{O}_{X}^a$ is integrally closed in $j'_!\mathcal{O}_{U'}$, and since $\mathcal{O}_{X}^a$ is integrally closed in $j_{!}\mathcal{O}_{U'}$, we are reduced to proving that the natural morphism $j'_*\mathcal{O}_{U'} \rightarrow j_{!}\mathcal{O}_{U'}$ is a monomorphism. However, let $V \subset X$ be any affine open subset, and write $U' \cap V = V_1 \cap \cdots \cap V_n$ for certain affine open subsets $V_1, \ldots, V_n$ of $X$; by assumption, the restriction map $\mathcal{O}_{X}^a(V_i) \rightarrow \mathcal{O}_{X}^a(U \cap V_i)$ is a monomorphism for every $i = 1, \ldots, n$, so the same holds for the restriction map $\mathcal{O}_{X}^a(U' \cap V) \rightarrow \mathcal{O}_{X}^a(U \cap V)$, whence the assertion.

(iv): Suppose that $(X, Z)$ is almost pure; in view of (ii), in order to check that $(X, Z')$ is almost pure, it suffices to show that every étale $\mathcal{O}_X^a$-algebra $\mathcal{A}$ of finite rank extends to an étale $\mathcal{O}_X^a$-algebra $\mathcal{B}$ as sought, and since $(X \setminus Z', Z \setminus Z')$ is normal (remark 14.4.3(iii)), (ii) says that the isomorphism $\mathcal{B}_{U'} \sim \mathcal{A}$ extends to an isomorphism $\mathcal{B}_{U} \sim \mathcal{A}$, i.e. $\mathcal{B}$ is an extension of $\mathcal{A}$, as required.

\begin{lemma}
Let $(A_i \mid i \in \mathbb{N})$ be a system of $V^a$-algebras, and set $A := \prod_{i \in \mathbb{N}} A_i$. Let also $P$ be an $A$-module, $B$ an $A$-algebra, and suppose that

(a) $\lim_{i \rightarrow \infty} \text{Ann}_{V^a}(A_i) = V^a$ for the uniform structure of [59, Def.2.3.1].

(b) For every $i \in \mathbb{N}$, the $A_i$-modules $P_i := P \otimes_A A_i$, $B_i := B \otimes_A A_i$ are almost projective of finite constant rank equal to $i$, and $B_i$ is an étale $A_i$-algebra. Then $P$ is an almost projective $A$-module of almost finite rank, and $B$ is an étale $A$-algebra.

\begin{proof}
For every $j \in \mathbb{N}$, the finite product $P_{\leq j} := \prod_{i=1}^{j} P_i$ is an almost projective $A$-module of finite rank, and clearly the induced morphism $\pi_j : P \rightarrow P_{\leq j}$ is an epimorphism. On the other hand, the $(j + 1)$-th exterior power of $P$ equals the $(j + 1)$-th exterior power of $\text{Ker} \pi_j$, and from condition (i) we see that $\lim_{j \rightarrow \infty} \text{Ann}_{V^a}(\text{Ker} \pi_j) = 0$, whence the assertion for $P$.

It follows already that $B$ is an almost projective $A$-module. It remains to show that $B$ is an unramified $A$-algebra, to which aim, we may apply the criterion of [59, Prop.3.1.4].

\end{proof}

\begin{claim}
Under the assumptions of the lemma, the natural morphism

$\varphi : B \otimes_A B \rightarrow C := \prod_{i \in \mathbb{N}} B_i \otimes_A B_i$

is an isomorphism of $A$-algebras.

\begin{proof}[Proof of the claim]
For every $j \in \mathbb{N}$, let $\pi_j : C \rightarrow \prod_{i \leq j} B_i \otimes_A B_i$ be the natural morphism. Then

$$\lim_{j \rightarrow \infty} \text{Ann}_{V^a} \text{Ker}(\pi_j \circ \varphi) = V^a = \lim_{j \rightarrow \infty} \text{Ann}_{V^a} \text{Ker} \pi_j.$$ \hspace{1cm} \Box$$

The first identity implies that $\varphi$ is a monomorphism. Next, since $\pi_j \circ \varphi$ is an epimorphism, the natural morphism $\text{Ker} \pi_j \rightarrow \text{Coker} \varphi$ is an epimorphism; then the second identity implies that $\varphi$ is also an epimorphism. \hspace{1cm} \Box$

Now, by [59, Prop.3.1.4], for every $i \in \mathbb{N}$ there exists an idempotent $e_i \in (B_i \otimes_A B_i)_*$ uniquely characterized by the conditions (i)–(iii) of loc.cit. In view of claim 14.4.7 the sequence $(e_i \mid i \in \mathbb{N})$ defines an idempotent in $(B \otimes_A B)_*$, which clearly fulfills the same conditions, whence the contention, again by [59, Prop.3.1.4]. \hspace{1cm} \Box$

\begin{proposition}
Let $(X, Z)$ be a normal pair, and set $U := X \setminus Z$. Then the following conditions are equivalent:

\end{proposition}
(a) The pair \((X, Z)\) is almost pure.

(b) The restriction functor

\[ \mathcal{O}_X^\alpha \rightarrow \mathcal{O}_U^\alpha : \mathcal{A} \mapsto \mathcal{A}|_U \]

from the category of étale \(\mathcal{O}_X^\alpha\)-algebras of finite rank, to the category of étale \(\mathcal{O}_U^\alpha\)-algebras of finite rank, is an equivalence.

(c) For every étale \(\mathcal{O}_U^\alpha\)-algebra \(\mathcal{A}\) of finite rank, the normalization \(\mathcal{A}'\) of \(\mathcal{A}\) over \(X\) is an étale \(\mathcal{O}_X^\alpha\)-algebra of finite rank (see remark \[14.4.3\](ii)).

(d) For every étale \(\mathcal{O}_U^\alpha\)-algebra \(\mathcal{A}\) of finite rank, \(\mathcal{A}'\) is a weakly unramified \(\mathcal{O}_X^\alpha\)-algebra.

(e) Every étale \(\mathcal{O}_U^\alpha\)-algebra \(\mathcal{A}\) of finite rank extends to an étale almost finite \(\mathcal{O}_X^\alpha\)-algebra.

**Proof.** The equivalence (b)\(\iff\)(c) is already clear from lemma \[14.4.5\](i,ii).

Next, clearly (c)\(\implies\)(d). Conversely, suppose that (d) holds, and let \(\mathcal{A}\) be any étale \(\mathcal{O}_U^\alpha\)-algebra of finite rank, so \(\mathcal{A}'\) is a weakly unramified \(\mathcal{O}_X^\alpha\)-algebra. Then \(\mathcal{A}'\) is actually an étale \(\mathcal{O}_X^\alpha\)-algebra, and an almost finitely presented \(\mathcal{O}_X^\alpha\)-module (lemma \[14.4.4\]). Fix any affine open subset \(V \subset X\), and pick a finite covering of \(U \cap V\) consisting of affine open subsets \(V_1, \ldots, V_k\) of \(U\).

Let \(r \in \mathbb{N}\) be an integer such that the \(r\)-th exterior power of the \(\mathcal{O}_V^\alpha(V_i)\)-modules \(\mathcal{A}(V_i)\) vanish.

The induced map

\[ B := \mathcal{O}_X^\alpha(V) \rightarrow B' := \mathcal{O}_X^\alpha(V_1) \times \cdots \times \mathcal{O}_X^\alpha(V_k) \]

is a morphism, since \((X, Z)\) is a normal pair. Moreover, the \(r\)-th exterior power of the \(B'\)-module \(\mathcal{A}'(V) \otimes_B B'\) vanishes; since \(\mathcal{A}'(V)\) is a flat \(B\)-module, we conclude that the \(r\)-th exterior power of \(\mathcal{A}'(V)\) vanishes as well. Especially, \(\mathcal{A}'\) is of finite rank, so (c) holds.

Since (c)\(\implies\)(e), we suppose that (e) holds, and deduce that (d) holds as well. Indeed, let \(\mathcal{B}\) be an almost finite étale \(\mathcal{O}_X^\alpha\)-algebra extending \(\mathcal{A}\). In the foregoing, we have already remarked that \(\mathcal{B} \subset \mathcal{A}'\); especially, the diagonal idempotent of \(\mathcal{A}\) lies in the image of the restriction map \(\mathcal{A}' \otimes_{\mathcal{O}_X^\alpha} \mathcal{A}'(U) \rightarrow \mathcal{A} \otimes_{\mathcal{O}_X^\alpha} \mathcal{A}(U)_s\). Then proposition \[14.3.21\] implies that \(\mathcal{A}'\) is an étale almost finite \(\mathcal{O}_X^\alpha\)-algebra, as sought.

Obviously, (a)\(\implies\)(e); to conclude, it suffices then to check that (c)\(\implies\)(a). Thus, let \(\mathcal{A}\) be an étale \(\mathcal{O}_U^\alpha\)-algebra of almost finite rank, \(V \subset U\) an affine open subset, and set \(A := \mathcal{O}_X^\alpha(V), B := \mathcal{A}(V)\). According to \[59\ Th.4.3.28\], there exists a decomposition of \(A\) as an infinite product of a system of \(V\)-algebras \(A_i | i \in \mathbb{N}\) fulfilling condition (a) of lemma \[14.4.6\]. Such a decomposition determines a system of idempotent elements \(e_{V,i} \in A_s\), for every \(i \in \mathbb{N}\), such that \(e_{V,i} \cdot e_{V,j} = 0\) whenever \(i \neq j\), and characterized by the identities \(e_{V,i}A = A_i\) for every \(i \in \mathbb{N}\). Since \(\mathcal{O}_X^\alpha\) is a sheaf (\[59\ §5.5.4\]), condition (ii) ensures that, for any fixed \(i \in \mathbb{N}\), and \(V\) ranging over the affine open subsets of \(U\), the idempotents \(e_{V,i}\) glue to a global section \(e_i \in \mathcal{O}_X^\alpha(U)_s\), which will still be an idempotent; moreover, the direct factor \(\mathcal{A}_i := e_i \mathcal{A}\) of \(\mathcal{A}\) is an étale \(\mathcal{O}_X^\alpha\)-algebra of finite rank, and the projection \(\mathcal{A} \rightarrow \mathcal{A}_i\) is a morphism of \(\mathcal{O}_U^\alpha\)-algebras.

Especially, \(A\) and \(B\) fulfill as well condition (b) of lemma \[14.4.6\]. By (c), we deduce that the normalization \(\mathcal{A}'\) of \(\mathcal{A}\) over \(X\) is an étale \(\mathcal{O}_X^\alpha\)-algebra of finite rank, for every \(i \in \mathbb{N}\). On the other hand, notice that the natural morphism

\[ \mathcal{O}_X^\alpha \rightarrow j_*(\mathcal{O}_{U,s}^\alpha) = (j_* \mathcal{O}_{U,s}^\alpha) \]

is a monomorphism, and its image is integrally closed in \(j_* \mathcal{O}_{U,s}^\alpha\) (\[59\ Rem.8.2.30(i)\]). It follows easily that \(e_i \mathcal{A}' \rightarrow \mathcal{A}'\) for every \(i \in \mathbb{N}\)

and the latter is the integral closure of \(e_i \mathcal{O}_X^\alpha\) in \(j_*(\mathcal{A}_i)\). Consequently, \(\mathcal{A}' = \prod_{i \in \mathbb{N}} \mathcal{A}'\) (\[59\ Rem.8.2.30(ii)\]). By lemma \[14.4.6\] it follows that \(\mathcal{A}'\) is an étale \(\mathcal{O}_X^\alpha\)-algebra of almost finite rank. This shows that the functor \[14.4.2\] is essentially surjective; combining with lemma \[14.4.5\](ii), we get (a). \(\square\)
Corollary 14.4.9. Let \((X, Z)\) be a normal pair, and suppose that:

(a) The scheme \(Z(z)\) is finite dimensional, for every \(z \in Z\).
(b) The pair \((X, \{z\})\) is almost pure, for every \(z \in Z\).

Then the pair \((X, Z)\) is almost pure.

Proof. Let \(\mathcal{A}\) be any étale \(\mathcal{O}_X\)-algebra of finite rank, and \(\mathcal{A}^{\nu}\) the normalization of \(\mathcal{A}\) over \(X\). In light of proposition 14.4.8 it suffices to show that \(\mathcal{A}^{\nu}_z\) is a weakly unramified \(\mathcal{O}_X^{\nu}\)-algebra, for every \(z \in Z\). Suppose, by way of contradiction, that the latter assertion fails; in view of condition (a), we may then find a point \(z \in Z\), such that \(\mathcal{A}^{\nu}_z\) is not weakly unramified over \(\mathcal{O}_X^{\nu}\), and for every proper generization \(w \in Z\) of \(z\), the \(\mathcal{O}_X^{\nu}\)-algebra \(\mathcal{A}^{\nu}_w\) is weakly unramified.

Now, set \(U(z) := U \cap X(z), V(z) := X(z) \setminus \{z\}\), and let \(j : V(z) \to U\) be the induced morphism. Notice that \((V(z), Z(z))\) is a normal pair, and our assumption implies that \(j^* \mathcal{A}^{\nu}\) is a weakly unramified \(\mathcal{O}_{V(z)}\)-algebra. By lemma 14.4.4 it follows that \(j^* \mathcal{A}^{\nu}\) is actually an étale \(\mathcal{O}_{V(z)}\)-algebra of finite rank. Since by assumption, \((X, \{z\})\) is almost pure, proposition 14.4.8 says that \(\mathcal{A}^{\nu}_z\) is an étale \(\mathcal{O}_X^{\nu}\)-module of finite rank, a contradiction. □

Proposition 14.4.10. Let \((X, Z)\) be a normal pair, and \(f : X' \to X\) a morphism of \(S\)-schemes; set \(Z' := f^{-1} Z\), and suppose that:

(a) \(f(Z') = Z\) and \(f\) is pro-smooth at every point of \(Z'\) (see definition 9.8.5).
(b) The pair \((X', Z')\) is almost pure.

Then the pair \((X, Z)\) is almost pure.

Proof. Set \(U := X \setminus Z, U' := X' \setminus Z'\), and let \(f|_U : U' \to U\) be the restriction of \(f\). Notice that the open immersion \(j' : U' \to X'\) is quasi-compact ([44, Ch.I, Prop.6.6.4]), and since \(f\) is flat at every point of \(Z'\) (corollary 9.8.6(ii)), \(U'\) is dense in \(X'\). Moreover:

Claim 14.4.11. (i) The pair \((X', Z')\) is normal.

(ii) More generally, let \(\mathcal{A}\) be any quasi-coherent \(\mathcal{O}_X\)-algebra. Then the natural morphism

\[ f^*(\mathcal{A}^\nu) \to (f^*|_U \mathcal{A})^\nu \]

is an isomorphism (notation of remark 14.4.3(ii)).

Proof of the claim. Since \(f\) is flat at every point of \(Z'\), and the unit of adjunction \(\mathcal{O}_X \to j_* \mathcal{O}_U\) is a monomorphism, the induced morphism \(\mathcal{O}_X^\nu \to (f^*|_U \mathcal{A})^\nu = j^* \mathcal{A}^\nu\) is a monomorphism as well (corollary 10.3.8). Also, \((\mathcal{A}^\nu)^\nu = \mathcal{O}_X^\nu\), since \((X, Z)\) is a normal pair; hence, (ii) implies (i).

(ii): Denote \(\mathcal{A}^\nu\) the integral closure in \(j^* (\mathcal{A}^\nu)\) of the image of of \(\mathcal{O}_X\); by corollary 10.3.8 the natural map

\[ f^* j_* (\mathcal{A}^\nu) \to j^* f^*|_U (\mathcal{A}^\nu) \]

is an isomorphism of \(\mathcal{O}_X\)-algebras. On the other hand, corollary 9.8.6(ii) implies that the integral closure of the image of \(\mathcal{O}_X\) in \(f^* j_* \mathcal{A}^\nu\) equals \(f^*(\mathcal{A}^\nu)^\nu\). The assertion follows. □

Suppose now that \(\mathcal{A}\) is an étale \(\mathcal{O}_X^\nu\)-algebra of finite rank. Since, by assumption, \((X', Z')\) is almost pure, proposition 14.4.8 says that \((f^*|_U \mathcal{A})^\nu\) is an étale \(\mathcal{O}_X^\nu\)-algebra of finite rank. By claim 14.4.11 and lemma 14.3.26(i) and corollary 9.8.6(ii), we deduce that \(\mathcal{A}^\nu\) is a weakly étale \(\mathcal{O}_X^\nu\)-algebra. To conclude the proof, it suffices now to invoke proposition 14.4.8. □

Lemma 14.4.12. Let \((A, I)\) be a tight henselian pair (see [59, Def.5.1.9]). Then we have:

(i) The base change functor

\[ \text{Cov} (\text{Spec} A) \to \text{Cov} (\text{Spec} A/I) \]

is an equivalence (notation of [59, §8.2.22]).
More generally, the base change functor $\text{A-}\hat{\text{Et}} \to A/I-\hat{\text{Et}}$ restricts to an equivalence $A-\hat{\text{Et}}_{\text{af}} \sim A/I-\hat{\text{Et}}_{\text{af}}$ on the respective full subcategories of étale algebras of almost finite rank.

**Proof.** In view of [59, Th.5.5.7(iii)], the assertions follow from lemma [14.3.17(ii)].

**Proposition 14.4.14.** In the situation of (14.4.13), suppose furthermore that:

(i) There exist $n \in \mathbb{N}$ and a finitely generated subideal $m_0 \subset m$ such that $I^n \subset m_0 R$.

(ii) The pair $(R, I)$ is henselian.

Then the pair $(X, Z)$ is almost pure if and only if the same holds for the pair $(X^\wedge, Z^\wedge)$.

**Proof.** Under the current assumptions, the pair $(R^n, I^n)$ is tight henselian ([59, §5.1.12]). Hence the assertion is a straightforward consequence of [59, Prop.5.4.53] and lemma [14.4.12(ii)] (details left to the reader).

**Corollary 14.4.15.** Let $p \in \mathbb{Z}$ be a prime integer with $p V \subset m$, and such that $p$ is a regular element of $V$, and suppose that $\overline{V}$ contains an element, denoted $p^{1/p}$, whose $p$-th power generates the ideal $p V$. Let $A$ and $B$ be two flat $V$-algebras, and for every $n \in \mathbb{N}$ set $V_n := V/p^{n+1} V$, $A_n := A/p^{n+1} A$, $B_n := B/p^{n+1} B$. Let also

$$A_0 \sim B_0$$

be a given isomorphism of $V_0$-algebras, and suppose that the Frobenius endomorphisms $\varphi_n : A_n \rightarrow B_n$ of $V$ such that $\varphi_n \otimes_{V_n} V_{n+1} = \varphi_{n-1}$ for every $n > 0$. To this aim, it suffices to show that

$$L_{A_n/V_n} = 0 \quad \text{in } D(s.A-\text{Mod}) \quad \text{for every } n \in \mathbb{N} \quad \text{([59, Prop.3.2.16])}.$$  

However, in view of [59, Th.2.5.36], for every $n \in \mathbb{N}$, the short exact sequence $0 \rightarrow p^{n+1} V/p^{n+2} V \rightarrow V_{n+1} \rightarrow V_n \rightarrow 0$ induces a distinguished triangle in $D(s.A-\text{Mod})$

$$L_{A_n/V_n} \rightarrow L_{A_{n+1}/V_{n+1}} \rightarrow L_{A_n/V_n} \rightarrow \sigma L_{A_0/V_0}.$$  

Hence, an easy induction further reduces to checking that $L_{A_0/V_0} = 0$ in $D(s.A-\text{Mod})$. According to [59, Lemma 6.5.13], this will follow, once we have shown that the natural map

$$V_0(\varphi) \otimes V_0 A_0 \rightarrow A_0(\varphi)$$

is an isomorphism in $D(V_0-\text{Mod})$ (notation of loc.cit.). Taking into account the isomorphisms (14.4.17), this holds if and only if the natural map

$$V/p^{1/p} V \otimes V_0 A_0 \rightarrow A/p^{1/p} A$$
14.5. **Normalized lengths.** Let \((V, |\cdot|)\) be any valuation ring, with value group \(\Gamma_V\); according to our general conventions, the composition law of \(\Gamma_V\) is denoted multiplicatively; however, sometimes it is convenient to switch to an additive notation. Hence, we adopt the notation :

\[
(\log \Gamma_V, \leq)
\]

to denote the ordered group \(\Gamma_V\) with additive composition law and whose ordering is the reverse of the original ordering of \(\Gamma_V\). The unit of \(\log \Gamma_V\) shall be naturally denoted by 0, and we shall extend the ordering of \(\log \Gamma_V\) by adding a largest element \(+\infty\), as customary. Also, we set :

\[
\log \Gamma_V^+ := \{ \gamma \in \log \Gamma_V \mid \gamma \geq 0 \}\) and \(\log |0| := +\infty\).

14.5.1. In this section, \((K, |\cdot|)\) denotes a valued field of rank one, with value group \(\Gamma\). We let \(\kappa\) be the residue field of \(K\). As usual, we set \(S := \text{Spec} K^+, \) and denote by \(s\) (resp. \(\eta\)) the closed (resp. generic) point of \(S\). Let \(m_K \subset K^+\) be the maximal ideal, and set \(m := m_K\) in case \(\Gamma\) is not discrete, or else \(m := K^+,\) in case \(\Gamma \simeq \mathbb{Z};\) in the following, whenever we refer to almost rings or almost modules, we shall assume – unless otherwise stated – that the underlying almost ring theory is the one defined by the standard setup \((K^+, m)\) (see [59, §6.1.15]).

Let \(A\) be any \(K^a\)-algebra, and \(c\) a cardinal number; following [59, §2.3], we denote by \(\mathcal{M}_c(A)\) the set of isomorphism classes of \(K^a\)-modules which admit a set of generators of cardinality \(\leq c\). The set \(\mathcal{M}_c(A)\) carries a natural uniform structure (see [59, Def.2.3.1]), which admits the fundamental system of entourages

\[
(E_\gamma \mid \gamma \in \log \Gamma^+ \setminus \{0\})
\]
defined as follows. For any \(b \in m \setminus \{0\},\) we let \(E_{[b]}\) be the set of all pairs \((M, M')\) of elements of \(\mathcal{M}_c(A)\) such that there exist a third \(A\)-module \(N\) and \(A\)-linear morphisms \(N \to M, N \to M'\) whose kernel and cokernel are annihilated by \(b\).

14.5.2. The aim of this section is to define and study a well-behaved notion of normalized length for torsion modules \(M\) over \(K^a\)-algebras of a fairly general type. This shall be achieved in several steps. Let us first introduce the categories of algebras with which we will be working.

**Definition 14.5.3.** Let \(V\) be any valuation ring, with maximal ideal \(m_V\).

(i) We let \(V\text{-m.Alg}_0\) be the subcategory of \(V\text{-Alg}\) whose objects are the local and essentially finitely presented \(V\text{-algebras}\) \(A\) whose maximal ideal \(m_A\) contains \(m_V A\). The morphisms \(\varphi : A \to B\) in \(V\text{-m.Alg}_0\) are the local maps. Notice that every morphism in \(V\text{-m.Alg}_0\) is an essentially finitely presented ring homomorphism ([48, Ch.IV, Prop.1.4.3(v)]).

Recall as well, that every object of \(V\text{-m.Alg}_0\) is a coherent ring (see [11, 4.4]). More generally, if \(\underline{A} := (A_i \mid i \in I)\) is any filtered system of essentially finitely presented \(V\)-algebras with flat transition morphisms, then the colimit of \(\underline{A}\) is still a coherent ring (lemma [11.3.7](ii.a)).

(ii) We say that a local \(V\)-algebra \(A\) is *measurable* if it admits an ind-étale local map of \(V\)-algebras \(A_0 \to A\), from some object \(A_0\) of \(V\text{-m.Alg}_0\). The measurable \(V\)-algebras form a category \(V\text{-m.Alg}\), whose morphisms are the local maps of \(V\)-algebras. As noted above, every measurable \(V\)-algebra is a coherent ring.

**Lemma 14.5.4.** In the situation of definition [14.5.3], let \((A, m_A)\) be any measurable \(V\)-algebra. Then the following holds :

(i) \(A/m_A V\) is a noetherian ring.

(ii) If the valuation of \(V\) has finite rank, every \(m_A\)-primary ideal of \(A\) contains a finitely generated \(m_A\)-primary subideal.

(iii) For every \(A\)-module \(M\) of finite type supported at the closed point of \(\text{Spec} A\), the \(A\)-module \(M/m_V M\) has finite length.

(iv) For every finitely generated ideal \(I \subset A\), the \(V\)-algebra \(A/I\) is measurable.
Proof. (i): Let $A_{\text{sh}}$ be the strict henselization of $A$ at a geometric point localized at the closed point; then $A_{\text{sh}}/m_V A_{\text{sh}}$ is a strict henselization of $A/m_V A$ ([51, Ch.IV, Prop.18.8.10]), and it is therefore also a strict henselization of a $V/m_V$-algebra of finite type. Hence $A_{\text{sh}}/m_V A_{\text{sh}}$ is noetherian, and then the same holds for $A/m_V A$ ([51, Ch.IV, Prop.18.8.8(iv)]).

(ii) If the valuation of $V$ has finite rank, there exists an element $t_0 \in m_V$ that generates a $m_V$-primary ideal. Let $I \subset A$ be a $m_A$-primary ideal; then $t_0^N \in I$, for some integer $N > 0$; moreover, the image $\overline{I}$ of $I$ in $A/m_V A$ is finitely generated, by (i). Pick elements $t_1, \ldots, t_n \in I$ whose images in $A/m_V A$ form a system of generators of $\overline{I}$; it follows that $t_0^N, t_1, \ldots, t_n$ form a $m_A$-primary ideal contained in $I$.

(iii) follows easily from (i): the details shall be left to the reader.

14.5.5. Now, suppose that $V$ is both a valuation ring and a flat, measurable $K^+$-algebra, and denote $m_V$ (resp. $\kappa(V)$, resp. $|\cdot|_V$) the maximal ideal (resp. the residue field, resp. the valuation) of $V$. We claim that $V$ has rank one, and the ramification index $(\Gamma_V : \Gamma)$ is finite. Indeed, let us write $V$ as the colimit of a filtered system $(V_i | i \in I)$ of objects of $K^+-\text{m.Alg}_{\text{sh}}$ with essentially étale transition maps; it follows that each $V_i$ is a valuation ring of rank one (claim 9.1.34). Also, the transition maps induce isomorphisms on the value groups: indeed, this is clear if $K^+$ is a discrete valuation ring, since in that case the same holds for the $V_i$, and the transition maps are unramified by assumption; in the case where $\Gamma$ is not discrete, the assertion follows from corollary [11.4.41]. Therefore, we are reduced to the case where $V$ is an object of $K^+-\text{m.Alg}_{\text{sh}}$, to which corollary [11.4.41] applies.

Suppose first that $M$ is a finitely generated torsion $V$-module; in this case the Fitting ideal $F_0(M) \subset V$ is well defined, and it is shown in [59, Lemma 6.3.1 and Rem.6.3.5] that the map $M \mapsto F_0(M)$ is additive on the set of isomorphism classes of finitely generated $V$-modules, i.e. for every short exact sequence $0 \to M_1 \to M_2 \to M_3 \to 0$ of such modules, one has:

$$
F_0(M_2) = F_0(M_1) \cdot F_0(M_3).
$$

Next, the almost module $F_0(M)^\wedge$ is an element of the group of fractional ideals $\text{Div}(V^\wedge)$ defined in [59, §6.1.16], and there is a natural isomorphism

$$
\text{Div}(V^\wedge) \simeq \log \Gamma_V^\wedge \\
I \mapsto |I|
$$

where $\Gamma_V^\wedge$ is the completion of $\Gamma_V$ for the uniform structure deduced from the ordering: see [59, Lemma 6.1.19]. Hence we may define:

$$
\lambda_V(M) := (\Gamma_V : \Gamma) \cdot |F_0(M)^\wedge| \in \log \Gamma_V^\wedge.
$$

In view of (14.5.6), we see that:

$$
\lambda_V(M') \leq \lambda_V(M) \quad \text{whenever } M' \subset M \text{ are finitely generated}.
$$

More generally, if $M$ is any torsion $V$-module, we let:

$$
\lambda_V(M) := \text{sup} \{ \lambda_V(M') | M' \subset M, M' \text{ finitely generated} \} \in \log \Gamma_V^\wedge \cup \{+\infty\}
$$

which, in view of (14.5.8), agrees with the previous definition, in case $M$ is finitely generated.

14.5.10. Suppose now that the $V^\wedge$-module $M^\wedge$ is uniformly almost finitely generated. Then according to [59, Prop.2.3.23] one has a well defined Fitting ideal $F_0(M^\wedge) \subset V^\wedge$, which agrees with $F_0(M)^\wedge$ in case $M$ is finitely generated.

Lemma 14.5.11. In the situation of (14.5.10), we have:

(i) $\lambda_V(M) = (\Gamma_V : \Gamma) \cdot |F_0(M^\wedge)|$. 

(ii) If \( 0 \to N_1 \to N_2 \to N_3 \to 0 \) is any short exact sequence of uniformly almost finitely generated \( V^a \)-modules, then
\[
|F_0(N_2)| = |F_0(N_1)| + |F_0(N_3)|.
\]

**Proof.** (ii): It is a translation of [59, Lemma 6.3.1 and Rem.6.3.5(ii)].

(i): Let \( k \) be a uniform bound for \( M^a \), and denote by \( \mathcal{A}_k(M) \) the set of all submodules of \( M \) generated by at most \( k \) elements. Set \( e := (\Gamma_V : \Gamma) \); if \( N \in \mathcal{A}_k(M) \), then \( \lambda_V(N) \leq e \cdot |F_0(M^a)| \), due to (ii). By inspecting the definitions, it then follows that
\[
e \cdot |F_0(M^a)| = \sup \{ \lambda_V(N) \mid N \in \mathcal{A}_k(M) \} \leq \lambda_V(M).
\]

Now, suppose \( M' \subset M \) is any submodule generated by, say \( r \) elements; for every \( \varepsilon \in \mathfrak{m} \) we can find \( N \in \mathcal{A}_k(M) \) such that \( \varepsilon M \subset N \), hence \( \varepsilon M' \subset N \), therefore \( \lambda_V(\varepsilon M') \leq \lambda_V(N) \leq \lambda_V(M^a) \). However, \( \lambda_V(M') = \lambda_V(\varepsilon M') = \lambda_V(M'/\varepsilon M') \leq \lambda_V(K^{+\oplus r}/\varepsilon K^{+\oplus r}) = r \cdot \lambda_V(K^{+}/\varepsilon K^{+}) \). We deduce easily that \( \lambda_V(M') \leq e \cdot |F_0(M^a)| \), whence the claim. 

**Proposition 14.5.12.** (i) Let \( 0 \to M_1 \to M_2 \to M_3 \to 0 \) be a short exact sequence of torsion \( V \)-modules. Then :
\[
\lambda_V(M_2) = \lambda_V(M_1) + \lambda_V(M_3).
\]

(ii) \( \lambda_V(M) = 0 \) if and only if \( M^a = 0 \).

(iii) Let \( M \) be any torsion \( V \)-module. Then :

(a) If \( M \) is finitely presented, \( \lambda_V(N) > 0 \) for every non-zero submodule \( N \subset M \).

(b) If \( (M_i \mid i \in I) \) is a filtered system of submodules of \( M \), then :
\[
\lambda_V(\operatorname{colim}_{i \in I} M_i) = \lim_{i \in I} \lambda_V(M_i).
\]

**Proof.** (ii): By lemma [14.5.11](i) it is clear that \( \lambda_V(M) = 0 \) whenever \( M^a = 0 \). Conversely, suppose that \( \lambda_V(M) = 0 \), and let \( m \in M \) be any element; then necessarily \( \lambda_V(Vm) = 0 \), and then it follows easily that \( m \subset \text{Ann}_V(m) \), so \( M^a = 0 \).

(iii.a): It suffices to show that \( M \) does not contain non-zero elements that are annihilated by \( m \), which follows straightforwardly from [59, Lemma 6.1.14].

(iii.b): Set \( M := \operatorname{colim}_{i \in I} M_i \). By inspecting the definitions we see easily that \( \lambda_V(M) \geq \sup \{ \lambda_V(M_i) \mid i \in I \} \). To show the converse inequality, let \( N \subset M \) be any finitely generated submodule; we may find \( i \in I \) such that \( N \subset M_i \), hence \( \lambda_V(N) \leq \lambda_V(M_i) \), and the assertion follows.

(i): Set \( e := (\Gamma_V : \Gamma) \). We shall use the following :

**Claim 14.5.13.** Every submodule of a uniformly almost finitely generated \( V^a \)-module is uniformly almost finitely generated.

**Proof of the claim.** Let \( N' \subset N \), with \( N \) uniformly almost finitely generated, and let \( k \) be a uniform bound for \( N \); for every \( \varepsilon \in \mathfrak{m} \) we can find \( N'' \subset \tilde{N} \) such that \( N'' \) is generated by at most \( k \) almost elements and \( \varepsilon N \subset N'' \). Clearly, it suffices to show that \( N' \cap N'' \) is uniformly almost finitely generated and admits \( k \) as a uniform bound, so we may replace \( N \) by \( N'' \) and \( N' \) by \( N' \cap N'' \), and assume from start that \( N \) is finitely generated. Let us pick an epimorphism \( \varphi : (V^a)^{\oplus k} \to N \); it suffices to show that \( \varphi^{-1}(N') \) is uniformly almost finitely generated with \( k \) as a uniform bound, so we are further reduced to the case where \( N \) is free of rank \( k \). Then we can write \( N' = L^{k} \) for some submodule \( L \subset V^{\oplus k} \); notice that \( (V^{\oplus k}/L)^a \) is almost finitely presented, since it is finitely generated ([59, Prop.6.3.6(ii)]), hence \( N' \) is almost finitely generated ([59, Lemma 2.3.18(iii)]). Furthermore, \( L \) is the colimit of the family \( (L_i \mid i \in I) \) of its finitely generated submodules, and each \( L_i \) is a free \( V \)-module ([28, Ch.VI, §3, n.6, Lemma 1]).Necessarily the rank of \( L_i \) is \( \leq k \) for every \( i \in I \), hence \( L_i^{k+1} \simeq \operatorname{colim}_{i \in I} L_i^{k+1} L_i = 0 \), and then the claim follows from [59, Prop.6.3.6(ii)].
Now, let $N \subseteq M_2$ be any finitely generated submodule, $\overline{N} \subseteq M_3$ the image of $N$; by claim \[14.5.13\] $M_1 \cap N$ is uniformly almost finitely generated, hence lemma \[14.5.11\] (i,ii) shows that:

$$\lambda_V(N) = e \cdot |F_0(N^a)| = e \cdot |F_0(M_1^a \cap N^a)| + e \cdot |F_0(\overline{N}^a)| = \lambda_V(M_1 \cap N) + \lambda_V(\overline{N}).$$

Taking the supremum over the family $(N_i | i \in I)$ of all finitely generated submodules of $M_2$ yields the identity:

$$\lambda_V(M_2) = \lambda_V(M_3) + \sup \{ \lambda_V(M_1 \cap N_i) | i \in I \}.$$ 

By definition, $\lambda_V(M_1 \cap N_i) \leq \lambda_V(M_1)$ for every $i \in I$; conversely, every finitely generated submodule of $M_1$ is of the form $N_i$ for some $i \in I$, whence the contention. \(\square\)

**Remark 14.5.14.** Suppose that $\Gamma \cong \mathbb{Z}$, and let $\gamma_0 \in \log \Gamma^+$ be the positive generator. Then by a direct inspection of the definition one finds the identity:

$$\lambda(M) = (\Gamma_V : \Gamma) \cdot \text{length}_V(M) \cdot \gamma_0$$

for every torsion $V$-module $M$. The verification shall be left to the reader.

14.5.15. Let $M$ be a torsion $V$-module, such that $M^a$ is almost finitely generated; we wish now to explain that $\lambda_V(M)$ can also be computed in terms of a suitable sequence of elementary divisors for $M^a$. Indeed, suppose first that $M$ is a finitely presented torsion $V$-module; then we have a decomposition

$$M = (V/a_0 V) \oplus \cdots \oplus (V/a_n V) \quad \text{where } n := \dim_{\kappa(V)} M/m_V M - 1$$

for certain $a_0, \ldots, a_n \in m_V$ (\[59,\] Lemma 6.1.14). Clearly $\gamma_i := \log |a_i|_V > 0$ for every $i = 0, \ldots, n$, and after reordering we may assume that $\gamma_0 \geq \cdots \geq \gamma_n$; then we may set $\gamma_i := 0$ for every $i > n$, and the resulting sequence $(\gamma_i | i \in \mathbb{N})$ of elementary divisors of $M$ is independent of the chosen decomposition \[14.5.16\], since we have more precisely:

$$a_i V = \text{Ann}_V(\Lambda^{i+1}_V M) \quad \text{for every } i \in \mathbb{N}.$$ 

Indeed, from a decomposition \[14.5.16\] with $a_i V \subseteq a_{i+1} V$ for every $j < n$, we get a $V$-linear surjection $M \rightarrow (V/a_i V)^{\oplus i+1}$, whence a surjection

$$N_i := \Lambda^{i+1}_V M \rightarrow \Lambda^{i+1}_V (V/a_i V)^{\oplus i+1} \cong V/a_i V$$

which shows that $J_i := \text{Ann}_V N_i \subseteq a_i V$. For the converse inclusion, notice that $N_i$ is generated by the system of all elements of the form $\omega := x_0 \cdots \times x_i$, where $x_0 \in M_{j(0)}, \ldots, x_i \in M_{j(i)}$ for some strictly increasing map $j : \{0, \ldots, i\} \rightarrow \{0, \ldots, n\}$; especially, $j(i) \geq i$, whence $a_i \omega = 0$, and the assertion follows. Moreover, a simple inspection yields the identity

$$\lambda_V(M) = (\Gamma_V : \Gamma) \cdot (\gamma_0 + \cdots + \gamma_n).$$

We regard the sequence $(\gamma_i | i \in \mathbb{N})$ as an element of the $\log \Gamma^+$-normed space $\mathcal{L}(\Gamma^+_V)$ of bounded sequences of elements of $\log \Gamma^+_V$, i.e. the set of all sequences $\delta := (\delta_i | i \in \mathbb{N})$ with

$$\|\delta\| := \sup \{ \delta_i | i \in \mathbb{N} \} < +\infty.$$ 

**Lemma 14.5.19.** Let $\varphi : N \rightarrow N'$ be a map of finitely presented torsion $V$-modules, and denote by $(\gamma_i | i \in \mathbb{N})$ (resp. $(\gamma'_i | i \in \mathbb{N})$) the sequence of elementary divisors of $N$ (resp. $N'$). Then:

(i) If $\varphi$ is injective, we have $\gamma_i \leq \gamma'_i$ for every $i \in \mathbb{N}$.
(ii) If $\varphi$ is surjective, we have $\gamma_i \geq \gamma'_i$ for every $i \in \mathbb{N}$.

**Proof.** Denote by $K_V$ the field of fractions of $V$, and set $P^\dagger := \text{Hom}_V(P, K_V/V)$ for every $V$-module $P$. We have a natural bilinear pairing $P \otimes_V P^\dagger \rightarrow K_V/V$, whence a $V$-linear map

$$\omega_P : P \rightarrow (P^\dagger)^\dagger.$$ 

**Claim 14.5.20.** (i) If $\varphi$ is injective, $\varphi^\dagger := \text{Hom}_V(\varphi, K_V/V)$ is surjective.
(ii) For every finitely presented $V$-module $P$, we have:
(a) The map $\omega_P$ is an isomorphism.
(b) $P$ and $P^\dagger$ are isomorphic $V$-modules.

Proof of the claim. (ii) is left to the reader. (i) follows immediately from lemma \[11.5.9\](i). \hfill \diamond

By virtue of claim \[14.5.20\](ii.b), the $V$-modules $N$ and $N^\dagger$ have the same sequences of elementary divisors. Taking into account claim \[14.5.20\](i), we deduce that (ii) $\Rightarrow$ (i), so it remains only to show that (ii) holds. However, if $\varphi$ is surjective, the same holds for $\Lambda V^{+1}_{\dagger}\varphi_i$, and then the assertion follows immediately from \[14.5.17\]. \hfill \Box

**Proposition 14.5.21.** Let $0 \to M' \to M \to M'' \to 0$ be a short exact sequence of finitely presented torsion $V$-modules. Then for every $i, j, t \in \mathbb{N}$ we have:

$$\sum_{k=i+j}^{i+j+t} \gamma_k(M) \leq \sum_{k=i}^{i+t} \gamma_k(M') + \sum_{k=j}^{j+t} \gamma_k(M'').$$

**Proof.** Let us choose a decomposition for $M$ as in \[14.5.16\], with $a_0 V \subset a_1 V \subset \cdots \subset a_n V$, and set $M := (V/b_i V) \oplus \cdots \oplus (V/b_i + t V)$, where $b_i = a_{i+j}$ for $i = 0, \ldots, i+j$ and $b_i = a_i$ for $i = i+j+1, \ldots, i+j+t$. We have an obvious $V'$-linear surjection $M \to M'$, and let us as well $M'$ be the image of $M'$ in $M$, and $M'' := M/M'$. By construction, we have $\sum_{k=i+j}^{i+j+t} \gamma_k(M) = \sum_{k=i+j}^{i+j+t} \gamma_k(M')$, and taking into account lemma \[4.5.19\](ii), we are easily reduced to checking the asserted inequality for the resulting short exact sequence $0 \to M' \to M \to M'' \to 0$. Next, for $k = 0, \ldots, i+j+t$ we consider the $V'$-linear map $\varphi_k : V \to V/a_{i+j+k} V$ that maps 1 to the class of $a_{i+j+k}/b_k$; clearly $\varphi_k$ factors through a $V$-linear injection $\pi_k : V/b_k V \to V/a_{i+j+k} V$, and the direct sum of the latter maps is a $V$-linear injection $\pi : M' \to N := (V/a_{i+j+k})^{\oplus i+j+t+1}$. Let $N' \subset N$ be the image of $M'$, and set $N'' := N/N'$; we notice that

$$\sum_{k=i+j}^{i+j+t} (\gamma_k(N) - \gamma_k(M')) = |F_0(N)| - |F_0(M)| = C := \sum_{k=1}^{t} (\log |a_{i+j+k} V| - \log |a_{i+j+k} V|).$$

Taking into account proposition \[14.5.12\](i), we deduce that

$$\sum_{k=j}^{j+t} (\gamma_k(N'') - \gamma_k(M'')) \leq |F_0(N'')| - |F_0(M'')| = C.$$

Summing up, we are further reduced to checking the sought inequality for the short exact sequence $0 \to N' \to N \xrightarrow{\pi} N'' \to 0$. Let us remark, quite generally:

**Claim 14.5.22.** Let $A$ be a local ring, $M$ a finitely generated $A$-module, $F, F'$ two free $A$-modules of the same rank $r \in \mathbb{N}$, and $\pi : F \to M, \pi' : F' \to M$ two $A$-linear surjections. Then there exists an $A$-linear isomorphism $\omega : F \xrightarrow{\sim} F'$ such that $\pi' \circ \omega = \pi$.

**Proof of the claim.** Let $\kappa$ be the residue field of $A$, and set $m := \dim_\kappa (M \otimes A \kappa)$; by Nakayama’s lemma, $M$ admits a minimal system of generators $x_1, \ldots, x_m$, and we choose $f_1, \ldots, f_m \in F$ with $\pi(f_i) = x_i$ for $i = 1, \ldots, m$. Next, notice that $G := \ker (\pi \otimes_A \kappa)$ is a $\kappa$-vector space of dimension $r - m$, and pick a system of elements $f_{m+1}, \ldots, f_r \in F$ whose image in $G$ is a basis; applying again Nakayama’s lemma, it is easily seen that the system $f_1, \ldots, f_r$ generates the $A$-module $F$, and it is therefore a basis of the latter. Likewise, we may find a basis $f_1', \ldots, f_r'$ of $F'$ such that $\pi'(f_i) = x_i$ for $i = 1, \ldots, m$ and $\pi'(f_i) = 0$ for $i = m+1, \ldots, r$; then the unique $A$-linear map $\omega : F \to F'$ such that $\omega(f_i) = f_i'$ for $i = 1, \ldots, r$ will do. \hfill \diamond

Now, say that $N'' = (V/c_0 V) \oplus \cdots \oplus (V/c_p V)$ is a minimal decomposition with $c_0 V \subset \cdots \subset c_p V$; clearly we must have $p \leq i+j+t$ and $a_{i+j} \subset c_p V$. Set $c_{p+1} = \cdots = c_{i+j+t} = 1,$
and let \( \pi'_k : V/a_{i+j+t} \rightarrow V/c_k V \) be the natural projection, for \( k = 0, \ldots, i + j + t; \) the direct sum of the maps \( \pi'_k \) is a \( V \)-linear surjection \( \pi' : N \rightarrow N'' \), and by virtue of claim 14.5.22 there exists a \( V \)-linear automorphism \( \omega \) of \( N \) such that \( \pi' \circ \omega = \pi \). Thus, it suffices to show the stated inequality for the short exact sequence \( 0 \rightarrow Q := \omega(N') \rightarrow N \xrightarrow{\pi'} N'' \rightarrow 0 \). But notice that \( Q = \bigoplus_{k=0}^{i+j+t} \ker \pi'_k \), and therefore

\[
\gamma_k(Q) = \log |a_{i+j}|_V - \log |a_{i+j+t-k}|_V \quad \text{for} \ k = 0, \ldots, i + j + t.
\]

On the other hand \( \gamma_k(N) = \log |a_{i+j}|_V \) and \( \gamma_k(N'') = \log |a_k|_V \) for \( k = 0, \ldots, i + j + t; \) summing up, we conclude the the sought inequality holds, and indeed it is an equality for this last short exact sequence.

**14.5.23.** We fix now a large cardinal number \( \omega \), and write just \( \mathcal{M}(V^a) \) instead of \( \mathcal{M}_\omega(V^a) \). Also, for any \( \gamma \in \log \Gamma^+_V \), set \([-\gamma, \gamma] := \{ \delta \in \log \Gamma^+_V \mid -\gamma \leq \delta \leq \gamma \} \). Suppose that \( N \) and \( N' \) are two finitely presented \( V \)-modules such that \( (N^a, N'^a) \in E_\delta \) for some \( \delta \in \log \Gamma^+_V \setminus \{0\} \).

Say that \( \delta = \log \|b\|_V \) for some \( b \in V \); by standard arguments, we obtain maps \( \varphi : N \rightarrow N' \) and \( \varphi' : N' \rightarrow N \) such that \( \varphi' \circ \varphi = b^4 \cdot 1_N \). Let now \((\gamma_i \mid i \in \mathbb{N})\) be the sequence of elementary divisors for \( N \) (resp. for \( N' \)). Then the sequence of elementary divisors for \( b^4 N \) is \( \max(0, \gamma_i - 4\delta) \mid i \in \mathbb{N} \), and likewise for \( b^4 N' \). In view of lemma 14.5.19 we deduce easily that

\[
\gamma_i - \gamma'_i \in [-4\delta, 4\delta] \quad \text{for every} \ i \in \mathbb{N}.
\]

Consider a torsion almost finitely generated \( V^a \)-module \( M \), and recall that \( M \) is almost finitely presented (Prop. 6.3.6(i)); we then may attach to \( M \) a net of elements of \( \ell^\infty(\log \Gamma^+_V) \), as follows. For every \( \delta \in \log \Gamma^+_V \setminus \{0\} \), pick a finitely presented \( V \)-module \( N_\delta \) such that \((M, N_\delta^a) \in E_\delta \), and denote by \( \gamma_\delta \) the sequence of elementary divisors of \( N_\delta \). The foregoing easily implies that the system \( \{\gamma_\delta \mid \delta \in \log \Gamma^+_V \setminus \{0\} \} \) is a net for the uniform structure of \( \ell^\infty(\log \Gamma^+_V) \) induced by the norm \( \| \cdot \| \). However, \( (\ell^\infty(\log \Gamma^+_V), \| \cdot \|) \) is a complete normed space, hence this net converges to a well defined sequence \( \gamma_M := (\gamma_i \mid i \in \mathbb{N}) \in \ell^\infty(\log \Gamma^+_V) \). It is easily seen that \( \gamma_M \) is independent of the chosen net, and defines an invariant which we call the \emph{sequence of elementary divisors} of \( M \). A simple inspection of the construction shows that the sequence \( \gamma_M \) is monotonically decreasing, and

\[
\lim_{i \to +\infty} \gamma_i = 0.
\]

**14.5.24.** Denote again by \( K_V \) the field of fractions of \( V \); as in the proof of lemma 14.5.19 we consider the functor

\[
V^a\text{-Mod} \rightarrow V^a\text{-Mod} : M \mapsto M^\dagger := \text{alHom}_{V^a}(M, K_V^a/V^a).
\]

For every \( V^a \)-module \( M \) we have a natural \( V^a \)-bilinear pairing

\[
M \otimes_{V^a} M^\dagger \rightarrow K_V^a/V^a
\]

which in turns yields a natural transformation

\[
(14.5.25) \quad M \rightarrow (M^\dagger)^\dagger.
\]

Together with the constructions of (14.5.23), we may now extend lemma 14.5.19 \emph{verbatim} to arbitrary almost finitely generated \( V^a \)-modules.

**Proposition 14.5.26.** Let \( \varphi : M \rightarrow M' \) be a morphism of almost finitely generated torsion \( V^a \)-modules, and denote by \((\gamma_i \mid i \in \mathbb{N})\) (resp. \((\gamma'_i \mid i \in \mathbb{N})\)) the sequence of elementary divisors of \( M \) (resp. \( M' \)). Then :

(i) \( M^\dagger \) is an almost finitely generated torsion \( V^a \)-module, the morphism \((14.5.25)\) is an isomorphism, and the sequences of elementary divisors of \( M \) and \( M^\dagger \) coincide.
(ii) If \( \varphi \) is a monomorphism, we have \( \gamma_i \leq \gamma_i' \) for every \( i \in \mathbb{N} \).

(iii) If \( \varphi \) is an epimorphism, we have \( \gamma_i \geq \gamma_i' \) for every \( i \in \mathbb{N} \).

Proof. (i): Since \( M \) is almost finitely presented ([59] Prop. 6.3.6(i)), the assertion follows immediately from [59] Lemma 2.3.7(iii) and claim 14.5.20(ii).

(iii): To begin with, we remark more generally:

Claim 14.5.27. Let \( P, Q \) be two torsion almost finitely generated \( V^a \)-modules, and \( \delta \in \log \Gamma^+_\psi \) any element such that \( (P, Q) \in E_\delta \). Denote by \( (\gamma_i^P | i \in \mathbb{N}) \) (resp. \( (\gamma_i^Q | i \in \mathbb{N}) \)) the sequence of elementary divisors of \( P \) (resp. of \( Q \)). Then

\[
\gamma_i^P - \gamma_i^Q \in [-4\delta, 4\delta]
\]

for every \( i \in \mathbb{N} \).

Proof of the claim. For any \( \varepsilon \in \log \Gamma^+_\psi \) pick a torsion finitely presented \( V \)-module \( N \) such that \( (P, N^a) \in E_\varepsilon \), and let \( (\gamma_i^N | i \in \mathbb{N}) \) be the sequence of elementary divisors of \( N \). It follows that \( (Q, N^a) \in E_{\delta + \varepsilon} \), and from the construction of (14.5.23) we see that

\[
\gamma_i^N - \gamma_i^P \in [-4\varepsilon, 4\varepsilon]
\]

so \( \gamma_i^P - \gamma_i^Q \in [-8\varepsilon - 4\delta, 8\varepsilon + 4\delta] \) for every \( i \in \mathbb{N} \). Since \( \varepsilon \) is arbitrary, the claim follows. \( \diamond \)

Fix \( \delta \in \log \Gamma^+_\psi \setminus \{0\} \), pick finitely presented \( V \)-modules \( N, N' \) such that

\[
(N^a, M), (N'^a, M') \in E_\delta
\]

and denote by \( (\beta_i | i \in \mathbb{N}) \) (resp. \( (\beta_i' | i \in \mathbb{N}) \)) the sequence of elementary divisors of \( N \) (resp. of \( N' \)). According to claim 14.5.27 we have:

\[
\gamma_i - \beta_i, \gamma_i' - \beta_i' \in [-4\delta, 4\delta]
\]

for every \( i \in \mathbb{N} \).

On the other hand, by the usual arguments we may find \( V \)-linear maps \( f : N \to M \) and \( g : M' \to N' \) such that \( b^2 \cdot \text{Coker } f = b^2 \cdot \text{Coker } g = 0 \) for every \( b \in V \) with \( \log |b|_V = \delta \). Set \( h := g \circ \psi \circ f \); it follows easily that \( b^5 \cdot \text{Coker } h = 0 \). The sequence of elementary divisors of \( b^5 N' \) is \( (\max(0, \beta_i' - 5\delta) | i \in \mathbb{N}) \), and since \( N'' := \text{Im } h \) is a finitely presented \( V \)-module, the sequence \( (\beta_i'' | i \in \mathbb{N}) \) of its elementary divisors satisfies the inequalities

\[
\beta_i \geq \beta_i'' \geq \beta_i' - 5\delta
\]

for every \( i \in \mathbb{N} \).

by lemma 14.5.19(i,ii). Combining with (14.5.28), we deduce that

\[
\gamma_i \geq \gamma_i' - 13\delta
\]

and since \( \delta \) is arbitrary, the assertion follows.

(ii): in light of [59] Lemma 2.3.7(iii) and claim 14.5.20(i), it is easily seen that \( \varphi^! \) is an epimorphism, so the assertion follows formally from (i) and (iii), as in the proof of lemma 14.5.19(i). \( \square \)

One may ask, to which extent the sequence of elementary divisors of a \( V^a \)-module \( M \) determines the isomorphism class of \( M \). To address this question, we make the following:

Definition 14.5.29. Let \( (V, m) \) be an arbitrary basic setup, \( A \) any \( V^a \)-algebra, \( M \) an \( A \)-module and \( \omega \) (very large) cardinal number, such that \( \mathcal{M}_\omega(A) \) contains the isomorphism class of \( M \). The topological space underlying the uniform space \( \mathcal{M}_\omega(A) \) is not necessarily separated, but it admits a maximal separated quotient space \( \mathcal{M}_\omega^{sep}(A) \). The \( \omega \)-type of \( M \) is the image in \( \mathcal{M}_\omega^{sep}(A) \) of the isomorphism class of \( M \). If \( \omega' \) is any cardinal larger than \( \omega \), clearly the \( \omega' \)-type of \( M \) maps to the \( \omega' \)-type of \( M \), under the natural map \( \mathcal{M}_\omega^{sep}(A) \to \mathcal{M}_{\omega'}^{sep}(A) \). For this reason, we shall usually omit explicit mention of \( \omega \), and shall call the type of \( M \) any one of these invariants.

Lemma 14.5.30. In the situation of definition 14.5.29 suppose that \( M \) and \( M' \) are two \( A \)-modules of the same type. Then we have:
(i) $M$ is almost finitely presented (resp. almost finitely generated) if and only if the same holds for $M'$.

(ii) $M$ is a flat (resp. almost projective) $A$-module if and only if the same holds for $M'$.

Proof. (i) follows directly from the definitions.

(ii) follows easily from [59, Lemma 2.3.7(iii,iv)] : details left to the reader.

We may now answer as follows to the foregoing question :

**Proposition 14.5.31.** Let $(V, \mathfrak{m}_V)$ be as in (14.5.5), and $M, M'$ any two almost finitely generated torsion $V^a$-modules. The following conditions are equivalent :

(a) $M$ and $M'$ have the same type.

(b) The sequences of elementary divisors of $M$ and $M'$ coincide.

Proof. (a)$\Rightarrow$(b): Condition (a) means that $(M, M') \in E_\delta$ for every $\delta \in \log \Gamma^+_V \setminus \{0\}$, so the assertion is immediate from the construction of the sequences of elementary divisors.

(b)$\Rightarrow$(a): Let $(\gamma_i \mid i \in \mathbb{N})$ be the common sequence of elementary divisors for $M$ and $M'$. Fix $\delta$ as in the foregoing, pick finitely presented $V$-modules $N, N'$ such that

$$(M, N), (M', N') \in E_\delta$$

and let $(\beta_i \mid i \in \mathbb{N})$, respectively $(\beta'_i \mid i \in \mathbb{N})$ be the sequences of elementary divisors of $N$ and $N'$. From claim [14.5.27] we deduce

$$\beta_i - \gamma, \beta'_i - \gamma_i \in [-4\delta, 4\delta] \quad \text{for every } i \in \mathbb{N}.$$ 

Thus, $\beta_i - \beta'_i \in [-8\delta, 8\delta]$ for every $i \in \mathbb{N}$. Say that $8\delta = \log |a|_V$ for some $a \in V$.

**Claim 14.5.32.** There exists a $V$-linear map $f : N \to N'$ whose kernel and cokernel is annihilated by $a$.

Proof of the claim. By [59, Lemma 6.1.14] we reduce easily to the case where $N$ and $N'$ are cyclic $V$-modules, so $N = V/bV$ and $N' = V/b'V$, for $b, b' \in V \setminus \{0\}$ such that $\log |b/b'|_V \in [-2\delta, 2\delta]$. Now, if $b \in b'V$, we let $f$ be the natural projection $V/bV \to V/b'V$. If $b' \in bV$, we notice that $b'b^{-1}1_N$ factors through a map $N \to N'$ with the sought properties (details left to the reader).

Clearly claim [14.5.32] implies that $(N, N') \in E_{8\delta}$, and therefore $(M, M') \in E_{10\delta}$. Since $\delta$ is arbitrary, the assertion follows.

**Corollary 14.5.33.** Let $b \in \mathfrak{m}_V$ be any non-zero element, $M$ an almost finitely generated $V^a/bV^a$-module, and $(\gamma_i \mid i \in \mathbb{N})$ the sequence of elementary divisors of $M$. The following conditions are equivalent :

(a) $M$ is a flat $V^a/bV^a$-module.

(b) There exists $n \in \mathbb{N}$ such that $\gamma_i = \log |a|_V$ for every $i \leq n$, and $\gamma_i = 0$ for every $i > n$.

Proof. For every $i \in \mathbb{N}$, pick $a_i \in V$ with $\log |a_i|_V = \gamma_i$. According to proposition [14.5.31] the type of $M$ coincides with that of $M' := \bigoplus_{i \in \mathbb{N}} V^a/a_i V^a$, and by lemma [14.5.30](ii), we may then assume that $M = M'$, in which case clearly (b)$\Rightarrow$(a). For the converse, notice that a standard computation gives

$$\text{Tor}_1^{V/bV}(V/aV, V/aV) \cong V/(aV + a^{-1}bV) \quad \text{for every } a \in V \text{ such that } \log |a|_V \leq \log |b|_V$$

from which the assertion follows easily (details left to the reader).

**Proposition 14.5.34.** Let $(V, \mathfrak{m}_V)$ be as in (14.5.5), and $M$ a torsion $V$-module such that $M^a$ is almost finitely generated. Let $(\gamma_i \mid i \in \mathbb{N})$ be the sequence of elementary divisors of $M^a$. Then

$$\lambda_V(M) = (\Gamma_V : \Gamma) \cdot \sum_{i \in \mathbb{N}} \gamma_i.$$
 Especially, \( \lambda_V(M) \) depends only on the type of \( M^a \).

**Proof.** Fix a sequence \((a_k | k \in \mathbb{N})\) of elements of \( m_V \setminus \{0\} \) with \( \lim_{k \to +\infty} \log |a_k|_V = 0 \). For every \( k \in \mathbb{N} \), let \( M_k \subset M \) be a finitely generated submodule such that \( a_k M \subset M_k \) (\cite[Prop. 2.3.10(i)]{59}), and denote also by \( (\gamma^k_i | i \in \mathbb{N}) \) the sequence of elementary divisors of \( M^a_k \). After replacing each \( M_k \) by \( \sum_{j=0}^k M_j \), we may also assume that \( M_k \subset M_{k+1} \) for every \( k \in \mathbb{N} \).

**Claim 14.5.35.** For every \( i, k \in \mathbb{N} \) we have
\[
4\delta_k \geq \gamma_i - \gamma_i^k \geq 0
\]
where \( \delta_k := \log |a_k| \).

**Proof of the claim.** The inequalities \( \gamma_i \geq \gamma_i^{k+1} \geq \gamma_i^k \) follow from proposition 14.5.26(ii). Next, clearly we have \( (M^a_k, M^a) \in \mathcal{E}_\delta \) for every \( k \in \mathbb{N} \), so the upper bound for \( \gamma_i - \gamma_i^k \) follows from claim 14.5.27.

Set \( L^k := \sum_{i \in \mathbb{N}} \gamma_i^k \) and \( L := \sum_{i \in \mathbb{N}} \gamma_i \). It follows easily from claim 14.5.35 that
\[
\lim_{k \to +\infty} L^k = \sum_{i \in \mathbb{N}} \lim_{k \to +\infty} \gamma_i^k = L.
\]

In light of proposition 14.5.12(iii.b), it then suffices to check the proposition with \( M \) replaced by \( M_k \), for every \( k \in \mathbb{N} \). We may therefore assume from start that \( M \) is finitely generated, and let \( g \) be the cardinality of a finite system of generators for \( M \). We may then find a surjective \( V \)-linear map \( f : F := V^{\oplus g} \to M \), and \( N := \text{Ker } f^a \) is almost finitely generated (claim 14.5.13). Thus, for every \( k \in \mathbb{N} \) we may replace \( M \) by a finitely generated \( V \)-submodule \( N_k \subset N \) with \( a_k N \subset N_k \), so that \( (F^a/N^a_k, M) \in \mathcal{E}_\delta \). After replacing each \( N_k \) by \( \sum_{j=0}^k N_j \), we may also assume that \( N_k \subset N_{k+1} \) for every \( k \in \mathbb{N} \). Denote by \( (\beta_i^k | i \in \mathbb{N}) \) the sequence of elementary divisors of \( F/N_k \), and notice that \( \beta_i^k = 0 \) for every \( i \geq g \). Taking into account (14.5.18), claim 14.5.27 and proposition 14.5.26(iii) we get
\[
\lambda_V(F/N_k) = \sum_{i \in \mathbb{N}} \beta_i^k \geq 4\delta_k \geq \beta_i^k - \gamma_i \geq 0 \quad \text{for every } i, k \in \mathbb{N}.
\]

Therefore \( \lim_{k \to +\infty} \lambda_V(F/N_k) = L \), and in view of proposition 14.5.12(i), it remains only to check that \( \lim_{k \to +\infty} \lambda_V(N/N_k) = 0 \), or equivalently, that \( \lim_{k \to +\infty} \lambda_V(N_k) = \lambda_V(N) \) (proposition 14.5.12(i)). However, set \( N' := \bigcup_{k \in \mathbb{N}} N_k \); by proposition 14.5.12(iii.b), the latter identity holds if and only \( \lambda_V(N') = \lambda_V(N) \), and since \( (N/N')^a = 0 \), this follows from proposition 14.5.12(ii.i). \( \square \)

14.5.36. In order to deal with general measurable \( K^+ \)-algebras, we introduce hereafter some further notation which shall be standing throughout this section.

- To begin with, any ring homomorphism \( \varphi : A \to B \) induces functors
\[
\varphi_* : B\text{-Mod} \to A\text{-Mod} \quad \text{and} \quad \varphi^* : A\text{-Mod} \to B\text{-Mod}.
\]
Namely, \( \varphi_* \) assigns to any \( B \)-module \( M \) the \( A \)-module \( \varphi_* M \) obtained by restriction of scalars, and \( \varphi^*(M) := B \otimes_A M \).

- For any local ring \((A, m_A)\), we let \( \kappa(A) := A/m_A \), and we denote by \( s(A) \) the closed point of \( \text{Spec } A \). If \( A \) is also a coherent ring, we denote by \( A\text{-Mod}_{\text{coh.}(s)} \) the full subcategory of \( A\text{-Mod} \) consisting of all the finitely presented \( A \)-modules \( M \) such that \( \text{Supp } M \subset \{s(A)\} \). Notice that the coherence of \( A \) implies that \( A\text{-Mod}_{\text{coh.}(s)} \) is an abelian category.

- Lastly, let \( \mathcal{A} \) be any small abelian category; recall that \( K_0(\mathcal{A}) \) is the abelian group defined by generators and relations as follows. The generators are the isomorphism classes \([T] \) of objects \( T \) of \( \mathcal{A} \), and the relations are generated by the elements of the form \([T_1] - [T_2] + [T_3] \), for every short exact sequence \( 0 \to T_1 \to T_2 \to T_3 \to 0 \) of objects of \( \mathcal{A} \). One denotes by \( K_0^+(\mathcal{A}) \subset K_0(\mathcal{A}) \) the submonoid generated by the classes \([T] \) of all objects of \( \mathcal{A} \). We shall use the following well known dévissage lemma:
Lemma 14.5.38. Let $\iota : \mathcal{B} \subset \mathcal{A}$ be an additive exact and fully faithful inclusion of abelian categories, and suppose that:

(a) If $T \in \text{Ob}(\mathcal{B})$ and $T'$ is a subquotient of $\iota(T)$, then $T'$ is in the essential image of $\iota$.
(b) Every object $T$ of $\mathcal{A}$ admits a finite filtration $\text{Fil}^{\ast}T$ such that the associated graded object $\text{gr}^{\ast}T$ is in the essential image of $\iota$.

Then $\iota$ induces an isomorphism:

$$K_0(\mathcal{B}) \xrightarrow{\sim} K_0(\mathcal{A}).$$

Proof. Left to the reader. \qed

Proposition 14.5.39. Let $\varphi : A \to B$ be a morphism of measurable $K^+$-algebras. We have:

(i) If $\varphi$ induces a finite field extension $\kappa(A) \to \kappa(B)$, then the functor $\varphi_*$ of (14.5.37) restricts to a functor

$$\varphi_* : B\text{-Mod}_{\text{coh},\{s\}} \to A\text{-Mod}_{\text{coh},\{s\}}$$

which induces a group homomorphism of the respective $K_0$-groups:

$$\varphi_* : K_0(B\text{-Mod}_{\text{coh},\{s\}}) \to K_0(A\text{-Mod}_{\text{coh},\{s\}}).$$

(ii) If $\varphi$ induces an integral morphism $\kappa(A) \to B/\mathfrak{m}_A B$, then $\text{length}_B(B/\mathfrak{m}_A B)$ is finite, and the functor $\varphi^*$ of (14.5.37) restricts to a functor

$$\varphi^* : A\text{-Mod}_{\text{coh},\{s\}} \to B\text{-Mod}_{\text{coh},\{s\}}$$

and if $\varphi$ is also a flat morphism, $\varphi^*$ induces a group homomorphism:

$$\varphi^* : K_0(A\text{-Mod}_{\text{coh},\{s\}}) \to K_0(B\text{-Mod}_{\text{coh},\{s\}}).$$

Proof. Write $A$ (resp. $B$) as the colimit of a filtered system $A := (A_i \mid i \in I)$ (resp. $B := (B_j \mid j \in J)$) of objects of $K^+\text{-m.Alg}_{0}$, with local and essentially étale transition maps. After replacing $J$ (resp. $I$) by a cofinal subsets, we may assume that the indexing set admits an initial element $0 \in J$ (resp. $0 \in I$). Furthermore, we may assume that the induced map $A_0 \to B$ factors through a morphism $A_0 \to B_0$ in $K^+\text{-m.Alg}_{0}$.

(i): Let $M$ be any object of $B\text{-Mod}_{\text{coh},\{s\}}$. We need to show that $\varphi_* M$ is finitely presented. We may find $j \in J$ and a finitely presented $B_j$-module $M_j$, with an isomorphism $M \xrightarrow{\sim} M_j \otimes_{B_j} B$ of $B$-modules. After replacing $J$ by $J/j$, we may assume that $j = 0$ is the initial index.

Since the natural map $B_0 \to B$ is local and ind-étale, it is easily seen that $M_0$ is an object of $B_0\text{-Mod}_{\text{coh},\{s\}}$. Especially, there exists a finitely generated $\mathfrak{m}_{B_0}$-primary ideal $I \subset \text{Ann}_{B_0} M_0$. We may then replace the system $B$ by $(B_j / IB_j \mid j \in J)$ and assume that each $B_j$ has Krull dimension zero.

Claim 14.5.40. Let $\varphi : A \to B$ be a morphism of measurable $K^+$-algebras inducing a finite residue field extension $\kappa(A) \to \kappa(B)$, and such that $B$ has dimension zero. Let also $M$ be any finitely presented $B$-module. Then we may find:

(a) a cocartesian diagram of local maps of $K^+$-algebras

$$
\begin{array}{ccc}
A_l & \xrightarrow{\varphi_l} & C_l \\
\downarrow & & \downarrow \\
A & \xrightarrow{\varphi} & B
\end{array}
$$

whose vertical arrows are ind-étale, and where $\varphi_l$ is a morphism in $K^+\text{-m.Alg}_{0}$

(b) and an object $M_l$ of $C_l\text{-Mod}_{\text{coh},\{s\}}$, with an isomorphism $M_l \otimes_{C_l} B \xrightarrow{\sim} M$. 

 Fonduations for Almost Ring Theory 1305
Proof of the claim. Define $A$ and $B$ as in the foregoing. Notice that – under the current assumptions – $B_j$ is a henselian ring, for every $j \in J$. Moreover, we may find $j \in J$ such that $\kappa(B_j)$ is generated by the image of $\kappa(A) \otimes_{\kappa(B_0)} \kappa(B_j)$; after replacing again $J$ by $J/j$, we may then also assume that $\kappa(B_j) = (\kappa(A)) \cdot \kappa(B_0)$.

For every $i \in I$, set $B_i := A_i \otimes_{A_0} B_0$; the natural map $B_0 \to B$ factors through a map $B_i \to B$, and we let $p_i \subset B_i$ be the preimage of $m_B$. Set also $C_i := B_i/p_i$, so we deduce a filtered system of local maps $(C_i \to B \mid i \in I)$, whose limit is a local map $\psi : C \to B$ of local ind-étale $B_0$-algebras, which – by construction – induces an isomorphism $\kappa(C) \cong \kappa(B)$ on residue fields. It follows easily that $\psi$ is itself ind-étale, so say that $\psi$ is the colimit of a filtered system $(\psi_\lambda : C \to D_\lambda \mid \lambda \in \Lambda)$ of étale $C$-algebras. Notice that $C$ is a henselian local ring; in light of [51] Ch.IV, Th.18.5.11] we may then assume that $D_\lambda$ is a local ring and $\psi_\lambda$ is a finite étale map, for every $\lambda \in \Lambda$. Clearly the induced residue field extension $\kappa(C) \to \kappa(D_\lambda)$ is an isomorphism; in view of [51] Ch.IV, Prop.18.5.15] it follows that $\psi_\lambda$ is an isomorphism, for every $\lambda \in \Lambda$, so the same holds for $\psi$.

Notice that the sequence of residue degrees $d_i := [\kappa(C_i) : \kappa(A_i)]$ is non-increasing, hence there exists $l \in I$ such that $d_i = d := d_l$ for every index $i \geq l$. Notice as well that, for $i \geq l$, the local algebra $C_i$ is also a localization of $C_l := A_l \otimes_{A_0} C_l$, and the latter is an essentially finitely presented $K^+$-algebras of Krull dimension zero, hence its spectrum is finite and discrete (lemma 9.1.28). Moreover, since the image of the map $\text{Spec} C_l \to \text{Spec} A_l$ is the closed point, it is clear that the same holds for the image of the induced map $\text{Spec} C'_i \to \text{Spec} A_i$. Since the extension $\kappa(A_l) \to \kappa(A_i)$ is finite and separable, we conclude that

$$\kappa(A_i) \otimes_{\kappa(A_l)} \kappa(C_l) = \prod_{p \in \text{Spec} C'_i} \kappa(C'_{i,p}). \quad (14.5.41)$$

However, clearly the left-hand side of (14.5.41) is a $\kappa(A_l)$-algebra of degree $d$, whereas one of factors of the right-hand side – namely $\kappa(C'_l)$ – is already of degree $d$ over $\kappa(A_l)$. Hence $\text{Spec} C'_i = C_i$ is a local ring, and $C = A \otimes_{A_l} C_l$. Summing up, we have obtained the sought cocartesian diagram, and the claim holds with $M_l := M_0 \otimes_{B_0} C_l$. ♦

Let $M_l$ and $\varphi_l$ be as in claim 14.5.40, then $\varphi_l^* M$ is isomorphic to $A \otimes_{A_l} \varphi_{l,*} M_l$, so may replace from start $\varphi$ by $\varphi_l$, and assume that $\varphi$ is a morphism in $K^+\text{-Alg}$, with $B$ of Krull dimension zero. In such situation, one sees easily that $\varphi$ is integral, hence $B/I$ is a finitely presented $A$-module, by proposition 9.1.32(i), therefore $\varphi_* M$ is a finitely presented $A$-module, as required. Lastly, since the functor $\varphi_*$ is exact, it is clear that it induces a map on $K_0$-groups as stated.

(ii): Under the current assumptions, the induced map $\kappa(A_0) \to B_0/m_{A_0} B_0$ is integral and essentially finitely presented, hence it is finite, so $B_0/m_{A_0} B_0$ is a $B_0$-module of finite length; but this is also the length of the $B$-module $B/m_B B$, whence the first assertion. Next, let $M$ be an object of $A\text{-Mod}_{\text{coh.}(s)}$; then $\varphi^* M$ is a finitely presented $B$-module; moreover, we may find a $m_A$-primary ideal $I \subset A$ such that $M$ is an $A/I$-module, hence $\varphi^* M$ is a $B/I B$-module. Notice that the induced map $\text{Spec} B/m_A B \to \text{Spec} B/I B$ is bijective, and its target is a local scheme of dimension zero (since $B/m_A B$ is integral over a field). It follows easily that $IB$ is a $m_B$-primary ideal, so $\varphi^* M$ is an object of $B\text{-Mod}_{\text{coh.}(s)}$. The last assertion is then a trivial consequence of the exactness of the functor $\varphi^*$, when $\varphi$ is flat. □

Lemma 14.5.42. Let $A$ be any measurable $K^+$-algebra. Then there exists a morphism

$$V \xrightarrow{\varphi} A/I$$

of measurable $K^+$-algebras, where:

(a) $I \subset A$ is a finitely generated $m_A$-primary ideal.
(b) $V$ is a valuation ring, $\varphi$ is a finitely presented surjection and the natural map $K^+ \to V$ induces an isomorphism of value groups $\Gamma \xrightarrow{\sim} \Gamma_V$.

**Proof.** Suppose first that $A$ is an object of $K^+-\text{m.} \text{Alg}_0$. In this case, choose an affine finitely presented $S$-scheme $X$ and a point $x \in X$ such that $A = \mathcal{O}_{X,x}$; next, take a finitely presented closed immersion $h: X \to Y := \mathbb{A}^n_{K^+}$ of $S$-schemes; set $Y' := \mathbb{A}^n_{\kappa} \subseteq Y$, pick elements $f_1, \ldots, f_d \in B := \mathcal{O}_{Y,h(x)}$ whose images in the regular local ring $\mathcal{O}_{Y,h(x)}$ form a regular system of parameters (i.e. a regular sequence that generates the maximal ideal), and let $J \subseteq B$ be the ideal generated by the $f_i$, $i = 1, \ldots, d$. Let $I \subseteq A$ be any finitely generated $m_A$-primary ideal containing the image of $J$. We deduce a surjection $\varphi: V := B/J \to A/I$, and by construction $V/\mathfrak{m}_K V$ is a field; moreover, the induced map $K^+ \to V$ is flat by virtue of [50, Ch.IV, Th.11.3.8]. It follows that $V$ is a valuation ring with the sought properties, by proposition 9.1.32(ii). Also, $\varphi$ is finitely presented, by proposition 9.1.32(i).

Next, let $A$ be a general measurable $K^+$-algebra, and write $A$ as the colimit of a filtered system $(A_j | j \in J)$ of objects of $K^+-\text{m.} \text{Alg}_0$. We may assume that $0 \in J$ is an initial index, and the foregoing case yields an $m_{A_0}$-primary ideal $I_0 \subseteq A_0$, and a surjective finitely presented morphism $\varphi_0: V_0 \to A_0/I_0$ in $K^+-\text{m.} \text{Alg}_0$, from a valuation ring $V_0$, such that $\Gamma_V = \Gamma$. Notice that $A/I_0$ is a henselian ring, hence $\varphi_0$ extends to a ring homomorphism $\varphi_0^h: V_0^h \to A_0/I_0$ from the henselization $V_0^h$ of $V_0$; more precisely, $\varphi_0$ induces an isomorphism of $V_0^h$-algebras:

$$V_0^h \otimes_{V_0} (A_0/I_0) \xrightarrow{\sim} A_0/I_0$$

so $\varphi_0^h$ is still finitely presented. On the one hand, $\varphi_0^h$ induces an identification

$$\kappa(V_0^h) = \kappa(A_0).$$

On the other hand, we have the filtered system of separable field extensions $(\kappa(A_j) | j \in J)$, whose colimit is $\kappa(A)$. There follows a corresponding filtered system $(V_j^h | j \in J)$ of finite étale $V_0^h$-algebras, whose colimit we denote $V$ ([51, Ch.IV, Prop.18.5.15]). Then $V$ is a valuation ring, and the map $V_0^h \to V$ induces an isomorphism on value groups. Moreover, the induced isomorphisms $\kappa(V_j^h) \xrightarrow{\sim} \kappa(A_j)$ lift uniquely to morphisms of $A_0$-algebras $\varphi_j^h: V_j^h \to A_j/I_0 A_j$, for every $j \in J$ ([51, Ch.IV, Cor.18.5.12]). Due to the uniqueness of $\varphi_j^h$, we see that the resulting system $(\varphi_j^h | j \in J)$ is filtered, and its colimit is a morphism $\varphi: V \to A/I_0 A$. Moreover, $\varphi_j^h$ induces an isomorphism $V_j^h \otimes_{V_0} A_0/IA_0 \xrightarrow{\sim} A_j/I_0 A_j$, especially $\varphi_j^h$ is surjective for every $j \in J$, so the same holds for $\varphi$. More precisely, $\varphi_0^h$ induces an isomorphism $V \otimes_{V_0} (A_0/I_0) \xrightarrow{\sim} A/I_0 A$, hence $\varphi$ is still finitely presented. \hfill $\square$

**Theorem 14.5.43.** With the notation of (14.5.36), the following holds:

(i) For every measurable $K^+$-algebra $A$ there is a natural group isomorphism:

$$\lambda_A: K_0(A-\text{Mod}_{\text{coh},(s)}) \xrightarrow{\sim} \log \Gamma$$

which induces an isomorphism $K_0^+(A-\text{Mod}_{\text{coh},(s)}) \xrightarrow{\sim} \log \Gamma^+$.  

(ii) The family of isomorphisms $\lambda_A$ (for $A$ ranging over the measurable $K^+$-algebras) is characterized uniquely by the following two properties.

(a) If $V$ is a valuation ring and a flat measurable $K^+$-algebra, then

$$\lambda_V([M]) = \lambda_V(M)$$

for every object $M$ of $V-\text{Mod}_{\text{coh},(s)}$ where $\lambda_V(M)$ is defined as in (14.5.2).

(b) Let $\psi: A \to B$ be a morphism of measurable $K^+$-algebras inducing a finite residue field extension $\kappa(A) \to \kappa(B)$. Then

$$\lambda_A(\psi_*[M]) = [\kappa(B) : \kappa(A)] \cdot \lambda_B([M])$$

for every $[M] \in K_0(B-\text{Mod}_{\text{coh},(s)})$.

(iii) For every $a \in K^+\setminus\{0\}$ and any object $M$ of $A-\text{Mod}_{\text{coh},(s)}$ we have:
(a) $[M] = 0$ in $K_0(A\text{-Mod}_{coh,(s)})$ if and only if $M = 0$.
(b) If $M$ is flat over $K^+/aK^+$, then:

$$\lambda_A([M]) = |a| \cdot \text{length}_A(M \otimes_{K^+} \kappa) \quad (14.5.44)$$

(iv) Let $\psi : A \to B$ be a flat morphism of measurable $K^+$-algebras inducing an integral map $\kappa(A) \to B/m_AB$. Then:

$$\lambda_B(\psi^*[M]) = \text{length}_B(B/m_AB) \cdot \lambda_A([M]) \quad \text{for every } [M] \in K_0(A\text{-Mod}_{coh,(s)}).$$

Proof. We start out with the following:

Claim 14.5.45. Let $(\kappa, \cdot | \cdot) \to (E, \cdot | \cdot)$ be an extension of valued fields of rank one inducing an isomorphism of value groups, $a \in K^+ \setminus \{0\}$ any element, $M$ an $E^+/aE^+$ module. Then:

(i) $M$ is a flat $E^+/aE^+$-module if and only if it is a flat $K^+/aK^+$-module.
(ii) $M \otimes_{K^+} \kappa = M \otimes_{E^+} \kappa(E) \quad (14.5.45\text{ii}).$

Proof of the claim. According to [100, Th.7.8], in order to show (i) it suffices to prove that

$$\text{Tor}_1^{E^+/aE^+}(E^+/bE^+, M) = \text{Tor}_1^{K^+/aK^+}(K^+/bK^+, M)$$

for every $b \in K^+$ such that $|b| \geq |a|$. The latter assertion is an easy consequence of the faithful flatness of the extension $K^+ \to E^+$. (ii) follows from the identity : $m_E = m_K E^+$, which holds since $\Gamma = \Gamma_E = \Gamma$.

Claim 14.5.46. Let $f : K^+ \to V$ be a morphism of measurable $K^+$-algebras, where $V$ is a valuation ring and $f$ induces an isomorphism on value groups. Then $\lambda_V$ (defined by (ii.a)) is an isomorphism and assertion (iii) holds for $A = V$.

Proof of the claim. According to (ii.a), $\lambda_V([M]) = \lambda_V(M)$ for every finitely presented torsion $V$-module. However, every such module $M$ admits a decomposition of the form $M \cong (V/a_1 V) \oplus \cdots \oplus (V/a_k V)$, with $a_1, \ldots, a_k \in m_K$ ([59, Lemma 6.1.14]). Then by claim 14.5.45(i), $M$ is flat over $K^+/aK^+$ if and only if $M$ is flat over $V/a_i V$, if and only if $|a| = |a_i|$ for every $i \leq k$. In this case, an explicit calculation shows that $\lambda_V(M) = |a| \cdot \text{length}(M \otimes_V \kappa(V))$, which is equivalent to (14.5.44), in view of claim 14.5.45(ii). Next, we consider the map:

$$\mu : \log \Gamma^+ \to K_0(V\text{-Mod}_{coh,(s)}) : \quad |a| \mapsto [V/a_i V] \quad \text{for every } a \in K^+ \setminus \{0\}. $$

We leave to the reader the verification that $\mu$ extends to a group homomorphism well-defined on the whole of $\Gamma$, that provides an inverse to $\lambda_V$. Finally, it is clear that $\lambda_V(M) = 0$ if and only if $M = 0$, so also (iii.a) holds.

Claim 14.5.47. Let $A$ be any measurable $K^+$-algebra. For every object $N$ of $A\text{-Mod}_{coh,(s)}$ there exist a finite filtration $0 = N_0 \subset \cdots \subset N_k = N$ by finitely presented $A$-submodules, and elements $a_1, \ldots, a_k \in m$ such that $N_i/N_{i-1}$ is a flat $K^+/a_i K^+$-module for every $1 \leq i \leq k$.

Proof of the claim. Let us find $I \subset A$ and $\varphi : V \to A/I$ as in lemma 14.5.42. It suffices to show the claim for the finitely presented $A$-modules $I^n N/I^{n+1} N$ (for every $n \in \mathbb{N}$), hence we may assume that $N$ is an $A/I$-module. Then $\varphi_* N$ is a finitely presented $V$-module, hence of the form $(V/a_1 V) \oplus \cdots \oplus (V/a_k V)$ for some $a_i \in m$; we may order the summands so that $|a_i| \geq |a_{i+1}|$ for all $i < k$. We argue by induction on $d(N) := \dim_k(N \otimes_V \kappa(V))$. If $d(N) = 0$, then $N = 0$ by Nakayama’s lemma. Suppose $d \geq 0$; we remark that $N/a_1 N$ is a flat $V/a_1 V$-module, hence a flat $K^+/a_1 K^+$-module (claim 14.5.45), and $d(a_1 N) < d(N)$; the claim follows.

\[\diamondsuit\]
Claim 14.5.48. Let \( A \) be any measurable \( K^+ \)-algebra, \( I \subset A \) a finitely generated \( \mathfrak{m}_A \)-primary ideal, and \( \pi_I : A \to A/I \) the natural projection. Then the map:

\[
\pi_I^* : K_0(A/I - \text{Mod}_{\text{coh}}) \to K_0(A - \text{Mod}_{\text{coh}, \{a\}})
\]

is an isomorphism.

Proof of the claim. On the one hand we have:

\[
A - \text{Mod}_{\text{coh}, \{a\}} = \bigcup_{n \in \mathbb{N}} A/I^n - \text{Mod}_{\text{coh}}
\]

and on the other hand, in view of lemma [14.5.38], we see that the projections \( A/I^{n+1} \to A/I^n \) induce isomorphisms \( K_0(A/I^n - \text{Mod}_{\text{coh}}) \to K_0(A/I^{n+1} - \text{Mod}_{\text{coh}}) \) for every \( n > 0 \), whence the claim.

Let \( A, I \) and \( \varphi : V \to A/I \) be as in lemma [14.5.42] and \( \pi_I : A \to A/I \) the natural surjection; taking into account claim [14.5.48] we may let:

\[
\lambda_A := \lambda_V \circ \varphi_* \circ \pi_I^*
\]

where \( \lambda_V \) is given by the rule of (ii.a). In view of claim [14.5.46] we see that \( \lambda_A([M]) = 0 \) if and only if \( M = 0 \), so (iii.a) follows already.

Claim 14.5.50. The isomorphism \( \lambda_A \) is independent of the choice of \( I, V \) and \( \varphi \).

Proof of the claim. Indeed, suppose that \( J \subset A \) is another ideal and \( \psi : W \to A/J \) is another surjection from a valuation ring \( W \), fulfilling the foregoing conditions. We consider the commutative diagram

\[
\begin{array}{ccc}
A/I & \xrightarrow{\varphi'} & V \\
\pi_I & \downarrow \pi_J & \uparrow \pi_J \\
A & \xrightarrow{\pi_J} & A/(I + J) \\
\pi_J & \downarrow \pi_J & \uparrow \psi \\
A/J & \xleftarrow{\psi'} & W.
\end{array}
\]

We compute:

\[
\varphi' \circ \pi_J^* = \varphi_* \circ \pi_J^* \circ \pi_J^* = \varphi_* \circ \pi_J^*.
\]

and a similar calculation shows that \( \psi_* \circ \pi_J^* = \psi' \circ \pi_J^* \). We are thus reduced to showing that \( \lambda_V \circ \varphi_*([M]) = \lambda_W \circ \psi_*([N]) \) for every \( A/(I + J) \)-module \( N \). In view of claim [14.5.47] we may assume that \( N \) is flat over \( K^+/aK^+ \), for some \( a \in \mathfrak{m} \), in which case the assertion follows from claim [14.5.46].

Claims [14.5.46] and [14.5.50] show already that (i) holds. Next, let \( \psi : A \to B \) be as in (ii.b). Choose an ideal \( I \subset A \) and a surjection \( \varphi : V \to A/I \) as in lemma [14.5.42]. Let also \( J \subset B \) be a finitely generated \( \mathfrak{m}_B \)-primary ideal containing \( \psi(I) \), and \( \overline{\psi} : A/I \to B/J \) the induced map.

By inspecting the definitions we see that (ii.b) amounts to the identity:

\[
\lambda_V((\overline{\psi} \circ \varphi)_*[M]) = [\kappa(B) : \kappa(A)] \cdot \lambda_B([M]),
\]

for every finitely presented \( B/J \)-module \( M \). Furthermore, up to enlarging \( J \), we may assume that there is a finitely presented surjection \( \xi : W \to B/J \) of \( K^+ \)-algebras, where \( W \) is a valuation ring with value group \( \Gamma \), and then we come down to showing:

\[
\lambda_V((\overline{\psi} \circ \varphi)_*[M]) = [\kappa(B) : \kappa(A)] \cdot \lambda_W(\xi_*[M]).
\]

In view of claim [14.5.47] we may also assume that \( M \) is a flat \( K^+/aK^+ \)-module for some \( a \in \mathfrak{m} \), in which case the identity becomes:

\[
|a| \cdot \text{length}_V(M \otimes_{K^+} \kappa) = [\kappa(B) : \kappa(A)] \cdot |a| \cdot \text{length}_W(M \otimes_{K^+} \kappa).
\]
thanks to claim 14.5.46. However, the latter is an easy consequence of the identities: \( \kappa(A) = \kappa(V) \) and \( \kappa(B) = \kappa(W) \). Next, we show that (iii.b) holds for a general measurable \( K^+ \)-algebra \( A \). Indeed, let \( M \) be any object of \( A \text{-Mod}_{\text{coh},(s)} \); as usual, we may find a local ind-étale map \( A_0 \to A \) from some object \( A_0 \) of \( K^+ \text{-m.Alg}_0 \), and an object \( M_0 \) of \( A_0 \text{-Mod}_{\text{coh},(s)} \) with an isomorphism of \( A \)-modules \( A \otimes_{A_0} M_0 \to M \) (cp. the proof of proposition 14.5.39(i)). Since (ii.b) is already proved, we have

\[
\lambda_A([M]) = \lambda_{A_0}([M_0]) \quad \text{and} \quad \text{length}_A(M \otimes_{K^+} \kappa) = \text{length}_{A_0}(M \otimes_{K^+} \kappa).
\]

Therefore, we may replace \( A \) by \( A_0 \), and assume that \( A \) is an object of \( K^+ \text{-m.Alg}_0 \). In this case, by lemma 9.1.30 we may find morphisms \( f : K^+ \to V \) and \( g : V \to A \) in \( K^+ \text{-m.Alg}_0 \) such that \( V \) is a valuation ring with value group \( \Gamma \) and \( g \) induces a finite extension of residue fields \( \kappa(V) \to \kappa(A) \). Let \( N \) be an \( A \)-module supported at an \( A \text{-primary ideal} \ I \subset A \) such that \( I \subset Ann_A(N) \), and since (ii.b) is already known in general, we reduce to showing that (iii.b) holds for the \( A/I \)-module \( N \). However, the induced map \( \overline{f} : V \to A/I \) is finite and finitely presented (proposition 9.1.32(i)), so another application of (ii.b) reduces to showing that \( (14.5.44) \) holds for \( A := V \) and \( M := \overline{f}_* N \), in which case the assertion is already known by claim 14.5.46.

(ii.a): Suppose that \( A \) is a valuation ring, and let \( M \) be any object of \( A \text{-Mod}_{\text{coh},(s)} \). The sought assertion is obvious when \( \Gamma_I = \Gamma \), since in that case we can choose \( A = V \) and \( \varphi = \pi_I \) in (14.5.49). However, we know already that the rank of \( A \) equals one, and \( e := ([\Gamma] : \Gamma) \) is finite (see (14.5.5)); we can then assume that \( e > 1 \), in which case corollary 11.4.41(ii) implies that \( \Gamma \simeq \mathbb{Z} \). Then it suffices to check (ii.a) for \( M = \kappa(A) \), which is a (flat) \( \kappa \)-module, so that – by assertion (iii) – one has \( \lambda_A([M]) = e \cdot \gamma_0 \), where \( \gamma_0 \in \log \Gamma^+_A \) is the positive generator. In view of remark 14.5.14 we see that this value agrees with \( \lambda^*_V(M) \), as stated.

(iv): In view of claim 14.5.47, we may assume that \( M \) is a flat \( K^+/aK^+ \)-module, for some \( a \in \mathfrak{m} \), and then the same holds for \( \psi^* M \), since \( \psi \) is flat. In view of (iii.b), it then suffices to show that:

\[
\text{length}_B(B \otimes_A M) = \text{length}_A(M) \cdot \text{length}_B(B/\mathfrak{m}_A B)
\]

for any \( A \)-module \( M \) of finite length. In turn, this is easily reduced to the case where \( M = \kappa(A) \), for which the identity is obvious.

14.5.51. Let \( A \) be a measurable \( K^+ \)-algebra. The next step consists in extending the definition of \( \lambda_A \) to the category \( A \text{-Mod}_{(s)} \) of arbitrary \( A \)-modules \( M \) supported at \( s(A) \). First of all, suppose that \( M \) is finitely generated. Let \( \mathcal{C}_M \) be the set of isomorphism classes of objects \( M' \) of \( A \text{-Mod}_{\text{coh},(s)} \) that admit a surjection \( M' \to M \). Then we set:

\[
\lambda^*_A(M) := \inf \{ \lambda_A([M']) \mid M' \in \mathcal{C}_M \} \in \log \Gamma^+.
\]

Notice that – by the positivity property of theorem 14.5.43(i) – we have \( \lambda^*_A(M) = \lambda_A([M]) \) whenever \( M \) is finitely presented. Next, for a general object of \( A \text{-Mod}_{(s)} \) we let:

\[
\lambda_A(M) := \sup \{ \lambda^*_A(M') \mid M' \subset M \text{ and } M' \text{ is finitely generated} \} \in \log \Gamma^+ \cup \{+\infty\}.
\]

Lemma 14.5.53. If \( M \) is finitely generated, then \( \lambda^*_A(M) = \lambda_A(M) \).

Proof. Let \( M' \subset M \) be a finitely generated submodule; we have to show that \( \lambda^*(M') \leq \lambda^*(M) \). To this aim, let \( f : N \to M \) and \( g : N' \to M' \) be two surjections of \( A \)-modules with \( N \in \mathcal{C}_M \) and \( N' \in \mathcal{C}_{M'} \); by filtering the kernel of \( f \) by the system of its finitely generated submodules, we obtain a filtered system \( (N_i \mid i \in I) \) of finitely presented quotients of \( N \), with surjective transition maps, such that \( \text{colim}_{i \in I} N_i = M \). By [59, Prop.2.3.16(ii)] the induced map \( N' \to M \) lifts to a map \( h : N' \to N_i \) for some \( i \in I \). Since \( A \) is coherent, \( h(N') \) is a finitely presented \( A \)-module with a surjection \( h(N') \to M' \), hence \( \lambda^*_A(M') \leq \lambda_A([h(N')]) \leq \lambda_A([N_i]) \leq \lambda_A(N) \). Since \( N \) is arbitrary, the claim follows.
**Proposition 14.5.54.** (i) If $A$ is a valuation ring, \(14.5.52\) agrees with \(14.5.9\).

(ii) If \((M_i \mid i \in I)\) is a filtered system of objects of $A$-$\text{Mod}_{(s)}$ with injective (resp. surjective) transition maps, then:

\[
\lambda_A(\text{colim}_{i \in I} M_i) = \lim_{i \in I} \lambda_A(M_i)
\]

(resp. provided there exists $i \in I$ such that $\lambda_A(M_i) < +\infty$).

(iii) If $\psi : A \to B$ is a morphism of measurable $K^+$-algebras inducing a finite extension $\kappa(A) \to \kappa(B)$ of residue fields, then:

\[
\lambda_B(M) = \frac{\lambda_A(\psi_* M)}{[\kappa(B) : \kappa(A)]}
\]

for every object $M$ of $B$-$\text{Mod}_{(s)}$.

(iv) Let $0 \to M_1 \to M_2 \to M_3 \to 0$ be a short exact sequence in $A$-$\text{Mod}_{(s)}$. Then:

\[
\lambda_A(M_2) = \lambda_A(M_1) + \lambda_A(M_3).
\]

(v) Let $\psi$ be a flat morphism of measurable $K^+$-algebras inducing an integral map $\kappa(A) \to B/m_A B$. Then:

\[
\lambda_B(\psi^* M) = \text{length}_B(B/m_A B) \cdot \lambda_A(M)
\]

for every object $M$ of $A$-$\text{Mod}_{(s)}$.

**Proof.** (i): Set $e := (\Gamma_i : \Gamma)$. It suffices to check the assertion for a finitely generated $A$-module $M$, in which case one has to show the identity:

\[
e \cdot |F_0(M)^a| = \lambda_A^*(M).
\]

By proposition \(14.5.12\) we have $|F_0(M)^a| \geq |F_0(M)^a|$ for every $M' \in \mathcal{C}_M$, hence $\lambda_A^*(M) \geq e \cdot |F_0(M)^a|$. On the other hand, let us fix a surjection $V^\oplus \to M$, and let us write its kernel in the form $K = \bigcup_{i \in I} K_i$, for a filtered system $(K_i \mid i \in I)$ of a finitely generated $V$-submodules; it follows that:

\[
F_0(M) = \bigcup_{i \in I} F_0(V^\oplus / K_i).
\]

In view of proposition \(14.5.12\) we deduce:

\[
e \cdot |F_0(M)^a| = \lim_{i \in I} e \cdot |F_0(V^\oplus / K_i)^a| \geq \lambda_A^*(M).
\]

The proof of (ii) in the case where the transition maps are injective, is the same as that of proposition \(14.5.12\). iii.b).

(iii): Let us write $M = \bigcup_{i \in I} M_i$ for a filtered family $(M_i \mid i \in I)$ of finitely generated $B$-submodules. By the case already known of (ii) we have:

\[
\lambda_B(M) = \lim_{i \in I} \lambda_B(M_i),
\]

and likewise for $\lambda_A(\psi_* M)$, hence we may assume from start that $M$ is a finitely generated $B$-module, in which case the annihilator of $M$ contains a finitely generated $m_B$-primary ideal $J' \subset B$. Choose a finitely generated $m_A$-primary ideal $J \subset A$ contained in the kernel of the induced map $A \to B/J'$.

**Claim 14.5.55.** $\lambda_B(M) = \lambda_{B/J'}(M)$ and $\lambda_A(\psi_* M) = \lambda_{A/J}(\psi_* M)$.

**Proof of the claim.** Directly on the definition (and by applying theorem \(14.5.43\) ii.b) to the surjection $B \to B/J'$ we see that $\lambda_B(M) \leq \lambda_{B/J'}(M)$. On the other hand, any surjection of $B$-modules $M' \to M$ with $M'$ finitely presented, factors through the natural map $M' \to M'/J'M'$, and by theorem \(14.5.43\) i.ii.b we have $\lambda_B(M') - \lambda_{B/J'}(M'/J'M') = \lambda_B(J'M') \geq 0$, whence the first stated identity. The proof of the second identity is analogous.

In view of claim \(14.5.55\) we are reduced to proving the assertion for the morphism $\overline{\psi}$ and the $B/J'$-module $M$, hence we may replace $\psi$ by $\overline{\psi}$, and assume from start that $A$ and $B$ have Krull dimension zero.
Claim 14.5.56. Let \( A \) be a measurable \( K^+ \)-algebra of Krull dimension zero. Then there exists a morphism \( \varphi : V \to A \) of measurable \( K^+ \)-algebras, with \( V \) a valuation ring flat over \( K^+ \), such that the residue field extension \( \kappa(V) \to \kappa(A) \) is finite, and the induced map of value groups \( \Gamma \to \Gamma_V \) is an isomorphism.

Proof of the claim. Let \( A_0 \to A \) be a local ind-étale map, from an object \( A_0 \) of \( K^+-\mathbf{Alg}_0 \). By lemma 9.1.30 we may find a \( K^+ \)-flat valuation ring \( V_0 \) in \( K^+-\mathbf{Alg}_0 \) and a local map \( \varphi_0 : V \to A_0 \), inducing a finite residue field extension \( \kappa(V_0) \to \kappa(A_0) \) and an isomorphism on value groups \( \Gamma \to \Gamma_V \). Then \( A_0 \) has also Krull dimension zero; especially, it is henselian, hence \( \varphi_0 \) factors through a morphism \( \varphi_0^h : V_0^h \to A_0 \), from the henselization \( V_0^h \) of \( V_0 \). Let \( E \subset \kappa(A) \) be the largest separable subextension of \( \kappa(V_0) = \kappa(V_0^h) \) contained in \( \kappa(A) \); there exists a unique (up to unique isomorphism) finite étale morphism \( V_0^h \to V' \) with an isomorphism \( \kappa(V') \to E \) of \( \kappa(V_0)-\)algebras, and \( \varphi_0^h \) factors through a morphism \( V' \to A_0 \). Notice that \( V' \) is still a henselian valuation ring and a measurable \( K^+ \)-algebra, hence we may replace \( V_0 \) by \( V' \), and assume that \( V_0 \) is henselian, and the residue field extension \( \varphi_0 : \kappa(V_0) \to \kappa(A_0) \) is purely inseparable. Since \( A_0 \) is henselian, we may write \( A \) as the colimit of a filtered system \( (A_i \mid i \in I) \) of finite étale \( A_0 \)-algebras. Now, on the one hand, \( \varphi_0_i \) induces an equivalence from the category of finite étale \( \kappa(V_0)-\)algebras, to the category of finite étale \( \kappa(A_0)-\)algebras (lemma 13.1.7(i)). On the other hand, the category of finite étale \( V_0 \)-algebras is equivalent to the category of finite étale \( \kappa(V_0)-\)algebras, and likewise for \( A_0 \). Therefore, for every \( i \in I \) we may find a finite étale morphism \( V_0 \to V_i \), unique up to unique isomorphism, inducing an isomorphism of \( \kappa(A_0)-\)algebras:

\[
\kappa(V_i) \otimes_{\kappa(V_0)} \kappa(A_0) \cong \kappa(A_i)
\]

and the transition maps of residue fields \( \kappa(A_i) \to \kappa(A_j) \) induce unique maps \( V_i \to V_j \) of \( V_0 \)-algebras, compatible with the isomorphisms (14.5.57). Hence, the resulting system \( (V_i \mid i \in I) \) is filtered, and its colimit is a valuation ring \( V \), which is still a measurable \( K^+ \)-algebra. Moreover, the field extensions \( \kappa(V_i) \to \kappa(V) \) induced from (14.5.57) lift uniquely to maps of \( V_0 \)-algebras \( V_i \to A_i \) ([51, Ch.IV, Cor.18.5.12]); taking colimits, we get finally a map \( V \to A \) as sought.

Let \( \varphi \) be as in claim 14.5.56; clearly it suffices to prove the sought identity for the two morphisms \( \psi \circ \varphi \) and \( \varphi \), so we may replace \( A \) by \( V \), and assume from start that \( A \) is a valuation ring. Let us set \( d := [\kappa(B) : \kappa(A)] \); we deduce:

\[
\lambda_B(M) = \inf \{d^{-1} \cdot \lambda_A(\psi_* M') \mid M' \in \mathcal{C}_M\} \geq d^{-1} \cdot \lambda_A(\psi_* M)
\]

by theorem 14.5.43(ii.b). Furthermore, let us choose a surjection \( B^{\oplus k} \to M \), whose kernel we write in the form \( \bigcup_{i \in I} K_i \) where \( (K_i \mid i \in I) \) is a filtered family of finitely generated \( B \)-submodules of \( K \). Next, by applying (i), proposition 14.5.12(i,iii.b), and theorem 14.5.43(ii.b) we derive:

\[
\begin{align*}
\lambda_B(M) &\leq \inf \{\lambda_B(B^{\oplus k}/K_i) \mid i \in I\} = \inf \{d^{-1} \cdot \lambda_A(\psi_* (B^{\oplus k}/K_i)) \mid i \in I\} \\
&= d^{-1} \cdot \lambda_A(\psi_* B^{\oplus k}) - \sup \{\lambda_A(\psi_* K_i) \mid i \in I\} \\
&= d^{-1} \cdot \lambda_A(\psi_* B^{\oplus k}) - \lambda_A(\psi_* K) \\
&= d^{-1} \cdot \lambda_A(\psi_* M)
\end{align*}
\]

whence the claim.

(iv): Let \( (N_i \mid i \in I) \) be the filtered system of finitely generated submodules of \( M_2 \). For every \( i \in I \) we have short exact sequences: \( 0 \to M_1 \cap N_i \to N_i \to \overline{N}_i \to 0 \), where \( \overline{N}_i \) is the image of \( N_i \) in \( M_3 \). In view of the case of (ii) already known, we may then replace \( M_2 \) by \( N_i \), and thus assume from start that \( M_2 \) is finitely generated, so that we may find a finitely generated \( \mathfrak{m}_A \)-primary ideal \( J \subset A \) that annihilates \( M_2 \). By (iii) we have \( \lambda_A(M_2) = \lambda_{A/J}(M_2) \), and likewise for \( M_1 \) and \( M_3 \), hence we may replace \( A \) by \( A/J \). By claim 14.5.56 we may then
find a morphism $V \to A$ of measurable $K^+$-algebras with $V$ a valuation ring, inducing a finite residue field extension $\kappa(V) \to \kappa(A)$; then again (iii) reduces to the case where $A = V$, to which one may apply (i) and proposition $[14.5.12]$ (i) to conclude the proof.

Next we consider assertion (ii) for the case where the transition maps are surjective. We may assume that $I$ admits a smallest element $i_0$; for every $i \in I$ let $K_i$ denote the kernel of the transition map $M_{i_0} \to M_i$. We deduce a short exact sequence:

$$0 \to \bigcup_{i \in I} K_i \to M_{i_0} \to \text{colim}_{i \in I} M_i \to 0$$

and we may then compute using (iv) and the previous case of (ii):

$$\lambda_A(\text{colim}_{i \in I} M_i) = \lambda_A(M_{i_0}) - \lambda_A\left(\bigcup_{i \in I} K_i\right) = \lim_{i \in I} (\lambda_A(M_{i_0}) - \lambda_A(K_i)) = \lim_{i \in I} \lambda_A(M_{i_0}/K_i)$$

whence the claim.

(v): Since $\psi_i$ is an exact functor which commutes with colimits, we may use (ii) to reduce to the case where $M$ is finitely presented, for which the assertion is already known, in view of theorem $[14.5.43]$ (iv).

Remark 14.5.58. Suppose that the valuation of $K$ is discrete; then one sees easily that theorem $[14.5.43]$ (i,iii) still holds (with simpler proof) when $A$ is replaced by any local noetherian $K^+$-algebra, and by inspecting the definition, the resulting map $\lambda_A$ is none else than the standard length function for modules supported on $\{s(A)\}$.

Lemma 14.5.59. Let $A$ be a measurable $K^+$-algebra, and $M$ an $A$-module supported at $s(A)$ with $\lambda_A(M) < \infty$. Then

$$\{ a \in K^+ \mid \log |a| > \lambda_A(M) \} \subset \text{Ann}_{K^+} M.$$

Proof. Using proposition $[14.5.54]$ (ii), we easily reduce, first, to the case where $M$ is finitely generated, and second, to the case where $M$ is finitely presented. Pick an ideal $I \subset A$ and a valuation ring $V$ mapping onto $A/I$, as in lemma $[14.5.42]$ by considering the $I$-adic filtration of $M$, the additivity properties of $\lambda_A$ allow to further reduce to the case where $M$ is an $A/I$-module. Next, by theorem $[14.5.43]$ (ii.b) we may replace $A$ by $V$, and therefore assume that $A$ is a valuation ring whose value group equals $\Gamma$. In this case, $\lambda_A$ is computed by Fitting ideals, so the assertion follows easily from $[59]$ Prop.6.3.6(iii)).

14.5.60. Let us consider a $K^+$-algebra $R_\infty$ that is the colimit of an inductive system

$$(14.5.61)\quad R_0 \to R_1 \to R_2 \to \cdots$$

of morphisms of measurable $K^+$-algebras inducing integral ring homomorphisms $\kappa(R_i) \to R_{i+1}/m_{R_i} R_i$ for every $i \in \mathbb{N}$. The final step consists in generalizing the definition of normalized length to the category $R_\infty\text{-Mod}_{(a)}$ of $R_\infty$-modules supported at the closed point $s(R_\infty)$ of $\text{Spec } R_\infty$. To this purpose, we shall axiomatize the general situation in which we can solve this problem. Later we shall see that our axioms are satisfied in many interesting cases.

14.5.62. Hence, let $R_\infty$ be as in $(14.5.60)$. After fixing an order-preserving isomorphism

$$(14.5.63)\quad (\mathbb{Q} \otimes \mathbb{Z} \log \Gamma)^{^\wedge} \overset{\sim}{\to} \mathbb{R}$$

we may regard the mappings $\lambda_A$ (for any measurable $K^+$-algebra $A$) as real-valued functions on $A$-modules. To ease notation, for every $R_n$-module $N$ supported on $\{s(R_n)\}$ we shall write $\lambda_n(N)$ instead of $\lambda_{R_n}(N)$. Notice that, for every such $N$, and every $m \geq n$, the $R_m$-module $R_m \otimes_{R_n} N$ is supported at $\{s(R_m)\}$, since by assumption the map $R_n \to R_m/m_{R_n}R_m$ is integral.

Definition 14.5.64. In the situation of \( \text{(14.5.62)} \), we say that \( R_\infty \) is an ind-measurable \( K^+ \)-algebra, if there exists a sequence of real normalizing factors \((d_n > 0 \mid n \in \mathbb{N})\) such that:

(a) For every \( n \in \mathbb{N} \) and every object \( N \) of \( R_n\text{-Mod}_{\text{coh},(s)} \), the sequence:

\[
m \mapsto d_n^{-1} \cdot \lambda_m(R_m \otimes_{R_n} N)
\]

converges to an element \( \lambda_\infty(R_\infty \otimes_{R_n} N) \in \mathbb{R} \).

(b) For every \( m \in \mathbb{N} \), every finitely generated \( mR_0 \)-primary ideal \( I \subset R_0 \), and every \( \varepsilon > 0 \) there exists \( \delta(m,\varepsilon,I) > 0 \) such that the following holds. For every \( n \in \mathbb{N} \) and every surjection \( N \to N' \) of finitely presented \( R_n/IR_n \)-modules generated by \( m \) elements, such that

\[
|\lambda_\infty(R_\infty \otimes_{R_n} N) - \lambda_\infty(R_\infty \otimes_{R_n} N')| \leq \delta(m,\varepsilon,I)
\]

we have:

\[
d_n^{-1} \cdot |\lambda_n(N) - \lambda_n(N')| \leq \varepsilon.
\]

14.5.65. Assume now that \( R_\infty \) is ind-measurable, and let \( N \) be a finitely presented \( R_n \)-module supported on \( \{s(R_n)\} \). The first observation is that \( \lambda_\infty(R_\infty \otimes_{R_n} N) \) only depends on the \( R_\infty \)-module \( R_\infty \otimes_{R_n} N \). Indeed, suppose that \( R_\infty \otimes_{R_n} M \simeq R_\infty \otimes_{R_n} N \) for some \( m \in \mathbb{N} \) and some finitely presented \( R_m \)-module \( M \); then there exists \( p \geq m, n \) such that \( R_p \otimes_{R_n} M \simeq R_p \otimes_{R_n} N \), and then the assertion is clear.

The second observation – contained in the following lemma \( \text{[14.5.66]} \) – will show that the conditions of definition \( \text{[14.5.64]} \) impose some non-trivial restrictions on the inductive system \( (R_n \mid n \in \mathbb{N}) \).

Lemma 14.5.66. Let \( (R_n; d_n \mid n \in \mathbb{N}) \) be an inductive system of measurable \( K^+ \)-algebras and a sequence of positive reals, fulfilling conditions (a) and (b) of definition \( \text{[14.5.64]} \). Then:

(i) The natural map

\[
M \to R_m \otimes_{R_n} M
\]

is injective for every \( n, m \in \mathbb{N} \) with \( m \geq n \) and every \( R_n \)-module \( M \).

(ii) Especially, the transition maps \( R_n \to R_{n+1} \) are injective for every \( n \in \mathbb{N} \).

(iii) Suppose that \( (d'_n \mid n \in \mathbb{N}) \) is another sequence of positive reals such that conditions (a) and (b) hold for the datum \( (R_n; d'_n \mid n \in \mathbb{N}) \). Then the sequence \( (d_n/d'_n \mid n \in \mathbb{N}) \) converges to a non-zero real number.

Proof. (i): We reduce easily to the case where \( M \) is finitely presented over \( R_n \). Let \( N \subset \text{Ker}(M \to R_m \otimes_{R_n} M) \) be a finitely generated \( R_n \)-module; since \( R_n \) is coherent, \( N \) is a finitely presented \( R_n \)-module. We suppose first that \( M \) is in \( R_n\text{-Mod}_{\text{coh},(s)} \).

Claim 14.5.67. The natural map \( R_m \otimes_{R_n} M \to R_m \otimes_{R_n} (M/N) \) is an isomorphism.

Proof of the claim. On the one hand, the \( R_m \)-module \( R_m \otimes_{R_n} M \) represents the functor

\[
R_m\text{-Mod} \to \text{Set} : Q \mapsto \text{Hom}_{R_n}(M,Q).
\]

On the other hand, the assumption on \( N \) implies that \( \text{Hom}_{R_n}(M,Q) = \text{Hom}_{R_n}(M/N,Q) \) for every \( R_n \)-module \( Q \), so the claim follows easily.

From claim \( \text{[14.5.67]} \) we deduce that the natural map \( R_\infty \otimes_{R_n} M \to R_\infty \otimes_{R_n} (M/N) \) is an isomorphism, and then condition (b) says that \( \lambda_n(M) = \lambda_n(M/N) \), hence \( \lambda_n(N) = 0 \) and finally \( N = 0 \), as stated. Next, suppose \( M \) is any finitely presented \( R_n \)-module, and pick a finitely generated \( mR_n \)-primary ideal \( I \subset R_n \).

Claim 14.5.68. There exists \( c \in \mathbb{N} \) such that \( N \cap I^{k+c}M = I^k(N \cap I^cM) \) for every \( k \geq 0 \).
Proof of the claim. We may find a local ind-étale map $A \to R_n$ of $K^+$-algebras, where $A$ is an object of $K^+-\mathbf{Alg}_0$, and such that $I$, $M$ and $N$ descend respectively to a finitely generated ideal $I_0 \subset A$, a finitely presented $A$-module $M_0$, and a finitely generated submodule $N_0 \subset M_0$. Then theorem 11.4.45 ensures the existence of $c \in \mathbb{N}$ such that $N_0 \cap I_0^{k+c} M_0 = I_0^c (N_0 \cap I_0^c M_0)$ for every $k \geq 0$. Since $R_n$ is a faithfully flat $A$-algebra, the claim follows. \hfill \diamond

Pick $c \in \mathbb{N}$ as in claim 14.5.68: then $N/(N \cap I^k c M)$ is in the kernel of the natural map $M/I^k c M \to R_m \otimes_{R_n} (M/I^k c M)$, hence $N = N \cap I^k c M$ by the foregoing, so that $N \subset I^k N$ for every $k \geq 0$, and finally $N = 0$ by Nakayama’s lemma.

(ii) is a special case of (i). To show (iii), let us denote by $\lambda^\prime_M(M)$ the normalized length of any object $M$ of $R_\infty-\mathbf{Mod}_{\mathbf{coh},(s)}$, defined using the sequence $(d^\prime_n | n \in \mathbb{N})$. From (b) it is clear that $\lambda^\prime_M(M), \lambda^\prime_M(M) \neq 0$ whenever $M \neq 0$. Then, for any such non-zero $M$, the quotient $\lambda^\prime_M(M)/\lambda_M(M)$ is the limit of the sequence $(d_n/d^\prime_n | n \in \mathbb{N})$. \hfill \Box

Remark 14.5.69. (i) There is another situation of interest which leads to a well-behaved notion of normalized length. Namely, suppose that $R_* := (R_n | n \in \mathbb{N})$ is an inductive system of local homomorphisms of local noetherian rings, such that the fibres of the induced morphisms $\text{Spec } R_{n+1} \to \text{Spec } R_n$ have dimension zero, and denote by $R_\infty$ the inductive limit of the system $R_*$. For every $n \in \mathbb{N}$, let also $\lambda_n$ be the usual length function on the set of isomorphism classes of finitely generated $R_n$-modules supported on $s(R_n)$. Then for every $m, n \in \mathbb{N}$ with $m \geq n$, and every $R_n$-module $M$ of finite length, the $R_m$-module $R_m \otimes_{R_n} M$ has again finite length, so the analogues of conditions (a) and (b) of (14.5.62) can be formulated (cp. remark 14.5.58), and if these conditions hold for $R_*$, we shall say that $R_\infty$ is an ind-measurable ring. In such situation, lemma 14.5.66 – as well as the forthcoming lemma 14.5.70 and theorem 14.5.75 – still hold, with simpler proofs: we leave the details to the reader.

(ii) In spite of the uniqueness properties expressed by lemma 14.5.66, we do not know to which extent the normalized length of an ind-measurable $K^+$-algebra depends on the chosen tower of measurable algebras. Namely, suppose that $(R_n | n \in \mathbb{N})$ and $(R_n' | n \in \mathbb{N})$ are two such towers, with isomorphic colimit $R_\infty$, and suppose that we have found normalizing factors $(d_n | n \in \mathbb{N})$ (resp. $(d^\prime_n | n \in \mathbb{N})$) for the first (resp. second) tower, whence a normalized length $\lambda_\infty$ (resp. $\lambda^\prime_\infty$) for $R_\infty$-modules. Then we do not know whether the ratio of $\lambda_\infty$ and $\lambda^\prime_\infty$ is a constant.

Next, for a given finitely generated $R_\infty$-module $M$ supported on $\{s(R_\infty)\}$, we shall proceed as in (14.5.51): we denote by $\mathcal{C}_M$ the set of isomorphism classes of finitely presented $R_\infty$-modules supported on $\{s(R_\infty)\}$ that admit a surjection $M' \to M$, and we set

$$\lambda^*_{\infty}(M) := \inf \{\lambda_\infty(M') | M' \in \mathcal{C}_M\} \in \mathbb{R}.$$

Directly on the definitions, one checks that $\lambda^*_{\infty}(M) = \lambda_\infty(M)$ if $M$ is finitely presented.

Lemma 14.5.70. Let $M$ be a finitely generated $R_\infty$-module, $\Sigma \subset M$ any finite set of generators, $(N_i | i \in I)$ any filtered system of objects of $R_\infty-\mathbf{Mod}_{\mathbf{coh},(s)}$, with surjective transition maps, such that $\text{colim}_{i \in I} N_i \simeq M$. Then:

(i) $\lambda^*_{\infty}(M) = \lim_{n \to \infty} d^{-1} \cdot \lambda_n(\Sigma R_n)$.

(ii) If every $N_i$ is finitely generated, we have:

$$\inf \{\lambda^*_{\infty}(N_i) | i \in I\} = \lambda^*_{\infty}(M).$$

Proof. To start out, we show assertion (ii) in the special case where all the modules $N_i$ are finitely presented. Indeed, let us pick any surjection $\varphi : M' \to M$ with $M' \in \mathcal{C}_M$. We may find $i \in I$ such that $\varphi$ lifts to a map $\varphi_i : M' \to N_i$ (55 Prop.2.3.16(ii)), and up to replacing $I$ by a cofinal subset, we may assume that $\varphi_i$ is defined for every $i \in I$. Moreover

$$\text{colim}_{i \in I} \text{Coker} \varphi_i = \text{Coker} \varphi = 0.$$
hence there exists $i \in I$ such that $\varphi_i$ is surjective. It follows easily that $\lambda_\infty(N_i) \leq \lambda_\infty(M')$, whence (ii) in this case.

(i): Let $k$ be the cardinality of $\Sigma$, $\varepsilon > 0$ any real number, $Q \subset \text{Ann}_R\Sigma$ a finitely generated $m_R$-primary ideal, $S := R_\infty/Q R_\infty$ and $\beta : S^{\oplus k} \to M$ a surjection that sends the standard basis onto $\Sigma$. By filtering $\text{Ker}\ \beta$ by the system $(K_j | j \in J)$ of its finitely generated submodules, we obtain a filtered system $(N_j := S^{\oplus k}/K_j | j \in J)$ of finitely presented $R_\infty$-modules supported on $\{s(R_\infty)\}$, with surjective transition maps and colimit isomorphic to $M$. Let $\psi_j : N_j \to M$ be the natural map; by the foregoing, we may find $j_0 \in J$ such that

$$0 \leq \lambda_\infty(N_{j_0}) - \lambda_\infty^*(M) \leq \min(\delta(k, \varepsilon, Q), \varepsilon) \tag{14.5.71}$$

(notation of definition $14.5.64$ (b)). We can then find $n \in \mathbb{N}$ and a finitely presented $R_n$-module $M'_n$ supported on $\{s(R_n)\}$ and generated by at most $k$ elements, such that $N_{j_0} = R_\infty \otimes R_n M'_n$; we set $M'_m := R_m \otimes R_n M_n$ for every $m \geq n$ and let $M_m$ be the image of $M'_m$ in $M$. Up to replacing $n$ by a larger integer, we may assume that $M_m = \Sigma R_m$ for every $m \geq n$. Choose $m \in \mathbb{N}$ so that:

$$|\lambda_\infty(N_{j_0}) - d_m^{-1} \cdot \lambda_m(M'_m)| \leq \varepsilon. \tag{14.5.72}$$

Let $\langle M_{m,i} | i \in I \rangle$ be a filtered system of finitely presented $R_m$-modules supported at $\{s(R_m)\}$, with surjective transition maps, such that $\text{colim}_{i \in I} M_{m,i} = M_m$. Arguing as in the foregoing, we show that there exists $i \in I$ such that the natural map $\varphi : M'_m \to M_m$ factors through a surjection $\varphi_i : M'_m \to M_{m,i}$, and up to replacing $I$ by a cofinal subset, we may assume that such a surjection $\varphi_i$ exists for every $i \in I$. We obtain therefore a compatible system of surjections of $R_\infty$-modules:

$$N_{j_0} \simeq R_\infty \otimes R_m M'_m \to R_\infty \otimes R_m M_{m,i} \to M$$

and combining with (14.5.71) we find:

$$|\lambda_\infty(N_{j_0}) - \lambda_\infty(R_\infty \otimes R_m M_{m,i})| \leq \delta(k, \varepsilon, Q) \quad \text{for every } i \in I.$$

In such situation, condition (b) of definition $14.5.64$ ensures that:

$$d_m^{-1} \cdot |\lambda_m(M'_m) - \lambda_m(M_{m,i})| \leq \varepsilon \quad \text{for every } i \in I.$$

Therefore:

$$d_m^{-1} \cdot |\lambda_m(M'_m) - \lambda_m(M_{m,i})| \leq \varepsilon, \quad \text{by proposition } 14.5.54 \text{ ii).} \tag{14.5.72}$$

Combining with (14.5.71) and again (14.5.72) we obtain:

$$|\lambda^*_\infty(M) - d_m^{-1} \cdot \lambda_m(M)| \leq 3\varepsilon$$

which implies (i).

(ii): With no loss of generality, we may assume that $I$ admits a smallest element $i_0$. Let us fix a surjection $F := R_\infty^{\oplus k} \to N_{i_0}$, and for every $i \in I$, let $C_i$ denote the kernel of the induced surjection $F \to N_i$. We consider the filtered system $(D_j | j \in J)$ consisting of all finitely generated submodules $D_j \subset F$ such that $D_j \subset C_i$ for some $i \in I$. It is clear that $\text{colim}_{j \in J} F/D_j \simeq M$, hence $\lambda^*_\infty(M) = \inf \{\lambda_\infty(F/D_j) | j \in J\}$, by (i). On the other, by construction, for every $j \in J$ we may find $i \in I$ such that $\lambda^*_\infty(N_i) \leq \lambda_\infty(F/D_j)$; since clearly $\lambda^*_\infty(N_i) \geq \lambda^*_\infty(M)$ for every $i \in I$, the assertion follows.

14.5.73. Let now $M$ be an arbitrary object of the category $R_\infty\text{-Mod}_R$. We let:

$$\lambda_\infty(M) := \sup \{\lambda^*_\infty(M') | M' \subset M \text{ and } M' \text{ is finitely generated} \} \in \mathbb{R} \cup \{+\infty\}.$$

**Lemma 14.5.74.** If $M$ is finitely generated, then $\lambda_\infty(M) = \lambda^*_\infty(M)$.

**Proof.** Let $N \subset M$ be any finitely generated submodule. We choose finite sets of generators $\Sigma \subset N$ and $\Sigma' \subset M$ with $\Sigma \subset \Sigma'$. In view of proposition $14.5.54$ iv) we have $\lambda_n(\Sigma R_n) \leq \lambda_n(\Sigma' R_n)$ for every $n \in \mathbb{N}$, hence $\lambda^*_\infty(N) \leq \lambda^*_\infty(M)$, by lemma $14.5.70$ i). The contention follows easily.

$$\square$$
Theorem 14.5.75. (i) Let \((M_i \mid i \in I)\) be a filtered system of objects of \(\text{R}_\infty\text{-Mod}_{(s)}\), and suppose that either:

(a) all the transition maps of the system are injections, or
(b) all the transition maps are surjections and \(\lambda_\infty(M_i) < +\infty\) for every \(i \in I\).

Then:

\[\lambda_\infty(\text{colim} M_i) = \lim_{i \in I} \lambda_\infty(M_i).\]

(ii) Let \(0 \to M' \to M \to M'' \to 0\) be a short exact sequence in \(\text{R}_\infty\text{-Mod}_{(s)}\). Then:

\[\lambda_\infty(M) = \lambda_\infty(M') + \lambda_\infty(M'').\]

(iii) Let \(M\) be a finitely presented \(\text{R}_\infty\text{-module}, N \subset M\) a submodule supported at \(s(\text{R}_\infty)\). Then \(\lambda_\infty(N) = 0\) if and only if \(N = 0\).

Proof. The proof of (i) in case (a) is the same as that of proposition 14.5.54(iii.b).

(ii): We proceed in several steps:

- Suppose first that \(M\) and \(M''\) are finitely presented, hence \(M'\) is finitely generated (Lemma 2.3.18(ii)). We may then find an integer \(n \in \mathbb{N}\) and finitely presented \(\text{R}_\infty\text{-modules} M_n\) and \(M''_n\) such that \(M \simeq \text{R}_\infty \otimes_{\text{R}_\infty} M_n\) and \(M'' \simeq \text{R}_\infty \otimes_{\text{R}_\infty} M''_n\). For every \(m \geq n\) we set \(M_m := R_m \otimes_{R_n} M_n\) and likewise we define \(M''_m\). Up to replacing \(n\) by a larger integer, we may assume that the given map \(\varphi : M \to M''\) descends to a surjection \(\varphi_n : M_n \to M''_n\), and then \(\varphi\) is the colimit of the induced maps \(\varphi_m := 1_{R_m} \otimes_{R_n} \varphi_n\), for every \(m \geq n\). Moreover, \(M' \simeq \text{colim}_{m \geq n} \text{Ker} \varphi_m\), and by the right exactness of the tensor product, the image of \(\text{Ker} \varphi_m\) generates \(M'\) for every \(m \geq n\). Furthermore, since the natural maps \(M_m \to M_p\) are injective for every \(p \geq m \geq n\) (lemma 14.5.66), the same holds for the induced maps \(\text{Ker} \varphi_m \to \text{Ker} \varphi_p\). The latter factors as a composition:

\[\text{Ker} \varphi_m \xrightarrow{\alpha} R_p \otimes_{R_m} \text{Ker} \varphi_m \xrightarrow{\beta} \text{Ker} \varphi_p\]

where \(\alpha\) is injective (lemma 14.5.66) and \(\beta\) is surjective. In other words, \(R_p \cdot \text{Ker} \varphi_m = \text{Ker} \varphi_p\) for every \(p \geq m \geq n\). In such situation, lemma 14.5.70(i) ensures that:

\[\lambda_\infty(M') = \lim_{m \geq n} d^{-1} \cdot \lambda_m(\text{Ker} \varphi_m)\]

and likewise:

\[\lambda_\infty(M) = \lim_{m \geq n} d^{-1} \cdot \lambda_m(M_m)\]
\[\lambda_\infty(M'') = \lim_{m \geq n} d^{-1} \cdot \lambda_m(M''_m)\]

To conclude this case of (ii) in this case, it suffices then to apply proposition 14.5.54(iv).

- Suppose next that \(M, M'\) (and hence \(M''\)) are finitely generated. We choose a filtered system \((M_i \mid i \in I)\) of finitely presented \(\text{R}_\infty\text{-modules, with surjective transition maps, such that} M \simeq \text{colim}_{i \in I} M_i\). After replacing \(I\) by a cofinal subset, we may assume that \(M'\) is generated by a finitely generated submodule \(M'_i\) of \(M_i\) for every \(i \in I\), and that \((M'_i \mid i \in I)\) forms a filtered system with surjective transition maps, whose colimit is necessarily \(M'\); set also \(M''_i := M_i/M'_i\) for every \(i \in I\), so that the colimit of the filtered system \((M''_i \mid i \in I)\) is \(M''\). In view of lemmas 14.5.70(ii) and 14.5.74 we are then reduced to showing the identity:

\[\inf \{\lambda^*_\infty(M_i) \mid i \in I\} = \inf \{\lambda^*_\infty(M'_i) \mid i \in I\} + \inf \{\lambda^*_\infty(M''_i) \mid i \in I\}\]

which follows easily from the previous case.

- Suppose now that \(M\) is finitely generated. We let \((M'_i \mid i \in I)\) be the filtered family of finitely generated submodules of \(M'\). Then:

\[M' \simeq \text{colim}_{i \in I} M'_i\] and \[M'' \simeq \text{colim}_{i \in I} M/M'_i.\]
Hence:

\[ \lambda_\infty(M') = \lim_{i \in I} \lambda_\infty(M'_i) \quad (\text{resp. } \lambda_\infty(M'') = \lim_{i \in I} \lambda_\infty(M/M'_i)) \]

by (i.a) (resp. by lemmata 14.5.70(ii) and 14.5.74). However, the foregoing case shows that \( \lambda_\infty(M) = \lambda_\infty(M'_i) + \lambda_\infty(M/M'_i) \) for every \( i \in I \), so assertion (ii) holds also in this case.

Finally we deal with the general case. Let \( (M_i) \mid i \in I \) be the filtered system of finitely generated submodules of \( M \); we denote by \( M'' \) the image of \( M_i \) in \( M'' \), and set \( M'_i := M' \cap M_i \) for every \( i \in I \). By (i.a) we have:

\[ \lambda_\infty(M) = \lim_{i \in I} \lambda_\infty(M_i) \]

and likewise for \( M' \) and \( M'' \). Since we already know that \( \lambda_\infty(M_i) = \lambda_\infty(M'_i) + \lambda_\infty(M/M'_i) \) for every \( i \in I \), we are done.

(iii): Let \( f \in N \) be any element; in view of (ii) we see that \( \lambda_\infty(fR_\infty) = 0 \), and it suffices to show that \( f = 0 \). However, we may find \( n \in \mathbb{N} \) and a finitely presented \( R_n \)-module \( M_n \) such that \( M \simeq R_\infty \otimes R_n M_n \); notice that the natural map \( M_n \to M \) is injective, by lemma 14.5.66(i). We may also assume that \( f \) is in the image of \( M_n \). Let \( I \subset \text{Ann}_{R_n}(f) \) be a finitely generated \( m_{R_n} \)-primary ideal; after replacing \( M \) by \( M/IM \), we may assume that \( M_n \) is supported at \( s(R_n) \). In light of (ii), we see that \( \lambda_\infty(M) = \lambda_\infty(M/\lambda R_\infty) \), hence \( \lambda_n(M_n) = \lambda_n(M_n/fR_n) \), due to condition (b) of definition 14.5.64. Hence \( \lambda_n(fR_n) = 0 \) by proposition 14.5.54(iv), and finally \( f = 0 \) by theorem 14.5.43(iii.a).

To conclude, we consider assertion (i) in case (b): set \( M := \text{colim}_{i \in I} M_i \); it is clear that \( \lambda_\infty(M) \leq \lambda_\infty(M_i) \leq \lambda_\infty(M_j) \) whenever \( i \geq j \), hence

\[ \lim_{i \in I} \lambda_\infty(M_i) = \inf \{ \lambda_\infty(M_i) \mid i \in I \} \geq \lambda_\infty(M). \]

For the converse inequality, fix \( \varepsilon > 0 \); without loss of generality, we may assume that \( I \) admits a smallest element \( i_0 \), and we can find a finitely generated submodule \( N_{i_0} \subset M_{i_0} \) such that \( \lambda_\infty(M_{i_0}) - \lambda_\infty(N_{i_0}) < \varepsilon \). For every \( i \in I \), let \( N_i \subset M_i \) be the image of \( N_{i_0} \), and let \( N \subset M \) be the colimit of the filtered system \( (N_i) \mid i \in I \); then \( M_i/N_i \) is a quotient of \( M_{i_0}/N_{i_0} \), and the additivity assertion (ii) implies that \( \lambda_\infty(M_i) - \lambda_\infty(N_i) < \varepsilon \) for every \( i \in I \). According to lemma 14.5.70(ii) (and lemma 14.5.74) we have:

\[ \lambda_\infty(M) \geq \lambda_\infty(N) = \inf \{ \lambda_\infty(N_i) \mid i \in I \} \geq \inf \{ \lambda_\infty(M_i) \mid i \in I \} - \varepsilon \]

whence the claim. \( \square \)

14.5.76. We wish now to show that the definition of normalized length descends to almost modules (see (14.5)). Namely, we have the following:

**Proposition 14.5.77.** Let \( M, N \) be two objects of \( R_\infty\text{-Mod}_{(s)} \) such that \( M^a \simeq N^a \). Then \( \lambda_\infty(M) = \lambda_\infty(N) \).

**Proof.** Using additivity (theorem 14.5.75(ii)), we easily reduce to the case where \( M^a = 0 \), in which case we need to show that \( \lambda_\infty(M) = 0 \). Using theorem 14.5.75(ii) we may further assume that \( M \) is finitely generated. Then, in view of lemma 14.5.70(i), we are reduced to showing the following:

**Claim 14.5.78.** Let \( A \) be any measurable \( K^+ \)-algebra, and \( M \) any object of \( A\text{-Mod}_{(s)} \) such that \( M^a = 0 \). Then \( \lambda_A(M) = 0 \).

**Proof of the claim.** Arguing as in the foregoing we reduce to the case where \( M \) is finitely generated. Then, let us pick \( I \subset A \) and \( \varphi : V \to A/I \) as in lemma 14.5.42. It suffices to show the assertion for the finitely generated module \( \bigoplus_{n \in \mathbb{N}} I^n M/I^{n+1} M \), hence we may assume that \( I \subset \text{Ann}_A M \), in which case, by proposition 14.5.54(iii) we may replace \( A \) by \( V \) and assume
throughout that $A$ is a valuation ring. Then the claim follows from propositions \[14.5.54\](i) and \[14.5.12\](ii).

14.5.79. Proposition \[14.5.77\] suggests the following definition. We let $R^a_{\infty}\text{-Mod}_{\{s\}}$ be the full subcategory of $R^a_{\infty}\text{-Mod}$ consisting of all the $R^a_{\infty}$-modules $M$ such that $M_0$ is supported at $s(R_{\infty})$, in which case we say that $M$ is supported at $s(R_{\infty})$. Then, for every such $M$ we set:

$$\lambda_{\infty}(M) := \lambda_{\infty}(M_0).$$

With this definition, it is clear that theorem \[14.5.75\](i,ii) extends mutatis mutandis to almost modules. For future reference we point out:

**Lemma 14.5.80.** Let $0 \to M' \to M \to M'' \to 0$ be a short exact sequence of $R^a_{\infty}$-modules. We have:

(i) If $M$ lies in $R^a_{\infty}\text{-Mod}_{\{s\}}$, then $\lambda_{\infty}(abM) \leq \lambda_{\infty}(aM') + \lambda_{\infty}(bM'')$ for every $a, b \in \mathfrak{m}$.

(ii) If $M$ is almost finitely presented, and $M'$ is supported at $s(R_{\infty})$, then $\lambda_{\infty}(M') = 0$ if and only if $M' = 0$.

**Proof.** (i): To start out, we deduce a short exact sequence: $0 \to bM \cap M' \to bM \to bM'' \to 0$. Next, let $N := \text{Ker}(a : bM \to bM)$, and denote by $N'$ the image of $N$ in $bM''$; there follows a short exact sequence: $0 \to a(bM \cap M') \to abM \to bM''/N' \to 0$. The claim follows.

(ii): We reduce easily to the case where $M'$ is a cyclic $R^a_{\infty}$-module, say $M' = R^a_{\infty}x$ for some $x \in M$. In this case, let $I \subset \text{Ann}_{R_{\infty}}(x)$ be a finitely generated $m_{R_{\infty}}$-primary ideal; we may then replace $M$ by $M/IM$, and assume that $M$ lies in $R^a_{\infty}\text{-Mod}_{\{s\}}$ as well. We remark:

**Claim 14.5.81.** $M$ is almost finitely presented if and only if, for every $b \in \mathfrak{m}$ there exist a finitely presented $R_{\infty}$-module $N$ and a morphism $M \to N^a$ whose kernel and cokernel are annihilated by $b$. Moreover if $M$ is supported at $s(R_{\infty})$, one can choose $N$ to be supported at $s(R_{\infty})$.

**Proof of the claim.** The “if” direction is clear. For the “only if” part, we use \[59\text{, Cor.2.3.13},\] which provides us with a morphism $\varphi : N \to M$ with $N$ finitely presented over $R_{\infty}$, such that $b \cdot \text{Ker} \varphi = b \cdot \text{Coker} \varphi = 0$. Then $b \cdot 1^a_N$ factors through a morphism $\varphi' : \text{Im} \varphi^a \to N^a$, and $b \cdot 1_M$ factors through a morphism $\varphi'' : M \to \text{Im} \varphi^a$; the kernel and cokernel of $\varphi' \circ \varphi''$ are annihilated by $b^2$. Finally, suppose that $M$ is supported on $s(R_{\infty})$, and let $I \subset R_{\infty}$ be any finitely generated ideal such that $V(I) = \{s(R_{\infty})\}$. By assumption, for every $f \in I$ and every $m \in M$, there exists $n \in \mathbb{N}$ such that $f^n \cdot m = 0$; it follows that $I^n$ annihilates $\text{Im} \varphi$ for every sufficiently large $n \in \mathbb{N}$, and we may then replace $N$ by $N/I^nN$. \hfill \Box

Let $M$ and $M'$ be as in (ii), and choose a morphism $\varphi : M \to N^a$ as in claim \[14.5.81\], by adjunction we get a map $\psi : M' \to M_0 \to N$ with $b \cdot \mathfrak{m} \cdot \text{Ker} \psi = 0$. It follows that $\lambda_{\infty}(\text{Im} \psi) = 0$, hence $\text{Im} \psi = 0$, by theorem \[14.5.75\](iii). Hence $bM' = 0$; since $b$ is arbitrary, the assertion follows. \hfill \Box

Simple examples show that an almost finitely generated (or even almost finitely presented) $R^a_{\infty}$-module may fail to have finite normalized length. The useful finiteness condition for almost modules is contained in the following:

**Definition 14.5.82.** Let $M$ be a $R^a_{\infty}$-module supported at $s(R_{\infty})$. We say that $M$ has almost finite length if $\lambda_{\infty}(bM) < +\infty$ for every $b \in \mathfrak{m}$.

**Lemma 14.5.83.** (i) The set of isomorphism classes of $R^a_{\infty}$-modules of almost finite length forms a closed subset of the uniform space $\mathbb{M}(A)$ (notation of \[59\text{, §2.3}].)

(ii) Especially, every almost finitely generated $R^a_{\infty}$-module supported at $s(R_{\infty})$ has almost finite length.

**Proof.** Assertion (i) boils down to the following:
Claim 14.5.84. Let \( a, b \in \mathbb{m} \), and \( f : N \to M, g : N \to M' \) morphisms of \( R_\infty^a \)-modules, such that the kernel and cokernel of \( f \) and \( g \) are annihilated by \( a \in \mathbb{m} \), and such that \( \lambda_\infty(abM) < +\infty \). Then \( \lambda_\infty(a^2bM') < +\infty \).

Proof of the claim. By assumption, \( \ker f \subset \ker a \cdot 1_N \), whence an epimorphism \( f(N) \to aN \); likewise, we have an epimorphism \( g(N) \to aM' \). It follows that
\[
\lambda_\infty(a^2bM') \leq \lambda_\infty(ab \cdot g(M)) \leq \lambda_\infty(abN) \leq \lambda_\infty(b \cdot f(N)) < +\infty
\]
as stated. \( \diamondsuit \)

(ii) follows from (i) and the obvious fact that every finitely generated \( R_\infty \)-module supported at \( s(R_\infty) \) has finite normalized length. \( \square \)

14.5.85. For the case of a measurable \( K^+ \)-algebra \( A \) of dimension zero, we can show a further Lipschitz type uniform estimate for the normalized length. Namely, for any integer \( k > 0 \) define the set \( \mathcal{M}_k(A^e) \) with its uniform structure as in (14.5.1); i.e. we have the fundamental system of entourages
\[
\left( E_r \mid r \in \mathbb{R}_{>0} \right)
\]
where each \( E_r \) consists of the pairs \( (N, N') \) such that there exist a third \( A^e \)-module \( N'' \) and \( A^e \)-linear maps \( N'' \to N, N'' \to N' \) whose kernel and cokernels are annihilated by any \( b \in K^+ \) such that \( \log |b| \geq r \).

Lemma 14.5.86. In the situation of (14.5.85), we have :
\[
|\lambda_{A^e}(N) - \lambda_{A^e}(N')| \leq 4k \cdot \text{length}_A(A/mA) \cdot r
\]
for every \( r \in \mathbb{R}_{>0} \) and every \( (N, N') \in E_r \).

Proof. We begin with the following

Claim 14.5.87. For any finitely generated \( A \)-module \( N \), and every \( b \in K^+ \setminus \{0\} \) we have
\[
\lambda_A(N/bN) \leq \text{length}_A(N/mN) \cdot \log |b|.
\]

Proof of the claim. Choose a map \( \psi : V \to A \) of measurable \( K^+ \)-algebras, inducing a finite residue field extension \( \kappa(V) \to \kappa(A) \), where \( V \) is a \( K^+ \)-flat valuation ring, and the induced map of value groups \( \Gamma \to \Gamma_V \) is an isomorphism (claim 14.5.56). Let \( d := \dim_{\kappa(V)} N/mV \cdot N \); applying Nakayama’s lemma, we get a surjection \( (V/bV)^{\text{red}} \to N/bN \) of \( V \)-modules, for every \( b \in K^+ \). Hence
\[
\lambda_A(N/bN) = \frac{\lambda_A(\psi(N/bN))}{[\kappa(V) : \kappa(A)]} \leq \frac{d \log |b|}{[\kappa(V) : \kappa(A)]} = \text{length}_A(N/mN) \cdot \log |b|
\]
as stated. \( \diamondsuit \)

Now, suppose that \( (N, N') \in E_{\log |b|} \) for some \( b \in K^+ \), and pick maps \( \varphi : N'' \to N, \psi : N'' \to N' \) whose kernel and cokernel are annihilated by \( b \). Especially, if \( n_1, \ldots, n_k \in N \) (resp. \( n'_1, \ldots, n'_k \in N' \)) is a system of generators for \( N \) (resp. for \( N' \)), we may find \( n''_1, \ldots, n''_{2k} \in N'' \) such that \( \varphi(n''_i) = b^2 n_i \) for \( i = 1, \ldots, k \) and \( \psi(n''_i) = b^2 n'_{i-k} \) for \( i = k+1, \ldots, 2k \). After replacing \( N'' \) by its submodule generated by \( n''_1, \ldots, n''_{2k} \), we may assume that \( N'' \in \mathcal{M}_{2k}(A) \), \( \ker \varphi \) is still annihilated by \( b \), but \( \text{Coker} \varphi \) is only annihilated by \( b^2 \). On the one hand, we deduce that
\[
\lambda_{A^e}(N''') \geq \lambda_{A^e}(\varphi(N''')) \geq \lambda_{A^e}(b^2 N) = \lambda_{A^e}(N) - \lambda_{A^e}(N/b^2 N)
\]
therefore
\[
\lambda_{A^e}(N) - \lambda_{A^e}(N'') \leq \lambda_{A^e}(N/b^2 N).
\]
On the other hand, the map $N'' \to N''$ given by the rule $n'' \mapsto bn''$ for every $n'' \in N''$, factors through $\varphi(N'')$, therefore $\lambda_{A^n}(N) \geq \lambda_{A^n}(bN'')$ so the same calculation yields the inequality
$$\lambda_{A^n}(N'') - \lambda_{A^n}(N) \leq \lambda_{A^n}(N''/bN'').$$

Taking into account claim 14.5.87 (and proposition 14.5.77) we see that $\psi_{\varphi}$ through $On the other hand, the map $g_{S} \varphi$ where $S$ maps $R$ system $(x)$ the image of $\text{special fibre}$ where $T_{R}$

The foregoing discussion then yields a well-behaved notion of normalized length for arbitrary $g$ $\in \mathbb{A}$. In the situation of example 14.5.89, it is easy to construct Example 14.5.90. Suppose that all the transition maps $R_{n} \to R_{n+1}$ of the inductive system in (14.5.62) are flat. Then, proposition 14.5.54(v) implies that conditions (a) and (b) hold with:

$$d_{n} := \text{length}_{R_{n}}(R_{n}/m_{R_{n}}R_{n}) \quad \text{for every } n \in \mathbb{N}.$$ 

Example 14.5.89. Suppose that $p := \text{char } \kappa > 0$. Let $d \in \mathbb{N}$ be any integer, $f : X \to \mathbb{A}_{K+}^{d} := \text{Spec } K^{+}[T_{1}, \ldots, T_{d}]$ an étale morphism. For every $r \in \mathbb{N}$ we consider the cartesian diagram of schemes

$$
\begin{align*}
X_{r} & \xrightarrow{f_{r}} \mathbb{A}_{K+}^{d} \\
\psi_{r} & \downarrow \quad \varphi_{r} \\
X & \xrightarrow{f} \mathbb{A}_{K+}^{d}
\end{align*}
$$

where $\varphi_{r}$ is the morphism corresponding to the $K^{+}$-algebra homomorphism

$$\varphi_{r}^{\sharp} : K^{+}[T_{1}, \ldots, T_{d}] \to K^{+}[T_{1}, \ldots, T_{d}]$$

defined by the rule: $T_{j} \mapsto T_{j}^{r}$ for $j = 1, \ldots, d$. For every $r, s \in \mathbb{N}$ with $r \geq s$, $\psi_{r}$ factors through an obvious $S$-morphism $\psi_{rs} : X_{r} \to X_{s}$, and the collection of the schemes $X_{r}$ and transition morphisms $\psi_{rs}$ gives rise to an inverse system $X := (X_{r} \mid r \in \mathbb{N})$, whose inverse limit is representable by an $S$-scheme $X_{\infty}$ ([50, Ch.IV, Prop.8.2.3]). Let $g_{\infty} : X_{\infty} \to S$ (resp. $g_{r} : X_{r} \to S$ for every $r \in \mathbb{N}$) be the structure morphism, $x \in g_{\infty}^{-1}(s)$ any point, $x_{r} \in X_{r}$ the image of $x$ and $R_{r} := \mathcal{O}_{X_{\infty}, x_{r}}$ for every $r \in \mathbb{N}$. Clearly the colimit $R_{\infty}$ of the inductive system $(R_{r} \mid r \in \mathbb{N})$ is naturally isomorphic to $\mathcal{O}_{X_{\infty}, x}$. Moreover, notice that the restriction $g_{r+1}^{-1}(s) \to g_{r}^{-1}(s)$ is a radicial morphism for every $r \in \mathbb{N}$. It follows easily that the transition maps $R_{r} \to R_{r+1}$ are finite; furthermore, by inspection one sees that $\varphi_{r}^{\sharp}$ is flat and finitely presented, so $R_{r+1}$ is a free $R_{r}$-module of rank $p^{d}$, for every $r \in \mathbb{N}$. Hence, the present situation is a special case of example 14.5.88 and therefore conditions (a) and (b) hold if we choose the sequence of integers $(d_{i} \mid i \in \mathbb{N})$ with

$$d_{i} := p^{id}/[\kappa(x_{i}) : \kappa(x_{0})]$$

The foregoing discussion then yields a well-behaved notion of normalized length for arbitrary $R_{\infty}$-modules supported at $\{s(R_{\infty})\}$.

Example 14.5.90. In the situation of example 14.5.89 it is easy to construct $R_{\infty}^{m}$-modules $M \neq 0$ such that $\lambda_{\infty}(M) = 0$. For instance, for $d := 1$, let $x \in X_{\infty}$ be the point of the special fibre where $T_{1} = 0$; then we may take $M := R_{\infty}/I$, where $I$ is the ideal generated by a non-zero element of $m_{K}$ and by the radical of $T_{1}R_{\infty}$. The verification shall be left to the reader.

14.6. Finite group actions on almost algebras. In this section we fix a basic setup $(V, m)$ such that $m := m \otimes_{V} m$ is a flat $V$-module (see [59, §2.1.1]), and we consider some descent problems for $V$-algebras endowed with a finite group of automorphisms. Hence, the results below overlap with those of [59, §4.5].
14.6.1. Let $G$ be a finite group, $A$ a $V^a$-algebra, and let $S := \text{Spec } V^a$, $X := \text{Spec } A$. A right action of $G$ on $X$ is a group homomorphism:

$$\rho : G \to \text{Aut}_{V^a,\text{Alg}}(A)$$

from $G$ to the group of automorphisms of $A$. Let $G_S$ be the affine group $S$-scheme defined by $G$; hence every $g \in G$ determines a section $g_S : S \to G_S$ of the structure morphism $G_S \to S$, and the resulting morphism:

$$\prod_{g \in G} g_S : S \times \cdots \times S \to G_S$$

is an isomorphism of $S$-schemes. Then $\rho$ can be also regarded as a right action of $G_S$ on $X$, as defined in [59] 3.3.6. Especially, $\rho$ induces morphisms of $S$-schemes:

$$\partial_i : X \times G := X \times_S G_S \to X \quad i = 0, 1$$

as in loc. cit., and we may define a $G$-action on an $A$-module $M$ (covering the given action of $G$ on $X$) as a morphism of quasi-coherent $\theta_{X,G}$-modules:

$$\beta : \partial_0^* M \to \partial_1^* M$$

fulfilling the conditions of [59] 3.3.7. One also says that $(M, \beta)$ is a $G$-equivariant $A$-module. We denote by $A[G]\text{-Mod}$ the category of all $G$-equivariant $A$-modules and $G$-equivariant $A$-linear morphisms. Notice that $A[G]\text{-Mod}$ is an abelian tensor category: indeed, for any two objects $(M, \beta), (M', \beta')$ we may set $(M, \beta) \otimes_A (M', \beta') := (M \otimes_A M', \beta \otimes_{\theta_{X,G}} \beta')$.

14.6.2. Likewise, if $B$ is any $A$-algebra, a $G$-action on $B$ is a morphism $\beta : \partial_0^* B \to \partial_1^* B$ of quasi-coherent $\theta_{X,G}$-algebras, such that the pair $(B, \beta)$ is a $G$-equivariant $A$-module. We say that $(B, \beta)$ is a $G$-equivariant $A$-algebra, and we denote by $A[G]\text{-Alg}$ the category of such pairs, with $G$-equivariant morphisms of $A$-algebras. One verifies easily that the datum $(B, \beta)$ is the same as a morphism $\psi : A \to B$ of $V^a$-algebras, together with a $G$-action $\rho_B : G \to \text{Aut}_{V^a,\text{Alg}}(B)$ on the affine scheme $\text{Spec } B$, such that the diagram:

$$\begin{array}{ccc} 
A & \xrightarrow{\psi} & B \\
\rho(g) \downarrow & & \downarrow \rho_B(g) \\
A & \xrightarrow{\psi} & B 
\end{array}$$

commutes for every $g \in G$. We shall also consider the full subcategory $A[G]\text{-Alg}_{\text{fl}}$ (resp. $A[G]\text{-w.\text-.\text{Ét}}$, resp. $A[G]\text{-\text{Ét}}$, resp. $A[G]\text{-\text{Ét}_{\text{alf}}}$) of all such pairs, where $B$ is a flat (resp. weakly étale, resp. étale, resp. étale and almost finitely presented) $A$-algebra.

14.6.3. The trivial $G$-action on $X$ is the map $\rho$ with $\rho(g) = 1_A$ for every $g \in G$; this is the same as saying that $\partial_0 = \partial_1$. If $G$ acts trivially on $X$, a $G$-equivariant $A$-module $(M, \beta)$ is the same as a group homomorphism $\overline{\beta} : G \to \text{Aut}_A(M)$ from $G$ to the group of $A$-linear automorphisms of $M$. Namely, for every $g \in G$, one lets:

$$(14.6.4)\quad \overline{\beta}(g) := (1_X \times_S g_S)^* \beta$$

and conversely, to a given map $\overline{\beta}$ there corresponds a unique pair $(M, \beta)$ such that (14.6.4) holds.

Under this correspondence, the trivial $G$-action $\overline{\beta}_0^*$ (such that $\overline{\beta}(g) = 1_M$ for every $g \in G$) corresponds to the identity morphism $\beta_0 : \partial_0^* M \to \partial_1^* M$.

More generally, let $(M, \beta)$ be a $G$-action on an $A$-module $M$, covering the trivial $G$-action on $X$; for every $A_*$-valued character $\chi : G \to A_*^\times$ of $G$, we let

$$M_\chi := \bigcap_{g \in G} \text{Ker}(\overline{\beta}(g) - \chi(g) \cdot 1_M).$$
The restriction of $\overline{\beta}$ defines a $G$-action on $M_\chi$, such that the monomorphism $M_\chi \subset M$ is $G$-equivariant. In the special case where $\chi$ is the trivial character, we have $M_\chi = (M, \beta)^G$, the largest $G$-equivariant $A$-submodule of $(M, \beta)$ on which $\beta$ restricts to the trivial $G$-action (i.e. the submodule fixed by $G$). When the notation is not ambiguous, we shall often just write $M^G$ instead of $(M, \beta)^G$.

14.6.5. If $H \subset G$ is a subgroup, any $G$-action $\rho$ on $X$ induces by restriction an $H$-action $\rho|_H$; then the morphisms $\partial_i : X \times H \to X$ are just the restrictions of the corresponding morphisms for $G$ (under the natural closed immersion $X \times H \to X \times G$). Similarly, a $G$-action $\beta$ on an $A$-module $M$ induces by restriction an $H$-action $\beta|_H$ on the same module.

Let $Y := \Spec B$ be any affine $S$-scheme. The $G$-action $\rho$ induces a $G$-action $Y \times_S \rho$ on $Y \times_S X$; namely, $Y \times_S \rho(g) := 1_Y \times_S \rho(g)$ for every $g \in G$. In terms of the group scheme $G_S$, this is the action given by the morphisms:

$$\partial_{Y,i} := 1_Y \times_S \partial_i : (Y \times_S X) \times G \to (Y \times_S X) \quad i = 0, 1.$$ 

Let $\pi_X : Y \times_S X \to X$ be the natural morphism; then every $G$-equivariant $A$-module $(M, \beta)$ induces a $G$-equivariant $B \otimes_{\psi_a} A$-module $\pi_X^* (M, \beta) := (\pi_X^* M, \pi_X^* \beta)$, whose action covers the $G$-action $Y \times_S \rho$ on $Y \times_S X$.

14.6.6. Let us set:

$$X/G := \Coequal(X \times G \xrightarrow{\partial_1} X) \quad \text{and} \quad X^{(g)} := \Equal(X \xrightarrow{\rho(g)} X) \quad \text{for every } g \in G.$$ 

In other words, $X/G = \Spec A^G$, the subalgebra fixed by $G$, and $X^{(g)}$ is the closed subscheme fixed by the subgroup $\langle g \rangle \subset G$ generated by $g$. Thus, $X^{(g)}$ is the spectrum of a quotient $A/I_g$ of $A$, where $I_g \subset A$ is the ideal generated by the almost elements of the form $a - \rho(g)(a)$, for every $a \in A$.

Let $\pi : X \to X/G$ be the natural morphism, $N$ any quasi-coherent $\mathcal{O}_{X/G}$-module; the pullback $\pi^* N$ is the quasi-coherent $\mathcal{O}_X$-module $A \otimes_{A^G} N$. By construction, there is a natural isomorphism $\beta_N : \partial_0^* (\pi^* N) \xrightarrow{\sim} \partial_1^* (\pi^* N)$ (deduced from the natural isomorphisms of functors $\partial_i^* \circ \pi^* \simeq (\pi \circ \partial_i)^*$, for $i = 0, 1$), and one verifies easily that $\beta_N$ is a $G$-action on $\pi^* N$.

Moreover, let $i_g : X^{(g)} \to X$ be the natural closed immersion; if $M$ is any $A$-module, then $i_g^* M$ is the $A/I_g$-module $M/I_g M$. Especially, take $M := \pi^* N$; we notice that the restriction $\rho_{(g)}$ of the given action $\rho$, induces the trivial $\langle g \rangle$-action on $X^{(g)}$, and directly from the construction, we see that the natural action $\beta_{N^{(g)}}$ restricts to the trivial $\langle g \rangle$-action on $i_g^* M$.

We are thus led to the :

**Definition 14.6.7.** Let $G$ be a finite group, $A$ a $V^a$-algebra, $\rho$ a $G$-action on $X := \Spec A$.

(i) The category $A[G]\text{-}\mathbf{Mod}_{\text{hor}}$ of $A$-modules with horizontal $G$-action is the full subcategory of $A[G]\text{-}\mathbf{Mod}$ consisting of all pairs $(M, \beta)$ subject to the following condition. For every $g \in G$, the restriction $\beta_{(g)}$ induces the trivial action on $i_g^* M$.

(ii) We denote by $A[G]\text{-}\mathbf{Mod}_{\text{hor,fl}}$ the full subcategory of $A[G]\text{-}\mathbf{Mod}_{\text{hor}}$ consisting of the pairs $(M, \beta)$ as above, such that $M$ is a flat $A$-module.

Notice that the tensor product of horizontal modules (resp. algebras) is again horizontal. By the foregoing, the rule $N \mapsto (\pi^* N, \beta_N)$ defines a functor :

$$A^G\text{-}\mathbf{Mod} \to A[G]\text{-}\mathbf{Mod}_{\text{hor}}.$$
On the other hand, if \((M, \beta)\) is any \(G\)-equivariant \(A\)-module, the pair \(\pi_*(M, \beta) := (\pi_* M, \pi_* \beta)\) may be regarded as a \(G\)-action on \(\pi_* M\), covering the trivial \(G\)-action on \(\text{Spec} \, A^G\), i.e. a group homomorphism \(G \to \text{Aut}_{A^G}(M)\) (see \((14.6.3)\)). One verifies easily that the functor \(N \mapsto (\pi^* N, \beta N)\) is left adjoint to the functor \(A[G]\text{-Mod} \to A^G\text{-Mod} : (M, \beta) \mapsto \pi_*(M, \beta)^G\) (details left to the reader). Hence, also \((14.6.8)\) admits a right adjoint, given by the same rule. Similar assertions hold for the analogous functors:

\[(14.6.9)\]

\[A^G\text{-Alg} \to A[G]\text{-Alg}_{\text{hor}}\]

and the variants considered in definition \([14.6.7]\)(iii).

**Lemma 14.6.10.** In the situation of definition \([14.6.7]\) suppose furthermore that the order \(o(G)\) of \(G\) is invertible in \(A_\ast\), and let \((M, \beta)\) be any \(G\)-equivariant \(A\)-module. Then:

(i) For every \(A^G\)-valued character \(\chi : G \to (A^G)^\times\), the natural \(A^G\)-linear monomorphism \(\pi_* M_\chi \to \pi_* M\) admits a \(G\)-equivariant \(A^G\)-linear right inverse \(\pi_* M \to \pi_* M_\chi\).

(ii) For every \(A^G\)-module \(N\), the unit of adjunction:

\[\varepsilon_N : N \to (A \otimes_{A^G} N)^G\]

is an isomorphism.

(iii) Let \(Y := \text{Spec} \, B\) be any affine \(S\)-scheme; denote by \(\pi_X : Y \times_S X \to X\) and \(\pi_{X/G} : Y \times_S (X/G) \to X/G\) the natural projections. Then the natural morphism:

\[\pi^*_{X/G}(M, \beta)^G \to (\pi^*_X M, \pi^*_X \beta)^G\]

is an isomorphism of \(B \otimes_{V^A} A^G\)-modules.

**Proof.** This is standard: for every \(\chi\) as in (i), the group algebra \(A_\ast[G]\) admits the central idempotent:

\[(14.6.11)\]

\[e_\chi := \frac{1}{o(G)} \cdot \sum_{g \in G} \chi(g) \cdot g\]

and \(M_\chi = e_\chi M\) for any \(G\)-equivariant \(A\)-module \(M\). Especially, we may take \(M := N \otimes_{A^G} A\), and \(e_0\) the central idempotent associated with the trivial character, in which case \(e_0 A = A^G\), and \(M = N \oplus (N \otimes_{A^G} (1 - e_0) A)\), so all the claims follow easily.

**Definition 14.6.12.** Let \(\Gamma\) be any finite abelian group with neutral element \(0 \in \Gamma\).

(i) A \(\Gamma\)-graded \(V^a\)-algebra is a pair \(\underline{A} := (A, \gr_A)\) consisting of a \(V^a\)-algebra \(A\) and a decomposition \(A = \bigoplus_{\chi \in \Gamma} \gr_A\) as a direct sum of \(V^a\)-modules, such that:

\[1 \in \gr_0 A\quad \text{and} \quad \gr_\chi A \cdot \gr_{\chi'} A \subseteq \gr_{\chi + \chi'} A\quad \text{for every} \quad \chi, \chi' \in \Gamma\]

(where as usual \(\gr_\chi A \cdot \gr_{\chi'} A\) denotes the image of the restriction \(\gr_\chi A \otimes_{V^a} \gr_{\chi'} A \to A\) of the multiplication morphism \(\mu_A\)). Especially, \(\gr_0 A\) is a \(V^a\)-subalgebra of \(A\), and every submodule \(\gr_{\chi'} A\) is a \(\gr_0 A\)-module.

(ii) A \(\Gamma\)-graded \(A\)-module is a pair \(\underline{N} := (N, \gr_N)\) consisting of an \(A\)-module \(N\) and a decomposition \(N = \bigoplus_{\chi \in \Gamma} \gr_N\) as a direct sum of \(V^a\)-modules, such that:

\[\gr_\chi A \cdot \gr_{\chi'} N \subseteq \gr_{\chi + \chi'} N \quad \text{for every} \quad \chi, \chi' \in \Gamma\]

Of course, a morphism of \(\Gamma\)-graded \(A\)-modules \(\underline{N} \to \underline{N}' := (N', \gr_{N'})\) is an \(A\)-linear morphism \(N \to N'\) that respects the gradings.

(iii) For every subgroup \(\Delta \subset \Gamma\), let \(J_\Delta \subset A\) be the graded ideal generated by \(\bigoplus_{\chi \in \Delta} \gr_\chi A\).

We say that \(\underline{N}\) is horizontal if \(\gr_\chi (N/J_\Delta N) := \gr_\chi N/(\gr_\chi N \cap J_\Delta N) = 0\) for every subgroup \(\Delta \subset \Gamma\) and every \(\chi \notin \Delta\).
(iv) If $\Delta \subset \Gamma$ is any subgroup, $p : \Gamma \to \Gamma/\Delta$ the natural projection, and $\rho \in \Gamma/\Delta$ any element, we let:

$$\gr^\rho_{\Gamma/\Delta} N := \bigoplus_{\chi \in p^{-1}(\rho)} \gr_\chi N$$

and set $N_{\Gamma/\Delta} := (N, \gr^\cdot_{\Gamma/\Delta} N)$. Then $A^\Gamma_{\Gamma/\Delta}$ is a $\Gamma/\Delta$-graded $V^\ast$-algebra, and $N_{\Gamma/\Delta}$ is a $\Gamma/\Delta$-graded $A_{\Delta}$-module. Moreover, let also $\mathbb{N}_{\Gamma/\Delta}$ be the pair consisting of $N_{\Gamma/\Delta} := \gr^0_{\Gamma/\Delta} N$ together with its decomposition $N_{\Gamma/\Delta} = \bigoplus_{\chi \in \Delta} \gr_\chi N$; then $A_{\Delta}$ is a $\Delta$-graded $V^\ast$-algebra, and $N_{\Gamma/\Delta}$ is a $\Delta$-graded $A_{\Delta}$-module.

Proposition 14.6.13. In the situation of definition [14.6.12] let $N$ be any $\Gamma$-graded $A$-module. Then the following conditions are equivalent:

(a) $N$ is horizontal.

(b) The natural morphism $A \otimes_{\gr_0 A} \gr_0 N \to N$ is an epimorphism.

Proof. (b)$\Rightarrow$(a): The assertion is obvious for the $\Gamma$-graded $A$-module consisting of $A \otimes_{\gr_0 A} \gr_0 N$ and its natural grading deduced from $\gr_\ast A$; however any (graded) quotient of a horizontal module is horizontal, hence the assertion follows also for $N$.

(a)$\Rightarrow$(b): We argue by induction on $o(\Gamma)$. The first case is covered by the following:

Claim 14.6.14. The proposition holds if $o(\Gamma)$ is a prime number.

Proof of the claim. Indeed, suppose that $N_{\Gamma/\Delta}$ is horizontal. We may replace $N$ by $N/(A \cdot \gr_0 N)$, which is a horizontal $\Gamma$-graded $A$-module, when endowed with the grading induced from $\gr_\ast N$. Then $\gr_0 N = 0$, and we have to show that $N = 0$. By assumption, $N \subset J(0) N$, i.e.:

$$\gr_\chi N \subset \sum_{\sigma \neq 0, \chi} \gr_\sigma A \cdot \gr_{\chi - \sigma} N \quad \text{for every } \chi \neq 0.$$

For every $n > 0$, the symmetric group $S_n$ acts on the set $(\Gamma \setminus \{0\})^n$ by permutations; we let $Q_n := (\Gamma \setminus \{0\})^n/S_n$, the set of equivalence classes under this action. For every $\sigma := (\sigma_1, \ldots, \sigma_n) \in Q_n$, let $|\sigma| := \sum_{i=1}^n \sigma_i$. By an easy induction, it follows that:

$$\gr_\chi N \subset \sum_{\sigma \in Q_n} \gr_{\sigma_1} A \cdots \gr_{\sigma_n} A \cdot \gr_{\chi - |\sigma|} N.$$

Since every element of $\Gamma \setminus \{0\}$ generates $\Gamma$, it is also clear that there exists $n \in \mathbb{N}$ large enough such that every sequence $\sigma$ in $Q_n$ admits a subsequence, say $\tau := (\tau_1, \ldots, \tau_m)$ for some $m \leq n$, with $|\tau| = \chi$ (details left to the reader). Up to a permutation, we may assume that $\tau$ is the final segment of $\sigma$; then we have:

$$\gr_{\sigma_1} A \cdots \gr_{\sigma_n} A \cdot \gr_{\chi - |\tau|} N \subset \gr_{\sigma_1} A \cdots \gr_{\sigma_n-m} A \cdot \gr_0 N = 0$$

whence the claim. $\diamond$

Next, suppose that the assertion is already known for every subgroup $\Gamma' \subset \Gamma$, every graded $\Gamma'$-algebra $B$, and every $\Gamma'$-graded $B$-module $P$. We choose a subgroup $\Gamma' \subset \Gamma$ such that $(\Gamma : \Gamma')$ is a prime number. We shall use the following:

Claim 14.6.15. Let $G$ be a group, $0 \in G$ the neutral element, $H \subset G$ a subgroup. For every subgroup $L \subset G$ with $H \cap L = \{0\}$, choose an element $g_L \in G \setminus L$; denote by $S$ the subgroup generated by all these elements $g_L$. Then $S \cap H \neq \{0\}$.

Proof of the claim. Indeed, if $S \cap H = \{0\}$, we would have $g_S \in S$, a contradiction. $\diamond$

Claim 14.6.16. Suppose that $N$ is horizontal. Then $N_{\Gamma'}$ is a horizontal $\Gamma'$-graded $A_{\Gamma'}$-module.
Proof of the claim. For any given subgroup $\Delta \subset \Gamma'$, let $J'_\Delta \subset A_{\Gamma'}$ be the ideal generated by $\bigoplus_{\chi \in \Gamma' \setminus \Delta} \gr_{\chi} A$; have to show that $\gr_{\chi}(N/J'_\Delta N) = 0$ for every $\chi \in \Gamma' \setminus \Delta$. To this aim, we may replace $\Gamma$, $\Gamma'$, $A$, $A_{\Gamma'}$, $N$ and $N_{\Gamma'}$, by respectively $\Gamma/\Delta$, $\Gamma'/\Delta$, $(A_{\Gamma'})_{\Gamma'/\Delta}$, $N_{\Gamma/\Delta}$ and $(N_{\Gamma'})_{\Gamma'/\Delta}$, which allows to assume that $\Delta = \{0\}$. In this case, we have to show that:

\begin{equation}
N_{\Gamma'} = \gr_0 N + J'_{(0)} \cdot N_{\Gamma'}.
\end{equation}

Notice that $A_{\Gamma'} \cdot \gr_0 N = \gr_0 N + J'_{(0)} \cdot \gr_0 N$; the quotient $P := N/(A \cdot \gr_0 N)$ carries a unique $\Gamma$-grading $\gr_P$ such that the projection $N \to P := (P, \gr_P)$ is a morphism of $\Gamma$-graded $A$-modules (namely, $\gr_\chi P := N_{N/\gr_\chi A \cdot \gr_0 N}$ for every $\chi \in \Gamma$). Moreover, $P$ is horizontal, $\gr_0 P = 0$, and (14.6.17) is equivalent to: $P_{\Gamma'} = J'_{(0)} \cdot P_{\Gamma'}$. Therefore we may replace $N$ by $P$, and assume from start that $\gr_0 N = 0$. Similarly, notice that $J'_{(0)} \cdot N$ is a $\Gamma$-graded $A$-submodule of $N$, and the pair $Q$ consisting of $Q := N/(J'_{(0)} \cdot N)$ and its quotient grading, is horizontal. Moreover, $\gr_{\chi} Q = \gr_{\chi}(N_{\Gamma'}/J'_{(0)} N_{\Gamma'})$, for every $\chi \in \Gamma'$. Hence, we may replace $N$ by $Q$, which allows to assume as well that

\begin{equation}
J'_{(0)} N_{\Gamma'} = 0
\end{equation}

in which case, we are reduced to showing that $N = 0$. Now, by assumption, for every subgroup $H \subset \Gamma$ we have:

\begin{equation}
N = N_{H} + J_{H} N.
\end{equation}

Let $\mathcal{C}$ be the set of all subgroups $H \subset \Gamma$ with $H \cap \Gamma' = \{0\}$; we deduce that:

\begin{equation}
\gr_{\chi} N \subset \sum_{\sigma \in H} \gr_{\sigma} A \cdot \gr_{\chi - \sigma} N \quad \text{for every } \chi \in \Gamma' \setminus \{0\} \text{ and every } H \in \mathcal{C}.
\end{equation}

Moreover, in view of (14.6.18) we may omit from the sum in (14.6.19) all the elements $\sigma$ that lie in $\Gamma'$; for the remaining elements we have $\chi - \sigma \notin \Gamma'$, hence we may apply claim 14.6.14 to the horizontal $\Gamma/\Gamma'$-graded $A_{\Gamma/\Gamma'}$-module $N_{\Gamma/\Gamma'}$, to deduce that:

\begin{equation}
\gr_{\chi - \sigma} N \subset \sum_{\delta \in \Gamma \setminus \{0\}} \gr_{\chi - \sigma - \delta} A \cdot \gr_{\delta} N.
\end{equation}

Therefore:

\[
\gr_{\chi} N \subset \sum_{\sigma \notin H \cup \Gamma'} \sum_{\delta \in \Gamma \setminus \{0\}} \gr_{\sigma} A \cdot \gr_{\chi - \sigma - \delta} A \cdot \gr_{\delta} N \quad \text{for every } \chi \in \Gamma' \setminus \{0\} \text{ and every } H \in \mathcal{C}.
\]

However – again due to (14.6.18) – we may omit from this sum all the terms corresponding to the pairs $(\sigma, \delta)$ with $\chi \neq \delta$, hence we conclude that:

\[
\gr_{\chi} N \subset \sum_{\sigma \notin H \cup \Gamma'} \gr_{\sigma} A \cdot \gr_{\sigma} A \cdot \gr_{\chi} N \quad \text{for every } \chi \in \Gamma' \setminus \{0\} \text{ and every } H \in \mathcal{C}.
\]

Denote by $\Sigma$ the set of all mappings $\sigma : \mathcal{C} \to \Gamma$ such that $\sigma(H) \notin H \cup \Gamma'$ for every $H \in \mathcal{C}$. Moreover, for every $\sigma \in \Sigma$, set:

\[
B_{\sigma} := \prod_{H \in \mathcal{C}} \gr_{\sigma(H)} A \cdot \gr_{-\sigma(H)} A
\]

which is an ideal of $\gr_0 A$ and let $S_{\sigma} \subset \Gamma$ be the subgroup generated by the image of $\sigma$. By an easy induction we deduce that:

\[
\gr_{\chi} N \subset \sum_{\sigma \in \Sigma} B_{\sigma} \cdot \gr_{\chi} N 
\]

for every $n > 0$. 

By claim 14.6.15, for every \( \sigma \in \Sigma \) we may find \( \gamma(\sigma) \in S_\sigma \cap \Gamma' \setminus \{0\} \). On the other hand, since \( \Gamma \) is finite and abelian, it is easy to verify that there exists \( n \in \mathbb{N} \) large enough such that
\[
B_n^\sigma \subset \text{gr}_{\gamma(\sigma)} A \cdot \text{gr}_{-\gamma(\sigma)} A
\]
for every \( \sigma \in \Sigma \) (details left to the reader). But (14.6.18) implies that \( \text{gr}_{\gamma(\sigma)} A \cdot \text{gr}_\chi N = 0 \) whenever \( \chi \in \Gamma' \setminus \{0\} \), so the claim follows.

To conclude, we apply first claim 14.6.14 to the horizontal \( \Gamma/\Gamma' \)-graded \( A_{\Gamma/\Gamma'} \)-module \( N_{\Gamma/\Gamma'} \), to see that \( N_{\Gamma/\Gamma'} \) generates the \( A \)-module \( N \), and then claim 14.6.22(ii)–together with our inductive assumption–to deduce that \( \text{gr}_0 N \) generates that \( A_{|\Gamma/\Gamma'} \)-module \( N_{|\Gamma/\Gamma'} \). The proposition follows.

14.6.20. Recall that a morphism \( M \to N \) of \( A \)-modules is said to be pure if the natural morphism \( Q \otimes_A M \to Q \otimes_A N \) is a monomorphism for every \( A \)-module \( Q \). A morphism \( A \to B \) of \( V^a \)-algebras is called pure if it is pure when regarded as a morphism of \( A \)-modules.

**Lemma 14.6.21.** Let \( f : A \to B \) be a pure morphism of \( V^a \)-algebras, \( M \) an \( A \)-module. Then:

(i) If \( B \otimes_A M \) is a flat \( B \)-module, then \( M \) is a flat \( A \)-module (i.e. \( f \) descends flatness).

(ii) If \( B \otimes_A M \) is almost finitely generated (resp. almost finitely presented) as a \( B \)-module, then \( M \) is almost finitely generated (resp. almost finitely presented) as an \( A \)-module.

**Proof.** (i): To begin with, we remark:

**Claim 14.6.22.** Let \( R \) be any \( V \)-algebra such that \( A = R^a \).

(i) A morphism \( \varphi : M_1 \to M_2 \) of \( A \)-modules is pure if and only if the same holds for the induced morphism \( \varphi : M_1!! \to M_2!! \) of \( R \)-modules.

(ii) A morphism \( g : A \to B \) of \( V^a \)-algebras is pure if and only if the same holds for the induced morphism \( g!! : A!! \to B!! \).

**Proof of the claim.** (i): Suppose that \( \varphi \) is pure, and let \( Q \) be any \( R \)-module. Then \( Q \otimes_R M_1 \simeq (Q^a \otimes_A M_i) \) for \( i = 1, 2 \). Since the functor \( M \mapsto M_i \) is exact (\([59\text{, Cor.2.2.24}(i)]\)), we deduce that \( \varphi \) is pure. The converse is easy, and shall be left to the reader.

(ii): From (i) we already see that \( g \) is pure whenever \( g!! \) is. Next, suppose that \( g \) is pure; we may assume that \( R = A!! \), and then (i) says that \( g!! \) is a pure morphism of \( A!! \)-modules. However, the natural diagram of \( A!! \)-modules:

\[
\begin{array}{ccc}
A & \longrightarrow & B'_i \\
\downarrow & & \downarrow \\
A!! & \longrightarrow & B!!
\end{array}
\]

is cofibred; since tensor products are right exact functors, the claim follows.

The assertion now follows from claim 14.6.22(ii) and \([69\text{, Partie II, Lemme 1.2.1}]. \)

(ii): Suppose first that \( B \otimes_A M \) is an almost finitely generated \( B \)-module. The assumption on \( f \) implies that \( \text{Ann}_A(B \otimes_A M) \subset \text{Ann}_A M \); then \([59\text{, Rem.3.2.26}(i)]\) shows that \( M \) is an almost finitely generated \( A \)-module.

Finally, we suppose that \( B \otimes_A M \) is an almost finitely presented \( B \)-module, and we wish to show that \( M \) is an almost finitely presented \( A \)-module. To this aim, let \( \varphi : N \to N' \) be a morphism of \( A \)-modules. The assumption on \( f \) implies that the natural morphism \( \text{Ker} \varphi \to \text{Ker}(1_B \otimes_A \varphi) \) is a monomorphism; especially:

\[
\text{Ann}_A(\text{Ker}(1_B \otimes_A \varphi)) \subset \text{Ann}_A(\text{Ker} \varphi).
\]

Then one may easily adapt the proof of \([59\text{, Lemma 3.2.25}(i)]\), to derive the assertion.
**Theorem 14.6.23.** In the situation of definition [4.6.7] suppose furthermore that $G$ is abelian and the order $o(G)$ of $G$ is invertible in $A$. Then the following holds:

(i) Let $M$ be any $G$-equivariant $A$-module. The $G$-action on $M$ is horizontal if and only if the counit of adjunction:

$$\eta_M : A \otimes_{A^G} M^G \to M$$

is an epimorphism (of $A$-modules).

(ii) The functor $\Gamma$ restricts to an equivalence on the full subcategory of flat $A^G$-modules:

$$A^G \text{-Mod}_\text{fl} \sim A[G] \text{-Mod}_{\text{hor.fl}}.$$

**Proof.** (i): For $m := o(G)$, let $\mu_m \subset \mathbb{Q}^\times$ be the group of $m$-th roots of 1, and set $B := V^m [\mu_m] := (V[T]/(T^m - 1))^m$. Since $B$ is a faithfully flat $V$-algebra, lemma [14.6.10][iii] allows to replace $A$ by $B \otimes_{V^a} A$ and $M$ by $B \otimes_{V^a} M$, and therefore we may assume from start that $\mu_m \subset (A^G)^\times$. Set $\Gamma := \text{Hom}_\mathbb{Z}(G, \mu_m)$. For every $\chi \in \Gamma$, let $e_\chi \in A_s[G]$ be the central idempotent defined as in [14.6.11]. A standard calculation shows that:

$$\sum_{\chi \in \Gamma} e_\chi = 1.$$

Hence, every $G$-equivariant $A^G$-module $(N, \beta)$ admits the $G$-equivariant decomposition:

$$(14.6.25) \quad N \simeq \bigoplus_{\chi \in \Gamma} N_\chi.$$

Especially, $A = \bigoplus_{\chi \in \Gamma} A_\chi$, and clearly the datum $A$ consisting of $A$ and its decomposition, is a $\Gamma$-graded $V^a$-algebra. Furthermore, the datum $N$ consisting of $N$ and its decomposition $\Gamma$ is a $\Gamma$-graded $A$-module.

**Claim 14.6.26.** The functor $(N, \beta) \mapsto N$ is an equivalence from $A[G]$-$\text{Mod}$ to the category of $\Gamma$-graded $A$-modules.

**Proof of the claim.** Indeed, if $Q$ is a $\Gamma$-graded $A$-module, we may define a $G$-action on $Q$ by requiring that $Q_\chi = \text{gr}_\chi Q$, the $\chi$-graded direct summand of $Q$. This gives a quasi-inverse for the functor $(N, \beta) \mapsto N$. (Details left to the reader.)

**Claim 14.6.27.** Let $(N, \beta)$ be any $G$-equivariant $A$-module, and $N$ its associated $\Gamma$-graded $A$-module. The following conditions are equivalent:

(a) $(N, \beta)$ is horizontal.

(b) $N$ is horizontal.

**Proof of the claim.** For every $g \in G$, let $\Delta(g) \subset \Gamma$ be the subgroup consisting of all $\chi \in \Gamma$ such that $\chi(g) = 1$; a direct inspection of the definitions shows that $J_{\Delta(g)}$ is the ideal $I_g$, as defined in [14.6.6], and $(N, \beta)$ is horizontal if and only if $N_\chi/(N_\chi \cap I_g N) = 0$ for every $g \in G$ and every $\chi \notin \Delta(g)$. This already shows that (b)$\Rightarrow$(a); it also shows that condition (b) holds for the subgroups $\Delta(g)$, when $(N, \beta)$ is horizontal. However, every subgroup of $\Gamma$ can be written in the form $\Delta = \Delta(g_1) \cap \cdots \cap \Delta(g_n)$, for appropriate $g_1, \ldots, g_n \in G$, and then $J_{\Delta(g_1)} + \cdots + J_{\Delta(g_n)} \subset J_{\Delta}$, hence (b) follows for all subgroups.

Assertion (i) now follows from claim [14.6.27] and proposition [14.6.13]

(ii): Let $(M, \beta)$ be any object of $A[G]$-$\text{Mod}_{\text{hor.fl}}$, and denote by $L$ the kernel of the counit $\eta_M$. Since $M$ is a flat $A$-module and $\eta_M$ is an epimorphism by (i), it follows that $i_g^* L$ is the kernel of $i_g^* \eta_M$, for every $g \in G$ (notation of [14.6.6]). Since the category $A[G]$-$\text{Mod}_{\text{hor}}$ is abelian, we deduce that the natural $G$-action on $L$ is horizontal, and then (i) says that $L$ is generated by $L^G$. But lemma [14.6.10][ii] easily implies that $L^G = 0$, so $\eta_M$ is an isomorphism. Next, letting
\( M := A \) in lemma 14.6.10(ii), we deduce easily that the natural morphism \( A^G \rightarrow A \) is pure, hence \( M^G \) is a flat \( A^G \)-module, by lemma 14.6.21(ii). Now the assertion follows from lemma 14.6.10(ii) and [22, Prop. 3.4.3].

**Corollary 14.6.28.** In the situation of theorem 14.6.23 the following holds:

(i) The functor \((14.6.24)\) restricts to an equivalence from the subcategory of flat, almost finitely generated (resp. almost finitely presented) \( A^G \)-modules, onto the subcategory of \( G \)-equivariant, flat, horizontal and almost finitely generated (resp. almost finitely presented) \( A[G] \)-modules.

(ii) The functor \((14.6.9)\) restricts to an equivalence:

\[ A^G \text{-Alg}_{fl} \rightarrow A[G] \text{-Alg}_{hor,fl} \]

and likewise for the subcategories of weakly \( \acute{e} \text{tale} \) (resp. \( \acute{e} \text{tale}, \) resp. \( \acute{e} \text{tale} \) and almost finitely presented) algebras.

**Proof.** (i) follows from theorem 14.6.23(ii), lemma 14.6.21(ii), and the fact that the morphism \( A^G \rightarrow A \) is pure.

(ii): The assertion concerning \( A^G \text{-Alg}_{fl} \) is an immediate consequence of theorem 14.6.23.

Next, let \((B, \beta)\) be an object of \( A[G] \text{-w. \acute{E}t} \); by the foregoing, \( B \) descends to a flat \( A^G \)-algebra \( B^G \) with a \( G \)-equivariant isomorphism: \( B \cong A \otimes_{A^G} B^G \). However, on the one hand, \( B \) is \( \beta \)-generated – by assumption – a flat \( B \otimes_A B^G \)-algebra, and on the other hand, \( B \otimes_A B \) underlies a flat, horizontal \( A[G] \)-algebra with \( (B \otimes_A B)^G \cong B^G \otimes_{A^G} B^G \); theorem 14.6.23 then says that \( B^G \) is a flat \( B^G \otimes_{A^G} B^G \)-algebra, whence the assertion for \( A^G \text{-w. \acute{E}t} \). Next, since an almost finitely generated module is almost projective if and only if it is flat and almost finitely presented (\([59, \text{Prop. 2.4.18}]\)), the assertion for \( A^G \text{-\acute{E}t} \) follows from the same assertion for \( A^G \text{-w. \acute{E}t} \) and lemma 14.6.21(ii). Likewise, the assertion for \( \acute{e} \text{tale} \) almost finitely presented \( A^G \)-algebras follows from the assertion for \( A^G \text{-\acute{E}t} \) and lemma 14.6.21(ii). \( \square \)

**Remark 14.6.29.** In case the \( G \)-action on \( X \) is free, i.e. when \((\partial_0, \partial_1): X \times G \rightarrow X \times_S X \) is a monomorphism, corollary 14.6.28 also follows from [59, Prop. 4.5.25].

### 14.7 Almost Witt vectors.

In this section we show that the construction of the ring of Witt vectors descends to almost rings, and we study some properties of the resulting functor of *almost Witt vectors*. We begin with some general observation concerning liftings of basic setups (in the sense of \([59, \S 2.1.1]\)) along ring homomorphisms. These preliminaries shall then be applied to find natural basic setups on truncated rings of Witt vectors of arbitrary rings \( R \), by lifting given setups on \( R \) along the 0-th ghost map.

**Lemma 14.7.1.** Let \( A \) be a ring, \( I \subset A \) a nilpotent ideal, \( \pi: A \rightarrow A_0 := A/I \) the projection, and \( m_0 \subset A_0 \) an ideal such that \( m_0^2 = m_0 \). We have:

(i) There exists a unique ideal \( m \subset A \) such that \( m^2 = m \) and \( \pi(m) = m_0 \).

(ii) \( m \) is the smallest of the ideals \( J \subset A \) such that \( \pi(J) = m_0 \).

(iii) \( m \) fulfills condition (B) of [59, \S 2.1.6] if and only if the same holds for \( m_0 \).

**Proof.** (i): Say that \( I^N = 0 \) for some \( N \in \mathbb{N} \), and set \( J := \pi^{-1}m_0 \). We remark:

**Claim 14.7.2.** \( J^{2N+1} = J^{2N+2} \).

**Proof of the claim.** Indeed, let \( a_1, \ldots, a_{2N+1} \in J^{2N+1} \); we may find an integer \( r \geq 0 \) and elements \( b_{1i}, c_{1i}, \ldots, b_{ri}, c_{ri} \in m_0 \) for every \( i = 1, \ldots, 2N+1 \), such that \( \pi(a_i) = \sum_{j=1}^r b_{ji} c_{ji} \).

Lift each \( b_{ji} \) and each \( c_{ji} \) to elements \( b_{ji}', c_{ji}' \in J \); it follows that \( x_i := a_i - \sum_{j=1}^r b_{ji}' c_{ji}' \in I \) for every \( i = 1, \ldots, 2N+1 \). Thus:

\[
\prod_{i=1}^{2N+1} a_i = \prod_{i=1}^{2N+1} \left( x_i + \sum_{j=1}^{r} b_{ji}' c_{ji}' \right) \in J^{2(N+1)} + I^N = J^{2N+2}
\]
Lemma 14.7.3. Let \( m := J^{2N+1} \); claim \[14.7.2\] implies that \( m = m^2 \), and clearly \( \pi(m) = m_0^{2N+1} = m \). Next, let \( m' \subset A \) be any ideal such that \( m'^2 = m' \) and \( \pi(m') = m_0 \); it follows that

\[
m' = m^{2N+1} \subset J^{2N+1} = (m + I)^{2N+1} \subset m'^{2N+1} = m'
\]

whence \( m' = m \).

(ii): Let \( J \subset A \) be any ideal such that \( \pi(J) = m_0 \); it follows that

\[
m = m^N \subset (J + I)^N \subset J + I^N = J.
\]

(iii): It is clear that if \( m \) fulfills condition (B), then the same holds for \( m_0 \). Conversely, if condition (B) holds for \( m_0 \), then for every integer \( k \geq 1 \) the system of elements \( \langle x^k | x \in m \rangle \) generates an ideal \( J \subset A \) such that \( \pi(J) = m_0 \) and \( J \subset m \). By (ii), we must then have \( J = m \), which shows that condition (B) holds for \( m \).

\[ \Box \]

Let us also point out the following result, which shall not be needed in the sequel:

Lemma 14.7.3. Let \((A, m)\) be a basic setup and \( f : B \to A \) a ring homomorphism such that:

(a) \( p^k A = 0 \) for some integer \( k \in \mathbb{N} \).
(b) \( m \) fulfills condition (B) of \[59\] 2.1.6.
(c) \( f \otimes \mathbb{F}_p \) is invertible up to \( \Phi^n \) for some \( n \in \mathbb{N} \), in the sense of \[59\] Def.3.5.8.

Then there exists a unique basic setup \((B, n)\) with \( nA = m \) and with \( n \) fulfilling condition (B).

Proof. Using lemma \[14.7.1\], we are easily reduced to the case where \( A \) and \( B \) are \( \mathbb{F}_p \)-algebras, and \( f \) is invertible up to \( \Phi^n \). The latter means that there exists a morphism \( g : A \to B \) such that \( g \circ f = \Phi^n_B \) and \( f \circ g = \Phi^n_A \).

Suppose first that \( A = B \) and \( f = \Phi^n_A \); in this case, we claim that \( n := m \) will do. Indeed, obviously \( n^2 = n \), and assumption (b) says that \( \Phi^n_A(m) \) generates the ideal \( m \); moreover, if \( n' \subset A \) is another ideal fulfilling these conditions, we see that \( x^n \in m \) for every \( x \in n' \), whence \( n' \subset m \), since \( n' \) fulfills condition (B), and conversely, \( m = \Phi^n_A(n') \cdot A \subset n' \).

In the general case, we claim that \( n := g(m) \cdot B \) will do. Indeed, clearly \( n^2 = n \) and \( f(n) \cdot A = \Phi^n_A(m) \cdot A = m \), due to assumption (b); it is also easily seen that \( n \) fulfills condition (B). Moreover, if \( n' \subset B \) is another ideal fulfilling these conditions, it follows that

\[
\Phi^n_B(n') \cdot B = g(f(n') \cdot A) \cdot B = g(m) \cdot B = n
\]

whence \( n = n' \), by the foregoing case.

\[ \Box \]

14.7.4. Consider now a cartesian diagram of rings

\[
\begin{array}{ccc}
A & \xrightarrow{p_1} & A_1 \\
p_2 \downarrow & & \downarrow \pi_1 \\
A_2 & \xrightarrow{\pi_2} & A_3
\end{array}
\]

such that \( \pi_2 \) (and hence \( p_1 \)) is surjective.

Proposition 14.7.5. (i) In the situation of \[14.7.4\], let \( m_1 \subset A_1 \), \( m_2 \subset A_2 \) be two ideals with \( m_1^2 = m_1 \), \( m_2^2 = m_2 \), \( m_1 A_3 = m_2 A_3 \).

Then there exists a unique ideal \( m \subset A \) such that

\[
m^2 = m \quad m A_1 = m_1 \quad m A_2 = m_2.
\]

(ii) Moreover, \( m \) is the smallest of the ideals \( J \subset A \) such that \( JA_1 = m_1 \) and \( JA_2 = m_2 \).

(iii) Furthermore, \( m \) fulfills condition (B) if and only if the same holds for both \( m_1 \) and \( m_2 \).
Proof. (i): We shall regard $A$ as a subset of $A_1 \times A_2$, in the natural fashion. Now, set $I := m_1 \times_{A_3} m_2$; then $I$ is an ideal of $A$, and we remark:

Claim 14.7.7. $IA_1 = m_1$ and $IA_2 = m_2$.

Proof of the claim. Since $\pi_2$ is surjective, it is easily seen that $p_1$ restricts to a surjection $I \rightarrow m_1$. Next, let $a \in m_2$ be any element; we may find an integer $r_1 \in \mathbb{N}$ and elements $x_1, \ldots, x_r \in m_1$ and $y_1, \ldots, y_r \in A_3$ such that $a = \sum_{i=1}^r y_i \cdot \pi_1(x_i)$. For every $i = 1, \ldots, r$, pick $b_i \in m_2$ and $c_i \in A_2$ such that $\pi_2(b_i) = \pi_1(x_i)$ and $\pi_2(c_i) = y_i$; then $(x_i, b_i) \in I$ for $i = 1, \ldots, r$, and $a - \sum_{i=1}^r p_2(x_i, b_i) \cdot c_i \in \ker \pi_2$. However, $0 \in \ker \pi_2 \subset I$, whence $IA_2 = m_2$.

Claim 14.7.8. Let $J \subset A$ be any ideal such that $JA_1 = m_1$ and $JA_2 = m_2$. Then

$$(A_1 \times A_3 m_2) \cdot (m_1 \times A_3 A_2) \subset J.$$

Proof of the claim. Indeed, let $(a_1, a_2), (b_1, b_2) \in A$ be two elements such that $a_2 \in m_2$ and $b_1 \in m_1$. Since $p_1$ is surjective, we may find $(b_1, x) \in J$ such that $\pi_2(x) = \pi_1(b_1)$, and we have

$$(a_1, a_2) \cdot (b_1, b_2) - (a_1, a_2) \cdot (b_1, x) = (a_1, a_2) \cdot (0, b_2 - x) = (0, a_2 \cdot y)$$

where $y := b_2 - x \in \ker \pi_2$. We are thus reduced to checking that $(0, ab) \in J$ for every $a \in m_2$ and $b \in \ker \pi_2$. However, say that $a = \sum_{i=1}^r \pi_2(c_i) d_i$ for elements $c_1, \ldots, c_r \in J$ and $d_1, \ldots, d_r \in A_2$; it follows that $(0, d_2 b) \in A$ for every $i = 1, \ldots, r$, and $\sum_{i=1}^r c_i \cdot (0, d_i b) = (0, ab)$, whence the contention.

From claim 14.7.7 we deduce that $I^2 A_1 = m_1^2 = m_1$, and likewise, $I^2 A_2 = m_2^2$; from claim 14.7.8 it then follows that $(m_1 \times A_3 A_2) \cdot (A_1 \times A_3 m_2) \subset I^3$. Especially, $I^2 \subset I^3$, so that $I^3 = I^2$, and therefore the ideal $m := I^2$ fulfills conditions (14.7.6).

(ii): For every ideal $J$ as in claim 14.7.8 we also get: $m \subset J \subset m_1 \times_{A_3} m_2$; if we have as well $J^2 = J$, it follows that $J \subset m$, i.e. $J = m$, as required.

(iii): Due to [59] Claim 2.19], it suffices to show, for every prime $p$, that the following conditions are equivalent:

(a) The $A$-module $m/pm$ is generated by the $p$-th powers of its elements

(b) For $i = 1, 2$, the $A_i$-module $m_i/pm_i$ is generated by the $p$-th powers of its elements.

However, it is easily seen that (a)$\Rightarrow$(b). For the converse, consider the ideal $J \subset A$ generated by the system $\{x^p | x \in m\} \cup \{px | x \in m\}$; since $p_1$ is surjective, (b) implies that $JA_1 = m_1$. Likewise, $JA_2 = m_2$: indeed, since $m_2/pm_2$ is generated by the $p$-th powers of its elements, it suffices to check that for every $a \in m_2$ we have $a^p \in JA_2$. But say that $a = \sum_{i=1}^n x_i a_i$ for some $x_1, \ldots, x_n \in m$ and $a_1, \ldots, a_n \in A_2$; then $a^p = \sum_{i=1}^n x_i^p a_i^p + py$ for some $y \in m_2$, whence the contention. In view of (ii), we conclude that $J = m$, whence (a).

14.7.9. Henceforth, we fix a prime number $p$, and the notation $W(A)$ and $W_{n+1}(A)$ will refer to the ring of $p$-typical Witt vector of section (9.3), for every ring $A$ and every integer $n \in \mathbb{N}$. Notice that the functors $W$ and $W_{n+1}$ introduced in section (9.3) are defined on the category of topological rings; however, in this section we shall be interested only in the underlying rings, and the topologies will play no role; if one wishes, one may assume that all the rings in this section carry the discrete topology. We consider first the case where $p$ is nilpotent on $A$:

Corollary 14.7.10. Let $A$ be any ring such that $p^k A = 0$ for some $k \in \mathbb{N}$, and $m \subset A$ an ideal with $m^2 = m$. For every $n \in \mathbb{N}$ we have:

(i) There exists a unique ideal $n_{n+1} \subset W_{n+1} A$ such that

$$n_{n+1}^2 = n_{n+1} \quad \text{and} \quad \omega_0(n_{n+1}) = m.$$

(ii) The image of $n_{n+2}$ under the projection $W_{n+2} A \rightarrow W_{n+1} A$ agrees with $n_{n+1}$. 
Proof. (See remark 9.3.28(i) for the definition of the ring homomorphism \( \overline{\omega}_0 \).) (i) follows immediately from corollary 9.3.32 and lemma 14.7.1. (ii) follows immediately from (i). \( \square \)

For a general ring \( A \), we may state :

**Proposition 14.7.11.** Let \( A \) be a ring, \( n \in \mathbb{N} \) an integer, \( m \subset A \) an ideal with \( m = m^2 \) and fulfilling condition (B) of [59], §2.1.6. Set \( n_{n+1} = \{ a \in W_{n+1}A \mid a_0, \ldots, a_n \in m \} \). We have : (i) \( n_{n+1} \) is an ideal of \( W_{n+1}A \) with \( n_{n+1}^2 = n_{n+1} \) and fulfilling condition (B). (ii) Moreover, \( n_{n+1} \) is the unique ideal with \( n_{n+1}^2 = n_{n+1} \) and such that

\[
\overline{\omega}_i(n_{n+1}) \cdot A = m \quad \text{for } i = 0, \ldots, n.
\]

**Proof.** We consider the ring homomorphism

\[
\pi_n : W_{n+1}A \to A^{n+1}
\]

of proposition 9.3.30(i). By proposition 9.3.30(i), the kernel of the surjection \( W_{n+1}A \to R := \text{Im } \pi_n \) is nilpotent, hence every basic setup \( (\overline{R}, m_R) \) lifts uniquely to a basic setup \( (W_{n+1}A, \overline{m}) \), and \( \overline{m} \) satisfies condition (B) if and only if the same holds for \( m_R \) (lemma 14.7.1(i,iii)). Moreover, by proposition 9.3.30(ii), the subring \( R \) of \( A^{n+1} \) contains the ideal \( p^{n+1}A^{n+1} \), and lies in the larger subring \( S \subset A^{n+1} \) consisting of all sequences \( (a_0, \ldots, a_n) \) such that \( a_i \equiv a_0^i \pmod{pA} \) for \( i = 0, \ldots, n \); there follows a cartesian diagram of rings

\[
\begin{array}{ccc}
R & \longrightarrow & R_0 := R/p^{n+1}A^{n+1} \\
\downarrow & & \downarrow \\
S & \longrightarrow & S_0 := S/p^{n+1}A^{n+1}
\end{array}
\]

(14.7.13)

whose horizontal arrows are surjections. By proposition 14.7.5(i,iii), the datum of \( (R, m_R) \) is then equivalent to that of a pair of basic setups \( (R_0, m_{R_0}) \) and \( (S, m_S) \) with \( m_{R_0}S_0 = m_S S_0 \). Also, \( m_R \) fulfills condition (B) if and only if the same holds for both \( m_{R_0} \) and \( m_S \). Next, set \( A_0 := A/pA \), and notice that we have a cartesian diagram of rings

\[
\begin{array}{ccc}
S & \longrightarrow & A^{n+1} \\
\downarrow & & \downarrow \\
A_0 & \longrightarrow & A_0^{n+1}
\end{array}
\]

(14.7.14)

where \( \varphi \) is given by the rule : \( x \mapsto (x, x^p, \ldots, x^{p^n}) \) for every \( x \in A_0 \); the top horizontal arrow is the inclusion map, and the right vertical arrow is the projection. Moreover, \( \psi \) is a surjection. Hence – again by virtue of proposition 14.7.5(i) – the datum of \( (S, m_S) \) is equivalent to that of a system of basic setups \( (A, m_i) \) such that

\[
m_iA_0 = \Phi_{A_0}^i(m_0A_0) \cdot A_0 \quad \text{for } i = 1, \ldots, n
\]

where \( \Phi_{A_0} : A_0 \to A_0 \) is the Frobenius endomorphism. Especially, if \( (A, m) \) is a basic setup on \( A \) such that \( m \) fulfills condition (B), then we can take \( m_i := m \) for every \( i = 0, \ldots, n \), and in this way we obtain a natural basic setup \( (S, m_S) \) on \( S \) with \( m_S A^{n+1} = m^{n+1} \), and such that condition (B) still holds for \( m_S \). Furthermore, the restriction of \( \psi \) to \( R \) factors through a surjection \( R_0 \to A_0 \) whose kernel is also nilpotent, so that the basic setup \( (A_0, m_A) \) lifts uniquely to a basic setup \( (R_0, m_{R_0}) \) with \( m_{R_0} \) fulfilling condition (B) (lemma 14.7.1(i)). Lastly, both ideals \( m_{R_0}S_0 \) and \( m_SS_0 \) lift \( m_A \) along the map \( S_0 \to A_0 \) induced by \( \psi \), whose kernel is also nilpotent; by invoking again [14.7.1(i)], we deduce that \( m_{R_0}S_0 = m_SS_0 \). Summing up, we have finally associated with the basic setup \( (A, m) \) a natural basic setup \( (W_{n+1}A, \overline{m}) \) which is the unique one with property (14.7.12), and with \( \overline{m} \) fulfilling condition (B). To conclude
Indeed, arguing by induction on \(N\), Namely, for every \(n\), it remains to check that \(n+1 = n^2\). Now, let us define a descending filtration by subideals of \(n\), by setting \(\mathcal{F}_i n_{n+1} = n_{n+1} \cap \mathcal{V}_i A\), where \(\mathcal{V}_i A = V_i A / V_{i+1} A\) for every \(i = 0, \ldots, n\). Let also \(\text{gr}_i n_{n+1}\) be the associated graded \(W_{n+1}\)-module. We are then further reduced to showing that \(n_{n+1} \cdot \text{gr}_i n_{n+1} = \text{gr}_i n_{n+1}\) for \(i = 0, \ldots, n\). However, we have a natural identification of \(W_{n+1}\)-modules : \(\text{gr}_i n_{n+1} \cong m\), for the \(W_{n+1}\)-module structure on \(m\) induced by restriction of scalars along the ghost map \(\mathcal{V}_i A \to A\) (claim 9.3.31). Since \(m^2 = m\), we then come down to the assertion that \(\mathcal{V}_i(n_{n+1}) \cdot A = m\), which was already remarked.

14.7.15. Let \((A, m)\) be a basic setup such that either \(p^k A = 0\) for some integer \(k \in \mathbb{N}\), or else such that \(m\) fulfills condition (B). For every \(n \in \mathbb{N}\) let \(n_{n+1} \subset W_{n+1} A\) be the ideal provided by corollary 14.7.10(i), or respectively by proposition 14.7.11; especially, \((W_{n+1} A, n_{n+1})\) is also a basic setup. Let also \(f : B \to C\) be a morphism of \(A\)-algebras such that \(f^a : B^a \to C^a\) is an isomorphism of \((A, m)^a\)-algebras. Then we claim that \(f\) induces an isomorphism of \((W_{n+1} A, n_{n+1})^a\)-algebras

\[(W_{n+1} f)^a : (W_{n+1} B)^a \cong (W_{n+1} C)^a \quad \text{for every } n \in \mathbb{N}.\]

Indeed, arguing by induction on \(n \in \mathbb{N}\), we are easily reduced to checking that \(f\) induces an isomorphism of \((W_{n+1} A)^a\)-modules \((V_n B / V_{n+1} B)^a \cong (V_n C / V_{n+1} C)^a\) for every \(n \in \mathbb{N}\). However, in light of claim 9.3.31 we have a commutative diagram of \(W_{n+1} A\)-modules

\[
\begin{array}{ccc}
B & \longrightarrow & V_n B / V_{n+1} B \\
\downarrow f & & \downarrow \\
C & \longrightarrow & V_n C / V_{n+1} C
\end{array}
\]

whose horizontal arrows are isomorphisms of \(W_{n+1} A\)-modules, and where the \(W_{n+1} A\)-module structures on \(B\) and \(C\) are induced by the \(n\)-th ghost maps. By assumption, \(m\) annihilates \(\text{Ker } f\) and \(\text{Coker } f\); since \(\mathcal{V}_n(n_{n+1}) \subset m\), it follows that \(n_{n+1}\) annihilates these \(W_{n+1} A\)-modules as well, whence the contention. Thus, we obtain a well defined functor

\[W_{n+1} : (A, m)^a \text{-Alg} \to (W_{n+1} A, n_{n+1})^a \text{-Alg} \quad B^a \mapsto (W_{n+1} B)^a \quad \text{for every } n \in \mathbb{N}.\]

Moreover, for every \(k \leq n\), the ghost component \(\mathcal{V}_k : W_n B \to B\) induces pull-back functors

\[\mathcal{V}_k^* : B^a \text{-Alg} \to W_{n+1} B^a \text{-Alg} \quad \mathcal{V}_k^* : B^a \text{-Mod} \to W_{n+1} B^a \text{-Mod}.
\]

Namely, for every \(B\)-algebra \(C\) we let \(\mathcal{V}_k^* C\) be the \(W_{n+1} B\)-algebra whose underlying ring is \(C\), and whose structure morphism is the composition of \(\mathcal{V}_k\) and the structure morphism \(B \to C\) of \(C\). Since \(\mathcal{V}_k(n_{n+1}) \subset m\), it is clear that this functor on \(B\)-algebras descends to a well defined functor \(\mathcal{V}_k^*\) on \(B^a\)-algebras, as stated. Likewise one argues to define the functor \(\mathcal{V}_k^*\) on \(B^a\)-modules. Furthermore, we have a well defined ideal

\[\mathcal{V}_k B^a := (V_k B / V_{k+1} B)^a \subset W_{n+1} B^a \quad \text{for every } k = 0, \ldots, n\]

and claim 9.3.31 yields a natural isomorphism of \(W_{n+1} B^a\)-modules:

\[(14.7.16) \quad \mathcal{V}_k B^a / \mathcal{V}_{k+1} B^a \cong \mathcal{V}_k B^a \quad \text{for every } k = 0, \ldots, n.\]
14.7.17. In the situation of (14.7.15), suppose that \( m \) fulfills condition (B), and let \( B \) be any \( A \)-algebra; denote by
\[
B^a \xrightarrow{\varepsilon_B} B \xrightarrow{n_B} B^a
\]
and
\[
(W_{n+1}B)^a \xrightarrow{\varepsilon B} W_{n+1}B \xrightarrow{\eta B} (W_{n+1}B)^a
\]
the units and counits of adjunction. We have:

**Proposition 14.7.18.** In the situation of (14.7.17), the following holds:

(i) There exist isomorphisms of \( W_{n+1}A \)-algebras
\[
\omega : W_{n+1}(B^a) \iso (W_{n+1}B)^a \quad \text{and} \quad \tau : W_{n+1}(B^a) \iso (W_{n+1}B)^a
\]
such that \( \omega \circ W_{n+1}(n_B) = \eta W_{n+1}(B^a) \) and \( \varepsilon W_{n+1}(B^a) \circ \tau = W_{n+1} \varepsilon B \).

(ii) Moreover, we have a natural isomorphism of non-unital rings (see remark 9.3.16)
\[
\tilde{n}_n := n_n \otimes W_{n+1} A \quad \text{n}_n \iso W_{n+1} (\tilde{m})
\]

**Proof.** (i): We consider the commutative diagrams
\[
\begin{align*}
W_{n+1}B & \longrightarrow W_{n+1}(B^a) \\
\eta W_{n+1}B & \downarrow \quad \downarrow (W_{n+1}n_B) \varepsilon W_{n+1}B \\
(W_{n+1}B)^a & \longrightarrow W_{n+1}(B^a)
\end{align*}
\]
and notice that \((W_{n+1}\varepsilon B)^a\) and \((W_{n+1}n_B)^a\) are isomorphisms, by the discussion of (14.7.15).
Hence, it suffices to show that \( \eta W_{n+1}(B^a) \) and \( \varepsilon W_{n+1}(B^a) \) are isomorphisms, which follows from:

**Claim 14.7.19.** If \( \eta_B \) (resp. \( \varepsilon_B \)) is an isomorphism, the same holds for \( \eta W_{n+1}B \) (resp. \( \varepsilon W_{n+1}B \)).

**Proof of the claim.** Let \( \text{gr}_i(W_{n+1}B) \) be the graded ring associated with the filtration \((V_kB \mid k = 0, \ldots, n)\) of \( W_{n+1}B \); consider also the filtration \((\text{gr}_i B^a) \mid k = 0, \ldots, n)\) of \( (W_{n+1}B)^a \), and let \( \text{gr}_i(W_{n+1}B)^a \) be the associated graded ring. We get a commutative diagram
\[
\begin{array}{ccc}
\text{gr}_i(W_{n+1}B) & \text{gr}_i(W_{n+1}B)^a & \text{gr}_i(W_{n+1}B)^a \\
\eta \varepsilon_i & \eta \varepsilon_i & \eta \varepsilon_i \\
(\text{gr}_i(W_{n+1}B)^a) & \text{gr}_i(W_{n+1}B)^a & (\text{gr}_i(W_{n+1}B)^a)
\end{array}
\]
whose bottom horizontal arrow is injective, since the functor \((-)^a\) is left exact. Here \( \eta \varepsilon_i (W_{n+1}B) \) is again the unit of adjunction, which, by virtue of (14.7.16), is naturally identified with the unit of adjunction
\[
\eta \varepsilon_i : \text{gr}_i B \to (\text{gr}_i B)^a
\]
for every \( i = 0, \ldots, n \).

Let now \( \mathcal{B} \) be the category of basic setups, and \( \mathcal{B}-\text{Alg} \to \mathcal{B} \) (resp. \( \mathcal{B}^a-\text{Alg} \to \mathcal{B} \)) the fibréd and cofibred category of \( \mathcal{B} \)-algebras (resp. of almost \( \mathcal{B} \)-algebras), as in [59] §3.5. The localization \( \mathcal{B}-\text{Alg} \to \mathcal{B}^a-\text{Alg} \) admits a right adjoint
\[
(-)_a : \mathcal{B}^a-\text{Alg} \to \mathcal{B}-\text{Alg} \quad ((V, m), R) \mapsto ((V, m), R_a)
\]
which is a \( \mathcal{B} \)-cartesian functor ([59] §3.5.4). By (14.7.12), we have the morphism \( \omega_i : (W_{n+1}A, n_{n+1}) \to (A, m) \) in \( \mathcal{B} \), whence a commutative diagram in \( \mathcal{B}-\text{Alg} \):
\[
\begin{array}{ccc}
(W_{n+1}A, n_{n+1}), \omega_i B & \longrightarrow & ((A, m), B) \\
\eta_B \downarrow & & \eta_B \downarrow \\
(W_{n+1}A, n_{n+1}), (\omega_i B)^a & \longrightarrow & ((A, m), B^a)
\end{array}
\]
whose top horizontal arrow is given by the identity map of \( \omega_i B \), and is therefore a cartesian morphism of \( \mathcal{B}-\text{Alg} \). Then also the bottom vertical arrow is a cartesian morphism, since \((-)_a\).
is a cartesian functor. We conclude that $\eta_{\mathfrak{B}(i)(W_{n+1}B)}$ is an isomorphism, under our assumptions. Then the same holds for $\text{gr}_i(\eta W_{n+1}B)$, for every $i = 0, \ldots, n$, whence the assertion for $\eta W_{n+1}B$.

To show the assertion concerning $\varepsilon W_{n+1}B$, we argue by induction on $n \in \mathbb{N}$; the case $n = 0$ is trivial. Let then $n > 0$, and suppose that the assertion is already known for $\varepsilon W_nB$; recall that for every $i \in \mathbb{N}$, the ring $(W_{i+1}B)_{||}$ is the cokernel of a map of $W_i A$-modules

$$\delta_i : \tilde{n}_{i+1} \to W_{i+1}A \oplus (\tilde{n}_{i+1} \otimes W_{i+1}A W_{i+1}B) \quad x_\bullet \otimes y_\bullet \mapsto (x_\bullet \cdot y_\bullet, x_\bullet \otimes y_\bullet \otimes 1).$$

We consider the commutative ladder with right exact rows:

\[
\begin{array}{ccccccccc}
\tilde{n}_{n+1} & \xrightarrow{\delta} & W_{n+1}A \oplus (\tilde{n}_{n+1} \otimes W_{n+1}A W_{n+1}B) & \xrightarrow{\alpha} & (W_{n+1}B)_{||} & \xrightarrow{\gamma} & 0 \\
\alpha \downarrow & & \downarrow \beta & & \downarrow \gamma & & \\
\tilde{n}_n & \xrightarrow{\delta-1} & W_nA \oplus (\tilde{n}_n \otimes W_nA W_nB) & \xrightarrow{\alpha} & (W_nB)_{||} & \xrightarrow{0} & 0
\end{array}
\]

whose vertical arrows are induced by the projections $\pi^A_n : W_{n+1}A \to W_nA$ and $\pi^B_n : W_{n+1}B \to W_nB$ (notice that the almost structure used to compute $(W_{n+1}B)_{||}$ is the one relative to the basic setup $(W_{n+1}A, n_{n+1})$, whereas for $(W_nB)_{||}$ we use the almost structure relative to the basic setup $(W_nA, n_n)$). Since $\pi^A_n(M_{n+1}) = n_n$, by [59, Rem.2.1.4(ii)] we have a natural isomorphism

$$\tilde{n}_{n+1} \otimes W_{n+1}A W_{n+1}A \sim \tilde{n}_n \quad x_\bullet \otimes y_\bullet \otimes a_\bullet \mapsto a_\bullet \cdot \pi^A_n(x_\bullet) \otimes \pi^A_n(y_\bullet)$$

which identifies $\alpha$ with $\tilde{n}_{n+1} \otimes W_{n+1}A \pi^A_n$, and $\beta$ with $\pi^A_n \oplus (\tilde{n}_{n+1} \otimes W_{n+1}A \pi^B_n)$. Taking claim [9.3.31] into account, we deduce natural $W_{n+1}A$-linear surjections:

\[
(14.7.20) \quad \tilde{n}_{n+1} \otimes W_{n+1}A \varpi_n(A) \to \text{Ker} \alpha \quad \varpi_n(A) \oplus (\tilde{n}_{n+1} \otimes W_{n+1}A \varpi_n(B)) \to \text{Ker} \beta.
\]

Then, in light of (14.7.12) and [59, Rem.2.1.4(ii)], we have as well the natural isomorphism

$$\tilde{n}_{n+1} \otimes W_{n+1}A \varpi_n(A) \sim \tilde{m} \quad x_\bullet \otimes y_\bullet \otimes a \mapsto a \cdot \varpi_n(x_\bullet) \otimes \varpi_n(y_\bullet)$$

which identifies (14.7.20) with $W_{n+1}A$-linear surjections:

\[
(14.7.21) \quad \varpi_n(\tilde{m}) \to \text{Ker} \alpha \quad \varpi_n(A \oplus (\tilde{m} \otimes A B)) \to \text{Ker} \beta.
\]

By a direct inspection, we then get a commutative diagram:

\[
\begin{array}{cccccc}
\varpi_n(\tilde{m}) & \xrightarrow{\varpi_n(\delta_0)} & \varpi_n(A \oplus (\tilde{m} \otimes A B)) & \xrightarrow{\delta_0} & \text{Ker} \alpha & \xrightarrow{\text{Ker} \beta} \\
\downarrow & & \downarrow & & \downarrow & \\
\text{Ker} \alpha & \xrightarrow{\text{Ker} \beta} & \text{Ker} \beta
\end{array}
\]

whose vertical arrows are the surjections (14.7.21), and $\delta_0$ is the restriction of $\delta_n$. Since $\alpha$ and $\beta$ are surjective, the induced map $\text{Coker} \delta_n \to \text{Ker} \gamma$ is bijective, by the snake lemma, and $\gamma$ is surjective, so finally we get a right exact sequence of $W_{n+1}A$-modules:

$$\varpi_n(B^n_0) \xrightarrow{\rho} (W_{n+1}B)^n_{||} \xrightarrow{\gamma} (W_nB)^n_{||} \to 0.$$

We consider then the diagram of $W_{n+1}A$-modules:

\[
\begin{array}{cccccccc}
\varpi_n(B^0_0) & \xrightarrow{\rho} & (W_{n+1}B)^0_{||} & \xrightarrow{\gamma} & (W_nB)^0_{||} & \xrightarrow{0} \\
\varpi_n(\varepsilon B) & \xrightarrow{\varepsilon W_{n+1}B} & (W_{n+1}B)^0_{||} & \xrightarrow{\varepsilon W_nB} & (W_nB)^0_{||} & \xrightarrow{0} \\
0 & \xrightarrow{0} & \varpi_n B & \xrightarrow{\rho'} & W_{n+1}B & \xrightarrow{\gamma'} & W_nB & \xrightarrow{0}
\end{array}
\]

where $\gamma'$ is the projection, and $\rho'$ is the natural identification of $\varpi_n B$ with $\text{Ker} \gamma'$ given by claim [9.3.31]. Thus, the bottom horizontal sequence is exact, and by inductive assumption the first and third vertical arrows are bijective; therefore, in order to conclude the proof, it will suffice to check the diagram commutes. The commutativity of the right square subdiagram
is clear. To see the commutativity of the left square subdiagram, let \( w \in \overline{\omega}_n(B_n^m) \) be any element; hence \( w \) is the class \([a, z]\) of a pair \((a, z) \in A \oplus (m \otimes A - B)\), and we may assume that \( z = x \otimes y \otimes b \) for some \( x, y \in m \) and \( b \in B \). Then, by inspecting the constructions, we see that \( w' := \rho(w) \) is the class \([0, \ldots, 0, a, (0, \ldots, 0, xyb)]\) of the corresponding pair in \( W_{n+1}A \oplus (\tilde{m}_{n+1} \otimes W_{n+1}A W_{n+1}B) \). On the other hand, \( \overline{\omega}_n \varepsilon_B(w) = a + xyb \); then, again by claim 9.3.31 we deduce that \( \varepsilon_{W_{n+1}B}(w') = (0, \ldots, 0, a + xyb) = \rho'(a + xyb) \), as required. \( \Diamond \)

(ii): For every \( n \in \mathbb{N} \), we have a natural map of non-unital \( W_{n+1}A \)-algebras:

\[
\mu_n : W_{n+1}(m) \otimes W_{n+1}A W_{n+1}(m) \to W_{n+1}(\tilde{m}) \quad a \otimes b \mapsto (P_i(a_i \otimes 1, 1 \otimes b_i) \mid i = 0, \ldots, n)
\]

for the non-unital ring structure of \( W_{n+1}(m) = n_{n+1} \) and \( W_{n+1}(\tilde{m}) \) induced by those of \( m \) and respectively \( \tilde{m} \) (remark 9.3.16). We show by induction on \( n \in \mathbb{N} \), that \( \mu_n \) is an isomorphism; the assertion is trivial for \( n = 0 \), since \( \mu_0 = 1_{\tilde{m}} \). Thus, let \( n > 0 \), and suppose that the assertion is already known for \( n - 1 \); we consider the commutative diagram of \( W_{n+1}A \)-modules:

\[
\begin{array}{ccc}
W_{n+1}(m) & \xrightarrow{\mu_n} & W_{n+1}(\tilde{m}) \\
\uparrow{\alpha} & & \downarrow{\beta} \\
n_{n} \otimes W_{n+1}A n_{n+1} & \xrightarrow{\mu_{n-1}} & W_{n}(\tilde{m})
\end{array}
\]

whose left vertical arrow is induced by the projection \( W_{n+1}(m) \to W_{n}(m) \), and whose right vertical arrow is likewise the natural projection. Claim 9.3.31 yields a natural isomorphism of \( W_{n+1}A \)-modules:

\[
(14.7.22) \quad \overline{\omega}_n(\tilde{m}) \xrightarrow{\text{Ker } \beta} \text{Ker } \beta.
\]

**Claim 14.7.23.** We have a commutative diagram of \( W_{n+1}A \)-modules:

\[
\begin{array}{ccc}
\overline{\omega}_n(\tilde{m}) & \xrightarrow{\overline{\omega}_n(\mu_n)} & \overline{\omega}_n(\tilde{m}) \\
\downarrow{\text{Ker } \alpha} & & \downarrow{\text{Ker } \beta} \\
\text{Ker } \alpha & \xrightarrow{\text{Ker } \beta} & \text{Ker } \beta
\end{array}
\]

whose bottom horizontal arrow is the restriction of \( \mu_n \), and whose right (resp. left) vertical arrow is induced by those of \( \tilde{m} \).

**Proof of the claim.** By construction, the left vertical arrow is characterized as the map such that \( a \cdot \overline{\omega}_n(x\bullet) \otimes \overline{\omega}_n(y) \mapsto (0, \ldots, 0, a) \cdot (x\bullet \otimes y) \) for every \( a \in A \) and every \( x\bullet, y \in n_{n+1} \). On the other hand, the right vertical arrow is the map such that \( x \otimes y \mapsto (0, \ldots, 0, x \otimes y) \) for every \( x, y \in m \). Hence, we need to check the identity:

\[
\mu_n((0, \ldots, 0, a) \cdot (x\bullet \otimes y)) = (0, \ldots, 0, a \cdot \overline{\omega}_n(x\bullet) \otimes \overline{\omega}_n(y))
\]

for every \( a \in A \) and every \( x\bullet, y \in n_{n+1} \). To this aim, endow \( R := A \oplus m \) with its natural \( A \)-algebra structure as in remark 9.3.16(iii), and recall that \( \mu_n \) is the restriction of the map of unital \( W_{n+1}A \)-algebras

\[
W_{n+1}R \otimes W_{n+1}A W_{n+1}R \to W_{n+1}(R \otimes A) \quad x\bullet \otimes y \mapsto (x\bullet \otimes 1) \cdot (1 \otimes y) .
\]

Thus, we are reduced to checking that

\[
((V_R^m(\tau_R(a)) \cdot x\bullet) \otimes 1) \cdot (1 \otimes y) = V_R^n(\tau_{R \otimes A}(a \cdot \overline{\omega}_n(x\bullet) \otimes \overline{\omega}_n(y)))
\]

for every \( a \in A \) and every \( x\bullet, y \in W_{n+1}R \), where \( V_R \) and \( \tau_R \) denote respectively the Verschiebung and the Teichmüller maps, and likewise for \( V_{R \otimes A}^n \) and \( \tau_{R \otimes A} \) (see 9.3.18). Let
also \( F_R \) be the Frobenius map; using proposition\(^{9.3.22}\) (ii) we compute:

\[
((V^n_R(\tau_R(a)) \cdot x_\bullet) \otimes 1) \cdot (1 \otimes y_\bullet) = (V^n_R(\tau_R(a) \cdot F^n_R(x_\bullet)) \otimes 1) \cdot (1 \otimes y_\bullet) = V^n_R((\tau_R(a) \cdot F^n_R(x_\bullet)) \otimes 1) \cdot (1 \otimes y_\bullet) = V^n_{R \otimes A R}(((\tau_R(a) \cdot F^n_R(x_\bullet)) \otimes 1) \cdot (1 \otimes F^n_R(y_\bullet))) = V^n_{R \otimes A R}(\tau_R \otimes A R(a) \cdot F^n_{R \otimes A R}(x_\bullet \otimes 1) \cdot F^n_{R \otimes A R}(1 \otimes y_\bullet)).
\]

Hence, we are reduced to checking that:

\[
\varpi_n(x_\bullet) \otimes \varpi_n(y_\bullet) = \varpi_0(F^n_{R \otimes A R}(x_\bullet \otimes 1) \cdot F^n_{R \otimes A R}(1 \otimes y_\bullet)) \quad \text{in } W_{n+1}(R \otimes A R).
\]

The latter follows easily from \(^{9.3.19}\): details left to the reader.

Claim \(^{14.7.22}\) implies that also \(^{14.7.21}\) is an isomorphism, and the same for \(\mu_{n-1}\), by inductive assumption; so the same follows for \(\mu_n\) and the proof is concluded.

\[\square\]

14.7.24. Let now \(A_0\) be any \(\mathbb{F}_p\)-algebra, \((A_0, m_0)\) any basic setup, and \(R\) any \(A_0\)-algebra. Recall that the Frobenius endomorphism \(\Phi_R : R \to R\) induces an endofunctor

\[\Phi^{k \ast}_R : R{-}\text{Alg} \to R{-}\text{Alg}\]

that assigns to every \(R\)-algebra \(S\) the \(R\)-algebra \(\Phi^{k \ast}_R S\) whose underlying ring is the same as \(S\), and whose structure morphism is the composition of \(\Phi^{k}_S\) with the structure morphism \(R \to S\) of \(S\). Moreover, the Frobenius endomorphism \(\Phi^{k}_S\) induces a natural transformation

\[\Phi^{k}_{S/R} : S \otimes_R \Phi^{k}_R S \to \Phi^{k}_R S \quad x \otimes y \mapsto x^{p^k} y \quad \text{for every } R{-}\text{algebra } S\]

Let \(R^a\) be the \((A_0, m)^a\)-algebra represented by \(R\); then \(\Phi^{k \ast}_R\) descends to an endofunctor

\[\Phi^{k \ast}_{R^a} : R^a{-}\text{Alg} \to R^a{-}\text{Alg}\]

that assigns to every \(R^a\)-algebra \(S^a\) the \(R^a\)-algebra \(\Phi^{k \ast}_{R^a}(S^a) := (\Phi^{k \ast}_R S)^a\), where \(S\) is any \(R\)-algebra representing \(S^a\) : see \(^{59}, \S3.5.7\). Likewise, the Frobenius endomorphism \(\Phi^{k}_S\) induces a natural transformation

\[\Phi^{k \ast}_{S^a/R^a} := (\Phi^{k \ast}_{S/R})^a : (S^a \otimes_R R^a) \to (\Phi^{k \ast}_{R^a} R^a) \to (\Phi^{k \ast}_{R^a}(S^a \otimes_R R^a)) \quad \text{for every } R^a{-}\text{algebra } S^a\]

Moreover, notice that \(\Phi^{k+1 \ast}_{S^a/R^a}\) also equals the composition of \(\Phi^{k \ast}_{S^a/R^a} \otimes_R \Phi^{k \ast}_{R^a R^a}\) \(\Phi^{k+1 \ast}_R R^a\):

\[
S^a \otimes_R \Phi^{k+1 \ast}_R R^a \to S^a \otimes_R \Phi^* R^a \otimes R^a \Phi^{k \ast}_R R^a \otimes_R R^a \Phi^{k+1 \ast}_R R^a \to \Phi^{k \ast}_{R^a}(S^a \otimes_R R^a) \Phi^{k \ast}_{R^a}(R^a) \to \Phi^{k+1 \ast}_R S^a.
\]

together with \(\Phi^{k \ast}_{R^a}(\Phi^{k \ast}_{S^a/R^a}) = \Phi^{k \ast}_{R^a}(S^a \otimes_R R^a) \Phi^{k \ast}_{R^a}(R^a) \to \Phi^{k+1 \ast}_R S^a\).

Especially, if \(\Phi^{k \ast}_{S^a/R^a}\) is an isomorphism, the same holds for \(\Phi^{k \ast}_{S^a/R^a}\), for every \(k \in \mathbb{N}\).

**Remark 14.7.25.** In the situation of \(^{14.7.24}\), suppose that \(m\) fulfills condition (B) of \(^{59}, \S2.1.6\), and let \(f : R \to S\) be any weakly étale morphism of \(A_0\)-algebras. Then \(\Phi^{k \ast}_{S/R}\) is an isomorphism. Indeed, the assertion is \(^{59}, \text{Th.3.5.13(ii)}\) in case \(m \otimes A_0 m\) is a flat \(A_0\)-module, but by direct inspection one sees easily that the proof of loc.cit. is valid more generally, whenever condition (B) holds.

**Theorem 14.7.26.** In the situation of \(^{14.7.15}\), let \(f : B \to C\) be a flat morphism of \(A^a\)-algebras; set \(B_0 := B/pB, C_0 := C/pC\), and suppose that \(\Phi^{k \ast}_{C_0/B_0}\) is an isomorphism. Then:

(i) \(f\) induces a flat morphism of \(W_{n+1}A^a\)-algebras

\[W_{n+1}f : W_{n+1}B \to W_{n+1}C \quad \text{for every } n \in \mathbb{N}\]
(ii) For every \( n \in \mathbb{N} \) and every \( i = 0, \ldots, n \), the following diagram is cocartesian:

\[
\begin{array}{ccc}
W_{n+1}B & \xrightarrow{W_{n+1}f} & W_{n+1}C \\
\omega_i \downarrow & & \omega_i' \downarrow \\
\omega_i' B & \xrightarrow{\omega_i' f} & \omega_i' C.
\end{array}
\]

**Proof.** We prove first both assertions in the case where \( p^kA = 0 \) for some integer \( k \in \mathbb{N} \). For every \( j \in \mathbb{N} \), and every \( A^e \)-algebra \( R \) set

\[ W_{n,j}R := W_{n+1}(R)/p^jV_n(R) \quad \text{with} \quad V_n(R) := V_nR/V_{n+1}R \subset W_{n+1}R. \]

Hence, \( W_{n,0}R = W_nR \), and in light of corollary \([3.32]\) we see that \( W_{n,j}R = W_{n+1}R \) for every sufficiently large \( j \in \mathbb{N} \). We shall show, by induction on \( j \) and \( n \), the following assertions:

(a) \(_{n,j} \) The induced map \( W_{n,j}f : W_{n,j}B \to W_{n,j}C \) is flat for every \( j, n \in \mathbb{N} \).

(b) \(_{n,j} \) The morphism \( f \) induces a cocartesian diagram of \( W_{n+1}B \)-algebras:

\[
\begin{array}{ccc}
W_{n,j}B & \xrightarrow{W_{n,j}f} & W_{n,j}C \\
\downarrow & & \downarrow \\
\omega_i B & \xrightarrow{\omega_i f} & \omega_i C.
\end{array}
\]

Both assertions are trivial for \( n = 0 \) and every \( j \in \mathbb{N} \). Let then \( n, j \in \mathbb{N} \) be any integers, and suppose that (a)\(_{n,j} \) and (b)\(_{n,j} \) hold. According to \([14.7.16]\), the kernel \( K_{n,j} \) of the projection \( W_{n,j+1}B \to W_{n,j}B \) is isomorphic, as a \( W_{n+1}B \)-module, to \( \omega_i(p^jB/p^{j+1}B) \). Likewise for the kernel \( K'_{n,j} \) of the projection \( W_{n,j+1}C \to W_{n,j}C \), and the induced morphism \( K_{n,j} \to K'_{n,j} \) corresponds to the restriction of \( \omega_i(f \otimes \mathbb{Z}/p^{j+1}\mathbb{Z}) \), under these identifications. By the (almost version of the) local flatness criterion (see \([100] \) Th.22.3), assertion (a)\(_{n,j+1} \) will follow from:

**Claim 14.7.27.** The induced morphism \( \omega_i(p^jB/p^{j+1}B) \otimes_{W_{n,j}B} W_{n,j}C \to \omega_i(p^jC/p^{j+1}C) \) is an isomorphism.

**Proof of the claim.** Clearly \( \omega_i(p^jB/p^{j+1}B) \) is a \( \omega_iB_0 \)-module and \( \omega_i(p^jC/p^{j+1}C) \) is a \( C_0 \)-module, and notice that \( \omega_i(B_0) = \omega_i \circ \Phi_{B_0}(B_0) \), and likewise for \( \omega_i(C_0) \). Then the stated morphism agrees with the composition

\[
\begin{align*}
\omega_i(p^jB/p^{j+1}B) \otimes_{W_{n,j}B} W_{n,j}C & \xrightarrow{\omega_i(B_0)} \omega_i(\Phi_{B_0}(p^jB/p^{j+1}B) \otimes_{B_0} B_0) \\
& = \omega_i(\Phi_{B_0}(p^jB/p^{j+1}B) \otimes_{B_0} \Phi_{B_0}(B_0) C_0) \\
& = \omega_i(\Phi_{B_0}(p^jB/p^{j+1}B) \otimes_{B_0} \Phi_{B_0}(B_0) \Phi_{B_0}(C_0) \otimes_{B_0} C_0) \\
& = \omega_i(\Phi_{B_0}(p^jB/p^{j+1}B) \otimes_{B_0} \Phi_{B_0}(C_0)) \\
& = \omega_i(\Phi_{B_0}(p^jC/p^{j+1}C)) \\
& = \omega_i(p^jC/p^{j+1}C)
\end{align*}
\]

where the second isomorphism follows from (b)\(_{n,j} \), the fourth follows from our assumption about \( \Phi_{C_0/B_0} \), and the fifth follows from the flatness of \( f \).
Claim 14.7.27 also implies that the diagram
\[
\begin{array}{ccc}
W_{n,j+1}B & \longrightarrow & W_{n,j}B \\
W_{n,j+1}f & \downarrow & W_{n,j}f \\
W_{n,j+1}C & \longrightarrow & W_{n,j}C \\
\end{array}
\]
is cocartesian; combining with (b)\(_{n,j}\), we see that (b)\(_{n,j+1}\) holds. Thus, we conclude that (a)\(_{n,j}\) and (b)\(_{n,j}\) hold for every \(j \in \mathbb{N}\); for large values of \(j\), we deduce that (a)\(_{n+1,0}\) and (b)\(_{n+1,0}\) both hold. By induction on \(n \in \mathbb{N}\), the assertion follows. This concludes the proof of (i) in case \(p^kA = 0\). To prove (ii) under the same assumption, we show first that the natural morphism
\[
(14.7.28) \quad \overline{\omega}^i B_0 \otimes_{W_{n+1}B} W_{n+1}C \rightarrow \overline{\omega}^i C_0
\]
is an isomorphism. Indeed, notice that \(\overline{\omega}^i B_0 = \overline{\omega}^i_0(\Phi^{i_0}_B B_0)\), and likewise for \(\overline{\omega}^i C_0\). Then the foregoing morphism is the composition:
\[
\begin{align*}
\overline{\omega}^i B_0 \otimes_{W_{n+1}B} W_{n+1}C &= \overline{\omega}^i_0(\Phi^{i_0}_B B_0) \otimes_{W_{n+1}B} W_{n+1}C \\
&\sim \overline{\omega}^i_0(\Phi^{i_0}_B B_0) \otimes_{\omega^i_0 B_0} \omega^i_0 B_0 \otimes_{W_{n+1}B} W_{n+1}C \\
&\sim \overline{\omega}^i_0(\Phi^{i_0}_B B_0) \otimes_{\omega^i_0 B_0} \omega^i_0 C_0 \\
&= \overline{\omega}^i(\Phi^{i_0}_B B_0 \otimes_{\omega^i_0 B_0} C_0) \\
&\sim \overline{\omega}^i(\Phi^{i_0}_B C_0) \\
&= \overline{\omega}^i C_0
\end{align*}
\]
where the second isomorphism follows from the foregoing condition (b)\(_{n+1,0}\), and the third isomorphism follows from our assumption on \(\Phi_{C_0/B_0}\). Now, since \(p^kB = 0\), the assertion follows from the isomorphism (14.7.28) together with the following:

Claim 14.7.29. Let \(g : R \rightarrow S\) be a flat morphism of \(A^a\)-algebras, \(I \subset R\) a nilpotent ideal, and suppose that \(g \otimes_R R/I\) is an isomorphism. Then \(g\) is an isomorphism.

Proof of the claim. By a simple induction, we are reduced to the case where \(I^2 = 0\). Then we have the commutative ladder with exact rows:
\[
\begin{array}{ccc}
0 & \longrightarrow & I \\
& \longrightarrow & R \\
& \longrightarrow & R/I \\
& \longrightarrow & 0
\end{array}
\]
\[
\begin{array}{ccc}
0 & \longrightarrow & I \otimes_R S \\
& \longrightarrow & S \\
& \longrightarrow & S/IS \\
& \longrightarrow & 0
\end{array}
\]
and a natural identification \(I \otimes_R S \rightarrow I \otimes_{R/I} S/IS \rightarrow I\). Thus, the first and third vertical arrows are both isomorphisms, and the same then follows for the middle one. \(\diamond\)

We consider next the case where \(A\) is a general ring, and \(m\) fulfills condition (B). We shall use the following criterion:

Claim 14.7.30. Let \((V, m_V)\) be any basic setup, \(R\) a \((V, m_V)^a\)-algebra and \(M\) an \(R\)-module. Set
\[
M_{tor} := \bigcup_{n \in \mathbb{N}} \text{Ann}_M(p^n) \quad R_{tor} := \bigcup_{n \in \mathbb{N}} \text{Ann}_R(p^n).
\]
Then \(M\) is a flat \(R\)-module if and only if the following three conditions hold:

(a) \(M/p^iM\) is a flat \(R/p^iR\)-module for every \(i \in \mathbb{N}\).
(b) \(M \otimes_R R[p^{-1}]\) is a flat \(R[p^{-1}]\)-module.
(c) The natural morphism \(R_{tor} \otimes_R M \rightarrow M_{tor}\) is an isomorphism.
**Proof of the claim.** Clearly if $M$ is flat, conditions (a)–(c) hold. Thus, suppose that (a)–(c) hold; according to [59, Lemma 5.2.1] it suffices to prove that

$$\text{Tor}_i^R(M, R/pR) = 0 \quad \text{for } i = 1, 2.$$  

However, a standard calculation shows that

$$\text{Tor}_1^R(M, R/pR) = \frac{\text{Ann}_R(p)}{\text{Ann}_R(p)M} \quad \text{and} \quad \text{Tor}_2^R(M, R/pR) = \text{Ker}(\text{Ann}_R(p) \otimes_R M \to M).$$

Let us then consider the commutative ladder:

$$\begin{array}{cccccc}
0 & \longrightarrow & \text{Ann}_R(p) \otimes_R M & \longrightarrow & R_{\text{tor}} \otimes_R M & \longrightarrow & R_{\text{tor}} \otimes_R M \\
\downarrow & & \downarrow & & \downarrow & & \downarrow \\
0 & \longrightarrow & \text{Ann}_M(p) & \longrightarrow & M_{\text{tor}} & \longrightarrow & M_{\text{tor}}
\end{array}$$

whose bottom horizontal row is exact, and whose central and right vertical arrows are isomorphisms; in order to verify (14.7.31), it suffices therefore to check that the top horizontal row is also exact; the latter is the inductive limit of the system of morphisms:

$$\text{Ann}_R(p) \otimes_R M \to \text{Ann}_R(p^n) \otimes_R M \to \text{Ann}_R(p^n) \otimes_R M \quad \text{for every } n \in \mathbb{N}.$$  

But clearly \(\text{Ann}_R(p') \otimes_R M = \text{Ann}_R(p^i) \otimes_{R/p^iR} M/p^nM\) for every \(i, n \in \mathbb{N}\) with \(i \leq n\); in view of (a), the assertion follows.

Now, example 9.3.39(ii), implies easily that \(W_{n+1}(C[p^{-1}])\) is a flat \(W_{n+1}(B[p^{-1}])\)-algebra. Next, for every \(k \in \mathbb{N}\) let \(\pi_k : C \to C/p^kC\) be the projection; from example 9.3.38(iii) we get

$$\text{Ker} W_{n+1}(\pi_{n+k}) \subset p^k W_{n+1}(C) \quad \text{for every } k \in \mathbb{N}$$

so that \(\pi_{n+k}\) induces an isomorphism of \(W_{n+1}A^n\)-algebras

$$W_{n+1}(C) \otimes_\mathbb{Z} \mathbb{Z}/p^k\mathbb{Z} \cong W_{n+1}(C/p^{n+k}C) \otimes_\mathbb{Z} \mathbb{Z}/p^k\mathbb{Z} \quad \text{for every } k \in \mathbb{N}.$$  

But, by the foregoing case, we know already that \(W_{n+1}(C/p^{n+k}C)\) is a flat \(W_{n+1}(B/p^{n+k}B)\)-algebra for every \(k \in \mathbb{N}\), so we conclude that \(W_{n+1}(C) \otimes_\mathbb{Z} \mathbb{Z}/p^k\mathbb{Z}\) is a flat \(W_{n+1}(B) \otimes_\mathbb{Z} \mathbb{Z}/p^k\mathbb{Z}\)-algebra for every \(k \in \mathbb{N}\). In light of claim 14.7.30, we are therefore reduced to checking that the natural morphism

$$W_{n+1}(B)_{\text{tor}} \otimes_{W_{n+1}B} W_{n+1}C \to W_{n+1}(C)_{\text{tor}}$$

is an isomorphism. More precisely, we shall show, by descending induction on \(i\), that:

- the induced morphism \((\overline{V}_iB)_{\text{tor}} \otimes_{W_{n+1}B} W_{n+1}C \to (\overline{V}_iC)_{\text{tor}}\) is an isomorphism of \(W_{n+1}B\)-modules for every \(i = 0, \ldots, n+1\);
- the induced morphism \((\overline{V}_{i+1}B)_{\text{tor}} \otimes_{W_{n+1}B} W_{n+1}C \to (\overline{V}_iB)_{\text{tor}} \otimes_{W_{n+1}B} W_{n+1}C\) is a monomorphism of \(W_{n+1}B\)-modules for \(i = 0, \ldots, n\).

Indeed, both assertions are trivial for \(i = n+1\). Suppose that both assertions are already known for some strictly positive integer \(i \leq n+1\); from the commutative diagram

$$\begin{array}{ccc}
(\overline{V}_iB)_{\text{tor}} \otimes_{W_{n+1}B} W_{n+1}C & \longrightarrow & (\overline{V}_iC)_{\text{tor}} \\
\downarrow & & \downarrow \\
(\overline{V}_{i-1}B)_{\text{tor}} \otimes_{W_{n+1}B} W_{n+1}C & \longrightarrow & (\overline{V}_{i-1}C)_{\text{tor}}
\end{array}$$

we then deduce that the left vertical arrow is a monomorphism, i.e. the second assertion holds for \(i-1\). Moreover, in order to prove the first assertion for \(i-1\), it suffices to check that the induced morphism

$$(\overline{V}_{i-1}B)_{\text{tor}}/(\overline{V}_iB)_{\text{tor}} \otimes_{W_{n+1}B} W_{n+1}C \to (\overline{V}_{i-1}C)_{\text{tor}}/(\overline{V}_{i-1}C)_{\text{tor}}$$
is an isomorphism of $W_{n+1}B$-modules. On the other hand, from example \[9.3.39\] (i) we see that $W_{n+1}(B)_{\text{tor}}$ is the kernel of the natural morphism $W_{n+1}B \to W_{n+1}(B[p^{-1}])$, and likewise for $W_{n+1}(C)_{\text{tor}}$; taking into account \[14.7.16\], we deduce a natural isomorphism:

$$(\overline{V}_{i-1}B)_{\text{tor}}/(\overline{V}_iB)_{\text{tor}} \sim (\overline{\omega}^*_{i-1}B)_{\text{tor}}$$

of $W_{n+1}B$-modules, and likewise for $(\overline{V}_{i-1}C)_{\text{tor}}/(\overline{V}_iC)_{\text{tor}}$. We are then further reduced to checking that the induced morphism

$$\overline{\omega}^*_{i-1}(\text{Ann}_B(p^k)) \otimes W_{n+1}(B) W_{n+1}C \to \overline{\omega}^*_{i-1}\text{Ann}_C(p^k)$$

is an isomorphism for every $k \in \mathbb{N}$. However, the latter is the composition of the isomorphisms

$$\overline{\omega}^*_{i-1}(\text{Ann}_B(p^k)) \otimes W_{n+1}(B) W_{n+1}C \sim \overline{\omega}^*_{i-1}(\text{Ann}_B(p^k)) \otimes W_{n+1}(B/p^{n+k}B) W_{n+1}(C/p^{n+k}C)$$

$$\sim \overline{\omega}^*_{i-1}(\text{Ann}_B(p^k)) \otimes \overline{\omega}^*_{i-1}(B/p^{n+k}B) \overline{\omega}^*_{i-1}(C/p^{n+k}C)$$

$$= \overline{\omega}^*_{i-1}(\text{Ann}_B(p^k) \otimes B C)$$

$$\sim \overline{\omega}^*_{i-1}\text{Ann}_C(p^k)$$

where the first isomorphism is due to \[14.7.32\], the second one follows from the part of assertion (ii) that we have already proved, and the third one follows from the flatness of $f$.

To conclude the proof of (ii) for a general ring $A$, we shall need the following:

**Claim** 14.7.33. Let $(V, m_V)$ be a basic setup, $R$ a $(V, m^\alpha)$-algebra and $\varphi : M \to N$ a morphism of flat $R$-modules. Suppose that:

(a) $\varphi \otimes_{\mathbb{Z}} \mathbb{F}_p$ is an isomorphism of $R/pR$-modules.

(b) $\varphi \otimes_{\mathbb{Z}} \mathbb{Z}[p^{-1}]$ is an isomorphism of $R[p^{-1}]$-modules.

Then $\varphi$ is an isomorphism.

**Proof of the claim.** Denote by $C_\bullet$ the complex of $R$-modules $[M \xrightarrow{i} N]$, say with $M$ placed in degree $0$. Consider as well the acyclic complex

$$D_\bullet : 0 \to \text{Ann}_R(p) \to R \xrightarrow{p1_R} R \to R/pR \to 0.$$  

Since $C_\bullet$ is flat in every degree, the complex $D_\bullet \otimes_R C_\bullet$ is still exact; the latter is also the total complex of the double complex

$$0 \to E_\bullet := \text{Ann}_R(p) \otimes_{R/pR} (C_\bullet \otimes_{\mathbb{Z}} \mathbb{F}_p) \to C_\bullet \xrightarrow{p1_{C_\bullet}} C_\bullet \to C_\bullet \otimes_{\mathbb{Z}} \mathbb{F}_p \to 0.$$  

On the other hand, assumption (a) says that $C_\bullet \otimes_{\mathbb{Z}} \mathbb{F}_p$ is an acyclic complex of flat $R/pR$-modules, hence also $E_\bullet$ is acyclic. Summing up, we find that the morphism of complexes $p1_{C_\bullet} : C_\bullet \to C_\bullet$ is a quasi-isomorphism, and hence induces isomorphisms $p \cdot 1_{H_i(C_\bullet)} : H_i(C_\bullet) \sim H_i(C_\bullet)$ for $i = 0, 1$. In other words, $H_i(C_\bullet) = H_i(C_\bullet) \otimes_{\mathbb{Z}} \mathbb{Z}[p^{-1}]$ for $i = 0, 1$; combining with assumption (b), we conclude that $\ker \varphi = \text{Coker} \varphi = 0$, whence the claim.

Now, we need to show that the morphism

$$\varphi_f : \overline{\omega}^*_i B \otimes_{W_{n+1}B} W_{n+1}C \to \overline{\omega}^*_i C$$

resulting from the diagram of (ii) is an isomorphism of $W_{n+1}B$-modules; however, set as well

$$g := f \otimes_{\mathbb{Z}} \mathbb{Z}/p^{n+1}\mathbb{Z} : B/p^{n+1}B \to C/p^{n+1}C;$$

according to the part of (ii) that has already been proved, the corresponding morphism

$$\varphi_g : \overline{\omega}^*_i (B/p^{n+1}B) \otimes_{W_{n+1}(B/p^{n+1}B)} W_{n+1}(C/p^{n+1}C) \to \overline{\omega}^*_i (C/p^{n+1}C)$$

is an isomorphism; on the other hand, in view of \[14.7.32\] the morphism $\varphi_f \otimes_{\mathbb{Z}} \mathbb{F}_p$ is naturally identified with $\varphi_g \otimes_{\mathbb{Z}} \mathbb{F}_p$, so $\varphi_f \otimes_{\mathbb{Z}} \mathbb{F}_p$ is an isomorphism as well. Next, recall that the ghost
map induces an isomorphism of $W_{n+1}A^n$-algebras

$$(W_{n+1}B)[p^{-1}] \xrightarrow{\sim} B[p^{-1}]^{n+1} := \prod_{i=0}^{n} \varpi_i^*B[p^{-1}]$$

and likewise for $(W_{n+1}C)[p^{-1}]$ (example [9.3.39(ii)]); under these isomorphisms, the morphism $\varpi_i \otimes_{\mathbb{Z}} \mathbb{Z}[p^{-1}]$ on $(W_{n+1}B)[p^{-1}]$ is identified with the projection $\pi_i : B[p^{-1}]^{n+1} \to B[p^{-1}]$ on the $(i+1)$-th factor, and likewise for the corresponding morphism on $(W_{n+1}C)[p^{-1}]$. Thus, $\varphi_f \otimes_{\mathbb{Z}} \mathbb{Z}[p^{-1}]$ is identified with the natural isomorphism of $B[p^{-1}]^{n+1}$-modules

$$\pi_i^*B[p^{-1}] \otimes_{B[p^{-1}]^{n+1}} C[p^{-1}]^{n+1} \xrightarrow{\sim} \pi_i^*C[p^{-1}]$$

From claim [14.7.33] and (i) we deduce that $\varphi_f$ is an isomorphism, as required. □

**Corollary 14.7.34.** In the situation of theorem [14.7.26] for every $n \in \mathbb{N}$ we have:

(i) Every $B$-algebra $D$ induces a cocartesian diagram of $W_{n+1}A^n$-algebras:

$$
\begin{array}{ccc}
W_{n+1}B & \longrightarrow & W_{n+1}C \\
\downarrow & & \downarrow \\
W_{n+1}D & \longrightarrow & W_{n+1}(C \otimes_B D).
\end{array}
$$

(ii) The $W_{n+1}B$-module $W_{n+1}C$ is almost finitely generated (resp. almost finitely presented, resp. almost projective) if and only if the same holds for the $B$-module $C$.

(iii) Suppose that condition (B) of [59] §2.1.6 holds for $m$. Then $W_{n+1}(f)$ is étale (resp. weakly étale) if and only if the same holds for the morphism $f$.

(iv) The projection $W_{n+2}C \to W_{n+1}C$ induces an isomorphism of $W_{n+1}B$-algebras:

$$W_{n+2}C \otimes_{W_{n+2}B} W_{n+1}B \xrightarrow{\sim} W_{n+1}C.$$

**Proof.** (i): Notice that the natural morphism $h : W_{n+1}C \otimes_{W_{n+1}B} W_{n+1}D \to W_{n+1}(C \otimes_B D)$ restricts to morphisms of $W_{n+1}B$-modules

$$W_{n+1}C \otimes_{W_{n+1}B} \nabla_k D \to \nabla_k (C \otimes_B D) \quad \text{for every } k = 0, \ldots, n.$$

Taking into account [14.7.16], we are then reduced to checking that $h$ induces isomorphisms

$$\text{gr}_k h : W_{n+1}C \otimes_{W_{n+1}B} \varpi_k^* D \to \varpi_k^*(C \otimes_B D) \quad \text{for every } k = 0, \ldots, n.$$

However, a simple inspection shows that $\text{gr}_k h$ agrees with the composition

$$W_{n+1}C \otimes_{W_{n+1}B} \varpi_k^* D \xrightarrow{\sim} W_{n+1}C \otimes_{W_{n+1}B} \varpi_k^* B \otimes_{\varpi_k^* B} \varpi_k^* B \otimes_{\varpi_k^* B} D \xrightarrow{\sim} \varpi_k^* C \otimes_{\varpi_k^* B} \varpi_k^* D = \varpi_k^*(C \otimes_B D)$$

where the second isomorphism follows from theorem [14.7.26(ii)].

(ii): The proof of (i) also shows that the natural morphism

$$W_{n+2}C \otimes_{W_{n+2}B} \nabla_{n+1} B \to \nabla_{n+1} C$$

is an isomorphism. The assertion is an immediate consequence.

(iii): Let $\psi : W_{n+1}B \to B^{n+1} := \prod_{i=0}^{n} \varpi_i^* B$ be the morphism of $W_{n+1}A^n$-algebras whose composition with the projection $B^{n+1} \to \varpi_i^* B$ is the morphism $\varpi_i$, for $i = 0, \ldots, n$; denote by $R \subset B^{n+1}$ the image of $\psi$. Let also $P$ be one of the properties: “almost finitely generated”, “almost finitely presented”, or “almost projective”, and suppose that $f$ enjoys $P$; in view of theorem [14.7.26(ii)], proposition [9.3.30(i)] and [59] Lemma 3.2.25, it suffices to prove that the $R$-module $W_{n+1}C \otimes_{W_{n+1}B} R$ enjoys property $P$. Next, by proposition [9.3.30(ii)] we know that

$$p^{n+1}B^{n+1} \subset R \quad \text{and we let} \quad R_0 := R/p^{n+1}B^{n+1} \quad B_0^{n+1} := B^{n+1}/pB^{n+1}.$$

With this notation, it is easily seen that there exists a well defined morphism of $W_{n+1}B$-algebras

$$\varphi : B_0 \to B_0^{n+1} \quad \text{such that} \quad \pi_i \circ \varphi = \Phi_i^{B_0} : B_0 \to \varpi_i^* B_0 = \Phi_i^{B_0} B_0 \quad \text{for } i = 0, \ldots, n$$
where $\pi_i : B_{i+1} \rightarrow B_i$ is the projection on the $(i + 1)$-th factor. Arguing as in the proof of proposition 14.7.11 we get cartesian diagrams

$$
\begin{align*}
S & \rightarrow B^{n+1} & R & \rightarrow R_0 \\
\downarrow & \quad & \downarrow & \\
B_0 & \varphi \quad B_0^{n+1} & S & \rightarrow S_0 := S/p^{n+1}B^{n+1}.
\end{align*}
$$

In case $P$ is “almost finitely generated” or “almost finitely presented” we may then apply [59, Rem.3.2.26(i) and Lemma 3.4.18(i)] to the second of these cartesian diagrams, and thereby reduce to checking property $P$ for the $(S \times R_0)$-module $W^{n+1}_n \otimes_{W^{n+1}_n} B_0$. In case $P$ is the property “almost projective”, we may argue as in the proof of [59, Prop.3.4.21] to achieve the same reduction. But notice as well that the restriction $R_0 \rightarrow \omega_0B_0$ of $\pi_0$ is an epimorphism (on the underlying modules), and has nilpotent kernel (see the proof of proposition 14.7.11), so the $R_0$-module $W^{n+1}_n \otimes_{W^{n+1}_n} B_0$ enjoys $P$ if and only if the same holds for the $\omega_0B_0$-module $W^{n+1}_n \otimes_{W^{n+1}_n} B_0$. Next, by invoking again [59, Rem.3.2.26(i) and Lemma 3.4.18(i)] or the proof of [59, Prop.3.4.21] to the first of the two above diagrams we deduce that the $S$-module $W^{n+1}_n \otimes_{W^{n+1}_n} S$ enjoys $P$ if and only if the same holds for the $(\omega_0B_0 \times B^{n+1})$-module $W^{n+1}_n \otimes_{W^{n+1}_n} (\omega_0B_0 \times B^{n+1})$. Since $\omega_0B_0$ is a quotient of $B^{n+1}$, we are finally reduced to checking that the $B^{n+1}$-module $W^{n+1}_n \otimes_{W^{n+1}_n} B^{n+1}$ enjoys $P$; but according to theorem 14.7.26 (ii), the latter is isomorphic to the $B^{n+1}$-module $\prod_{i=0}^{n} \omega_i C$, so the assertion is clear.

(iii): Suppose first that $f$ is weakly étale, so that the multiplication morphism $\mu_{C/B} : C \otimes_B C \rightarrow C$ is flat; since it is also an epimorphism on the underlying $B$-modules, it follows easily that $\mu_{C/B}$ is weakly étale. Specifically, $\Phi_{C/C\otimes B C}$ is an isomorphism, by remark 14.7.25 and our assumption on $m$. Then theorem 14.7.26 says that $W^{n+1}_n(\mu_{C/C\otimes B C})$ is flat. Lastly, according to (i), the multiplication morphism $\mu_{W^{n+1}_nC/W^{n+1}_nB}$ of $W^{n+1}_n C$ factors through $W^{n+1}_n(\mu_{C/C\otimes B C})$ and an isomorphism

\((14.7.35)\)

$$
W^{n+1}_nC \otimes_{W^{n+1}_nB} W^{n+1}_nC \cong W^{n+1}_n(C \otimes_B C).
$$

Hence $\mu_{W^{n+1}_nC/W^{n+1}_nB}$ is flat, and combining with theorem 14.7.26 we conclude that $W^{n+1}_n f$ is weakly étale. In case $f$ is étale, we deduce from (ii), the isomorphism (14.7.35), and [59, Prop.2.4.18] that $W^{n+1}_n f$ is étale as well. Conversely, (iv) implies that if $W^{n+1}_n f$ is weakly étale (resp. étale), then the same holds for $f$. □

Remark 14.7.36. (i) It is shown in [83, 1.5.8] that if $f : B \rightarrow C$ is a homomorphism of $\mathbb{F}_p$-algebras and $n \in \mathbb{N}$ any integer, then $W^{n+1}_n f$ is étale (in the usual sense of [51], which includes the condition that $f$ is finitely presented), if and only if the same holds for $f$. This result can be deduced from corollary 14.7.34(iii) and extended to arbitrary rings, as follows. Resume the notation of the proof of the corollary, and suppose that $m = A$, so we are dealing with the “classical limit” for which almost rings are just usual rings; then, $W^{n+1}_n f$ is a weakly étale ring homomorphism, and by [59, §3.4.44] we know already that $W^{n+1}_n f$ is finitely presented if and only if the same holds for $W^{n+1}_n f \otimes_{W^{n+1}_n B} R$. We claim next that $W^{n+1}_n f \otimes_{W^{n+1}_n B} R$ is finitely presented if and only if the same holds for $W^{n+1}_n f \otimes_{W^{n+1}_n B} (R_0 \times S)$. For the proof, arguing as in [59, §3.4.44] we reduce to checking that the natural morphism $R \rightarrow R_0 \times S$ is of universal effective descent for the fibred category of weakly étale morphisms of rings. The latter assertion is already known by corollary 14.1.92. By the same token, $W^{n+1}_n f \otimes_{W^{n+1}_n B} S$ is finitely presented if and only if the same holds for $W^{n+1}_n f \otimes_{W^{n+1}_n B} (B^{n+1} \times B_0)$. Moreover, the surjective ring homomorphism $R_0 \rightarrow B_0$ has nilpotent kernel, so again by [59, §3.4.44] we know that $W^{n+1}_n f \otimes_{W^{n+1}_n B} R_0$ is finitely presented if and only if the same holds for $W^{n+1}_n f \otimes_{W^{n+1}_n B} B_0$. Since $B_0$ is a quotient of $B^{n+1}$, we are finally reduced to checking that $W^{n+1}_n f \otimes_{W^{n+1}_n B} B^{n+1}$
is finitely presented; but it was observed in the proof of corollary \[14.7.34\](ii) that the latter is isomorphic to the \(B^{n+1}\)-module \(\prod_{i=0}^{n+1} \omega_j^i C\), so the assertion is clear.

(ii) A version of corollary \[14.7.34\](iii) for truncated big Witt vectors of usual rings is found in \[56\], Th.2.4]. Another proof and generalization is given by \[25\], Th.9.2].

14.8. Complements : locally measurable algebras. This section studies the global counterpart of the class of measurable algebras introduced in section 14.5. To begin with – and until (14.8.42) – we consider an arbitrary valued field \((K, |·|)\), and we resume the notation of (11.4) and (14.5). Our first result is the following generalization of proposition 9.1.26:

\[\textbf{Proposition 14.8.1.} \text{Let } A \text{ be a measurable } K^+\text{-algebra, } M \text{ a } K^+\text{-flat and finitely generated } A\text{-module. Then } M \text{ is a finitely presented } A\text{-module.} \]

\[\text{Proof.} \text{Let } \Sigma \text{ be a finite system of generators for } M; \text{ also let us write } A \text{ as the colimit of a filtered system } (A_i \mid i \in I) \text{ of finitely presented } K^+\text{-algebras, with étale transition maps. For every } i \in I, \text{ let } M_i \text{ be the } A_i\text{-submodule of } M \text{ generated by } \Sigma; \text{ notice that } M_i \text{ is still } K^+\text{-flat, hence it is a finitely presented } A_i\text{-module (proposition 9.1.26). We may then write } M \text{ as the colimit of the filtered system } (M_i \otimes_{A_i} A \mid i \in I) \text{ of finitely presented } A\text{-modules, with surjective transition maps. Moreover, since } \overline{A} := A/m_KA \text{ is noetherian (lemma 14.5.4(i)), there exists } i \in I \text{ such that } M_j \otimes_{A_j} \overline{A} = M/m_KM \text{ for every } j \geq i. \text{ Since the ring homomorphism } \overline{A}_j := A_j/m_KA_j \rightarrow \overline{A} \text{ is faithfully flat, we deduce that}

\[M_i \otimes_{A_i} \overline{A}_j = M_j \otimes_{A_j} \overline{A}_j \text{ for every } j \geq i. \]

Consider the short exact sequence

\[C : 0 \rightarrow N \rightarrow M_i \otimes_{A_i} A_j \rightarrow M_j \rightarrow 0.\]

Since \(M_i\) is \(K^+\)-flat, the same holds for \(N\), and the latter is a finitely generated \(A_j\)-module, since both \(M_j\) and \(M_i \otimes_{A_i} A_j\) are finitely presented; therefore, the sequence \(C \otimes_{K^+} \kappa\) is still exact. Taking into account (14.8.2), we see that \(N/m_KN = 0\). By Nakayama’s lemma, it follows that \(N = 0\), and finally, \(M = M_i \otimes_{A_i} A\) is finitely presented, as stated. \]

\[\textbf{Definition 14.8.3.} \text{Let } A \text{ be a } K^+\text{-algebra. Set } X := \text{Spec } A, S := \text{Spec } K^+, \text{ and denote by } f : X \rightarrow S \text{ the structure morphism. We say that } A \text{ is locally measurable, if the following holds. For every } x \in X \text{ and every point } \xi \text{ of } X \text{ localized at } x, \text{ the strict henselization of } A \text{ at } \xi \text{ is a measurable } \mathcal{O}_{S,f(x)}\text{-algebra.} \]

\[\textbf{Remark 14.8.4.} \text{Let } A \text{ be a local } K^+\text{-algebra, } A^\text{sh} \text{ the strict henselization of } A \text{ at a geometric point localized at the closed point, and } M \text{ an } A\text{-module.}

(i) Clearly, } A \text{ is locally measurable if and only if } A^\text{sh} \text{ is measurable.}

(ii) However, if } A^\text{sh} \text{ is measurable, it does not necessarily follow that } A \text{ is measurable.}

(iii) On the other hand, if } A \text{ is a normal local domain, one can show that } A \text{ is measurable if and only if the same holds for } A^\text{sh}.

(iv) Suppose that } A \text{ is local and locally measurable. Since the natural map } A \rightarrow A^\text{sh} \text{ is faithfully flat, and since every measurable } K^+\text{-algebra is a coherent ring, it is easily seen that } A \text{ is coherent. If furthermore, the structure map } K^+ \rightarrow A \text{ is local, lemma 14.5.4(i) implies that } A/m_KA \text{ is a noetherian ring.} \]

\[\textbf{Remark 14.8.5.} \text{Let } A \text{ be a locally measurable } K^+\text{-algebra. Then, for every finitely generated ideal } I \subset A, \text{ the } K^+\text{-algebra } A/I \text{ is also locally measurable. Indeed, for every geometric point } \xi \text{ of Spec } A, \text{ let } A^\text{sh}_\xi \text{ (resp. } (A/I)^\text{sh}_\xi) \text{ be the strict henselization of } A \text{ (resp. of } A/I) \text{ at } \xi. \text{ Then the natural map } A^\text{sh}_\xi/I A^\text{sh}_\xi \rightarrow (A/I)^\text{sh}_\xi \text{ is an isomorphism for every such } \xi \text{ ([51], Ch.IV, Prop.18.8.10]), so the assertion follows from lemma 14.5.4(iv).} \]

\[\textbf{Definition 14.8.6.} \text{Let } A \text{ be a } K^+\text{-algebra, } M \text{ an } A\text{-module, and } \gamma \in \log \Gamma^+ \text{ any element.} \]
(i) A $K^+$-flattening sequence for the $A$-module $M$ is a finite sequence $b := (b_0, \ldots, b_n)$ of elements of $K^+$ such that
(a) $\log |b_{i+1}| > \log |b_i|$ for every $i = 0, \ldots, n - 1$, $b_0 = 1$ and $b_n = 0$.
(b) $b_i M/b_{i+1} M$ is a $K^+ / b_i^{1} b_{i+1} K^+$-flat module, for every $i = 0, \ldots, n - 1$.

We say that a $K^+$-flattening sequence $b$ for $M$ is minimal, if no proper subsequence of $b$ is still flattening for $M$.

(ii) Say that $\gamma \in \text{log } |b|$ for some $b \in K^+$, and let $b_M : M \to bM$ be the map given by the rule: $m \mapsto bm$, for every $m \in M$. We say that $\gamma$ breaks $M$ if the $\kappa$-linear map
$$b_M \otimes_{K^+} \kappa : M \otimes_{K^+} \kappa \to bM \otimes_{K^+} \kappa$$
is not an isomorphism.

**Remark 14.8.7.** Let $A$ be a $K^+$-algebra, $M$ an $A$-module.

(i) Suppose that $\gamma \in \text{log } \Gamma^+$ breaks $M$, and say that $\gamma = \text{log } |c|$ for some $c \in K^+$. Clearly, for every $b \in cK^+$, the map $b_M$ factors through $cM$. We deduce that every $\gamma' \in \text{log } \Gamma^+$ with $\gamma' \geq \gamma$ also breaks $M$.

(ii) For given $b \in K^+$, suppose that $M$ is a flat $K^+/bK^+$-module. Then we claim that no $\gamma < \text{log } |b|$ breaks $M$. Indeed, for such $\gamma$ pick $c \in K^+$ with $\text{log } |c| = \gamma$, and set $W := K^+/bK^+$; notice that the map $c_W : W \to cW$ induces an isomorphism $c_W \otimes_W 1_K : \kappa \to cW \otimes_W \kappa$ (notation of definition [14.8.6(ii)]), whence an isomorphism
$$1_M \otimes_W c_W \otimes_W 1_K : M \otimes_W \kappa \to M \otimes_W (cW \otimes_W \kappa).$$
Since $M$ is a flat $W$-module, the natural map $M \otimes_W cW \to cM$ is an isomorphism, and the resulting isomorphism $M \otimes_W \kappa \to cM \otimes_W \kappa$ is naturally identified with $c_M$, whence the contention.

(iii) Let $b := (b_0, \ldots, b_n)$ be a sequence of elements of $K^+$ fulfilling condition (a) of definition [14.8.6(i)], and suppose that $b$ admits a subsequence that is $K^+$-flattening for $M$. Then $b$ is $K^+$-flattening for $M$ as well. Indeed, an easy induction reduces the contention to the following.

Let $b, c \in K^+$ be any two elements such that $\text{log } |c| < \text{log } |b|$, and suppose that $M$ is $K^+/bcM$-flat; then $M/cM$ is $K^+/cK^+$-flat, and $cM$ is $K^+/c^{-1}bK^+$-flat. Of this two assertion, the first is trivial; to show the second, recall that $M$ can be written as the colimit of a filtered system of free $K^+/bK^+$-modules ([95, Ch.I, Th.1.2]). Then we may assume that $M$ is free, in which case the assertion is easily verified.

**Lemma 14.8.8.** Let $A$ be a $K^+$-algebra, $M$ a coherent $A$-module that admits a $K^+$-flattening sequence, and suppose that the Jacobson radical of $A$ contains $m_A$. Then we have:

(i) $M$ admits a minimal $K^+$-flattening sequence, unique up to units of $K^+$.

(ii) Let $(b_0, \ldots, b_n)$ be a minimal $K^+$-flattening sequence for $M$. For every $\gamma \in \text{log } \Gamma^+$ and every $i = 0, \ldots, n - 1$, the following conditions are equivalent:
   (a) $\gamma$ breaks $b_i M$.
   (b) $\gamma \geq \text{log } |b_i| b_{i+1}$. (As usual, we set $\text{log } |0| := +\infty$ : see (14.5).)

**Proof.** It is clear that $M$ admits a minimal $K^+$-flattening sequence $(1, b_1, \ldots, b_{n-1}, 0)$, and (i) asserts that every other such minimal sequence is of the type $(1, u_1 b_1, \ldots, u_{n-1} b_{n-1}, 0)$ for some elements $u_1, \ldots, u_{n-1} \in (K^+)^\times$. However, notice that the condition of (ii) characterize uniquely such a sequence, so we only have to show that (ii) holds. We may also assume that $n > 1$; indeed, when $n = 1$, the module $M$ is $K^+$-flat, and the assertion is immediate. Moreover, since $M$ is coherent, the same holds for $b_i M$, for every $b_i \in K^+$. Thus, an easy induction reduces to showing the equivalence of conditions (ii.a) and (ii.b) for $i = 0$.

However, notice that if $\gamma$ breaks $M$, then it obviously also breaks $M/b_1 M$; in light of remark [14.8.7(ii)], it follows already that (a)⇒(b). Therefore, taking into account remark [14.8.7(i)], it remains only to show that $\text{log } |b_1|$ breaks $M$. 

If \( n = 2 \), then \( b_1 M \) is a flat \( K^+ \)-module; let \( N := \ker b_{1,M} \). We have already observed that \( b_1 M \) is a finitely presented \( A \)-module, hence \( N \) is a finitely generated \( A \)-module, and \( N \otimes_{K^+} \kappa \) is the kernel of \( b_{1,M} \otimes_{K^+} \kappa \). Suppose that \( \log |b_1| \) does not break \( M \); then \( N \otimes_{K^+} \kappa \) vanishes, and then \( N = 0 \), by Nakayama’s lemma. It follows that \( M \) is \( K^+ \)-flat, which contradicts the minimality of the sequence \((1, b_1, 0)\).

Next, we consider the case where \( n > 2 \) and set \( M' := M/b_2 M, b := b_1^{-1}b_2 \); since \( b_2 M \subset b_1 M \), it suffices to show that \( \log |b_1| \) breaks \( M' \), hence we may assume that \( b_2 M = 0, b_1 M \) is a flat \( K^+/bK^+ \)-module, and the flattening sequence is \((1, b_1, b_2, 0)\). We remark:

**Claim 14.8.9.** If \( \log |b_1| \) does not break \( M \), the map \( b_{1,M/bM} : M/bM \to b_1 M \) is an isomorphism of \( K^+/bK^+ \)-modules.

**Proof of the claim.** Indeed, let \( N := \ker b_{1,M/bM} \); since \( b_1 M \) is \( K^+/bK^+ \)-flat, \( N \otimes_{K^+} \kappa \) is the kernel of \( b_{1,M/bM} \otimes_{K^+} \kappa \), and the latter vanishes if \( \log |b_1| \) does not break \( M \); on the other hand, \( N \) is a finitely generated \( A \)-module, hence \( N = 0 \), by Nakayama’s lemma.

We shall use the following variant of the local flatness criterion:

**Claim 14.8.10.** Let \( R \) be a ring, \( I_1, I_2 \subset A \) two ideals, and \( M \) an \( R \)-module such that:

(a) \( I_1 I_2 = 0 \)

(b) \( M/I_i M \) is \( R/I_i \)-flat for \( i = 1, 2 \)

(c) the natural map \( I_1 \otimes_R M/I_2 M \to I_1 M \) is an isomorphism.

Then \( M \) is a flat \( R \)-module.

**Proof of the claim.** Set \( I_3 := I_1 \cap I_2 \); to begin with, \([59, \text{Lemma 3.4.18}]\) and (b) imply that \( M/I_3 M \) is a flat \( R/I_3 \)-module. We have an obviously commutative diagram

\[
\begin{array}{ccc}
I_3 \otimes_R M/I_3 M & \xrightarrow{\alpha} & I_3 M \\
\beta \downarrow & & \gamma \\
I_3 \otimes_{R/I_2} M/I_2 M & \xrightarrow{\delta} & I_1 \otimes_{R/I_2} M/I_2 M \\
& \xrightarrow{\tau} & I_1 M
\end{array}
\]

of \( R \)-linear maps. From (a) we see that \( I_3^2 = 0 \), and it follows easily that \( \beta \) is an isomorphism; \( \gamma \) is clearly injective, and the same holds for \( \delta \), since \( M/I_2 M \) is a flat \( R/I_2 \)-module; by the same token, \( \tau \) is an isomorphism. We conclude that \( \alpha \) is an isomorphism, and then the local flatness criterion \((100, \text{Th.22.3})\) yields the contention. \( \diamond \)

We shall apply claim \([14.8.10]\) with \( R := K^+/bK^+, I_1 := b_1 R, I_2 := b_2 R \). Indeed, condition (a) obviously holds with these choices; by assumption, \( M/I_1 M \) is a \( R/I_1 \)-flat module, and if \( \log |b_1| \) does not break \( M \), claim \([14.8.9]\) implies that \( M/I_2 M \) is a flat \( R/I_2 \)-module. Lastly, condition (c) is equivalent to claim \([14.8.9]\). Summing up, we have shown that if \( \log |b_1| \) does not break \( M \), then \( M \) is a flat \( K^+/bK^+ \)-module, contradicting again the minimality of our flattening sequence. \( \square \)

**Proposition 14.8.11.** Let \( A \) be a \( K^+ \)-algebra, \( M \) a finitely presented \( A \)-module, and suppose that either one of the following two conditions holds:

(a) \( A \) is an essentially finitely presented \( K^+ \)-algebra.

(b) \( A \) is a local and locally measurable \( K^+ \)-algebra.

Then \( M \) admits a \( K^+ \)-flattening sequence.

**Proof.** Suppose first that (b) holds, and let \( A^{sh} \) be the strict henselization of \( A \) at a geometric point localized at the closed point. Since \( A^{sh} \) is a faithfully flat \( A \)-algebra, it suffices to show that \( M \otimes_A A^{sh} \) admits a \( K^+ \)-flattening sequence. Hence, we may assume that \( A \) is measurable, in which case we may find a finitely presented \( K^+ \)-algebra \( A_0 \) with an ind-étale map \( A_0 \to A \).
and a finitely presented $A_0$-module $M_0$ with an isomorphism $M_0 \otimes_{A_0} A \xrightarrow{\sim} M$ of $A$-modules. We may then replace $A$ by $A_0$, $M$ by $M_0$, and therefore assume that $A$ is finitely presented over $K^+$, especially, we are reduced to showing the assertion in the case where (a) holds. To this aim, let us remark:

**Claim** 14.8.12. Let $B := \bigoplus_{n \in \mathbb{N}} B_n$ be a $\mathbb{N}$-graded finitely presented $K^+$-algebra with $B_0 = K^+$, and $N := \bigoplus_{n \in \mathbb{N}} N_n$ a $\mathbb{N}$-graded finitely presented $B$-module. We have:

(i) The $K^+$-module $N_n$ is finitely presented, for every $n \in \mathbb{N}$.

(ii) For every $n \in \mathbb{N}$, let $(\gamma_{n,i} \mid i \in \mathbb{N})$ be the sequence of elementary divisors of $N_n$ (see 14.5.15). Then $\Gamma(N) := \{\gamma_{n,i} \mid n, i \in \mathbb{N}\}$ is a finite set.

(iii) $N$ admits a $K^+$-flattening sequence.

**Proof of the claim.** (i) is just a special case of proposition 7.6.23 (iii).

(ii): Let $\mathcal{Q}$ be the set of all finitely presented graded quotients $Q$ of the $B$-modules $N$, for which $\Gamma(Q)$ is infinite. We have to show that $\mathcal{Q} = \emptyset$. However, for every $Q \in \mathcal{Q}$, the $B \otimes_{K^+} \kappa$-module $\overline{Q} := Q \otimes_{K^+} \kappa$ is a quotient of $\overline{N} := N \otimes_{K^+} \kappa$; since $B \otimes_{K^+} \kappa$ is a noetherian ring, the set $\mathcal{Q} := \{\overline{Q} \mid Q \in \mathcal{Q}\}$ admits minimal elements, if it is not empty. In the latter case, we may then replace $N$ by any $Q_0 \in \mathcal{Q}$ such that $\overline{Q}_0$ is a minimal element of $\mathcal{Q}$, and assume that, for every graded quotient $Q$ of $N$, either $\overline{Q} = \overline{N}$, or else $\Gamma(Q)$ is a finite set. Now, for every $n \in \mathbb{N}$, let $\gamma_n$ be the minimal non-zero elementary divisor of $N_n$, and pick $a_n \in \mathfrak{m}_K$ with $\log |a_n| = \gamma_n$ (if $N_n = 0$, set $a_n = 0$). Let $I \subset K^+$ be the ideal generated by $\{a_n \mid n \in \mathbb{N}\}$; it is easily seen that $N_n/I\mathcal{N}_n$ is a free $K^+/I$-module for every $n \in \mathbb{N}$, hence $N/I\mathcal{N}$ is a $K^+/I$-flat finitely presented $B/I\mathcal{B}$-module. We may then find $a \in I$ such that $N/a\mathcal{N}$ is already a $K^+/aK^+$-flat $B/a\mathcal{B}$-module ([50, Ch.IV, Cor.11.2.6.1]), so $N_n/a\mathcal{N}$ is a free $K^+/aK^+$-module for every $n \in \mathbb{N}$, and we easily deduce that $\log |a| \leq \gamma_n$ for every $n \in \mathbb{N}$, i.e. $I = aK^+$. Notice that $a\mathcal{N}$ is a finitely presented $B$-module (corollary 9.1.27); it follows that

$$\Gamma(N) = \{\gamma + \log |a| \mid \gamma \in \Gamma(a\mathcal{N})\} \cup \{0\}.$$ 

Especially, $\Gamma(a\mathcal{N})$ is an infinite set. On the other hand, there exists some $n \in \mathbb{N}$ such that $\dim_C(a\mathcal{N}_n) \otimes_{K^+} \kappa < \dim_C N_n \otimes_{K^+} \kappa$, so $(a\mathcal{N}) \otimes_{K^+} \kappa$ is a proper quotient of $\overline{N}$, a contradiction.

(iii): Let $|b_0|, |b_{n-1}|$ be the finitely many elements of $\Gamma(N)$ (for suitable $b_1, \ldots, b_n \in K^+$), and set $b_n := 0$; after permutation, we may assume that $b_{i+1} \in b_i \mathfrak{m}_K$ for every $i = 0, \ldots, n-1$, and $b_1 = 1$. Then we claim that $(b_0, \ldots, b_n)$ is a $K^+$-flattening sequence for $N$, i.e. $b_i N_j/b_{i+1} N_k$ is $K^+/b_i^{-1} b_{i+1} K^+$-flat for every $i = 0, \ldots, n$ and every $k \in \mathbb{N}$. However, say that $(\log |c_j| \mid j \in \mathbb{N})$ is the sequence of elementary divisors of $N_k$; we are reduced to checking that $(c_j K^++b_i K)^+(c_j K^++b_{i+1} K)$ is a flat $K^+/b_i^{-1} b_{i+1} K$-module for every $j \in \mathbb{N}$. However, by construction we have either $c_j K^+ \subset b_{i+1} K^+$, or $b_i K^+ \subset c_j K^+$; in either case the assertion is clear.

Let now $A$ be an arbitrarily essentially finitely presented $K^+$-algebra, and $M$ an arbitrary finitely presented $A$-module. We easily reduce to the case where $A = K^+[T_1, \ldots, T_r]$ is a free polynomial $K^+$-algebra. In this case, we define a filtration $\text{Fil}_k A$ on $A$, by declaring that $\text{Fil}_k A$ is the $K^+$-submodule of all polynomials of total degree $\leq k$, for every $k \in \mathbb{N}$; then $R := R(A, \text{Fil}_k A)_k$ is a free polynomial $K^+$-algebra as well (see example 7.9.5). Let

$$L_1 \xrightarrow{\varphi} L_0 \rightarrow M$$

be a presentation of $M$ as quotient of free $A$-modules of finite rank. Let

$$e := (e_1, \ldots, e_n) \quad \text{(resp. } f := (f_1, \ldots, f_m)\text{)}$$

be a basis of $L_0$ (resp. of $L_1$); we endow $L_0$ with the good $(A, \text{Fil}_k A)$-filtration $\text{Fil}_k L_0$ associated with the pair $(e, (1, \ldots, 1))$ as in (7.9.6) (this means that $e_i \in \text{Fil}_1 L_0$ for every $i = 1, \ldots, n$). Also, for every $i = 1, \ldots, m$, pick $j_i \in \mathbb{N}$ such that $\varphi(f_i) \in \text{Fil}_{j_i} L_0$, and endow $L_1$ with the good
(A, Fil\textsubscript{A})-filtration Fil\textsubscript{A}L\textsubscript{1} associated with the pair (f, (j\textsubscript{1}, \ldots, j\textsubscript{m})). Set L\textsubscript{i} := R(L\textsubscript{i}, Fil\textsubscript{A}L\textsubscript{i}), and notice that L\textsubscript{i} is a free R-module of finite rank, for i = 0, 1. With these choices, \( \varphi \) is a map of filtered A-modules, and there follows an R-linear map of \( \mathbb{N} \)-graded R-modules \( R(\varphi) : L\textsubscript{i} \to L\textsubscript{0} \), whose cokernel is a \( \mathbb{N} \)-graded finitely presented R-module \( N_\bullet \). By inspecting the construction, it is easily seen that the inclusion Fil\textsubscript{k}L\textsubscript{0} \subset Fil\textsubscript{k+1}L\textsubscript{0} induces a \( K^+ \)-linear map \( N_k \to N_{k+1} \), for every \( k \in \mathbb{N} \), as well as an isomorphism of \( K^+ \)-modules

\[
\text{colim}_{k \in \mathbb{N}} N_k \cong M.
\]

On the other hand, claim \[14.8.12\] ensures that \( N_\bullet \) admits a \( K^+ \)-flattening sequence. We easily deduce that the same sequence is also flattening for \( M \).

**Corollary 14.8.13.** Let \( A \) be a local and locally measurable \( K^+ \)-algebra, \( I \subset K^+ \) any ideal, \( M \) a finitely generated \( A/IA \)-module, and suppose that the structure map \( K^+ \to A \) is local. Then the following conditions are equivalent:

1. \( M \) is a flat \( \mathbb{K}^+/I \)-module.
2. For every \( c \in K^+ \) such that \( I \subset c \cdot m_K \), the value \( \log |c| \) does not break \( M \).
3. \( M \) is a \( K^+/I \)-flat finitely presented \( A/IA \)-module.

**Proof.** (a)\( \Rightarrow \) (b): in light of remark \[14.8.7\](ii), it suffices to remark that \( M \otimes_{K^+} bK^+ \) is a flat \( K^+/bK^+ \)-module, for every \( b \in K^+ \) such that \( I \subset bK^+ \).

(b)\( \Rightarrow \) (c): Let us write \( M \) as the colimit of a filtered system \( (M_\lambda | \lambda \in \Lambda) \) of finitely presented \( A \)-modules, with surjective transition maps. Then each \( M_\lambda \) is a coherent \( A \)-module, and \( A/m_K A \) is noetherian (remark \[14.8.4\](iv)), so we may also assume that the induced maps \( \varphi_\lambda : M_\lambda/m_K M_\lambda \to M/m_K M \) are isomorphisms for every \( \lambda \in \Lambda \). In view of the commutative diagram

\[
\begin{align*}
M_\lambda & \otimes_{K^+} K^+ \quad \varepsilon_{M_\lambda} \quad cM_\lambda & \otimes_{K^+} K^+ \\
M & \otimes_{K^+} K^+ \quad \varepsilon_{M} & \otimes_{K^+} M
\end{align*}
\]

it easily follows that \( \log |c| \) does not break \( M_\lambda \), for any \( \lambda \in \Lambda \) and any \( c \in K^+ \) such that \( I \subset c \cdot m_K \). Thus, if \( (b_0, \ldots, b_n) \) is the minimal flattening sequence for \( M_\lambda \), we see that \( b_1 \in I \) (lemma \[14.8.8\](ii)), and therefore \( M_\lambda/IM_\lambda \) is a flat \( \mathbb{K}^+/I \)-module for every \( \lambda \in \Lambda \). Now, for \( \lambda, \mu \in \Lambda \) with \( \mu \geq \lambda \), let \( \psi_{\lambda\mu} : M_\lambda \to M_\mu \) be the transition map, and set \( N_{\lambda\mu} := \text{Ker}(\psi_{\lambda\mu} \otimes_{K^+} K^+/I) \); it follows that \( N_{\lambda\mu} \otimes_{K^+} K^+ \) is the kernel of \( \psi_{\lambda\mu} \otimes_{K^+} \). But the latter map is an isomorphism, since the same holds for \( \varphi_\lambda \) and \( \varphi_\mu \). By Nakayama’s lemma, we deduce that \( N_{\lambda\mu} = 0 \), therefore \( M = M_\lambda/IM_\lambda \) for any \( \lambda \in \Lambda \), whence (c).

Lastly, (c)\( \Rightarrow \) (a) is obvious.

**Proposition 14.8.14.** Let \( A \) be a locally measurable \( K^+ \)-algebra. Suppose that

1. \( A/m_K A \) is a noetherian ring.
2. The Jacobson radical of \( A \) contains \( m_K A \).

Then we have:

1. \( A \otimes_{K^+} K^+ \) is a noetherian ring.
2. Every finitely generated \( K^+ \)-flat \( A \)-module is finitely presented.
3. If the valuation of \( K^+ \) is discrete, \( A \) is noetherian.

**Proof.** For any \( K^+ \)-algebra \( B \), and any ideal \( I \subset B_K := B \otimes_{K^+} K^+ \), let us set \( I^\text{sat} := \text{Ker}(B \to B_K/I) \), and notice that \( I^\text{sat} \otimes_{K^+} K^+ = I \). To begin with, we remark:

**Claim 14.8.15.** Let \( B \) be a measurable \( K^+ \)-algebra, \( I \subset B_K \) an ideal. Then \( I^\text{sat} \) is a finitely generated ideal of \( B \).
Proof of the claim. Clearly $B/I_n$ is a $K^+$-flat finitely generated $B$-module, hence it is finitely presented, by proposition [14.8.1]; now the claim follows from [59] Lemma 2.3.18(ii). \( \diamond \)

(i): Suppose $(I_k \mid k \in \mathbb{N})$ is an increasing sequence of ideals of $A \otimes_{K^+} K$; assumption (a) implies that there exists $n \in \mathbb{N}$ such that the images of $I_n$ and $I_m$ agree in $A/m_K A$, for every $m \geq n$. This means that

\[(14.8.16) \quad (I_m / I_n) \otimes_{K^+} \kappa = 0 \quad \text{for every } m \geq n.
\]

Next, for any geometric point $\xi$ of $\text{Spec } A$, let $A_{\xi}^\text{sh}$ be the strict henselization of $A$ at $\xi$; since the natural map $A \to A_{\xi}^\text{sh}$ is flat, $I_k \otimes A_{\xi}^\text{sh}$ is an ideal of $A_{\xi}^\text{sh} \otimes_{K^+} K$, and clearly $I_m^\text{sat} \otimes A_{\xi}^\text{sh} = (I_k \otimes A_{\xi}^\text{sh})^\text{sat}$, for every $k \in \mathbb{N}$. Especially $I_m^\text{sat} \otimes A_{\xi}^\text{sh}$ is a finitely generated ideal of $A_{\xi}^\text{sh}$, by claim [14.8.15]. In view of (14.8.16), and assumption (b), Nakayama's lemma then says that $I_m^\text{sat} \otimes A_{\xi}^\text{sh} = 0$ for every $m \geq n$. Since $\xi$ is arbitrary, we conclude that $I_m^\text{sat} / I_n = 0$ for every $m \geq n$, therefore the sequence $(I_k \mid k \in \mathbb{N})$ is stationary.

(ii): Let $M$ be a $K^+$-flat and finitely generated $A$-module, pick an $A$-linear surjection $\varphi : A^{\oplus n} \to M$, and set $N := \ker \varphi$. Since $M$ is $K^+$-flat, $N/m_K N$ is the kernel of $\varphi \otimes_{K^+} \kappa$, and assumption (a) implies that $N/m_K N$ is a finitely generated $A/m_K A$-module. Hence we may find a finitely generated $A$-submodule $N' \subset N$ such that $N = N' + m_K N$. For any geometric point $\xi$ of $\text{Spec } A$, define $A_{\xi}^\text{sh}$ as in the foregoing; by proposition [14.8.1] (and by [59] Lemma 2.3.18(ii)), $N \otimes A_{\xi}^\text{sh}$ is a finitely generated $A_{\xi}^\text{sh}$-module; then (b) and Nakayama’s lemma imply that $N' \otimes A_{\xi}^\text{sh} = N \otimes A_{\xi}^\text{sh}$. Since $\xi$ is arbitrary, it follows that $N = N'$; especially, $M$ is finitely presented, as stated.

(iii): It suffices to show that every prime ideal of $A$ is finitely generated ([100] Th.3.4). However, let $p \subset A$ be such a prime ideal, and fix a generator $t$ of $m_K$. Suppose first that $t \in p$; in that case (a) implies that $p/tA$ is a finitely generated ideal of $A/tA$, so then clearly $p$ is finitely generated as well. Next, in case $t \notin p$, the quotient $A/p$ is a $K^+$-flat finitely generated $A$-module, hence it is finitely presented (proposition [14.8.1], so again $p$ is finitely generated ([59] Lemma 2.3.18(ii))). \( \Box \)

**Theorem 14.8.17.** Let $A$ be a locally measurable $K^+$-algebra, $M$ a finitely presented $A$-module, and suppose that :

(a) The valuation of $K$ has finite rank.

(b) For every $t \in \text{Spec } K^+$, the ring $A \otimes_{K^+} \kappa(t)$ is noetherian.

Then we have :

(i) $M$ admits a $K^+$-flattening sequence.

(ii) $\text{Ass } M$ is a finite set.

**Proof.** (i): Set $X := \text{Spec } A, S := \text{Spec } K^+$, let $f : X \to S$ be the structure morphism, and denote by $\mathcal{M}$ the quasi-coherent $\mathcal{O}_X$-module associated with $M$. Also, for every quasi-coherent $\mathcal{O}_X$-module $\mathcal{F}$ and every $c \in K^+$, let $c_{\mathcal{F}} : \mathcal{F} \to c\mathcal{F}$ be the unique $\mathcal{O}_X$-linear morphism such that $c_{\mathcal{F}}(U) = c_{\mathcal{F}}(U)$ for every affine open subset $U \subset X$ (notation of definition [14.8.6(ii)]). For every $x \in X$, set $K^+_x := \mathcal{O}_{S,f(x)}$; then $K^+_x$ is a valuation ring whose valuation we denote $\vert \cdot \vert_{(x)}$, and $\mathcal{O}_{X,x}$ is a locally $K^+_x$-measurable algebra. By proposition [14.8.11] the $\mathcal{O}_{X,x}$-module $\mathcal{M}_x$ admits a $K^+_x$-flattening sequence $(b_{x,0}, \ldots, b_{x,n})$; we wish to show that there exists an open neighborhood $U(x)$ of $x$ in $X$, such that $(b_{x,i}\mathcal{M} / b_{x,i+1}\mathcal{M})_y$ is a $K^+/b_{x,i+1}K^+$-flat module, for every $y \in U(x)$ and every $i = 0, \ldots, n - 1$. To this aim, we remark :

**Claim** 14.8.18. Let $\mathcal{M}$ be a quasi-coherent $\mathcal{O}_X$-module of finite type, $x \in X$ a point, and $b \in K^+$ such that $\mathcal{M}_x$ is a flat $K^+/bK^+$-module. Then there exists an open neighborhood $U \subset X$ of $x$ such that the map

$c_{\mathcal{N},y} \otimes_{K^+} \kappa(f(y)) : \mathcal{N}_y \otimes_{K^+} \kappa(f(y)) \to c_{\mathcal{N}} \otimes_{K^+} \kappa(f(y))$
is an isomorphism for every \( y \in U \) and every \( c \in K^+ \) with \( \log |c|_{f(y)} < \log |b|_{f(y)} \).

**Proof of the claim.** Let \( z \in X(x) \) be any point, and set \( t := f(z) \); under our assumptions, \( \mathcal{N} \) is a flat \( K^+/bK^+ \)-module. Therefore, the sequence of \( \mathcal{O}_{X,z} \)-modules

\[
0 \to c^{-1} b\mathcal{N}_z \xrightarrow{f} \mathcal{N}_z \xrightarrow{c} \mathcal{N}_z \to 0
\]

is exact, for every \( c \in K^+ \) with \( \log |c| < \log |b| \), and a fortiori, whenever \( \log |c|_t < \log |b|_t \). If the latter inequality holds, the map \( f \otimes K^+ \kappa(t) \) vanishes, hence \( c\mathcal{N}_z \otimes K^+ \kappa(t) \) is injective.

Let now \( y \in X \) be any point; set \( u := f(y) \), pick \( c \in K^+ \) with \( \log |c|_u < \log |b|_u \), set \( \mathcal{N}'(u) := \text{Ker}(c\mathcal{N} \otimes K^+ \kappa(u)) \), and suppose that \( \mathcal{N}'(u)_y \neq 0 \). The foregoing shows that in this case \( y \notin X(x) \). On the other hand, by assumption \( f^{-1}(u) \) is a noetherian scheme, and \( \mathcal{N}(u) := \mathcal{N} \otimes K^+ \kappa(u) \) is a coherent \( \mathcal{O}_{f^{-1}(u)} \)-module, therefore \( \text{Ass} \mathcal{N}'(u) \) is a finite set ([100] Th.6.5(i)).

In view of proposition 10.5.6(ii), we conclude that \( \text{Ass} \mathcal{N}'(u) \) is contained in the finite set \( \text{Ass} \mathcal{N}(u)|X(x) \). Let \( Z \) be the topological closure in \( X \) of the (finite) set \( \bigcup_{u \in S} \text{Ass} \mathcal{N}(u)|X(x) \); taking into account lemma 10.5.5(ii,iii), we see that \( U := X \setminus Z \) will do.

Fix \( x \in X \) and \( i \leq n \); taking \( \mathcal{N} = b_{x,i} \mathcal{M}|/b_{x,i+1} \mathcal{M} \) and \( b := b_{x,i}^{-1} b_{x,i+1} \) in claim 14.8.18 and invoking the criterion of corollary 14.8.13, we obtain an open neighborhood \( U_i \) of \( x \) in \( X \) such that \( \mathcal{N}_z \) is \( K^+/bK^+ \)-flat for every \( y \in U_i \). Clearly the subset \( U(x) := U_i \cap \cdots \cap U_n \) fulfills the sought condition. Next, pick finitely many points \( x_1, \ldots, x_k \in X \) and corresponding \( K^+ \)-flattening sequences \( b_i \) for \( \mathcal{N}_{x_i} \), for each \( i = 1, \ldots, k \), such that \( U(x_1) \cup \cdots \cup U(x_k) = X \); after reordering, the sequence \( (b_1, \ldots, b_k) \) becomes \( K^+ \)-flattening for \( M \) (see remark 14.8.7(iii)).

(ii): Let \( (b_0, \ldots, b_n) \) be a \( K^+ \)-flattening sequence for \( M \); in view of proposition 10.5.6(ii), it suffices to prove that \( \text{Ass} b_i M/b_{i+1} M \) is a finite set, for every \( i = 0, \ldots, n - 1 \). Taking into account remark 14.8.4(iv), we are then reduced to showing

**Claim 14.8.19.** Let \( \mathcal{N} \) be a quasi-coherent \( \mathcal{O}_X \)-module, and \( b \in K^+ \) any element such that \( \mathcal{N}_z \) is a \( K^+/bK^+ \)-flat and finitely presented \( \mathcal{O}_{X,z} \)-module for every \( x \in X \). Then \( \mathcal{N} \) is finite.

**Proof of the claim.** For given \( x \in X \) and any geometric point \( \xi \) of \( X \) localized at \( x \), let \( A^\text{sh} \) be the strict henselization of \( A \) at \( \xi \), and \( B \) a local and essentially finitely presented \( K^+ \)-algebra with a local and ind-étale map \( B \to A^\text{sh} \). We may assume that \( \mathcal{N}_z \otimes A^\text{sh} \) descends to a finitely presented \( K^+/bK^+ \)-flat \( B \)-module \( N_B \) ([50] Ch.IV, Cor.11.2.6.1(ii)). Denote by \( \overline{\xi} \) (resp. by \( x_B \)) the closed point of \( X(\xi) = \text{Spec} A^\text{sh} \) (resp. of \( \text{Spec} B \)); in light of corollary 10.4.37 we have

\[
(14.8.20) \quad x \in \text{Ass} \mathcal{N} \iff x \in \text{Ass}_{\mathcal{O}_{X,x}} \mathcal{N}_x \iff \overline{\xi} \in \text{Ass}_{A^\text{sh},x} \mathcal{N}_x \otimes A^\text{sh} \iff x_B \in \text{Ass}_B N_B.
\]

On the other hand, it is easily seen that \( \text{Ass}_{K^+/bK^+} \) consists of only one point, namely the maximal point \( t \) of \( \text{Spec} K^+/bK^+ \). From corollary 10.5.9 we deduce :

\[
x_B \in \text{Ass}_B N_B \iff x_B \in \text{Ass}_B N_B \otimes K^+ \kappa(t).
\]

Summing up, we conclude that \( \text{Ass} \mathcal{N} = \text{Ass} \mathcal{N} \otimes K^+ \kappa(t) \), and the latter is a finite set, by ([100] Th.6.5(i)).

**Corollary 14.8.21.** Let \( (K, | \cdot |) \) be a valued field, and \( A \) a locally measurable \( K^+ \)-algebra fulfilling conditions (a) and (b) of theorem 14.8.17. Let also \( M \) be a finitely generated \( A \)-module, and \( \mathfrak{p} \subset A \) any prime ideal such that \( M_\mathfrak{p} \) is a finitely presented \( A_\mathfrak{p} \)-module. We have:

(i) There exists \( f \in A \setminus \mathfrak{p} \) such that \( M_f \) is a finitely presented \( A_f \)-module.

(ii) \( A \) is coherent.
Proof. (i): We may find a finitely presented $A$-module $M'$ with an $A$-linear surjection $\varphi : M' \to M$ such that $\varphi_p$ is an isomorphism. Set $M'' := \ker \varphi$; it follows that $\text{Ass } M'' \subset \text{Ass } M' \setminus \text{Spec } A_p$. However, $\text{Ass } M'$ is a finite set (theorem 14.8.17(ii)); therefore the support of $\ker \varphi$ is contained in a closed subset of $X := \text{Spec } A$ that does not contain $p$, and the assertion follows.

(ii): Let $M$ be a finitely presented $A$-module, $M' \subset M$ a finitely generated submodule, and let $\mathcal{M}$ be the quasi-coherent $\mathcal{O}_X$-module associated with $M'$. By remark 14.8.4(iv), we know that $\mathcal{M}_x$ is a finitely presented $\mathcal{O}_{X,x}$-module for every $x \in X$; from (i), it follows that $\mathcal{M}$ is a finitely presented $\mathcal{O}_X$-module, and the assertion follows easily. \qed

In view of theorem 14.8.17 and corollary 14.8.21, it is interesting to have criteria ensuring that the fibres over $\text{Spec } K$ of the spectrum of a locally measurable $K^+$-algebra are noetherian. We present two results in this direction. To state them, let us make first the following:

**Definition 14.8.22.** Let $f : X \to Y$ be a morphism of schemes.

(i) We say that $f$ is absolutely flat if the following holds. For every geometric point $\xi$ of $X$, the induced morphism $f_\xi : X(\xi) \to Y(f(\xi))$ is an isomorphism.

(ii) We say that $f$ has finite fibres if the set $f^{-1}(y)$ is finite, for every $y \in Y$.

(iii) We say that $Y$ admits a geometrically unibranch stratification if every irreducible closed subset $Z$ of $Y$ contains a subset $U \neq \emptyset$, open in $Z$, and geometrically unibranch.

(iv) We say that a ring homomorphism $\varphi : A \to B$ is absolutely flat if $\text{Spec } \varphi$ is absolutely flat.

**Remark 14.8.23.** In practice, it is often the case that a noetherian scheme admits a geometrically unibranch stratification; for instance, this holds (essentially by definition) for the spectrum of a quasi-excellent noetherian ring (see definition 9.7.3(ii)).

**Lemma 14.8.24.** Let $f : X \to Y$ be an absolutely flat morphism of schemes. Then $\mathbb{L}_{X/Y} \simeq 0$ in $D(\mathcal{O}_X$-$\text{Mod}$).

**Proof.** We easily reduce to the case where both $X$ and $Y$ are local schemes. Let $\xi$ be a geometric point of $X$ localized at the closed point; then $\mathbb{L}_{X(\xi)/X} \simeq 0$ in $D(\mathcal{O}_{X(\xi)}$-$\text{Mod}$) ([59, Th.2.5.37]). Hence, by transitivity ([59, Th.2.5.33]), we are reduced to showing that $\mathbb{L}_{X/Y} \simeq 0$ in $D(\mathcal{O}_{X}$-$\text{Mod}$). The latter assertion holds, again by virtue of [59, Th.2.5.37], since $f_\xi$ is an isomorphism. \qed

**Proposition 14.8.25.** Let $\varphi : A \to B$ be a local and absolutely flat morphism of local rings. Assume that either one of the following two conditions holds:

(a) $A$ is a normal local domain.

(b) $B$ is a henselian local ring.

Then $\varphi$ is an ind-étale ring homomorphism.

**Proof.** Pick a geometric point $\xi$ of $\text{Spec } B$ localized at the closed point, and let $\xi'$ denote the image of $\xi$ in $\text{Spec } A$. Let also $A^{\text{sh}}$ (resp. $B^{\text{sh}}$) be the strict henselization of $A$ at $\xi'$ (resp. of $B$ at $\xi$). Notice first that $A$ is a normal local domain if and only if the same holds for $B$ ([51, Ch.IV, Prop.18.8.12(i)]). In case (a) holds, let $F_A$ (resp. $F_B$) be the field of fractions of $A$ (resp. $B$). We remark:

**Claim** 14.8.26. Let $R$ be any normal local domain, and $R^{\text{sh}}$ the strict henselization of $R$ at a geometric point localized at the closed point of $\text{Spec } R$. We have:

(i) $R = R^{\text{sh}} \cap \text{Frac } R$ (where the intersection takes place in $\text{Frac } R^{\text{sh}}$).

(ii) For every field extension $F$ of $\text{Frac } R$ contained in $\text{Frac } R^{\text{sh}}$, the $R$-algebra $F \cap R^{\text{sh}}$ is ind-étale.
Proof of the claim. (i): More generally, let \( C \to D \) be any faithfully flat ring homomorphism, and denote by \( \text{Frac} \, C \) (resp. \( \text{Frac} \, D \)) the total ring of fractions of \( C \) (resp. \( D \)); then it is easily seen that \( C = D \cap \text{Frac} \, C \), where the intersection takes place in \( \text{Frac} \, D \); the proof shall be left as an exercise for the reader.

(ii): We easily reduce to the case where \( F \) is a finite extension of \( F_\mathfrak{R} := \text{Frac} \, R \). Then, let \( E \) be a finite Galois extension of \( F_\mathfrak{R} \), contained in a fixed separable closure \( F_\text{sep}^\mathfrak{R} \) of \( F_\mathfrak{R} \), and containing \( F \); also, denote by \( R^\nu \) (resp. \( R^\nu_\mathfrak{E} \)) the integral closure of \( R \) in \( F_\text{sep}^\mathfrak{R} \) (resp. in \( E \)). Recall that there exists a unique maximal ideal \( \mathfrak{p}_\text{sep} \subset R^\nu \) lying over the maximal ideal of \( R \), such that \( R^\mathfrak{R} = (R^\nu)^{\mathfrak{p}_\text{sep}} \), where \( I \subset \text{Gal}(F_\text{sep}^\mathfrak{R}/F_\mathfrak{R}) \) is the inertia subgroup associated with \( \mathfrak{p}_\text{sep} \) (Ch.IX, §3, Th.2); therefore, \( F^\mathfrak{R} = (F_\text{sep}^\mathfrak{R})^I \). On the other hand, \( F = E^H \) for a subgroup \( H \subset \text{Gal}(E/F_\mathfrak{R}) \), and recall that the natural surjection \( \text{Gal}(F_\text{sep}^\mathfrak{R}/F_\mathfrak{R}) \to \text{Gal}(E/F_\mathfrak{R}) \) maps \( I \) onto the inertia subgroup \( I_F \) associated with the maximal ideal \( \mathfrak{p}_F := \mathfrak{p}_E \cap E \subset R^\nu_\mathfrak{E} \). It follows that \( H \) contains \( I_F \). Set \( p_F := p_E \cap F \); then \( R_F := (R^\nu_\mathfrak{E} \cap F)^{p_F} \) is a faithfully flat and essentially étale \( R \)-algebra (Ch.X, §1, Th.1(1}). Especially, \( R^\mathfrak{R} \) is also a strict henselization of \( R_F \), and notice that \( \text{Frac} \, R_F = F \), so the assertion follows from (i).

By assumption, \( \varphi \) extends to an isomorphism of local domains \( A^\mathfrak{R} \to B^\mathfrak{R} \); in view of claim [14.8.26(i)], we see that \( B = F_B \cap A^\mathfrak{R} \), and then the proposition follows from claim [14.8.26(ii)].

Next, suppose assumption (b) holds. Then, \( \varphi \) extends uniquely to a local ring homomorphism \( \varphi^\mathfrak{R} : A^\mathfrak{R} \to B \) from the henselization of \( A \) (Ch.IV, Th.18.6.6(ii)); clearly \( \varphi^\mathfrak{R} \) is still absolutely flat, hence we may replace \( A \) by \( A^\mathfrak{R} \) and assume that both \( A \) and \( B \) are henselian. Since \( \varphi \) is absolutely flat, the residue field extension \( \kappa(A) \to \kappa(B) \) is separable and algebraic; then for every finite extension \( E \) of \( \kappa(A) \) contained in \( \kappa(B) \) there exists a finite étale local \( A \)-algebra \( A_E \), unique up to isomorphism, whose residue field is \( E \) (Ch.IV, Prop.18.5.15). The natural map \( \kappa(B) \to E \otimes_{\kappa(A)} \kappa(B) \) admits a well defined section, given by the multiplication in \( \kappa(B) \), and the latter extends to a section \( s_E \) of the induced finite étale ring homomorphism \( B \to A_E \otimes_A B \) (Ch.IV, Th.18.5.11]). The composition of \( s_E \) with the natural map \( A_E \to A_E \otimes_A B \) is a ring homomorphism \( A_E \to B \) that extends \( \varphi \). The construction is clearly compatible with inclusion of subextensions \( E \subset E' \), hence let \( A' \) be the colimit of the system \( (A_E \mid E \subset \kappa(B)) \); summing up, \( \varphi \) extends to a local and absolutely flat map \( A' \to B \). We may therefore replace \( A \) by \( A' \) and assume from start that \( \kappa(A) = \kappa(B) \). In this case, set \( B' := A^\mathfrak{R} \otimes_A B \), and notice that \( \kappa(A^\mathfrak{R}) \otimes_{\kappa(A)} \kappa(B) = \kappa(A^\mathfrak{R}) \), so that \( B' \) is a local ring, ind-étale, faithfully flat over \( B \), and with separably closed residue field. Since \( B \) is already henselian, it follows that \( B' \) is a strict henselization of \( B \), and therefore the induced map \( A^\mathfrak{R} \to B' \) is an isomorphism; by faithfully flat descent, we deduce that \( \varphi \) is already an isomorphism, and the proof of the proposition is concluded.

Lemma 14.8.27. Let \( A \) be a locally measurable \( K^+ \)-algebra, and set \( X := \text{Spec} \, K \). Let also \( f : X \to Y \) be a morphism of \( K^+ \)-schemes with \( \Omega_X/Y = 0 \), and \( Y \) a finitely presented \( K^+ \)-scheme. Then \( f_\xi \) is a finitely presented closed immersion, for every geometric point \( \xi \) of \( X \).

Proof. Fix such a geometric point \( \xi \); by definition, we may find a local \( K^+ \)-scheme \( Z \) essentially finitely presented, and an ind-étale morphism \( g : X(\xi) \to Z \) of \( K^+ \)-schemes. We may also assume that the morphism \( X(\xi) \to Y \) deduced from \( f \) factors through \( g \), in which case the resulting morphism \( h : Z \to Y \) is essentially finitely presented. Under the current assumptions, \( \Omega_{X(\xi)/Y} = 0 \), and then lemma [14.8.26] easily implies that \( \Omega_{Z/Y} \) vanishes as well, so \( h \) is essentially unramified, and therefore it factors as the composition of a finitely presented closed immersion \( Z \to Z' \) followed by an essentially étale morphism \( Z' \to Y \) (Ch.IV, Cor.18.4.7]). The lemma is an immediate consequence.

Proposition 14.8.28. Let \( A \) be a local, henselian, and locally measurable \( K^+ \)-algebra, whose structure map \( K^+ \to A \) is local. Then \( A \) is a measurable \( K^+ \)-algebra.
By construction, the resulting map \( \xi \) the geometric point \( \set{\phi} \) of \( X \). Let \( \varphi: B^h \to A^h \) be a finitely presented surjection (lemma \[14.8.27\]), especially \( I := \ker \varphi^h \) is a finitely generated ideal, and it follows as well that the residue field extension \( \kappa(B) \to \kappa(A) \) is separable and algebraic. Let \( B^h \) be the henselization of \( B \), and for every field extension \( E \) of \( \kappa(A) \) contained in \( \kappa(B)^{sep} = \kappa(B)^{sep} \), let \( I_E \) denote the local ind-étale \( B^h \)-algebra – determined up to isomorphism – whose residue field is \( E \) (\[51\] Ch.IV, Prop.18.5.15). We may find a finite Galois extension \( E \) of \( \kappa(B) \) such that \( I \) descends to a finitely generated ideal \( I_E \subset B^h \). For any automorphism \( \sigma \in G := \text{Gal}(\kappa(B)^{sep}/\kappa(B)) \), let \( \overline{\sigma} \in G_E := \text{Gal}(E/\kappa(B)) \) be the image of \( \sigma \). Recall that \( G \) (resp. \( G_E \)) is the group of automorphisms of the \( B^h \)-algebra \( B^h \) (resp. \( B^h_E \)). With this notation, we have the identity 
\[
\sigma(I_E)B^h = \sigma(I) = I \quad \text{for every } \sigma \in G
\]
and since \( B^h \) is a faithfully flat \( B^h \)-algebra, it follows that \( I_E \) is invariant under the action of \( G_E \); by Galois descent, we conclude that \( I \) descends to a finitely generated ideal \( I_0 \subset B^h \). Set \( C := B^h/I_0 \), and let \( C^{sh} \) denote the strict henselization of \( C \) at (the unique lifting of) the geometric point \( \xi' \). Since \( A \) is henselian, \( \varphi \) extends uniquely to a local homomorphism \( \varphi^h: B^h \to A \) (\[51\] Ch.IV, Th.18.6.6(ii)), and it is easily seen that \( \varphi^h \) factors through \( C \). By construction, the resulting map \( C \to A \) is absolutely flat, so the assertion follows from proposition \[14.8.25\].

Lemma 14.8.29. Let \( X \) be a noetherian scheme that admits a geometrically unibranch locally closed stratification, and \( \mathcal{F} \) a coherent \( \mathcal{O}_{X,\text{sh}} \)-module. Then there exists a partition 
\[
X = X_1 \cup \cdots \cup X_k
\]
of \( X \) into finitely many disjoint irreducible locally closed subsets, such that the following holds. For every \( i = 1, \ldots, k \), every geometric point \( \overline{x} \) of \( X_i \), and every generalization \( \overline{u} \) of \( \overline{x} \) in \( X_i \), every strict specialization map 
\[
s_{\overline{x},\overline{u}}: \mathcal{F}_{\overline{x}} \to \mathcal{F}_{\overline{u}}
\]
is injective (see \[4.9.23\]).

Proof. Arguing by noetherian induction, it suffices to show that every reduced and irreducible closed subscheme \( W \) of \( X \) contains a subset \( U \neq \emptyset \) that is open in \( W \), and such that every strict specialization map \( s_{\overline{x},\overline{u}} \) with \( \overline{x}, \overline{u} \) localized in \( U \), is injective. However, \( W \) contains an open subset \( U \neq \emptyset \) such that

(a) \( U \) is geometrically unibranch 
(b) \( U \) is affine and irreducible
(c) \( \mathcal{F} \) is normally flat along \( W \) at every point of \( U \) (see \[49\] Ch.IV,§6.10.1]).

Indeed, (a) holds by assumption; (b) can be easily arranged by shrinking \( U \), since \( X \) is noetherian. Lastly, (c) follows from \[49\] Ch.IV, Prop.6.10.2]. We claim that such \( U \) will do. Indeed, let \( i : W \to W \) be the closed immersion; set 
\[
\mathcal{I} := \ker(\mathcal{O}_X \to i_*\mathcal{O}_W) \quad \mathcal{R}^n := \bigoplus_{n \in \mathbb{N}} \mathcal{I}^n/\mathcal{I}^{n+1}\mathcal{F}
\]
and recall that condition (c) means that \( \mathcal{R}^n \) is a flat \( \mathcal{O}_{W,u} \)-module, for every \( u \in U \). Now, for a given \( s_{\overline{x},\overline{u}} \) as in the foregoing, denote by \( x \) (resp. \( u \)) the support of \( \overline{x} \) (resp. of \( \overline{u} \)) and define descending filtrations by the rule:
\[
\text{Fil}^k \mathcal{F}_{\overline{x}} := \mathcal{I}^k \cdot \mathcal{F}_{\overline{x}} \quad \text{Fil}^k \mathcal{F}_{\overline{u}} := \mathcal{I}^k \cdot \mathcal{F}_{\overline{u}} \quad \text{for every } k \in \mathbb{N}.
\]
By [100, Th.8.9], both these filtrations are separated, and obviously \( s_{\pi,\pi} \) is a map of filtered modules; thus, it suffices to show that the induced maps \( g^k F_{\pi} \to g^k F_{\pi} \) of associated graded modules are injective, for every \( k \in \mathbb{N} \). However, notice the natural identifications:

\[
g^* F_{\pi} = C_{\pi} \otimes_{\mathcal{O}_{W,z}} \mathcal{O}_{W,z,\pi} \quad \quad g^* F_{\pi} = C_{\pi} \otimes_{\mathcal{O}_{W,z}} \mathcal{O}_{W,z,\pi}.
\]

Then, the normal flatness condition reduces to checking that the induced strict specialization map \( \mathcal{O}_{W,z,\pi} \to \mathcal{O}_{W,z,\pi} \) is injective; the latter assertion holds by the following:

**Claim** 14.8.30. Let \( W \) be a reduced, irreducible scheme, \( \bar{w} \) a geometric point of \( W \), and suppose that \( W \) is unibranch at the support \( w \) of \( \bar{w} \). Then, for every generalization \( \bar{w} \) of \( w \) in \( W \), every strict specialization map \( \mathcal{O}_{W,z,\pi} \to \mathcal{O}_{W,z,\pi} \) is injective.

**Proof of the claim.** Let \( W' \) be the normalization of \( W \), and \( \bar{w}' \) a geometric point of \( W' \) whose image in \( X \) is isomorphic to \( \bar{w} \), and denote by \( w' \) the support of \( \bar{w}' \). The assumption on \( w' \) means that the induced morphism \( W'(w') \to W(w) \) is integral, and the residue field extension \( \kappa(w) \to \kappa(w') \) is radicial, hence the natural morphism of \( W'(w') \)-schemes

\[
W(\bar{w}) \times_{W(w)} W'(w') \to W'(w')
\]

is an isomorphism ([51, Ch.IV, Prop.18.8.10]). Since \( W'(\bar{w}') \) is a normal local scheme ([51 Prop.18.8.12(i)]), it follows easily that \( W(\bar{w}) \) is reduced and irreducible. However, any specialization map is the composition of a localization map, followed by a local ind-étale map of local rings, whence the claim.

14.8.31. Now, consider quite generally a ring homomorphism \( A \to B \), with \( A \) a noetherian. Set \( Y := \text{Spec} A \), \( X := \text{Spec} B \), and denote by \( f : X \to Y \) the associated morphism of affine schemes.

**Lemma 14.8.32.** In the situation of (14.8.31), suppose moreover that \( f \) is absolutely flat. Then the following conditions are equivalent:

(a) \( B \) is noetherian.

(b) \( f \) has finite fibres.

**Proof.** Let \( \xi \) be any geometric point of \( X \), and \( x \) (resp. \( y \)) the support of \( \xi \) (resp. of \( f(\xi) \)).

(a)\( \Rightarrow \) (b): \( X(\xi) \times_{\mathcal{O}_{Y,y}} \kappa(y) \) is the strict henselization of \( X_y := f^{-1}(y) \) (with its reduced subscheme structure) at \( \xi \). Under our assumptions, \( X_y(\xi) \) is isomorphic to \( \text{Spec} \kappa(y) \), and (a) implies that \( X_y(x) \) is a noetherian scheme of dimension \( \leq 0 \). Since \( x \) is arbitrary, (b) follows.

(b) \( \Rightarrow \) (a): Let \( I \subset B \) be any ideal, and denote by \( \mathcal{J} \) the associated quasi-coherent \( \mathcal{O}_X \)-module. We need to show that \( \mathcal{J} \) is an \( \mathcal{O}_X \)-module of finite type. Since \( f_\xi \) is an isomorphism, we may find a commutative diagram of affine schemes

\[
\begin{array}{ccc}
X' & \xrightarrow{g} & Y' \\
\downarrow h & & \downarrow \\
X & \xrightarrow{f} & Y
\end{array}
\]

whose left (resp. right) vertical arrow is an étale neighborhood of \( \xi \) (resp. of \( f(\xi) \)), and a quasi-coherent ideal \( \mathcal{J} \subset \mathcal{O}_Y \) such that \( g^*\mathcal{J} \subset h^*\mathcal{J} \) and such that \( (g^*\mathcal{J})_{x'} = (h^*\mathcal{J})_{x'} \) for some \( x' \in h^{-1}(x) \) (notice that \( g \) is a flat morphism). Set \( \mathcal{M} := \mathcal{O}_Y / \mathcal{J} \); let \( z' \in X' \) be an arbitrary point, and set \( y' := g(z') \); in light of corollary [10.4.37] we have

\[
z' \in \text{Ass} g^*\mathcal{M} \iff z' \in \text{Ass} g^*\mathcal{M}|_{X'(x')} \iff y' \in \text{Ass} \mathcal{M}|_{Y'(y')} \iff y' \in \text{Ass} \mathcal{M}.
\]

In other words, \( \text{Ass} g^*\mathcal{M} = g^{-1}\text{Ass} \mathcal{M} \). However, \( \text{Ass} \mathcal{M} \) is finite ([100 Th.6.5(i)]), hence the same holds for \( \text{Ass} g^*\mathcal{M} \), in view of (b). Now, notice that \( \text{Ass} h^*\mathcal{J}/g^*\mathcal{J} \subset \text{Ass} g^*\mathcal{M} \setminus X'(x') \) (proposition [10.5.6(ii)]). It follows that there exists an open neighborhood \( U \) of \( x' \) in \( X' \) such
that \((h^*\mathcal{F}/g^*\mathcal{F})_U = 0\) (lemma 10.5.3 (iii)), i.e. \((g^*\mathcal{F})_U = h^*\mathcal{F}_U\); especially, \(h^*\mathcal{F}_U\) is an \(\mathcal{O}_U\)-module of finite type. Since \(h\) is an open map, we deduce that \(h(U)\) is an open neighborhood of \(x\) in \(X\), and \(\mathcal{F}_{h(U)}\) is an \(\mathcal{O}_{h(U)}\)-module of finite type. Since \(x\) is arbitrary, the lemma follows. □

14.8.33. For our second criterion, keep the situation of \(14.8.31\), and suppose additionally that, for every geometric point \(\xi\) of \(X\), the induced morphism \(f_\xi : X(\xi) \to Y(\xi)\) is a closed immersion. Under this weaker assumption, it is not necessarily true that conditions (a) and (b) of lemma 14.8.32 are equivalent. For instance, we have:

**Example 14.8.34.** Take \(A := k[X]\), the free polynomial algebra over a given infinite field \(k\); also, let \((a_i | i \in \mathbb{N})\) be a sequence of distinct elements of \(k\). We construct an \(A\)-algebra \(B\), as the colimit of the inductive system \((B_i | i \in \mathbb{N})\) of \(A\)-algebras, such that

- \(B_i := k[X] \times k^{i+1}\) (the product of \(k[x]\) and \(i + 1\) copies of \(k\), in the category of rings)
- the structure map \(A \to B_i\) is the unique map of \(k\)-algebras given by the rule : \(X \mapsto (X, a_0, \ldots, a_i)\)
- the transition maps \(B_i \to B_{i+1}\) are given by the rule : \(X \mapsto (X, 0, \ldots, 0, a_{i+1})\) and \((0, e_i) \mapsto (0, e_i, 0)\) for \(i = 0, \ldots, i\). (Here \(e_0, \ldots, e_i\) is the standard basis of the \(k\)-vector space \(k^{i+1}\).)

Then one can check that \(X := \text{Spec} B = \text{Spec} k[X] \cup \mathbb{N}\), and \(\mathbb{N}\) is an open subset of \(X\) with the discrete topology. Moreover, the induced map \(\text{Spec} B \to Y := \text{Spec} A\) restricts to the continuous map \(\mathbb{N} \to Y\) given by the rule \(i \mapsto p_i\), for every \(i \in \mathbb{N}\), where \(p_i\) is the prime ideal generated by \(X - a_i\). It follows easily that the condition of (14.8.33) is fulfilled; nevertheless, clearly \(X\) has infinitely many maximal points, hence its underlying topological space is not noetherian, and a fortiori, \(B\) cannot be noetherian.

However, we have the following positive result:

**Proposition 14.8.35.** In the situation of (14.8.33), suppose additionally that \(Y\) admits a geometrically unibranch stratification. Then the following conditions are equivalent :

(a) \(B\) is noetherian.
(b) The topological space underlying \(X\) is noetherian.
(c) For every geometric point \(\xi\) of \(X\) there exist a neighborhood \(X'_i\) of \(\xi\) in \(X_{\text{et}}\), an unramified \(Y\)-scheme \(Y'\), and an absolutely flat morphism \(X'_i \to Y'\) of \(Y\)-schemes, with finite fibres.

**Proof.** Obviously (a)⇒(b).

(c)⇒(a): Indeed, under assumption (c), we may find finitely many geometric points \(\xi_1, \ldots, \xi_k\) of \(X\), and for every \(i = 1, \ldots, k\), a neighborhood \(X'_i\) of \(\xi_i\) in \(X_{\text{et}}\), and a \(Y\)-morphism \(X'_i \to Y'\) with the stated properties, such that moreover, the family \((X'_i | i = 1, \ldots, k)\) is an étale covering of \(X\). Furthermore, we may assume that \(X'_i\) and \(Y'_i\) are affine for every \(i \leq k\). In this case, lemma 14.8.32 shows that every \(X'_i\) is noetherian, and then the same holds for \(X\).

(b)⇒(c): Fix a geometric point \(\xi\) of \(X\), and let \(B^\text{sh}_\xi\) (resp. \(A^\text{sh}_\xi\)) denote the strict henselization of \(B\) at \(\xi\) (resp. of \(A\) at \(f(\xi)\)); by assumption, we may find a (finitely generated) ideal \(I \subset A^\text{sh}_\xi\) such that \(f_\xi\) induces an isomorphism \(A^\text{sh}_\xi/I \simeq B^\text{sh}_\xi\). Then we may find an affine étale neighborhood \(Y'\) of \(f(\xi)\), say \(Y' := \text{Spec} A'\) for some étale \(A\)-algebra \(A'\), and an ideal \(I' \subset A'\) such that \(I'A^\text{sh}_\xi = I\). Next, we may find an affine étale neighborhood \(X' := \text{Spec} B'\) of \(\xi\) such that \(f_\xi\) extends to a morphism \(g : X' \to Y'\), and we may further suppose that the corresponding ring homomorphism \(A' \to B'\) factors through \(A'/I'\), so \(g\) factors through a morphism

\[
h : X' \to Z := \text{Spec} A'/I'
\]

and the closed immersion \(Z \to Y'\). By construction, \(\xi\) lifts to a geometric point \(\xi'\) of \(X'\), and \(h_{\xi'} : X'((\xi')) \to Z(h(\xi'))\) is an isomorphism (51, Ch.IV, Prop.18.8.10)). To conclude the proof,
it then suffices to exhibit an open subset $U \subset X'$ containing the support of $\xi'$, and such that the restriction $U \to Z$ of $h$ is absolutely flat with finite fibres.

**Claim 14.8.36.** Let $\varphi : W \to W'$ be a quasi-finite, separated, dominant and finitely presented morphism of reduced, irreducible schemes, and suppose that $W'$ contains a non-empty geometrically unibranch open subset. Then the same holds for $W$.

**Proof of the claim.** After replacing $W'$ by some open subset $U' \subset W'$, and $W$ by $\varphi^{-1}U'$, may assume that $W'$ is affine and unibranch; then we may also suppose that $\varphi$ is finite ([50, Ch.IV, Th.8.12.6]), in which case $W$ is affine as well, and $\varphi$ is surjective.

Let $\eta \in W$ and $\eta' \in W'$, with generic point $\eta^\prime$; such that $\varphi$ factors as the composition of finite surjective morphisms $\varphi' : W \to W'', \varphi'' : W'' \to W'$, and such that $\kappa(\eta'') = E$. By virtue of [50, Ch.IV, Th.8.10.5] and [51, Ch.IV, Prop.17.7.8(ii)], we may then replace $W''$ by a non-empty open subset, and assume that $\varphi'$ is radicial, and $\varphi''$ is étale. Then $W''$ is geometrically unibranch ([49, Ch.IV, Prop.6.15.10]); hence, we may replace $W'$ by $W''$, and reduce to the case where $\varphi$ is radicial. Let $p$ be the characteristic of $\kappa(\eta')$; if $p = 0$, $\varphi$ is birational, in which case the assertion follows from [49, Prop.6.15.5(ii)]. In case $p > 0$, write $W = \Spec C, W' = \Spec C'$; the induced ring homomorphism $C' \to C$ is finite and injective, and we have $C'^n \subset C'$ for $n \in \mathbb{N}$ large enough. Denote by $C''$ (resp. $C'''$) the normalization of the domain $C$ (resp. of $C'$); it follows easily that $(C''')^n \subset C''$, so the morphism $\Spec C'' \to \Spec C'''$ is radicial. On the other hand, since $W''$ is geometrically unibranch, the normalization morphism $\Spec C'' \to W''$ is radicial ([48, Ch.0, Lemme 23.2.2]) and therefore the normalization map $\Spec C'' \to W$ is radicial as well ([49, Ch.IV, Lemme 6.15.3.1(i)]). Then $W$ is geometrically unibranch, again by [48, Ch.0, Lemme 23.2.2].

From claim 14.8.36 and our assumption on $Y$, it follows easily that $Z$ admits a geometrically unibranch stratification. The morphism $h$ induces as usual a morphism of étale topoi

$$
\eta \mapsto h_\eta : (X')_{\text{ét}} \to (Z')_{\text{ét}}
$$

as well as a morphism $h^\natural : h^* \mathcal{O}_{Z_{\text{ét}}} \to \mathcal{O}_{X_{\text{ét}}}^{-}$ of $(X')_{\text{ét}}$-rings. By construction, for every geometric point $\tau$ of $X'$, the induced map on stalks $h^\natural_\tau : \mathcal{O}_{Z_{\text{ét}}, h(\tau)} \to \mathcal{O}_{X_{\text{ét}}, \tau}$ is surjective, and $h^\natural_{\text{ét}}$ is a bijection. It follows easily that $h^\natural_{\text{ét}}$ is also bijective for every generalization $\tau$ of $\xi'$. Now, choose a partition $Z = Z_1 \cup \cdots \cup Z_k$ as in lemma 14.8.29 (with $\mathcal{F} = \mathcal{O}_{Z_{\text{ét}}}$), and for given $i \leq k$, suppose that $\tau$ and $\eta$ are two geometric points of $h^{-1}Z_i$, with $\eta$ a generalization of $\tau$. The choice of a strict specialization morphism $X'(\eta) \to X'(\tau)$ yields a commutative diagram

$$
h^\natural_{\text{ét}} : \mathcal{O}_{Z_{\text{ét}}, h(\tau)} \to \mathcal{O}_{X_{\text{ét}}, \tau}
$$

whose vertical arrows are strict specialization maps (see remark 14.9.26(i)); in light of lemma 14.8.29, we deduce that $h^\natural_{\text{ét}}$ is injective, whenever the same holds for $h^\natural_{\text{ét}}$. Now, let $x' \in X'$ be the support of $\xi'$, and $\Sigma_i$ the set of maximal points of $h^{-1}Z_i$. Condition (b) and proposition 8.1.62 imply that $h^{-1}Z_i$ is a noetherian topological space, hence $\Sigma_i$ is a finite set; it follows that the topological closure $W$ of $\bigcup_{i=1}^k \Sigma_i \setminus X'(x')$ in $X'$ is a closed subset that does not contain $x'$; by construction, $h^\natural$ restricts to a monomorphism on $U := X' \setminus W$, i.e. the restriction $h^\natural_U : U \to Z$ of $h$ is absolutely flat, as required. It also follows that the fibres of $h_U$ are noetherian topological...
spaces of dimension zero (cp. the proof of lemma [14.8.32], hence they are finite, and the proof is complete.

**Lemma 14.8.39.** Suppose that the valuation of $K$ has finite rank, and let $X$ be a finitely presented $K^+$-scheme, $\mathcal{F}$ a coherent $\mathcal{O}_{X_{\mathrm{et}}}$-module. Then there exists a partition

$$X = X_1 \cup \cdots \cup X_k$$

of $X$ into finitely many disjoint irreducible locally closed subsets, such that the following holds. For every $i = 1, \ldots, k$, every geometric point $\overline{\pi}$ of $X_i$, and every generalization $\pi$ of $\overline{\pi}$ in $X_i$, every strict specialization map

$$s_{\pi,\pi} : \mathcal{F}_\pi \to \mathcal{F}_\pi$$

is injective (see (4.9.23)).

**Proof.** We easily reduce to the case where $X$ is affine, say $X = \text{Spec } A$, and then $\mathcal{F}$ is the coherent $\mathcal{O}_{X_{\mathrm{et}}}$-module arising from a finitely presented $A$-module $M$. By theorem [14.8.17](i), $M$ admits a $K^+$-flattening sequence $(b_0, \ldots, b_n)$. Then we are further reduced to showing the assertion for the subquotients $b_i M/b_{i+1} M$ (that are finitely presented, by corollary [14.8.21](ii)). So, we may assume from start that $f : X \to S_0 := \text{Spec } K^+/bK^+$ is a finitely presented morphism for some $b \in K^+$, and $\mathcal{F}$ is $f$-flat. For every $t \in S_0$, let

$$i_t : X_t := f^{-1}(t) \to X$$

be the locally closed immersion; since $X_t$ is an excellent noetherian scheme, we may apply lemma [14.8.29] and remark [14.8.22] to produce a partition $X_t = X_{t,1} \cup \cdots \cup X_{t,k}$ by finitely many disjoint irreducible locally closed subsets such that, for every $i = 1, \ldots, k$, every geometric point $\overline{\pi}$ of $X_{t,i}$ and every generalization $\pi$ of $\overline{\pi}$ in $X_{t,i}$, every specialization map

$$(i_t^* \mathcal{F})_\pi \to (i_t^* \mathcal{F})_\pi$$

is injective. Since $|S_0|$ is a finite set, the lemma will then follow from :

**Claim 14.8.40.** Let $g : Y \to T$ be any finitely presented morphism of schemes, $\mathcal{G}$ a finitely presented, quasi-coherent $g$-flat $\mathcal{O}_T$-module, and $t \in T$. Let also $\overline{\gamma}, \pi$ be two geometric points of $g^{-1}(t)$, such that $\overline{\pi}$ is a generalization of $\overline{\gamma}$. Let $s_{\gamma,\pi} : \mathcal{G}_\gamma \to \mathcal{G}_\pi$ be a strict specialization map, and suppose that $s_{\gamma,\pi} \otimes_{\mathcal{O}_{T,t}} \kappa(t)$ is injective. Then the same holds for $s_{\gamma,\pi}$.

**Proof of the claim.** Set $Y' := Y(\overline{\gamma})$, denote by $j : Y' \to Y$ the natural morphism, and set $\mathcal{G}' := j^* \mathcal{G}$. The map $s_{\gamma,\pi}$ is deduced from a morphism $Y(\overline{\pi}) \to Y'$ of $Y$-schemes; the latter factors through a faithfully flat morphism $Y(\overline{\pi}) \to Y'(u)$, where $u \in Y'$ is the image of the closed point of $Y(\overline{\pi})$. Hence, $s_{\gamma,\pi}$ is the composition of the specialization map $s' : \mathcal{G}'_\gamma \to \mathcal{G}'_\pi$, and the injective map $\mathcal{G}'_\pi \to \mathcal{G}'_\pi$. Our assumption implies that $s' \otimes_{\mathcal{O}_{T,t}} \kappa(t)$ is injective, and it suffices to show that the same holds for $s'$. However, $Y'$ is the limit of a cofiltered system $(j_\lambda : Y_\lambda \to Y \mid \lambda \in \Lambda)$ of local, essentially étale $Y$-schemes. Write $G_\lambda := j_\lambda^* \mathcal{G}$ for every $\lambda \in \Lambda$, and notice that the transition morphisms $Y_\lambda \to Y_\mu$ are faithfully flat, for every $\lambda \geq \mu$; it follows that $G'_\lambda$ is the filtered union of the system of modules $(G_\lambda := \Gamma(Y_\lambda, G_\lambda) \mid \lambda \in \Lambda)$ (proposition [10.1.10](i)); likewise, $G'_\gamma \otimes_{\mathcal{O}_{T,t}} \kappa(t)$ is the filtered union of the submodules $(G_\lambda \otimes_{\mathcal{O}_{T,t}} \kappa(t) \mid \lambda \in \Lambda)$. We are then reduced to checking that all the restrictions $s_\lambda : G_\lambda \to G'_\lambda$ of $s'$ are injective, and we know already that $s_\lambda \otimes_{\mathcal{O}_{T,t}} \kappa(t)$ is injective for every $\lambda \in \Lambda$. For every such $\lambda$, let $u_\lambda \in Y_\lambda$ be the image of $u$; then $s_\lambda$ factors through the injective map $G_{\lambda,u_\lambda} \to G'_\lambda$ and the specialization map $s'_\lambda : G_\lambda \to G_{\lambda,u_\lambda}$. Consequently, it suffices to show that $s'_\lambda$ is injective, and we know already that the same holds for $s'_\lambda \otimes_{\mathcal{O}_{T,t}} \kappa(t)$. However, $G_{\lambda,u_\lambda}$ is a localization $Q_\lambda^{-1} G_\lambda$, for a multiplicative set $Q_\lambda \subset \Gamma(Y_\lambda, \mathcal{O}_{Y_\lambda})$, and $s'_\lambda$ is the localization map. The claim therefore boils down to the assertion that, for every $\lambda \in \Lambda$ and every $q \in Q_\lambda$, the endomorphism $q : 1_{G_\lambda}$ is injective on $G_\lambda$, and our assumption already ensures that $(q : 1_{G_\lambda}) \otimes_{\mathcal{O}_{T,t}} \kappa(t)$ is injective on
$G_{\lambda} \otimes_{\partial_{Y_{\lambda}}} \kappa(t)$. However, let $g_{\lambda} : Y_{\lambda} \to T$ be the morphism induced by $g$; by construction, $G_{\lambda}$ is a $g_{\lambda}$-flat $\partial_{Y_{\lambda}}$-module, hence the contention follows from [50] Prop.11.3.7].

**Proposition 14.8.41.** Let $(K,|\cdot|)$ be a valued field, and $A$ a locally measurable $K^+$-algebra fulfilling conditions (a) and (b) of theorem [14.8.17] The following conditions are equivalent:

(c) For every geometric point $\xi$ of $X := \text{Spec } A$ there exist a neighborhood $U$ of $\xi$ in $X_{\text{st}}$, and a finitely presented $K^+$-scheme $Z$ with an absolutely flat morphism of $K^+$-schemes $X' \to Z$.

(d) $\Omega_{A/K^+}$ is an $A$-module of finite type.

**Proof.** (c)⇒(d): follows easily from lemma [14.8.24].

(d)⇒(c): Let $a_1, \ldots, a_k \in A$ be a finite system of elements such that $da_1, \ldots, da_k$ generate the $A$-module $\Omega_{A/K^+}$. We define a map of $K^+$-algebras $A_0 := K^+[T_1, \ldots, T_k] \to A$ by the rule: $T_i \mapsto a_i$ for $i = 1, \ldots, k$. Clearly $\Omega_{A/A_0} = 0$. Let $Z_0 := \text{Spec } A_0$, and denote by $f : X \to Z_0$ the induced morphism of schemes. Let $A_{\text{sh}}(\xi)$ be the strict henselization of $A$ at $\xi$ (resp. of $A_0$ at $f(\xi)$). According to lemma [14.8.27] the induced map $A_{\text{sh}}(\xi) \to A_{\text{sh}}$ is surjective, and its kernel is a finitely generated ideal $I \subset A_{\text{sh}}$. In this situation, we may argue as in the proof of proposition [14.8.35] to produce an affine étale neighborhood $X'$ of $\xi$, a finitely presented affine unramified $Z_0$-scheme $Z$, and a morphism of $Z_0$-schemes $h : X' \to Z$ such that $h_\xi : X'(\tau) \to Z(h(\tau))$ is a closed immersion for every geometric point $\tau$ of $X'$, and $h_\xi$ is an isomorphism for some lifting $\xi'$ of $\xi$.

Then we consider the associated morphism of étale topoi in (14.8.37) and the morphism $h^\xi : h^\xi_\eta Z_\xi \to \partial_{X_{\text{sh}}^\xi}$ of $(X_{\text{sh}}^\xi)_{\text{st}}$-rings. Again, the induced map on stalks $h^\xi_\eta$ is surjective for every geometric point $\eta$ of $X'$, and is bijective if $\eta$ is a generalization of $\xi'$. We pick a finite partition $Z = Z_1 \cup \cdots \cup Z_k$ as in lemma [14.8.39] (for $\mathcal{F} := \partial Z$). For any $i \leq k$, let $\tau, \eta$ be two geometric points of $h^{-1} Z_i$, such that $\eta$ is a generalization of $\tau$; by considering the commutative diagram (14.8.38), we see again that $h^\xi_\eta$ is injective whenever the same holds for $h^\xi_\eta$.

Now, condition (b) of theorem [14.8.17] easily implies that $h^{-1} Z_i$ is a noetherian topological space, hence its set $\Sigma_i$ of maximal points is finite. Again we let $x' \in X'$ be the support of $\xi'$, and $W$ the topological closure of $\bigcup_{i=1}^k \Sigma_i \setminus X'(x')$ in $X'$, and it is easily seen that the restriction $U \to Z$ of $h$ is absolutely flat, so (c) holds.

14.8.42. Henceforth we restrict to the case where the value group $\Gamma$ of $K$ is not discrete and of rank one. As usual, we consider the almost structure attached to the standard setup attached to $(K,|\cdot|)$.

**Definition 14.8.43.** In the situation of (14.8.42), let $A$ be a $K^+$-algebra and $M$ an $A$-module.

(i) We say $M$ is an almost noetherian $A$-module, if every $A$-submodule of $M$ is almost finitely generated.

(ii) We say that $A$ is an almost noetherian $K^+$-algebra, if $A$ is an almost noetherian $A$-module.

**Remark 14.8.44.** In the situation of (14.8.42), suppose that $A$ is an almost noetherian $K^+$-algebra. Then the same argument as in the “classical limit” case shows that every almost finitely generated $A$-module $M$ is almost noetherian. The details shall be left to the reader.

**Theorem 14.8.45.** Let $A$ be a locally measurable $K^+$-algebra. Suppose that both $A \otimes_{K^+} \kappa$ and $A \otimes_{K^+} \bar{K}$ are noetherian rings. Then $A^\alpha$ is an almost noetherian $K^+$-algebra.

**Proof.** If the valuation of $K$ is discrete, the assertion is proposition [14.8.14](iii). Hence, we may assume that the valuation of $K$ is not discrete. Moreover, let $\mathcal{D}$ be the set of all locally measurable $K^+$-algebras $B$ that are quotients of $A$, and such that $B^\alpha$ is not almost noetherian.
We have to show that $\mathcal{Q} = \emptyset$. However, for every $B \in \mathcal{Q}$ the $\kappa$-algebra $\overline{B} := B \otimes_{K^+} \kappa$ is a quotient of the noetherian $\kappa$-algebra $\overline{A} := A \otimes_{K^+} \kappa$; it follows that the set $\mathcal{Q} := \{ \overline{B} \mid B \in \mathcal{Q} \}$ admits minimal elements, if it is not empty. In the latter case, we may then replace $A$ by any quotient $B \in \mathcal{Q}$ such that $\overline{B}$ is minimal in $\mathcal{Q}$, and therefore assume that for every locally measurable quotient $B$ of $A$, either $\overline{B} = \overline{A}$, or else $B^a$ is almost noetherian.

Let $I \subset A$ be any ideal; we have to show that $I^a$ is almost finitely generated. By assumption, the image $\overline{I}$ of $I$ in $\overline{A}$ is finitely generated, and the same holds for the ideal $I_K := I \otimes_{K^+} K$ of $A_K := A \otimes_{K^+} K$. Thus, we may find a finitely generated subideal $I_0 \subset I$ whose image in $\overline{A}$ agrees with $\overline{I}$, and such that $I_0 \otimes_{K^+} K = I_K$. After replacing $A$ by $A/I_0$ and $I$ by $I/I_0$, we are then reduced to the case where both $\overline{I}$ and $I_K$ vanish. Let $J \subset A$ denote the kernel of the localization map $A \to A_K$, set $S := 1 + m_K A$, and let $B := S^{-1} A \times A_K$. Clearly $B$ is a faithfully flat $A$-algebra, and $A/J$ is a $K^+$-flat $A$-module; therefore $(A/J) \otimes_A B$ is a $K^+$-flat $B$-module of finite type, and since $A_K$ is noetherian, proposition [14.8.14(ii)] implies that $(A/J) \otimes_A B$ is finitely presented. Then $A/J$ is finitely presented as well, and therefore $J$ is a finitely generated ideal. We conclude that there exists $c \in m_K$ such that $cJ = 0$. Then notice that $J \cap cA = 0$; indeed, if $a \in J \cap cA$, we have $a = cx$ for some $x \in A$, and $ca = 0$, therefore $c^2 x = 0$, so $x \in J$, and consequently $a = cx = 0$. Now, fix $b \in m_K$; since the valuation of $K$ has rank one, and since $I \subset J$, it follows that there exists $n \in \mathbb{N}$ large enough, so that $I \cap b^n A = 0$.

Let $i_0 := \max\{ i \in \mathbb{N} \mid I \subset b^i A \}$, and set $N := b^{i_0} A/(I + b^{i_0+1} A)$, $N' := b^{i_0} A/b^{i_0+1} A$.

Let $\varphi : N' \to N$ be the natural surjection, and set $c_N := c_N \circ \varphi : N' \to cN$ for every $c \in K^+$ (notation of definition [14.8.6(ii)]).

**Claim** 14.8.46. There exists $c \in K^+$ with $\log |c| < \log |b|$ such that $c_N \otimes_{K^+} \kappa$ is not an isomorphism.

**Proof of the claim.** Suppose that the claim fails; then it is easily seen that no $\gamma \in \log \Gamma^+$ with $\gamma < \log |b|$ breaks $N$. For every geometric point $\xi$ of $\text{Spec} \ A$, let $A_{\xi}^{sh}$ denote the strict henselization of $A$ at $\xi$; since $A_{\xi}^{sh}$ is a flat $A$-algebra, we have a natural identification

$$cN \otimes_A A_{\xi}^{sh} = c(N \otimes_A A_{\xi}^{sh})$$

of $A_{\xi}^{sh}$-modules; therefore, no $\gamma < \log |b|$ breaks $N \otimes_A A_{\xi}^{sh}$. By corollary [14.8.13] we deduce that $N \otimes_A A_{\xi}^{sh}$ is a $K^+/bK^+$-flat and finitely presented $A_{\xi}^{sh}$-module, for every geometric point $\xi$. Hence, $C_{\xi} := \text{Ker} \varphi \otimes_A A_{\xi}^{sh}$ is a finitely generated $A_{\xi}^{sh}$-module, and $C_{\xi} \otimes_{K^+} \kappa = 0$, for every geometric point $\xi$. By Nakayama’s lemma, it follows that $C_{\xi} = 0$ for every such $\xi$, so finally $\text{Ker} \varphi = 0$, which means that $I \subset b^{i_0+1} A$, contradicting the choice of $i_0$.

Let $c$ be as in claim [14.8.46] and set $d := cb^{i_0}$; notice the natural isomorphism of $\overline{A}$-modules

$$cN \otimes_{K^+} \kappa \sim \frac{dA}{I \cap dA} \otimes_{K^+} \kappa,$$

Let $\varphi : A \to dA/(I \cap dA)$ be the composition of $d_A : A \to dA$ and the projection $dA \to dA/(I \cap dA)$ (notation of definition [14.8.6(ii)]); by construction, $\varphi \otimes_{K^+} \kappa$ is not an isomorphism, hence there exists $x \in I \cap dA$ such that the composition $\varphi_x : A \to dA/xA$ of $d_A$ and the projection $dA \to dA/xA$ induces a map $\varphi_x \otimes_{K^+} \kappa$ with non-trivial kernel. In other words, $dA/xA$ is a cyclic module over a locally measurable quotient $B$ of $A$ such that the projection $\overline{A} \to \overline{B}$ is not an isomorphism, so $B^a$ is almost noetherian. Set $I_0 := (I \cap dA)/xA$; then $I_0$ is a submodule of $dA/xA$, and consequently $I_0^a$ is an almost finitely generated $B^a$-module (remark [14.8.44]). Then clearly $(I \cap dA)^a$ is an almost finitely generated ideal of $A^a$. But by
Corollary 14.8.47. In the situation of theorem [14.8.45] the following holds:

(i) Every almost finitely generated \( A^n \)-module is almost finitely presented.
(ii) Every flat almost finitely generated \( A^n \)-module is almost projective of finite rank.

Proof. Assertion (i) is an easy consequence of theorem [14.8.45] and remark [14.8.44]; the details shall be left to the reader.

(ii) Let \( M \) be a flat and almost finitely generated \( A^n \)-module; by (i) and [59] Prop.2.4.18(ii), \( M \) is almost projective. It remains to show that there exists \( n \in \mathbb{N} \) such that \( \Lambda^n_{A^n} M = 0 \), or equivalently, that \( (\Lambda^n_{A^n} M)^n = 0 \). However, \( M \) is a flat \( A \)-module, so \( \text{Ass} M \subset \text{Ass} A \); in view of theorem [14.8.17]ii, we may argue by induction on the cardinality of \( \text{Ass} A \), and it suffices to check that, for every \( p \in \text{Ass} A \) there exists \( n \in \mathbb{N} \) such that \( \Lambda^n_{A_p} (M_p)^p = 0 \). If \( c = 0 \), we have \( A = 0 \), and there is nothing to prove. Suppose that \( c > 0 \) and the assertion is known for every locally measurable \( K^n \)-algebra \( B \) such that \( B \otimes_{K^n} B \) and \( B \otimes_{K^n} \kappa \) are noetherian, and such that \( \text{Ass} B \) has cardinality < \( c \). Especially, for a fixed \( p \in \text{Ass} A \), we can cover \( \text{Spec} A_p \setminus \{p\} \) by finitely many affine open subsets \( \text{Spec} B_1, \ldots, \text{Spec} B_k \), and then the inductive assumption yields \( n \in \mathbb{N} \) such that \( \Lambda^n_{B_i} (M_i \otimes A B_i) = \Lambda^n_{B_i} (M \otimes A^i B_i^p) = 0 \) for every \( i = 1, \ldots, k \). In other words, \( N := \Lambda^n_{A_p} (M_p) \) is a flat \( A_p^n \)-module with \( \text{Supp} N_1 \subset \{p\} \).

Let \( A^n_{\lambda} \) denote the strict henselization of \( A \) at some geometric point localized at \( p \); on the one hand, the \( A^n_{\lambda} \)-algebra \( A^n_{\lambda} \) is faithfully flat, and \( M_i \otimes A A^n_{\lambda} = (M \otimes A^i (A^n_{\lambda})^p) \). On the other hand, exterior powers commute with arbitrary base change; thus, we are reduced to showing:

Claim 14.8.48. Let \( B \) be a measurable \( K^n \)-algebra, and \( N \) a flat almost finitely generated \( B^n \)-module whose support is contained in \( \{s(B)\} \) (notation of [14.5.36]). Then \( \Lambda^n_{B} N_1 = 0 \) for every sufficiently large \( n \in \mathbb{N} \).

Proof of the claim. By assumption, we may find an essentially finitely presented \( K^n \)-algebra \( B_0 \) and an ind-étale and faithfully flat map \( B_0 \to B \) of \( K^n \)-algebras. Set \( X_0 := \text{Spec} B_0 \) and \( X := \text{Spec} B \); since \( \{s(B_0)\} \) is a constructible subset of \( X_0 \), the natural map

\[
B \otimes_{B_0} \Gamma_{\{s(B_0)\}} \mathcal{O}_{X_0} \to \Gamma_{\{s(B)\}} \mathcal{O}_X
\]

is an isomorphism (lemma [10.4.17]iii). On the other hand, there exists a finitely generated \( s(B_0) \)-primary ideal \( J \subset B_0 \) such that the natural map \( \Gamma_{\{s(B_0)\}} \mathcal{O}_{X_0} \to B_0/J \) is injective (lemma [10.5.15] and theorem [11.4.36]i). It follows that the natural map \( \Gamma_{\{s(B)\}} \mathcal{O}_X \to B/JB \) is injective as well. Now, \( N_1 \) can be written as the colimit of a filtered system \( (L_{\lambda} \mid \lambda \in \Lambda) \) of free \( B \)-modules of finite rank; for each \( \lambda \in \Lambda \), let \( L_{\lambda} \) be the quasi-coherent \( \mathcal{O}_X \)-module arising from \( L_{\lambda} \), and define likewise \( N_{1}^{-} \); taking into account lemma [10.4.4]iii.b we deduce that the natural map

\[
N_1 = \Gamma_{\{s(B)\}} N_1^{-} = \colim_{\lambda \in \Lambda} \Gamma_{\{s(B)\}} L_{\lambda}^{-} \to \colim_{\lambda \in \Lambda} L_{\lambda}/JL_{\lambda} = N_1/JN_1
\]

is injective. In other words, \( N \) is a \( B^n/JB^n \)-module. We may then replace \( B \) by \( B/JB \), and assume from start that \( B \) has Krull dimension zero. In this situation, we may find a nilpotent ideal \( I \subset B \), a valuation ring \( V \) that is a measurable \( K^n \)-algebra, and a finitely presented surjection \( V \to B/I \) (lemma [14.4.2]). It suffices to find \( n \in \mathbb{N} \) such that \( (\Lambda^n_{B} N_1)^n \otimes B/I B/I = 0 \); hence, we may replace \( N \) by \( N/IN \) and \( B \) by \( B/I \), and assume as well that \( B = V/bV \) for some \( b \in V \). In this case, the assertion follows easily from corollary [14.5.33].

15. Continuous valuations and adic spaces

In this chapter we present Huber’s theory of adic spaces.
15.1. **Formal schemes.** In this section we define a category of topologically ringed spaces that generalize the usual formal schemes from [44]. This generalization was crucial for the previous releases of this work, that followed closely Faltings’s original method for proving the almost purity theorem. In the current release, where we have switched to the new approach invented by Scholze, and based on his theory of perfectoid spaces, formal schemes are still useful, but they play a rather different role: we will employ them to establish some foundational properties of adic spaces (and later, of perfectoid spaces): for such purposes, the standard adic formal schemes of [44] would already suffice, but the generalization that we worked out in the previous releases might be interesting in its own right, and for other applications. Besides, our former treatment included some complements on the cohomology of formal schemes that do not appear explicitly in [46], which will come in handy in section 15.5.

15.1.1. In this section we shall deal with topological rings whose topology is linear, so that $0 \in A$ admits a fundamental system of open neighborhoods $I_\lambda := (I_\lambda \mid \lambda \in \Lambda)$ consisting of ideals of $A$ (see definition 8.3.1(v)). Then the separated completion $A^\Lambda$ of $A$ is also a topological ring of this type; namely, its topology is linear, defined by the system $I^\Lambda_\lambda := (I^\Lambda_\lambda \mid \lambda \in \Lambda)$, where $I^\Lambda_\lambda$ denotes the topological closure of $I_\lambda$ in $A^\Lambda$, for every $\lambda \in \Lambda$.

15.1.2. Keep the notation of (15.1.1). We shall consider topological $A$-modules $(M, \mathcal{T}_M)$ whose topology is $A$-linear (see definition 8.3.1(iv)); additionally, we shall assume that $\mathcal{T}_M$ is coarser than the $I_\lambda$-adic topology, i.e., for every open submodule $N \subset M$, there exists $\lambda \in \Lambda$ such that $I_\lambda M \subset N$ (see remark 8.3.2(ii)). (Notice that [44] Ch.0, §7.7.1] is slightly ambiguous: it is not clear whether all the topological modules considered there are supposed to satisfy the foregoing additional condition.) Then, the topology of the separated completion $(M^\Lambda, \mathcal{T}_M^\Lambda)$ is $A^\Lambda$-linear and coarser than the $I^\Lambda_\lambda$-adic topology. Let $N$ be any other topological $A$-module of this type; notice that the topology $\mathcal{T}^\Lambda_{M,N}$ on $M \otimes_A N$ (see (8.3.7)) is also coarser than the $I^\Lambda_\lambda$-adic topology, so the topology of $M \otimes_A N$ is coarser than the $I^\Lambda_\lambda$-adic topology. We also denote

$$\text{top} \hom_A(M, N)$$

the $A$-module of all continuous $A$-linear maps $M \to N$. Notice the natural identification:

$$\text{top} \hom_A(M, N^\Lambda) \simeq \lim_{N' \subset N} \text{colim} \hom_A(M/M', N/N')$$

where $N'$ (resp. $M'$) ranges over the family of open submodules of $N$ (resp. of $M$).

**Definition 15.1.4.** Let $X := (\mathcal{X}, J)$ be any site, and $\mathcal{G}$ any other category.

(i) A sheaf of topological spaces on $X$, any sheaf on $X$ with values in the category Top of topological spaces (see definition 5.5.1(ii)). Likewise, a sheaf of topological groups (resp. of topological rings) on $X$ is a sheaf $\mathcal{A}$ on $X$ with values in the category of topological groups (resp. topological rings).

(ii) Let $\mathcal{A}$ be a sheaf of topological rings on $X$. A sheaf of topological $\mathcal{A}$-modules – or briefly, a topological $\mathcal{A}$-module – is the datum of an $\mathcal{A}$-module $\mathcal{F}$, and for every $U \in \mathrm{Ob}(\mathcal{X})$, a topology $\mathcal{T}_U$ on $\mathcal{F}(U)$, such that $\mathcal{F}(U) := (\mathcal{F}(U), \mathcal{T}_U)$ is a topological $\mathcal{A}(U)$-module, and the rule $U \mapsto \mathcal{F}(U)$ defines a sheaf of topological groups on $X$.

(iii) An $\mathcal{A}$-linear map $\varphi : \mathcal{F} \to \mathcal{G}$ between topological $\mathcal{A}$-modules is said to be continuous if it is a morphism of sheaves of topological groups, i.e., if $\varphi_U : \mathcal{F}(U) \to \mathcal{G}(U)$ is a continuous map for every $U \in \mathrm{Ob}(\mathcal{X})$. We denote by:

$$\text{top} \hom_{\mathcal{A}}(\mathcal{F}, \mathcal{G})$$

the $A$-module of all continuous $\mathcal{A}$-linear morphisms $\mathcal{F} \to \mathcal{G}$. 

Remark 15.1.5. Keep the notation of definition [15.1.4]

(i) Since the forgetful functor $\text{Top} \to \text{Set}$ commutes with all limits, remark [5.5.2](i,ii) implies that the presheaf (of sets) underlying any sheaf of topological spaces on $X$ is a sheaf (of sets). Likewise, the presheaf underlying any sheaf of topological groups or topological rings is also a sheaf of sets.

(ii) For any sheaf $\mathcal{A}$ of topological rings on $X$, and any topological $\mathcal{A}$-modules $\mathcal{F}$ and $\mathcal{G}$, consider the presheaf on $X$ defined by the rule:

\begin{equation}
U \mapsto \text{top.}\text{Hom}_A(\mathcal{F}|_U, \mathcal{G}|_U).
\end{equation}

From the discussion of remark [5.5.2](v) we deduce that (15.1.6) is a sheaf on $X$, which we denote by:

$\text{top.}\text{Hom}_A(\mathcal{F}, \mathcal{G})$.

15.1.7. In the situation of (15.1.1), set $X_\lambda := \text{Spec } A/I_\lambda$ for every $\lambda \in \Lambda$; we define the formal spectrum of $A$ as the colimit of topological spaces:

$\text{Spf } A := \text{colim}_{\lambda \in \Lambda} X_\lambda$.

Hence, the set underlying $\text{Spf } A$ is the filtered union of the $X_\lambda$, and a subset $U \subset \text{Spf } A$ is open (resp. closed) in $\text{Spf } A$ if and only if $U \cap X_\lambda$ is open (resp. closed) in $X_\lambda$ for every $\lambda \in \Lambda$.

Let $I \subset A$ be any open ideal of $A$; then $I$ contains an ideal $I_\lambda$, and therefore $\text{Spec } A/I$ is a closed subset of $\text{Spec } A/I_\lambda$, hence also a closed subset of $\text{Spf } A$.

15.1.8. We endow $\text{Spf } A$ with a sheaf of topological rings as follows. For every $\lambda \in \Lambda$, the structure sheaf $\mathcal{O}_{X_\lambda}$ carries a natural pseudo-discrete topology that makes it a sheaf of topological rings (see [44, Ch.0, §3.8]). Let $j_\lambda : X_\lambda \to \text{Spf } A$ be the closed immersion; we set

$\mathcal{O}_{\text{Spf } A} := \text{lim}_{\lambda \in \Lambda} j_\lambda^* \mathcal{O}_{X_\lambda}$

where the limit is taken in the category of sheaves of topological rings ([44, Ch.0, §3.2.6]). By remark [5.5.2](iii), it follows that:

\begin{equation}
\mathcal{O}_{\text{Spf } A}(U) = \text{lim}_{\lambda \in \Lambda} \mathcal{O}_{X_\lambda}(U \cap X_\lambda)
\end{equation}

for every open subset $U \subset \text{Spf } A$. In this equality, the right-hand side is endowed with the topology of the (projective) limit, and the identification with the left-hand side is a homeomorphism. Set $X := \text{Spf } A$; directly from the definitions we get natural maps of locally ringed spaces:

\begin{equation}(X_\lambda, \mathcal{O}_{X_\lambda}) \xrightarrow{j_\lambda} (X, \mathcal{O}_X) \xrightarrow{i_X} (\text{Spec } A^\wedge, \mathcal{O}_{\text{Spec } A^\wedge}) \text{ for every } \lambda \in \Lambda
\end{equation}

where $A^\wedge := \mathcal{O}_X(X)$ is the (separated) completion of $A$, and $i_X$ is given by the universal property [43, Ch.I, Prop.1.6.3] of the spectrum of a ring. Clearly the composition $i_X \circ j_\lambda$ is the map of affine schemes induced by the surjection $A^\wedge \to A/I_\lambda$. Therefore $i_X$ identifies the set underlying $X$ with the subset $\bigcup_{\lambda \in \Lambda} X_\lambda \subset \text{Spec } A^\wedge$. However, the topology of $X$ is usually strictly finer than the subspace topology on the image of $i_X$. For any $f \in A^\wedge$ we let:

$\mathcal{D}(f) := i_X^* D(f)$

where as usual, $D(f) \subset \text{Spec } A^\wedge$ is the open subset consisting of all prime ideals that do not contain $f$. 

15.1.11. Let $f : A \to B$ be a continuous map of topological rings whose topologies are linear. For every open ideal $J \subset B$, we have an induced map $A/f^{-1}J \to B/J$, and after taking colimits, a natural continuous map of topologically ringed spaces:

$$\text{Spf } f : (\text{Spf } B, \mathcal{O}_{\text{Spf } B}) \to (\text{Spf } A, \mathcal{O}_{\text{Spf } A}).$$

**Lemma 15.1.12.** In the situation of (15.1.11), we have:

(i) $\text{Spf } A$ is a locally and topologically ringed space.

(ii) $\varphi := \text{Spf } f : \text{Spf } B \to \text{Spf } A$ is a morphism of locally and topologically ringed spaces; in particular, the induced map on stalks $\mathcal{O}_{\text{Spf } A, \varphi(x)} \to \mathcal{O}_{\text{Spf } B, x}$ is a local ring homomorphism, for every $x \in \text{Spf } B$.

(iii) Let $I \subset A$ be any open ideal, $x \in \text{Spec } A/I \subset \text{Spf } A$ any point. The induced map:

$$\mathcal{O}_{\text{Spf } A, x} \to \mathcal{O}_{\text{Spec } A/I, x}$$

is a surjection.

**Proof.** (i): We need to show that the stalk $\mathcal{O}_{X, x}$ is a local ring, for every $x \in X := \text{Spf } A$. Let $(I_\lambda | \lambda \in \Lambda)$ be a cofiltered fundamental system of open ideals. Then $x \in X_\mu := \text{Spec } A/I_\mu$ for some $\mu \in \Lambda$; let $\kappa(x)$ be the residue field of the stalk $\mathcal{O}_{X_\mu, x}$; there follows a ring homomorphism

$$\mathcal{O}_{X, x} \to (j_{\mu*}\mathcal{O}_{X_\mu})_x = \mathcal{O}_{X_\mu, x} \to \kappa(x).$$

Moreover, for every $\lambda \geq \mu$, the closed immersion $X_\mu \to X_\lambda$ induces an identification of $\kappa(x)$ with the residue field of $\mathcal{O}_{X_\mu, x}$, so (15.1.14) is independent of $\mu$.

Suppose now that $g \in \mathcal{O}_{X, x}$ is mapped to a non-zero element in $\kappa(x)$; according to (15.1.9) we may find an open subset $U \subset X$, such that $g$ is represented as a compatible system $(g_\lambda | \lambda \geq \mu)$ of sections $g_\lambda \in \mathcal{O}_{X_\lambda}(U \cap X_\lambda)$. For every $\lambda \geq \mu$, let $V_\lambda \subset X_\lambda$ denote the open subset of all $y \in X_\lambda$ such that $g_\lambda(y) \neq 0$ in $\kappa(y)$. Then $V_\eta \cap X_\lambda = V_\lambda$ whenever $\eta \geq \lambda \geq \mu$. It follows that $V := \bigcup_{\lambda \geq \mu} V_\lambda$ is an open subset of $X$, and clearly $g$ is invertible at every point of $V$, hence $g$ is invertible in $\mathcal{O}_{X, x}$, which implies the contention.

(ii): The assertion is easily reduced to the corresponding statement for the induced morphisms of schemes: $\text{Spec } B/J \to \text{Spec } A/f^{-1}J$, for any open ideal $J \subset B$. The details shall be left to the reader.

(iii): Indeed, using (15.1.10) with $X := \text{Spf } A$ and $I_\lambda := I$, we see that the natural surjection $\mathcal{O}_{\text{Spec } A, x} \to \mathcal{O}_{\text{Spec } A/I, x}$ factors through (15.1.13). \qed

15.1.15. Let $A$ and $B$ be as in (15.1.2), and fix a (cofiltered) fundamental system $(M_\lambda | \lambda \in \Lambda)$ of open submodules $M_\lambda \subset M$. For every $\lambda \in \Lambda$ we may find an open ideal $I_\lambda \subset A$ such that $M/M_\lambda$ is an $A/I_\lambda$-module. Let $j_\lambda : X_\lambda := \text{Spec } A/I_\lambda \to X := \text{Spec } A$ be the natural closed immersion (of ringed spaces). We define the topological $\mathcal{O}_X$-module:

$$M^\sim := \lim_{\lambda \in \Lambda} j_\lambda(M/M_\lambda)^\sim$$

where, as usual, $(M/M_\lambda)^\sim$ denotes the quasi-coherent pseudo-discrete $\mathcal{O}_{X_\lambda}$-module associated with $M/M_\lambda$, and the limit is formed in the category of sheaves of topological $\mathcal{O}_X$-modules ([44, Ch.0, §3.2.6]). Thus, for every open subset $U \subset X$ one has the identity of topological modules

$$M^\sim(U) = \lim_{\lambda \in \Lambda} (M/M_\lambda)^\sim(U \cap X_\lambda)$$

that generalizes (15.1.9), and follows likewise from remark 5.5.2 (iii).

To proceed beyond these simple generalities, we need to add further assumptions. The following definition covers all the situations that we shall find in the sequel.

**Definition 15.1.17.** Let $A$ be a topological ring whose topology is linear.

(i) We say that $A$ is $\omega$-admissible if $A$ is separated and complete, and $0 \in A$ admits a countable fundamental system of open neighborhoods.
(ii) We say that an open subset \( U \subseteq \text{Spf} \ A \) is \textit{affine} if there exist an \( \omega \)-admissible topological ring \( B \) and an isomorphism \( (\text{Spf} \ B, \mathcal{O}_{\text{Spf} \ B}) \xrightarrow{\sim} (U, \mathcal{O}_{\text{Spf} A|U}) \) of topologically ringed spaces.

(iii) We say that an open subset \( U \subseteq \text{Spf} \ A \) is \textit{truly affine} if \( U \cap \text{Spec} \ A/I \) is an affine open subset of \( \text{Spec} \ A/I \) for every open ideal \( I \subseteq A \).

(iv) An \textit{affine} \( \omega \)-\textit{formal scheme} is a topologically and locally ringed space \( (X, \mathcal{O}_X) \) that is isomorphic to the formal spectrum of an \( \omega \)-admissible topological ring.

(v) An \( \omega \)-\textit{formal scheme} is a topologically and locally ringed space \( (X, \mathcal{O}_X) \) that admits an open covering \( X = \bigcup_{i \in I} U_i \) such that, for every \( i \in I \), the restriction \( (U_i, \mathcal{O}_X|U_i) \) is an affine \( \omega \)-formal scheme.

(vi) A \textit{morphism of} \( \omega \)-\textit{formal schemes} \( f : (X, \mathcal{O}_X) \rightarrow (Y, \mathcal{O}_Y) \) is a map of topologically and locally ringed spaces, i.e. a morphism of locally ringed spaces such that the corresponding map \( \mathcal{O}_Y \rightarrow f^* \mathcal{O}_X \) induces continuous ring homomorphisms \( \mathcal{O}_Y(U) \rightarrow \mathcal{O}_X(f^{-1}U) \), for every open subset \( U \subseteq Y \).

\textbf{Remark 15.1.18.} (i) Let \( X \) be any \( \omega \)-formal scheme, and \( U \subseteq X \) any open subset. Using the condition of definition \( \text{[5.5.1]} \text{(ii)} \), it is easily seen that :

(a) \( \mathcal{O}_X(U) \) is a complete and separated topological ring.

(b) If additionally, \( U = \bigcup_{i \in I} U_i \) for a countable family \( \langle U_i \mid i \in I \rangle \) of open subsets, such that \( (U_i, \mathcal{O}_X|U_i) \) is an affine \( \omega \)-formal scheme for every \( i \in I \) (briefly, each \( U_i \) is an affine open subset of \( X \)), then \( \mathcal{O}_X(U) \) is \( \omega \)-admissible.

(ii) In \( \text{[43]} \) one finds a notion of \textit{admissible topological ring}, and to any such ring \( A \) it is assigned an affine formal scheme \( \text{Spf} \ A \). These notions relate to ours as follows. Let us say that a topological ring is \( c \)-admissible if it is admissible in the sense of \( \text{[43]} \text{Ch.0, D\textsuperscript{é}f.7.1.2]} \) and \( 0 \notin A \) admits a countable fundamental system of open neighborhoods. Then, an admissible topological ring \( A \) is \( \omega \)-admissible if and only if it is \( c \)-admissible. Likewise, if \( A \) is admissible, then the formal scheme \( \text{Spf} \ A \) defined in \( \text{[43]} \text{Ch.I, D\textsuperscript{é}f.10.1.2]} \) is an \( \omega \)-formal scheme if and only if \( A \) is \( c \)-admissible. Indeed, if \( A \) is \( c \)-admissible, obviously \( \text{Spf} \ A \) coincides with the affine \( \omega \)-formal scheme attached to \( A \) as in \( \text{[15.1.7]} \) and \( \text{[15.1.8]} \). For the converse, notice that \( \text{Spf} \ A \) (in the sense of \( \text{[43]} \)) is quasi-compact, so if it is an \( \omega \)-formal scheme we may cover it by finitely many of its affine open subsets \( U_1, \ldots, U_n \); say that \( U_i = \text{Spf} \ B_i \) for \( i = 1, \ldots, n \), where \( B_1, \ldots, B_n \) are \( \omega \)-admissible. There follows a natural continuous map \( \rho : A \rightarrow B := \prod_{i=1}^n B_i \), and the topology of \( A \) agrees with the topology induced by \( B \) via \( \rho \) (remark \( \text{[5.5.2]} \text{(i)} \)); however, clearly \( 0 \in B \) admits a countable fundamental system of open neighborhoods, so the same holds for \( A \).

(iii) In the same vein, if \( A \) is \( \omega \)-admissible, then \( \text{Spf} \ A \) as defined in \( \text{[15.1.7]} \) and \( \text{[15.1.8]} \) is a quasi-compact formal scheme in the sense of \( \text{[43]} \) if and only if \( A \) is \( c \)-admissible. Indeed, the condition is obviously sufficient; conversely, if \( \text{Spf} \ A \) is a quasi-compact formal scheme in the sense of \( \text{[43]} \), we may cover it by finitely many open subsets \( U_1, \ldots, U_n \) such that, for every \( i = 1, \ldots, n \) we have \( U_i = \text{Spf} \ B_i \) for some topological ring that is admissible in the sense of \( \text{[43]} \), and the topology of \( A \) is induced by the natural inclusion map into \( B := \prod_{i=1}^n B_i \). For each such \( B_i \), pick an open and nilpotent ideal \( I_i \subseteq B_i \); then \( I := \prod_{i=1}^n I_i \) is an open and nilpotent ideal of \( B \), and \( I \cap A \) is open and nilpotent in \( A \), so the latter is \( c \)-admissible.

\textbf{Proposition 15.1.19.} \textit{Suppose that} \( A \) \textit{is an} \( \omega \)-\textit{admissible topological ring. Then} :

(i) \textit{The truly affine open subsets form a basis for the topology of} \( X := \text{Spf} \ A \).

(ii) \textit{Let} \( I \subseteq A \) \textit{be an open ideal,} \( U \subseteq X \) \textit{a truly affine open subset. Then} :

(a) \textit{The natural map} \( \rho_U : A \rightarrow A_U := \mathcal{O}_X(U) \) \textit{induces an isomorphism} :

\[
(\text{Spf} \ A_U, \mathcal{O}_{\text{Spf} A_U}) \xrightarrow{\sim} (U, \mathcal{O}_{\text{Spf} A|U}).
\]
(b) The topological closure \( I_U \) of \( IA_U \) in \( A_U \) is an open ideal, and the natural map:
\[
\text{Spec } A_U/IA_U \to \text{Spec } A/I
\]
is an isomorphism of topological sheaves, which implies the assertion.

(c) \( U \) is affine.

(d) Every open covering of \( U \) admits a countable subcovering.

**Proof.** (i): By assumption, we may find a countable fundamental system \((I_n \mid n \in \mathbb{N})\) of open ideals of \( A \), and clearly we may assume that this system is ordered under inclusion (so that \( I_n \subseteq I_m \) whenever \( n \geq m \)). Let \( x \in \text{Spf } A \) be any point, and \( U \subset \text{Spf } A \) an open neighborhood of \( x \). Then \( x \in X_n := \text{Spec } A/I_n \) for sufficiently large \( n \in \mathbb{N} \). We are going to exhibit, by induction on \( m \in \mathbb{N} \), a sequence \((f_m \mid m \geq n)\) of elements of \( A \), such that:
\[
(15.1.20) \quad x \in \mathcal{O}(f_p) \cap X_m = \mathcal{O}(f_m) \cap X_m \subset U \quad \text{whenever } p \geq m \geq n
\]
To start out, we may find \( f_n \in \mathcal{O}_n \subset A/I_n \) such that \( x \in \mathcal{O}(f_n) \cap X_n \subset U \cap X_n \). Next, let \( m \geq n \) and suppose that \( f_m \) has already been found; we may write
\[
U \cap X_{m+1} = X_{m+1} \setminus V(J) \quad \text{for some ideal } J \subset A/I_{m+1}.
\]
Let \( \overline{J} \subset A/I_m \) and \( \overline{J}_m \subset A/I_m \) be the images of \( J \) and \( f_m \); then \( V(\overline{J}) \subset V(\overline{J}_m) \), hence there exists \( k \in \mathbb{N} \) such that \( \overline{J}_m^k \subset J \). Pick \( \overline{J}_m^{k+1} \subset J \) such that the image of \( \overline{J}_m^{k+1} \) in \( A/I_m \) agrees with \( \overline{J}_m^k \), and let \( f_{m+1} \in A \) be any lifting of \( \overline{J}_m^{k+1} \); with this choice, one verifies easily that \((15.1.20)\) holds for \( p := m + 1 \). Finally, the subset:
\[
U' := \bigcup_{m \geq n} \mathcal{O}(f_m) \cap X_m
\]
is an admissible affine open neighborhood of \( x \) contained in \( U \).

(ii.a): For every \( n, m \in \mathbb{N} \) with \( n \geq m \), we have a closed immersion of affine schemes:
\[
U \cap X_m \subset U \cap X_n \quad \text{whence induced surjections :}
\]
\[
A_{U,n} := \mathcal{O}_n(U \cap X_n) \to A_{U,m} := \mathcal{O}_m(U \cap X_m)
\]
By [44], Ch.0, §3.8.1, \( A_{U,n} \) is a discrete topological ring, for every \( n \in \mathbb{N} \), hence \( A_U \cong \lim_{n \in \mathbb{N}} A_{U,n} \) carries the linear topology that admits the fundamental system of open ideals \((\ker(A_U \to A_{U,n}) \mid n \in \mathbb{N})\), especially \( A_U \) is \( \omega \)-admissible. It follows that the topological space underlying \( \text{Spf } A_U \) is \( \text{colim}_{n \in \mathbb{N}}(U \cap X_n) \), which is naturally identified with \( U \), under \( \text{Spf } \rho_U \). Likewise, let \( i : U \to X \) be the open immersion; one verifies easily (e.g. using \((15.1.9)\)) that the natural map:
\[
i^* \lim_{n \in \mathbb{N}} j_{ns*} \mathcal{O}_{X_n} \to \lim_{n \in \mathbb{N}} i^* j_{ns*} \mathcal{O}_{X_n}
\]
is an isomorphism of topological sheaves, which implies the assertion.

(ii.b): We may assume that \( I_0 = I \). Since \( U \cap X_n \) is affine for every \( n \in \mathbb{N} \), we deduce short exact sequences:
\[
\mathcal{E}_n := (0 \to I \cdot \mathcal{O}_n(U \cap X_n) \to \mathcal{O}_n(U \cap X_n) \to \mathcal{O}_{X_0}(U \cap X_0) \to 0)
\]
and \( \lim_{n \in \mathbb{N}} \mathcal{E}_n \) is the exact sequence:
\[
0 \to I_U \to A_U \to \mathcal{O}_{X_0}(U \cap X_0) \to 0.
\]
Since \( U \cap X_0 \) is an open subset of \( X_0 \), both assertions follow easily.

(ii.c): It has already been remarked that \( A_U \) is \( \omega \)-admissible. More precisely, for every \( n \in \mathbb{N} \) let \((I_nA_U)\) be the topological closure of \( I_nA_U \) in \( A_U \); then the proof of (ii.b) shows that the family of ideals \((I_nA_U) \mid n \in \mathbb{N})\) is a fundamental system of open neighborhoods of \( 0 \in A_U \). Hence the assertion follows from (ii.a).

(ii.d): By definition, \( U \) is a countable union of quasi-compact subsets, so the assertion is immediate. \( \square \)
Corollary 15.1.21. Let \( X \) be an \( \omega \)-formal scheme, \( U \subset X \) any open subset. Then \((U, \mathcal{O}_X|_U)\) is an \( \omega \)-formal scheme.

Proposition 15.1.22. Let \( X \) be an \( \omega \)-formal scheme, \( A \) an \( \omega \)-admissible topological ring. Then the rule:

\[
(f : X \to \text{Spf} \ A) \mapsto (f^\#: A \to \Gamma(X, \mathcal{O}_X))
\]

establishes a natural bijection between the set of morphisms of \( \omega \)-formal schemes \( X \to \text{Spf} \ A \) and the set of continuous ring homomorphisms \( A \to \Gamma(X, \mathcal{O}_X) \).

Proof. We reduce easily to the case where \( X = \text{Spf} \ B \) for some \( \omega \)-admissible topological ring \( B \). Let \( f : X \to Y := \text{Spf} \ A \) be a morphism of \( \omega \)-formal schemes; we have to show that \( f = \text{Spf} \ f^\#: A \to B \) is the map on global sections induced by the morphism of sheaves \( \mathcal{O}_Y \to f^* \mathcal{O}_X \) that defines \( f \). Let \( U \subset X \) and \( V \subset Y \) be two truly affine open subsets, such that \( f(U) \subset V \), and let likewise:

\[
f^\#: A_V := \mathcal{O}_Y(V) \to B_U := \mathcal{O}_X(U)
\]

be the map induced by \( f|_U \). Using the universal property of \([43, \text{Ch.I, Prop.1.6.3}]\), we obtain a commutative diagram of morphisms of locally ringed spaces:

\[
\begin{array}{ccc}
\text{Spec } B_U & \xrightarrow{\text{Spec } f^\#: U} & \text{Spec } A_V \\
\downarrow {i_U} & & \downarrow {i_V} \\
\text{Spec } B & \xrightarrow{\text{Spec } f} & \text{Spec } A \\
\downarrow {i_X} & & \downarrow {i_Y} \\
\end{array}
\]

where \( i_X, i_Y, i_U \) and \( i_V \) are the morphisms of \((15.1.10)\). Since \( i_X \) and \( i_Y \) are injective on the underlying sets, it follows already that \( f \) and \( \text{Spf} \ f^\# \) induce the same continuous map of topological spaces. Let now \( J \subset B \) be any open ideal, \( I \subset f^\#(J) \) an open ideal of \( A \), and let \( J_U \) (resp. \( I_V \)) be the topological closure of \( J B_U \) in \( B_U \) (resp. of \( I A_V \) in \( A_V \)). Since the map \( f^\#: B_U \to A_V \) is continuous, we derive a commutative diagram of schemes:

\[
\begin{array}{ccc}
\text{Spec } B_U/J_U & \xrightarrow{\varphi} & \text{Spec } A_V/I_V \\
\downarrow {\alpha} & & \downarrow {\beta} \\
\text{Spec } B/J & \xrightarrow{\psi} & \text{Spec } A/I
\end{array}
\]

where \( \alpha \) and \( \beta \) are open immersions, by proposition \([15.1.19]\) (ii.b), and \( \varphi \) (resp. \( \psi \)) is induced by \( f^\#: B_U \to A_V \) (resp. by \( f^\# \)). Let \( \mathcal{S} \) be a fundamental system of open neighborhoods of \( 0 \in A \) consisting of ideals, and for every \( I \in \mathcal{S} \) denote by \( (I A_V)^c \) the topological closure of \( I A_V \) in \( A_V \); from proposition \([15.1.19]\) (ii.b) (and its proof) it follows as well that \( A_V \cong \lim_{I \in \mathcal{S}} A_V/(I A_V)^c \). Summing up, this shows that \( f^\#: B_U \to A_V \) is determined by \( f^\# \), whence the contention. \( \square \)

Corollary 15.1.25. Let \( A \) be an \( \omega \)-admissible topological ring, \( U \subset \text{Spf} \ A \) an affine open subset, \( \overset{\wedge}{V} \subset U \) a truly affine open subset of \( U \). Then \( \overset{\wedge}{V} \) is a truly affine open subset of \( U \).

Proof. Say that \( U = \text{Spf} \ B \), for some \( \omega \)-admissible topological ring \( B \); by proposition \([15.1.22]\) the immersion \( j : U \to X \) is of the form \( j = \text{Spf} \ \varphi \) for a unique map \( \varphi : A \to B \). Let now
$J \subset B$ be any open ideal, and set $I := \varphi^{-1}J$; there follows a commutative diagram of locally ringed spaces:

$$
\begin{array}{ccc}
U_0 := \text{Spec} \, B/J & \longrightarrow & X_0 := \text{Spec} \, A/I \\
\downarrow & & \downarrow \\
U & \longrightarrow & X.
\end{array}
$$

By assumption, $V \cap X_0 = \text{Spec} \, C$ for some $A/I$-algebra $C$; it follows that:

$$
V \cap U_0 = \text{Spec} \, B/J \otimes_{A/I} C
$$

and since $J$ is arbitrary, the claim follows. \qed

**Remark 15.1.26.** (i) Let $A$ be an $\omega$-admissible topological ring, and $B$, $C$ two topological $A$-algebras whose topologies are linear (and the structure maps $A \rightarrow B$, $A \rightarrow C$ are continuous). Recall that $B \hat{\otimes}_A C$ represents the product of $B$ and $C$ in the category of $\omega$-admissible $A$-algebras (see (8.3.7)). By standard arguments, we deduce from proposition 15.1.22 that Spf $B \hat{\otimes}_A C$ represents the product of Spf $B$ and Spf $C$ in the category of $\omega$-formal Spf $A$-schemes; especially, the category of $\omega$-formal schemes admits arbitrary fibre products.

(ii) We shall say that a topological $A$-module $M$ is $\omega$-admissible if $M$ is complete and separated, and admits a countable fundamental system of open neighborhoods of $0 \in M$. Notice that the completion functor $N \rightarrow N^\wedge$ on topological $A$-modules is not always “right exact”, in the following sense. Suppose $N \rightarrow N'$ is a quotient map; then the induced map $N^\wedge \rightarrow N'^\wedge$ is not necessarily onto. However, this is the case if $N^\wedge$ is $\omega$-admissible (see proposition 8.2.13(v)). For such $A$-modules, we have moreover the following:

**Lemma 15.1.27.** Let $A$ be a topological ring, $M$, $M'$, $N$ three $\omega$-admissible topological $A$-modules, and $f : M \rightarrow M'$ a quotient map. Then:

(i) The homomorphism $f \hat{\otimes}_A 1_N : M \hat{\otimes}_A N \rightarrow M' \hat{\otimes}_A N$ is a quotient map.

(ii) Let us endow $\text{Ker} \, f$ with the subspace topology induced from $M$, and suppose additionally that, for every open ideal $I \subset A$:

(a) The topological closure $(I N)^c$ of $IN$ in $N$ is an open submodule of $N$.

(b) $N/(IN)^c$ is a flat $A/I$-module.

Then the complex:

$$
0 \rightarrow (\text{Ker} \, f) \hat{\otimes}_A N \rightarrow M \hat{\otimes}_A N \rightarrow M' \hat{\otimes}_A N \rightarrow 0
$$

is an admissible short exact sequence of topological $A^\wedge$-modules.

**Proof.** By assumption, we may find an inverse system of discrete $A$-modules, with surjective transition maps $(M_n \mid n \in \mathbb{N})$ (resp. $(N_n \mid n \in \mathbb{N})$), and an isomorphism of topological $A$-modules: $M \simeq \lim_{n \in \mathbb{N}} M_n$ (resp. $N \simeq \lim_{n \in \mathbb{N}} N_n$); let us define $M'_{n} := M' \amalg_{M} M_n$ for every $n \in \mathbb{N}$ (the cofibred sum of $M'$ and $M_n$ over $M$). Since $f$ is a quotient map, $M'_{n}$ is a discrete $A$-module for every $n \in \mathbb{N}$, and the natural map: $M' \rightarrow \lim_{n \in \mathbb{N}} M'_{n}$ is a topological isomorphism. We deduce an inverse system of short exact sequences of discrete $A$-modules:

$$
0 \rightarrow K_n \rightarrow M_n \otimes_A N_n \rightarrow M'_{n} \otimes_A N_n \rightarrow 0
$$

where $K_n$ is naturally a quotient of $\text{Ker} \, (M_n \rightarrow M'_{n}) \otimes_A N_n$, for every $n \in \mathbb{N}$; especially, the transition maps $K_{j} \rightarrow K_{i}$ are surjective whenever $j \geq i$. Then assertion (i) follows from lemma 8.6.2.

(ii) We may find open ideals $I_n \subset A$ such that $I_n N_n = I_n M_n = 0$ for every $n \in \mathbb{N}$, hence $(I_n N)^c \subset \text{Ker} \, (N \rightarrow N_n)$, and from (a) we deduce that $((I_n N)^c \mid n \in \mathbb{N})$ is a fundamental system of open neighborhoods of $0 \in N$. Due to (b), we obtain short exact sequences:

$$
0 \rightarrow \text{Ker} \, (M_n \rightarrow M'_{n}) \otimes_A N/(I_n N)^c \rightarrow M_n \otimes_A N/(I_n N)^c \rightarrow M'_{n} \otimes_A N/(I_n N)^c \rightarrow 0
$$
for every \( n \in \mathbb{N} \). Then it suffices to invoke again lemma 8.6.2. \( \square \)

**Lemma 15.1.28.** Let \( A \) be an \( \omega \)-admissible topological ring, \( M \) a topological \( A \)-module, and \( U \subset X := \text{Spf} A \) any affine open subset. Then the following holds:

(i) There is a natural isomorphism of topological \( \mathcal{O}_X(U) \)-modules:

\[
M^\sim(U) \cong M \hat{\otimes}_A \mathcal{O}_X(U).
\]

(ii) If \( L \) is any other topological \( A \)-module, the natural map:

\[
\text{top.Hom}_A(L, M^\sim) \to \text{top.Hom}_{\mathcal{O}_X}(L^\sim, M^\sim) \quad \varphi \mapsto \varphi^\sim
\]

is an isomorphism.

(iii) The functor \( M \mapsto M^\sim \) on topological \( A \)-modules, is left adjoint to the global sections functor \( \mathcal{F} \mapsto \mathcal{F}(X) \), defined on the category of complete and separated topological \( \mathcal{O}_X \)-modules and continuous maps.

**Proof.** (i): First we remark that the assertion holds whenever \( U \) is a truly affine open subset of \( X \); the easy verification shall be left to the reader. For a general \( U \), set \( M_U := M \hat{\otimes}_A \mathcal{O}_X(U) \), and denote by \( M^\sim_U \) the associated \( \mathcal{O}_U \)-module. Let \( V \subset U \) be any open subset which is truly affine in \( X \); by corollary 15.1.25 \( V \) is truly affine in \( U \) as well. We deduce natural isomorphisms:

\[
M^\sim(V) \cong M_U \hat{\otimes}_{\mathcal{O}_X(U)} \mathcal{O}_X(V) \cong M^\sim_U(V)
\]

which – in view of proposition [15.1.19](i) – amount to a natural isomorphism of topological \( \mathcal{O}_U \)-modules : \( (M^\sim)_U \to M^\sim_U \). Assertion (i) follows easily.

(iii): Given a continuous map \( M^\sim \to \mathcal{F} \), we get a map of global sections \( M = M^\sim(X) \to \mathcal{F}(X) \). Conversely, suppose \( f : M \to \mathcal{F}(X) \) is a given continuous map; let \( U \subset X \) be any affine open subset, and \( f_U : M \to \mathcal{F}(U) \) the composition of \( f \) and the restriction map \( \mathcal{F}(X) \to \mathcal{F}(U) \). Then \( f_U \) extends first – by linearity – to a map \( M \otimes_A \mathcal{O}_X(U) \to \mathcal{F}(U) \), and second – by continuity – to a map \( M \hat{\otimes}_A \mathcal{O}_X(U) \to \mathcal{F}(U) \); the latter, in view of (i), is the same as a map \( f^\sim_U : M^\sim(U) \to \mathcal{F}(U) \). Clearly the rule \( U \mapsto f^\sim_U \) thus defined is functorial for inclusion of open subsets \( U \subset U' \), whence (iii).

(ii) is a straightforward consequence of (iii). \( \square \)

**Proposition 15.1.29.** Let \( A \) be an \( \omega \)-admissible topological ring, \( M \) an \( \omega \)-admissible topological \( A \)-module, \( N \subset M \) a submodule, and \( U \subset X := \text{Spf} A \) an affine open subset. Then:

(i) If we endow \( M/N \) with the quotient topology, the sequence of \( \mathcal{O}_X \)-modules:

\[
0 \to N^\sim \to M^\sim \to (M/N)^\sim \to 0
\]

is short exact.

(ii) The induced sequence

\[
0 \to N^\sim(U) \to M^\sim(U) \to (M/N)^\sim(U) \to 0
\]

is short exact and admissible in the sense of 8.6.

**Proof.** (i): We recall the following:

**Claim 15.1.30.** Let \( j : Z' := \text{Spec} R' \to Z := \text{Spec} R \) be an open immersion of affine schemes. Then \( R' \) is a flat \( R \)-algebra.

**Proof of the claim.** The assertion can be checked on the localizations at the prime ideals of \( R' \); however, the induced maps \( \mathcal{O}_{Z,j(z)} \to \mathcal{O}_{Z',z} \) are isomorphisms for every \( z \in Z' \), so the claim is clear. \( \diamond \)
Let \( V \subset X \) be any truly affine open subset. It follows easily from proposition 15.1.19(ii,b) and claim 15.1.30 that \( \mathcal{O}_X(V) \) fulfills conditions (a) and (b) of lemma 15.1.27(ii). In light of lemma 15.1.28(i), we deduce that the sequence:

\[
0 \to N^\sim(V) \to M^\sim(V) \to (M/N)^\sim(V) \to 0
\]

is admissible short exact, whence the contention.

(ii): Clearly the sequence is left exact; using lemmata 15.1.27(i) and 15.1.28(i), we see that it is also right exact, and moreover \( M^\sim(U) \to (M/N)^\sim(U) \) is a quotient map. It remains only to show that the topology on \( N^\sim(U) \) is induced from \( M^\sim(U) \), and to this aim we may assume – thanks to the condition of definition 5.5.1(ii) – that \( U \) is a truly affine open subset of \( X \), in which case the assertion has already been observed in the proof of (i).

\[\square\]

**Definition 15.1.31.** Let \( X \) be an \( \omega \)-formal scheme, and \( \mathcal{F} \) a topological \( \mathcal{O}_X \)-module \( \mathcal{F} \).

(i) We say that \( \mathcal{F} \) is *quasi-coherent* if there exist a covering \( \mathcal{U} := (U_i \mid i \in I) \) of \( X \) consisting of affine open subsets, and for every \( i \in I \), an \( \omega \)-admissible topological \( \mathcal{O}_X(U_i) \)-module \( M_i \) with an isomorphism \( \mathcal{F}|_{U_i} \simrightarrow M_i^\sim \) of topological \( \mathcal{O}_U \)-modules (in the sense of definition 15.1.4(ii,iii)).

(ii) We denote by \( \mathcal{O}_X-\text{Mod}_{\text{qcoh}} \) the category of quasi-coherent \( \mathcal{O}_X \)-modules and continuous \( \mathcal{O}_X \)-linear morphisms.

(iii) We say that a continuous morphism \( f : \mathcal{F} \to \mathcal{G} \) of quasi-coherent \( \mathcal{O}_X \)-modules is a *quotient map* if the induced map \( f(U) : \mathcal{F}(U) \to \mathcal{G}(U) \) is a quotient map of topological \( \mathcal{O}_X(U) \)-modules, for every affine open subset \( U \subset X \).

**Remark 15.1.32.**

(i) The category \( \mathcal{O}_X-\text{Mod}_{\text{qcoh}} \) is usually not abelian (see (8.6)); more than that, the kernel (in the category of abelian sheaves) of a continuous map \( f : \mathcal{F} \to \mathcal{G} \) of quasi-coherent \( \mathcal{O}_X \)-modules may fail to be quasi-coherent. However, using proposition 15.1.29 one may show that \( \ker f \) is quasi-coherent whenever \( f \) is a quotient map, and in this case \( \ker f \) is also the kernel of \( f \) in the category \( \mathcal{O}_X-\text{Mod}_{\text{qcoh}} \).

(ii) Furthermore, any (continuous) morphism \( f \) in \( \mathcal{O}_X-\text{Mod}_{\text{qcoh}} \) admits a cokernel. This can be exhibited as follows. To start out, let us define presheaves \( \mathcal{I} \) and \( \mathcal{L} \) by declaring that \( \mathcal{I}(U) \subset \mathcal{G}(U) \) is the topological closure of the \( \mathcal{O}_X(U) \)-submodule \( \text{Im}(f(U)) : \mathcal{F}(U) \to \mathcal{G}(U) \), and \( \mathcal{L}(U) := \mathcal{G}(U)/\mathcal{I}(U) \), which we endow with its natural quotient topology, for every open subset \( U \subset X \). Now, suppose that \( V \subset U \) is an inclusion of sufficiently small affine open subsets of \( X \) (so that \( \mathcal{F}|_U \) and \( \mathcal{G}|_U \) are of the form \( M^\sim \) for some topological \( \mathcal{O}_X(U) \)-module \( M \)); since \( \mathcal{F}(U) \otimes_{\mathcal{O}_X(U)} \mathcal{O}_X(V) = \mathcal{F}(V) \), we see that the image of \( \mathcal{I}(U) \) in \( \mathcal{I}(V) \) generates a dense \( \mathcal{O}_X(V) \)-submodule. On the other hand, by construction the exact sequence \( \mathcal{E} := (0 \to \mathcal{I}(U) \to \mathcal{G}(U) \to \mathcal{L}(U) \to 0) \) is admissible, hence the same holds for the sequence \( \mathcal{E} \otimes_{\mathcal{O}_X(U)} \mathcal{O}_X(V) \) (lemma 15.1.28(i) and proposition 15.1.29(ii)). It follows that \( \mathcal{I}(V) = \mathcal{I}(U) \otimes_{\mathcal{O}_X(U)} \mathcal{O}_X(V) \) and \( \mathcal{L}(V) = \mathcal{L}(U) \otimes_{\mathcal{O}_X(U)} \mathcal{O}_X(V) \). Thus \( \mathcal{I} \) and \( \mathcal{L} \) are sheaves of topological \( \mathcal{O}_X \)-modules on the site \( C \) of all sufficiently small affine open subsets of \( X \), and their sheafifications \( \mathcal{I}' \) and \( \mathcal{L}' \) are the topological \( \mathcal{O}_X \)-modules obtained as in [44, Ch.0, §3.2.1], by extension of \( \mathcal{I} \) and \( \mathcal{L} \) from the site \( C \) to the whole topology of \( X \). It follow that \( \mathcal{I}' \) and \( \mathcal{L}' \) are quasi-coherent \( \mathcal{O}_X \)-modules; then it is easy to check that \( \mathcal{L}' \) is the cokernel of \( f \) in the category \( \mathcal{O}_X-\text{Mod}_{\text{qcoh}} \) (briefly : the *topological cokernel of \( f \)*), and shall be denoted \( \text{top.Coker } f \).

The sheaf \( \mathcal{I}' \) shall be called the *topological closure of the image of \( f \)*, and denoted \( \text{Im}(f) \).

A morphism \( f \) with \( \text{top.Coker } f = 0 \) shall be called a *topological epimorphism.*
(iii) Notice also that the natural map $\text{Coker } f \to \text{top. Coker } f$ is an epimorphism of abelian sheaves, hence a continuous morphism of quasi-coherent $\mathcal{O}_X$-modules which is an epimorphism of $\mathcal{O}_X$-modules, is also a topological epimorphism.

**Proposition 15.1.33.** Let $X$ be an affine $\omega$-formal scheme, $\mathcal{F}$ a quasi-coherent $\mathcal{O}_X$-module. Then $\mathcal{F}(X)$ is an $\omega$-admissible $\mathcal{O}_X(X)$-module, and the natural map

$$\mathcal{F}(X) \rightarrow \mathcal{F}$$

is an isomorphism of topological $\mathcal{O}_X$-modules.

**Proof.** By assumption we may find an affine open covering $\mathcal{V} := (U_i \mid i \in I)$ of $X$ such that, for every $i \in I$, $\mathcal{F}|_{U_i} \simeq M_i$ for some $\mathcal{O}_X(U_i)$-module $M_i$. In view of lemma 15.1.28(i) we may assume – up to replacing $\mathcal{V}$ by a refinement – that $U_i$ is a truly affine subset of $X$ for every $i \in I$. Furthermore, we may write $X = \bigcup_{n \in \mathbb{N}} X_n$ for an increasing countable family of quasi-compact subsets; for each $n \in \mathbb{N}$ we may then find a finite subset $I(n) \subset I$ such that $X_n \subset \bigcup_{i \in I(n)} U_i$, and therefore we may replace $I$ by $\bigcup_{n \in \mathbb{N}} I(n)$, which allows to assume that $I$ is countable.

Next, for every $i \in I$ we may find a countable fundamental system of open submodules $(M_{i,n} \mid n \in \mathbb{N})$ of $M_i$, and for every $n \in \mathbb{N}$ an open ideal $J_{i,n} \subset A_i := \mathcal{O}_X(U_i)$ such that $N_{i,n} := M_i/J_{i,n}$ is an $A_i/J_{i,n}$-module. Let $j_{i,n} : U_{i,n} := \text{Spec } A_i/J_{i,n} \to U_i$ be the natural closed immersion; we may write:

$$\mathcal{F}|_{U_i} \simeq \varprojlim_{n \in \mathbb{N}} j_{i,n*}N_{i,n}.$$  \text{(15.1.34)}

Let also $\iota_{i,n} : U_{i,n} \to X$ be the locally closed immersion obtained as the composition of $j_{i,n}$ and the open immersion $j_i : U_i \to X$; we deduce natural maps of $\mathcal{O}_X$-modules:

$$\varphi_{i,n} : \mathcal{F} \to j_{i*}\mathcal{F}|_{U_i} \rightarrow \mathcal{G}_{i,n} := \iota_{i,n*}N_{i,n}.$$  \text{Claim 15.1.35. (i) There exists $m \in \mathbb{N}$ such that $\mathcal{G}_{i,n}$ is the extension by zero of a quasi-coherent $\mathcal{O}_{X_m}$-module.}

(ii) $\varphi_{i,n}$ is continuous for the pseudo-discrete topology on $\mathcal{G}_{i,n}$.

**Proof of the claim.** (i): It is easy to see that $U_{i,n} \subset X_m$ for $m \in \mathbb{N}$ large enough; then the assertion follows from ([44 Ch.I, Cor.9.2.2]).

(ii): We need to check that the map $\varphi_{i,n,V} : \mathcal{F}(V) \to \mathcal{G}_{i,n}(V)$ is continuous for every open subset $V \subset X$. However, the condition of definition 5.5.1(ii) implies that the assertion is local on $X$, hence we may assume that $V$ is a truly affine open subset of $X$, in which case $\mathcal{G}_{i,n}(V)$ is a discrete space. We may factor $\varphi_{i,n,V}$ as a composition:

$$\mathcal{F}(V) \xrightarrow{\alpha} \mathcal{F}(V \cap U_i) \xrightarrow{\beta} N_{i,n}(U_i \cap V)$$

where the restriction map $\alpha$ is continuous, and $\beta$ is continuous for the pseudo-discrete topology on $N_{i,n}(U_i \cap V)$. However, $U_i \cap V$ is a truly affine open subset of $U_i$; therefore $U_i \cap V$ is quasi-compact, and the pseudo-discrete topology on $N_{i,n}$ induces the discrete topology on $N_{i,n}(U_i \cap V)$.

The claim follows.

For every finite subset $S \subset I \times \mathbb{N}$, let $\varphi_S : \mathcal{F} \to \mathcal{G}_S := \prod_{(i,n) \in S} \mathcal{G}_{i,n}$ be the product of the maps $\varphi_{i,n}$; according to claim 15.1.35(ii), $\varphi_S$ is continuous for the pseudo-discrete topology on $\mathcal{G}_S$. Hence, for every $i \in I$, the restriction $\varphi_{S,U_i} : \mathcal{F}|_{U_i} \to \mathcal{G}_S|_{U_i}$ is of the form $f^*_{S|i}$, for some continuous map $f_{S|i} : M_i \rightarrow \mathcal{G}_S(U_i)$ (lemma 15.1.28(ii)). It follows easily that $(\text{Im } \varphi_{S})|_{U_i}$ is the quasi-coherent $\mathcal{O}_{U_i}$-module $(\text{Im } f_{S|i})^\sim$, especially $\text{Im } \varphi_S$ is quasi-coherent. Notice that $\mathcal{G}_S$ is already a quasi-coherent $\mathcal{O}_{X_m}$-module for $m \in \mathbb{N}$ large enough, hence the same holds for $\text{Im } \varphi_S$; we may therefore find an $\mathcal{O}_{X_m}(X_m)$-module $G_S$ such that $G_S \simeq \text{Im } \varphi_S$. Furthermore, for every other finite subset $S' \subset I \times \mathbb{N}$ containing $S$, we deduce a natural $\mathcal{O}_X(X)$-linear surjection $G_{S'} \to G_S$, compatible with compositions of inclusions $S \subset S' \subset S''$. Let $(S_n \mid n \in \mathbb{N})$ be a
countable increasing family of finite subsets, whose union is \( I \times \mathbb{N} \); we endow \( G := \lim_{n \in \mathbb{N}} G_{S_n} \) with the pro-discrete topology. It is then easy to check that \( G \) is an \( \omega \)-admissible \( \mathcal{O}_X(X) \)-module; furthermore, by construction we get a unique continuous map \( \varphi : \mathcal{F} \to G ^{\sim} \) whose composition with the projection onto \( G_{S_n} \) agrees with \( \varphi_{S_n} \) for every \( n \in \mathbb{N} \). In light of \((15.1.34)\) we see easily that \( \varphi_{|U_i} \) is an isomorphism of topological \( \mathcal{O}_{U_i} \)-modules for every \( i \in I \), hence the same holds for \( \varphi \). Then \( \varphi \) necessarily induces an isomorphism \( \mathcal{F}(X) \to G ^{\sim} \).

**Corollary 15.1.36.** Let \( X \) be an \( \omega \)-formal scheme, \((\mathcal{F}_n \mid n \in \mathbb{N})\) an inverse system of quasi-coherent \( \mathcal{O}_X \)-modules, whose transition maps are topological epimorphisms. Then \( \lim_{n \in \mathbb{N}} \mathcal{F}_n \) (with its inverse limit topology) is a quasi-coherent \( \mathcal{O}_X \)-module.

**Proof.** We may assume that \( X \) is affine; then, for every \( n \in \mathbb{N} \) we have \( \mathcal{F}_n = M_n ^{\sim} \) for some complete and separated \( \mathcal{O}_X(X) \)-module \( M_n \) (by proposition [15.1.33]), and the transition maps \( \mathcal{F}_{n+1} \to \mathcal{F}_n \) come from corresponding continuous linear maps \( f_n : M_{n+1} \to M_n \). We choose inductively, for every \( n \in \mathbb{N} \), a descending fundamental system of open submodules \( (N_{n,k} \mid k \in \mathbb{N}) \) of \( M_n \), such that \( f_n(N_{n+1,k}) \subseteq N_{n,k} \) for every \( n,k \in \mathbb{N} \). Set \( M_{n,k} := M_n/N_{n,k} \) for every \( n,k \in \mathbb{N} \). By assumption, \text{top.Coker} \( f_n ^{\sim} = 0 \); hence the induced maps \( M_{n+1,k} \to M_{n,k} ^{\sim} \) are topological epimorphisms; since \( M_{n,k} ^{\sim} \) is pseudo-discrete (on the closure of its support), it follows that the latter maps are even epimorphisms (of abelian sheaves) so the corresponding maps \( M_{n+1,k} \to M_{n,k} \) are onto for every \( n,k \in \mathbb{N} \). Thus:

\[
\lim_{n \in \mathbb{N}} \mathcal{F}_n \cong \lim_{n \in \mathbb{N}} \lim_{k \in \mathbb{N}} M_{n,k} ^{\sim} \cong \lim_{n \in \mathbb{N}} M_{n,n} ^{\sim} \cong (\lim_{n \in \mathbb{N}} M_{n,n}) ^{\sim}
\]

and it is clear that the \( \mathcal{O}_X(X) \)-module \( \lim_{n \in \mathbb{N}} M_{n,n} \) is \( \omega \)-admissible. \( \square \)

**Theorem 15.1.37.** Let \( X \) be an \( \omega \)-formal scheme, \( \mathcal{F} \) a quasi-coherent \( \mathcal{O}_X \)-module, \( \underline{\Lambda} := (U_i \mid i \in I) \) an open covering of \( X \), such that the intersection \( U_{t_0} \cap \cdots \cap U_{t_n} \) is affine for every \( n \in \mathbb{N} \) and every \((t_0, \ldots, t_n) \in I ^{n+1} \). Then :

(i) There is a natural isomorphism (notation of \((10.2.18)\))

\[
H^*_\text{alt}(\underline{\Lambda}, \mathcal{F}) \cong H^*(X, \mathcal{F}).
\]

(ii) If moreover \( X \) is affine, we have \( H^i(X, \mathcal{F}) = 0 \) for every \( i > 0 \).

**Proof.** (The statements refer to the cohomology of the abelian sheaf underlying \( \mathcal{F} \), in other words, we forget the topology of the modules \( \mathcal{F}(U) \).)

(iii): Say that \( X = \text{Spf} \ A \) for an \( \omega \)-admissible topological ring \( A \). Let \( U \subset X \) be any truly affine open subset, and \( \underline{\Lambda} := (U_i \mid i \in I) \) a covering of \( U \) consisting of truly affine open subsets. By proposition \([15.1.33]\) we have \( \mathcal{F}_{U} \cong M ^{\sim} \), where \( M := \mathcal{F}(U) \).

**Claim 15.1.38.** The augmented alternating Čech complex \( C^*_\text{alt}(\underline{\Lambda}, M ^{\sim}) \) is acyclic.

**Proof of the claim.** Let \((M_n \mid n \in \mathbb{N})\) be a fundamental system of neighborhoods of \( 0 \in M \), consisting of open submodules, and for every \( n \in \mathbb{N} \), choose an open ideal \( I_n \subset A \) such that \( I_n M \subset M_n \). Set \( X_n := \text{Spec} \ A/I_n \) and \( \underline{\Lambda}_n := (U_i \cap X_n \mid i \in I) \) for every \( n \in \mathbb{N} \). For every \( n \in \mathbb{N} \) we may consider the augmented alternating Čech complex \( C^*_\text{alt}(\underline{\Lambda}_n, (M/M_n) ^{\sim}) \), and in view of \((15.1.16)\) we obtain a natural isomorphism of complexes :

\[
C^*_\text{alt}(\underline{\Lambda}, M ^{\sim}) \cong \lim_{n \in \mathbb{N}} C^*_\text{alt}(\underline{\Lambda}_n, (M/M_n) ^{\sim}).
\]

We may view the double complex \( C^*_\text{alt}(\underline{\Lambda}_n, (M/M_n) ^{\sim}) \) also as a complex of inverse systems of modules, whose term in degree \( i \in \mathbb{N} \) is \( C^*_\text{alt}(\underline{\Lambda}_n, (M/M_n) ^{\sim}) \). Notice that, for every \( i \in \mathbb{N} \), all the transition maps of this latter inverse system are surjective. Hence ([125, Lemma 3.5.3]) :

\[
\lim_{n \in \mathbb{N}} q C^i_\text{alt}(\underline{\Lambda}_n, (M/M_n) ^{\sim}) = 0 \quad \text{for every } q > 0.
\]
In other words, these inverse systems are acyclic for the inverse limit functor. It follows (e.g. by means of [125 Th.10.5.9]) that:

\[ R\lim_{n \in \mathbb{N}} C^\bullet_{\text{alt}}(\mathcal{U}_n, (M/M_n)^\sim) \simeq C^\bullet_{\text{alt}}(\mathcal{U}, M^\sim). \]

On the other hand, the complexes \( C^\bullet_{\text{alt}}(\mathcal{U}_n, (M/M_n)^\sim) \) are acyclic for every \( n \in \mathbb{N} \) ([46 Ch.III, Th.1.3.1 and Prop.1.4.1]), hence \( C^\bullet_{\text{alt}}(\mathcal{U}_n, (M/M_n)^\sim) \) is acyclic, when viewed as a cochain complex of inverse systems of modules. The claim follows.

Assertion (ii) follows from claim [15.1.38] proposition [15.1.19] (i) and theorem [10.2.24] (i).

Assertion (i) follows from (ii) and corollary [10.2.21] (ii).

**Corollary 15.1.39.** In the situation of (15.1.15), suppose that \( A \) and \( M \) are \( \omega \)-admissible. Then:

\[ \lim_{\lambda \in \Lambda}^q j_{\lambda*}(M/M_\lambda)^\sim = 0 \quad \text{for every } q > 0. \]

**Proof.** For every truly affine open subset \( U \subset X \), we have a topos \( U^\Lambda \) defined as in [59 §7.3.4], and the cofiltered system \( \mathcal{M} := (j_{\lambda*}(M/M_\lambda)^\sim : \lambda \in \Lambda) \) defines an abelian sheaf on \( U^\Lambda \).

According to loc.cit. there are two spectral sequences:

\[
E_2^{pq} := R^p\Gamma(U, \lim_{\lambda \in \Lambda}^q j_{\lambda*}(M/M_\lambda)^\sim) \Rightarrow H^{p+q}(U^\Lambda, \mathcal{M})
\]

\[
F_2^{pq} := \lim_{\lambda \in \Lambda}^q R^p\Gamma(U, j_{\lambda*}(M/M_\lambda)^\sim) \Rightarrow H^{p+q}(U^\Lambda, \mathcal{M})
\]

and we notice that \( F_2^{pq} = 0 \) whenever \( p > 0 \) (since \( U \cap X_\lambda \) is affine for every \( \lambda \in \Lambda \)) and whenever \( q > 0 \), since the cofiltered system \( (\Gamma(U, j_{\lambda*}(M/M_\lambda)^\sim) : \lambda \in \Lambda) \) has surjective transition maps. One can then argue as in the proof of [59 Lemma 7.3.5]: the sheaf \( L^q := \lim_{\lambda \in \Lambda}^q j_{\lambda*}(M/M_\lambda)^\sim \) is the sheafification of the presheaf : \( U \mapsto H^q(U^\Lambda, \mathcal{M}) \) and the latter vanishes by the foregoing. We supply an alternative argument. Since the truly affine open subsets form a basis of \( X \), it suffices to show that \( E_2^{0q} = 0 \) whenever \( q > 0 \). We proceed by induction on \( q \). For \( q = 1 \), we look at the differential \( d_2^{01} : E_2^{01} \to E_2^{20} \); by theorem [15.1.37] we have \( E_2^{20} = 0 \), hence \( E_2^{01} = E_2^{01} \), and the latter vanishes by the foregoing. Next, suppose that \( q > 1 \), and that we have shown the vanishing of \( L^1 \) for \( 1 \leq j < q \). It follows that \( E_2^{pq} = 0 \) whenever \( 1 \leq j < q \), hence \( E_2^{pq} = 0 \) for every \( r \geq 2 \) and the same values of \( j \). Consequently:

\[ 0 = E_\infty^{0q} \simeq \ker(d_2^{0q} : E_2^{0q} = E_{q+1}^{0q} \to E_{q+1}^{q+1,0}). \]

However, theorem [15.1.37] implies that \( E_2^{0q} = 0 \) whenever \( p > 0 \) and \( r \geq 2 \), therefore \( E_2^{pq} = E_\infty^{pq} \), i.e. \( E_2^{pq} = 0 \), which completes the inductive step.

15.1.40. Let \( X \) be an \( \omega \)-formal scheme, \( \mathcal{F} \) a quasi-coherent \( \mathcal{O}_X \)-module. For every affine open subset \( U \subset X \), we let \( \text{Cl}_{\mathcal{F}}(U) \) be the set consisting of all closed \( \mathcal{O}_X(U) \)-submodules of \( \mathcal{F}(U) \). It follows from proposition [15.1.29] (ii) that the rule

\[ U \mapsto \text{Cl}_{\mathcal{F}}(U) \]

defines a presheaf on the site of all affine open subsets of \( X \). Namely, for an inclusion \( U' \subset U \) of affine open subsets, the restriction map \( \text{Cl}_{\mathcal{F}}(U) \to \text{Cl}_{\mathcal{F}}(U') \) assigns to \( N \subset \mathcal{F}(U) \) the submodule \( N^\sim(U') \subset \mathcal{F}(U') \) (here \( N^\sim \) is a quasi-coherent \( \mathcal{O}_{U'} \)-module).

**Proposition 15.1.41.** With the notation of (15.1.40), the presheaf \( \text{Cl}_{\mathcal{F}} \) is a sheaf on the site of affine open subsets of \( X \).

**Proof.** Let \( U \subset X \) be an affine open subset, and \( U = \bigcup_{i \in I} U_i \) a covering of \( U \) by affine open subsets \( U_i \subset X \). For every \( i, j \in I \) we let \( U_{ij} := U_i \cap U_j \). Suppose there is given, for every \( i \in I \), a closed \( \mathcal{O}_X(U_i) \)-submodule \( N_i \subset \mathcal{F}(U_i) \), with the property that:

\[ N_{ij} := N_i^\sim(U_{ij}) = N_j^\sim(U_{ij}) \quad \text{for every } i, j \in I \]
(an equality of topological $\mathcal{O}_X(U_{ij})$-submodules of $\mathcal{F}(U_{ij})$). Then $(N_i^\sim)_{U_{ij}} = (N_j^\sim)_{U_{ij}}$, by proposition [15.1.33] hence there exist a quasi-coherent $\mathcal{O}_U$-module $\mathcal{N}$, and isomorphisms $\mathcal{N}_{|U_i} \sim N_j^\sim$, for every $i \in I$, such that the induced $\mathcal{O}_U$-linear maps $N_i^\sim \to \mathcal{F}(U_i)$ assemble into a continuous $\mathcal{O}_U$-linear morphism $\varphi : \mathcal{N} \to \mathcal{F}(U_i)$. By construction, we have a commutative diagram of continuous maps with exact rows:

$$
\begin{array}{ccc}
0 & \longrightarrow & \mathcal{N}(U) \\
\downarrow & & \downarrow \\
0 & \longrightarrow & \prod_{i \in I} N_i \\
\end{array}
$$

where the central vertical arrow is a closed immersion. However, the condition of definition [5.5.1(ii)] implies that both $\rho, \varphi$ are admissible monomorphisms (in the sense of (8.6)), and moreover the image of $\rho, \varphi$ is a closed submodule, since each $N_{ij}$ is a separated module. Hence also the left-most vertical arrow is a closed immersion, and the assertion follows. 

**Definition 15.1.42.** Let $f : X \to Y$ be a morphism of $\omega$-formal schemes. We say that $f$ is affine (resp. a closed immersion) if there exists a covering $Y = \bigcup_{i \in I} U_i$ by affine open subsets, such that for every $i \in I$, the open subset $f^{-1}U_i \subset X$ is an affine $\omega$-formal scheme (resp. is isomorphic, as a $U$-scheme, to an $\omega$-formal scheme of the form $\text{Spf} \, A_i/J_i$, where $A_i := \mathcal{O}_Y(U_i)$ and $J_i \subset A_i$ is a closed ideal).

**Corollary 15.1.43.** Let $f : X \to Y$ be a morphism of $\omega$-formal schemes. The following conditions are equivalent:

1. $f$ is an affine morphism (resp. a closed immersion).
2. For every affine open subset $U \subset Y$, the preimage $f^{-1}U$ is an affine $\omega$-formal scheme (resp. is isomorphic, as a $U$-scheme, to the $\omega$-formal scheme $\text{Spf} \, A/J$, where $A := \mathcal{O}_Y(U)$, and $J := \text{Ker}(A \to \mathcal{O}_X(f^{-1}U)) \subset A$ is a closed ideal).

**Proof.** Of course, it suffices to show that (i)$\Rightarrow$(ii). Hence, suppose that $f$ is an affine morphism, and choose an affine open covering $Y = \bigcup_{i \in I} U_i$ such that $f^{-1}U_i$ is an affine $\omega$-formal scheme for every $i \in I$. We may find an affine open covering $U = \bigcup_{j \in J} V_j$ such that, for every $j \in J$ there exists $i \in I$ with $V_j \subset U_i$; moreover, we may assume that $J$ is countable, by proposition [15.1.19(ii.d)]. The assumption implies that $f^{-1}V_j$ is affine for every $j \in J$, and then remark [15.1.18(i.b)] says that $A := \mathcal{O}_X(f^{-1}U)$ is an $\omega$-admissible topological ring, so there exists a unique morphism $g : f^{-1}U \to \text{Spf} \, A$ such that $g^* : A \to \mathcal{O}_X(f^{-1}U)$ is the identity (proposition [15.1.22]), and $f_{|f^{-1}U}$ factors as the composition of $g$ and the morphism $h : \text{Spf} \, A \to U$ induced by the natural map $B := \mathcal{O}_Y(U) \to A$. It remains to check that $g$ is an isomorphism. To this aim, it suffices to verify that the restriction $g_{|V_j} : f^{-1}V_j \to h^{-1}V_j$ is an isomorphism for every $j \in J$. However, it is clear that $f, \mathcal{O}_X$ is a quasi-coherent $\mathcal{O}_U$-module, whence a natural isomorphism of $A$-algebras:

$$
\mathcal{O}_X(f^{-1}V_j) = f_*\mathcal{O}_X(V_j) \sim A_j := A \otimes_B \mathcal{O}_Y(V_j)
$$

(proposition [15.1.33]) as well as an isomorphism $f^{-1}V_j \sim \text{Spf} \, A$. On the other hand, $h^{-1}V_j = \text{Spf} \, A_j$, and by construction $g_{|V_j}$ is the unique morphism such that $(g_{|V_j})^*$ is the identity map of $A_j$. The assertion follows.

Next, suppose that $f$ is a closed immersion, and choose an affine open covering $Y = \bigcup_{i \in I} U_i$, and closed ideals $J_i \subset A_i := \mathcal{O}_Y(U_i)$ such that we have isomorphisms $f^{-1}U_i \sim \text{Spf} \, A_i/J_i$, for every $i \in I$. Set $U_{ij} := U_i \cap U_j$ for every $i, j \in I$. Clearly, $J_i^\sim(U_{ij}) = J_j^\sim(U_{ij})$ for every $i, j \in I$, hence there exists a unique closed ideal $J \subset A := \mathcal{O}_Y(U)$ such that:

$$
J^\sim(U_i) = J_i \quad \text{for every } i \in I
$$
Asion, and set Proof. (i): Obviously (i.a) in every subset. We have: 

\[ \Omega \text{ quasi-coherent} \]

The finite subsets of \( N \):= affine subsets that are not truly affine. As an example, consider the one point compactification (i) Let \( \text{Remark 15.1.46.} \)

Remark 15.1.46. (i) Let \( X \) be a scheme, \( I \in \mathcal{O}_X \) a quasi-coherent sheaf of ideals of finite type, and \( \mathcal{F} \) a quasi-coherent \( \mathcal{O}_X \)-module. Let also \( i : X_0 := \text{Spec} \mathcal{O}_X/I \to X \) be the closed immersion. For every \( n \in \mathbb{N} \), set \( \mathcal{F}_n := \mathcal{F}/\mathcal{I}^{n+1}; \) we endow the \( i^{-1} \mathcal{O}_X \)-module \( i^{-1}(\mathcal{F}_n) \) with its pseudo-discrete topology. Following [43, Ch.I, Déf.10.8.2], we define the completion of \( \mathcal{F} \) along \( X_0 \) \( \mathcal{F}^\wedge := \lim_{\to \! n \in \mathbb{N}} i^{-1} \mathcal{F}_n \)

\[ \text{Corollary 15.1.45. Let } A \text{ be an } \omega \text{-admissible topological ring, } U \subset X := \text{Spf } A \text{ an affine open subset. We have :} \]

(i) The following conditions are equivalent:

(a) \( U \) is truly affine.

(b) \( U \cap \text{Spec } A/I \) is quasi-compact, for every open ideal \( I \subset A \).

(ii) Especially, every quasi-compact affine open subset of \( X \) is truly affine.

\[ \text{Proof. (i): Obviously (i.a) } \Rightarrow (i.b). \text{ Conversely, let } j : Y := \text{Spf } A/I \to X \text{ be the closed immersion, and set } A_U := \mathcal{O}_X(U). \text{ On the one hand, we have } j_* \mathcal{O}_Y = (A/I)^\wedge; \text{ on the other hand, proposition [15.1.29(ii)] gives an admissible short exact sequence of topological } A_U \text{-modules} \]

\[ 0 \to i^*(U) \to A_U \to B := (A/I)^\wedge(U) \to 0, \]

and notice that the topology of \( B \) is discrete, since \( U \) is quasi-compact. Thus, \( (Y \cap U, (\mathcal{O}_Y)|_U) = \text{Spec } B = \text{Spec } B, \) by corollary [15.1.43(ii)].

(ii) is an immediate consequence of (i). \( \square \)

Remark 15.1.46. (i) Let \( A \) be an \( \omega \)-admissible topological ring. Then \( \text{Spf } A \) may well contain affine subsets that are not truly affine. As an example, consider the one point compactification \( X := \mathbb{N} \cup \{ \infty \} \) of the discrete topological space \( \mathbb{N} \) (this is the space which induces the discrete topology on its subset \( \mathbb{N} \), and such that the open neighborhoods of \( \infty \) are the complements of the finite subsets of \( \mathbb{N} \)). We choose any field \( F \), which we endow with the discrete topology, and let \( A \) be the ring of all continuous functions \( X \to F \). We endow \( A \) with the discrete topology, in which case \( \text{Spf } A = \text{Spec } A \), and one can exhibit a natural homeomorphism \( \text{Spec } A \cong X \) (exercise for the reader). On the other hand, we have an isomorphism of topological rings:

\[ \mathcal{O}_{\text{Spf } A}(\mathbb{N}) = \lim_{b \in \mathbb{N}} \mathcal{O}_{\text{Spec } A}(\{0, \ldots, b\}) \simeq k^\mathbb{N} \]

where \( k^\mathbb{N} \) is endowed with the product topology. A verification that we leave to the reader, shows that the natural injective ring homomorphism \( A \to k^\mathbb{N} \) induces an isomorphism of ringed spaces

\[ \text{Spf } k^\mathbb{N} \cong (\mathbb{N}, \mathcal{O}_{\text{Spf } A}|_\mathbb{N}) \]

hence \( \mathbb{N} \subset \text{Spf } A \) is an affine subset. However, \( \mathbb{N} \) is not an affine subset of \( \text{Spec } A \), hence \( \mathbb{N} \) is not a truly affine open subset of \( \text{Spf } A \).

(ii) On the other hand, suppose that \( A \) is c-admissible, in the sense of remark [15.1.18(ii)], and let \( U \subset \text{Spf } A \) be any open subset. Combining corollary [15.1.45(ii)] and remark [15.1.18], we see that \( U \) is an affine formal scheme in the sense of [43] if and only if it is an affine and quasi-compact \( \omega \)-formal scheme, if and only if it is truly affine.

We conclude this section by reviewing briefly a standard method for getting formal schemes out of usual schemes.

15.1.47. Let \( X \) be a scheme, \( \mathcal{I} \subset \mathcal{O}_X \) a quasi-coherent sheaf of ideals of finite type, and \( \mathcal{F} \) a quasi-coherent \( \mathcal{O}_X \)-module. Let also \( i : X_0 := \text{Spec} \mathcal{O}_X/\mathcal{I} \to X \) be the closed immersion. For every \( n \in \mathbb{N} \), set \( \mathcal{F}_n := \mathcal{F}/\mathcal{I}^{n+1}; \) we endow the \( i^{-1} \mathcal{O}_X \)-module \( i^{-1}(\mathcal{F}_n) \) with its pseudo-discrete topology. Following [43, Ch.I, Déf.10.8.2], we define the completion of \( \mathcal{F} \) along \( X_0 \) \( \mathcal{F}^\wedge := \lim_{\to \! n \in \mathbb{N}} i^{-1} \mathcal{F}_n \)
where the limit is taken in the category of sheaves of topological abelian groups. Especially, we may consider the completion $\mathcal{O}_X^\wedge := \mathcal{O}_X^{\wedge}$ which is naturally a sheaf of topological rings on $X_0$, and clearly $\mathcal{F}^\wedge$ is naturally an $\mathcal{O}_X^\wedge$-module. For every open subset $U \subset X$, set $U_0 := U \cap X_0$; notice that, if $U \subset U'$ are two such open subsets with $U_0 = U'_0$, then the restriction map $\mathcal{F}_n(U') \to \mathcal{F}_n(U)$ is an isomorphism for every $n \in \mathbb{N}$, since the support of $\mathcal{F}_n$ lies in $X_0$. There follows a natural identification

$$i^{-1}\mathcal{F}_n(U_0) \iso \mathcal{F}_n(U) \quad \text{for every } n \in \mathbb{N} \text{ and every open subset } U \subset X$$

whence, by virtue of remark [5.5.2](iii) a natural isomorphism of topological groups

$$\mathcal{F}^\wedge(U_0) \iso \lim_{n \in \mathbb{N}} \mathcal{F}_n(U) \quad \text{for every open subset } U \subset X.$$  

If moreover $U$ is quasi-compact, then $\mathcal{F}_n(U)$ is a discrete topological group for every $n \in \mathbb{N}$. If $U$ is affine, and $A_U := \mathcal{O}_X(U)$, $I_U := \mathcal{J}(U)$, we have $\mathcal{F}_n(U) = A_U/I^n_U \otimes_{A_U} \mathcal{F}(U)$ for every $n \in \mathbb{N}$, so that

$$\mathcal{F}^\wedge(U_0) = \mathcal{F}(U)^\wedge$$

where $\mathcal{F}(U)^\wedge$ denotes the $I_U$-adic completion of $\mathcal{F}(U)$. Especially, the ringed space

$$(U_0, (\mathcal{O}_X^\wedge)_{|U_0})$$

is an affine $\omega$-formal scheme (see definition [15.1.17](iv)), isomorphic to $\text{Spf } \mathcal{O}_X(U)^\wedge$. Thus

$$X^\wedge := (X_0, \mathcal{O}_X^\wedge)$$

is an $\omega$-formal scheme called the completion of $X$ along $X_0$, and $\mathcal{F}^\wedge$ is a quasi-coherent $\mathcal{O}_X^\wedge$-module (see definition [15.1.31](i)). Furthermore, the system of projections $(i^{-1}\mathcal{F} \to \mathcal{F}_n)$ yields a morphism of $i^{-1}\mathcal{O}_X$-modules

$$i^{-1}\mathcal{F} \to \mathcal{F}^\wedge.$$  

Especially, the map $\vartheta : i^{-1}\mathcal{O}_X \to \mathcal{O}_X^\wedge$ is a morphism of sheaves of rings, and the pair

$$\pi_X := (i, \vartheta) : X^\wedge \to X$$

is a natural morphism of ringed spaces. By inspecting the proof of lemma [15.1.12](i), we see more precisely that $\pi_X$ is a morphism of locally ringed spaces.

**Remark 15.1.48.** In the situation of (15.1.47), let $U \subset X^\wedge$ be any quasi-compact open subset. Then the topology of $\mathcal{F}(U)$ is the linear topology defined by the system of submodules

$$(\Gamma(U, (\mathcal{F}^n)^\wedge) \mid n \in \mathbb{N}).$$

Indeed, the assertion is clear if $U$ is affine, since in this case the ideal $I_U$ is finitely generated (see remark [8.3.3](ii,iv)). For the general case, let $(U_\lambda \mid \lambda \in \Lambda)$ be a finite affine covering of $U$, and endow $M := \prod_{\lambda \in \Lambda} \mathcal{F}(U_\lambda)$ with the product topology; according to remark [5.5.2](i), the topology of $\mathcal{F}(U)$ agrees with the topology induced by $M$ via the natural injection $\mathcal{F}(U) \to M$. However, the topology of $M$ is $I_U$-adic, and we have $\mathcal{F}(U) \cap I^n_U M = \Gamma(U, (\mathcal{F}^n)^\wedge)$ for every $n \in \mathbb{N}$, whence the contention.

15.1.49. Keep the notation of (15.1.47), and let $Y$ be another scheme, $J \subset \mathcal{O}_Y$ another quasi-coherent sheaf of ideals, and $f : X \to Y$ a morphism of schemes such that the associated map of sheaves $\mathcal{O}_Y \to f_* \mathcal{O}_X$ restricts to a morphism $J \to f_* \mathcal{O}_X$. We may then consider the completion $Y^\wedge$ of $Y$ along $Y_0 := \text{Spec } \mathcal{O}_Y / J$. Let also $U \subset X$ and $V \subset Y$ be two affine open subsets with $f(U) \subset V$, set $I_U := J(U) \subset A_U := \mathcal{O}_X(U)$, $J_V := J(V) \subset B_V := \mathcal{O}_Y(V)$, and endow $A_U$ (resp. $B_V$) with its $I_U$-adic (resp. $J_V$-adic) topology; it follows that the resulting map $B_V \to A_U$ is continuous, and therefore we get an induced morphism

$$f^\wedge_{U,V} : (U_0, (\mathcal{O}_X^\wedge)_{|U_0}) \to (V_0, (\mathcal{O}_Y^\wedge)_{|V_0}).$$
If moreover, $U' \subset U$ and $V' \subset V$ is another pair of affine open subsets such that $f(U') \subset V'$, it is clear that $f|_{U',V'}$ agrees with the restriction of $f_{U,V}$. We deduce a well-defined morphism of formal schemes

$$f^\wedge : X^\wedge \to Y^\wedge$$

that makes commute the diagram

$$\begin{array}{ccc}
X^\wedge & \xrightarrow{f^\wedge} & Y^\wedge \\
\pi_X \downarrow & & \downarrow \pi_Y \\
X & \xrightarrow{f} & Y.
\end{array}$$

Especially, if $f$ is an open immersion and $I = f^{-1}J$, then clearly $f^\wedge$ is an open immersion.

15.2. **Analytically noetherian rings.**

**Definition 15.2.1.** Let $A$ be an adic topological ring with a finitely generated ideal $I$ of adic definition.

(i) We say that $A$ is *analytically noetherian* if the following two conditions hold:

(a) The analytic locus of $\text{Spec } A$ is a noetherian scheme (see definition 8.3.28).

(b) For every finitely generated $A$-module $M$, the increasing sequence of submodules

$$\langle \text{Ann}_M(I^n) | n \in \mathbb{N} \rangle$$

is stationary.

(ii) We say that $A$ is *universally analytically noetherian* if, for every $n \in \mathbb{N}$, the polynomial $A$-algebra $A[ X_1, \ldots, X_n ]$, endowed with its $I$-adic topology, is analytically noetherian.

(iii) We say that $A$ *satisfies the topological Artin-Rees condition*, if the following holds. For every $A$-module $M$ of finite type, and every submodule $N \subset M$, the $I$-adic topology on $N$ agrees with the topology induced by the $I$-adic topology of $M$.

(iv) We say that an $A$-module $M$ is *analytically of finite type*, if there exists a submodule $N \subset M$ of finite type and an integer $n \in \mathbb{N}$ such that $I^n M \subset N$.

**Remark 15.2.2.** (i) It is easily seen that condition (b) of definition 15.2.1(i) does not depend on the chosen finitely generated ideal $I$ of adic definition of $A$. Likewise, the class of $A$-modules of analytically finite type is determined solely by the topology of $A$.

(ii) Obviously, every noetherian ring is analytically noetherian when endowed with the adic topology defined by any of its ideals.

(iii) Let $A$ be an analytically noetherian ring, and $M$ an $A$-module of analytically finite type; then the sequence $\langle \text{Ann}_M(I^k) | k \in \mathbb{N} \rangle$ is stationary. Indeed, pick a finitely generated submodule $N \subset M$ such that $I^n M \subset N$ for some $n \in \mathbb{N}$; by assumption, there exists $t \in \mathbb{N}$ such that $\text{Ann}_N(I^t) = \text{Ann}_N(I^s)$ for every $s \geq t$. It follows easily that $\text{Ann}_N(I^k) = \text{Ann}_M(I^{k+n})$ for every $k \geq t + n$.

**Lemma 15.2.3.** Let $A$ be an adic topological ring that admits a finitely generated ideal $I$ of adic definition. Then we have:

(i) The following conditions are equivalent:

(a) $A$ satisfies the topological Artin-Rees condition.

(b) For every $A$-module $M$ of finite type, every $n \in \mathbb{N}$, and every submodule $N \subset M$ such that $I^n N = 0$, there exists $m \in \mathbb{N}$ such that $N \cap I^m M = 0$.

(ii) Suppose that the equivalent conditions of (i) hold for $A$, let $M$ be any $A$-module of analytically finite type, and $N \subset M$ any submodule. Then the $I$-adic topology on $N$ agrees with the topology induced by the $I$-adic topology of $M$. 
Proof. (i): Clearly (a)⇒(b). Conversely, let \( M \) be an \( A \)-module of finite type, \( N \subset M \) a submodule, and \( n \in \mathbb{N} \) any integer. Set \( M' := M/I^nN \) and \( N' := N/I^nN \); clearly \( I^nN' = 0 \), so (b) implies that \( N' \cap I^mM = 0 \) for some \( m \in \mathbb{N} \), and the latter means that \( N \cap I^mM \subset I^nN \), whence (a).

(ii): By assumption, there exist \( n \in \mathbb{N} \) and a submodule \( M' \subset M \) of finite type such that \( I^nM \subset M' \); set \( N' := M' \cap N \). Then, for every \( t \in \mathbb{N} \) there exists \( s \in \mathbb{N} \) such that \( I^nM' \cap N = I^nM' \cap N' \subset I^sN' \subset I^tN \). We conclude that \( I^{s+n}M \cap N \subset I^tN \), whence the assertion. \( \square \)

Lemma 15.2.4. Let \( A \) be any analytically noetherian (resp. universally analytically noetherian) topological ring, and \( I \subset A \) any ideal of adic definition. We have:

(i) For every multiplicative subset \( S \subset A \), the localization \( S^{-1}A \) is analytically noetherian (resp. universally analytically noetherian) for its \( S^{-1}I \)-adic topology.

(ii) Let \( f : A \to B \) be a ring homomorphism, and \( \mathcal{T}_B \) the \( IB \)-adic topology on \( B \). If \( f \) is finite (resp. of finite type) Then \( (B, \mathcal{T}_B) \) is analytically noetherian (resp. universally analytically noetherian).

Proof. (i): Suppose that \( A \) is analytically noetherian. Clearly the analytic locus of \( \text{Spec} S^{-1}A \) is noetherian. Next, let \( M \) be any \( S^{-1}A \)-module of finite type; pick a finite system of generators \( x_\bullet := (x_1, \ldots, x_k) \) for \( M \), and let \( N \) be the \( A \)-submodule of \( M \) generated by \( x_\bullet \). Then \( S^{-1}N = M \), and \( \text{Ann}_M(S^{-1}I^n) = S^{-1}\text{Ann}_N(I^n) \) for every \( n \in \mathbb{N} \), whence the assertion. The assertion for the case where \( A \) is universally analytically noetherian case follows immediately.

(ii): Again, suppose first that \( A \) is analytically noetherian, and \( f \) is finite. The analytic locus of \( \text{Spec} B \) is finite over the analytic locus of \( \text{Spec} A \), hence it is noetherian. Next, if \( M \) is a \( B \)-module of finite type, then it is also an \( A \)-module of finite type, and \( \text{Ann}_M(I^nB) = \text{Ann}_M(I^n) \) for every \( n \in \mathbb{N} \), whence the assertion. Lastly, suppose that \( A \) is universally analytically noetherian and \( f \) is of finite type. For every \( n \in \mathbb{N} \), the \( A \)-algebra \( B[T_1, \ldots, T_n] \) is a quotient of a free polynomial \( A \)-algebra of finite type, so it is analytically noetherian, by the foregoing case, whence the assertion. \( \square \)

Proposition 15.2.5. Let \( A \) be a ring, \( I, J \subset A \) two finitely generated ideals, and denote by \( \mathcal{T}_I \) (resp. \( \mathcal{T}_J \), resp. \( \mathcal{T}_{I+J} \)) the \( I \)-adic (resp. \( J \)-adic, resp. \( (I+J) \)-adic) topology on \( A \). We have:

(i) If \( (A, \mathcal{T}_I) \) is analytically noetherian, and \( \mathcal{T}_I \) is finer than \( \mathcal{T}_J \), then \( (A, \mathcal{T}_J) \) is analytically noetherian.

(ii) If \( (A, \mathcal{T}_I) \) and \( (A, \mathcal{T}_J) \) are analytically noetherian, then the same holds for \( (A, \mathcal{T}_{I+J}) \).

(iii) If \( (A, \mathcal{T}_I) \) and \( (A, \mathcal{T}_J) \) satisfy the topological Artin-Rees condition, the same holds for \( (A, \mathcal{T}_{I+J}) \).

Proof. (i): After replacing \( J \) by \( J^n \) for a suitable \( n \in \mathbb{N} \), we may assume that \( J \subset I \), in which case it is clear that the analytic locus \( U_I \subset X := \text{Spec} A \) of \( (A, \mathcal{T}_I) \) contains the analytic locus \( U_J \) of \( (A, \mathcal{T}_J) \). Since by assumption \( U_I \) is noetherian, the same holds for the scheme \( U_J \). Next, let \( M \) be any \( A \)-module of finite type, and for every \( n \in \mathbb{N} \), denote by \( \mathcal{M}_n \) the quasi-coherent \( \mathcal{O}_X \)-module associated with \( M_n := \text{Ann}_M(I^n) \). Since \( U_I \) is noetherian, there exists \( t \in \mathbb{N} \) such that \( \mathcal{M}_{n|U_I} = \mathcal{M}_{t|U_I} \) for every \( n \geq t \). Set \( M' := M/M_t \), and \( M'_n := \text{Ann}_M'(I^n) \) for every \( n \in \mathbb{N} \). It is easily seen that

\[
(15.2.6) \quad M'_n = M_{n+t}/M_t \quad \text{for every } n \in \mathbb{N}.
\]

On the other hand, since \( (\mathcal{M}_n|U_+) \cup \mathcal{M}_t ) = 0 \), we get

\[
\bigcup_{n \in \mathbb{N}} M'_n = N := \bigcup_{n \in \mathbb{N}} \text{Ann}_M'(I^n).
\]

By assumption, there exists \( s \in \mathbb{N} \) such that \( N = \text{Ann}_M'(I^s) \), and therefore \( N \subset M'_s \subset N \). Combining with (15.2.6) we conclude that \( M_n = M_{s+t} \) for every \( n \geq s + t \), whence the assertion.
(ii): Let \( U_I \) and \( U_J \) be as in the foregoing, and define \( U_{I+J} \) likewise as the analytic locus of \((A, \mathcal{T}_{I+J})\). Then \( U_{I+J} = U_I \cup U_J \); since by assumption \( U_I \) and \( U_J \) are noetherian, the same then holds for \( U_{I+J} \). Next, let \( M \) be as in the foregoing; by assumption, there exists \( t \in \mathbb{N} \) such that \( \text{Ann}_M(I^n) = \text{Ann}_M(I^t) \) and \( \text{Ann}_M(J^n) = \text{Ann}_M(J^t) \) for every \( n \geq t \). It then follows easily that \( \text{Ann}_M((I + J)^n) = \text{Ann}_M((I + J)^{2t-1}) \) for every \( n \geq 2t-1 \), whence the assertion.

(iii): Let \( M \) be any \( A \)-module of finite type, \( N \subset M \) a submodule such that \( (I + J)^n M = 0 \) for some \( n \in \mathbb{N} \); in light of lemma [15.2.3](i), it suffices to show that there exists \( m \in \mathbb{N} \) such that \( N \cap (I + J)^m M = 0 \). However, again by lemma [15.2.3](i), our assumption on \((A, \mathcal{T})\) implies that \( N \cap I^t M = 0 \) for some \( t \in \mathbb{N} \); set \( M' := M/I^tM \) and let \( N' \subset M' \) be the image of \( N \). Notice that \( J^n N' = 0 \); invoking again lemma [15.2.3](i), our assumption on \((A, \mathcal{T})\) implies that \( N' \cap J^s M' = 0 \) for some \( s \in \mathbb{N} \). We conclude that \( N \cap (I + J^s) M = 0 \), and then \( m := t + s - 1 \) will do. \( \Box \)

As a corollary, we get the following weak form of the Artin-Rees lemma:

**Corollary 15.2.7.** Let \((A, \mathcal{T})\) be an analytically noetherian topological ring, \( f := (f_1, \ldots, f_n) \) a finite sequence of elements of \( A \) that generates an ideal of adic definition. We have:

(i) \( A \) satisfies the topological Artin-Rees condition.

(ii) \( A \) satisfies condition (d) of [7.8.21].

**Proof.** For every \( i = 1, \ldots, n \), let \( \mathcal{T}_i \) be the \( f_i \)-adic topology on \( A \); by proposition [15.2.5](i), \((A, \mathcal{T}_i)\) is analytically noetherian for every \( i = 1, \ldots, n \). Taking into account lemma [15.2.4](ii), we see that \( A \) fulfills the assumptions of lemma [7.8.44] whence (ii).

Next, if the topological Artin-Rees condition holds for each \((A, \mathcal{T}_i)\), proposition [15.2.5](iii) and a simple induction show that the same holds for \((A, \mathcal{T})\). Thus, we may assume from start that \( n = 1 \) and \( A \) admits a principal ideal \( I = fA \) of adic definition.

Now, let \( M \) be any \( A \)-module of finite type, \( N \subset M \) a submodule, and set \( M' := M/N \). Pick \( t \in \mathbb{N} \) such that \( \text{Ann}_{M'}(f^n) = \text{Ann}_{M'}(f^t) \) for every \( n \geq t \); it follows easily that

\[
N \cap f^{n+t}M = f^n(N \cap f^tM) \quad \text{for every } n \in \mathbb{N}
\]

whence the contention. \( \Box \)

**Corollary 15.2.8.** Let \( A \) be an analytically noetherian ring, \( I \subset A \) a finitely generated ideal of adic definition, and

\[
0 \to M_1 \to M_2 \to M_3 \to 0
\]

a short exact sequence of \( A \)-modules, which we endow with their \( I \)-adic topologies. We have:

(i) \( M_2 \) is analytically of finite type if and only if the same holds for both \( M_1 \) and \( M_3 \).

(ii) Suppose that \( M_2 \) is analytically of finite type. Then the induced sequence of separated completions

\[
0 \to M_1^\wedge \to M_2^\wedge \to M_3^\wedge \to 0
\]

(15.2.9)

is short exact.

**Proof.** (i): Suppose that \( M_2 \) is analytically of finite type. Then it is easily seen that the same holds for \( M_3 \). Next, set \( X := \text{Spec} \ A \), so that \( U := X \setminus \text{Spec} \ A/I \) is the analytic locus of \( X \). Let also \( \mathcal{M}_1 \) and \( \mathcal{M}_2 \) be the quasi-coherent \( \mathcal{O}_X \)-modules associated with \( M_1 \) and respectively \( M_2 \). Then \( \mathcal{M}_2|_U \) is a quasi-coherent \( \mathcal{O}_U \)-module of finite type, and since \( U \) is noetherian, the same then holds for its submodule \( \mathcal{M}_1|_U \). Hence, we may find a quasi-coherent \( \mathcal{O}_X \)-module \( \mathcal{P} \subset \mathcal{M}_1 \) of finite type such that \( \mathcal{P}|_U = \mathcal{M}_1|_U \), and we denote by \( P \subset M_1 \) the submodule corresponding to \( \mathcal{P} \). Set \( M'_1 := M_1/P \) and \( M'_2 := M_2/P \); by construction, the support of \( M'_1 \) lies in \( \text{Spec} \ A/I \), and since \( A \) is analytically noetherian, it follows that \( f^n M'_1 = 0 \) for some \( n \in \mathbb{N} \). Thus, \( f^n M_1 \subset P \), which shows that \( M_1 \) is analytically of finite type.
Lastly, suppose that $M_1$ and $M_3$ are analytically of finite type, and pick $n \in \mathbb{N}$ and finitely generated submodules $N_i \subset M_i$ such that $I^n M_i \subset N_i$ for $i = 1, 3$. Then we may find a submodule $P \subset M_2$ of finite type whose image in $M_3$ equals $M_3$, and it is easily seen that $I^n M_2 \subset P + N_1$.

(ii) By virtue of corollary [15.2.7] and lemma [15.2.3(ii), the sequence (15.2.9) is isomorphic to the sequence of natural maps

$$0 \to \lim_{n \in \mathbb{N}} M_1/(M_1 \cap I^n M_2) \to \lim_{n \in \mathbb{N}} M_2/I^n M_2 \to \lim_{n \in \mathbb{N}} M_3/I^n M_3 \to 0$$

whose exactness follows easily from [125, Lemma 3.5.3].

**Proposition 15.2.10.** Let $A$ and $I$ be as in corollary [15.2.8] and $M$ any $A$-module of analytically finite type. Endow $M$ with its $I$-adic topology, and denote by $A^\wedge$ and $M^\wedge$ the separated completions of $A$ and $M$. We have:

(i) The natural map $\varphi_M : A^\wedge \otimes_A M \to M^\wedge$ is an isomorphism.

(ii) The completion map $A \to A^\wedge$ is flat.

**Proof.** We consider first the case where $M$ is of finite type. Pick any surjective $A$-linear map $\psi : L \to M$, from a finitely presented $A$-module $L$, and endow $K := \ker \psi$ with its $I$-adic topology. We consider the induced commutative diagram

$$
\begin{array}{ccccccccc}
0 & \longrightarrow & A^\wedge \otimes_A K & \longrightarrow & A^\wedge \otimes_A L & \longrightarrow & A^\wedge \otimes_A M & \longrightarrow & 0 \\
\varphi_K & \downarrow & \varphi_L & \downarrow & \varphi_M & & & & \\
0 & \longrightarrow & K^\wedge & \longrightarrow & L^\wedge & \longrightarrow & M^\wedge & \longrightarrow & 0
\end{array}
$$

whose bottom row is short exact, by corollary [15.2.8]. If $L$ is free of finite rank, $\varphi_L$ is an isomorphism; then $\varphi_M$ is surjective and $\varphi_K$ is injective. Since we can always find such a surjection $\varphi$ with $L$ free of finite rank, we conclude already that $\varphi_M$ is surjective for every finitely generated $A$-module $M$.

Next, suppose that $M$ is finitely presented and $L$ is still free of finite rank; in this case, $K$ is an $A$-module of finite type ([59, Lemma 2.3.18(iii)]), so $\varphi_K$ is also surjective, by the foregoing, hence $\varphi_K$ is an isomorphism and therefore the same holds for $\varphi_M$.

For a general $M$ of finite type, in view of corollary [15.2.8(i)] we may find a submodule $K' \subset K$ of finite type such that $I^n K \subset K'$. Set $L' := L/K'$, and let $\psi' : L' \to M$ be the surjective map induced by $\psi$; then $L'$ is still finitely presented, so we may replace $L$ by $L'$ and $\psi$ by $\psi'$, and assume from start that the $I$-adic topology is discrete on $K$, in which case the completion map $K \to K^\wedge$ is an isomorphism, consequently $\varphi_K$ is again surjective, and we conclude as in the foregoing that $\varphi_M$ is an isomorphism, as required.

Lastly, suppose that $M$ is of analytically finite type, and pick a submodule $N \subset M$ such that $I^n(M/N) = 0$ for some $n \in \mathbb{N}$. We consider the analogous commutative diagram

$$
\begin{array}{ccccccccc}
0 & \longrightarrow & A^\wedge \otimes_A N & \longrightarrow & A^\wedge \otimes_A M & \longrightarrow & A^\wedge \otimes_A (M/N) & \longrightarrow & 0 \\
\varphi_N & \downarrow & \varphi_M & \downarrow & \varphi_{M/N} & & & & \\
0 & \longrightarrow & N^\wedge & \longrightarrow & M^\wedge & \longrightarrow & (M/N)^\wedge & \longrightarrow & 0
\end{array}
$$

and it is easily seen that both $\varphi_{M/N}$ and the completion map $M/N \to (M/N)^\wedge$ are isomorphisms. The same holds for $\varphi_N$, by the foregoing, so finally $\varphi_M$ is an isomorphism.

(ii): Let $N \to M$ be any injective homomorphism of $A$-modules; we need to check that the induced map $A^\wedge \otimes_A N \to A^\wedge \otimes_A M$ is still injective. Since the tensor product commutes with all colimits, we are easily reduced to the case where $M$ and $N$ are $A$-modules of finite type. In this case, endow $M$ and $N$ with their $I$-adic topologies; by corollary [15.2.8], the induced map on $I$-adic completions $N^\wedge \to M^\wedge$ is injective. Then it suffices to apply (i) to conclude. \hfill \Box
15.2.11. Let $(A, \mathcal{T})$ be a complete and separated adic topological ring that admits a principal ideal $I = Aa$ of adic definition. Let also $M$ be an $A$-module whose $I$-adic topology $\mathcal{T}_M$ is complete and separated. For a submodule $N \subset M$ let $N^c$ be the topological closure of $N$ in $M$, and for every $k \in \mathbb{N}$ denote by $N_k \subset M$ the submodule of all $x \in M$ such that $a^k x \in N$. Set

$$N^* := \bigcup_{k \in \mathbb{N}} N_k.$$ 

**Lemma 15.2.12.** In the situation of (15.2.11), let $N' \subset N \subset M$ be two submodules, such that $N'$ is dense in $N$ (for the topology $\mathcal{T}_M$) and $N = N^*$. The following holds:

(i) The $I$-adic topology on $N$ agrees with the topology induced by $\mathcal{T}_M$.

(ii) $N^c = (N^c)^*$. 

(iii) If $N = N^c$ as well, and $N[a^{-1}]$ is an $A[a^{-1}]$-module of finite type, then $N$ is analytically of finite type, and $N' = N$.

**Proof.** (i): Since $N = N^*$ we have $a^m N = a^m M \cap N$ for every $m \in \mathbb{N}$, whence the assertion.

(ii): If $x \in M$ and $ax \in N^c$, then for every $a \in N$ there exists $z_n \in M$ such that $ax - a^n z_n \in N$, and therefore $x - a^{n-1} z_n \in N$ for every $n \geq 1$, whence $x \in N^c$.

(ii): By assumption, there exists a finitely generated submodule $L \subset N$ with 

$$N = L^* = \bigcup_{k \in \mathbb{N}} (L_k)^c$$

(indeed, the first identity holds if we choose $L$ such that $N[a^{-1}] = L[a^{-1}]$, and the second follows, since $N = N^c$). Notice next that we may regard $M$ as a complete metric space, with the metric defined by the rule

$$d(x, y) := \begin{cases} 0 & \text{if } x = y \\ 2^{-b} & \text{if } x \neq y, \text{where } b := \max(n \in \mathbb{N} \mid x - y \in a^n M). \end{cases}$$

By Baire’s category theorem ([3, Ch.IX, §5, n.3, Th.1]), it follows that $(L_k)^c$ is open in $N$ for some $k \in \mathbb{N}$ (for the topology of $N$ induced by $\mathcal{T}_M$), and therefore it contains $a^m N$ for some $m \in \mathbb{N}$; thus $a^{k+m} N \subset a^k (L_k)^c \subset L^c$. Combining with (i) we deduce that the $I$-adic topology of $L^c$ agrees with the topology induced by $\mathcal{T}_M$; then by lemma [8.3.22(i)] we conclude that $L = L^c$, so $a^{k+m} N \subset L$, which shows that $N$ is analytically of finite type.

Lastly, since $N'$ is dense in $N$, from (i) we see that $N = N' + a^m N \subset N' + a L$. It follows that $L = (N' \cap L) + a L$, and by Nakayama’s lemma we get $L = N' \cap L$, i.e. $L \subset N'$, so $N'$ is open in $N$ and thus $N = N'$.

**Theorem 15.2.13.** Let $(A, \mathcal{T})$ be a complete and separated adic topological ring that admits a finitely generated ideal $I$ of adic definition, and suppose that the analytic locus of $\text{Spec } A$ is noetherian. Then $A$ is analytically noetherian.

**Proof.** (This is [55, Th.5.1.2].) Let $a_1, \ldots, a_k$ be a finite system of elements of $A$ that generates $I$, and for every $i = 1, \ldots, k$ denote by $\mathcal{T}_i$ that $Aa_i$-adic topology on $A$; taking into account proposition [15.2.3(ii)], it suffices to show that $(A, \mathcal{T}_i)$ is analytically noetherian for $i = 1, \ldots, k$. However, since the analytic locus of $(A, \mathcal{T}_i)$ is noetherian, the same holds for the analytic locus of $(A, \mathcal{T}_i)$, and the topology $\mathcal{T}_i$ is also complete and separated for every $i = 1, \ldots, k$, by virtue of lemma [8.3.12]. We are then reduced to the case where $I = Aa$ is a principal ideal.

Now, let $M$ be an $A$-module of finite type; we need to show that the sequence of submodules $(\text{Ann}_M(a^n) \mid n \in \mathbb{N})$ is stationary. Let us write $M = L/Q$ for a free $A$-module $L$ of finite rank, and a submodule $Q \subset L$, and set $N := Q^*$ (notation of (15.2.11)). Notice that

$$N/Q = \bigcup_{n \in \mathbb{N}} \text{Ann}_M(a^n)$$
so it suffices to show that $a^kN \subset Q$ for some $k \in \mathbb{N}$. Now, obviously $N^s = N$, so $N^c = (N^c)^s$ as well, by lemma \[15.2.12(ii)\]. Moreover, since $A[a^{-1}]$ is noetherian, $N^c[a^{-1}]$ is an $A[a^{-1}]$-module of finite type, and consequently $N^c$ is analytically of finite type, and $N = N^c$, by lemma \[15.2.12(ii)\]. It follows that $N/Q$ is also analytically of finite type; so, pick a submodule $N' \subset N/Q$ of finite type and an integer $k \in \mathbb{N}$ such that $a^k(N/Q) \subset N'$; since $N'$ is finitely generated, there exists as well $n \in \mathbb{N}$ such that $a^n N' = 0$, so finally $a^{k+n}(N/Q) = 0$, as required. □

Next, we globalize definition \[15.2.1\] to schemes as follows.

**Definition 15.2.14.** Let $A$ be an adic topological ring that has a finitely generated ideal $I$ of adic definition, $X$ an $A$-scheme, and $\mathcal{F}$ a quasi-coherent $O_X$-module.

(i) We say that $X$ is **locally analytically noetherian** if every point of $X$ admits an affine open neighborhood $U$ such that the following holds. Endow $A_U := O_X(U)$ with the $I$-adic topology $\mathcal{T}_U$; then $(A_U, \mathcal{T}_U)$ is analytically noetherian.

(ii) We say that $X$ is **analytically noetherian** if it is quasi-compact, quasi-separated and locally analytically noetherian.

(iii) We say that $\mathcal{F}$ is **analytically of finite type** if every point of $X$ admits an affine open neighborhood $U$ such that $\mathcal{F}(U)$ is an $(A_U, \mathcal{T}_U)$-module of analytically finite type.

**Remark 15.2.15.** If $A$ is a universally analytically noetherian ring, then every $A$-scheme of finite type is analytically noetherian, by virtue of lemma \[15.2.4\].

**Lemma 15.2.16.** Let $A$ and $I$ be as in definition \[15.2.14\]. Let also $X$ be a quasi-compact and quasi-separated $A$-scheme, and $\mathcal{F}$ a quasi-coherent $O_X$-module. We have:

(i) If $\mathcal{F}$ is analytically of finite type, there exist an integer $n \in \mathbb{N}$ and a quasi-coherent $O_X$-submodule of finite type $\mathcal{G} \subset \mathcal{F}$ such that $I^n \mathcal{F} \subset \mathcal{G}$.

(ii) If $\mathcal{F}$ is analytically of finite type and $X$ is analytically noetherian, there exists $p \in \mathbb{N}$ such that $\text{Ann}_{\mathcal{F}}(I^p) = \text{Ann}_{\mathcal{F}}(I^q)$ for every integer $q \geq p$.

(iii) If $\mathcal{F}$ is of finite type and $X$ is analytically noetherian, there exist a finitely presented $O_X$-module $\mathcal{G}$, an epimorphism $\varphi : \mathcal{G} \to \mathcal{F}$ of $O_X$-modules, and an integer $n \in \mathbb{N}$ such that $I^n \text{Ker } \varphi = 0$.

**Proof.** (i): By assumption, we may find a finite affine open covering $(U_\lambda \mid \lambda \in \Lambda)$ of $X$, and for every $\lambda \in \Lambda$ a quasi-coherent $O_{U_\lambda}$-submodule $\mathcal{H}_\lambda$ of finite type of $\mathcal{F}_{U_\lambda} := \mathcal{F}|_{U_{\lambda}}$ and an integer $n_\lambda \in \mathbb{N}$ such that $I^n_{\lambda} \mathcal{F}_{U_{\lambda}} \subset \mathcal{H}_\lambda$. We may also find, for every $\lambda \in \Lambda$, a finitely presented quasi-coherent $O_{U_{\lambda}}$-module $\mathcal{H}_\lambda'$ with an $O_{U_{\lambda}}$-linear morphism $\varphi_\lambda : \mathcal{H}_\lambda \to \mathcal{F}$ whose image is $\mathcal{H}_\lambda'$. According to lemma \[10.3.25(i)\] there exist a finitely presented quasi-coherent $O_{U_{\lambda}}$-module $\mathcal{G}_{U_{\lambda}}$ with $\mathcal{G}_{U_{\lambda}}|_{U_{\lambda}} = \mathcal{H}_\lambda'$ and a morphism $\psi_\lambda : \mathcal{G}_{U_{\lambda}} \to \mathcal{F}_{U_{\lambda}}$ of $O_X$-modules such that $\psi_{U_{\lambda}} = \varphi_\lambda$. Then we may take $\mathcal{G} := \sum_{\lambda \in \Lambda} \text{Im } \psi_\lambda$.

(ii): Suppose that for every $\lambda \in \Lambda$ there exists $p_\lambda \in \mathbb{N}$ such that $\text{Ann}_{\mathcal{F}_{U_{\lambda}}}(I^q) = \text{Ann}_{\mathcal{F}_{U_{\lambda}}}(I^{p_\lambda})$ for every $q \geq p_\lambda$. Then $p := \max(p_\lambda \mid \lambda \in \Lambda)$ fulfills the stated condition. Thus, we may suppose that $X = \text{Spec } A$ for an analytically noetherian ring $A$, in which case the assertion follows from remark \[15.2.2(iii)\].

(iii): By assumption, we may find a finite affine covering $(U_\lambda \mid \lambda \in \Lambda)$ of $X$ such that $A_\lambda := O_X(U_\lambda)$ is analytically noetherian relative to its $I A_\lambda$-adic topology, for every $\lambda \in \Lambda$. Pick a finitely presented quasi-coherent $O_{U_{\lambda}}$-module $\mathcal{H}_\lambda$ and an epimorphism $\psi_\lambda : \mathcal{H}_\lambda \to \mathcal{F}_{U_{\lambda}}$ for every $\lambda \in \Lambda$. By lemma \[10.3.25(i)\] there exist a finitely presented quasi-coherent $O_{U_{\lambda}}$-module $\mathcal{H}'_{U_{\lambda}}$ with $\mathcal{H}'_{U_{\lambda}}|_{U_{\lambda}} = \mathcal{H}_{U_{\lambda}}'$ and a morphism of $O_X$-modules $\psi'_{U_{\lambda}} : \mathcal{H}'_{U_{\lambda}} \to \mathcal{F}_{U_{\lambda}}$ such that $\psi'_{U_{\lambda}} = \psi_\lambda$, for every $\lambda \in \Lambda$. Set $\mathcal{H}' := \bigoplus_{\lambda \in \Lambda} \mathcal{H}'_{U_{\lambda}}$; the sum of the morphisms $\psi'_{U_{\lambda}}$ is an epimorphism $\psi : \mathcal{H}' \to \mathcal{F}$, and $\mathcal{H}'$ is clearly finitely presented. For every $\lambda \in \Lambda$, let also $V_\lambda \subset U_\lambda$ be the analytic locus; then $V := \bigcup_{\lambda \in \Lambda} V_\lambda$ is locally noetherian, quasi-compact and
On $\mathcal{V}$-module $\lambda$ an epimorphism quasi-separated, and therefore $K_{1382}$ OFER GABBER AND LORENZO RAMERO

\begin{proof}
(i): Clearly (a) \[(a)\] (b) $F$ is an $O_X$-module of analytically finite type.
(ii) The following conditions are equivalent:
\begin{enumerate}
\item $F$ is an $O_X$-module of analytically finite type.
\item $F$ is an $O_X$-module of analytically finite type.
\end{enumerate}
\end{proof}

Proposition 15.2.17. Let $A$ be an adic topological ring with a finitely generated ideal $I$ of adic definition, $B$ an $A$-algebra, that we endow with its $IB$-adic topology $\mathcal{B}_B$. Let also $F$ be any $B$-module, and denote by $\mathcal{F}$ the quasi-coherent $O_{\text{Spec} B}$-module arising from $F$. We have:

\begin{enumerate}
\item The following conditions are equivalent:
\begin{enumerate}
\item $(B, \mathcal{B}_B)$ is analytically noetherian.
\item $\text{Spec} B$ is an analytically noetherian $A$-scheme.
\end{enumerate}
\item The following conditions are equivalent:
\begin{enumerate}
\item $F$ is a $B$-module of analytically finite type.
\item $\mathcal{F}$ is an $O_{\text{Spec} B}$-module of analytically finite type.
\end{enumerate}
\end{enumerate}

\begin{proof}
(i): Clearly (a) $\Rightarrow$ (b). Hence, suppose that $X := \text{Spec} B$ is analytically noetherian, and let $(U_i \mid i = 1, \ldots, k)$ be a finite affine covering of $X$ such that $B_i := O_X(U_i)$ is analytically noetherian for its $IB_i$-adic topology for every $i = 1, \ldots, k$. By virtue of lemma 15.2.4 we may assume that for every $i = 1, \ldots, k$ there exists $b_i \in B$ such that $B_i = B[b_i^{-1}]$. Clearly the analytic locus $U$ of $X$ is the union of the analytic loci of $\text{Spec} B_i, \ldots, \text{Spec} B_k$, so $U$ is noetherian. Next, let $M$ be any $B$-module of finite type, and for every $i = 1, \ldots, k$, set $M_i := B_i \otimes_B M$; choose $n \in \mathbb{N}$ such that $\text{Ann}_{M_i}(I^r B_i) = \text{Ann}_{M_i}(I^n B_i)$ for every $i = 1, \ldots, n$ and every $r \geq n$. It follows that $\text{Ann}_M(I^r) = \text{Ann}_M(I^n)$ for every $r \geq n$, whence the contention.

(ii) follows easily from lemma 15.2.16(i).
\end{proof}

15.2.18. Let $A$ be a universally analytically noetherian ring, $I \subset A$ a finitely generated ideal of adic definition, $X$ a quasi-separated $A$-scheme locally of finite type, and $\mathcal{F}$ a quasi-coherent $O_X$-module. According to [15.1.47] we may consider the completions $X^\wedge$ and $\mathcal{F}^\wedge$ of $X$ and $\mathcal{F}$ along the closed subscheme $X_0 := \text{Spec} \ O_X/I \otimes \text{Spec} A = \text{Spec} A/I \times \text{Spec} A X$, which are respectively a formal scheme endowed with a natural morphism of locally ringed spaces

$$\pi : X^\wedge \to X$$

and a quasi-coherent $O_{X^\wedge}$-module with a natural map of $O_{X^\wedge}$-modules

$$\pi^* \mathcal{F} \to \mathcal{F}^\wedge.$$

Proposition 15.2.20. With the notation of (15.2.18), the following holds:

(i) If $\mathcal{F}$ is analytically of finite type, the map (15.2.19) is an isomorphism.

(ii) We have $H^i(U, \pi^* \mathcal{F}) = 0$ for every affine quasi-compact open subset $U \subset X^\wedge$ and every $i > 0$.

(iii) If $X$ is affine, the natural map

$$\theta_{X^\wedge}(X^\wedge) \otimes_{\theta_X(X)} H^0(X, \mathcal{F}) \to H^0(X^\wedge, \pi^* \mathcal{F})$$

is an isomorphism.

(iv) Let $\mathcal{U} := \{(U_i \mid i \in I)\}$ be an open covering of $X^\wedge$, and suppose that $U_i \cap U_j$ is affine for every $i, j \in I$. Then there is a natural isomorphism (notation of (10.2.18)):

$$H^r_{\text{aff}}(\mathcal{U}, \pi^* \mathcal{F}) \cong H^r(X^\wedge, \pi^* \mathcal{F}).$$
Proof. (i): The assertion is local on $X$, hence we may assume that $X$ is local, say $X = \text{Spec} B$, and $\mathcal{F}$ is the quasi-coherent $\mathcal{O}_X$-module attached to the module $F := \mathcal{F}(X)$. Let $T$ be any final object in the category of topological spaces (i.e. $T$ is the unique topology over a set that has only one point), and endow $T$ with a structure sheaf $\mathcal{O}_T$ by declaring that $\mathcal{O}_T(T) := B$ and $\mathcal{O}_T(\emptyset) := 0$. The module $F$ defines an $\mathcal{O}_T$-module $F_T$ by the rule: $F_T(T) := F$ and $F_T(\emptyset) := 0$. The system of restriction maps $B \to \mathcal{O}_X(U)$ for $U$ ranging over the open subsets of $X$, may be viewed as a morphism of ringed spaces

$$\varepsilon : X \to T$$

and with this notation we then have $\mathcal{F} = \varepsilon^* F_T$. Set as well $\varepsilon^\wedge := \varepsilon \circ \pi$; there follows a natural isomorphism of $\mathcal{O}_{X^\wedge}$-modules

$$\pi^* \mathcal{F} \sim \varepsilon^\wedge F_T.$$  

In other words, $\pi^* \mathcal{F}$ is the sheaf associated to the presheaf given by the rule:

$$U_0 \mapsto \mathcal{O}_{X^\wedge}(U_0) \otimes_B F \quad \text{for every open subset } U_0 \subset X^\wedge = X_0$$

and the discussion of (15.2.21) shows that (15.2.19) is the morphism associated to the morphism of presheaves given, on every affine open subset $U_0 \subset X_0$, by the natural map

$$(15.2.21) \quad \mathcal{O}_X(U)^\wedge \otimes_B F \to \mathcal{F}(U)^\wedge$$

where $U \subset X$ is any affine open subset such that $U_0 = U \cap X_0$, and where $\mathcal{O}_X(U)^\wedge$ and $\mathcal{F}(U)^\wedge$ denote the $I$-adic completions of $\mathcal{O}_X(U)$ and respectively $\mathcal{F}(U)$. However, since $\mathcal{F}$ is quasi-coherent, we have $\mathcal{F}(U) = \mathcal{O}_X(U) \otimes_B F$; taking into account remark [15.2.15] and propositions [15.2.10] and [15.2.17](ii) we deduce that (15.2.21) is an isomorphism for every such $U_0$. Since the affine open subsets are a basis of the topology of $X^\wedge$ that is closed under finite intersections, the assertion follows.

(ii): Since $U$ is quasi-compact, $\pi(U)$ is contained in a quasi-compact open subset $V \subset X$; we may then replace $X$ by $V$, and assume from start that $X$ is quasi-compact and quasi-separated. In this case, $\mathcal{F}$ is the colimit of the filtered family $(\mathcal{F}_\lambda | \lambda \in \Lambda)$ of its quasi-coherent $\mathcal{O}_X$-submodules of finite type (proposition 10.3.29), hence $\pi^* \mathcal{F}$ is the colimit of the system $(\pi^* \mathcal{F}_\lambda | \lambda \in \Lambda)$. Since $U$ is a spectral topological space, proposition 10.1.10 then reduces to showing that $H^i(U, \pi^* \mathcal{F}_\lambda) = 0$ for every $\lambda \in \Lambda$. Hence, we may assume from start that $\mathcal{F}$ is of finite type, in which case $\pi^* \mathcal{F}$ is a quasi-coherent $\mathcal{O}_{X^\wedge}$-module, by (i), and then the assertion follows from theorem [15.1.37](ii).

(iii): Arguing as in the proof of (ii), we reduce to the case where $\mathcal{F}$ is analytically of finite type; then $\mathcal{F}(X)$ is an $\mathcal{O}_X(X)$-module of analytically finite type (proposition [15.2.17](ii)), and the discussion of (15.1.47) says that $\mathcal{O}_{X^\wedge}(X^\wedge)$ (resp. $\mathcal{F}(X^\wedge)$) is the $I$-adic completion of $\mathcal{O}_X(X)$ (resp. of $\mathcal{F}(X)$). Then the assertion follows from (i), lemma [15.1.28](i) and proposition [15.2.10](i).

(iv) follows from (ii), together corollary [10.2.21](ii) and [43 Ch.I, Prop.10.7.2].

Theorem 15.2.22. Let $A$ be a universally analytically noetherian ring, $X$ a proper and finitely presented $A$-scheme, and $\mathcal{F}$ a quasi-coherent $\mathcal{O}_X$-module of analytically finite type. Then the $A$-module $H^i(X, \mathcal{F})$ is analytically of finite type for every $i \in \mathbb{N}$.

Proof. Let $I \subset A$ be any ideal of adic definition. The first observation is the following:

Claim 15.2.23. Let $i \in \mathbb{N}$ be any integer, and suppose that $H^i(X, \mathcal{F}')$ is analytically of finite type for every finitely presented $\mathcal{O}_X$-module $\mathcal{F}'$. Then $H^i(X, \mathcal{F})$ is analytically of finite type for every $\mathcal{O}_X$-module $\mathcal{F}$ of analytically finite type.

Proof of the claim. Let $\mathcal{G} \subset \mathcal{F}$ be an $\mathcal{O}_X$-submodule as in lemma [15.2.16](i), so that $I^n \mathcal{F} \subset \mathcal{G}$ for some $n \in \mathbb{N}$, and denote by $j : \mathcal{G} \to \mathcal{F}$ the inclusion morphism. Then, for every $a \in I^n$
the endomorphism $a \cdot 1_{\mathcal{I}}$ factors through an $\mathcal{O}_X$-linear morphism $\varphi_\alpha : \mathcal{I} \to \mathcal{J}$. Set $H^i := H^i(X, \mathcal{I})$; we deduce that $a \cdot 1_{\mathcal{I}'} = H^i(X, j) \circ H^i(X, \varphi_\alpha)$. Especially, $H^i(X, \mathcal{J})$ is contained in the image of $H^i(X, \mathcal{J})$. Hence, if $H^i(X, \mathcal{J})$ is analytically of finite type, the same follows for $H^i$. We may then replace $\mathcal{I}$ by $\mathcal{J}$, and assume from start that $\mathcal{I}$ is quasi-coherent of finite type. Next, by lemma [15.2.16(iii)] and remark [15.2.15] we may find a short exact sequence of quasi-coherent $\mathcal{O}_X$-modules $0 \to \mathcal{K} \to \mathcal{I} \to \mathcal{J} \to 0$ such that $\mathcal{J}$ is finitely presented and $I^n \mathcal{K} = 0$ for some $n \in \mathbb{N}$. It follows easily that $I^n$ annihilates the cokernel of the induced map $H^i(X, \mathcal{I}) \to H^i$, whence the claim.

Thus, suppose henceforth that $\mathcal{I}$ is finitely presented, and set $S := \text{Spec} A$; according to [50, Ch.IV, Prop.8.9.1(i,iii)] we may assume that there exist a noetherian subring $A_0 \subset A$, a finitely presented morphism of schemes $X_0 \to S_0 := \text{Spec} A_0$ and a coherent $\mathcal{O}_{X_0}$-module $\mathcal{I}_0$ such that $X = S \times_{S_0} X_0$ and $\mathcal{I} = \pi^* \mathcal{I}_0$, where $\pi : X \to X_0$ is the projection. By [50, Ch.IV, Th.8.10.5], we may moreover assume that $X_0$ is a proper $A_0$-scheme.

**Claim 15.2.24.** The $\mathcal{O}_X$-module $\text{Tor}_q^{S_0}(\mathcal{O}_S, \mathcal{I}_0)$ is analytically of finite type for every $q \in \mathbb{N}$.

**Proof of the claim.** The assertion is local on $X_0$, so we may assume that $X_0$ is affine and finitely presented $S_0$-scheme; then we may find an integer $n \in \mathbb{N}$ and a closed immersion $i : X_0 \to A^n_{S_0}$. Set $i_S := S \times_{S_0} i : X \to A^n_S$; according to [47, Ch.III, Prop.6.5.11] there is a natural isomorphism of $\mathcal{O}_X$-modules:

\[ i_{S*} \text{Tor}_q^{S_0}(\mathcal{O}_S, \mathcal{I}_0) \cong \text{Tor}_q^{S_0}(\mathcal{O}_S, i_* \mathcal{I}_0) \]

so we may replace $X_0$ by $A^n_{S_0}$ and $\mathcal{I}_0$ by $i_* \mathcal{I}_0$, and assume from start that $X_0$ is a flat and affine $S_0$-scheme. In this situation, there exists as well a natural isomorphism of $\mathcal{O}_X$-modules:

\[ \mathcal{I} = \text{Tor}_q^{S_0}(\mathcal{O}_S, \mathcal{I}_0) \cong \text{Tor}_q^{S_0}(\mathcal{O}_S, i_* \mathcal{I}_0) \]

Indeed, for every $V_0$, $V$ and $U$ as in the foregoing condition (a) we have an isomorphism

\[ \gamma_{V,U} : \text{Tor}_q^{S_0}(\mathcal{O}_S(V), \mathcal{I}_0(U)) \cong \text{Tor}_q^{S_0}(\mathcal{O}_X(V \times_{S_0} U), \mathcal{I}_0(U)) \]

of $\mathcal{O}_X(V \times_{S_0} U)$-modules, such that for every inclusion of open subsets $V_0 \subset V$, $V' \subset V \cap (S \times_{S_0} V'_0)$ and $U' \subset U \cap (S \times_{S_0} V'_0)$ the resulting diagram commutes:

\[
\begin{array}{ccc}
\text{Tor}_q^{S_0}(\mathcal{O}_S(V), \mathcal{I}_0(U)) & \xrightarrow{\gamma_{V,U}} & \text{Tor}_q^{S_0}(\mathcal{O}_X(V \times_{S_0} U), \mathcal{I}_0(U)) \\
\downarrow & & \downarrow \\
\text{Tor}_q^{S_0}(\mathcal{O}_S(V'), \mathcal{I}_0(U')) & \xrightarrow{\gamma_{V',U'}} & \text{Tor}_q^{S_0}(\mathcal{O}_X(V' \times_{S_0} U'), \mathcal{I}_0(U'))
\end{array}
\]

([125, Prop.3.2.9]) whence the assertion. Thus, it suffices to check that $\mathcal{I}$ is analytically of finite type; however, since $X_0$ is affine, $\mathcal{I}_0$ admits a resolution $\mathcal{P}_* \to \mathcal{I}_0$ consisting of free $\mathcal{O}_{X_0}$-modules of finite type, and $\mathcal{I}$ is isomorphic to $H_q(\mathcal{O}_X \otimes_{\mathcal{O}_{X_0}} \mathcal{P}_*)$. The claim then follows easily from corollary [15.2.8(i)].

Let $\mathfrak{U} := (U_i \mid i = 1, \ldots, n)$ be a finite affine covering of $X_0$; we have natural isomorphisms in $\text{D}(A_0\text{-Mod})$ and respectively $\text{D}(A\text{-Mod})$

\[ R\Gamma(X_0, \mathcal{I}_0) \to \overline{C}_{alt}^*(\mathfrak{U}, \mathcal{I}_0) \quad R\Gamma(X, \mathcal{I}) \to A \otimes_{A_0} \overline{C}_{alt}^*(\mathfrak{U}, \mathcal{I}_0) \]

where $\overline{C}_{alt}^*(\mathfrak{U}, -)$ denotes the truncated alternating Čech complex associated with the covering $\mathfrak{U}$ (theorem [10.2.28(ii)]). Let us choose a Cartan-Eilenberg projective resolution $P^{**} \to \overline{C}_{alt}^*(\mathfrak{U}, \mathcal{I}_0)[0]$ such that $P^{q,q} = 0$ whenever $q > 0$ (see [125, Lemma 5.7.2]); the double complex $A \otimes_{A_0} P^{**}$ gives rise to a spectral sequence

\[ E_2^{p,q} := \text{Tor}_q^A(A, H^p \overline{C}_{alt}^*(\mathfrak{U}, \mathcal{I}_0)) \Rightarrow M_{p,q} := H^{p+q}(A \otimes_{A_0} \overline{C}_{alt}^*(\mathfrak{U}, \mathcal{I}_0)) \]
as well as a spectral sequence
\[ F_1^{p,q} := \text{Tor}_q^{A_0}(A, \overline{C}_p^{\ast}(\mathcal{U}, \mathcal{F}_0)) \Rightarrow M_{p-q} \]
whose differentials \( d_1^{p,q} : F_1^{p,q} \to F_1^{p+1,q} \) are induced by those of \( \overline{C}_p^{\ast}(\mathcal{U}, \mathcal{F}_0) \), whence natural isomorphisms for every \( p, q \in \mathbb{N} \):
\[
(15.2.25) \quad E_2^{p,q} \xrightarrow{\sim} \text{Tor}_q^{A_0}(A, H^p(X_0, \mathcal{F}_0)) \quad F_2^{p,q} \xrightarrow{\sim} H^p(X, \mathcal{F}r_{q}^{S_n}(\mathcal{O}_S, \mathcal{F}_0))
\]
and especially, we have natural isomorphisms
\[
(15.2.26) \quad F_2^{i,0} \xrightarrow{\sim} H^i \quad \text{for every } i \in \mathbb{N}.
\]

Claim 15.2.27. \( M_{p-q} \) is analytically of finite type, for every \( p, q \in \mathbb{N} \).

Proof of the claim. The \( A_0 \)-module \( H^p(X_0, \mathcal{F}_0) \) is finitely generated for every \( p \in \mathbb{N} \), because \( X_0 \) is a proper \( A_0 \)-scheme (46, Ch.III, Th.3.2.1); since \( A_0 \) is noetherian, we may then find a resolution \( P_\bullet \) of \( H^p(X_0, \mathcal{F}_0) \) consisting of free \( A_0 \)-modules of finite type, and there are natural isomorphisms \( E_2^{p,q} \xrightarrow{\sim} H_q(A \otimes_{A_0} P_\bullet) \); taking into account corollary 15.2.8(i), we conclude that \( E_2^{p,q} \) is an \( A \)-module of analytically finite type, for every \( p, q \in \mathbb{N} \). Then, again by corollary 15.2.8(i), a simple induction on \( r \in \mathbb{N} \) shows that \( E_r^{p,q} \) is analytically of finite type, for every \( p, q, r \in \mathbb{N} \). We deduce that the \( A \)-module \( M_{p-q} \) admits a finite filtration whose subquotients are analytically of finite type, and to conclude it suffices to invoke again corollary 15.2.8(i). \( \diamond \)

Now the theorem is a special case of the following more general

Claim 15.2.28. \( F_r^{p,q} \) is an \( A \)-module of analytically finite type, for every \( p, q, r \in \mathbb{N} \).

Proof of the claim. We argue by descending induction on \( p \), and notice that \( F_r^{p,q} = 0 \) for every \( p \geq n - 1 \), so the assertion is clear for \( p \geq n - 1 \). Next, let \( t \leq n - 1 \), and suppose that the claim has already been shown for every \( p, q, r \in \mathbb{N} \) with \( r \geq 2 \) and \( p \geq t \). First we prove, by descending induction on \( r \geq 2 \), that \( F_r^{t-1,0} \) is analytically of finite type. Indeed, there exists \( s \in \mathbb{N} \) large enough, such that \( F_r^{t-1,0} \) is a subquotient of \( M_{t-1} \) for every \( r \geq s \), whence the assertion for every \( r \geq s \), by virtue of claim 15.2.27 and corollary 15.2.8(i). Thus, suppose that \( 2 < r \leq s \), and we know already that \( F_r^{t-1,0} \) is analytically of finite type; we have an exact sequence
\[
0 \to F_r^{t-1,0} \to F_r^{t-1,0} \to F_r^{t-2+r,2-r}
\]
and by inductive assumption we also know that \( F_r^{t-2+r,2-r} \) is analytically of finite type. From corollary 15.2.8(i), it follows that the same holds for \( F_r^{t-1,0} \), as required. Especially, in light of 15.2.26, the foregoing implies that \( H^{t-1}(X, \mathcal{F}) \) is analytically of finite type, for every finitely presented \( \mathcal{O}_X \)-module \( \mathcal{F} \), hence the same holds more generally whenever \( \mathcal{F} \) is analytically of finite type, by virtue of claim 15.2.23. Taking into account claim 15.2.24 and 15.2.25, we deduce that \( F_r^{t-1,0} \) is analytically of finite type for every \( q \in \mathbb{N} \), and finally, the same follows for \( F_r^{t-1,q} \), whenever \( q, r \in \mathbb{N} \) and \( r \geq 2 \), after invoking once more corollary 15.2.8(i). \( \square \)

15.2.29. In the situation of theorem 15.2.22, let \( I \subset A \) be any finitely generated ideal of adic definition; we notice that \( I^n \mathcal{F} \) is a quasi-coherent \( \mathcal{O}_X \)-module of analytically finite type for every \( n \in \mathbb{N} \), and we define a descending filtration \( \text{Fil}_n^I H^i \) on \( H^i \) by setting
\[ \text{Fil}_n^I H^i := \text{Im}(\psi_{i,n} : H^i(X, I^n \mathcal{F}) \to H^i) \quad \text{for every } i, n \in \mathbb{N}. \]

Corollary 15.2.30. With the notation of 15.2.29, the following holds for every \( i \in \mathbb{N} \):

(i) The linear topology on \( H^i \) defined by the descending filtration \( \text{Fil}_n^I H^i \) agrees with the \( I \)-adic topology.

(ii) The system \( \{ \ker(\psi_{i,n} \mid n \in \mathbb{N}) \} \) is essentially zero.
Proof. Let us show first that (i) \(\Rightarrow\) (ii). To ease notation, set \(K^i_n := \text{Ker} \psi_{i,n}\) for every \(i, n \in \mathbb{N}\). For every \(a \in I^n\), the endomorphism \(a \cdot 1_F\) is the composition of the inclusion map \(j_n : I^n F \to F\) and a morphism \(\varphi_{a,n} : F \to I^n F\) of \(\mathcal{O}_X\)-modules, and we have as well
\[
\varphi_{a,n} \circ j_n = a \cdot 1_{I^n F}
\]
whence \(H^i(X, \varphi_{a,n}) \circ \psi_{i,n} = a \cdot 1_{H^i(X, I^n F)}\). We deduce immediately that
\[(15.2.31)\]
\[I^n K^i_n = 0 \quad \text{for every } p, n \in \mathbb{N}.\]

Next, notice that
\[
\text{Im}(K^i_p \to K^i_n) = K^i_n \cap \text{Im}(H^i(X, I^p F) \to H^i(X, I^n F)) \quad \text{for all integers } p \geq n \geq 0.
\]
Suppose now that (i) holds for every \(\mathcal{O}_X\)-module \(F\) of analytically finite type; especially, it applies to \(I^n F\), and therefore for every \(k \in \mathbb{N}\) we may find an integer \(p \geq n \geq 0\) such that
\[
\text{Im}(H^i(X, I^p F) \to H^i(X, I^n F)) \subset I^k H^i(X, I^n F),
\]
whence
\[
\text{Im}(K^i_p \to K^i_n) \subset K^i_n \cap I^k H^i(X, I^n F).
\]
By theorem \[15.2.22\] we know that \(H^i(X, I^n F)\) is analytically of finite type; by corollary \[15.2.7\] and lemma \[15.2.3\] (ii), it follows that there exists \(k \in \mathbb{N}\) large enough, such that \(K^i_n \cap I^k H^i(X, I^n F) \subset I^n K^i_n\), and then the assertion follows from \[(15.2.31)\].

(i): Let \(a_1, \ldots, a_k\) be a finite system of generators for \(I\); we argue by induction on \(k\). If \(k = 1\), let \(p \in \mathbb{N}\) such that \(\text{Ann}_F(a_1^p) = \text{Ann}_F(a_1^q)\) for every \(q \geq p\) (lemma \[15.2.16\] (ii)); there follows a commutative diagram of \(\mathcal{O}_X\)-modules
\[
\begin{array}{ccc}
\ell_F & \xrightarrow{a_1^p} & \ell_F \\
\downarrow & & \downarrow \\
\mathcal{F} & \xrightarrow{a_1^{p-1}} & \mathcal{F}
\end{array}
\]
whose top horizontal arrow is an isomorphism, and whose vertical arrows are the inclusion maps. We deduce easily that \(\text{Fil}^q H^i = a_1^{-p} \text{Fil}^q H^i\) for every \(q \geq p\), whence
\[a_1^q H^i \subset \text{Fil}^q H^i \subset a_1^{-p} H^i\]
as required. Next, let \(k > 1\), and set \(J := Aa_1 + \cdots + Aa_{k-1}\) and \(L := Aa_k\). Denote by \(T_1, T_J\), and \(T_L\), respectively the \(I\)-adic, \(J\)-adic and \(L\)-adic topologies on \(A\).

Fix \(p \in \mathbb{N}\); it is easily seen that \(I^p H^i \subset \text{Fil}^p H^i\), so it remains only to check that there exists \(n \in \mathbb{N}\) such that \(\text{Fil}^n H^i \subset I^p H^i\). To this aim, notice first that \(X\) is also an analytically noetherian \((A, T_L)\)-scheme (proposition \[15.2.5\] (i)), and \(F\) is also analytically of finite type relative to the topology \(T_L\); since \(L\) is principal, it follows that we may find \(t \in \mathbb{N}\) such that
\[(15.2.32)\]
\[\text{Fil}^t L H^i \subset I^p H^i.
\]
Notice also that
\[J^{r+t} \subset I^{r+t} \subset J^r + L^t \quad \text{for every } r, t \in \mathbb{N}\]
which implies that the \(I\)-adic topology on any \(A/L^t\)-module agrees with the \(J\)-adic topology. By the same token, an \(A/L^t\)-module is an \((A, T_J)\)-module of analytically finite type if and only if it is an \((A, T_J)\)-module of analytically finite type. Taking into account proposition \[15.2.5\] (i) we deduce that \(X\) is also an analytically noetherian \((A, T_J)\)-scheme and \(F/L^t F\) is analytically of finite type relative to the topology \(T_J\) as well, for every \(t \in \mathbb{N}\). Then, theorem \[15.2.22\] says that \(H^i_t := H^i(X, F/L^t F)\) is an \(A\)-module analytically of finite type relative to the topology \(T_J\), hence also relative to the topology \(T_I\), since it is an \(A/L^t A\)-module. Moreover, by inductive assumption the linear topology on \(H^i_t\) defined by the filtration \(\text{Fil}^q H^i_t\) agrees with the \(J\)-adic topology, hence the linear topology on \(H^i_t\) defined by the filtration \(\text{Fil}^q H^i_t\) agrees with the \(I\)-adic topology, by the foregoing observation.
Now, the image of Fil^i_n H^i in H^i lies in the intersection of Fil^i_n H^i with the submodule H^i/Fil^i_n H^i ⊂ H^i, and the I-adic topology on the latter agrees with the one induced by the I-adic topology of H^i (corollary 15.2.7 and lemma 15.2.3(ii)), so

\[ \text{Im}(\text{Fil}^i_n H^i \to H^i/Fil^i_n H^i) \subset I^n(H^i/Fil^i_n H^i) \quad \text{for some } n \in \mathbb{N} \]

i.e. Fil^i_n H^i ⊂ P^n H^i + Fil^i_n H^i, and combining with (15.2.32), the assertion follows. □

15.2.33. Keep the notation of (15.2.29), and define \( \pi : X^\wedge \to X \) and \( \mathcal{F}^\wedge \) as in (15.2.18). Moreover, for every \( i, n \in \mathbb{N} \) endow \( H^i(X, \mathcal{F}) \) with its I-adic topology and \( H^i(X, \mathcal{F}/I^n \mathcal{F}) \) with the discrete topology, and denote by \( A^\wedge \) and \( H^i(X, \mathcal{F}^\wedge) \) the separated completions of \( A \) and respectively \( H^i(X, \mathcal{F}) \).

**Corollary 15.2.34.** In the situation of (15.2.33), the following holds:

(i) There exist natural \( A^\wedge \)-linear isomorphisms

\[ H^i(X^\wedge, \mathcal{F}^\wedge) \sim \lim_{n \in \mathbb{N}} H^i(X, \mathcal{F}/I^n \mathcal{F}) \sim H^i(X, \mathcal{F})^\wedge \quad \text{for every } i \in \mathbb{N}. \]

(ii) For \( i = 0 \), the maps of (i) are even isomorphisms of topological \( A^\wedge \)-modules.

(iii) For every quasi-coherent \( \mathcal{O}_X \)-module \( \mathcal{F} \), there exists a natural isomorphism

\[ H^i(X^\wedge, \pi^* \mathcal{F}) \sim A^\wedge \otimes_A H^i(X, \mathcal{F}) \quad \text{for every } i \in \mathbb{N}. \]

**Proof.** (i): Fix a finite affine covering \( U_\cdot := \{ U_\lambda | \lambda \in \Lambda \} \) of \( X \), and for every \( \lambda \in \Lambda \) let \( U_\lambda^\wedge \) be the completion of \( U_\lambda \) along its closed subscheme \( \text{Spec} A/I_\lambda \times \text{Spec} A U_\cdot \). In light of lemma 15.1.28(i) we have a natural identification of complexes of topological \( A^\wedge \)-modules

\[ \overline{C}_\text{alt}^\wedge(U_\cdot^\wedge, \mathcal{F}^\wedge) \sim \lim_{n \in \mathbb{N}} \overline{C}_\text{alt}^\wedge(U_\cdot, \mathcal{F}/I^n \mathcal{F}) \]

(where \( \overline{C}_\text{alt}^\wedge(U_\cdot, \mathcal{F}/I^n \mathcal{F}) \) is endowed with the discrete topology, for every \( n, q \in \mathbb{N} \). On the other hand, by theorems 15.1.37(i) and 10.2.28(ii), we have natural isomorphisms

\[ H^i(X, \mathcal{F}/I^n \mathcal{F}) \sim H^i(U_\cdot, \mathcal{F}/I^n \mathcal{F}) \quad H^i(X^\wedge, \mathcal{F}^\wedge) \sim H^i(\overline{C}_\text{alt}^\wedge(U_\cdot^\wedge, \mathcal{F}^\wedge) \quad \text{for every } i, n \in \mathbb{N}. \]

Taking into account [125, Th.3.5.8] there follows a short exact sequence

\[ 0 \to \lim_{n \in \mathbb{N}} H^{i-1}(X, \mathcal{F}/I^n \mathcal{F}) \to H^i(X^\wedge, \mathcal{F}^\wedge) \to \lim_{n \in \mathbb{N}} H^i(X, \mathcal{F}/I^n \mathcal{F}) \to 0 \]

of \( A^\wedge \)-modules, for every \( i \in \mathbb{N} \). Set also

\[ F^i_k := \text{Im}(H^i(X, \mathcal{F}) \to H^i(X, \mathcal{F}/I^k \mathcal{F})) \quad \text{for every } i, k \in \mathbb{N}. \]

We notice:

**Claim 15.2.36.** \( \lim_{n \in \mathbb{N}} H^{i-1}(X, \mathcal{F}/I^n \mathcal{F}) = 0 \) for every \( i \in \mathbb{N} \).

**Proof of the claim.** By virtue of [125, Prop.3.5.7], it suffices to check that the descending system of submodules

\[ (M^i_{k, k+n} := \text{Im}(H^{i-1}(X, \mathcal{F}/I^{k+n} \mathcal{F}) \to H^{i-1}(X, \mathcal{F}/I^k \mathcal{F})) | n \in \mathbb{N}) \]

is stationary, for every \( i, k \in \mathbb{N} \). However, the short exact sequence of \( \mathcal{O}_X \)-modules

\[ 0 \to I^n \mathcal{F} \to \mathcal{F} \to \mathcal{F}/I^n \mathcal{F} \to 0 \]

induces a commutative diagram of \( A \)-modules with exact rows

\[ \begin{array}{cccccc}
H^{i-1}(X, \mathcal{F}) & \longrightarrow & H^{i-1}(X, \mathcal{F}/I^{n+k} \mathcal{F}) & \longrightarrow & H^i(X, I^{n+k} \mathcal{F}) & \longrightarrow & H^i(X, \mathcal{F}) \\
\| & & \| & & \| & & \\
H^{i-1}(X, \mathcal{F}) & \longrightarrow & H^{i-1}(X, \mathcal{F}/I^k \mathcal{F}) & \longrightarrow & H^i(X, I^k \mathcal{F}) & \longrightarrow & H^i(X, \mathcal{F})
\end{array} \]
which shows that
\[ F^{-1}_k \subset M^{-1}_{k,k+n} \quad \text{for every } i,k,n \in \mathbb{N}. \]

On the other hand, corollary \[15.2.30\](ii) implies that
\[ M^{-1}_{k,k+n} \subset \text{Ker}(H^{-1}(X, \mathcal{F}/I^n\mathcal{F}) \to H^i(X, I^n\mathcal{F})) = F^{-1}_k \]
for every \( k \in \mathbb{N} \) and every sufficiently large \( n \in \mathbb{N} \). The claim follows.

From \(15.2.35\) and claim \(15.2.36\), we already get the first stated isomorphism. Next, the proof of claim \(15.2.36\) shows that the system of inclusion maps \( (F^i_n \to H^i(X, \mathcal{F}/I^n\mathcal{F}) \mid n \in \mathbb{N}) \) induces an isomorphism of \( A^\wedge \)-modules
\[ \lim_{n \in \mathbb{N}} F^i_n \xrightarrow{\sim} \lim_{n \in \mathbb{N}} H^i(X, \mathcal{F}/I^n\mathcal{F}) \quad \text{for every } i \in \mathbb{N}. \]

But the system \( (F^i_n \mid n \in \mathbb{N}) \) is also isomorphic to the system \( (H^i/\text{Fil}^i_n H^i \mid n \in \mathbb{N}) \) (notation of \(15.2.29\)), and lastly, from corollary \[15.2.30\](i) we obtain a natural isomorphism
\[ \lim_{n \in \mathbb{N}} H^i/\text{Fil}^i_n H^i \xrightarrow{\sim} H^i(X, \mathcal{F})^\wedge \]
whence the second stated isomorphism.

(ii): The topology of \( H^0(X, \mathcal{F})^\wedge \) is \( I \)-adic, by remark \[8.3.3\](ii,iv). On the other hand, the topology of \( H^0(X^\wedge, \mathcal{F})^\wedge \) is the linear topology given by the system of submodules
\[ (H^0(X^\wedge, (I^n\mathcal{F})^\wedge) \mid n \in \mathbb{N}) \]
by remark \[15.1.48\]. Denote \( H^0(X, I^n\mathcal{F})^\wedge \) the \( I \)-adic completion of \( H^0(X, I^n\mathcal{F}), \) for every \( n \in \mathbb{N}; \) by (i) we get a commutative diagram of \( A^\wedge \)-modules
\[
\begin{array}{ccc}
H^0(X^\wedge, (I^n\mathcal{F})^\wedge) & \longrightarrow & H^0(X, I^n\mathcal{F})^\wedge \\
\downarrow & & \downarrow \\
H^0(X^\wedge, \mathcal{F})^\wedge & \longrightarrow & H^0(X, \mathcal{F})^\wedge
\end{array}
\]
whose horizontal arrows are isomorphisms, and whose left (resp. right) vertical arrow is induced by the inclusion \((I^n\mathcal{F})^\wedge \subset \mathcal{F}^\wedge\) (resp. is the \( I \)-adic completion of the natural map \( H^0(X, I^n\mathcal{F}) \to H^0(X, \mathcal{F})\)). By corollary \[15.2.30\](ii), the topology on \( H^0(X, \mathcal{F})^\wedge \) given by the filtration \( (H^0(X, I^n\mathcal{F})^\wedge \mid n \in \mathbb{N}) \) agrees with the topology given by the filtration \( ((I^n H^0(X, \mathcal{F})^\wedge) \mid n \in \mathbb{N}), \) and the latter is none else than the \( I \)-adic filtration, again by remark \[8.3.3\](ii,iv). We conclude already that the bottom horizontal arrow of \(15.2.37\) is an isomorphism of topological \( A^\wedge \)-modules. The same holds for the natural map \( H^0(X^\wedge, \mathcal{F}^\wedge) \to \lim_{n \in \mathbb{N}} H^0(X, \mathcal{F}/I^n\mathcal{F}), \) by the discussion of \[15.1.47\].

(iii): Since \( X \) is quasi-compact and quasi-separated, \( \mathcal{G} \) is the colimit of the filtered family \( (\mathcal{G}_\lambda \mid \lambda \in \Lambda) \) of its quasi-coherent \( \mathcal{O}_X \)-submodules of finite type (proposition \[10.3.29\]), hence \( \pi^* \mathcal{G} \) is the colimit of the system \( (\pi^* \mathcal{G}_\lambda \mid \lambda \in \Lambda) \). Since \( X^\wedge \) is a spectral topological space, proposition \[10.1.10\] then reduces to showing the assertion for each \( \mathcal{G}_\lambda, \) so we may assume from start that \( \mathcal{G} \) is analytically of finite type, in which case it suffices to apply (i), propositions \[15.2.10\](i) and \[15.2.20\](i), and theorem \[15.2.22\].

**Remark 15.2.38.** (i) The assertions of theorem \[15.2.22\] and of its corollaries \[15.2.30\] and \[15.2.34\] hold also in case \( X \) is projective but not necessarily finitely presented: indeed, if \( \iota : X \to \mathbb{P}^n_A \) is a closed immersion in a projective space over \( \text{Spec } A \), then \( H^*(X, \mathcal{F}) = H^*(\mathbb{P}^n_A, \iota_* \mathcal{F}) \), and \( \iota_* \mathcal{F} \) is clearly an \( \mathcal{O}_{\mathbb{P}^n_A} \)-module of analytically finite type, so we are reduced to the case where \( X = \mathbb{P}^n_A \), which is covered by theorem \[15.2.22\].

(ii) More generally, theorem \[15.2.22\] and its two corollaries hold for any proper \( A \)-scheme \( X \) (and any \( \mathcal{O}_X \)-module \( \mathcal{F} \) of analytically finite type): indeed, according to [39, Th.4.1 and Th.4.3] there exists a locally closed immersion \( i : X \to X' \) of \( A \)-scheme, with \( X' \) proper and
The Lemma 15.3.2. In the situation of $\gamma \in \Delta$ we say that an element $Spv$ closed subsets of $X$. Let $v$ with $\gamma \in \Delta$ us say that an element $Spv$ closed subsets of $\Gamma$. Then we have:

Proof. (i): Let $a_1, \ldots, a_n$ be a finite system of generators of $I$; the stated assumptions on $v$ imply that $v(a_i) < 1$ for every $i = 1, \ldots, n$, and $v(a_k) > 0$ for at least one index $k \leq n$. Let $\Delta$ be the convex hull of the subgroup $\Delta_0$ of $\Gamma$, generated by $\max\{v(a_i) \mid i = 1, \ldots, n\}$. It remains only to check that $\Delta \subset \Delta'$ for every convex subgroup $\Delta' \subset \Gamma$, with $\Delta' \cap v(I) \neq \emptyset$. To this aim, notice first that $cI_v \subset \Delta'$ for every such $\Delta'$; indeed, otherwise there exists $\gamma \in cI_v$ such that $\gamma < \delta$ for every $\delta \in \Delta$. Then, pick $i \in I$ with $v(i) \in \Delta'$; it follows that $1 > v(i) > \gamma$, so $v(i) \in cI_v$, contradicting our assumptions. Now, let $i \in I$ be any element with $v(i) \in \Delta'$, and write $i = a_1b_1 + \cdots + a_nb_n$ for some $b_1, \ldots, b_n \in A$; since $cI_v \subset \Delta'$ and $v(i) \leq \max\{v(a_i) \cdot v(b_i) \mid i = 1, \ldots, n\}$, it follows that $v(a_k) \in T$ for some $k \leq n$ (details left

Corollary 15.2.39. Let $A$ be a universally analytically noetherian ring, $f := (f_1, \ldots, f_r)$ a sequence of elements of $A$ that generates an ideal of adic definition. Then $A$ satisfies condition (a) of (7.8.21).

Proof. Let $X := \text{Spec } A$, denote by $I \subset A$ the ideal generated by $f$, and by $\mathcal{I} \subset \mathcal{O}_X$ the quasi-coherent ideal arising from $I$. Let also $\pi : Y \rightarrow X$ be the blowing up morphism of $\mathcal{I}$. It follows easily from remark 10.6.39(iii) that the support of the $A$-module $H^p := H^p(Y, \mathcal{I}_Y)$ is contained in $\text{Spec } A/I$, for every $p > 0$, and the same holds for the kernel and cokernel of the natural map $\varphi : A \rightarrow H^0(Y, \mathcal{O}_Y)$. Combining with theorem 15.2.22 and remark 15.2.2(iii), we deduce that there exists $n \in \mathbb{N}$ such that $I^n \cdot H^p = 0$ for every $p > 0$, and $I^n \cdot \ker \varphi = I^n \cdot \coker \varphi = 0$. Then it suffices to invoke theorem 10.6.50.

15.3. Continuous valuations. As already mentioned in (8.1.51), the study of the valuation spectrum of a topological ring $A$ will lead us to consider certain subsets of $Spv A$ that are not pro-constructible, but nevertheless are spectral spaces, with the topology induced via the inclusion map into $Spv A$.

15.3.1. As a first step, let $A$ be any ring, $I \subset A$ a finitely generated ideal; we attach to $I$ a set of specializations $S_I$ of $Spv A$ (see (8.1.51)), by declaring that $(v, w) \in S_I$ if and only if:

- either, $w(I) \neq \{0\}$ and $w$ is a primary specialization of $v$
- or else, $v = w$.

The $S_I$-admissible specializations in $Spv A$ will be simply called $I$-admissible, and the $S_I$-closed subsets of $Spv A$ shall be called $I$-closed. It is clear that the set of $I$-admissible specializations of $Spv A$ is transitive, and it satisfies condition (S3) of corollary 8.1.54(i) by lemma 9.2.15(i). We shall show hereafter that it fulfills also conditions (S1) and (S2) of proposition 8.1.52. This shall be achieved in several steps; to start out, for any abelian ordered group $\Delta$, let us say that an element $\delta \in \Delta$ is final in $\Delta$ if the following holds. For every $\gamma \in \Delta$ there exists $n \in \mathbb{N}$ such that $\delta^n < \gamma$. We remark :

Lemma 15.3.2. In the situation of (15.3.1), let $v$ be a valuation of $A$ with

$$v(I) \neq \{0\} \quad \text{and} \quad v(I) \cap cI_v = \emptyset.$$

Then we have:

(i) There exists a smallest convex subgroup $\Delta$ of $\Gamma$, with $v(I) \cap \Delta \neq \emptyset$.

(ii) $cI_v \subset \Delta$.

(iii) For every $i \in I$, either $v(i) < \delta$ for every $\delta \in \Delta$, or else $v(i)$ is final in $\Delta$.

Proof. (i): Let $a_1, \ldots, a_n$ be a finite system of generators of $I$; the stated assumptions on $v$ imply that $v(a_i) < 1$ for every $i = 1, \ldots, n$, and $v(a_k) > 0$ for at least one index $k \leq n$. Let $\Delta$ be the convex hull of the subgroup $\Delta_0$ of $\Gamma$, generated by $\max\{v(a_i) \mid i = 1, \ldots, n\}$. It remains only to check that $\Delta \subset \Delta'$ for every convex subgroup $\Delta' \subset \Gamma$, with $\Delta' \cap v(I) \neq \emptyset$. To this aim, notice first that $cI_v \subset \Delta'$ for every such $\Delta'$; indeed, otherwise there exists $\gamma \in cI_v$, such that $\gamma < \delta$ for every $\delta \in \Delta$. Then, pick $i \in I$ with $v(i) \in \Delta'$; it follows that $1 > v(i) > \gamma$, so $v(i) \in cI_v$, contradicting our assumptions. Now, let $i \in I$ be any element with $v(i) \in \Delta'$, and write $i = a_1b_1 + \cdots + a_nb_n$ for some $b_1, \ldots, b_n \in A$; since $cI_v \subset \Delta'$ and $v(i) \leq \max\{v(a_i) \cdot v(b_i) \mid i = 1, \ldots, n\}$, it follows that $v(a_k) \in T$ for some $k \leq n$ (details left
to the reader). Then clearly \( \Delta_0 \subset \Delta' \), and the contention follows. Moreover, the argument also shows (ii).

(iii): Let \( a_0 \in I \) be any element; the sequence \( a_0, a_1, \ldots, a_n \) is also a system of generators for \( I \), and the foregoing shows that \( \Delta \) is the convex hull of the subgroup generated by \( \max\{v(a_i) \mid i = 0, \ldots, n\} \). The assertion follows immediately.

**Definition 15.3.3.** Keep the situation of (15.3.1). To every \( \mathfrak{I} \) shows (ii). Then clearly

\[
\text{max } \mathfrak{I} \left[ 57x662 \right]
\]

as follows:

- If \( v(I) = \{0\} \), we set \( c \Gamma_v(I) := \Gamma_v \).
- If \( v(I) \cap c \Gamma_v \neq \emptyset \), we set \( c \Gamma_v(I) := c \Gamma_v \).
- Otherwise, \( v \) fulfills the conditions of lemma [15.3.2](#) and we let \( c \Gamma_v(I) \) be the smallest of the convex subgroups \( \Delta \) such that \( v(I) \cap \Delta \neq \emptyset \).

**Lemma 15.3.4.** Keep the notation of definition [15.3.3](#) and let \( a_1, \ldots, a_n \) be a system of generators for the ideal \( I \). We have:

(i) The following conditions are equivalent:

- (a) \( \Gamma_v = c \Gamma_v(I) \).
- (b) \( \Gamma_v = c \Gamma_v \), or else \( v(a) \) is final in \( \Gamma_v \) for every \( a \in I \).
- (c) \( \Gamma_v = c \Gamma_v \), or else \( v(a_i) \) is final in \( \Gamma_v \), for every \( i = 1, \ldots, n \).

(ii) An element \( w \in \text{Spv } A \) is an \( I \)-admissible specialization of \( v \) if and only if \( w = v^\Delta \) for a convex subgroup \( \Delta \) of \( \Gamma_v \) with \( c \Gamma_v(I) \subset \Delta \).

(iii) \( v \) has no proper \( I \)-admissible specializations if and only if \( \Gamma_v = c \Gamma_v(I) \).

**Proof.** (i): The equivalence of (a) and (b) follows directly from the definitions and lemma [15.3.2](#) (iii). The equivalence of (b) and (c) follows by remarking that the set

\[
\{a \in A \mid v(a) = 0 \text{ or else } v(a) \text{ is final in } \Gamma_v\}
\]

is an ideal in \( A \), provided \( \Gamma_v \neq c \Gamma_v \) (details left to the reader).

(ii) and (iii) are immediate from the definitions.

**Lemma 15.3.5.** Let \( A \) be a ring, \( I \subset A \) a finitely generated ideal. We have:

(i) Let also \( f_* := (f_0, f_1, \ldots, f_n) \) be a finite sequence of elements of \( A \), and \( J \subset A \) the ideal generated by \( f_* \). Suppose that the radical of \( J \) contains \( I \). Then the rational subset \( R_A(\frac{f_0}{f_0}, \ldots, \frac{f_n}{f_0}) \) is \( I \)-closed.

(ii) Let \( v \) be any valuation of \( A \) such that \( \Gamma_v = c \Gamma_v(I) \). Then for every open neighborhood \( U \) of \( v \) in \( \text{Spv } A \) there exists a finite sequence \( f_* := (f_0, f_1, \ldots, f_n) \) of elements of \( A \) such that:

- (a) \( v \in R_A(\frac{f_0}{f_0}, \ldots, \frac{f_n}{f_0}) \subset U \).
- (b) \( I \) is contained in the radical of the ideal generated by \( f_* \).

**Proof.** (i): Let \( w \in \text{Spv } A \) be an \( I \)-admissible specialization of some \( v \in R := \text{Spv } A(\frac{f_0}{f_0}, \ldots, \frac{f_n}{f_0}) \). If \( v(I) = \{0\} \), then \( v = w \), and there is nothing to prove. Thus, we may assume \( v(I) \neq \{0\} \), in which case \( w(I) \neq \{0\} \) as well. Since \( w \) is a primary specialization of \( v \), we have \( w(f_i) \leq w(f_0) \) for every \( i = 1, \ldots, n \). Suppose, by way of contradiction, that \( w \notin R \); then we must have \( w(f_0) = 0 \), and consequently \( w(f_i) = 0 \) for every \( i \leq n \) as well. Thus, \( J \subset \text{Ker } w \), and since the support of \( w \) is a prime ideal, it contains also the radical of \( J \); hence, \( I \subset \text{Ker } w \), a contradiction.

(ii): We may assume that \( U = \text{Spv } A(\frac{g_0}{g_0}, \ldots, \frac{g_n}{g_0}) \) for some \( g_0, g_1, \ldots, g_k \in A \). Pick also a finite system \( a_1, \ldots, a_n \) of generators of \( I \). We distinguish two cases:
Suppose first that $\Gamma_v = c\Gamma_v$. In this case, since $v(g_0) \neq 0$, there exists $d \in A$ such that $v(g_0) \cdot v(d) = v(g_0d) > 1$. Then $v \in R_A(\frac{1}{g_0d}) \cap U$, and we may take $f_\bullet := (g_0d, \ldots, g_kd, 1)$.

Lastly, suppose that $\Gamma_v \neq c\Gamma_v$. In this case, since $v(g_0) \neq 0$, lemma 15.3.4(i) implies that there exists $r \in \mathbb{N}$ with $v(g_0) \geq v(a_i^r)$ for every $i = 1, \ldots, n$. Then $v \in R_A(\frac{a_1^r}{g_0}, \ldots, \frac{a_n^r}{g_0}) \cap U$, and the sequence $f_\bullet := (g_0, \ldots, g_k, a_1^r, \ldots, a_n^r)$ will do.

**Definition 15.3.6.** Let $A$ be any ring and $I \subset A$ any finitely generated ideal.

(i) We set

$$Spv(A, I) := \{v \in Spv A \mid \Gamma_v = c\Gamma_v(I)\}$$

and we endow $Spv(A, I)$ with the topology induced by $Spv A$ via the inclusion map.

(ii) The rational subsets of $Spv(A, I)$ are the subsets of the form

$$Spv(A, I) \cap R_A(\frac{f_1}{f_0}, \ldots, \frac{f_n}{f_0})$$

where $f_\bullet := (f_0, f_1, \ldots, f_n)$ is any sequence of elements of $A$ such that $I$ is contained in the radical of the ideal generated by $f_\bullet$.

**Theorem 15.3.7.** With the notation of definition 15.3.6 we have :

(i) The topological space $Spv(A, I)$ is spectral, and the retraction

$$r_I : Spv A \to Spv(A, I) \quad v \mapsto v^{c\Gamma_v(I)}$$

is spectral.

(ii) The rational subsets of $Spv(A, I)$ are constructible in $Spv(A, I)$, and form a basis of the topology of $Spv(A, I)$ that is closed under finite intersections.

(iii) A subset $T \subset Spv(A, I)$ is constructible in $Spv(A, I)$ if and only if $r_I^{-1}T$ is constructible in $Spv A$.

**Proof.** (i): From lemma 15.3.5 we see that the set of $I$-admissible specializations of $Spv A$ fulfills conditions (S1) and (S2) of proposition 8.1.52, whence the assertion.

(ii): Lemma 15.3.5 already shows that the rational subsets form a basis $\mathcal{B}$ of the topology of $Spv(A, I)$. If $R_A(\frac{f_1}{f_0}, \ldots, \frac{f_n}{f_0})$ and $R_A(\frac{g_1}{g_0}, \ldots, \frac{g_n}{g_0})$ are any two rational open subset of $Spv A$ such that the radicals of the ideals $J$ and $J'$ generated respectively by $f_\bullet$ and $g_\bullet$ contain $I$, then the same holds for the radical of the ideal $JJ'$; taking into account remark 9.2.4(i), it follows that $\mathcal{B}$ is closed under finite intersections.

Lastly, let $f_\bullet$ and $J$ be as in the foregoing, with $I$ contained in the radical of $J$, and set $R := R_A(\frac{f_0}{f_0}, \ldots, \frac{f_n}{f_0})$. By lemma 15.3.5 the set $R$ is $I$-closed, so $r_I(R) = R \cap Spv(A, I)$; since $R$ is quasi-compact in $Spv A$, the subset $r_I(R)$ is quasi-compact in $Spv(A, I)$, so $R \cap Spv(A, I)$ is a constructible open subset of $Spv(A, I)$.

(iii) follows from proposition 8.1.52(iii).

**Example 15.3.8.** Let $A$ be any ring.

(i) We may take $I = 0$, in which case $c\Gamma_v(I) = \Gamma_v$ for every $v \in Spv A$, so that $Spv(A, 0) = Spv A$. Also, the rational subsets of $Spv(A, 0)$ are the same as the rational subsets of $Spv A$.

(ii) We may also take $I = A$, in which case $c\Gamma_v(I) = c\Gamma_v$ for every $v \in Spv A$, so that $Spv(A, A) = \{v \in Spv A \mid \Gamma_v = c\Gamma_v\}$. The rational subsets of $Spv(A, A)$ can be described as the sets of the form

$$Spv(A, A) \cap \{v \in Spv A \mid v(f_1) \leq v(f_0), \ldots, v(f_n) \leq v(f_0)\}$$

where $f_0, f_1, \ldots, f_n$ is any sequence of elements with $\sum_{i=1}^n f_iA = A$ (details left to the reader).

**Lemma 15.3.9.** Let $A$ be any ring, and $I, J \subset A$ two finitely generated ideals. We have :
(i) If $I$ is contained in the radical of $J$, then $\text{Spv}(A, J) \subseteq \text{Spv}(A, I)$. The inclusion map $\text{Spv}(A, J) \rightarrow \text{Spv}(A, I)$ is not spectral in general. On the other hand, there is a spectral retraction

$$r_{I,J} : \text{Spv}(A, I) \rightarrow \text{Spv}(A, J) \quad \text{such that} \quad r_{I,J} \circ r_I = r_J.$$

(ii) Especially, the spectral map $r_{I,I+J}$ is well defined, and it coincides with the restriction of $r_J$ to $\text{Spv}(A, I)$.

(iii) $\text{Spv}(A, I \cdot J) = \text{Spv}(A, I) \cup \text{Spv}(A, J)$.

(iv) $\text{Spv}(A, I + J) = \text{Spv}(A, I) \cap \text{Spv}(A, J)$.

**Proof.**

(i): Indeed, the assumption easily implies that $c\Gamma_v(J) \subseteq c\Gamma_v(I)$ for every $v \in \text{Spv} A$, from which the assertion follows immediately.

(ii): Let $v \in \text{Spv} A$ be any element, and set $w := r_I(v)$, $u := r_J(w)$; then $u$ does not have proper $J$-admissible specializations, nor any proper $I$-admissible specialization, because any $I$-admissible specialization of $u$ would be also an $I$-admissible specialization of $w$. It follows easily that $u$ is a primary specialization of $v$ that does not have any proper $(I+J)$-specialization, whence the assertion.

**Claim 15.3.10.** For every $v \in \text{Spv} A$ we have:

$$c\Gamma_v(I + J) = c\Gamma_v(I) \cap c\Gamma_v(J) \quad \text{and} \quad c\Gamma_v(I \cdot J) = c\Gamma_v(I) \cup c\Gamma_v(J).$$

**Proof of the claim.** We consider first the assertion for $c\Gamma_v(I \cdot J)$: it is easily seen that $v(IJ) = \{0\}$ if and only if either $v(I) = \{0\}$ or $v(J) = \{0\}$, so the assertion holds in case $v(IJ) = \{0\}$. Similarly, $v(IJ) \cap c\Gamma_v \neq \emptyset$ if and only if both $v(I)$ and $v(J)$ intersect $c\Gamma_v$, so the assertion holds also in case $v(IJ)$ intersects $c\Gamma_v$. Lastly, suppose that $v(IJ) \neq \{0\}$ and $v(IJ) \cap c\Gamma_v = \emptyset$, and pick a finite system of generators $a_1, \ldots, a_n$ (resp. $b_1, \ldots, b_m$) for $I$ (resp. for $J$), with

$$v(a_1) = \max(v(a_i) \mid i = 1, \ldots, n) \quad \text{and} \quad v(b_1) = \max(v(b_i) \mid i = 1, \ldots, m).$$

Then the system $(a_i b_j \mid i \leq n, j \leq m)$ generates $IJ$, and $v(ab) = \max(v(a_i b_j) \mid i \leq n, j \leq m)$. Hence $v(a_1)$ (resp. $v(b_1)$) is final in $c\Gamma_v(I)$ (resp. in $c\Gamma_v(J)$, resp. in $c\Gamma_v(IJ)$) by lemma [15.3.2](iii). Without loss of generality we may assume that $c\Gamma_v(J) \subseteq c\Gamma_v(I)$, in which case there exists $n \in \mathbb{N}$ such that $v(a_1^n) \leq v(b_1)$, hence $v(a_1 b_1)^n \geq v(a_1)^{2^n}$, which shows that $c\Gamma_v(IJ) \subseteq c\Gamma_v(I)$, and the converse inclusion is clear.

We argue similarly for the calculation of $c\Gamma_v(I + J)$: first, it is clear that $v(I + J) = \{0\}$ if and only if $v(I) = v(J) = \{0\}$. Next, we have $v(I + J) \cap c\Gamma_v \neq \emptyset$ if and only if $(v(I) \cup v(J)) \cap c\Gamma_v \neq \emptyset$ (details left to the reader). Lastly, if $v(IJ) \neq \{0\}$ and $v(IJ) \cap c\Gamma_v = \emptyset$, pick $a_1, \ldots, a_n$ and $b_1, \ldots, b_m$ as in the foregoing; without loss of generality we may assume that $v(a_1) \geq v(b_1)$. Since the system $a_1, \ldots, a_n, b_1, \ldots, b_m$ generates $I + J$, we deduce that $v(a_1)$ is final in $c\Gamma_v(I + J)$ (lemma [15.3.2](iii)), whence the contention. \qed

Assertion (iii) and (iv) follow immediately from claim [15.3.10]: details left to the reader. \square

**Example 15.3.11.** Let $A$ be any ring, $I \subseteq A$ a finitely generated ideal.

(i) Every element of the subset $L := \{v \in \text{Spv} A \mid v(I) = \{0\}\}$ has no proper $I$-admissible specializations, so $L$ lies in $\text{Spv}(A, I)$. Clearly, $L$ is constructible in $\text{Spv} A$, and $r_I^{-1}(L) = L$, so $L$ is constructible in $\text{Spv}(A, I)$, by theorem [15.3.7](iii).

(ii) Let $(\text{Spv} A)_0$ be the set of trivial valuations of $A$; from remark [9.2.4](iii) we know already that $(\text{Spv} A)_0$ is a spectral space, with the topology induced by the inclusion into $\text{Spv} A$. Moreover, if $R := R_A(\frac{1}{j_0}, \ldots, \frac{1}{j_0})$ is any rational subset of $\text{Spv}(A, I)$, then $R \cap (\text{Spv} A)_0 = \{v \in (\text{Spv} A)_0 \mid v(f_0) = 1\}$, which is a constructible (open) subset of $(\text{Spv} A)_0$. Hence, the inclusion map $(\text{Spv} A)_0 \rightarrow \text{Spv}(A, I)$ is spectral.
(iii) Pick a finite system $a_1, \ldots, a_n$ of generators for $I$, and set
\[
E_0 := \{ v \in (\text{Spv} A)_0 \mid v(I) = \{0\}\}
\]
\[
E_i := \{ v \in \text{Spv} A \mid v(a_i) = 1 \text{ and } v(a) \leq 1 \text{ for every } a \in A \} \quad \text{for every } i = 1, \ldots, n.
\]
Then $E_0, \ldots, E_n$ are pro-constructible subsets of $\text{Spv} A$ that are closed under $I$-admissible specializations and generizations. We have $(\text{Spv} A)_0 = \text{Spv}(A, I) \cap \bigcap_{i=0}^{n} E_i$, and therefore $r_I^{-1}(\text{Spv} A)_0 = \bigcup_{i=0}^{n} E_i$, by corollary \ref{corollary:continuity_of_generizations}.

We are now ready to introduce the spectrum of continuous valuations of a topological ring.

**Definition 15.3.12.** Let $(A, \mathcal{T}_A)$ be any topological ring, and $v$ a valuation of $A$.

(i) We endow $\Gamma_{v_0}$ with a topology $\mathcal{T}_{\Gamma_{v_0}}$, by ruling that a subset $U \subset \Gamma_{v_0}$ is open if either $0 \notin U$, or else there exists $\delta \in \Gamma_{v_0}$ such that $\{ \gamma \in \Gamma_{v_0} \mid \gamma < \delta \} \subset U$. Then, we say that $v$ is *continuous* if it is a continuous map $(A, \mathcal{T}_A) \to (\Gamma_{v_0}, \mathcal{T}_{\Gamma_{v_0}})$.

(ii) We set
\[
\text{Cont}(A) := \{ v \in \text{Spv} A \mid v \text{ is continuous} \} \quad \text{Cont}^+(A) := \text{Cont}(A) \cap \text{Spv}^+(A)
\]
and we endow $\text{Cont}(A)$ and $\text{Cont}^+(A)$ with the topology induced by $\text{Spv} A$.

**Remark 15.3.13.** Let $A$ be any topological ring, any $v$ any valuation of $A$.

(i) Endow $\kappa(v)$ with its valuation topology $\mathcal{T}_\kappa$ (see definition\ref{definition:valuation_topology}(ii)). A simple inspection of the definitions shows that the residual valuation $\overline{v} : (\kappa(v), \mathcal{T}_\kappa) \to \Gamma_{v_0}$ of $v$ is continuous. Moreover, $v$ is continuous if and only if the same holds for the natural map $\pi_v : A \to (\kappa(v), \mathcal{T}_\kappa)$. Indeed, clearly if $\pi_v$ is continuous, the same holds for $v = \overline{v} \circ \pi_v$. Conversely, suppose that $v$ is continuous; it suffices to check that $\pi_v$ is continuous at the point $0 \in A$. However, for every $\delta \in \Gamma_v$, let $U_\delta := \{ \gamma \in \Gamma_{v_0} \mid \gamma < \delta \}$; then the family $\{ U_\delta \mid \delta \in \Gamma_v \}$ is a fundamental system of open neighborhoods of $0 \in \Gamma_{v_0}$, and $(\overline{\pi_v} U_\delta \mid \delta \in \Gamma_v)$ is a fundamental system of open neighborhoods of $0 \in \kappa(v)$, whence the contention.

(ii) It follows easily from (i) that the valuation $v$ is continuous if and only if it is continuous at the point $0 \in A$.

(iii) Let $\varphi : \Gamma \to \Gamma'$ be a morphism of ordered groups, and endow $\Gamma_0$ and $\Gamma'_0$ with the topologies $\mathcal{T}_\Gamma$ and $\mathcal{T}_{\Gamma'}$ described in definition\ref{definition:valuation_topology}(ii). In general, the induced map $\varphi_0 : \Gamma_0 \to \Gamma'_0$ is not necessarily continuous for these topologies; for instance :

- If $\Gamma$ is a subgroup of $\Gamma'$, and $\varphi$ is the inclusion map, then $\varphi_0$ is continuous if and only if the convex hull of $\Gamma$ equals $\Gamma'$ (see remark\ref{remark:valuation_topology}(iii)), and if the latter condition holds, then the topology $\mathcal{T}_\Gamma$ agrees with the topology induced by $\mathcal{T}_{\Gamma'}$.
- If $\Gamma' = \Gamma/\Delta$ for a proper convex subgroup $\Delta \subset \Gamma$, and $\varphi$ is the projection, then $\varphi_0$ is continuous.
- If $\Gamma \neq \{1\}$ and $\Gamma' = \{1\}$, then $\varphi_0$ is not continuous.

Especially, a secondary generization $w$ of $v$ is continuous if either $v = w$ or else $\Gamma_w \neq \{1\}$, but $w$ may fail to be continuous in case $\Gamma_v \neq \{1\}$ and $\Gamma_w = \{1\}$. On the other hand, if $\varphi_0 \circ v$ is a continuous map, then it is easily seen that $v$ is continuous as well.

(iv) Let $\Delta \subset \Gamma_v$ be any convex subgroup containing $c\Gamma_v$, denote by $\Gamma_{v_0}^+ \cdot \Delta$ the smallest submonoid of $\Gamma_{v_0}$ containing $\Gamma_{v_0}^+$ and $\Delta$, and endow $\Gamma_{v_0}^+ \cdot \Delta$ with the topology $\mathcal{T}_{\Gamma_{v_0}^+ \cdot \Delta}$ induced by $\mathcal{T}_{\Gamma_{v_0}}$ via the inclusion map. Let also $\mathcal{T}_\Delta$ be the topology on $\Delta$, described in definition\ref{definition:valuation_topology}(ii). Then the inclusion map $\Delta_\Delta : \Gamma_{v_0}^+ \cdot \Delta \to \Gamma_{v_0}^+ \cdot \Delta$ admits a unique continuous retraction
\[
\rho : (\Gamma_{v_0}^+ \cdot \Delta, \mathcal{T}_{\Gamma_{v_0}^+ \cdot \Delta}) \to (\Delta_\Delta, \mathcal{T}_\Delta) \quad \text{such that } \rho(\gamma) = 0 \text{ whenever } \gamma \notin \Delta_\Delta.
\]

On the other hand, since $c\Gamma_v \subset \Delta$, the map $v$ factors through a (unique) mapping $v' : A \to \Gamma_{v_0}^+ \cdot \Delta$, and if $v$ is continuous, the same holds for $v'$. Clearly $\rho \circ v' = v\Delta$, so the latter is continuous as well. Combining with (iii) and proposition\ref{proposition:continuity_of𬣳}, we conclude that every
specialization of a continuous valuation is continuous. However, in general \( \text{Cont}(A) \) is not a closed subset (not even a pro-constructible subset) of \( \text{Spv}(A) \).

(v) Since \( \text{Spv}(A) \) is a \( T_0 \) topological space, the same holds for \( \text{Cont}(A) \). Especially, the specializations in \( \text{Cont}(A) \) define a partial ordering on \( \text{Cont}(A) \); see remark [8.1.43(ii)].

(vi) It follows also from (ii) that if \( \text{Ker} v \) is an open prime ideal, then \( v \) is continuous. We shall say that \( v \) is non-analytic if \( \text{Ker} v \) is an open prime ideal. If \( v \) is continuous and its support is not an open prime ideal, we shall say that \( v \) is analytic. We denote by

\[
\text{Cont}(A)_a \quad \text{and} \quad \text{Cont}(A)_{na}
\]

the sets of all analytic and respectively non-analytic valuations of \( A \).

(vii) Let \( f : A \to B \) be any continuous ring homomorphism of topological rings. Then \( \text{Spv}(f) \) restricts to continuous maps

\[
\text{Cont}(f) : \text{Cont}(B) \to \text{Cont}(A) \quad \text{Cont}^+(f) : \text{Cont}^+(B) \to \text{Cont}^+(A).
\]

Indeed, let \( w \) be a continuous valuation of \( B \); obviously \( v := w \circ f : A \to \Gamma_w \) is a continuous map. The value group \( \Gamma_v \) of \( v \) is a subgroup of \( \Gamma_w \), and \( v \) factors uniquely through a valuation \( v' : A \to \Gamma_v \) that is obviously equivalent to \( v \); by (iii), the continuity of \( w \) implies the continuity of \( v' \), whence the claim. It is then also clear that \( \text{Cont}(f) \) in turns restricts to a mapping

\[
\text{Cont}(f)_{na} : \text{Cont}(B)_{na} \to \text{Cont}(A)_{na}.
\]

Lemma 15.3.14. Let \( A \) be any \( f \)-adic topological ring, and \( v \in \text{Cont}(A) \). We have :

(i) \( \text{Cont}(A) = \{ w \in \text{Spv}(A) \mid w(a) \text{ is final in } \Gamma_w, \text{ for every } a \in A^{\infty} \} \).

(ii) Suppose that \( v \) is analytic, and endow \( \kappa(v) \) with its valuation topology \( \mathcal{T}_v \). Then \( v \) is a Tate valuation (see definition 9.1.14(iv)), and the natural map

\[
\pi_v : A \to (\kappa(v), \mathcal{T}_v)
\]

is an \( f \)-adic continuous ring homomorphism.

(iii) Let \( w \in \text{Cont}(A) \) be any proper primary specialization of \( v \). Then \( w \) is non-analytic.

(iv) Let \( w \in \text{Cont}(A)_a \) be a specialization of \( v \). Then \( v \in \text{Cont}(A)_a \) and \( w \) is a secondary specialization of \( v \).

(v) If \( v \) is analytic, the totally ordered set of continuous generizations of \( v \) admits a maximal element, which is a rank one analytic valuation.

Proof. Let \( A_0 \subset A \) be a subring of definition, \( I \subset A_0 \) a finitely generated ideal of adic definition, and \( a_1, \ldots, a_n \) a finite system of generators of \( I \); for every \( w \in \text{Spv}(A) \) we set

\[
\gamma_w := \max(w(a_1), \ldots, w(a_n)).
\]

(i): The condition is clearly necessary. Conversely, suppose that \( w \in \text{Spv}(A) \) fulfills this condition; by remark [15.3.13(ii)], it suffices to check that, for every \( \delta \in \Gamma_w \) there exists an open neighborhood \( U_\delta \) of 0 in \( A \) such that \( w(a) < \delta \) for every \( a \in U_\delta \). However, we have \( w(a) < 1 \) for every \( a \in I \), since \( I \subset A^{\infty} \), and we may find \( k \in \mathbb{N} \) such that \( \delta > \gamma_w^k \). Hence \( U_\delta := I^{k+1} \) will do.

(ii): Denote by \( \overline{v} \) the residual valuation of \( v \); if \( v \) is analytic, the value \( \gamma_v \) lies in \( \Gamma_v \), and if \( x \in \kappa(v)^+ \) is any element with \( \overline{v}(x) = \gamma_v \), it follows easily that the valuation topology on \( \kappa(v)^+ \) agrees with the \( x \)-adic topology, so \( v \) is a Tate valuation. Next, after replacing \( A_0 \) by the smallest \( \mathbb{Z} \)-subalgebra of \( A_0 \) containing \( I \), we may assume that \( \pi_v(A_0) \subset \kappa(v)^+ \), and notice that \( \pi_v(I^n) \) generates \( x^n \cdot \kappa(v)^+ \) for every \( n \in \mathbb{N} \), so that \( \pi_v \) is continuous and \( f \)-adic (details left to the reader).

(iii): Say that \( w = v^\Delta \) for some convex subgroup \( \Delta \) strictly contained in \( \Gamma_v \). Then the value \( \gamma_v \) cannot lie in \( \Delta \), so \( w(I) = 0 \), whence the assertion.
(iv): Proposition 9.2.24 says that \( w \) is a primary specialization of a secondary specialization \( u \) of \( v \), and \( u \) is a continuous valuation of \( A \), by remark 15.3.13 iv. In light of (iii), it follows that \( u = w \), whence the contention.

(v): First, from (iv) we see that every continuous generization of \( v \) must be a secondary generization and must be analytic; hence, let \( \Delta \subset \Gamma_v \) be the largest convex subgroup that does not contain \( \gamma_v \), and set \( w := v \Delta \). It is easily seen that the image \( \pi_v \) of \( \gamma_v \) in \( \Gamma_w = \Gamma_v / \Delta \) is still final, and by definition \( \gamma_w = \pi_v \), so \( w \) is continuous, by (i). It remains only to check that \( w \) does not admit any proper (secondary) generization; however, by construction, every non-trivial convex subgroup \( \Delta' \subset \Gamma_w \) contains \( \gamma_w \), and on the other hand, \( \gamma_w \) cannot lie in any proper convex subgroup of \( \Gamma_w \). Thus, the only convex subgroups of \( \Gamma_w \) are \{1\} and \( \Gamma_w \), whence the assertion.

**Theorem 15.3.15.** Let \( A \) be any \( f \)-adic ring, and \( J \subset A \) any finitely generated ideal such that \( \text{Spec} A/J \) is the non-analytic locus of \( \text{Spec} A \). Then we have:

(i) \( \text{Cont}(A) = \{ v \in \text{Spv}(A, J) \mid v(a) < 1 \text{ for every } a \in A^{\infty} \} \).

(ii) \( \text{Cont}(A) \) is a closed (in particular, pro-constructible) subset of \( \text{Spv}(A, J) \). Especially, \( \text{Cont}(A) \) is a spectral topological space.

**Proof.** (i): Let \( A_0 \subset A \) be a subring of definition, and \( I \subset A_0 \) an ideal of adic definition; by lemma 8.3.29(i) we have \( \text{Spec} A/IA = \text{Spec} A/J \), so that the ideals \( J \) and \( IA \) have the same radical; from lemma 15.3.9(i) we deduce that \( \text{Spv}(A, J) = \text{Spv}(A, IA) \), so we may assume from start that \( J = IA \). Since \( I \) is an open subset of \( A \), for every \( a \in A^{\infty} \) we may find \( n \in \mathbb{N} \) such that \( a^n \in I \); combining with lemma 15.3.14(i) we easily deduce that

\[ \text{Cont}(A) = \{ v \in \text{Spv} A \mid v(a) \text{ is final in } \Gamma_v, \text{ for every } a \in I \}. \]

In light of lemma 15.3.4(i) we then see that

\[ \text{Cont}(A) \subset \{ v \in \text{Spv} A, J \mid v(a) < 1 \text{ for every } a \in I \} \]

and to conclude, it suffices to prove the converse inclusion. Hence, let \( v \in \text{Spv}(A, J) \) be any valuation such that \( v(a) < 1 \) for every \( a \in I \). If \( \Gamma_v \neq c \Gamma_v \), lemma 15.3.4(i) implies that either \( v(a) = 0 \) or \( v(a) \) is final in \( \Gamma_v \) for every \( a \in J \), and then \( v \in \text{Cont}(A) \), by the foregoing.

Lastly, suppose that \( \Gamma_v = c \Gamma_v \), and let \( a \in I \) be any element; in this case, it suffices to show that, for every \( b \in A \) with \( v(b) \neq 0 \), there exists \( n \in \mathbb{N} \) such that \( v(a)^n < v(b)^{-1} \). However, we may find \( n \in \mathbb{N} \) such that \( a^n b \in I \), so \( v(a^n b) < 1 \) by assumption, whence the contention.

(ii): From (i) we see that \( \text{Cont}(A) = \bigcap_{a \in A^{\infty}} \left( \text{Spv}(A, J) \setminus R_A \left( \frac{1}{a} \right) \right) \). Combining with corollary 8.1.40 we obtain the assertion. \( \square \)

15.3.16. Let \( A \) be and \( J \) be as in theorem 15.3.15. We say that a subset of \( \text{Cont}(A) \) is rational, if it can be written as an intersection \( \text{Cont}(A) \cap R \), where \( R \) is a rational subset of \( \text{Spv}(A, J) \) (see definition 15.3.6(iii)). Hence, a rational subset is of the form \( \text{Cont}(A) \cap R_A \left( \frac{f_0}{f_1}, \ldots, \frac{f_n}{f_0} \right) \), where \( (f_0, f_1, \ldots, f_n) \) is any sequence of elements of \( A \) that generates an open ideal. Especially, the class of rational subsets of \( \text{Cont}(A) \) does not depend on the choice of the ideal \( J \), and provides a basis of quasi-compact open subsets of \( \text{Cont}(A) \) that is closed under finite intersections (theorem 15.3.7(ii)).

**Corollary 15.3.17.** Let \( f : A \to B \) be an \( f \)-adic morphism of \( f \)-adic topological rings. We have:

(i) \( \text{Cont}(f) \) is a spectral map. More precisely, if \( R \) is a rational subset of \( \text{Cont}(A) \), then \( \text{Cont}(f)^{-1}(R) \) is a rational subset of \( \text{Cont}(B) \).

(ii) \( \text{Cont}(f) \) restricts to maps \( \text{Cont}(B)_a \to \text{Cont}(A)_a \) and \( \text{Cont}(B)_n \to \text{Cont}(A)_na \).
Proof. (i): Indeed, if \( R = \text{Cont}(A) \cap R_A(\frac{a_0}{a_0}, \ldots, \frac{a_n}{a_0}) \) for a sequence \( a_0, a_1, \ldots, a_n \) that generates an open ideal of \( A \), then \( \text{Cont}(f)^{-1}(R) = \text{Cont}(B) \cap R_A(\frac{f(a_0)}{f(a_0)}, \ldots, \frac{f(a_n)}{f(a_0)}) \), and since \( f \) is adic, it is easily seen that the sequence \( f(a_0), f(a_1), \ldots, f(a_n) \) generates an open ideal of \( B \).
(ii) is clear.

**Proposition 15.3.18.** Let \( A \) be an \( f \)-adic ring, \( B \subset A \) an open subring, and denote by \( i : B \rightarrow A \) the inclusion map. Then we have:

(i) \( \text{Cont}(A) = \text{Spv}(i)^{-1}\text{Cont}(B) \).

(ii) \( \text{Cont}(i) \) restricts to a homeomorphism \( \text{Cont}(A)_a \overset{\sim}{\rightarrow} \text{Cont}(B)_a \).

**Proof.** (i): Let \( v \) be a valuation of \( A \) such that \( w := \text{Spv}(i)(v) = v|_B \) is a continuous valuation of \( B \); we have to show that \( v \) is a continuous valuation of \( A \), and by remark 15.3.13(vi), we may assume that \( \text{Ker} v \) is not open. In this case, lemma 8.3.29(iii) implies that \( \kappa(v) = \kappa(w) \), and therefore \( v \) and \( w \) have the same value group; the assertion follows immediately.

(ii): Define \( X_A \) and \( X_A^{\infty} \) as in definition 8.3.28; we have

\[
\text{Cont}(A)_a = \text{Spv}(X_A \setminus X_A^{\infty}) \cap \text{Cont}(A)
\]

and likewise for \( \text{Cont}(B)_a \), so the assertion follows from (i) and lemma 8.3.29(iii).

**Proposition 15.3.19.** Let \( A \) be a topological ring, \( A^\wedge \) the separated completion of \( A \). We have:

(i) The completion map \( i : A \rightarrow A^\wedge \) induces a bijective and continuous map

\[
\text{Cont}(i) : \text{Cont}(A^\wedge) \rightarrow \text{Cont}(A).
\]

(ii) Moreover, with the ordering given by specializations on \( \text{Cont}(A) \) and \( \text{Cont}(A^\wedge) \), the map \( \text{Cont}(i) \) is also an isomorphism of partially ordered sets (see remark 15.3.13(v))

\[
(\text{Cont}(A^\wedge), \leq) \overset{\sim}{\rightarrow} (\text{Cont}(A), \leq).
\]

(iii) Furthermore, \( \text{Cont}(i) \) restricts to bijections

\[
\text{Cont}(A^\wedge)_a \overset{\sim}{\rightarrow} \text{Cont}(A)_a \quad \text{and} \quad \text{Cont}(A^\wedge)_{\text{na}} \overset{\sim}{\rightarrow} \text{Cont}(A)_{\text{na}}.
\]

(iv) If \( A \) is \( f \)-adic, \( \text{Cont}(i) \) is a homeomorphism.

**Proof.** (i): For the injectivity of \( \text{Cont}(i) \) we show the following more precise:

**Claim 15.3.20.** Let \( w \in \text{Cont}(A^\wedge) \) be any element, and set \( v := \text{Cont}(i)(w) \). Let \( \Gamma_w \) and \( \Gamma_v \) be the value groups of \( w \) and respectively \( v \). Then we have:

(i) \( \Gamma_w = \Gamma_v \) and \( c\Gamma_w = c\Gamma_v \).

(ii) The induced map of residue fields \( \kappa(v) \rightarrow \kappa(w) \) has dense image, for the valuation topology of \( \kappa(v) \) (notation of remark 9.1.14(v)).

**Proof of the claim.** (i): Let \( a \in A^\wedge \) be any element such that \( \gamma := w(a) \in \Gamma_w \); by assumption, there exists an open neighborhood \( U_\gamma \) of \( 0 \) in \( A^\wedge \) such that \( w(x) < \gamma \) for every \( x \in U_\gamma \), hence \( w(a + U_\gamma) = \{ \gamma \} \), and since \( a + U_\gamma \) intersects the image of \( A \) in \( A^\wedge \), we deduce that \( \gamma \in \Gamma_v \), whence the claim.

(ii): According to remark 15.3.13(i), the natural map \( \pi_v : A \rightarrow \kappa(v) \) is continuous for the valuation topology \( \mathcal{T}_v \) of \( \kappa(v) \), hence it extends uniquely to a continuous ring homomorphism \( \pi_v^\wedge : A^\wedge \rightarrow \kappa(v)^\wedge \), where \( (\kappa(v)^\wedge, \mathcal{T}_v^\wedge) \) denotes the completion of \( (\kappa(v), \mathcal{T}_v) \). However, \( v \) extends uniquely to a valuation \( v^\wedge : \kappa(v)^\wedge \rightarrow \Gamma_v^\wedge \) and \( \mathcal{T}_v^\wedge \) agrees with the corresponding valuation topology of \( \kappa(v)^\wedge \) (proposition 9.1.15(iv,v)). It follows that \( v^\wedge \circ \pi_v^\wedge : A^\wedge \rightarrow \Gamma_v^\wedge \) is the unique continuous valuation whose composition with \( i \) agrees with \( v \). Consequently, there exists as well a unique inclusion of fields \( j : \kappa(w) \rightarrow \kappa(v)^\wedge \) whose composition with the projection \( \pi_w : A^\wedge \rightarrow \kappa(w) \) agrees with \( \pi_v^\wedge \), and \( v^\wedge \circ j \) is the residual valuation \( \mathcal{T}_w \) of \( \kappa(w) \).
Especially, $\mathcal{T}_w$ agrees with the topology induced by $\mathcal{T}_w^\wedge$ via $j$; since the image of $\kappa(v)$ is dense in $\kappa(v)^\wedge$ relative to the topology $\mathcal{T}_w^\wedge$ (theorem 8.2.8(ii)), the assertion follows.

Now, let $w, w' \in \text{Cont}(A^\wedge)$ be two valuations such that $w \circ i$ is equivalent to $w' \circ i$, and denote by $\Gamma_w$ (resp. $\Gamma_w'$) the value group of $w$ (resp. of $w'$). From claim 15.3.20 we may assume that $\Gamma_w = \Gamma_w'$ and $w \circ i = w' \circ i$. Since the image of $A$ is dense in $A^\wedge$ and the topology of $\Gamma_w$ is separated, we conclude that $w = w'$, as required.

Next, we show that $\text{Cont}(i)$ is surjective. Indeed, let $v$ be any continuous valuation of $A$ with value group $\Gamma$, so that, for every $\gamma \in \Gamma$ there exists an open neighborhood $U_\gamma$ of 0 in $A$ such that $v(x) < \gamma$ for every $x \in U_\gamma$; we need to show that there exists a valuation $v^\wedge : A^\wedge \to \Gamma_0$ such that $v = v^\wedge \circ i$. We define $v^\wedge$ as follows. Let $\mathcal{C}' := \{a_i \mid i \in I\}$ be any Cauchy net in $A$ (indexed by some filtered ordered set $I$); for every $\gamma \in \Gamma$, we may then find $i(\gamma) \in I$ such that $a_j - a_k \in U_\gamma$ for every $j, k \in I$ with $j, k \geq i(\gamma)$. We let $\mathcal{C}'_{\gamma}$ be the Cauchy net $(a_j \mid j \in I, j \geq i(\gamma))$ for every such $\gamma$. Now, suppose that there exists $\gamma \in \Gamma$ and $a \in \mathcal{C}'_{\gamma}$ with $\delta := v(a) \geq \gamma$; then $v(b) = \delta$ for every $b \in \mathcal{C}'_{\gamma}$, and in this case we set $v^\wedge(\mathcal{C}') := \delta$. Otherwise, we set $v^\wedge(\mathcal{C}') := 0$. It is easily seen that this definition depends only on the equivalence class of $\mathcal{C}'$ in $A^\wedge$, so that it yields a well defined map $v^\wedge : A^\wedge \to \Gamma_0$, and it is clear that $v^\wedge \circ i = v$. We leave to the reader the verification that $v^\wedge$ is indeed a continuous valuation on $A^\wedge$.

(ii): Let $u \in \text{Cont}(A^\wedge)$ be any element, and $u'$ a specialization of $u' := \text{Cont}(i)(u)$ in $\text{Cont}(A)$. By proposition 9.2.24 there exists $v' \in \text{Spv} A$ that is both a secondary specialization of $u'$ and a primary specialization of $w'$ in $\text{Spv} A$. By lemma 9.2.25(iii) we may find a secondary specialization $v$ of $u$ in $\text{Spv} A^\wedge$ with $\text{Spv}(i)(v) = v'$; then $v \in \text{Cont}(A^\wedge)$ and $v' \in \text{Cont}(A)$ (remark 15.3.13(iv)). By claim 15.3.20 we know that $v$ and $v'$ have the same value groups and the same specialization subgroups; hence, we may find a primary specialization $w$ of $v$ in $\text{Spv} A$ with $w' = \text{Spv}(i)(w)$, and $w \in \text{Cont}(A)$ (remark 15.3.13(iv)), as required.

(iii): We have already observed that $\text{Cont}(i)$ restricts to a map $\text{Cont}(A^\wedge)_{na} \to \text{Cont}(A)_{na}$ (remark 15.3.13(vii)); in light of (i), it then suffices to show that $\text{Cont}(i)$ restricts as well to a map $\text{Cont}(A^\wedge)_{na} \to \text{Cont}(A)_{na}$. Thus, let $v : A^\wedge \to \Gamma_0$ be any continuous analytic valuation, and suppose that $p := \ker v \circ i$ is open in $A$; by continuity, the topological closure $i(p)^c$ of $i(p)$ in $A^\wedge$ lies in $\ker v$. However, $i(p)^c$ contains an open subset of $A^\wedge$ (claim 8.2.11(ii)), and therefore it is open, a contradiction.

(iv): From (i), we know already that $\text{Cont}(i)$ is continuous and bijective. It then suffices to show that $\text{Cont}(i)$ is a closed map, if $A$ is f-adic. However, in this case $\text{Cont}(A)$ and $\text{Cont}(A^\wedge)$ are spectral topological spaces (theorem 15.3.15(ii)) and $\text{Cont}(i)$ is a spectral map (corollary 15.3.17(i) and proposition 8.3.33(ii)), so it suffices to check that $\text{Cont}(i)$ is specializing (proposition 8.1.44(ii) and corollary 8.1.47(i)). The latter follows immediately from (ii).

**Corollary 15.3.21.** Let $f : A \to B$ be a continuous ring homomorphism of f-adic rings. Suppose that $B$ is topologically local, and denote by $B^\wedge$ the separated completion of $B$. Then the following conditions are equivalent:

(a) $f$ is an f-adic map.
(b) The composition $A \to B^\wedge$ of $f$ with the completion map $B \to B^\wedge$ is f-adic.
(c) $\text{Cont}(f)$ restricts to a map $\text{Cont}(B)_{na} \to \text{Cont}(A)_{na}$.

**Proof.** (a)$\Rightarrow$(b) since the completion map $B \to B^\wedge$ is f-adic (proposition 8.3.33(i,ii)).
(b)$\Rightarrow$(c) by corollary 15.3.17(ii) and proposition 15.3.19(i).
(c)$\Rightarrow$(a): Let $B_0$ be a subring of definition of $B$, and $A_0$ a subring of definition of $A$ such that $A_0 \subset f^{-1}B_0$ (corollary 8.3.19(ii)), and let $f_0 : A_0 \to B_0$ be the restriction of $f$. From (c) and proposition 15.3.18(ii) we deduce that $\text{Cont}(f_0)$ restricts to a map $\text{Cont}(B_0)_{na} \to \text{Cont}(A_0)_{na}$, and it suffices to check that $f_0$ is f-adic. Moreover, $B_0$ is still topologically local (proposition 8.4.2(ii)). Thus, we may replace $f$ by $f_0$, and assume from start that $B = B^\wedge$, so that $B^\wedge$ lies in the Jacobson radical of $B$. Now, define $X_A$ and $X_A^0$ as in definition 8.3.28 and likewise for
the ring $B$; also, set $\varphi := \text{Spec } f$. By lemma 8.3.29(iv), it suffices to show that $\varphi^{-1}X^\infty_A = X^\infty_B$. However, suppose that the latter fails; then there exists a prime ideal $p \in X_B \setminus X^\infty_B$ with $\varphi(p) \in X^\infty_A$, and we pick any maximal ideal $m$ of $B$ containing $p$. Set $C := (B/p)_m$, and choose a valuation ring $V$ of $\text{Frac } C$ that dominates $C$ (corollary 9.1.24). The valuation ring $V$ corresponds to a point $v \in \text{Spv } B$; next, pick any finitely generated ideal of definition $I$ of $B$, and set $w := v^\Gamma(I)$. Since $B^\infty \subseteq m$, theorem 15.3.15(i) implies that $w$ is a continuous valuation of $B$. Since $p = \text{Ker } v$ and $I$ is not contained in $p$, it follows that $I$ is not contained in the support of $w$, therefore $w \in \text{Cont}(B)_a$. However, $w' := (f)(w)$ is a primary specialization of $\text{Spv } f(v)$, and the support of the latter is an open ideal of $A$, by construction, so $w' \in \text{Cont}(A)_\text{hat}$, which contradicts our assumptions. 

**Proposition 15.3.22.** Let $A$ be any $f$-adic topological ring, and denote by $A^\mathrm{sep}$ the maximal separated quotient of $A$. The following holds:

(i) $\text{Spv } A = \emptyset$ if and only if $A = 0$.

(ii) $\text{Cont}(A) = \emptyset$ if and only if $A^\mathrm{sep} = 0$.

(iii) $\text{Cont}(A)_a = \emptyset$ if and only if the topology of $A^\mathrm{sep}$ is discrete.

**Proof.** (i): Indeed, if $A \neq 0$, it has a prime ideal $p$, and the trivial valuation on $A/p$ yields an element of $\text{Spv } A$.

(iii): Let $A^\wedge$ be the separated completion of $A$; if $\text{Cont}(A)_a = \emptyset$, we have $\text{Cont}(A^\wedge)_a = \emptyset$ as well, by proposition 15.3.19(iii), and it suffices to show that the topology of $A^\wedge$ is discrete.

Let $B \subset A^\wedge$ be a subring of definition, and $I \subset B$ a finitely generated ideal of adic definition (proposition 8.3.33(i)); then

$$(15.3.23) \quad \text{Cont}(B)_a = \emptyset$$

as well (proposition 15.3.18(ii)), and we remark:

**Claim 15.3.24.** $I$ is a nilpotent ideal.

**Proof of the claim.** Let $p \subset B$ be any prime ideal, and suppose by way of contradiction, that $I$ is not contained in $p$. Choose a maximal ideal $m$ of $C := B/p$, and pick a valuation ring $V$ of $\text{Frac } C$ that dominates $C_m$ (corollary 9.1.24). Let $n \subset B$ be the maximal ideal such that $n/p = m$; then $V$ corresponds to a valuation $v$ of $B$ with support equal to $p$, and such that $v(a) < 1$ for every $a \in n$. Since $B$ is $I$-adically complete, we have $I \subset n$ (remark 8.3.10(v)), so it follows easily that $v(a) < 1$ for every $a \in B^\infty$. Let $\Gamma$, be the value group of $v$, and set $w := v^\Gamma(I)$ (notation of definition 15.3.3). Then $w \in \text{Spv } (B, I)$ and $w(a) < 1$ for every $a \in B^\infty$, so $w$ is continuous (theorem 15.3.15(i)). Lastly, since $v(I) \neq \{0\}$ by construction, we have $w(I) \neq \{0\}$ as well, since $w$ is an $I$-admissible specialization of $v$. Therefore $w \in \text{Cont}(B)_a$, which contradicts $(15.3.23)$. 

Claim 15.3.24 means that the topology of $B$ is discrete, hence the same holds for the topology of $A^\wedge$, as required.

(ii): From (iii) we know that the topological closure $\{0\}^c$ of the ideal $\{0\}$ of $A$ is open in $A$; hence, every prime ideal containing $\{0\}^c$ is open as well, and therefore every valuation with support equal to such a prime ideal would be continuous (remark 15.3.13(vi)); since $\text{Cont}(A) = \emptyset$, we conclude that no prime ideal of $A$ contains $\{0\}^c$, i.e. $\{0\}^c = A$, whence the assertion. 

**Lemma 15.3.25.** Let $A$ be a topologically local $f$-adic ring, $J \subset A$ an ideal. The following conditions are equivalent:

(a) $J$ is an open ideal.

(b) For every $v \in \text{Cont}(A)_a$ we have $J \not\subseteq \text{Ker } v$.

(c) For every $v \in \text{Cont}(A)_a$ of rank one, we have $J \not\subseteq \text{Ker } v$. 

Proof. Clearly (a)⇒(b)⇒(c).

Next, suppose that \( J \) is not open; to conclude, it suffices to exhibit a rank one continuous analytic valuation on \( A \) whose support contains \( J \). Now, let \( B \subset A \) be a subring of definition, and set \( J_B := B \cap J \); since \( J \) is not open in \( A \), the ideal \( J_B \) cannot be open in \( B \). Moreover, \( B \) is also topologically local, by proposition \[8.4.2\](i).

Claim 15.3.26. It suffices to exhibit a rank one continuous analytic valuation on \( B \) whose support contains \( J_B \).

Proof of the claim. Indeed, let \( v : B \to \Gamma_0 \) be such a valuation, and denote by \( \mathfrak{p} \subset B \) the support of \( v \); with the notation of definition \[8.3.28\] we have \( \mathfrak{p} \in X_B \setminus X_B^\circ \), and by lemma \[8.3.29\](iii) the inclusion map \( i : B \to A \) induces an isomorphism of schemes \( \varphi : X_A \setminus X_A^\circ \cong X_B \setminus X_B^\circ \). Set \( q := \varphi^{-1}(\mathfrak{p}) \); it follows that \( i \) extends to a ring isomorphism \( i_p : B_{q} \cong A_{q} \). Let also \( j : A \to A_{q} \) be the localization map; \( v \) extends uniquely to a valuation \( \overline{v} : B_{q} \to \Gamma_0 \), and composing with \( i_p^{-1} \circ j \) we deduce a valuation \( w : A \to \Gamma_0 \). Moreover, \( \text{Cont}(i) : \text{Cont}(A) \to \text{Cont}(B) \) is a homeomorphism (proposition \[15.3.18\](ii)), and a direct inspection of the definitions yields

\[ \text{Cont}(i)^{-1}(v) = w. \]

Especially, \( w \) is continuous, analytic and of rank one. Lastly, the support of \( \overline{v} \) contains \( J_{B,p} = i_p^{-1}J_q \), so the support of \( w \) contains \( J \).

Due to claim \[15.3.26\] we may replace \( A \) by \( B \) and \( J \) by \( J_B \), and assume from start that \( A = A^\circ \); especially, \( A^\circ \) lies in the Jacobson radical of \( A \). By lemma \[8.3.29\](v), there exists \( x \in \text{Spec}A/J \setminus X_A^\circ \); according to remark \[8.1.43\](ii) we may find a minimal specialization \( y \) of \( x \) in \( \text{Spec}A/J \setminus X_A^\circ \), and if \( \{y\}^c \) denotes the topological closure of \( \{y\} \) in \( \text{Spec}A/J \), the closed subset \( Z := \{y\}^c \cap X_A^\circ \) of \( \text{Spec}A/J \) is non-empty, since \( X_A^\circ \) contains all the maximal ideals of \( A \). We let \( \mathfrak{p} \subset A \) be any maximal point of \( Z \), and we notice that the image \( C \) of \( A_{\mathfrak{p}} \) in \( \kappa(y) \) is a one-dimensional local domain.

Claim 15.3.27. For any one-dimensional local domain \((R, \mathfrak{m}_R)\) there exists a one-dimensional valuation ring \( \text{Frac}R \) that dominates \( R \).

Proof of the claim. By corollary \[9.1.24\] we may find a valuation ring \( V \) of \( \text{Frac}R \) that dominates \( R \). Let \( \mathcal{F} \) be the set of all prime ideals \( \mathfrak{q} \) of \( V \) such that \( \mathfrak{q} \cap R = \mathfrak{m}_R \); then \( \mathcal{F} \) is non-empty, and it admits a minimal element \( \mathfrak{r} := \bigcap_{\mathfrak{q} \in \mathcal{F}} \mathfrak{q} \). It then suffices to check that the localization \( V_{\mathfrak{r}} \) is one-dimensional. However, let \( \mathfrak{p} \subset V_{\mathfrak{r}} \) be any non-zero prime ideal, and pick any \( a \in \mathfrak{p} \setminus \{0\} \); we may write \( a := b/b' \) for some \( b, b' \in R \), and then \( b \in \mathfrak{p} \) as well, so \( \mathfrak{p} \cap R = \mathfrak{m}_R \), in which case \( \mathfrak{p} \) must be the maximal ideal of \( V_{\mathfrak{r}} \), and the assertion follows.

By claim \[15.3.27\] we may find a one-dimensional valuation ring \( V \) of \( \kappa(y) \) that dominates \( C \), and denote by \( v \in \text{Spv}A \) the corresponding valuation. Let also \( I \subset A \) be any finitely generated ideal of adic definition; by construction, the support of \( v \) contains \( J \) and is not an open ideal, and \( v \) does not admit any proper \( I \)-admissible specializations (see \[15.3.1\]), so \( v \in \text{Spv}(A,I) \). Moreover \( A^\circ \subset \mathfrak{p} \), so that \( v(b) < 1 \) for every \( b \in A^\circ \), and consequently \( v \in \text{Cont}(A) \).

15.4. Affinoid rings and affinoid schemes. In this section we present an extension and refinement of Huber’s theory of affinoid rings.

Definition 15.4.1. (i) Let \( A \) be an \( f \)-adic ring. An open subring \( B \subset A \) is called a ring of integral elements of \( A \), if \( B \subset A^\circ \) and \( B \) is integrally closed in \( A \).

(ii) An affinoid ring is a datum \((A,A^+\)) consisting of an \( f \)-adic ring \( A \) and a ring \( A^+ \) of integral elements of \( A \). A morphism of affinoid rings \( f : (A,A^+) \to (B,B^+) \) is a continuous ring homomorphism \( f : A \to B \) such that \( f(A^+) \subset B^+ \). Then we say that \( f \) is \( f \)-adic, if the same holds for the underlying map \( A \to B \).
(iii) A quasi-affinoid ring is a datum $(A, A^+, U)$ consisting of an affinoid ring $(A, A^+)$ and a constructible open subset $U \subset X_A$ that contains the analytic locus (see definition \[8.3.28\]). A morphism of quasi-affinoid rings $f : (A, A^+, U) \to (B, B^+, V)$ is a morphism $f : (A, A^+) \to (B, B^+)$ of affinoid rings such that $\text{Spec} f$ restricts to a morphism of schemes $V \to U$. We say that such $f$ is $f$-adic, if the same holds for the underlying map $A \to B$.

(iv) A quasi-affinoid scheme is a datum $X := (X, \mathcal{F}_X, A_X^+)$ consisting of a (quasi-compact) quasi-affine scheme $X$ (see \[45\] Ch.II, Déf.5.1.1), an $f$-adic topology $\mathcal{F}_X$ on $A_X := \mathcal{O}_X(X)$, and a subring $A_X^+ \subset A_X$ such that the following holds:

- $(A_X, A_X^+)$ is an affinoid ring.
- For every $s \in A_X^{\infty}$, the open subscheme $X_s := X \times_{\text{Spec} A_X} \text{Spec} A_X[s^{-1}]$ is affine.

A morphism of quasi-affinoid schemes $\varphi : (X, \mathcal{F}_X, A_X^+) \to (Y, \mathcal{F}_Y, A_Y^+)$ is a morphism of schemes $\varphi : X \to Y$ whose associated morphism of sheaves of rings $\varphi^\#: \mathcal{O}_Y \to \varphi_* \mathcal{O}_X$ induces a morphism of affinoid rings $\varphi^+: (\mathcal{O}_Y(Y), A_Y^+) \to (\mathcal{O}_X(X), A_X^+)$. We say that $\varphi$ is $f$-adic if $\varphi^+_s$ is $f$-adic. We say that $X$ is an affinoid scheme if $X$ is an affine scheme.

(v) Let $\mathcal{A} := (A, A^+, U)$ (resp. $\mathcal{X} := (X, \mathcal{F}_X, A_X^+)$) be any quasi-affinoid ring (resp. quasi-affinoid scheme). We say that $\mathcal{A}$ (resp. $\mathcal{X}$) is topologically local (resp. topologically henselian, resp. complete, resp. separated) if the underlying $f$-adic ring $A$ (resp. $\mathcal{O}_X(X)$) enjoys the corresponding property.

**Remark 15.4.2.** (i) Clearly the affinoid rings, the quasi-affinoid rings, the affinoid schemes and the quasi-affinoid schemes with their morphisms as in definition \[15.4.1\] form categories denoted respectively:

$$\text{Afd.Ring} \quad \text{q.Afd.Ring} \quad \text{Afd.Sch} \quad \text{q.Afd.Sch}$$

(Afd.Sch is a full subcategory of q.Afd.Sch). Also, we have a natural fully faithful functor

$$\text{Afd.Ring} \to \text{q.Afd.Ring} \quad (A, A^+) \mapsto (A, A^+, \text{Spec} A)$$

so we may regard Afd.Ring as a full subcategory of q.Afd.Ring.

(ii) By virtue of \[45\] Ch.II, Prop.5.1.2], we have a natural fully faithful functor

$$\Gamma : \text{q.Afd.Sch}^{\circ} \to \text{q.Afd.Ring} \quad (X, \mathcal{F}_X, A_X^+) \mapsto (A_X, A_X^+, X)$$

(where $A_X := \mathcal{O}_X(X)$ and $X$ is naturally identified with the image of the open immersion $X \to \text{Spec} A_X$). Indeed, let $s \in A_X^{\infty}$ be any element, and define the open subscheme $X_s \subset X$ as in definition \[15.4.1\] (iv); by assumption, $X_s$ is affine, and on the other hand we have a natural isomorphism of $A_X^{\infty}$-algebras

$$\Gamma(X_s, \mathcal{O}_X) \xrightarrow{\sim} A_X[s^{-1}]$$

by \[44\] Ch.I, Cor.9.2.2]. Therefore the image of the open immersion $\text{Spec} A_X[s^{-1}] \to \text{Spec} A_X$ equals $X_s$; especially, $\text{Spec} A_X[s^{-1}] \subset X$ for every $s \in A_X^{\infty}$, so $(A_X, A_X^+, X)$ is indeed a quasi-affinoid ring. Especially, the analytic locus of $\text{Spec} A_X$ lies in $X$, and shall also be called the analytic locus of $X$.

(iii) Let $(A, A^+)$ be any affinoid ring, $B \subset A$ an open subring, and endow $B$ with the topology induced by the inclusion map $B \to A$. Then corollary \[8.3.20\] (i) implies that the pair $(B, A^+ \cap B)$ is an affinoid ring.

(iv) Let $A$ be any $f$-adic ring, and endow $R := \mathbb{Z} \oplus A^{\infty}$ with the multiplication map given by the rule $(n, a) \cdot (m, b) := (nm, ma + nb + ab)$ for every $n, m \in \mathbb{Z}$ and $a, b \in A^{\infty}$. Then $R$ is a ring, and we have a unique ring homomorphism $f : R \to A$ that restricts to the inclusion map on $A^{\infty}$. The integral closure $B$ of the image of $f$ is the smallest ring of integral elements of $A$. On the other hand, $A^\circ$ is the largest subring of integral elements of $A$.

**Proposition 15.4.3.** (i) The functor $\Gamma$ of remark \[15.4.2\] (ii) admits a left adjoint:

$$\text{Spec} : \text{q.Afd.Ring} \to \text{q.Afd.Sch}^{\circ} \quad (A, A^+, U) \mapsto (U, \mathcal{F}_U, A_U^+)$$
(ii) If $f : A \to B$ is an $f$-adic morphism of quasi-affinoid rings, then $\text{Spec}(f) : \text{Spec}(B) \to \text{Spec}(A)$ is an $f$-adic morphism of quasi-affinoid rings.

(iii) The functor $\text{Spec}$ is not fully faithful, but it restricts to an equivalence of categories

$$\text{Spec} : \text{Afd.Ring} \to \text{Afd.Sch}'$$

Proof. (i): For a quasi-affinoid ring $A := (A, A^+, U)$, we let $\mathcal{O}_U$ be the f-adic topology on $A_U := \mathcal{O}_U(U)$ provided by proposition 8.3.30(i), and let $A_U^+$ be the integral closure of $A^+$ in $A_U$. Indeed, notice that the restriction map $A \to A_U$ sends $A^+$ into $A_U^+$ (lemma 8.3.24(iii.a)); since $A^+ \subset A^0$, remark 8.3.10(iii) easily implies that $A_U^+ \subset A_U^0$. Next, let $\overline{A} := \text{Im}(A \to A_U)$ and endow $\overline{A}$ with the topology induced by $A_U$ via the open inclusion map $\overline{A} \to A_U$; since $A^{\text{an}}$ is an open subgroup of $A$, for every $s \in A^{\text{an}}$ we may find $n \in \mathbb{N}$ and $t \in A^{\text{an}}$ such that $s^n$ equals the image of $t$ in $\overline{A}$. Notice that $t$ annihilates the kernel of the projection $\pi : A \to \overline{A}$, so $\text{Spec} \pi$ restricts to an isomorphism of schemes $\text{Spec} \overline{A}[s^{-n}] \cong \text{Spec} A[t^{-1}] \subset U$. It follows that

$$U \times_{\text{Spec} A_U} \text{Spec} A_U[s^{-1}] = U \times_{\text{Spec} A} \text{Spec} A[t^{-1}] = \text{Spec} A[t^{-1}]$$

so the construction of $\text{Spec} (\overline{A})$ is achieved. Next, let $f : A \to B := (B, B^+, V)$ be any morphism of quasi-affinoid rings; set $(V, \mathcal{O}_V, B^+_V) := \text{Spec}(B)$ and denote by $\overline{B}$ the image of $B$ in $B^+_V := \mathcal{O}_V(V)$. We deduce easily from proposition 8.3.30(i) that (a) the subrings $\overline{A}$ and $\overline{B}$ are open in $A_U$ and $B_V$, so the induced map $\varphi : A_U \to B^+_V$ is continuous if and only the same holds for its restriction $\overline{f} : \overline{A} \to \overline{B}$, and (b) the topologies of $\overline{A}$ and $\overline{B}$ are induced from the surjections $A \to \overline{A}$ and $B \to \overline{B}$, so the continuity of $\overline{f}$ follows from that of $f$. Thus, $\varphi$ is continuous, and clearly $\varphi(\overline{A}_U) \subset B^+_V$, so $\varphi : \text{Spec}(B) \to \text{Spec}(A)$ is a well-defined morphism of quasi-affinoid schemes, and we let $\text{Spec}(f) := \varphi$.

Now, a simple inspection shows that $\text{Spec} \circ \Gamma$ is the identity automorphism of the category $\text{q.Afd.Sch}''$; on the other hand, for every quasi-affinoid ring $A := (A, A^+, U)$, the restriction map $A \to A_U$ determines a natural morphism $\eta_A : A \to \Gamma \circ \text{Spec}(A)$. Lastly, it is easily seen that the pair of natural transformations $(\varepsilon := 1_{\text{Spec}(A)}, \eta)$ fulfills the triangular identities of (1.1.13), so the assertion follows from proposition 1.1.15(i).

(ii): Indeed, set $A_U := \mathcal{O}_U(U)$ and $B_V := \mathcal{O}_V(V)$; by assumption there exist open and bounded subrings $A_0 \subset A$ and $B_0 \subset B$ such that $f(A_0) \subset B_0$, and $f$ restricts to an adic ring homomorphism $A_0 \to B_0$. Then, let $\overline{A}_0$ be the image of $A_0$ in $A_U$, and define likewise $\overline{B}_0 \subset B_V$; we know that $\overline{A}_0$ and $\overline{B}_0$ are open and bounded subrings of $A_U$ and respectively $B_V$, for the topologies induced by the latter topological rings, and the image of every ideal of adic definition of $A_0$ (resp. of $B_0$) is an ideal of adic definition of $\overline{A}_0$ (resp. of $\overline{B}_0$) (proposition 8.3.30(i)). It follows easily that the continuous map $A_U \to B_V$ restricts to an adic ring homomorphism $\overline{A}_0 \to \overline{B}_0$, whence the contention.

(iii) follows easily from the definitions. \qed

Example 15.4.4. Let $X := (X, \mathcal{X}, A_X^+)$ be any quasi-affinoid scheme, set $A_X := \mathcal{O}_X(X)$, and let $U \subset X$ be any quasi-compact open subset containing the analytic locus of $\text{Spec} A_X$. Let us denote by $F_U$ the presheaf on the category $\text{q.Afd.Sch}$ such that

$$F_U(Z) := \{ \varphi : Z \to X \mid \varphi(Z) \subset U \}$$

for every quasi-affinoid scheme $Z := (Z, \mathcal{O}_Z, A_Z^+)$, so that $F_U$ is a sub-presheaf of the presheaf $h_X$ represented by $X$. Let $A$ be the quasi-affinoid ring $(A_X, A_X^+, U)$; we claim that $F_U$ is representable by the quasi-affinoid scheme

$$U \times_X X := \text{Spec} A$$

Indeed, the identity map of $A_X$ yields a morphism of quasi-affinoid rings $i : \Gamma(X) \to A$; now, for every quasi-affinoid scheme $Z := (Z, \mathcal{O}_Z, A_Z^+)$, the datum of a morphism $\psi : Z \to U \times_X X$ of quasi-affinoid schemes is equivalent, by adjunction, to that of a morphism $g : A \to \Gamma(Z)$ of quasi-affinoid rings, and the composition $f := g \circ i : \Gamma(X) \to \Gamma(Z)$ is a morphism such that
Spec(f)(Z) ⊂ U, whence the morphism \( \varphi := \text{Spec}(f) : \mathbb{Z} \to \mathbb{X} \) with \( \varphi(Z) \subset U \). Conversely, any morphism \( \varphi : \mathbb{Z} \to \mathbb{X} \) with \( \varphi(Z) \subset U \) yields a morphism \( f(\varphi) : \Gamma(\mathbb{X}) \to \Gamma(Z) \) that factors uniquely through \( \mathbb{A} \), whence the contention.

**Example 15.4.5.** (i) Consider two f-adic morphisms of affinoid rings

\[
B' := (B', B'^+) \xleftarrow{g} B := (B, B^+) \xrightarrow{f} A := (A, A^+)
\]

and endow \( A' := B' \otimes_B A \) with the f-adic topology \( \mathcal{T}_{A'} \) characterized by proposition \[8.3.34\] i), so that the natural maps \( f' : B' \to A' \) and \( g_A : A \to A' \) are both f-adic. Let also \( R \subset A' \) be the image of \( B'^+ \otimes_B A^+ \), and denote by \( A'^+ \) the integral closure of \( R \) in \( A' \). Then the datum

\[
B' := (A', A'^+)
\]

is an affinoid ring. Indeed, a simple inspection of the definition of \( \mathcal{T}_{A'} \) shows that \( R \) is open in \( A' \), and we have \( g_A(A'^+), f(B'^+) \subset A'^0 \) by lemma \[8.3.24\] iii), so also \( R \subset A'^0 \), and then \( A'^+ \subset A'^0 \) as well, by remark \[8.3.10\] iv).

(ii) In the situation of (i), let also \( U_B \subset X_B := \text{Spec} B, U_A \subset X_A := \text{Spec} A \) and \( U_{B'} \subset X_{B'} := \text{Spec} B' \) be three open subsets, such that \( f \) and \( g \) are morphisms of quasi-affinoid rings

\[
(B', U_{B'}) \xleftarrow{g} (B, U_B) \xrightarrow{f} (A, U_A)
\]

and set \( U_{A'} := U_{B'} \times_{U_B} U_A \). Then the datum

\[
(B', U_{B'}) \otimes (U_B, U_A) := (B' \otimes_B A, U_{A'})
\]

is a quasi-affinoid ring as well. Indeed, let \( B_0 \subset B \) be a ring of definition, and \( I_0 \subset B_0 \) an ideal of adic definition; we need to show that \( \text{Spec} A \setminus \text{Spec} A'/I_0 A' \subset U_{A'} \). Set \( Z_B := X_B \setminus U_{B'} \) and \( Z_A := X_A \setminus U_A \), the assertion is equivalent to \( (Z_B \times_{X_B} X_A) \cup (X_{B'} \times_{X_B} Z_A) \subset \text{Spec} A'/I_0 A' \). The latter is clear, since by assumption \( Z_{B'} \subset \text{Spec} B'/I_0 B' \) and \( Z_A \subset \text{Spec} A/I_0 A \).

**Lemma 15.4.6.** With the notation of example \[15.4.5\] the resulting commutative diagrams

\[
\begin{array}{ccc}
B & \xrightarrow{f} & A \\
g \downarrow & & \downarrow g_A \\
B' & \xleftarrow{f'} & B' \otimes_B A
\end{array}
\quad
\begin{array}{ccc}
(B', U_{B'}) & \xrightarrow{f'} & (B' \otimes_B A, U_{A'}) \\
\downarrow g_A & & \downarrow g_A \\
(B', U_B) & \xrightarrow{f} & (A, U_A)
\end{array}
\]

are cocartesian in the categories \text{Afd.Ring} and respectively \text{q.Afd.Ring}.

**Proof.** Indeed, consider any two morphisms \( h : (A, A^+) \to (C, C^+) \), \( k : (B, B^+) \to (C, C^+) \) of affinoid rings such that \( h \circ f = k \circ g \); by proposition \[8.3.34\] i) there exists a unique continuous ring homomorphism \( l : A' \to C \) such that \( l \circ g_A = h \) and \( l \circ f' = k \), and it is easily seen that \( l(A'^+) \subset C^+ \), i.e. \( l : (A', A'^+) \to (C, C^+) \) is a morphism of affinoid rings, whence the assertion for the left diagram. The assertion for the right diagram is an immediate consequence.

**Example 15.4.7.** Consider a quasi-affinoid ring \( \mathbb{A} := (A, A^+) \) and any two f-adic morphisms \( f : B \to A, g : B' \to B' \) of f-adic rings.

(i) As a special case of example \[15.4.5\] i), take for \( B^+ \) and \( B'^+ \) the smallest subrings of integral elements of \( B \) and respectively \( B' \) (see remark \[15.4.2\] iv)) and set \( B := (B, B^+) \) and \( B' := (B', B'^+) \); we may regard \( f \) and \( g \) as morphisms \( B \to \mathbb{A} \) and \( B \to B' \) respectively. The resulting tensor product \( B' \otimes_B A \) shall be simply denoted

\[
B' \otimes_B \mathbb{A}
\]

By lemma \[15.4.6\] the resulting morphisms \( \mathbb{A} \xrightarrow{g_A} B' \otimes_B \mathbb{A} \xleftarrow{f'} B' \) enjoy the following universal property. Let \( (h, k) \) be any pair consisting of a morphism \( h : \mathbb{A} \to (C, C^+) \) of affinoid rings,
and a continuous ring homomorphism \( k : B' \to C \) such that \( h \circ f = k \circ g \); then there exists a unique morphism \( l : B' \otimes_B A \to (C, C^+) \) of affinoid rings such that \( l \circ g_A = h \) and \( l \circ f' = k \).

(ii) Likewise, let \((A, U)\) be a quasi-affinoid ring. As a special case of example [15.4.5(ii)], we may define \( B \) and \( B' \) as in (i), and take \( U_B := \text{Spec} B, U_{B'} := \text{Spec} B' \). There follow morphisms of quasi-affinoid rings \( f : (B, U_B) \to (A, U) \) and \( f' : (B, U_B) \to (B', U_{B'}) \). The resulting tensor product \( (B' \otimes_B A, U_{B'}) \) will be denoted simply
\[
B' \otimes_B (A, U)
\]
and notice that \( U_{B'} = \text{Spec} A' \times_{\text{Spec} A} U \). It follows easily from lemma [8.3.29(iv)] that this quasi-affinoid ring enjoys the corresponding universal property as in (i). Namely, let \((h, k)\) be any pair consisting of a morphism \( h : (A, U) \to (C, C^+, V) \) of quasi-affinoid rings, and \( k : B' \to C \) a continuous ring homomorphism such that \( h \circ f = k \circ g \); then there exists a unique morphism \( l : B' \otimes_B (A, U) \to (C, C^+, V) \) of quasi-affinoid rings such that \( l \circ g_A = h \) and \( l \circ f' = k \).

**Example 15.4.8.** Let \( X \to X \) and \( Y' \to Y \) be two \( f \)-adic morphisms of quasi-affinoid schemes. Then the fibre product \( X \times_Y Y' \) is representable in the category \qAfd.Sch. Indeed, the induced morphisms of quasi-affinoid rings \( \Gamma(X) \to \Gamma(Y) \) and \( \Gamma(X) \to \Gamma(Y') \) are \( f \)-adic, hence we may form the tensor product \( A := \Gamma(X) \otimes \Gamma(X) \Gamma(Y') \) as in example [15.4.5(ii)], and in view of lemma [15.4.6] the quasi-affinoid scheme \( \text{Spec} A \) represents the sought fibre product (details left to the reader).

**Example 15.4.9.** (i) Let \((A, A^+)\) be an affinoid ring and \( B \) a finite \( A \)-algebra. According to remark [8.3.43(iii)], the canonical topology \( T_B^A \) on \( B \) is \( f \)-adic, and the structure map \( \varphi : A \to B \) is \( f \)-adic and restricts to a finite map \( A_0 \to B_0 \) of suitable subrings of definition. Let \( B^+ \) be the integral closure of \( \varphi(A^+) \) in \( B \). We claim that \( B^+ \) is a ring of integral elements of \( B \). Indeed, \( B^+ \subseteq B^0 \) by lemma [8.3.24(iii.a)] and remark [8.3.10(iv)]. To check that \( B^+ \) is open in \( B \), pick a finite system \( b_1, \ldots, b_n \) of generators of the \( A_0 \)-module \( B_0 \); for every \( i = 1, \ldots, n \) there exist \( m_i \in \mathbb{N} \) and a polynomial \( P_i = X^{m_i} + \sum_{j=0}^{m_i-1} a_{ij} X^j \in A_0[X] \) with \( P_i(b_i) = 0 \). Let \( I_0 \subset A_0 \) be an ideal of adic definition; since \( A^+ \) is open, there exists \( k \in \mathbb{N} \) such that \( I_0^k a_{ij} \in A^+ \) for \( i = 1, \ldots, n \) and \( j = 0, \ldots, m_i - 1 \). Thus, for every \( c \in I_0^k b_0 \subset B^+ \) and any the contention. We call \((B, B^+)\) the affinoid ring associated with the finite \( A \)-algebra \( B \), and we denote it by
\[
B \otimes_A (A, A^+).
\]

(ii) Thus, we get an \( f \)-adic morphism \( \varphi : (A, A^+) \to B \otimes_A (A, A^+) \) of affinoid rings. We claim that the morphism of affinoid rings \( \varphi \) enjoys the following universal property. For every morphism \( f : (A, A^+) \to (C, C^+) \) of affinoid rings, every ring homomorphism \( g : B \to C \) such that \( g \circ \varphi = f \) is a morphism \( g : (B, B^+) \to (C, C^+) \) of affinoid rings. Indeed, a simple inspection shows that \( g(B^+) \subseteq C^+ \), and \( g \) is continuous by virtue of proposition [8.3.41(ii)].

(iii) As usual, the universal property determines the pair \((B \otimes_A (A, A^+), \varphi)\) up to unique isomorphism of affinoid rings. Especially, if \( \psi : B \to B' \) is any finite ring homomorphism, then \( \psi \circ \varphi : A \to B' \) is also finite, and it follows easily that
\[
B' \otimes_B (B \otimes_A (A, A^+)) = B' \otimes_A (A, A^+).
\]

(iv) Likewise, if \( A := (A, A^+, U) \) is any quasi-affinoid ring, and \( \varphi : A \to B \) as in (i), let us set \( U_B := \text{Spec} B \times_{\text{Spec} A} U \). According to example [15.4.7(ii)] we get a quasi-affinoid ring
\[
B \otimes_A A := (B, B^+, U_B)
(for the topology $\mathcal{T}_B^A$ on $B$) and $\varphi$ is an $f$-adic morphism of quasi-affinoid rings $A \to B \otimes_A A$ enjoying a corresponding universal property that the reader may spell out.

(v) In the same vein, let $X := (X, \mathcal{T}_X, A^+_X)$ be a quasi-affinoid scheme and $f : X' \to X$ a finite morphism of schemes; set $A_X := \mathcal{O}_X(X), Y := \text{Spec} A_X$ and let $i : X \to Y$ be the open immersion and $g := i \circ f : X' \to Y$. We have natural morphisms of quasi-coherent $\mathcal{O}_Y$-algebras $\tilde{g} : \mathcal{O}_Y \to i_* \mathcal{O}_X$ and $g^2 : i_* \mathcal{O}_X \to g_* \mathcal{O}_Y$, and we let $\mathcal{A}$ be the integral closure of the image of $i_* \mathcal{O}_X$ in $g_* \mathcal{O}_Y$. Notice that $\tilde{g}$ is an isomorphism, and $\mathcal{A}$ is a quasi-coherent $\mathcal{O}_Y$-algebra; hence $\mathcal{A}$ is the filtered union of its finite quasi-coherent $\mathcal{O}_Y$-subalgebras. Clearly $\mathcal{A}_X = f_* \mathcal{O}_Y$ is a finite $\mathcal{O}_X$-algebra; since $X$ is quasi-compact, it follows that there exists a finite quasi-coherent $\mathcal{O}_Y$-subalgebra $\mathcal{B} \subset \mathcal{A}$ such that $\mathcal{B}_X = f_* \mathcal{O}_Y$, and $B := \mathcal{B}(Y)$ is a finite $A_X$-algebra. We claim that the quasi-affinoid scheme $X' \times_X X := \text{Spec} (B \otimes_{A_X} \Gamma(X))$ is independent, up to unique isomorphism, of the choice of $\mathcal{A}$ and enjoys the following universal property. For every morphism of quasi-affinoid schemes $h : Z := (Z, \mathcal{T}_Z, A^+_Z) \to X$, every morphism $k : Z \to X'$ of schemes such that $f \circ k = h$ is a morphism of quasi-affinoid schemes $Z \to X' \times_X X$. Indeed notice that, by construction, the commutative diagram of schemes

$\begin{array}{ccc}
X' & \xrightarrow{j} & \text{Spec} B \\
| & & | \\
X & \xrightarrow{i} & Y
\end{array}$

is cartesian, hence $X'$ is the scheme underlying $X' \times_X X$. The morphisms $k$ and $j$ induce homomorphisms of $A_X$-algebras $\mathcal{O}_{X'} \to \mathcal{O}_Z(Z)$ and $B \to \mathcal{O}_Z$; their composition is a homomorphism of $A_X$-algebras $u : B \to \mathcal{O}_Z(Z)$, and since $\mathcal{O}_Z(Z)$ is a topological $(A_X, \mathcal{T}_X)$-algebra, (iv) implies that $u$ is a morphism of quasi-affinoid rings $B \otimes_{A_X} \Gamma(X) \to \Gamma(Z)$. By adjunction, $u$ induces a morphism of quasi-affinoid schemes $Z \to X' \times_X X$, and a simple inspection shows that this morphism is precisely given by $k$. Then the universal property implies as usual the stated independence of the choice of $\mathcal{A}$. By the same token, we also deduce that if $X'' \to X'$ is another finite morphism of schemes, we have a natural identification of quasi-affinoid schemes

$X'' \times_X X' \xrightarrow{(X' \times_X X) \sim} X' \times_X X$

(details left to the reader). Lastly, notice that the induced projection $X' \times_X X \to X$ is $f$-adic, by proposition 15.4.3(ii).

(vi) In the situation of (i) (resp. of (iv), resp. of (v)), suppose that $(A, A^+)$ (resp. $A$, resp. $X$) is topologically henselian; combining with proposition 8.4.2(iv) we deduce that the same holds for $B \otimes_A (A, A^+)$ (resp. for $B \otimes_A A$, resp. for $X' \times_X X$).

Remark 15.4.10. (i) Denote by $\text{Afd.Ring}_{\text{comp}}$ (resp. $\text{q.Afd.Ring}_{\text{comp}}$) the full subcategory of $\text{Afd.Ring}$ (resp. of $\text{q.Afd.Ring}$) whose objects are the complete and separated affinoid (resp. quasi-affinoid) rings. Then the inclusion functor

$\text{Afd.Ring}_{\text{comp}} \to \text{Afd.Ring}$ (resp. $\text{q.Afd.Ring}_{\text{comp}} \to \text{q.Afd.Ring}$)

admits a left adjoint, that assigns to every affinoid ring $(A, A^+)$ (resp. quasi-affinoid ring $(A, A^+, U)$) its completion, which is the datum

$(A, A^+) \mapsto (A^\wedge, (A^+)\wedge)$ (resp. $(A, A^+, U) \mapsto (A^\wedge, (A^+)\wedge, U^\wedge)$)

consisting of the separated completions of $A$ and $A^+$ (resp. and of the open subset $U^\wedge := U \times_{\text{Spec} A} \text{Spec} A^\wedge$). Indeed, taking into account proposition 8.3.33(i,iii) and lemma 8.3.6 we see that $(A, A^+)\wedge = A^\wedge \otimes_A (A, A^+)$ and $(A, A^+, U)\wedge = A^\wedge \otimes_A (A, A^+, U)$, so the sought adjunctions follow from example 15.4.7(i,ii).
(ii) Let \( Afd.Ring_{\text{hens}} \) (resp. \( q.Afd.Ring_{\text{hens}} \)) be the full subcategory of \( Afd.Ring \) (resp. of \( q.Afd.Ring \)) whose objects are the topologically henselian affinoid (resp. quasi-affinoid) rings. Then the inclusion functor

\[
Afd.Ring_{\text{hens}} \to Afd.Ring \quad \text{(resp. } q.Afd.Ring_{\text{hens}} \to q.Afd.Ring)\]

admits a left adjoint, that assigns to every affinoid ring \((A, A^+)\) (resp. quasi-affinoid ring \((A, A^+, U))\) its topological henselization, which is the datum

\[
(A, A^+)^h := (A^h, A^{+h}) \quad \text{(resp. } (A^h, A^{+h}, U^h))\]

consisting of the topological henselizations of \(A\) and \(A^+\) (resp. and of the open subset \(U^h := U \times_{\text{Spec } A} \text{Spec } A^h\) : see definition \[8.4.13\]). Indeed, by inspecting the construction of \[8.4.9\] it is easily seen that \(A^{+h}\) identifies naturally with an open subring of \(A^h\) contained in \((A^h)^{\circ}\). Moreover, \(A^{+h}\) is integrally closed in \(A^h\), by corollary \[9.8.6\](ii). Hence \((A, A^+)^h\) is a topologically henselian affinoid ring, and theorem \[8.4.10\](ii) easily implies that every morphism \((A, A^+) \to (B, B^+)\) of affinoid rings with \((B, B^+)\) topologically henselian, factors uniquely through a morphism \((A, A^+)^h \to (B, B^+)\). By the same token, we deduce that

\[
(A, A^+)^h = A^h \otimes_A (A, A^+)
\]

from which it follows that \((A, A^+, U)^h = A^h \otimes_A (A, A^+, U)\), whence also the second sought adjunction.

(iii) In the same vein, if \((A, A^+)\) (resp. \((A, A^+, U))\) is any affinoid (resp. quasi-affinoid) ring, we may define its topological localization by considering the datum \((A, A^+)_{\loc}\) (resp. \((A, A^+, U)_{\loc}\)) consisting of the topological localizations \(A_{\loc}\) and \(A^+_{\loc}\) of \(A\) and respectively \(A^+\), defined as in \[8.4.3\] (resp. and of the open subset \(U \times_{S_{\text{pec } A}} \text{Spec } A_{\loc}\)). Then it is easily seen that the rule \((A, A^+) \mapsto (A, A^+)_{\loc}\) (resp. \((A, A^+, U) \mapsto (A, A^+, U)_{\loc}\)) yields a left adjoint to the inclusion functor

\[
Afd.Ring_{\loc} \to Afd.Ring \quad \text{(resp. } q.Afd.Ring_{\loc} \to q.Afd.Ring)\]

from the full subcategory of \(Afd.Ring\) (resp. of \(q.Afd.Ring\)) whose objects are the topologically local affinoid (resp. quasi-affinoid) rings. Notice also that \((A, A^+)_{\loc} = A_{\loc} \otimes_A (A, A^+)\), and likewise for \((A, A^+, U)_{\loc}\).

(iv) Let \( X \) be any quasi-affinoid scheme; by definition, \( X \) is topologically local (resp. topologically henselian) if and only if the same holds for the quasi-affinoid ring \( \Gamma(X) \). On the other hand, let \( A := (A, A^+, U) \) be any quasi-affinoid ring; then \( A \) is topologically local (resp. topologically henselian) if and only if the same holds for the quasi-affinoid scheme \( \text{Spec } A \) (notation of proposition \[15.4.3\]). Indeed, set \( A_U := \mathcal{O}_U(U) \), and recall that the image \( B \) of \( A \) in \( A_U \) is open in the \( f \)-adic topology \( \mathcal{T}_U \) of \( A_U \) (proposition \[8.3.30\](i)). In light of proposition \[8.4.2\](ii,iii), we are then reduced to showing that \( A \) is topologically local (resp. topologically henselian) if and only if the same holds for \( B \), where the latter is endowed with the \( f \)-adic topology induced by the inclusion map into \( A_U \), which is the same as the topology induced by \( A \) via the surjection \( \pi : A \to B \). Let \( U_A \) and \( U_B \) be the analytic loci of \( \text{Spec } A \) and respectively \( \text{Spec } B \); since \( U \) contains \( U_A \), it is easily seen that \( \text{Spec } \pi \) induces a homeomorphism \( U_B \cong U_A \) (details left to the reader). On the other hand, notice that \( B^{\circ \circ} \) is the radical of the ideal \( A^{\circ \circ}B \); then the assertion follows from claim \[8.4.4\] and \[59\] Rem.5.1.10(i)].

(v) For every quasi-affinoid scheme \( X \), set

\[
X_{\loc} := \text{Spec}(\Gamma(X)_{\loc}) \quad X^h := \text{Spec}(\Gamma(X)^h).
\]

It follows easily from (iii),(iv), remark \[15.4.2\](ii) and proposition \[15.4.3\](ii) that \( X_{\loc} \) is a topologically local quasi-affinoid scheme endowed with a natural morphism \( j_X : X_{\loc} \to X \) with the
following property. Every morphism of quasi-affinoid schemes $Y \to X$ with $Y$ topologically local, factors uniquely through $j_X$. In other words, the rule $X \mapsto X_{\text{loc}}$ yields a right adjoint

$$q.\text{Afd.Sch} \to q.\text{Afd.Sch}_{\text{loc}}$$

to the inclusion functor of the full subcategory $q.\text{Afd.Sch}_{\text{loc}}$ of topologically local quasi-affinoid schemes. Likewise, $X^h$ is a topologically henselian quasi-affinoid scheme endowed with a universal morphism $h_X : X^h \to X$, so the rule $X \mapsto X^h$ yields a right adjoint

$$q.\text{Afd.Sch} \to q.\text{Afd.Sch}_{\text{hens}}$$

to the inclusion functor of the full subcategory $q.\text{Afd.Sch}_{\text{hens}}$ of topologically henselian quasi-affinoid schemes.

(vi) From (iv), we deduce that the adjunction $(\text{Spec}, \Gamma)$ of proposition 15.4.3(i) restricts to two adjoint pairs of functors

$$q.\text{Afd.Ring}_{\text{loc}} \xleftarrow{\Gamma} q.\text{Afd.Sch}_{\text{loc}}^o \quad q.\text{Afd.Ring}_{\text{hens}}^{\text{loc}} \xleftarrow{\Gamma} q.\text{Afd.Sch}_{\text{hens}}^o.$$ 

Taking into account (v) and remark [1.1.17](i), we then obtain natural isomorphisms

$$\text{Spec}(A_{\text{loc}}) \sim (\text{Spec } A)_{\text{loc}} \quad \text{Spec}(A_{\text{hens}}) \sim (\text{Spec } A)_{\text{hens}}$$

of quasi-affinoid schemes, for every quasi-affinoid ring $A$. On the other hand, we have as well natural identifications

$$(15.4.11) \quad \Gamma(X_{\text{loc}}) \sim \Gamma(X)_{\text{loc}} \quad \Gamma(X^h) \sim \Gamma(X)^h$$

for every quasi-affinoid scheme $X$. Indeed, if $\Gamma(X) = (A, A^+, U)$, we have $\Gamma(X)_{\text{loc}} = (A_{\text{loc}}, A^+_{\text{loc}}, U_{\text{loc}})$, where $U_{\text{loc}} = U \times_{\text{Spec } A} \text{Spec } A_{\text{loc}}$. Therefore $\Gamma(X_{\text{loc}}) = (B, B^+, U_{\text{loc}})$, where $B := \Theta_{h_{\text{loc}}}(U_{\text{loc}})$, and with $B^+$ equal to the integral closure of $A_{\text{loc}}^+$ in $B$. Since the localization map is flat, and since $A = \Theta(U)$, the assertion for $\Gamma(X_{\text{loc}})$ then follows from corollary 10.3.8.

The same argument applies to $\Gamma(X^h)$.

(vii) On the other hand, if $A := (A, A^+, U)$ is a complete and separated quasi-affinoid ring, the quasi-affinoid scheme $\text{Spec } A$ is not necessarily complete and separated (essentially, this is because the completion map $A \to A^\wedge$ is not necessarily flat, in this generality). Thus, in order to produce a completion functor for quasi-affinoid schemes, we have to proceed more carefully, as explained in the following proposition.

**Proposition 15.4.12.** Let $q.\text{Afd.Sch}_{\text{comp}}$ be the full subcategory of $q.\text{Afd.Sch}$ whose objects are the complete and separated quasi-affinoid schemes $(X, \mathcal{T}_X, A_X^+)$. Then the inclusion functor

$$q.\text{Afd.Sch}_{\text{comp}} \to q.\text{Afd.Sch}$$

admits a right adjoint, called the completion functor:

$$q.\text{Afd.Sch}_{\text{comp}} \to q.\text{Afd.Sch} \quad (X, \mathcal{T}_X, A_X^+) \mapsto (X, \mathcal{T}_X, A_X^+)^\wedge.$$ 

**Proof.** For any given quasi-affinoid scheme $(X, \mathcal{T}_X, A_X^+)$, set $A_X := \Theta(X, X)$, and denote by $(A_X^\wedge, \mathcal{T}_X^\wedge)$ the completion of $(A_X, \mathcal{T}_X)$. For every ideal $I \subset A_X^\wedge$, set as well

$$V(I) := \text{Spec } A_X^\wedge/I \quad \text{and} \quad X_I^\wedge := X \times_{\text{Spec } A_X} V(I).$$

We let $\mathcal{F}$ be the family of all topologically closed ideals $I \subset A_X^\wedge$ such that the induced map $\rho_I : A_X^\wedge/I \to \Theta_{V(I)}(X_I^\wedge)$ is injective. Set $J := \bigcap_{I \in \mathcal{F}} I$, so that the natural map $i : A_X^\wedge/J \to \prod_{I \in \mathcal{F}} A_X^\wedge/I$ is injective, and notice that $\prod_{I \in \mathcal{F}} \rho_I \circ i$ factors naturally through $\rho_J$, therefore the latter is injective, and thus $J \in \mathcal{F}$. We endow $A_I := A_X^\wedge/J$ with the quotient topology induced by the projection $\pi : A_X^\wedge \to A_I$; it is clear that $A_I$ is a complete and separated $\mathbb{F}$-adic ring, and $\pi$ is $\mathbb{F}$-adic (lemma [8.3.24](iv)), so we may define

$$(X, \mathcal{T}_X, A_X^+)^\wedge := \text{Spec } (A_I \otimes_{A_X^\wedge} (A_X, A_X^+, X)^\wedge).$$
Since the restriction map \( A' \to A'_X := \mathcal{O}_V(\mathcal{O}(X)^\wedge) \) is injective and open, the topology of \( A'_X \) is complete and separated, so the datum \((X, \mathscr{T}_X, A^+_X)\) is indeed an object of \( \text{q.Afd.Sch}_{\text{comp}} \).

On the other hand, let \( (Y, \mathcal{F}_Y, A^+_Y) \) be any complete and separated quasi-affinoid scheme, and \( f : (Y, \mathcal{F}_Y, A^+_Y) \to (X, \mathcal{F}_X, A^+_X) \) any morphism of quasi-affinoid schemes; by adjunction, \( \Gamma(f) \) factors uniquely through a morphism of complete quasi-affinoid rings

\[
\Gamma(f)^\wedge : (A_X, A^+_X, X) \to (Y, \mathcal{F}_Y, A^+_Y)
\]

and we let \( K \) be the kernel of the underlying continuous ring homomorphism \( h : A^+_X \to A_Y \). Clearly \( K \) is a closed ideal of \( A_X \), and \( \text{Spec} h \) restricts to a morphism of schemes \( g : Y \to V(K) \); then, the pair \((f, g)\) determines a unique morphism of \( X \)-schemes \( Y \to X^\wedge_K \). Therefore, the resulting map \( \bar{h} : A^+_X/K \to A_Y \) is injective by construction, and it factors through \( \rho_K \); so \( \rho_K \) is injective as well, and thus \( K \in \mathcal{F} \). Hence, \( h \) factors uniquely through a continuous ring homomorphism \( A' \to A_Y \), so in turns \( \Gamma(f)^\wedge \) factors uniquely through a morphism of quasi-affinoid rings

\[
\varphi : A' \otimes_{A_X} (A_X, A^+_X, X) \to \Gamma(Y, \mathcal{F}_Y, A^+_Y).
\]

and \( \text{Spec}(\varphi) : (Y, \mathcal{F}_Y, A^+_Y) \to (X, \mathcal{F}_X, A^+_X)^\wedge \) is the unique morphism of complete quasi-affinoid schemes that lifts \( f \), whence the proposition. \( \square \)

**Remark 15.4.13.** (i) Let \( X := (X, \mathcal{F}_X, A^+_X) \) be any quasi-affinoid scheme, set \((A_X, A^+_X, X) := \Gamma(X)\), and let \( A^+_X \) be the separated completion of \( A_X \). Let also \( I \subset A_X \) be any finitely generated ideal such that \( \text{Spec} A_X/I = \text{Spec} A_X \setminus X \). By inspecting the proof of proposition 15.4.12 we obtain a natural morphism of quasi-affinoid schemes

\[
X^\wedge \to \text{Spec}(\Gamma(X)^\wedge)
\]

which is an isomorphism if and only if \( \text{depth}_I A^+_X > 0 \) (notation of (10.4.29)).

(ii) The morphism of (i) induces by adjunction a morphism of quasi-affinoid rings

\[
\Gamma(X)^\wedge \to \Gamma(X^\wedge)
\]

which is an isomorphism if and only if \( \text{depth}_I A^+_X > 1 \).

**Definition 15.4.14.** Let \( A := (A, A^+, U) \) be any quasi-affinoid ring, and \( X := (X, \mathcal{F}_X, A^+_X) \) any quasi-affinoid scheme.

(i) The **adic spectrum** of the affinoid ring \((A, A^+)\) is the set

\[
\text{Spa}(A, A^+) := \{ v \in \text{Cont}(A) \mid v(a) \leq 1 \text{ for every } a \in A^+ \}
\]

(notation of definition 15.3.12). Hence, \( \text{Spa}(A, A^+) \) is a pro-constructible subset of \( \text{Cont}(A) \), and we endow \( \text{Spa}(A, A^+) \) with the topology induced by \( \text{Cont}(A) \). We also let

\[
\text{Spa}(A, A^+)_a := \text{Spa}(A, A^+) \cap \text{Cont}(A)_a \quad \text{Spa}(A, A^+)_\text{na} := \text{Spa}(A, A^+) \cap \text{Cont}(A)_\text{na}
\]

(notation of remark 15.3.13(vi)).

(ii) The **adic spectrum** of \( A \) is the set

\[
\text{Spa} A := \text{Spa}(A, A^+) \cap \text{Spv} U.
\]

We endow this subset with the topology induced by \( \text{Spa}(A, A^+) \).

(iii) The **adic spectrum** of \( X \) is the topological space

\[
\text{Spa} X := \text{Spa} \Gamma(X)
\]

and we set as well

\[
\text{Spa} (X)_a := \text{Spa} \Gamma(X)_a \quad \text{and} \quad \text{Spa} (X)_\text{na} := \text{Spa} \Gamma(X)_\text{na}.
\]

(iv) A **rational subset** of \( \text{Spa}(A, A^+, U) \) is a subset of the form \( R \cap \text{Spa}(A, A^+, U) \), where \( R \) is a rational subset of \( \text{Cont}(A) \) (see (15.3.16)). Likewise, a **rational subset** of \( \text{Spa} X \) is a subset of the form \( R \cap \text{Spa} X \), where \( R \) is a rational subset of \( \text{Cont}(\mathcal{O}(X), \mathcal{F}_X) \).
Remark 15.4.15. (i) Let \( f : (A, A^+) \to (B, B^+) \) be any morphism of affinoid rings. A simple inspection of definition 15.4.14(i) shows that the map \( \text{Cont}(f) \) restricts to a continuous map
\[
\text{Spa} f : \text{Spa}(B, B^+) \to \text{Spa}(A, A^+).
\]

(ii) More generally, a morphism \( g : (A, A^+, U) \to (B, B^+, V) \) of quasi-affinoid rings induces a continuous map
\[
\text{Spa} g : \text{Spa}(B, B^+, V) \to \text{Spa}(A, A^+, U)
\]
that agrees with the restriction of the map \( \text{Spa}(B, B^+) \to \text{Spa}(A, A^+) \) attached to \( g \) as in (i).

(iii) Likewise, any morphism \( \varphi : (X, \mathcal{T}_X, A^+_X) \to (Y, \mathcal{T}_Y, A^+_Y) \) of quasi-affinoid schemes induces a continuous map
\[
\text{Spa} \varphi := \text{Spa} \Gamma(\varphi) : \text{Spa}(X, \mathcal{T}_X, A^+_X) \to \text{Spa}(Y, \mathcal{T}_Y, A^+_Y).
\]

(iv) In light of theorem 15.3.15(i), it is easily seen that \( v(x) \leq 1 \) for every \( x \in A^0 \) and every \( v \in \text{Cont}(A) \) of rank \( \leq 1 \). Especially, the subset of \( \text{Spa}(A, A^+, U) \) consisting of rank one valuations is independent of the ring of integral elements \( A^+ \).

Example 15.4.16. For any \( f \)-adic ring \( A \), let \( A' \subset A \) be the smallest subring of integral elements (see remark 15.4.2(iv)). It is easily seen that \( \text{Spa}(A, A') = \text{Cont}(A) \). Also, every continuous map \( f : A \to B \) of \( f \)-adic rings yields a morphism of affinoid rings \( f : (A, A') \to (B, B') \), and clearly \( \text{Spa} \varphi = \text{Cont}(f) \).

(ii) On the other hand, every \( f \)-adic map \( f : A \to B \) of \( f \)-adic rings induces a continuous map \( \text{Spa} f : \text{Spa}(B, B^o) \to \text{Spa}(A, A^o) \) (lemma 8.3.24(iii.a)).

Lemma 15.4.17. Let \( A := (A, A^+, U) \) be any quasi-affinoid ring.

(i) The natural morphisms \( A \to A_{\text{loc}} \to A^h \to A^\wedge \) (notation of remark 15.4.10(ii,iii)) induce homeomorphisms
\[
\text{Spa} A^\wedge \iso \text{Spa} A^h \iso \text{Spa} A_{\text{loc}} \iso \text{Spa} A.
\]

(ii) The unit of the adjunction \( (\text{Spec}, \Gamma) \) of proposition 15.4.3(i) induces a homeomorphism
\[
\text{Spa}(\text{Spec } A) \iso \text{Spa} A.
\]

(iii) Let \( X := (X, \mathcal{T}_X, A^+_X) \) be any quasi-affinoid scheme, and \( X^\wedge \) the completion of \( X \) (see proposition 15.4.12). The completion map \( X \to X^\wedge \) induces a homeomorphism
\[
\text{Spa} X^\wedge \iso \text{Spa} X.
\]

(iv) Let \( \varphi : \text{Spa} A^\wedge \iso \text{Spa} A \) be the homeomorphism of (i), and \( R \subset \text{Spa} A^\wedge \) any rational subset. Then \( \varphi(R) \) is a rational subset of \( \text{Spa} A \).

Proof. (i): Let \( A_{\text{loc}} \) (resp. \( A^h \)) be the topological localization (resp. henselization) of \( A \); from corollary 8.4.14(i) and proposition 15.3.19(iv), we deduce that the natural maps \( A \to A_{\text{loc}} \to A^h \to A^\wedge \) induce homeomorphisms
\[
\text{Cont}(A^\wedge) \iso \text{Cont}(A^h) \iso \text{Cont}(A_{\text{loc}}) \iso \text{Cont}(A).
\]

Moreover, it was already remarked that the localization map induces a natural identification \( A_{\text{loc}} \iso A_{\text{loc}} \otimes_A (A, A^+) \), and likewise for the topological henselization and the completion of \( A \); the assertion follows easily (details left to the reader).

(ii): Set \( (U, \mathcal{T}_U, A^+_U) := \text{Spec } A \) and \( A_U := \mathcal{O}_U(U) \); the assertion boils down to the following:

Claim 15.4.18. The natural morphism of quasi-affinoid rings \( \rho : (A, A^+, U) \to (A_U, A^+_U, U) \) induces a homeomorphism \( \text{Spa} \rho : \text{Spa}(A_U, A^+_U, U) \iso \text{Spa}(A, A^+, U) \).
Proof of the claim. Let us first check that \( \rho \) induces a homeomorphism

\[
\text{Cont}(A_U) \cap \text{Spv} U \cong \text{Cont}(A) \cap \text{Spv} U.
\]

Indeed, since the topology of both of these spaces are induced from the inclusion into \( \text{Spv} U \), it suffices to check that \((15.4.19)\) is surjective. Hence, let \( v : A \to \Gamma_v \) be any continuous valuation with support given by a prime ideal \( p \subset A \), and suppose that \( p \in U \); then there exists a unique prime ideal \( p' \subset A_U \) such that \( p^{-1}p' = p \). Set \( B := A/p \) and \( C := A_U/p' \); the map \( v \) factors through a continuous valuation \( \pi : B \to \Gamma_v \) (for the quotient topology on \( B \) induced by the projection \( A \to B \)) and \( C \) is naturally identified with a subring of \( \text{Frac} B \), so \( v \) extends uniquely to a valuation \( w : C \to \Gamma_v \). It remains only to show that \( w \) is continuous, for the quotient topology on \( C \) induced by the projection \( A_U \to C \). By remark \((15.3.13)\) ii) it suffices to prove the continuity of \( w \) at the point \( 0 \in C \); however, \( \rho \) is an open map (proposition \((8.3.30)i))

\n
so the same holds for the induced injective map \( B \to C \), and the assertion follows.

Since \( A_U^+ \) is the integral closure of the image of \( A^+ \) in \( A_U \), the claim is an immediate consequence of the foregoing: details left to the reader.

\(\diamond\)

(iii): Let \( A_X := \mathcal{O}_X(X) \), and set \( (A_X^+, A_X^{+\wedge}, X^\wedge) := (A_X, A_X^+ \cap X^\wedge) \). Define the family \( \mathcal{F} \) of ideals of \( A_X \) as in the proof of proposition \((15.4.12)\), and denote by \( J \) the minimal element of \( \mathcal{F} \); also, endow \( A' := A_X^+/J \) with the quotient topology induced via the projection \( A_X^+ \to A' \). Then \( X^\wedge = \text{Spec}(A' \otimes A_X^+ (A_X^+, A_X^{+\wedge}, X^\wedge)) \). Taking into account (i) and (ii), we are then reduced to checking that the natural projection \( \pi : (A_X^+, A_X^{+\wedge}, X^\wedge) \to A' \otimes A_X^+ (A_X^+, A_X^{+\wedge}, X^\wedge) \) induces a homeomorphism

\[
\text{Spa} \pi : \text{Spa}(A' \otimes A_X^+ (A_X^+, A_X^{+\wedge}, X^\wedge)) \cong \text{Spa}(A_X^+, A_X^{+\wedge}, X^\wedge).
\]

However, \( \text{Spa} \pi \) is a closed immersion, so it suffices to show that it is a bijection. To this aim, let \( \pi : A_X^+ \to \Gamma_v \) be any continuous valuation whose support \( p \) lies in \( X^\wedge \); we come down to checking that \( \pi \in \mathcal{F} \). However, \( p \) is obviously a topologically closed ideal of \( A_X^+ \). Next, set \( B := A_X^+/p \) and \( X_p^\wedge := X \times_{\text{Spec} A_X} \text{Spec} B \); since \( B \) is a domain and \( X_p^\wedge \neq \emptyset \), the restriction map \( B \to \mathcal{O}_{\text{Spec} B}(X_p^\wedge) \) is injective, whence the contention.

(iv): Say that \( R = R_{A^+} \left( a_1 b_1, \ldots, a_n b_n \right) \cap \text{Spa} A^\wedge \) for a sequence of elements \( a_0, \ldots, a_n \in A^\wedge \) that generates an open ideal \( J \). Let also \( B \) be a ring of definition of \( A \), and \( I \subset B \) an ideal of adic definition. To begin with, we remark :

Claim 15.4.20. (i) Let \( T \) be a quasi-compact subset of \( \text{Spa} A^+ \), and \( t \) an element of \( A^\wedge \) such that \( v(t) \neq 0 \) for every \( v \in T \). Then there exists \( k \in N \) such that \( v(x) < v(t) \) for every \( v \in T \) and every \( x \in I^k \).

(ii) There exists \( q \in N \) such that every sequence \( b_0, \ldots, b_n \) with \( b_i \in a_i + I^q B^\wedge \) for \( i = 0, \ldots, n \), generates an open ideal of \( A^\wedge \), and \( R' := R_{A^+} \left( b_0 b_0, \ldots, b_n b_n \right) \cap \text{Spa} A^\wedge = R \).

Proof of the claim. (i): Let \( x_1, \ldots, x_m \) be a finite system of generators of \( I \). For every \( r \in N \) set

\[
T_r := \{ v \in \text{Spa} A^+ | v(x_i^r) \leq v(t) \} \text{ for every } i = 1, \ldots, m \}.
\]

Then \( T_r \) is open in \( \text{Spa} A^+ \) for every \( r \in N \), and \( T \subset \bigcup_{r \in N} T_r \). Thus, \( T \subset T_r \) for some \( r \in N \), and the assertion holds with \( k := r + 1 \).

(ii): Pick elements \( c_1, \ldots, c_m \in J \cap B^\wedge \) that generate an open ideal \( J_0 \) of \( B^\wedge \), and \( r \in N \) such that \( I^r \subset J_0 \). Then, every sequence \( d_1, \ldots, d_m \) of elements of \( B^\wedge \) with \( d_i \in c_i + I^r B^\wedge \) for \( i = 1, \ldots, m \), also generates \( J_0 \) \((100) \text{ Th.8.4})\). Next, for every \( i = 1, \ldots, m \) pick \( x_{i0}, \ldots, x_{in} \in A^\wedge \) such that \( c_i = \sum_{j=0}^n n_{ij} x_{ij} \), and let \( p \in N \) be large enough so that \( I^p x_{ij} \subset I^r B^\wedge \) for every \( i = 1, \ldots, m \) and every \( j = 0, \ldots, n \); it follows already that every sequence \( b_0, \ldots, b_n \) of elements of \( A^\wedge \) with \( b_i \in a_i + I^p B^\wedge \) for \( i = 0, \ldots, n \), generates an open ideal of \( A^\wedge \).

Next, we apply part (i) of the claim to the rational subsets \( R_i := R_{A^+} \left( a_1 b_1, \ldots, a_n b_n \right) \cap \text{Spa} A^\wedge \), to find an integer \( q \geq p \) such that \( v(x_i) < v(a_i) \) for every \( x_i \in I^p B^\wedge \), every \( i = 0, \ldots, n \) and
every $v \in R_i$. We claim that this $q$ will do. Indeed, let $v \in \text{Spa} A^\wedge_+$ and say that $v \in R = R_0$; since $b_i - a_i \in I^p B^\wedge$, we have $v(b_i - a_i) < v(a_0)$ for $i = 0, \ldots, n$. This implies that

$$v(b_i) = v(a_i + (b_i - a_i)) \leq \max(v(a_i), v(b_i - a_i)) \leq v(a_0) = v(a_0 + (b_0 - a_0)) = v(b_0)$$

for every $i = 0, \ldots, n$, which shows that $R \subset R'$. Next, suppose $v \notin R$, and consider first the case where $v(a_i) = 0$ for every $i = 0, \ldots, n$. Then $v$ is non-analytic, so that $v(b_0 - a_0) = 0$, whence $v(b_0) = 0$, and finally $v \notin R'$. Lastly, suppose that $v(a_i) \neq 0$ for some $i \leq n$, and choose $j \leq n$ so that $v \in R_j$. We must have $v(a_0) < v(a_j)$, since $v \notin R$; also, by construction $v(b_i - a_i) < v(a_j)$ for every $i = 0, \ldots, n$. Then

$$v(b_0) = v(a_0 + (b_0 - a_0)) \leq \max(v(a_0), v(b_0 - a_0)) < v(a_j) = v(a_j + (b_j - a_j)) = v(b_j)$$

which yields again $v \notin R'$, and the claim follows.

Now, by claim [15.4.20(ii)] there exist $b_0, \ldots, b_n$ in $A$ such that $R = R_A \bigcap \text{Spa} A^\wedge$. Also, by claim [15.4.20(i)] there exists $k \in \mathbb{N}$ such that $v(x) < v(b_0)$ for every $v \in R$ and every $x \in I^k$. Pick a finite system $b_{n+1}, \ldots, b_p$ of generators of $I^k$; it follows that $\varphi(R) = R_A \bigcap \text{Spa} A^\wedge$, whence the contention. □

**Remark 15.4.21.** By combining lemma [15.4.17](iv) and proposition [15.3.19](i) one may obtain another, more constructive, proof of lemma [15.4.17](i) (and of proposition [15.3.19](iv)). This is the route followed in [79].

**Proposition 15.4.22.** Let $(A, A^+, U)$ be any quasi-affinoid ring. The following holds:

(i) $\text{Spa}(A, A^+, U)$ is a constructible open subset of $\text{Spa}(A, A^+)$, and both these topological spaces are spectral.

(ii) The rational subsets are a basis of quasi-compact open subsets of $\text{Spa}(A, A^+)$ that is closed under finite intersections.

(iii) For any morphism $f : (A, A^+, U) \to (B, B^+, V)$ of quasi-affinoid rings, we have:

(a) If $f$ is $f$-adic, $\text{Spa} f$ is a spectral map. More precisely, if $R$ is a rational subset of $\text{Spa}(A, A^+, U)$, then $(\text{Spa} f)^{-1}(R)$ is a rational subset of $\text{Spa}(B, B^+, V)$.

(b) Suppose that $B$ is topologically local. Then $f$ is $f$-adic if and only if $\text{Spa} f$ restricts to a map $\text{Spa}(B, B^+)_a \to \text{Spa}(A, A^+)_a$.

(iv) For any quasi-affinoid scheme $(X, \mathcal{X}, A^+_X)$, the topological space $\text{Spa}(X, \mathcal{X}, A^+_X)$ is spectral.

(v) For any $f$-adic morphism $\varphi : (X, \mathcal{X}, A^+_X) \to (Y, \mathcal{Y}, A^+_Y)$ of quasi-affinoid schemes, the induced map $\text{Spa} \varphi$ is spectral.

**Proof.** Assertion (i) for $\text{Spa}(A, A^+)$ follows from theorem [15.3.15](ii) and corollary [8.1.40]. According to [15.3.16], the rational subsets of $\text{Cont}(A)$ form a basis of quasi-compact open subsets for the latter space; invoking again corollary [8.1.40], we obtain (ii) as well.

Next, let $I \subset A$ be any finitely generated ideal such that $\text{Spec} A/I = \text{Spec} A \setminus U$, and pick a finite system of generators $a_1, \ldots, a_n$ for $I$. Then

$$\text{Spa}(A, A^+, U) = \text{Spa}(A, A^+) \cap \bigcup_{i=1}^n R_A \left( \frac{a_1}{a_i}, \ldots, \frac{a_n}{a_i} \right).$$

Since $I$ is open in $A$, this identity presents $\text{Spa}(A, A^+, U)$ as a finite union of rational subsets of $\text{Spa}(A, A^+)$, and the latter are open and quasi-compact, by (ii), so the proof of (i) is complete.

(iii.a) follows immediately from corollary [15.3.17](i). The proofs of (iv) and (v) are similar, and the details shall be left to the reader.

(iii.b): Set $\varphi := \text{Spec} f$; in light of lemma [8.3.29](iv) and corollary [15.3.21], we need only check that $\varphi^{-1} X_A^\infty = X_B^\infty$, if $\text{Spa} f$ restricts to a map $\text{Spa}(B, B^+)_a \to \text{Spa}(A, A^+)_a$. 

Proposition 15.4.24. Proof of the claim.

Then of the claim. Then for every $f \in \mathbb{Q}$, if $\Gamma \in \mathbb{Q}$, then consider also the set $A \subset \mathbb{Q}$ for some $\Omega \in \mathbb{Q}$. Since $\Omega \in \mathbb{Q}$, then set $H_{\Omega}$ is a homogeneous polynomial.

Proof. In light of (b), we may next find $M \in \mathbb{Q}$ sufficiently large, finite subsets $\Sigma_0 \subset \Sigma$, $\Sigma' \subset \Sigma'$, and systems $(b_i \mid i \in \Sigma_0)$, $(c_j \mid j \in \Sigma'_0)$ of elements of $A$ such that

$$a^N f^n = \sum_{i \in \Sigma_0} b_i g_i^n + \sum_{j \in \Sigma'_0} c_j h_j^n.$$ 

In light of (b), we may next find $M \in \mathbb{Q}$ sufficiently large, so that $a^M b_i \in \mathbb{A}^+$ and $a^M c_j \in \mathbb{I}$ for every $i \in \Sigma_0$ and $j \in \Sigma'_0$. Summing up, we see that $a^{M+N} f^n = H(g_i, h_j)$ in $A$ for some homogeneous polynomial $H(X_i, Y_j) \in \mathbb{A}^+[X_i, Y_j]$ of degree $n$ and with $H(0, Y_j) \in \mathbb{I}[Y_j]$. Then set $u := 1 + a + \cdots + a^{M+N-1}$, so that $u \cdot (1 - a) = 1 - a^{M+N}$; it follows that the polynomial

$$P := u \cdot G + a^{M+N-1} Z^n - H$$

fulfills condition (e).
Now, if (e) fails for some $f \in A$, claim [15.4.25] and lemma [9.2.40] show that there exists $w \in \text{Spv} A'$ whose support is a minimal prime ideal of $A'$, and with $w(f) \neq 0$ and

$$
\begin{align*}
  w(a) &\leq 1 \\
  w(b) &< 1 \\
  w(g) &< w(f) \\
  w(h) &\leq w(f)
\end{align*}
$$

for every $a \in A^+$ and $b \in A^{\infty}$

Since $U'$ is dense in $\text{Spec} A'$, we have $w \in \text{Spv} U'$ (proposition [8.1.44](iii)); if $w$ is continuous, it follows that $w \in \text{Spa}(A', A^+, U') = \text{Spa}(A, A^+, U)$ (lemma [15.4.17](i)), and (d) fails for $w$. In case $w$ is not continuous, set $L := IA$ and $v := w^{\Gamma_v(L)}$ (notation of definition [15.3.3])

**Claim 15.4.26** (i) $v(L) \neq \{0\}$.

(ii) $v(f) \neq 0$.

**Proof of the claim.** (i): Since $v$ is an $L$-admissible specialization of $w$, it suffices to show that $w(L) \neq \{0\}$. But if the latter fails, then the support of $w$ is an open prime ideal, so $w$ is continuous (remark [15.3.13](vi)), contradicting our assumption.

(ii): Suppose that $v(f) = 0$; then $v(g) = v(h) = 0$ as well, for every $i \in \Sigma$ and $j \in \Sigma'$. Hence the support of $v$ is an open ideal of $A$, and especially, it contains $L$, contradicting (i). ◯

**Claim 15.4.26** (ii), theorem [15.3.15](i) and lemma [15.4.17](i) imply that $v$ is an analytic point of $\text{Spa}(A, A^+)$ and condition (d) fails for $v$; lastly, notice that $\text{Cont}(A)_v \subset \text{Spv} U$, so $v \in \text{Spa}(A, A^+, U)$ whence the proposition.

**Corollary 15.4.27.** Let $A := (A, A^+, U)$ be any quasi-affinoid ring such that $U$ is dense in $\text{Spec} A$, and $f \in A$ any element. We have:

(i) $f \in A^+$ if and only if $v(f) \leq 1$ for every $v \in \text{Spa} A$.

(ii) $f \in A^{\infty}$ if and only if $v(f) < 1$ for every $v \in \text{Spa} A$.

(iii) Let also $J \subset A^+$ be any finitely generated ideal whose radical is $A^{\infty}$. Then the following conditions are equivalent:

(a) $|[f]_v^*| = 0$ (notation of example [9.1.9]).

(b) $v(f) = 0$ for every $v \in \text{Spa} A$.

**Proof.** (i): We may assume that $v(f) \leq 1$ for every $v \in \text{Spa} A$, and we show that $f \in A^+$. To this aim, we apply proposition [15.4.24] with $g_• = \{1\}$, $h_•$ the empty subset and $I := A^{\infty}$; we deduce that there exists a monic polynomial $P(Z) \in A^+[Z]$ with $P(f) = 0$, i.e. $f$ is integral over $A^+$, whence the contention, since $A^+$ is integrally closed in $A$.

(ii): Again, we may assume that $v(f) < 1$ for every $v \in \text{Spa} A$, and we check that $f \in A^{\infty}$. To this aim, we apply proposition [15.4.24] with $h_• = \{1\}$, $g_•$ the empty subset and $I := A^{\infty}$; we deduce that there exist $n \in \mathbb{N}$ and $a_1, \ldots, a_n \in A^{\infty}$ with $f^n + f^{n-1}a_1 + \cdots + a_n = 0$. By (i), we know already that $f \in A^+$, so that $f^{n-1}a_1 + \cdots + a_n \in A^{\infty}$, and combining with remark [8.3.10](iv), the claim follows.

(iii.a)⇒(iii.b): Let $a_1, \ldots, a_r$ be any finite system of generators of $J$, and set

$$
\gamma_v := \max(v(a_1), \ldots, v(a_r)) \in \Gamma_v 
$$

for every $v \in \text{Spa}(A, A^+, U)$.

The assumption implies that for every $n \in \mathbb{N}$ there exists $k \in \mathbb{N}$ such that $f^k \in J^k$, hence $v(f^k) \leq \gamma_v^{kn}$, and therefore $v(f) \leq \gamma_v^n$ for every $n \in \mathbb{N}$ and every $v \in \text{Spa} A$ (details left to the reader). However $\gamma_v$ is final in $\Gamma_v$ for every such $v$ (lemma [15.3.14](ii)), whence the assertion.

(iii.b)⇒(iii.a): For every $v \in \mathbb{N}$, we apply the criterion of proposition [15.4.24] with $g_•$ equal to the empty set, $h_•^{(n)} := \{1\}$, and $I := J^n$. We deduce that for every $v \in \mathbb{N}$ there exist $k \in \mathbb{N}$ and elements $a_i^{(n)} \in J^{ni}$ for $i = 1, \ldots, k$, such that $f^{k+1} + a_i^{(n)}f^k + \cdots + a_k^{(n)} = 0$. Therefore:

$$
|f^{k+1}|^*_v \leq \max([a_i^{(n)}]_j^* \cdot |f^{k+1-i}|^*_j) \quad i = 1, \ldots, k
$$

(lemma [9.1.8](ii)) whence $|(f)^*_v| \leq |a_i^{(n)}|_j^* \leq \rho^{ni}$ for some $i \leq k$, (lemma [9.1.8](iii)), and consequently $|f|_v^* \leq \rho^n$ for every $n \in \mathbb{N}$, whence (iii.a). □
Corollary 15.4.28. Let $X := (X, \mathcal{T}_X, A_X)$ be any quasi-affinoid scheme, and $(X^\wedge, \mathcal{T}_X^\wedge, A_X^\wedge)$ the completion of $X$. Denote by $A_X^\wedge$ (resp. $A_X^{\wedge +}$) the separated completion of $A_X := \mathcal{O}_X(X)$ (resp. of $A_X^+$). Then we have:

(i) The kernel $\mathcal{J}$ of the natural map $\pi : A_X^\wedge \to \mathcal{O}_X(X^\wedge)$ is contained in $(A_X^\wedge)_{\infty}$.

(ii) $\pi^{-1}A_X^\wedge = A_X^{\wedge +}$.

Proof. (i): To begin with, we remark, quite generally:

Claim 15.4.29. Let $A$ be any ring, $I \subset A$ a finitely generated ideal, and set $X_A := \text{Spec } A$ $Z := \text{Spec } A/I$ $U := X_A \setminus Z$.

Then the following conditions are equivalent:

(a) $U$ is dense in $X_A$.

(b) The support of the $A$-module $I^n/I^{n+1}$ is $Z$, for every $n \in \mathbb{N}$.

Proof of the claim. Since $U$ is constructible in $X_A$, condition (a) is equivalent to:

(c) $I_q = A_q$ for every minimal prime ideal $q$ of $A$ (proposition 8.1.44(iii)). Now, if $A = 0$ there is nothing to prove, so assume that $A \neq 0$.

Suppose that (c) holds. Clearly the support of $I^n/I^{n+1}$ lies in $Z$, so we consider any $p \in Z$, and we have to show that $I_p^n/I_p^{n+1} \neq 0$ for every $n \in \mathbb{N}$. However, if the latter fails for some $n \in \mathbb{N}$, Nakayama’s lemma implies that $I^n_p = 0$; then $I^n_q = 0$ for every minimal prime ideal $q$ of $A$ contained in $p$, contradicting (c).

Conversely, if (c) fails for some minimal prime ideal $q$, it follows that $I_q$ is a nilpotent ideal of $A_q$. Say that $I^n_q \neq 0$ and $I_q^{n+1} = 0$ for some $n \in \mathbb{N}$; then $q$ lies in the support of $I^n/I^{n+1}$, hence $q \in Z$, and therefore $U$ cannot be dense in $X_A$.

Set $Y := \text{Spec } A_X$, $Y := \text{Spec } A_X^\wedge$, $X' := X \times_Y Y'$, and let $I \subset A_X$ be any ideal such that $A_X^\wedge \subset I$ and $Y \setminus X = \text{Spec } A_X/I$. Then $Y' \setminus X' = \text{Spec } A_X^\wedge/I'$, where $I' := IA_X^\wedge$, and since $I$ is open in $A_X$, the natural maps $I^n/I^{n+1} \to I^n/I^{n+1}$ are bijective for every $n \in \mathbb{N}$. Moreover, by assumption $X$ is dense in $Y$; taking into account claim 15.4.29 we deduce that $X'$ is dense in $Y'$. Pick any finitely generated ideal $J$ of $A_X^\wedge$ whose radical is $A_X^{\wedge +}$; in view of corollary 15.4.27(ii,iii), we see that

$$\bigcap_{v \in \text{Spa}(A_X^\wedge, A_X^{\wedge +}, X')} \ker v = \{a \in A_X^\wedge \mid |a|^v = 0\} \subset (A_X^\wedge)_{\infty}.$$  

But we have already noticed that $\mathcal{J}$ is contained in the support of every $v \in \text{Spa}(A_X^\wedge, A_X^{\wedge +}, X')$ (see the proof of lemma 15.4.17(iii)), whence (i).

(ii) follows immediately from (i) and corollary 15.4.27(i) and lemma 15.4.17(iii) (details left to the reader; more directly, one can also argue as in the proof of theorem 16.5.13(ii)).}

Proposition 15.4.30. Let $(X, \mathcal{T}_X, A_X^\wedge)$ be any topologically local quasi-affinoid scheme, and $f \in \mathcal{O}_X(X)$ any element. The following conditions are equivalent:

(a) $f \in \mathcal{O}_X(X)^\wedge$.

(b) $v(f) \neq 0$ for every $v \in \text{Spa}(X, \mathcal{T}_X, A_X^\wedge)$.

Proof. Clearly, it suffices to check that (b)⇒(a). Hence, suppose that (b) holds, and set $A_X := \mathcal{O}_X(X)$ $Y := \text{Spec } A_X$ $Y^{\infty} := \text{Spec } A_X/A_X^{\infty} \cdot A_X$.

Let $x \in X$ be any point; we need to show that the image $f(x)$ of $f$ does not vanish in $\kappa(x)$. If $x \in Y^{\infty}$, let $v$ be the trivial valuation with support equal to $x$; clearly $v \in \text{Spa}(X, \mathcal{T}_X, A_X^\wedge)$, so (b) says that $v(f) \neq 0$, whence the contention, in this case.

Next, if $x \in X \setminus Y^{\infty}$, we proceed as in the proof of proposition 15.4.22(iii,b) : we pick first a minimal specialization $y$ of $x$ in $X \setminus Y^{\infty}$, then a maximal point $p$ of the non-empty closed
subset \( \{y\}^c \cap Y^{\infty} \) of \( Y \) (where \( \{y\}^c \) denotes the topological closure of \( \{y\} \) in \( Y \)). The image \( C \) of \( A_{X,\pi} \) in \( \kappa(y) \) is a one-dimensional local domain, so we may find a valuation ring \( V \) of \( \kappa(y) \) with value group of rank one, that dominates \( C \) (claim 15.3.27). Let \( v \in \text{Spv} \ A_X \) be the valuation corresponding to \( V \); arguing as in \textit{loc. cit.} we see that \( v \in \text{Spa}(X, \mathcal{T}_X, A_X^+) \), hence \( v(f) \neq 0 \), so \( f(y) \neq 0 \) and finally \( f(x) \neq 0 \) as well.

\[ \square \]

15.5. Adic spaces. In this section we shall endow the adic spectra introduced in section 15.3 with certain natural presheaves of topological rings, and we shall show that, under suitable conditions, these presheaves are sheaves of rings or of topological rings. The first step is the following universal construction:

15.5.1. Let \( A := (A, A^+, U) \) be any quasi-affinoid ring, \( \Lambda \) a (small) set, \( S := (s_\lambda | \lambda \in \Lambda) \) a system of elements of \( A \), and \( T := (T_\lambda | \lambda \in \Lambda) \) a family of subsets of \( A \) such that \( T_\lambda \) generates an open ideal of \( A \), for every \( \lambda \in \Lambda \). We consider the \( f \)-adic ring \( A[X_\lambda | \lambda \in \Lambda]_T \) provided by proposition 8.3.37(ii), and its ideal \( J \) generated by the system \( \{1 - s_\lambda X_\lambda | \lambda \in \Lambda \} \). We set

\[ A\left(\frac{T}{S}\right) := A[X_\lambda]_T / J \]

and we endow this ring with the quotient topology induced by \( A[X_\lambda]_T \) via the natural projection. In other words, \( A(\frac{T}{S}) \) is an \( f \)-adic topological ring whose underlying \( A \)-algebra is naturally identified with the localization \( A[s_\lambda^{-1} | \lambda \in \Lambda] \). From proposition 8.3.37(iii,iv) we see that – under this identification – the subset \( \{t/s_\lambda | \lambda \in \Lambda, t \in T_\lambda\} \) is power bounded in \( A(\frac{T}{S}) \).

Moreover, the localization map \( h : A \to A(\frac{T}{S}) \) is \( f \)-adic, and enjoys the following universal property. For every \( f \)-adic ring \( B \) and every continuous map \( f : A \to B \) such that:

- \( f(s_\lambda) \in B^\times \) for every \( \lambda \in \Lambda \)
- the subset \( \{f(t)/f(s_\lambda) | \lambda \in \Lambda, t \in T_\lambda\} \) is power bounded in \( B \)

there exists a unique continuous map \( g : A(\frac{T}{S}) \to B \) such that \( g \circ h = f \). Furthermore, if \( A_0 \subset A \) is a subring of definition, \( A_0[\frac{t}{s_\lambda} | \lambda \in \Lambda, t \in T_\lambda] \) is a subring of definition of \( A(\frac{T}{S}) \).

Next, notice that \( C := A^+[\frac{t}{s_\lambda} | \lambda \in \Lambda, t \in T_\lambda] \) is an open subring of \( A(\frac{T}{S})^o \), and denote by \( C' \) the integral closure of \( C \) in \( A(\frac{T}{S}) \). Moreover, set \( X := \text{Spec} A[s_\lambda^{-1} | \lambda \in \Lambda] \), and notice that \( U' := U \cap X \) contains the analytic locus of \( X \), since \( h \) is \( f \)-adic (lemma 8.3.29(iv)). We obtain therefore a quasi-affinoid ring

\[ A\left(\frac{T}{S}\right) := \left(A\left(\frac{T}{S}\right), C', U'\right) \]

and the localization map yields a natural \( f \)-adic morphism of quasi-affinoid rings

\[ A \to A\left(\frac{T}{S}\right). \]

In case \( \Lambda = \{\lambda\} \) has only one element, \( T_\lambda = \{f_0, \ldots, f_n\} \) is a finite subset of \( A \) which generates an open ideal, and \( S = \{s\} \) for some \( s \in A \), we also denote this quasi-affinoid ring by:

\[ A\left(\frac{f_0, \ldots, f_n}{s}\right). \]

15.5.3. We consider now the Yoneda embedding (see 1.2.4)

\[ h : q.Afd.Sch^{\text{loc}} \to q.Afd.Sch^{\text{loc}}, \quad X \mapsto h_X \]

(notation of remark 15.4.10(v)). Let \( X \) be any topologically local quasi-affinoid scheme, and \( U \subset \text{Spa} X \) any open subset. We attach to \( U \) the sub-presheaf \( h_U \subset h_X \) given by the rule:

\[ h_U(Y) := \{\varphi \in h_X(Y) | \text{Im}\text{Spa} (\varphi) \subset U\} \]

for every \( Y \in \text{Ob}(q.Afd.Sch^{\text{loc}}) \).
Definition 15.5.4. (i) In the situation of (15.5.3), we say that \( U \) is a quasi-affinoid open subset of \( \text{Spa} \mathcal{X} \), if the presheaf \( h_U \) is representable by some \( Y \in \text{Ob}(\mathfrak{qAfdSch}_{\text{loc}}) \).

(ii) We say that \( U \) is an affinoid open subset of \( \text{Spa} \mathcal{X} \), if \( Y \) as in (i) is an affinoid scheme.

Theorem 15.5.5. Every rational subset of \( \text{Spa} \mathcal{X} \) is a quasi-affinoid open subset.

Proof. Let \( R \) be such a rational subset, and say that

\[
\Gamma(X) = (A_X, A_X^+, X) \quad \text{and} \quad R = R_{A_X}(f_1, \ldots, f_n) \cap \text{Spa} \mathcal{X}
\]

for a sequence \( (f_0, f_1, \ldots, f_n) \) of elements of \( A_X \) that generates an open ideal. We consider the quasi-affinoid rings

\[
\mathcal{A}_R := \Gamma(X)\left(\frac{f_0, \ldots, f_n}{f_0}\right)
\]

defined as in (15.5.1). Also, we let

\[
i_R : \Gamma(X) \to \mathcal{A}_{R, \text{loc}}
\]

be the composition of the natural morphism \( \Gamma(X) \to \mathcal{A}_R \) of (15.5.2) with the topological localization \( \mathcal{A}_R \to \mathcal{A}_{R, \text{loc}} \). Now, let \( Y \) be any topologically local quasi-affinoid scheme, and \( \varphi \in h_R(Y) \) any element. Set \((A_Y, A_Y^+, Y) := \Gamma(Y)\), and let \( \varphi^\#: A_X \to A_Y \) be the continuous map associated with \( \varphi \).

Claim 15.5.6. \( \varphi^\#(f_0) \in A_Y^+ \) and \( \varphi^\#(f_i)/\varphi^\#(f_0) \in A_Y^+ \) for every \( i = 1, \ldots, n \).

Proof of the claim. Indeed, for every \( v \in \text{Spa} Y \) we have by assumption \( v \circ \varphi^\# \in R \), so that \( v(\varphi^\#(f_0)) \neq 0 \) and \( v(\varphi^\#(f_i)) \leq v(\varphi^\#(f_0)) \) for \( i = 1, \ldots, n \). Then proposition (15.4.30) implies that \( \varphi^\#(f_0) \in A_Y^+ \), so we may write \( v(\varphi^\#(f_i)/\varphi^\#(f_0)) \leq 1 \) for every \( i = 1, \ldots, n \) and every \( v \in \text{Spa} Y \). To conclude, it then suffices to invoke corollary (15.4.27)(i).

From claim (15.5.6), remark 8.3.9(ii) and the discussion of (15.5.1) we see that \( \varphi^\# \) factors uniquely through a continuous ring homomorphism \( g : A_R \to A_Y \), and \( g(f_i/f_0) \in A_Y^+ \) for every \( i = 1, \ldots, n \). Thus, \( g \) defines a morphism of quasi-affinoid rings

\[
g : \mathcal{A}_R \to \Gamma(Y)
\]

and summing up, we easily conclude that \( \varphi \) factors uniquely through Spec\((i_R)\) and the morphism of topologically local quasi-affinoid schemes

\[
\psi := \text{Spec}(g_{\text{loc}}) : Y \to R := \text{Spec}(\mathcal{A}_{R, \text{loc}}).
\]

Lastly, taking into account lemma (15.4.17)(i) it is easily seen that Spa\((i_R)\) is an injective map inducing a homeomorphism Spa\( R \to R \), and the theorem follows. \( \Box \)

15.5.7. In the situation of (15.5.3), let \( U \subset \text{Spa} \mathcal{X} \) be a quasi-affinoid open subset, and \( Y \) any topologically local quasi-affinoid scheme that represents \( h_U \). Then the morphism \( 1_Y \) corresponds to a well defined section \( \varphi_{Y/X} \in h_U(Y) \), i.e. to a morphism \( \varphi_{Y/X} : Y \to X \) of quasi-affinoid schemes with \( \text{Im}(\text{Spa} \varphi_{Y/X}) \subset U \).

Corollary 15.5.8. With the notation of (15.5.1), the following holds:

(i) The map \( \text{Spa} \varphi_{Y/X} : \text{Spa} Y \to \text{Spa} X \) induces a homeomorphism \( \text{Spa} Y \xrightarrow{\sim} U \).

(ii) Especially, every quasi-affinoid open subset is quasi-compact.

(iii) More precisely, \( \text{Spa} \varphi_{Y/X} \) induces homeomorphisms

\[
(\text{Spa} Y)_a \xrightarrow{\sim} U \cap (\text{Spa} X)_a \quad (\text{Spa} Y)_{na} \xrightarrow{\sim} U \cap (\text{Spa} X)_{na}.
\]

(iv) The morphism \( \varphi_{Y/X} \) is f-adic.
Proof. (i): Let \((R_i \mid i \in I)\) be a system of rational subsets of \(\text{Spa} X\) such that \(U = \bigcup_{i \in I} R_i\), and for every \(i, j \in I\) set \(R_{ij} := R_i \cap R_j\) and choose topologically locally quasi-affinoid schemes \(Z_i\) and \(Z_{ij}\) that represent \(h_{R_i}\) and \(h_{R_{ij}}\). The inclusions \(R_i \subset U\) and \(R_{ij} \subset U\) are then represented by morphisms \(\psi_i : Z_i \to Y\) and respectively \(\psi_{ij} : Z_{ij} \to Y\) of quasi-affinoid schemes such that \(\varphi_{Z_i/X} = \varphi_{Y/X} \circ \psi_i\) and \(\varphi_{Z_{ij}/X} = \varphi_{Y/X} \circ \psi_{ij}\), for every \(i, j \in I\). For every \(i \in I\) set \(U_i := \text{Im} \text{Spa} \psi_i \subset \text{Spa} Y\); it was observed in the proof of theorem 15.5.5 that \(\text{Spa} \varphi_{Z_i/X}\) induces a homeomorphism \(\text{Spa} Z_i \overset{\sim}{\to} R_i\); it follows easily that \(\text{Spa} \psi_i\) and \(\text{Spa} \varphi_{Z_i/X}\) induce homeomorphisms \(\text{Spa} Z_i \overset{\sim}{\to} U_i\) and respectively \(U_i \overset{\sim}{\to} R_i\). It is also easily seen that \(U_i \cap U_j = \text{Im} \text{Spa} \psi_{ij}\), so the map \(\text{Spa} \varphi_{Z_i/X}\) restricts to a homeomorphism \(U' := \bigcup_{i \in I} U_i \overset{\sim}{\to} U\). To conclude, it suffices to check that \(U' = \text{Spa} Y\). However, suppose that \(v \in \text{Spa} Y \setminus U'\); we may find a rational subset \(R' \subset \text{Spa} Y\) that contains \(v\), and we may assume that \(\text{Spa} \varphi_{Y/X}(R') \subset R_i\) for some \(i \in I\). Pick a topologically local quasi-affinoid scheme \(Y'\) that represents the subsheaf \(h_{R'}\) of \(h_Y\), and let \(\varphi' : Y' \to Y\) be the morphism of quasi-affinoid schemes that represents the inclusion \(R' \subset \text{Spa} Y\). Then \(\varphi_{Y/X} \circ \varphi' : Y' \to X\) lies in \(h_{R_i}(Y')\), so it corresponds to a unique morphism \(\beta : Y' \to Z_i\) such that \(\varphi_{Z_i/X} \circ \varphi' = \varphi_{Y/X} \circ \beta = \varphi_{Y/X} \circ \psi_i \circ \beta\). Since \(\varphi_{Y/X}\) induces an injective morphism \(h_Y \to h_X\) (whose image is \(h_i\)), we deduce that \(\varphi' = \psi_i \circ \beta\). Especially, \(U_i\) contains the image of \(\text{Spa} \varphi_{Y'}\); but we know that the latter coincides with \(R'\), a contradiction.

(ii) is an immediate consequence of (i).

(iii): By virtue of remark 15.3.13 (vii), it suffices to show that \(\text{Spa} \varphi_{Y/X}\) maps \((\text{Spa} Y)_a\) into \((\text{Spa} X)_a\). Thus, let \(v \in (\text{Spa} Y)_a\) such that \(w := \text{Spa} \varphi_{Y/X}(v) \in R_i\), and let \(u := (\text{Spa} \varphi_{Z_i/X})^{-1}(w)\). Suppose that \(w \in (\text{Spa} X)_\text{na}\); by inspecting the proof of theorem 15.5.5, it is easily seen that \(\varphi_{Z_i/X}\) is f-adic, so \(u \in (\text{Spa} Z_i)_\text{na}\), by corollary 15.3.17 (ii). By the foregoing, we also know that \(\text{Spa} \psi_i(u) = v\), and then \(v \in (\text{Spa} Y)_\text{na}\), again by remark 15.3.13 (vii), whence the assertion.

(iv) follows immediately from (iii) and proposition 15.4.22 (iii.b).

\(\square\)

Remark 15.5.9. (i) In the situation of (15.5.3), we can also consider the Yoneda imbeddings for the categories of topologically locally henselian and of complete, separated quasi-affinoid schemes

\[ h' : \text{Afd.Sch}_{\text{hens}}^\wedge \to \text{Afd.Sch}_{\text{hens}}^\wedge \quad h'' : \text{Afd.Sch}_{\text{comp}} \to \text{Afd.Sch}_{\text{comp}}^\wedge \]

and if \(X\) is topologically henselian (resp. complete and separated) we set

\[ h'_U(Y') := h_U(Y') \subset h'_X(Y') \quad (\text{resp. } h''_U(Y'') := h_U(Y'') \subset h''_X(Y'')) \]

for every topologically locally henselian quasi-affinoid scheme \(Y'\) and every complete and separated quasi-affinoid scheme \(Y''\). Suppose that \(U\) is quasi-affinoid, and let \(\varphi_{Y/X} : Y \to X\) be a morphism of topologically locally quasi-affinoid schemes representing the sub-presheaf \(h_U \subset h_X\), as in (15.5.7); from remark 15.4.10 (v) and lemma 15.4.17 (i) we see that if \(X\) is topologically henselian, the topological henselization \(\varphi_{Y/X}^h : Y^h \to X\) of \(\varphi_{Y/X}\) represents \(h'_U\). Likewise, taking into account proposition 15.4.12 and lemma 15.4.17 (iii), we conclude that if \(X\) is complete and separated, the completion \(\varphi_{Y/X}^\wedge : Y^\wedge \to X\) of \(\varphi_{Y/X}\) represents \(h''_U\).

(ii) Moreover, we may consider the Yoneda imbedding for the opposite of the category of topologically local affinoid rings:

\[ h'' : \text{Afd.Ring}_{\text{loc}}^o \to \text{Afd.Ring}_{\text{loc}}^o \]

and if \(A := (A, A^+)\) is any topologically local affinoid ring, and \(U \subset \text{Spa} A\) any open subset, we may form again the sub-presheaf \(h''_U \subset h''_A\) by the rule \(h''_U(B) := h_U(\text{Spec } B)\) for every topologically local affinoid ring \(B\). We may regard \(U\) as an open subset of \(\text{Spa}(\text{Spec } A)\), and we say that \(U\) is a quasi-affinoid open subset of \(\text{Spa } A\) if it is such, as an open subset of \(\text{Spa } A\). Since \(\text{Spec}\) is fully faithful on the full subcategory \(\text{Afd.Ring}\), it follows that if \(U\) is quasi-affinoid, \(h''_U\) is representable: namely, a representing affinoid ring is \(f(Y)\), where \(Y\) is any topologically
local quasi-affinoid scheme that represents the presheaf $h_U$. Lastly, we may in the same way consider variants for topologically henselian (resp. complete and separated) affinoid rings: the reader may spell out the details. (However, the method does not produce representing objects on the whole category of quasi-affinoid rings, essentially because there is – in this generality – no counterpart of proposition [15.4.30] for quasi-affinoid rings).

(iii) It follows from lemma [15.4.6] and corollary [15.5.8]iv) that the intersection of two quasi-affinoid open subsets $U, U' \subset \text{Spa} X$ is quasi-affinoid. Indeed, if $Y$ and $Y'$ are topologically local quasi-affinoid schemes that represent $h_U$ and respectively $h_{U'}$, it is easily seen that

$$(Y \times X Y')_{\text{loc}}$$

represents $h_U \cap h_{U'} = h_{U \cap U'}$ (see example [15.4.8]).

(iv) In the same vein, if $f : X' \to X$ is any $f$-adic morphism of topologically local quasi-affinoid schemes, and $U \subset \text{Spa} X$ is any quasi-affinoid open subset, then $U' := (\text{Spa} f)^{-1}U$ is a quasi-affinoid open subset of $\text{Spa} X'$. Indeed, if $Y$ represents $h_U$, then $h_{U'}$ is represented by $(Y \times X X')_{\text{loc}}$, where the fibre product is given as in example [15.4.8].

(v) Lastly, let $U$ be a quasi-affinoid open subset of $\text{Spa} X$ such that the inclusion $h_U \subset h_X$ is represented by the morphism of topologically local quasi-affinoid schemes $\varphi_{Y/X} : Y \to X$, and $V$ a quasi-affinoid open subset of $\text{Spa} Y$ such that the inclusion $h_V \subset h_Y$ is represented by the morphism of topologically local quasi-affinoid schemes $\varphi_{Z/Y} : Z \to Y$, and set $U' := \text{Spa} \varphi_{Y/X}(V) \subset U$. Then $\varphi_{Y/X}$ induces an isomorphism $h_Y \sim h_U$ that identifies $h_Y$ with the sub-presheaf $h_U$ of $h_Y$. Especially, $U'$ is a quasi-affinoid open subset of $\text{Spa} X$, and the inclusion $h_{U'} \subset h_X$ is represented by $\varphi_{Y/X} \circ \varphi_{Z/Y}$.

**Lemma 15.5.10.** In the situation of remark [15.5.9]v), suppose furthermore that $U$ is a rational subset of $\text{Spa} X$ and $V$ is a rational subset of $\text{Spa} Y$. Then $V$ is a rational subset of $\text{Spa} X$.

**Proof.** Say that $\Gamma(X) = (A, A^+, X)$, and $U = R_A(l_0, \ldots, l_n) \cap \text{Spa} X$, with $(f_0, \ldots, f_n)$ a sequence of elements of $A$ that generates an open ideal. Set $(A_U, A_U^+) := A(l_0, \ldots, l_n)$, where $A^+ := (A, A^+)$, so that $A_U = A[f_0^{-1}]$. By inspecting the proof of theorem [15.5.5], we get an isomorphism of quasi-affinoid schemes

$$Y \sim \text{Spec} (A_U, A_U^+, X \cap \text{Spec} A_U)_{\text{loc}}$$

Since $X$ is quasi-compact, and Spec $A_U$ is an open affine subset of Spec $A$, we have $\varphi_X(X \cap \text{Spec} A_U) = \varphi_X(A \cap \{ x \in Y \mid f_0^{-1} \}) = A_U$ ([14, Ch.I, Prop.9.2.1]). Taking into account (15.4.11), we deduce that $\varphi(Y) = (B, B^+, X \cap \text{Spec} A_U)$, where $B := A_U$ and $B^+ := A_U^+$. Consequently, we have $V = R_B(g_0, \ldots, g_m) \cap \text{Spa} Y$ for a sequence $g_\bullet := (g_0, \ldots, g_m)$ of elements of $B$ that generates an open ideal $J$. Since $B$ is a localization of $A$, we may also find $b \in B^*$, such that $bg_i \in A^+ := \text{Im}(A \to B)$; after replacing $g_\bullet$ by the sequence $(bg_0, \ldots, bg_m)$, we may then assume that $g_0, \ldots, g_m \in A^+$, and for every $i = 0, \ldots, m$ we pick $h_i \in A$ whose image in $B$ agrees with $g_i$. Moreover, let $A_0 \subset A$ be a ring of definition, and $I \subset A_0$ a finitely generated ideal of adic definition; according to claim [15.4.20], there exists $k \in \mathbb{N}$ such that $v(a) < v(h_0)$ for every $a \in I^k$ and every $v \in V$. Pick a finite system $x_1, \ldots, x_r$ of generators for $I^k$ and set $h_i+m := x_i$ for every $i = 1, \ldots, r$; by construction, we easily see that

$$V = U \cap R \quad \text{where } R := R_A\left(\frac{h_1}{h_0}, \ldots, \frac{h_{m+r}}{h_0}\right)$$

and the system $(h_i \mid i = 1, \ldots, m + r)$ generates an open ideal of $A$, so $R$ is a rational subset of $\text{Spa} X$, and finally, the same holds for $V$.\[\square\]
15.5.11. Let $X := (X, \mathcal{F}_X, A_X^+)$ be any topologically local quasi-affinoid scheme; in view of remark [15.5.9]iii) we may associate with $X$ a site

$$(\mathcal{O}(X), J_{\mathcal{O}})$$

where $\mathcal{O}(X)$ is the category of all quasi-affinoid open subsets of $\text{Spa} X$; for every $U, U' \in \text{Ob}(\mathcal{O}(X))$, the set $\text{Hom}_{\mathcal{O}(X)}(U, U')$ contains exactly one morphism if $U \subset U'$, and is empty otherwise. For every such $U$, the sieves covering $U$ for the topology $J_{\mathcal{O}}$ are precisely those generated by the families $(U_\lambda | \lambda \in \Lambda)$ of quasi-affinoid open subsets of $\text{Spa} X$ such that $\bigcup_{\lambda \in \Lambda} U_\lambda = U$. We consider nine presheaves of topological $\mathcal{O}_X(X)$-algebras on $\mathcal{O}(X)$, related by natural morphisms of presheaves:

$$
\begin{array}{cccc}
\mathcal{O}_{\text{Spa} X}^{\text{loc}+} & \longrightarrow & \mathcal{O}_{\text{Spa} X}^{\text{loc}^o} & \longrightarrow & \mathcal{O}_{\text{Spa} X}^{\text{loc}} \\
\downarrow & & \downarrow & & \downarrow \\
\mathcal{O}_{\text{Spa} X}^{h+} & \longrightarrow & \mathcal{O}_{\text{Spa} X}^{h^o} & \longrightarrow & \mathcal{O}_{\text{Spa} X}^h \\
\downarrow & & \downarrow & & \downarrow \\
\mathcal{O}_{\text{Spa} X}^{h^+} & \longrightarrow & \mathcal{O}_{\text{Spa} X}^{h^o+} & \longrightarrow & \mathcal{O}_{\text{Spa} X}^h \\
\end{array}
$$

and constructed as follows. By theorem [15.5.5] for every $U \in \text{Ob}(\mathcal{O}(X))$ the sub-presheaf $h_U$ of $h_X$ is representable (notation of (15.5.3)); we choose a topologically local quasi-affinoid scheme $\overline{X}_U := (X_U, \mathcal{F}_U, A_U^+)$ that represents this presheaf, and we set

$$
\mathcal{O}_{\text{Spa} X}^{\text{loc}}(U) := \mathcal{O}_{X_U}(X_U) \quad \mathcal{O}_{\text{Spa} X}^{\text{loc}^o}(U) := \mathcal{O}_{X_U}(X_U)^o \quad \mathcal{O}_{\text{Spa} X}^{\text{loc}+}(U) := A_U^+.
$$

Any inclusion $U \subset U'$ of quasi-affinoid open subsets induces a morphism $h_U \to h_{U'}$ of presheaves, which is represented by a unique morphism $\overline{X}_U \to \overline{X}_{U'}$ of topologically local quasi-affinoid schemes (see remark [15.2.8](i)), whence well defined continuous homomorphisms

$$
\mathcal{O}_{\text{Spa} X}^{\text{loc}+}(U') \to \mathcal{O}_{\text{Spa} X}^{\text{loc}+}(U) \quad \mathcal{O}_{\text{Spa} X}^{\text{loc}^o}(U') \to \mathcal{O}_{\text{Spa} X}^{\text{loc}^o}(U)
$$

of topological $\mathcal{O}_X(X)$-algebras, and clearly the rules $U \mapsto \mathcal{O}_{\text{Spa} X}^{\text{loc}^o}(U)$ and $U \mapsto \mathcal{O}_{\text{Spa} X}^{\text{loc}+}(U)$ yield two functors from $\mathcal{O}(X)^o$ to the category of topologically local f-adic $\mathcal{O}_X(X)$-algebras. Likewise, in view of corollary [15.5.8]iv) and lemma [8.3.24](iii.a) we also get a continuous map

$$
\mathcal{O}_{\text{Spa} X}^{\text{loc}^o}(U') \to \mathcal{O}_{\text{Spa} X}^{\text{loc}^o}(U),
$$

whence the presheaf $\mathcal{O}_{\text{Spa} X}^{\text{loc}^o}$.

Similarly, let $\overline{X}_U^h := (X_U^h, \mathcal{F}_U^h, A_U^{h+})$ (resp. $\overline{X}_U^{h^o} := (X_U^{h^o}, \mathcal{F}_U^{h^o}, A_U^{h^o+})$) be a topologically henselian (resp. complete and separated) quasi-affinoid scheme representing the sub-presheaf $h_U'$ of $h_X'$ (resp. $h_U^{h^o}$ of $h_X^{h^o}$) as in remark [15.5.9]i); we define

$$
\mathcal{O}_{\overline{X}_U^h}(U) := \mathcal{O}_{X_U^h}(X_U^h) \quad \mathcal{O}_{\overline{X}_U^{h^o}}(U) := \mathcal{O}_{X_U^{h^o}}(X_U^{h^o}) \quad \mathcal{O}_{\overline{X}_U^{h^+}}(U) := A_U^{h^+}
$$
and arguing as in the foregoing, it is easily seen that these rules yield well defined presheaves of topologically henselian (resp. complete and separated) f-adic $\mathcal{O}_X(X)$-algebras. All these presheaves depend on the choices of representing quasi-affinoid schemes, but for any two such sets of choices there exists a unique isomorphism of presheaves of topological $\mathcal{O}_X(X)$-algebras between the corresponding presheaves. We notice as well that the rule

$$
U \mapsto \mathcal{O}_{\text{Spa} X}^{\text{loc}^o}(U)
$$

defines a sub-presheaf $\mathcal{O}_{\text{Spa} X}^{\text{loc}^o} \subset \mathcal{O}_{\text{Spa} X}^{\text{loc}}$ that is a presheaf of ideals in both $\mathcal{O}_{\text{Spa} X}^{\text{loc}^o}$ and $\mathcal{O}_{\text{Spa} X}^{\text{loc}+}$. Likewise we get presheaves of topologically nilpotent sections $\mathcal{O}_{\text{Spa} X}^{h^o o} \subset \mathcal{O}_{\text{Spa} X}^{h^o}$ (resp. $\mathcal{O}_{\text{Spa} X}^{h^+ o} \subset \mathcal{O}_{\text{Spa} X}^{h^+}$) that are presheaves of ideals in $\mathcal{O}_{\text{Spa} X}^{h^o}$ and $\mathcal{O}_{\text{Spa} X}^{h^+}$ (resp. in $\mathcal{O}_{\text{Spa} X}^{h^o}$ and $\mathcal{O}_{\text{Spa} X}^{h^+}$).
15.5.12. With the notation of \(15.5.11\), let \(x \in \text{Spa } X\) be any point; recall that \(x\) is the equivalence class of a continuous valuation \(v_x : A := \mathcal{O}_X(X) \to \Gamma_x\); if \(R \subset \text{Spa } X\) is any rational subset containing \(x\), the valuation \(v_x\) extends uniquely to a continuous valuation \(v_{x,R}^\wedge\) on \(\mathcal{O}_{\text{Spa } X}(R)\) with value group \(\Gamma_x\) (claim 15.3.20(ii)). Then, by restricting along the natural maps \(\mathcal{O}^\wedge_{\text{Spa } X}(R) \to \mathcal{O}^\wedge_{\text{Spa } X}(R) \to \mathcal{O}_{\text{Spa } X}(R)\) we get corresponding valuations \(v_{x,R}^h, v_{x,R}^\loc\), and – after taking colimits – unique valuations on the stalks of these presheaves

\[
\begin{align*}
\mathcal{O}^\loc_{\text{Spa } X,x} & \longrightarrow \mathcal{O}^h_{\text{Spa } X,x} & \longrightarrow \mathcal{O}^\wedge_{\text{Spa } X,x} \\
\Gamma_x & \longrightarrow \Gamma_x & \longrightarrow \Gamma_x
\end{align*}
\]

We denote by \(\kappa'(x^{\loc}), \kappa'(x^h), \kappa'(x^\wedge)\) the residue fields of \(\cdot \mid_{\text{loc}}, \cdot \mid_{h}\) and respectively \(\cdot \mid_{\wedge}\), and recall that the valuations of \((15.5.13)\) induce natural residual valuations on these fields : see remark 9.1.4(v). There follow natural inclusion of valued fields

\(\kappa'(x^{\loc}) \supset \kappa'(x^h) \supset \kappa'(x^\wedge)\)

and taking into account claim 15.3.20(ii) we see that the images of \(\kappa'(x^{\loc})\) and of \(\kappa'(x^h)\) in \(\kappa'(x^\wedge)\) are both dense for the valuation topology of the latter field. Especially, these inclusions induce natural identifications of the completions of these fields for their respective valuation topologies (theorem 8.2.8(iii)), and we denote this common completion by

\[(\kappa'(x)^\wedge, \cdot \mid_{\wedge})\]

which is a valued field with value group \(\Gamma_x\), by proposition 9.1.15(iii,v).

**Lemma 15.5.14.** In the situation of \((15.5.12)\), we have :

(i) The stalks \(\mathcal{O}^\loc_{\text{Spa } X,x}, \mathcal{O}^h_{\text{Spa } X,x}\) and \(\mathcal{O}^\wedge_{\text{Spa } X,x}\) are local rings, and \(\kappa'\)(\(x^{\loc}\)), \(\kappa'(x^h), \kappa'(x^\wedge)\) are their respective residue fields.

(ii) The stalks \(\mathcal{O}^{\loc+}_{\text{Spa } X,x}, \mathcal{O}^{h+}_{\text{Spa } X,x}\) and \(\mathcal{O}^{\wedge+}_{\text{Spa } X,x}\) are local rings, and the induced diagrams

\[
\begin{align*}
\mathcal{O}^{\loc+}_{\text{Spa } X,x} & \longrightarrow \mathcal{O}^{\loc}_{\text{Spa } X,x} & \longrightarrow \mathcal{O}^{\wedge}_{\text{Spa } X,x} \\
\kappa'(x^{\loc})+ & \longrightarrow \kappa'(x^{\loc}) & \longrightarrow \kappa'(x^\wedge)
\end{align*}
\]

are cartesian (here \(\kappa'(x^{\loc})\) is the valuation ring of the residual valuation on \(\kappa'(x^{\loc})\), and likewise for \(\kappa'(x^h)\) and \(\kappa'(x^\wedge)\).

(iii) The stalk \(\mathcal{O}^{\loc+}_{\text{Spa } X,x}\) (resp. \(\mathcal{O}^{h+}_{\text{Spa } X,x}\), resp. \(\mathcal{O}^{\wedge+}_{\text{Spa } X,x}\)) is the radical of the ideal \(A^{\loc}, \mathcal{O}^{\loc+}_{\text{Spa } X,x}\) of \(\mathcal{O}^{\loc+}_{\text{Spa } X,x}\) (resp. \(A^{h+} \mathcal{O}^{h+}_{\text{Spa } X,x}\), resp. \(A^{\wedge+} \mathcal{O}^{\wedge+}_{\text{Spa } X,x}\) of \(\mathcal{O}^{\wedge+}_{\text{Spa } X,x}\).

(iv) The pairs \(\mathcal{O}^\loc_{\text{Spa } X,x}, \mathcal{O}^h_{\text{Spa } X,x}\) and \(\mathcal{O}^\wedge_{\text{Spa } X,x}\) are henselian.

(v) Suppose that \(x\) is analytic, and let

\[
\mathcal{p}^{\loc} \subset \kappa'(x^{\loc})^+, \mathcal{p}^h \subset \kappa'(x^h)^+, \mathcal{p}^\wedge \subset \kappa'(x^\wedge)^+
\]

be the (unique) prime ideals of height one. Then :

(a) \(\mathcal{O}^{\loc+}_{\text{Spa } X,x} = \pi_{x}^{\loc-1}(\mathcal{p}^{\loc})\)

(b) The pairs \((\kappa'(x^{\loc})^+, \mathcal{p}^h)\) and \((\kappa'(x^\wedge)^+, \mathcal{p}^\wedge)\) are henselian.

(c) The local rings \(\mathcal{O}^h_{\text{Spa } X,x}\) and \(\mathcal{O}^\wedge_{\text{Spa } X,x}\) are henselian.

(d) The valuation rings \(\kappa'(x^h)^+_{\mathcal{p}^h}\) and \(\kappa'(x^\wedge)^+_{\mathcal{p}^\wedge}\) are henselian.

(vi) Suppose that \(x\) is non-analytic. Then :

(a) \(\mathcal{O}^{\loc+}_{\text{Spa } X,x}\) (resp. \(\mathcal{O}^{h+}_{\text{Spa } X,x}\), resp. \(\mathcal{O}^{\wedge+}_{\text{Spa } X,x}\)) is also an ideal of \(\mathcal{O}^\loc_{\text{Spa } X,x}\) (resp. of \(\mathcal{O}^h_{\text{Spa } X,x}\), resp. of \(\mathcal{O}^\wedge_{\text{Spa } X,x}\)), and it is the radical of the ideal generated by \(A^{\loc}\).
(b) The pairs $\left(\mathcal{O}_{\text{Spa} X,x}^h, \mathcal{O}_{\text{Spa} X,x}^{h,\infty}\right)$ and $\left(\mathcal{O}_{\text{Spa} X,x}^\Lambda, \mathcal{O}_{\text{Spa} X,x}^{\Lambda,\infty}\right)$ are henselian.

Proof. Let $f \in \mathcal{O}_{\text{Spa} X,x}^h$, and pick any rational subset $R$ in $\text{Spa} X$ with $x \in R$, and such that $f$ extends to a section $f_R \in B := \mathcal{O}_{\text{Spa} X}(R)$. Let $Y^\Lambda := (Y^\Lambda, \mathcal{T}_X^\Lambda, A(X)^\Lambda)$ be a complete and separated quasi-affinoid scheme representing the subsheaf $h''_R$ of $h''_X$ of $Y^\Lambda$, so that $B = \mathcal{O}_{Y^\Lambda}(Y^\Lambda)$.

(i): Suppose now that $|f|_x^\Lambda \neq 0$; then clearly $v_{x,R}^\Lambda(f_R) \neq 0$. We set $U := R_B(\frac{1}{f_R}) \cap \text{Spa} Y^\Lambda$. In view of lemma [15.4.17(ii)] and corollary [15.5.8(ii)], we may then identify $U$ with an open subset of $\text{Spa} X$ containing $x$, and we pick a rational subset $U' \subset U \subset \text{Spa} X$ with $x \in U'$; by construction the image of $f$ under the restriction map $\rho_{U'} : \mathcal{O}_{\text{Spa} X}^\Lambda(R) \to \mathcal{O}_{\text{Spa} X}(U')$ is an invertible element. This shows that $\ker | \cdot |^\Lambda$ is the unique maximal ideal of $\mathcal{O}_{\text{Spa} X,x}$, and it also easily implies that the projection $\pi_x^\Lambda : \mathcal{O}_{\text{Spa} X,x} \to \kappa(x)^\Lambda$ is surjective (details left to the reader). The same argument applies to $\mathcal{O}_{\text{Spa} X,x}^h$ and $\mathcal{O}_{\text{Spa} X,x}^{h,\infty}$, whence the contention.

(ii): Suppose next that $|f|_x^\Lambda \leq 1$. Then we let $U := R_B(\frac{1}{f}) \cap \text{Spa} Y^\Lambda$, which again we identify naturally with an open subset of $\text{Spa} X$ containing $x$, and we pick a rational subset $U' \subset U \subset \text{Spa} X$ with $x \in U'$; then $\rho_{U'}(f_R) \in \mathcal{O}_{\text{Spa} X}^\Lambda(U')$. This shows that $f \in \mathcal{O}_{\text{Spa} X,x}^\Lambda$, whence the assertion concerning the third square diagram. The same argument applies to the other two diagrams. It follows easily that the preimage in $\mathcal{O}_{\text{Spa} X,x}^{\Lambda,\infty}$ of the maximal ideal of $\kappa(x)^\Lambda$ is the unique maximal ideal of $\mathcal{O}_{\text{Spa} X,x}^{\Lambda,\infty}$ (details left to the reader); especially, the latter is a local ring. Again, the same applies to the other two rings.

(iii): It follows easily from corollary [15.5.8(iv)] that the natural map $A \to \mathcal{O}_{\text{Spa} X}(U)$ is $f$-adic, for every rational subset $U \subset \text{Spa} X$. Hence, $A^{\infty} \cdot \mathcal{O}_{\text{Spa} X}(U)$ is an open ideal of $\mathcal{O}_{\text{Spa} X}(U)$ consisting of topologically nilpotent sections, and therefore its radical equals $\mathcal{O}_{\text{Spa} X}(U)$. It suffices then to observe that the radical of $A^{\infty} \cdot \mathcal{O}_{\text{Spa} X,x}^h$ is the colimit of the filtered system of the radicals of the ideals $(A^{\infty} \cdot \mathcal{O}_{\text{Spa} X,x}^h(U)) | x \in U$. The same applies to the other ideals in (iii).

(iv): By proposition [8.4.2(iii)], both $\left(\mathcal{O}_{\text{Spa} Y,x}^h(U), \mathcal{O}_{\text{Spa} Y,x}^{h,\infty}(U)\right)$ and $\left(\mathcal{O}_{\text{Spa} Y,x}^\Lambda(U), \mathcal{O}_{\text{Spa} Y,x}^{\Lambda,\infty}(U)\right)$ are henselian pairs for every rational subset $U \subset \text{Spa} X$ containing $x$. The assertion follows, after taking colimits over the filtered family of such rational subsets.

(v.a): First, recall that the existence of a rank one prime ideal $p^h \subset \kappa(x)^\Lambda$ is ensured by lemma [15.3.14(v)]; it follows easily that $p^h = \kappa(x)^{\infty}$, and taking into account remark [15.3.13(i)] we deduce already that $\pi^h \left(\mathcal{O}_{\text{Spa} X,x}^{h,\infty}\right) \subset p^h$. Conversely, let $f \in \mathcal{O}_{\text{Spa} X,x} \setminus \mathcal{O}_{\text{Spa} X,x}^{h,\infty}$ be any element; denote by $\mathcal{U}$ the set of all rational subsets of $\text{Spa} X$ containing $x$, and for every $U \in \mathcal{U}$ set $U' := U \cap R_A(\frac{1}{f})$. The assumption on $f$ implies that $U'$ is a non-empty constructible subset of $\text{Spa} X$ for every $U \in \mathcal{U}$ (corollary [15.4.27(ii)]), and therefore $T := \bigcap U \in \mathcal{U} U' \neq \emptyset$ (proposition [8.1.13(ii.a)]). However, $T$ lies in the set $\mathcal{S}_X(x)$ of all generization of $x$ in $\text{Spa} X$ (remark [8.1.43(ii)]), and must then contain the unique maximal generalization of $x$; the latter means precisely that $\pi^h(f) \notin p^h$, as required.

Next, since $| \cdot |^h$ and $| \cdot |^x_R$ have the same value group, the existence of a (unique) height one prime ideal $p^h \subset \kappa(v^h)$ follows from the existence of $p^h$ and remark [9.1.13(vii)]; then, since $v_{x,R}^h$ is continuous, we deduce likewise that $\pi^h \left(\mathcal{O}_{\text{Spa} X,x}^{\Lambda,\infty}\right) \subset p^h$ for every rational subset $R \subset \text{Spa} X$. If now $f \in \mathcal{O}_{\text{Spa} X,x} \setminus \mathcal{O}_{\text{Spa} X,x}^{\Lambda,\infty}$, pick $R$ as in the foregoing and $Y$ representing $h''_R$, so that $x \in R$, and $f$ extends to a section $f_R \in B := \mathcal{O}_{\text{Spa} X}(Y)$; let $\mathcal{U}$ be the set of all rational subsets of $\text{Spa} Y$ containing $x$, and for every $U \in \mathcal{U}$ set $U' := U \cap R_B(\frac{1}{f_R})$. Due to corollary [15.5.8(i)] and lemma [15.4.17(iii)], the image of $T := \bigcap U \in \mathcal{U} U'$ in $\text{Spa} X$ lies in $\text{Spa} X(x)$, and is not empty, and arguing in the foregoing we deduce again that $\pi^h(f) \notin p^h$. The same argument applies to $p^h$.

(v.b): Let us remark more generally :
Claim 15.5.15. Let \( A \) be any ring, \( J \subset I \subset A \) two ideals. Then the pair \((A, I)\) is henselian if and only if the same holds for both \((A/J, I/J)\) and \((A, J)\).

Proof of the claim. From \([59]\) Rem.5.1.10(iv,v)] we see that if \((A, I)\) is henselian, the same holds for the pairs \((A, J)\) and \((A/J, I/J)\). Conversely, let \( A \to B \) be a finite ring homomorphism; if \((A, J)\) is henselian, the projection \( B \to B/JB \) restricts to a bijection \( \text{Idemp}(B) \to \text{Idemp}(B/JB) \) on the respective subsets of idempotent elements. Then, if also \((A/J, I/J)\) is henselian, the induced map \( \text{Idemp}(B/JB) \to \text{Idemp}(B/IB) \) is bijective as well. Summing up, we conclude that \((A, I)\) is henselian.

In view of (iv) and claim \([15.5.15]\) we are easily reduced to showing that the projections \( \mathcal{O}_{\text{Spa}}^{h}(x) \to \kappa(x)^{+} \) and \( \mathcal{O}_{\text{Spa}}^{h^+}(x) \to \kappa(x)^{+} \) are surjective. The latter follows from (ii) and from the surjectivity of \( \pi_{x}^{h} \) and \( \pi_{x}^{h^+} \), which has already been remarked in the proof of (i).

(v.c): Let \( m^{h} := \text{Ker} \pi_{x}^{h} \), the proof of (i) shows that \( m^{h} \) is the maximal ideal of \( \mathcal{O}_{\text{Spa}}^{h}(x) \), and (ii) implies that \( m^{h} \) is also an ideal in \( \mathcal{O}_{\text{Spa}}^{h^+}(x) \); moreover, in light of (iv) and \([59]\) Rem.5.1.10(iv)] the pair \((\mathcal{O}_{\text{Spa}}^{h^+}(x), m^{h})\) is henselian. Then the assertion follows from \([59]\) Rem.5.1.10(ii)]. The same argument applies to \( \mathcal{O}_{\text{Spa}}^{h}(x) \).

(v.d): It is easily seen that the localization map \( \kappa(x)^{+} \to \kappa(x)^{+} \) restricts to a bijection from \( p^{h} \) to the maximal ideal of \( \kappa(x)^{+} \). Then the assertion follows from \([59]\) Rem.5.1.10(ii)].

The same argument applies to \( \kappa(x)^{+} \).

(vi.a): By (iii) we know already that \( \mathcal{O}_{\text{Spa}}^{h}(x) \) lies in the radical of \( A^{\infty} \cdot \mathcal{O}_{\text{Spa}}^{h^+}(x) \); hence, suppose that \( f^{n} \in A^{\infty} \cdot \mathcal{O}_{\text{Spa}}^{h^+}(x) \) for some \( n \in \mathbb{N} \), and say that \( f^{n} = \sum_{i=1}^{k} a_{i} g_{i} \) for some \( a_{1}, \ldots, a_{k} \in A^{\infty} \) and \( g_{1}, \ldots, g_{k} \in \mathcal{O}_{\text{Spa}}^{h^+}(x) \). Notice that since \( x \) is non-analytic, we have \( \pi_{x}^{h}(a_{i}) = 0 \) for \( i = 1, \ldots, k \), whence \( \pi_{x}^{h}(f^{n}) = 0 \), and therefore \( \pi_{x}^{h}(f^{n} g_{i}) = 0 \) as well for \( i = 1, \ldots, k \); then (ii) implies that \( f^{n} g_{i} \in \mathcal{O}_{\text{Spa}}^{h^+}(x) \), so \( f^{2n} = \sum_{i=1}^{k} a_{i} \cdot (f^{n} g_{i}) \in A^{\infty} \cdot \mathcal{O}_{\text{Spa}}^{h^+}(x) \).

The same argument applies to \( \mathcal{O}_{\text{Spa}}^{\infty}(x) \) and \( \mathcal{O}_{\text{Spa}}^{h}(x) \).

(vi.b) follows directly from (vi.a), (iv) and \([59]\) Rem.5.1.10(ii)].

15.5.16. Let \( A := (A, A^{+}, U) \) be any quasi-affinoid ring, and \( J \subset A \) a finitely generated ideal such that \( U = \text{Spec} A \setminus \text{Spec} A/J \). The Zariski-Riemann spectrum of \( A \) is the subset of \( \text{Spv} A \)
\[
\text{ZR}(A) := \text{Spa}(A) \cap \text{Spv}(A, J)
\]

(definition of \([15.3.6]\) i)) that we endow with the topology induced by the inclusion into \( \text{Spv} A \). A rational subset of \( \text{ZR}(A) \) is a subset of the form \( R \cap \text{ZR}(A) \), where \( R \) is a rational subset of \( \text{Spv}(A, J) \) (see definition \([15.3.6]\) ii)). Notice that neither \( \text{ZR}(A) \) nor the class of its rational subsets depend on the choice of \( J \) (lemma \([15.3.9]\) i)).

Proposition 15.5.17. With the notation of \([15.5.16]\), the following holds :

(i) \( \text{ZR}(A) = \{v \in \text{Spa}(A) \mid v \text{ has no proper primary specializations in } \text{Spa}(A)\} \).

(ii) \( \text{ZR}(A) \) is a pro-constructible subset of \( \text{Spv}(A, J) \). In particular, it is a spectral topological space.

(iii) The rational subsets of \( \text{ZR}(A) \) are constructible in \( \text{ZR}(A) \), and form a basis of the topology of \( \text{ZR}(A) \) that is closed under finite intersections.

(iv) The unit of adjunction \( A \to \Gamma \circ \text{Spec } A \) induces a homeomorphism \( \text{ZR}(\Gamma \circ \text{Spec } A) \to \text{ZR}(A) \).

Especially, \( \text{ZR}(A) \) depends only on the quasi-affinoid scheme \( \text{Spec } A \).

Proof. (i): Recall that \( \text{Cont}(A) \) is closed under specializations in \( \text{Spv} A \) (remark \([15.3.13]\) iv)); it follows easily that \( \text{Spa}(A, A^{+}) \) is closed under primary specializations. Recall as well that a proper specialization \( (v, w) \) in \( \text{Spv} A \) is \( J \)-admissible if and only if \( w \) is a primary specialization
of \(v\) and the supports of \(v\) and \(w\) lie in \(U\) (see (15.3.1)); hence, if \(v \in \text{Spa} \ A\), the proper specialization \((v, w)\) is \(J\)-admissible if and only if \(w\) is a primary specialization of \(v\) that lies in \(\text{Spa} \ A\). Then the assertion follows from lemma [15.3.4(iii)].

(ii): Let \(A_0 \subset A\) be a subring of definition, and \(I \subset A_0\) a finitely generated ideal of adic definition; recall that \(\text{Spa} \ A\) is a pro-constructible subset of \(\text{Cont}(A)\) (proposition [15.4.22(i)]) and the inclusion map \(\text{Cont}(A) \to \text{Spv}(A,IA)\) is a closed immersion (theorem [15.3.15(ii)]) so \(\text{Spv}(A,IA)\) is a pro-constructible subset of \(\text{Spv}(A,IA)\) (corollary 8.1.47(i)). Moreover, the radical of \(J\) contains \(IA\), hence the inclusion map \(\text{Spv}(A, J) \to \text{Spv}(A, IA)\) admits a spectral retraction (lemma [15.3.9])

\[
(15.5.18) \quad r : \text{Spv}(A, IA) \to \text{Spv}(A, J).
\]

Namely, for every \(v \in \text{Spv}(A, IA)\), the valuation \(r(v)\) is the unique \(J\)-admissible specialization of \(v\) that does not admit further proper \(J\)-admissible specializations. We claim that

\[
\text{ZR}(A) = r(\text{Spa} \ A).
\]

Indeed, clearly \(\text{ZR}(A) = r(\text{ZR}(A)) \subset r(\text{Spa} \ A)\). The converse inclusion follows from the proof of (i). Then, the assertion follows from corollary 8.1.47(i).

(iii) follows immediately from (ii) and theorem 15.3.7(ii).

(iv) follows directly from (i) and lemmata 15.4.17(ii) and 9.2.25(i).

\(\square\)

**Remark 15.5.19.** In [121], Temkin associates with every separated morphism \(f : Y \to X\) of quasi-compact and quasi-separated schemes, a spectral space that he calls the Riemann-Zariski space of \(f\), and denotes \(\text{RZ}_Y(X)\), together with a continuous map \(\text{RZ}_Y(X) \to X\).

His construction generalizes earlier work by Zariski, and is related as follows to our \(\text{ZR}(A)\). Let \(U \to \text{Spec} A^+\) be the composition of the open immersion \(U \to \text{Spec} A\) with the natural morphism \(\text{Spec} A \to \text{Spec} A^+\); then we may consider the induced map \(\varphi : \text{RZ}_U(\text{Spec} A^+) \to \text{Spec} A^+\), and there is a natural homeomorphism \(\varphi^{-1}(\text{Spec} A^+ / A^{\infty}) \cong \text{ZR}(A)\).

15.5.20. Keep the notation of (15.5.16), and for some integer \(n \geq -1\), let \(R_* := (R_i \mid i = 0, \ldots, n)\) be a finite system of open subsets of \(\text{ZR}(A)\) such that \(\text{ZR}(A) = \bigcup_{i=0}^{n} R_i\) (the case \(n = -1\) occurs for the empty covering of the empty Zariski-Riemann spectrum). Then we say that \(R_*\) is a standard covering of \(\text{ZR}(A)\) if there exists a finite system \(f_* := (f_0, \ldots, f_n)\) of elements of \(A\) such that:

- \(R_i = R_A(\frac{f_0}{f_i}, \ldots, \frac{f_n}{f_i}) \cap \text{ZR}(A)\) for \(i = 0, \ldots, n\)
- \(J\) is contained in the radical of the ideal of \(A\) generated by the system \(f_*\).

Especially, each \(R_i\) is a rational subset of \(\text{ZR}(A)\). By construction, the retraction \(r\) of (15.5.18) restricts to a surjective continuous map

\[
s : \text{Spa} \ A \to \text{ZR}(A)
\]

and if \(f_*\) fulfills the foregoing conditions, lemma [15.3.3(i)] says that

\[
s^{-1}R_i = R_A(\frac{f_0}{f_i}, \ldots, \frac{f_n}{f_i}) \cap \text{Spa} \ A \quad \text{for every } i = 0, \ldots, n.
\]

Especially, the system \((R_A(\frac{f_0}{f_i}, \ldots, \frac{f_n}{f_i}) \cap \text{Spa} \ A \mid i = 0, \ldots, n)\) is a covering of \(\text{Spa} \ A\). A covering of \(\text{Spa} \ A\) of this type shall also be called a standard covering.

**Lemma 15.5.21.** If \(A\) is topologically local, every open covering of \(\text{ZR}(A)\) or \(\text{Spa} \ A\) can be refined by a standard covering.

**Proof.** Let \((U_\lambda \mid \lambda \in \Lambda)\) be an open covering of \(\text{ZR}(A)\); we need to find a standard covering \((R_i \mid i = 0, \ldots, n)\) such that, for every \(i = 0, \ldots, n\) there exists \(\lambda \in \Lambda\) with \(R_i \subset U_\lambda\). To this
Claim \ref{15.3.25}. Indeed, by claim \ref{15.4.23}, every continuous analytic rank one valuation of \( A \) lies in \( \text{Spa} A \), and from \ref{15.5.32} and claim \ref{15.5.23} we see that for every such valuation \( v \) there exists \( k_* \in T \) such that \( v(g_{k_*}) \neq 0 \), whence the assertion. By lemma \ref{8.3.29}(\ref{8.3.29(i)}), it follows that \( \text{Spec} A / J' \subset X_\lambda^0 := \text{Spec} A / A^0 A \). Hence, let \( p \in X_\lambda^0 \setminus \text{Spec} A / J' \); it suffices to show that \( J' \not\subset p \). To this aim, denote by \( v_p \) the trivial valuation of \( A \) supported at \( p \) (see remark \ref{9.1.4}(\ref{9.1.4(vii)})); since \( p \) is an open ideal (lemma \ref{8.3.29}(\ref{8.3.29(i)})), the valuation \( v_p \) is continuous (remark \ref{15.3.13}(\ref{15.3.13(ii)})), and then obviously \( v \in \text{Spa} A \). As in the foregoing, we deduce that \( v_p (g_{k_*}) \neq 0 \) for some \( k_* \in T \), i.e. \( g_{k_*} \notin p \), whence the claim.

Next, consider any open covering \( U^\lambda / A | \lambda \in A \) of \( \text{Spa} A \), and set \( U^\lambda := U^\lambda / \text{ZR} (A) \) for every \( \lambda \in A \); clearly \( U^\lambda / A | \lambda \in A \) is an open covering of \( \text{ZR} (A) \), which can be refined by a standard covering \( (R_0, \ldots, R_n) \); but then the system \( (s^{-1} R_0, \ldots, s^{-1} R_n) \) is a standard covering of \( \text{Spa} A \), and notice that if \( R_i \subset U^\lambda \), we get

\[
s^{-1} R_i \subset s^{-1} U^\lambda \subset U^\lambda
\]

where the last inclusion holds, since \( U^\lambda \) is open in \( \text{Spa} A \) and \( s^{-1} U^\lambda \) is the set of all primary generizations of the elements of \( U^\lambda \) in \( \text{Spa} A \). Thus, \( (s^{-1} R_0, \ldots, s^{-1} R_n) \) refines the covering \( (U^\lambda / \lambda \in A) \), as required.

Remark \ref{15.5.25}. The following constructions shall be exploited in the proofs of both theorem \ref{15.5.26} and theorem \ref{15.5.34}:

(1) Let \( X \) be a topologically local quasi-affindoid scheme, set \( (A, A^+, X) := \Gamma(X) \), and choose a subring of definition \( A_0 \subset A \) and a finitely generated ideal \( I_0 \subset A_0 \) of adic definition. Consider a sequence \( f_* := (f_0, \ldots, f_n) \) of elements of \( A \) that generates an ideal \( J \subset A \) such that \( X \cap \text{Spec} A / J = \emptyset \), and let \( R_* := (R_0, \ldots, R_n) \) be the standard covering of \( \text{Spa} X \) associated
with $f_*$. For every subset $\Lambda \subset \{0, \ldots, n\}$, let $A_\Lambda := A[f_i^{-1} \mid i \in \Lambda]$ and $X_\Lambda := X \cap \Spec A_\Lambda$; by inspecting the definitions we see that

$$R_\Lambda := \bigcap_{i \in \Lambda} R_i = \Spa A_\Lambda \quad \text{with} \quad A_\Lambda := (A_\Lambda, A_\Lambda^+, X_\Lambda)$$

where $A_\Lambda^+$ is the integral closure of $A^+[f_k/f_i \mid (k, i) \in \{0, \ldots, n\} \times \Lambda]$ in $A_\Lambda$; moreover, $A_{0, \Lambda} := A_0[f_k/f_i \mid (k, i) \in \{0, \ldots, n\} \times \Lambda]$ is a subring of definition of $A_\Lambda$, and the natural ring homomorphism $A_0 \to A_{0, \Lambda}$ is adic (here we let $R_\emptyset := \Spa \Lambda$). Furthermore, since $X$ is quasi-compact, we have $\mathcal{O}_X(X_\Lambda) = A_\Lambda$ ([44] Ch.I, Prop.9.2.1), and therefore

$$A_\Lambda = \Gamma \circ \Spec (A_\Lambda) \quad \text{for every } \Lambda \subset \{0, \ldots, n\}.$$ (ii) Denote by $(A_{0, \Lambda}^h, I_{0, \Lambda}^h)$ the henselization of the pair $(A_{0, \Lambda}, I_0 A_{0, \Lambda})$, and endow $A_{0, \Lambda}^h$ with the $I_{0, \Lambda}^h$-adic topology; we deduce a unique isomorphism of topological $A$-algebras:

$$\omega^h_\Lambda : A_\Lambda^h := A_\Lambda \otimes A_{0, \Lambda} A_{0, \Lambda}^h \cong \mathcal{O}_{\Spa \Lambda}(R_\Lambda) \quad \text{for every } \Lambda \subset \{0, \ldots, n\}$$

where the topology on $A_\Lambda^h$ is the unique one such that the natural map $A_{0, \Lambda}^h \to A_\Lambda^h$ is open (proposition 8.3.34(ii)). Likewise, let $A_\Lambda^h$ be the separated completion of $A_{0, \Lambda}$; we deduce a natural continuous homomorphism of $A$-algebras

$$\omega^h_\Lambda : A_\Lambda^h \to \mathcal{O}_{\Spa \Lambda}(R_\Lambda) \quad \text{for every } \Lambda \subset \{0, \ldots, n\}.$$ Notice also that for every $\Lambda' \subset \Lambda$ there exist unique continuous homomorphisms of $A$-algebras and respectively $A_{0, \Lambda}$-algebras

$$\mu_{\Lambda' A} : A_{\Lambda'} \to A_\Lambda \quad \text{and} \quad \mu_{0, \Lambda' A}^h : A_{0, \Lambda'} \to A_{0, \Lambda}$$

and set $\mu_{\Lambda' A}^h : = \mu_{\Lambda' A} \otimes A A_{0, \Lambda}^h$. Let also $\hat{\mu}_{\Lambda' A} : A_\Lambda^h \to A_\Lambda^h$ be the completion of $\mu_{\Lambda' A}$, and

$$\hat{\rho}_{\Lambda' A}^h : \mathcal{O}_{\Spa \Lambda}(R_{\Lambda'}) \to \mathcal{O}_{\Spa \Lambda}(R_\Lambda) \quad \text{and} \quad \rho_{\Lambda' A}^h : \mathcal{O}_{\Spa \Lambda}(R_\Lambda) \to \mathcal{O}_{\Spa \Lambda}(R_{\Lambda'})$$

the restriction homomorphisms associated with the inclusion $R_\Lambda \subset R_{\Lambda'}$.

(iii) We claim that the diagrams of $A$-algebras:

$$\begin{array}{ccc}
A_{\Lambda'}^h \xrightarrow{\omega_{\Lambda'}^h} \mathcal{O}_{\Spa \Lambda}(R_{\Lambda'}) & \quad & A_\Lambda^h \xrightarrow{\omega_\Lambda^h} \mathcal{O}_{\Spa \Lambda}(R_\Lambda) \\
\mu_{\Lambda' A}^h & & \mu_{\Lambda A}^h \\
A_{\Lambda'}^h \xrightarrow{\rho_{\Lambda' A}^h} \mathcal{O}_{\Spa \Lambda}(R_{\Lambda'}) & \quad & A_\Lambda^h \xrightarrow{\rho_{\Lambda A}^h} \mathcal{O}_{\Spa \Lambda}(R_\Lambda)
\end{array}$$

commute for every $\Lambda' \subset \Lambda \subset \{0, \ldots, n\}$. Indeed, a simple inspection shows that $\mu_{\Lambda' A}^h$ is continuous. On the other hand, all the arrows in the diagram are $A$-algebra homomorphisms, therefore also $A_{\Lambda'}$-algebra homomorphisms, and by the universal property of the topological henselization there is a unique continuous $A_{\Lambda'}$-algebra homomorphism $A_{\Lambda'}^h \to \mathcal{O}_{\Spa \Lambda}(R_\Lambda)$, whence the contention for the left diagram. For the right diagram one argues similarly, using the universal property of the separated completions.

(iv) Endow $A[Y]$ and $B := A_0[T_0, \ldots, T_n]$ with the standard $\mathbb{N}$-gradings such that $gr_k A[Y] = AY^k$ and $gr_k B$ is the free $A$-module generated by the monomials $T_0^{\nu_0} \cdots T_n^{\nu_n}$ of total degree $\nu_0 + \cdots + \nu_n = k$, for every $k \in \mathbb{N}$. Set as well

$$S := \Spec A_0 \quad \text{and} \quad \mathbb{P}^n_S := \Proj B$$

and recall that $\mathbb{P}^n_S$ admits the following finite affine open covering (see (10.6.1)). For every $i = 0, \ldots, n$ we have the subring $B_i := A_0[T_0/T_i, \ldots, T_n/T_i]$ of $B[1/T_i]$, and $\Omega_i := \Spec B_i$ is
naturally identified with the open subscheme of $\mathbb{P}^n_S$ consisting of all homogeneous prime ideals of $B$ that do not contain $T_i$; then

$$\mathbb{P}^n_S = \Omega_0 \cup \cdots \cup \Omega_n.$$ 

Next, according to (10.6.5), the homomorphism of $\mathbb{N}$-graded $A_0$-algebras

$$h : B \to A[Y] \quad T_j \mapsto f_j Y \quad \text{for every } j = 0, \ldots, n$$

induces a morphism of $A_0$-schemes

$$\varphi : \text{Spec } A \setminus \text{Spec } A/J \to \mathbb{P}^n_S.$$ 

Explicitly, $\varphi^{-1}\Omega_i = \text{Spec } A_{(i)}$ for every $i = 0, \ldots, n$, and the restriction $\varphi^{-1}\Omega_i \to \Omega_i$ of $\varphi$ corresponds to the homomorphism of $A_0$-algebras

$$h_i : B_i \to A_{(i)} \quad T_j/T_i \mapsto f_j/f_i \quad \text{for every } j = 0, \ldots, n.$$

(v) Now, quite generally, let $\beta : X \to Y$ be any quasi-compact and quasi-separated morphism of schemes. Then $\beta_*\mathcal{O}_X$ is a quasi-coherent $\mathcal{O}_Y$-module (44 Ch.I, Prop.9.2.1), hence $\mathcal{I} := \ker \beta^* : \mathcal{O}_Y \to \psi_*\mathcal{O}_X$ is a quasi-coherent sheaf of ideals of $\mathcal{O}_Y$, and therefore $\text{Spec } \mathcal{O}_Y/\mathcal{I}$ is a well defined closed subscheme of $Y$, called the schematic image of $\psi$. From the definition, it is clear that the construction of the schematic image is local on $Y$; namely, if $Y' \subset Y$ is any open subscheme, and $X' := \beta^{-1}Y'$, then the schematic image of $\beta|_{X'} : X' \to Y'$ is the intersection of $Y'$ with the schematic image of $\beta$.

Thus, if $V$ is the schematic image of our $\varphi$, we get a commutative diagram of schemes

$$\begin{array}{ccc}
X & \xrightarrow{\psi} & V \\
\downarrow & & \downarrow \\
\text{Spec } A \setminus \text{Spec } A/J & \xrightarrow{\varphi} & \mathbb{P}^n_S \\
\end{array}$$

whose left vertical arrow is an open immersion, and with $\iota$ a closed immersion. Lastly, set $V_\mathcal{I} := V$ and for every subset $\Lambda \subset \{0, \ldots, n\}$ let $V_\Lambda := \iota^{-1}\left(\cap_{i \in \Lambda} \Omega_i\right)$; then $V_\Lambda$ is naturally identified with $\text{Spec } A_{0,\Lambda}$, for every non-empty $\Lambda$.

(vi) Furthermore, let $U$ be the analytic locus of $S$; recall that the morphism $\text{Spec } A \to S$ (associated with the inclusion map $A_0 \to A$) identifies $U$ with the analytic locus of $\text{Spec } A$ (lemma 8.3.29(iii)), and $U$ is an open subset of $X$, under this identification. Then $\mathbb{P}^n_U := \mathbb{P}^n_S \times_S U$ is an open subset of $\mathbb{P}^n_S$, and we claim that $\psi$ restricts to an isomorphism of schemes

$$\psi|_U : U \cong V \cap \mathbb{P}^n_U.$$ 

Indeed, $\psi|_U$ is a closed immersion, by [44] Ch.I, Cor.5.4.6]. On the other hand, $\psi|_U$ is also the schematic closure of the restriction $U \to \mathbb{P}^n_U$ of $\varphi$, whence the claim.

**Theorem 15.5.26.** For any topologically local quasi-affinoid scheme $X := (X, \mathcal{F}_X, A^+)$, the presheaves $\mathcal{O}^h_{\text{Spa }X}$ and $\mathcal{O}^{h+}_{\text{Spa }X}$ are sheaves of rings on $(\mathcal{D}(X), J_\mathcal{D})$.

**Proof.** Notice first that – by virtue of corollary 15.4.27(i) – if $\mathcal{O}^h_{\text{Spa }X}$ is a sheaf, the same holds for $\mathcal{O}^{h+}_{\text{Spa }X}$, so it suffices to check the assertion for $\mathcal{O}^h_{\text{Spa }X}$. To this aim, for every $U \in \text{Ob}(\mathcal{D}(X))$ and every $\mathcal{I} \in J_\mathcal{D}(U)$, let $h_{\mathcal{I}}$ be the corresponding sub-presheaf of the presheaf $h_U$ on $\mathcal{D}(X)$ represented by $U$. According to claim 44.1.16(ii,iii), it suffices to show that the natural map

$$r_U : \mathcal{O}^h_{\text{Spa }X}(U) \to \colim_{\mathcal{I} \in J_\mathcal{D}(U)} \text{Hom}_{\mathcal{D}(X)}(h_{\mathcal{I}}, \mathcal{O}^h_{\text{Spa }X})$$
is a bijection for every such $U$. However, let $\varphi_{T/X} : T \to X$ be any morphism of topologically local quasi-affinoid schemes representing the inclusion $h_U \subset h_X$ (see (15.5.7)); by remark [15.5.9] it follows that $\varphi_{T/X}$ induces an equivalence of categories

$$\mathcal{Q}(T) \to \mathcal{Q}(X)/U \quad V \mapsto \text{Spa} \varphi_{T/X}(V) \subset U$$

so we may replace $X$ by $T$, and reduce to checking that $r_{\text{Spa}X}$ is an isomorphism. Next, lemma [15.5.21] implies that the sieves of $\mathcal{Q}(X)$ generated by the standard coverings of $\text{Spa}X$ form a final subset of $J_\varphi(\text{Spa}X)$. Hence, let $f_*$ and $R_*$ be as in remark [15.5.25](i); taking into account the discussion of (4.1.6), we are then reduced to checking that the natural map

$$\mathcal{O}^h_{\text{Spa}X}(\text{Spa}X) \to \text{Equal}\left(\prod_{i=0}^n \mathcal{O}^h_{\text{Spa}X}(R_i) \longrightarrow \prod_{i,j=0}^n \mathcal{O}^h_{\text{Spa}X}(R_{i,j})\right)$$

is a bijection. Now, say that $(A, A^+, X) = \Gamma(X)$. Recall that the henselization morphism

$$\lambda : X^h := (X^h, \mathcal{O}_X^h, A^{h+}) \to X$$

is $\varphi$-adic and induces a homeomorphism $\text{Spa}A : \text{Spa}X^h \to \text{Spa}X$, as well as an isomorphism of schemes $X^h \cong X \times_A A^h$; it follows easily that the system $((\text{Spa} \lambda)^{-1}R_i \mid i = 0, \ldots, n)$ is a rational covering of $\text{Spa}X^h$, and moreover there is a unique isomorphism of presheaves of topological $A$-algebras

$$\mathcal{O}^h_{\text{Spa}X^h}(\text{Spa}X) \cong (\text{Spa} \lambda)^{-1}\mathcal{O}^h_{\text{Spa}X}.$$ \(\text{We may then replace } X \text{ by } X^h, \text{ and assume from start that } X \text{ is topologically henselian.} \)

In this situation, let $A_0 \subset A$ be a subring of definition, and $I_0 \subset A_0$ an ideal of adic definition; consider the system of quasi-affinoid rings $(A_0 \mid \Lambda \subset \{0, \ldots, n\})$, their rings of definition $A_{0,A} \subset A_A$, and the systems of their topological henselizations $(A_0^h \mid \Lambda \subset \{0, \ldots, n\})$ and $(A_{0,A}^h \mid \Lambda \subset \{0, \ldots, n\})$ constructed in remark [15.5.25](i). Define also $S, V, \psi : X \to V$ and $V_\Lambda$ for every subset $\Lambda \subset \{0, \ldots, n\}$ as in remark [15.5.25](iv,v); set $S' := \text{Spec} A_0/I_0$, $V'_\Lambda := V_\Lambda \times_S V'$ for every such $\Lambda$, and consider the cartesian diagram of schemes

$$\begin{array}{ccc}
V' & \xrightarrow{\tau_V} & V \\
\downarrow{\pi'} & & \downarrow{\pi} \\
S' & \xrightarrow{\tau_S} & S
\end{array}$$

where $\pi$ is the restriction to $V$ of the projection $\mathbb{P}_S^n \to S$ and $\tau_S : S' \to S$ is the closed immersion. For every scheme $X$, let $X_{\text{ét}}$ be the étale site of $X$, and $\mathcal{O}_{X_{\text{ét}}}$ the structure sheaf of rings on $X_{\text{ét}}$. We define the sheaf on $V'_{\text{ét}}$

$$\mathcal{F} := \tau'_V \psi_* \mathcal{O}_{X_{\text{ét}}}.$$ \(\text{Claim 15.5.27. (i) For every } \Lambda \subset \{0, \ldots, n\} \text{ there exists a commutative diagram of rings} \)

$$\begin{array}{ccc}
A^h_{0,\Lambda} & \xrightarrow{\omega_{0,\Lambda}} & \Gamma(V'_\Lambda, \tau'_V \mathcal{O}_{V'_{\text{ét}}}) \\
\downarrow{\mathcal{D}_\Lambda} & & \downarrow{\mathcal{D}_\Lambda} \\
A^h_\Lambda & \xrightarrow{\omega_{\Lambda}} & \Gamma(V'_\Lambda, \mathcal{F})
\end{array}$$

whose left vertical arrow is the inclusion map, and whose right vertical arrow is deduced from the natural morphism $\mathcal{O}_{V'_{\text{ét}}} \to \psi_* \mathcal{O}_{X_{\text{ét}}}$. Moreover, $\omega_{0,\Lambda}$ is an isomorphism of $A_0$-algebras for every $\Lambda \neq \emptyset$, and $\omega_{\Lambda}$ is an isomorphism of $A$-algebras for every $\Lambda$. \(\text{(ii)} \) \text{By result [15.5.30] and remark [15.5.25](ii), the morphism }$\psi_* \mathcal{O}_{X_{\text{ét}}}$ is an isomorphism of topological $A_0$-algebras.
(ii) For every $\Lambda' \subset \Lambda$, let $\rho_{\Lambda',\Lambda} : \Gamma(V'_{\Lambda'}, \mathcal{F}) \to \Gamma(V'_{\Lambda}, \mathcal{F})$ be the restriction homomorphism associated with the inclusion $V'_{\Lambda} \subset V'_{\Lambda'}$. Then we have a commutative diagram

$$
\begin{array}{ccc}
A^h_{\Lambda'} & \xrightarrow{\omega_{\Lambda'}} & \Gamma(V'_{\Lambda'}, \mathcal{F}) \\
\rho_{\Lambda',\Lambda}^h & \downarrow & \downarrow \rho_{\Lambda',\Lambda} \\
A^h_{\Lambda} & \xrightarrow{\omega_{\Lambda}} & \Gamma(V'_{\Lambda}, \mathcal{F}).
\end{array}
$$

**Proof of the claim.** (i): We consider first the case where $\Lambda = \emptyset$, and notice that $V_{\emptyset} = V$, $A^h_{0,\emptyset} = A_0$ and $A^h_{\emptyset} = A$. Under the current assumptions, the pair $(A_0, I_0)$ is henselian; by [9, Exp.XII, Th.5.1(i) and Prop.6.5(i)] we then get for every sheaf $\mathcal{G}$ on $V_{\emptyset}$ natural isomorphisms

$$
\Gamma(V, \mathcal{G}) \xrightarrow{\sim} \Gamma(S, \pi_* \mathcal{G}) \xrightarrow{\sim} \Gamma(S', \tau_S^* \pi_* \mathcal{G}) \xrightarrow{\sim} \Gamma(S', \pi'_* \tau_V^* \mathcal{G}) \xrightarrow{\sim} \Gamma(V', \tau_V^* \mathcal{G}).
$$

Taking $\mathcal{G} := \psi_* \mathcal{O}_{X_A}$, we then obtain the sought isomorphism $\omega_{\emptyset}$

$$
A = (X, \mathcal{O}_X) \xrightarrow{\sim} \Gamma(V, \psi_* \mathcal{O}_{X_A}) \xrightarrow{\sim} \Gamma(V', \mathcal{F}).
$$

Likewise, the map $\omega_{0,\emptyset}$ is defined as the composition

$$
A_0 = \Gamma(S, \mathcal{O}_S) \xrightarrow{\sim} \Gamma(S, \pi_* \mathcal{O}_V) \xrightarrow{\sim} \Gamma(V', \tau_V^* \mathcal{O}_V)
$$

from which the commutativity of $\mathcal{O}_{\emptyset}$ is straightforward. Next, let $\Lambda \neq \emptyset$, so that $V_{\Lambda}$ is an affine scheme; set $V_{\Lambda}^h := \text{Spec} A_{0,\Lambda}^h$ and $X_{\Lambda} := X \cap \text{Spec} A_\Lambda$. We let $\psi_{\Lambda} : X_{\Lambda} \to V_{\Lambda}$ be the restriction of $\psi$, and we consider the cartesian diagram of schemes

$$
\begin{array}{ccc}
X_{\Lambda}^h & \xrightarrow{\tau_{X_{\Lambda}}^h} & X_{\Lambda} \\
\psi_{\Lambda}^h & \downarrow & \downarrow \psi_{\Lambda} \\
V_{\Lambda'}^h & \xrightarrow{\tau_{V_{\Lambda'}}^h} & V_{\Lambda'}
\end{array}
$$

where $\tau_{X_{\Lambda}}^h$ and $\tau_{V_{\Lambda'}}^h$ are induced by the natural projection $A_{0,\Lambda}^h \to A_{0,\Lambda}^h/I_{0,\Lambda}^h \xrightarrow{\sim} A_{0,\Lambda}/I_{0,\Lambda}A_\Lambda$, and respectively the henselization map $A_{0,\Lambda} \to A_{0,\Lambda}^h$. Then $\omega_{\Lambda}$ is defined as the composition of isomorphisms of $A$-algebras

$$
A_{\Lambda}^h = \Gamma(X_{\Lambda}^h, \mathcal{O}_{X_{\Lambda}^h}) \xrightarrow{\sim} \Gamma(V_{\Lambda'}^h, \psi_{\Lambda}^h \circ \tau_{X_{\Lambda}}^h \mathcal{O}_{X_{\Lambda},\text{ét}}) \xrightarrow{\sim} \Gamma(V_{\Lambda}, \psi_{\Lambda} \circ \tau_{X_{\Lambda}}^h \mathcal{O}_{X_{\Lambda},\text{ét}})
$$

$$
\xrightarrow{\sim} \Gamma(V_{\Lambda}, \tau_{V_{\Lambda}}^* \mathcal{O}_{V_{\Lambda},\text{ét}})
$$

$$
\xrightarrow{\sim} \Gamma(V_{\Lambda}^h, \tau_{V_{\Lambda}^h}^* \mathcal{O}_{V_{\Lambda}^h,\text{ét}})
$$

where the bijectivity of the third map is due to [9, Exp.XII, Prop.6.5(i)], and that of the second one is due to the fact that $\tau_{V_{\Lambda}^h}$ is the limit of a cofiltered system of affine étale $V_{\Lambda}$-schemes. Likewise, $\omega_{0,\Lambda}$ is obtained as the composition

$$
A_{0,\Lambda}^h = \Gamma(V_{\Lambda}^h, \mathcal{O}_{V_{\Lambda}^h}) \xrightarrow{\sim} \Gamma(V_{\Lambda}, \tau_{V_{\Lambda}}^* \mathcal{O}_{V_{\Lambda}}) \xrightarrow{\sim} \Gamma(V_{\Lambda}, \tau_{V_{\Lambda}}^* \mathcal{O}_V).
$$

Then the commutativity of $\mathcal{O}_A$ follows by a direct inspection.

(ii): We consider the diagram of $A_0$-algebras

$$
\begin{array}{ccc}
A_{0,\Lambda'}^h & \xrightarrow{\omega_{0,\Lambda'}} & \Gamma(V'_{\Lambda'}, \mathcal{O}_{V',\text{ét}}) \xrightarrow{\sim} \Gamma(V'_{\Lambda}, \mathcal{F}) \xrightarrow{\sim} \Gamma(V_{\Lambda}, \mathcal{O}_{X_{\text{ét}}}) = A_{\Lambda} \\
\rho_{0,\Lambda'}^h & \downarrow & \downarrow \rho_{0,\Lambda}^h \\
A_{0,\Lambda}^h & \xrightarrow{\omega_{0,\Lambda}} & \Gamma(V_{\Lambda}, \mathcal{O}_{V_{\text{ét}}}) \xrightarrow{\sim} \Gamma(V_{\Lambda}, \mathcal{F}) \xrightarrow{\sim} \Gamma(V_{\Lambda}, \mathcal{O}_{X_{\text{ét}}}) = A_{\Lambda}
\end{array}
$$

whose central square subdiagram is induced by the natural morphism $\mathcal{O}_{V_{\text{ét}}} \to \psi_* \mathcal{O}_{X_{\text{ét}}}$, and the right square subdiagram is induced by the unit of adjunction $\psi_* \mathcal{O}_{X_{\text{ét}}} \to \tau_{V_{\Lambda}}^* \psi_* \mathcal{O}_{X_{\text{ét}}}$.
for the adjoint pair \((\tau_Y^*, \tau_*^*)\), and where \(\mu_{X,A}^h\) and \(\mu_{0,A}^{h,0}\) are defined as in remark 15.5.25(ii). Therefore, both these subdiagrams commute; the left square subdiagram commutes as well, due to the universal property of henselization; taking into account (i), the assertion follows (details left to the reader).

Lastly, we have a natural map

\[
A \xrightarrow{\alpha} \text{Equal} \left( \prod_{i=0}^n A_{(i)}^{h} \xrightarrow{\beta} \prod_{i,j=0}^n A_{(i,j)}^{h} \right)
\]

induced by the maps \(\mu_{V,(i)}^{h,0}\), where \(\beta\) and \(\gamma\) are deduced from the maps \(\mu_{(i),(j)}^{h,0}\). From claim 15.5.27 we deduce that \(\alpha\) is an isomorphism, and taking into account remark 15.5.25(iii), the theorem follows.

\[\Box\]

\[\textbf{Remark 15.5.28.}\] Let \(X\) be any topologically local quasi-affinoid scheme.

(i) As explained in [44, Ch.0, §3.2.2], every sheaf on \(\mathcal{D}(X)\) admits a natural extension to a sheaf \(\mathcal{F}'\) on the topological space \(\text{Spa} X\). Namely, if \(U \subset \text{Spa} X\) is any open subset, one sets

\[
\mathcal{F}'(U) := \lim_{V \in (\mathcal{D}(X)/U)^{\text{et}}}(V)
\]

where \(\mathcal{D}(X)/U\) denotes the full subcategory of \(\mathcal{D}(X)\) whose objects are the quasi-affinoid open subsets of \(\text{Spa} X\) contained in \(U\). We shall use the notation \(\mathcal{O}_{\text{Spa} X}^h\) and \(\mathcal{O}_{\text{Spa} X}^{h+}\) also to refer to the sheaves on \(\text{Spa} X\) that extend naturally the respective sheaves on \(\mathcal{D}(X)\).

(ii) Simple examples show that, in most cases, the presheaves \(\mathcal{O}_{\text{Spa} X}^h\) and \(\mathcal{O}_{\text{Spa} X}^{h+}\) are not sheaves on the site \(\mathcal{D}(X)\). On the other hand, in several situations of interest the presheaves \(\mathcal{O}_{\text{Spa} X}^\wedge\) and \(\mathcal{O}_{\text{Spa} X}^{\wedge+}\) are sheaves of topological rings. In Huber’s work [78], this sheaf property is proven under two different types of assumptions, corresponding roughly to the two main classes of non-archimedean analytic spaces that are encountered in applications: the “generic fibers” of locally noetherian formal schemes, and the rigid analytic varieties locally of finite type over a complete rank one valued field. In the literature, one finds also some attempts to unify these cases (and the few other known ones) under a single axiomatic framework; hereafter we shall adopt the approach (though, not the terminology) proposed in [55], that is based on the notions introduced in section 15.2. Later, we shall prove the sheaf property also in the case where \(\mathcal{O}_X(X)\) admits a perfectoid ring of definition: this is a completely different situation, for which we shall need to develop an \textit{ad hoc} method.

\[\textbf{Definition 15.5.29.}\] (i) Let \(A\) be any \(f\)-adic ring. We say that \(A\) is \(f\)-adic analytically noetherian (resp. \(f\)-adic universally analytically noetherian), if it admits an analytically noetherian (resp. universally analytically noetherian) ring of definition (see definition [15.2.1(i)]).

(ii) Let \(A := (A, A^+)\) be any affinoid ring. We say that \(A\) is analytically noetherian (resp. universally analytically noetherian) if \(A\) is \(f\)-adic analytically noetherian (resp. \(f\)-adic universally analytically noetherian).

(iii) Let \(A := (A, A^+, U)\) be any quasi-affinoid ring. We say that \(A\) is analytically noetherian (resp. universally analytically noetherian) if the same holds for \((A, A^+)\).

(iv) Let \(X\) be any quasi-affinoid scheme. We say that \(X\) is analytically noetherian (resp. universally analytically noetherian) if the same holds for \(\Gamma(X)\).

\[\textbf{15.5.30.}\] Let \(A\) be any \(f\)-adic ring, and \(n \in \mathbb{N}\) any integer. According to proposition 8.3.37(i,ii), there exists a unique \(f\)-adic topology \(\mathcal{T}_n\) on \(A[T_1, \ldots, T_n]\) such that, if \(A_0\) is any subring of definition of \(A\), then \(A_0[T_1, \ldots, T_n]\) is a subring of definition of \(A[T_1, \ldots, T_n]\), and if \(I \subset A_0\) is an ideal of adic definition, then \(I[T_1, \ldots, T_n]\) is an ideal of adic definition for \(A_0[T_1, \ldots, T_n]\).

\[\textbf{Lemma 15.5.31.}\] With the notation of \([15.5.30]\), the following holds:
(i) $A$ is $f$-adic analytically noetherian (resp. $f$-adic universally analytically noetherian) if and only if every ring of definition of $A$ is analytically noetherian (resp. universally analytically noetherian).

(ii) $A$ is $f$-adic universally analytically noetherian if and only if $(A[T_1, \ldots, T_n], \mathcal{S}_n)$ is $f$-adic analytically noetherian for every $n \in \mathbb{N}$.

(iii) Let $B \subset A$ be any open subring, and endow $B$ with the topology induced from $A$. Then $A$ is $f$-adic analytically noetherian (resp. $f$-adic universally analytically noetherian) if and only if the same holds for $B$.

(iv) Let $f : A \to A'$ be a surjective ring homomorphism, and endow $A'$ with the topology induced by $A$ via $f$. Then, if $A$ is $f$-adic analytically noetherian (resp. $f$-adic universally analytically noetherian), the same holds for $A'$.

(v) If $A$ is any $f$-adic analytically noetherian (resp. $f$-adic universally analytically noetherian) quasi-affinoid scheme, $\text{Spec} A$ is an analytically noetherian (resp. universally analytically noetherian) quasi-affinoid scheme.

(vi) Let $X$ be a topologically local and universally analytically noetherian quasi-affinoid scheme, and $Y \to X$ a morphism of topologically local quasi-affinoid schemes that represents a rational subset of $\text{Spa} X$. Then $Y$ is universally analytically noetherian.

**Proof.** (i): Let $A_0, A_1 \subset A$ be two rings of definition, and let us show that $A_0$ is analytically noetherian if and only if the same holds for $A_1$. To this aim, suppose first that $A_0 \subset A_1$, and let $I \subset A_0$ be any finitely generated ideal of adic definition, so that $IA_1$ is an ideal of adic definition for $A_1$. Lemma 8.3.29(iii) says that the inclusion map $A_0 \to A_1$ identifies the analytic locus $U_0$ of $\text{Spec} A_0$ with the analytic locus $U_1$ of $\text{Spec} A_1$, so $U_0$ is a noetherian scheme if and only if the same holds for $U_1$. Next, suppose that $A_0$ is analytically noetherian; let $M_1$ be any $A_1$-module of finite type, $x_1, \ldots, x_n$ any system of generators for $M_1$, and set $M_0 := A_0 x_1 + \cdots + A_0 x_n \subset M_1$. By proposition 8.3.18(ii), there exists $n \in \mathbb{N}$ such that $I^n A_1 \subset A_0$, whence $I^n M_1 \subset M_0$. On the other hand, by assumption there exists $r \in \mathbb{N}$ such that $\text{Ann}_{M_0}(I^k) = \text{Ann}_{M_0}(I^r)$ for every $k \geq r$. Thus, let $x \in \text{Ann}_{M_1}(I^k A_1)$ for some $k \geq r$; we get $I^n x \in \text{Ann}_{M_1}(I^k A_1) \cap M_0 = \text{Ann}_{M_0}(I^k)$, so $I^{n+r} x = 0$, as asserted, in this case.

Suppose next that $A_1$ is analytically noetherian, and let $M_0$ be any $A_0$-module of finite type; the short exact sequence of $A_0$-modules $0 \to A_0 \to A_1 \to A_1/A_0 \to 0$ induces an exact sequence

$$T_1 := \text{Tor}_{A_0}(A_1/A_0, M_0) \to M_0 \xrightarrow{\varphi} M_1 := A_1 \otimes A_0 M_0$$

and notice that $I^n T_1 = 0$. By assumption, there exists $r \in \mathbb{N}$ such that $\text{Ann}_{M_1}(I^k A_1) = \text{Ann}_{M_1}(I^r A_1)$ for every $k \geq r$. Suppose then that $x \in \text{Ann}_{M_0}(I^k)$ for some $k \geq r$; it follows easily that $I^r x \subset \ker \varphi$, whence $I^{r+n} x = 0$, as required.

Lastly, if $A_0$ and $A_1$ are arbitrary rings of definition for $A$, the same holds for $A_2 := A_0 \cdot A_1$ (corollary 8.3.19(i)). Suppose that $A_0$ is analytically noetherian; by the foregoing, it follows that the same holds for $A_2$, and then by the same token it holds for $A_1$ as well.

The assertion for the universally noetherian case is an immediate consequence.

Assertion (ii) follows directly from (i): details left to the reader.

(iii) follows from (i) and corollary 8.3.19(ii).

(iv): First, we know that $A'$ is $f$-adic, by example 8.3.27(iii), and if $A_0 \subset A$ is a ring of definition, $f(A_0)$ is a ring of definition of $A'$. But if $A_0$ is analytically noetherian (resp. universally analytically noetherian), the same holds for $f(A_0)$, by lemma 15.2.4(ii). The assertion follows.

(v): Say that $A = (A, A^+, U)$, and let $\rho : A \to A_U := \mathcal{O}_{\text{Spec} A}(U)$ be the restriction map. By definition, the topology $\mathcal{T}_{\rho(A)}$ on $\rho(A)$ induced by the inclusion into $A_U$ agrees with the quotient topology induced by the surjection $A \to \rho(A)$. From (iv) we deduce that $(\rho(A), \mathcal{T}_{\rho(A)})$ is $f$-adic analytically noetherian (resp. $f$-adic universally analytically noetherian). Then, the assertion follows from (iii).
(vi) follows easily from (v) and lemma [15.2.4]ii, after inspecting the proof of theorem [15.5.5].

**Lemma 15.5.32.** Let \( X := (X, \mathcal{T}_X, A_X^+) \) be any analytically noetherian quasi-affinoid scheme. Then the natural morphism \( \Gamma(X)^{\wedge} \rightarrow \Gamma(X^{\wedge}) \) is an isomorphism (see remark [15.4.13]ii).

**Proof.** Let \( A_X^\wedge \) be the separated completion of \( A_X := \mathcal{O}_X(X) \), and set \( Y := \text{Spec } A_X^\wedge \times_{\text{Spec } A_X} X; \) in light of proposition [15.2.10]ii and corollary [10.3.8] the natural map \( A_X^\wedge \rightarrow \mathcal{O}_Y(Y) \) is an isomorphism. Then the assertion follows from remark [15.4.13]ii. \( \square \)

**15.5.33.** For any topologically local quasi-affinoid scheme \( X \), we may consider the site

\[(\mathcal{I}(X), J_{\mathcal{I}})\]

where \( \mathcal{I}(X) \) is the full subcategory of \( \mathcal{O}(X) \) whose objects are the rational subsets of \( \text{Spa } X \). The sieves covering a given object \( R \) of \( \mathcal{I}(X) \) for the topology \( J_{\mathcal{I}} \) are those generated by the families \( R_\lambda := (R_\lambda | \lambda \in \Lambda) \) of rational subsets of \( \text{Spa } X \) such that \( \bigcup_{\lambda \in \Lambda} R_\lambda = R \). For every such \( R_\lambda \), after fixing a total ordering on \( \Lambda \) we get an augmented alternating \( \check{\text{C}}ech \) complex \( C_{\text{alt}}(R_\lambda, \mathcal{O}_{\text{Spa } X}) \), whose degree \( n \) term, for every \( n \geq 0 \), is a product of topological rings of the form \( \mathcal{O}_{\text{Spa } X}(R_{\lambda_0} \cap \cdots \cap R_{\lambda_n}) \), with \( \lambda_0 < \cdots < \lambda_n \) ranging over all strictly increasing sequences of elements of \( \Lambda \) (see remark [10.2.7]i). We endow \( C^n_{\text{alt}}(R_\lambda, \mathcal{O}_{\text{Spa } X}) \) with the corresponding product topology, and we notice that this topology is independent of the chosen ordering for \( \Lambda \), and the differentials \( \partial^* \) of the \( \check{\text{C}}ech \) complex are continuous maps. With this notation, we have:

**Theorem 15.5.34.** For any topologically local and universally analytically noetherian quasi-affinoid scheme \( X \), we may consider the site

\[(\mathcal{I}(X), J_{\mathcal{I}})\]

where \( \mathcal{I}(X) \) is the full subcategory of \( \mathcal{O}(X) \) whose objects are the rational subsets of \( \text{Spa } X \). The sieves covering a given object \( R \) of \( \mathcal{I}(X) \) for the topology \( J_{\mathcal{I}} \) are those generated by the families \( R_\lambda := (R_\lambda | \lambda \in \Lambda) \) of rational subsets of \( \text{Spa } X \) such that \( \bigcup_{\lambda \in \Lambda} R_\lambda = R \). For every such \( R_\lambda \), after fixing a total ordering on \( \Lambda \) we get an augmented alternating \( \check{\text{C}}ech \) complex \( C_{\text{alt}}(R_\lambda, \mathcal{O}_{\text{Spa } X}) \), whose degree \( n \) term, for every \( n \geq 0 \), is a product of topological rings of the form \( \mathcal{O}_{\text{Spa } X}(R_{\lambda_0} \cap \cdots \cap R_{\lambda_n}) \), with \( \lambda_0 < \cdots < \lambda_n \) ranging over all strictly increasing sequences of elements of \( \Lambda \) (see remark [10.2.7]i). We endow \( C^n_{\text{alt}}(R_\lambda, \mathcal{O}_{\text{Spa } X}) \) with the corresponding product topology, and we notice that this topology is independent of the chosen ordering for \( \Lambda \), and the differentials \( \partial^* \) of the \( \check{\text{C}}ech \) complex are continuous maps. With this notation, we have:

**Proof.** (i): Arguing as in the proof of theorem [15.5.26], we reduce to checking the assertion for \( \mathcal{O}^\wedge_{\text{Spa } X} \). We remark:

**Claim 15.5.35.** For any given \( R \in \text{Ob}(\mathcal{I}(X)) \), let \( \varphi_{Y/X} : Y \rightarrow X \) be any morphism of quasi-affinoid schemes representing the sub-presheaf \( h_R \) of \( h_X \); then the morphism \( \varphi_{Y/X} \) induces an equivalence of categories

\[\mathcal{I}(Y) \cong \mathcal{I}(X)/R \quad V \mapsto \text{Spa } \varphi_{Y/X}(V) \subset R.\]

Moreover, \( Y \) is still universally analytically noetherian.

**Proof of the claim.** These assertions follow from lemmata [15.5.10] and [15.5.31]vi. \( \diamond \)

Now, say that \( \Gamma(X) = (A, A^+, X) \) and let \( R_\lambda := (R_0, \ldots, R_n) \) be the standard covering of \( \text{Spa } X \) attached to a given sequence \( f_* := (f_0, \ldots, f_n) \) of elements of \( A \); define also the rational subset \( R_\lambda \) as in remark [15.5.25]i), for every subset \( \Lambda \subset \{0, \ldots, n\} \). In light of claim [15.5.35] and remark [5.5.2]i), we are reduced to showing that the natural map

\[\Theta_{\text{Spa } X}(\text{Spa } X) \rightarrow \text{Equal} \left( \prod_{i=0}^n \Theta_{\text{Spa } X}(R_i) \right) \rightarrow \prod_{i,j=0}^n \Theta_{\text{Spa } X}(R_{(i,j)}) \]

is an isomorphism of topological rings. To this aim, we pick a subring of definition \( A_0 \subset A \), a finitely generated ideal \( I_0 \subset A_0 \) of adic definition, we set \( S := \text{Spec } A_0 \), we denote by \( J \subset A \) the ideal generated by \( f_* \), and we consider the system \( (A_{\Lambda} | \Lambda \subset \{0, \ldots, n\}) \) of quasi-affinoid rings, and their rings of definition \( A_{0,\Lambda} \subset A_{\Lambda} \) constructed in remark [15.5.25]i). Let also \( A_{\Lambda}^\wedge \) be the separated completion of \( A_{\Lambda} \), and notice that the map

\[\omega_{\Lambda}^\wedge : A_{\Lambda}^\wedge \rightarrow \Theta_{\text{Spa } X}(R_{\Lambda}) \]
of remark 15.5.25(ii) is an isomorphism of topological $\mathcal{A}$-algebras for every $\Lambda \subset \{0, \ldots, n\}$, by lemma 15.5.32. Define $S$, $V$, $\psi : X \to V$ and $V_\Lambda$ for every subset $\Lambda \subset \{0, \ldots, n\}$ as in remark 15.5.25(v); set also $S' := \text{Spec} A_0/I_0$ and let $V^\wedge$ be the completion of $V$ along $S' \times_S V$, and $\pi : V^\wedge \to V$ the induced morphism of locally ringed spaces. We define
\[ \mathcal{F} := \pi^* \psi_* \mathcal{O}_X \quad \text{and} \quad V^\wedge_\Lambda := \pi^{-1} V_\Lambda \quad \text{for every $\Lambda \subset \{0, \ldots, n\}$} \]
and we regard $\mathcal{F}$ as a presheaf of topological abelian groups, as follows. The natural morphism $\mathcal{O}_V \to \psi_* \mathcal{O}_X$ induces a morphism
\[ \varphi : \mathcal{O}_V^\wedge \to \mathcal{F} \]
and for every open subset $U \subset V^\wedge$ we endow $\mathcal{F}(U)$ with the unique group topology such that the resulting map $\varphi_U : \mathcal{O}_V^\wedge(U) \to \mathcal{F}(U)$ is continuous and open. It follows easily that for every inclusion $U' \subset U$ of open subsets of $V^\wedge$, the restriction map $\mathcal{F}(U) \to \mathcal{F}(U')$ is continuous.

Claim 15.5.37. (i) $\mathcal{F}(V^\wedge_\Lambda)$ is a topological ring for every $\Lambda \subset \{0, \ldots, n\}$, and there exists a natural isomorphism of topological $\mathcal{A}$-algebras
\[ \omega_\Lambda : A^\wedge_\Lambda \xrightarrow{\sim} \mathcal{F}(V^\wedge_\Lambda). \]

(ii) For every $\Lambda' \subset \Lambda$, let $\rho_{\Lambda', \Lambda} : \mathcal{F}(V^\wedge_\Lambda) \to \mathcal{F}(V^\wedge_{\Lambda'})$ be the restriction homomorphism associated with the inclusion $V^\wedge_{\Lambda'} \subset V^\wedge_\Lambda$. Then we have a commutative diagram
\[ \begin{array}{ccc}
A^\wedge_\Lambda & \xrightarrow{\omega_\Lambda} & \mathcal{F}(V^\wedge_\Lambda) \\
\rho_{\Lambda', \Lambda} & \downarrow & \downarrow \rho_{\Lambda', \Lambda} \\
A^\wedge_{\Lambda'} & \xrightarrow{\omega_{\Lambda'}} & \mathcal{F}(V^\wedge_{\Lambda'}). 
\end{array} \]

Proof of the claim. (i): We consider first the case where $\Lambda = \emptyset$, and recall that $V_\emptyset = V$. Notice also that $\psi_* \mathcal{O}_X$ is a quasi-coherent $\mathcal{O}_V$-module, by virtue of [44, Ch.I, Cor.9.2.2]. Since $V$ is a projective $S$-scheme, corollary 15.2.34(iii) and remark 15.2.38 yield a natural isomorphism
\[ \omega_\emptyset : A^\wedge \xrightarrow{\sim} A_0^\wedge \otimes_{A_0} A \xrightarrow{\sim} A_0^\wedge \otimes_{A_0} \Gamma(V, \psi_* \mathcal{O}_X) \xrightarrow{\sim} \mathcal{F}(V^\wedge) \]
fitting into a commutative diagram
\[ \begin{array}{ccc}
A_0^\wedge & \xrightarrow{\omega_\emptyset} & A^\wedge \\
\downarrow \quad & & \quad \downarrow \omega_\emptyset \\
\mathcal{O}_V^\wedge(V^\wedge) & \xrightarrow{\varphi^\wedge} & \mathcal{F}(V^\wedge) 
\end{array} \]
whose left vertical arrow is the $I_0$-adic completion of the natural map $A_0 \to \mathcal{O}_V(V)$, and whose top horizontal arrow is the inclusion map. It follows already that $\omega_\emptyset$ is a continuous map, and it thus remains only to check that $\omega_\emptyset$ is an open map. To this aim, it suffices to check that the same holds for the left vertical arrow $A_0^\wedge \to \mathcal{O}_V^\wedge(V^\wedge)$. However, $\mathcal{O}_V(V)$ is an $A_0^\wedge$-module of analytically finite type, by theorem 15.2.22, and the support of $\mathcal{O}_V(V)/A_0$ lies in the non-analytic locus of $S$, by virtue of remark 15.2.25(vi); by remark 15.2.25(iii) we deduce that $I_0^t \cdot \mathcal{O}_V(V) \subset A_0$ for some $t \in \mathbb{N}$, whence $I_0^t \cdot \mathcal{O}_V^\wedge(V^\wedge) \subset A_0^\wedge$. Since the topology of $\mathcal{O}_V^\wedge(V^\wedge)$ is $I_0$-adic (corollary 15.2.34(ii)), the assertion follows.

In case $\Lambda$ is not empty, $V_\Lambda$ is affine, and a direct inspection yields a natural isomorphism of topological rings $A^\wedge_{0, \Lambda} \xrightarrow{\sim} \mathcal{O}_V^\wedge(V^\wedge_\Lambda)$. We may then appeal to proposition 15.2.20(iii) to see that the natural map
\[ (15.5.38) \quad A^\wedge_{\Lambda} \xrightarrow{\sim} A^\wedge_{0, \Lambda} \otimes_{A_0, \Lambda} A_\Lambda \xrightarrow{\sim} A^\wedge_{0, \Lambda} \otimes_{A_0, \Lambda} \Gamma(V_\Lambda, \psi_* \mathcal{O}_X) \to \mathcal{F}(V^\wedge_\Lambda) \]
is also an isomorphism of rings, fitting into another commutative diagram

\[
\begin{array}{c}
A_{0,\Lambda}^\wedge \\
\downarrow \\
\frac{\varphi_{V^\wedge}}{\mathcal{F}(V^\wedge)} \\
\end{array}
\]

\[\text{(15.5.39)}\]

whose top horizontal arrow is again the inclusion map, so \(\mathcal{F}(V^\wedge)\) is also a topological ring with the topology defined in the foregoing, and \((15.5.38)\) is even an isomorphism of topological rings, if \(\Lambda \neq \emptyset\).

(ii): The abelian groups appearing in the diagram are all endowed with natural \(A_{\Lambda'}^\wedge\)-module structures, and it is easily seen that all the arrows are both \(A_{\Lambda',0}\)-linear and \(A_{\Lambda'}\)-linear maps, whence the assertion.

Next, consider the affine open covering \(V^\wedge := \{V^\wedge_{i} \mid i = 0, \ldots, n\}\) of \(V^\wedge\), and endow the terms of the augmented alternating Čech complex \(C^\wedge_{\text{alt}}(V^\wedge, \mathcal{F})\) with the product topologies, as in \((15.5.33)\). Combining claim \((15.5.37)\) and remark \((15.5.25)\)(iii) we deduce an isomorphism of complexes of topological abelian groups

\[
C^\wedge_{\text{alt}}(V^\wedge, \mathcal{F}) \sim C^\wedge_{\text{alt}}(R^\wedge, \mathcal{O}_{\text{Spa}X}).
\]

Hence, to conclude it suffices to show:

Claim 15.5.41. The complex \(C^\wedge_{\text{alt}}(V^\wedge, \mathcal{F})\) has strict differentials, and its cohomology has the discrete topology.

Proof of the claim. Diagram \((15.5.39)\) implies that \(\varphi_{V^\wedge}\) is injective for every \(\Lambda \neq \emptyset\); it follows easily that the same holds for \(\varphi_{V^\wedge}\). Hence the induced map of alternating Čech complexes

\[
C^\wedge_{\text{alt}}(V^\wedge, \varphi) : C^\wedge_{\text{alt}}(V^\wedge, \mathcal{O}_{V^\wedge}) \to C^\wedge_{\text{alt}}(V^\wedge, \mathcal{F})
\]

is injective in every degree, and by construction \(C^\wedge_{\text{alt}}(V^\wedge, \varphi)\) is an open map for every \(i \in \mathbb{Z}\), so we are reduced to showing that the differentials \(d^i\) of \(C^\wedge_{\text{alt}}(V^\wedge, \mathcal{O}_{V^\wedge})\) are strict and induce open maps \(C^\wedge_{\text{alt}}(V^\wedge, \mathcal{O}_{V^\wedge}) \to \text{Ker} \cdot d^{i+1}\) for every \(i \in \mathbb{Z}\). If \(i < -1\), there is nothing to show. For \(i = -1\), the assertion follows from remark \((5.5.2)\)(i). In the remaining cases, the assertion comes down to the following. For every \(i, t \in \mathbb{N}\) there exists \(s \in \mathbb{N}\) such that

\[
(15.5.42) \quad I_{0}^s \cdot C^\wedge_{\text{alt}}(V^\wedge, \mathcal{O}_{V^\wedge}) \cap \text{Ker} \cdot d^{i+1} \subset I_{0}^t \cdot \text{Im} \cdot d^i.
\]

For every \(k \in \mathbb{N}\), denote by \(d^i_k\) the differentials of the Čech complex \(C^\wedge_{\text{alt}}(V^\wedge, I_{0}^k \mathcal{O}_{V^\wedge})\); condition \((15.5.42)\) is equivalent to

\[
\text{Ker} \cdot d^{i+1} \subset \text{Im} \cdot d^i.
\]

Taking into account theorem \((15.1.37)\)(i), we are therefore reduced to showing that for every \(i, t \in \mathbb{N}\) there exists an integer \(s \geq t\) such that the natural map

\[
H^{i+1}(V^\wedge, I_{0}^s \mathcal{O}_{V^\wedge}) \to H^{i+1}(V^\wedge, I_{0}^t \mathcal{O}_{V^\wedge})
\]

vanishes. Taking into account corollaries \((15.2.30)\)(i) and \((15.2.34)\)(i), we are further reduced to showing that for every \(i, t \in \mathbb{N}\) there exists \(s \in \mathbb{N}\) such that \(I_{0}^{s} \cdot H^{i+1}(V^\wedge, I_{0}^k \mathcal{O}_{V}) = 0\). Notice that the \(A_{0}\)-module \(H^{i+1}(V, I_{0}^k \mathcal{O}_{V})\) is analytically of finite type (theorem \((15.2.22)\) and remark \((15.2.38)\)(ii)); in light of remark \((15.2.2)\)(iii) it then suffices to check that the support of \(H^{i+1}(V, I_{0}^k \mathcal{O}_{V})\) lies in the non-analytic locus of \(S\). The latter follows easily from remark \((15.5.25)\)(vi) : details left to the reader.

(ii): Arguing as in the proof of (i), we reduce easily to the case where \(R = \text{Spa}X\). Say that \(\Omega = \{(U_i \mid i \in I)\}\) for some set \(I\), and pick any standard covering \(\Omega' := \{(U'_i \mid i \in I')\}\) of \(\text{Spa}X\)
that refines \( \mathcal{U} \); after fixing total orderings for \( I \) and \( I' \) we may consider the double complex

\[
C_{alt}^\bullet((\mathcal{U}, \mathcal{U}')) := \text{Hom}_R^\bullet\left( P_{alt}^\bullet((\mathcal{U}, \mathcal{U}'), \mathcal{O}_{\text{Spa} X}^\wedge) \right)
\]

(notation of remark 10.2.14(ii)) which vanishes in every bidegree \((p, q)\) with either \( p < -1 \) or \( q < -1 \). For every \( n \in \mathbb{N} \), define \( I_{alt}^{n+1} \) and \( I_{alt}^{n+1} \) as in [10.2.24] and for every \( t \in I_{alt}^{n+1} \) and every \( t' \in I_{alt}^{n+1} \), set \( \mathcal{U}_{t,t'} := (\mathcal{U}_t | \mathcal{U}_{t'} \mid i \in I) \) and \( \mathcal{U}_{t,t'} := (\mathcal{U}_i \cap \mathcal{U}_{i'} \mid i \in I) \). We notice that :

- The complex \( C_{alt}^{n-1}(\mathcal{U}, \mathcal{U}') \) coincides with \( C_{alt}^\bullet(\mathcal{U}, \mathcal{O}_{\text{Spa} X}^\wedge) \).
- The complex \( C_{alt}^{n-1}(\mathcal{U}, \mathcal{U}') \) coincides with \( C_{alt}^\bullet(\mathcal{U}', \mathcal{O}_{\text{Spa} X}^\wedge) \).
- For every \( n \in \mathbb{N} \), the complex \( C_{alt}^{n}(\mathcal{U}, \mathcal{U}') \) is the product \( \prod_{t \in I_{alt}^{n+1}} C_{alt}^\bullet(\mathcal{U}_{t,t'}, \mathcal{O}_{\text{Spa} X}^\wedge) \).
- For every \( n \in \mathbb{N} \), the complex \( C_{alt}^{n}(\mathcal{U}, \mathcal{U}') \) is the product \( \prod_{t \in I_{alt}^{n+1}} C_{alt}^\bullet(\mathcal{U}_{t,t'}, \mathcal{O}_{\text{Spa} X}^\wedge) \).

Since \( \mathcal{U}'_t \) is a standard covering of \( U_t \), the proof of (i) shows that the differentials of the complex \( C_{alt}^\bullet(\mathcal{U}', \mathcal{O}_{\text{Spa} X}^\wedge) \) induce open maps \( \delta_n^{\mathcal{U}} \) as in (8.6.11), for every \( n \in \mathbb{N} \). Likewise, the same holds for the induced maps \( \delta_n^{\mathcal{U}'} \). Moreover, since \( \mathcal{U}' \) refines \( \mathcal{U} \), for every \( n \in \mathbb{N} \) and every \( t' \in I_{alt}^{n+1} \) there exists \( i \in I \) such that \( U'_t \subset U_i \), in which case remark 10.2.13 yields a homotopy \( h^* \) from the identity automorphism of \( C_{alt}^\bullet(\mathcal{U}', \mathcal{O}_{\text{Spa} X}^\wedge) \) to the zero map, and a simple inspection shows that \( h^* \) is a continuous map, for every \( i \in \mathbb{Z} \). Then, lemma 8.6.15(i) says that the differentials of \( C_{alt}^\bullet(\mathcal{U}', \mathcal{O}_{\text{Spa} X}^\wedge) \) induce open maps \( \delta_n^{\mathcal{U}'} \) as well, for every \( n \in \mathbb{N} \). Lastly, we invoke corollary 8.6.12 to conclude.

15.5.43. Let \( X := (X, \mathcal{T}_X, A_X^+) \) be a quasi-affinoid scheme fulfilling the assumptions of theorem 15.5.34 so that \( \mathcal{O}_{\text{Spa} X}^\wedge \) is a sheaf of topological rings on the site \((\mathcal{S}(X), J_{alt})\). Following [44, Ch.0, §3.2.2] (and see also remark 15.5.28(i)), we may extend (uniquely up to unique isomorphism) both \( \mathcal{O}_{\text{Spa} X}^\wedge \) and \( \mathcal{O}_{\text{Spa} X}^\wedge \) to sheaves of topological groups on the topological space \( \text{Spa} X \), and we shall denote these extensions with the same names. Then the pair \((\text{Spa} X, \mathcal{O}_{\text{Spa} X}^\wedge)\) is a topologically ringed space. Moreover, lemma 15.5.14 says that \( \text{Spa} X \) is a locally ringed space, so there exists a unique morphism of locally ringed spaces

\[
\sigma_X : (\text{Spa} X, \mathcal{O}_{\text{Spa} X}^\wedge) \to \text{Spec} A
\]

such that the corresponding map \( \mathcal{O}_{\text{Spec} A} \to \sigma_X^* \mathcal{O}_{\text{Spa} X}^\wedge \) yields on global sections the natural map \( A \to A^\wedge := \mathcal{O}_{\text{Spa} X}^\wedge(\text{Spa} X) \) ([43, Ch.I, Prop.1.6.3]). By inspecting loc.cit. it is easily seen that \( \sigma_X \) is the composition

\[
\text{Spa} X \subset \text{Cont} A \xrightarrow{\sigma_A} \text{Spec} A
\]

where \( \sigma_A \) is the restriction of the support map (see remark 9.2.4(iii)). Especially, the image of \( \sigma_X \) lies in \( X \), whence a well defined morphism of locally ringed spaces

\[
(\text{Spa} X, \mathcal{O}_{\text{Spa} X}^\wedge) \to (X, \mathcal{O}_X).
\]

**Corollary 15.5.45.** With the notation of \((\ref{15.5.43})\), the morphism \( \sigma_X \) induces an isomorphism

\[
A^\wedge \otimes_A H^i(X, \mathcal{O}_X) \sim H^i(\text{Spa} X, \mathcal{O}_{\text{Spa} X}^\wedge) \quad \text{for every } i \in \mathbb{N}.
\]

**Proof.** Let us show first the following special case :

**Claim 15.5.46.** In the situation of the corollary, suppose moreover that \( X \) is affinoid. Then \( H^i(\text{Spa} X, \mathcal{O}_{\text{Spa} X}^\wedge) = 0 \) for every \( i > 0 \).

**Proof of the claim.** In light of theorem 10.2.24(i) and lemma 15.5.21 it suffices to show that for every rational subset \( R \) of \( \text{Spa} X \) and every standard covering \( \mathcal{U} \) of \( R \), the alternating \( \check{\text{Cech}} \) complex \( C_{alt}^\bullet(\mathcal{U}, \mathcal{O}_{\text{Spa} X}^\wedge) \) is acyclic. However, notice that any such \( R \) is represented by an affinoid (topologically local) scheme; then, arguing as in the proof of theorem 15.5.34(i), we are easily reduced to the case where \( R = \text{Spa} X \). Then, after choosing a subring of definition for \( A \) we may define the scheme \( V \), its formal completion \( V^\wedge \), the affine open coverings \( V_\bullet \) and
$V^\wedge$, the projection $\pi : V^\wedge \to V$ and the morphism of schemes $\psi : X \to V$ as in the proof of theorem [15.5.34]. In light of theorem [15.1.37](i) and of the isomorphism ([15.5.40]), we are then reduced to showing that $H^i(V^\wedge, \pi^*\mathcal O_X) = 0$ for every $i > 0$. Then, corollary [15.2.34](iii) further reduces to checking that $H^i(V, \psi_*\mathcal O_X) = 0$ for every $i > 0$; but since $X$ is affine, the morphism $\psi$ is affine, so that $H^i(V, \psi_*\mathcal O_X) \simeq H^i(X, \mathcal O_X)$, whence the contention.

Now, say that $X = \text{Spec } A \setminus \text{Spec } A/J$ for a finitely generated ideal $J \subset A$, and pick a finite system of generators $f_\bullet := (f_0, \ldots, f_n)$ for $J$ and a subring of definition $A_0 \subset A$. Let also $R_\bullet$ be the standard covering of $\text{Spa } X$ associated with $f_\bullet$, and notice that $R_i$ is represented by an affinoid scheme, for every $i = 0, \ldots, n$. Set as well $U_i := \text{Spec } A[f_i^{-1}]$ for $i = 0, \ldots, n$, and notice that $\sigma_X(R_i) \subset U_i$ for $i = 0, \ldots, n$, and $X = U_0 \cup \cdots \cup U_n$. There follows a commutative diagram (notation of (10.2.18))

$$
\begin{array}{ccc}
A_0^\wedge \otimes_A H^i_{\text{alt}}(U_\bullet, \mathcal O_X) & \stackrel{\alpha}{\longrightarrow} & H^i_{\text{alt}}(R_\bullet, \mathcal O_{\text{Spa } X}) \\
\downarrow & & \downarrow \\
A_0^\wedge \otimes_A H^i(X, \mathcal O_X) & \longrightarrow & H^i(\text{Spa } X, \mathcal O_{\text{Spa } X})
\end{array}
$$

where the vertical arrows are isomorphisms, by virtue of claim [15.5.46] and corollary [10.2.21](ii). Since $A^\wedge = A_0^\wedge \otimes_A A$, it then suffices to check that $\alpha$ is an isomorphism. On the other hand, as in the proof of theorem [15.5.34], we may associate with the sequence $f_\bullet$ a morphism of schemes $\psi : X \to V$, the formal completion $V^\wedge$ of $V$ with its natural projection $\pi : V^\wedge \to V$, and an affine covering $V_\bullet := (V_i | i = 0, \ldots, n)$ of $V$ such that $\psi^{-1}V_i = U_i$ for $i = 0, \ldots, n$; we set $V_i^\wedge := \pi^{-1}V_i$ for $i = 0, \ldots, n$, and $F := \pi^*\psi_*\mathcal O_X$. There follows a commutative diagram

$$
\begin{array}{ccc}
A_0^\wedge \otimes_A H^i_{\text{alt}}(V_\bullet, \mathcal O_X) & \stackrel{\beta}{\longrightarrow} & H^i_{\text{alt}}(V^\wedge, F) \\
\downarrow & & \downarrow \\
A_0^\wedge \otimes_A H^i(V, \psi_*\mathcal O_X) & \longrightarrow & H^i(V^\wedge, F)
\end{array}
$$

whose vertical arrows are again isomorphisms, by virtue of proposition [15.2.20](iv), and the same holds for the bottom horizontal arrow, by corollary [15.2.34](iii). To conclude, it suffices to observe that $H^i_{\text{alt}}(U_\bullet, \mathcal O_X) = H^i_{\text{alt}}(V_\bullet, \mathcal O_X)$, and that the isomorphism of Čech complexes ([15.5.40]) identifies $\alpha$ with $\beta$.

**Example 15.5.47.** We present two counterexamples that show how theorem [15.5.34] can fail for affinoid schemes that are not analytically noetherian. To begin with, let $K$ be a rank one complete valued field, and fix an element $\pi \neq 0$ in the maximal ideal of $K^+$. For every $K^+[T]$-module $J$ without $\pi$-torsion, let us set

$$
A_J := K^+[T] \oplus J \quad A_{J,K} := A_J \otimes_{K^+} K
$$

and endow $A_J$ with the $\pi$-adic topology and with the $K^+[T]$-algebra structure such that the inclusion map $K^+[T] \to A$ is a ring homomorphism and $J$ is an ideal with $J^2 = 0$ (i.e. $(x, y) \cdot (x', y') := (xx', xy' + x'y)$ for every $(x, y), (x', y') \in A$). Clearly $A$ is an adic topological ring, and we endow $A_{J,K}$ with the $f$-adic topology such that $A_J$ is a ring of definition. Let also $A_J^f$ and $A_{J,K}^f$ be the completions of $A_J$ and respectively $A_{J,K}$, and $A_{J,K}^f$ the integral closure of $A_J^f$ in $A_{J,K}^f$, and set

$$
\mathcal X := \text{Spec}(A_{J,K}^f, A_{J,K}^f).
$$

* Take first $J := K^+[T, T^{-1}] / K^+[T]$. We claim that in this case the presheaf $\mathcal O_{\text{Spa } X}$ on $\mathcal R(\mathcal X)$ is not separated. Indeed, consider the standard covering associated with the sequence $(\pi, T)$; it consists of the rational subsets

$$
U_0 := \{ v \in \text{Spa } \mathcal X | v(T) \leq v(\pi) \} \quad \text{and} \quad U_1 := \{ v \in \text{Spa } \mathcal X | v(\pi) \leq v(T) \}
$$

...
and $\mathcal{O}_{\text{Spa} \mathcal{U}}(U_0) = B_0^\pi \otimes_{K^+} K$, where $B_0^\pi$ is the completion of $B_0 := A_J[T/\pi] \subset A_{J,K}$, where the latter is endowed with its $\pi$-adic topology. But notice that for every $k, n > 0$ the element $T^{-k}$ of $J$ can be written in $B_0$ as

$$T^{-k} = T^{-k-n} \cdot (T/\pi)^n \cdot \pi^n \in \pi^n B_0.$$

Since $n$ is arbitrary, it follows that $T^{-k}$ lies in the kernel of the restriction map $\rho_0 : A^\wedge_{J,K} \to \mathcal{O}_{\text{Spa} \mathcal{X}}(U_0)$, and since $k$ is arbitrary, we get $J \subset \text{Ker} \rho_0$. Likewise, $\mathcal{O}_{\text{Spa} \mathcal{U}}(U_1) = B_1^\pi \otimes_{K^+} K$, where $B_1^\pi$ is the completion of $B_1 := A_J[\pi/T] \subset A_J[T^{-1}]$, where the latter is endowed with its $\pi$-adic topology. Clearly $A_J[T] \to J^\wedge [T, T^{-1}]$, whence $J \subset \text{Ker} (\rho_1 : A_{J,K} \to \mathcal{O}_{\text{Spa} \mathcal{X}}(U_1))$ as well, and the claim follows.

- Next, we take $J$ to be the $\mathbb{N}$-graded $K^+[T]$-module such that

$$\text{gr}_n J := T^{-n} K^+[T]/K^+[T] \quad \text{for every } n \in \mathbb{N}.$$ 

It follows that $\mathcal{O}_{\text{Spa} \mathcal{X}}(U_0) = C_0 \otimes_{K^+} K$, where $C_0$ is the $\pi$-adic completion of $K^+[T/\pi] \oplus J'$, with $J'$ the $\mathbb{N}$-graded $K^+[T/\pi]$-module such that

$$\text{gr}_n J' := T^{-n} K^+[T/\pi]/K^+[T] \quad \text{for every } n \in \mathbb{N}.$$ 

Especially, $\mathcal{O}_{\text{Spa} \mathcal{X}}(U_0)$ contains the $\pi$-adic completion $J^\wedge$ of $J'$. On the other hand, it is clear that $A_J[T^{-1}] = K[T, T^{-1}]$, so the kernel of the restriction map $\rho_1 : \mathcal{O}_{\text{Spa} \mathcal{X}}(U_0) \to \mathcal{O}_{\text{Spa} \mathcal{X}}(U_0 \cap U_1)$ contains $J^\wedge$. Now, consider the series

$$P := \sum_{n \in \mathbb{N}} T^{-n} \quad \text{where } T^{-n} \in \text{gr}_{2n} J' \text{ for every } n \in \mathbb{N}.$$ 

Then $T^{-n} = T^{-2n} \cdot (T/\pi)^n \cdot \pi^n \in \pi^n \text{gr}_{2n} J'$, so the series $P$ converges $\pi$-adically to a well defined element of $J^\wedge$, and $\rho_1(P) = 0 = \rho_1(0)$ (where $\rho_1 : \mathcal{O}_{\text{Spa} \mathcal{X}}(U_1) \to \mathcal{O}_{\text{Spa} \mathcal{X}}(U_0 \cap U_1)$ is the other restriction map). We shall show that the series $P$ does not lie in the image of $\rho_0$, so again $\mathcal{O}_{\text{Spa} \mathcal{X}}(U_0)$ is not a sheaf, and more precisely, not even the maximal separated quotient of $\mathcal{O}_{\text{Spa} \mathcal{X}}(U_0)$ is a sheaf. Indeed, recall that the completion $J^\wedge$ of $J$ lies in the product of the completions $\text{gr}_n J^\wedge$ of its graded summands, and likewise for $J^\wedge$ (remark 8.5.2(iii)); moreover, the induced map $J^\wedge \to J^\wedge$ is the restriction of the product of the corresponding maps $\text{gr}_n J^\wedge \to \text{gr}_n J^\wedge$. It is easily seen that the latter maps are injective, so if $P$ were in the image of $\rho_0$, it would be represented by the sequence $(P_n | n \in \mathbb{N})$ where $P_{2k+1} = 0$ and $P_{2k} = T^{-k} \in \text{gr}_{2k} J^\wedge$ for every $k \in \mathbb{N}$. But then the series $\sum_{n \in \mathbb{N}} P_n$ must converge $\pi$-adically in $J^\wedge$ (proposition 8.5.3(ii)); the latter means that for every $t \in \mathbb{N}$ there exists $i \in \mathbb{N}$ such that $T^{-k} \in \pi^i \text{gr}_{2k} J$ for every $k \geq i$. But $T^{-k}$ is not divisible by $\pi$ in $\text{gr}_{2k} J$, for any $k \in \mathbb{N}$, a contradiction.

Remark 15.5.48. The constructions of example 15.5.47 and several others as well, may also be found in the recent preprint [37], which introduces an interesting general class of “stably uniform” affinoid rings $A$ for which the authors can prove that the presheaf $\mathcal{O}_{\text{Spa} A}$ is a sheaf.

15.6. Special loci of quasi-affinoid schemes. The results of this section will be used in chapter 16 for the study of perfectoid spaces.

Definition 15.6.1. Let $\mathcal{X} := (X, \mathcal{X}_A, A^\wedge_X)$ be any quasi-affinoid scheme, $V \subset X^+ := \text{Spec } A^+_X$ any open subset, and set $\mathcal{A}_V := \mathcal{O}_V(X)$. Let moreover $\beta^\wedge_X : X \to X^+$ be the restriction of the morphism of schemes $\beta^\wedge_X : \text{Spec } A_X \to X^+$ induced by the inclusion map $A^+_X \hookrightarrow A_X$.

- We say that $\mathcal{X}$ spreads over $V$, if $\beta^\wedge_X$ restricts to an isomorphism of schemes $\beta^\wedge_X^{-1} V \overset{\sim}{\to} V$.

- Let $\mathcal{Y} := (Y, \mathcal{Y}_A, A^\wedge_Y)$ be another quasi-affinoid scheme, and $\varphi : \mathcal{Y} \to \mathcal{X}$ an $\mathfrak{f}$-adic morphism of quasi-affinoid schemes. Then the induced ring homomorphism $\varphi^\wedge_Y : A_Y \to A_X$ restricts to an $\mathfrak{f}$-adic map $\varphi^\wedge_Y : A_Y^+ \to A_X^+$, and we set

$$\varphi^\wedge := \text{Spec } \varphi^\wedge_Y : Y^+ \to X^+.$$
We say that \( \varphi \) spreads over \( V \), if \( Y \) spreads over \((\varphi^+)^{-1}(V)\) (in which case, we also say that \( Y \) spreads over \( V \), if no ambiguity is likely to arise).

(iii) We shall also denote by \( \Omega_X \subset X^+ \) the largest open subset such that \( X \) spreads over \( \Omega_X \).

**Remark 15.6.2.** (i) Let \( X := (X, \mathcal{X}_X, A^+_X) \) be any quasi-affinoid scheme; then \( X \) spreads over the analytic locus of \( \text{Spec} \ A^+_X \), by virtue of lemma \( \ref{8.3.29} \)(iii).

(ii) Keep the notation of definition \( \ref{15.6.1} \)(ii), let \( \psi : Z \rightarrow Y \) be another morphism of quasi-affinoid schemes, and suppose that \( \varphi \) spreads over \( V \) and \( \psi \) spreads over \((\varphi^+)^{-1}(V)\); then clearly \( \varphi \circ \psi \) spreads over \( V \).

**Lemma 15.6.3.** With the notation of definition \( \ref{15.6.1} \) we have :

(i) Let \( W \subset X \) be an open subset such that \( \beta_X \) restricts to an open immersion \( W \rightarrow X^+ \). Then \( \beta_X(W) \subset \Omega_X \).

(ii) \( \gamma_X \) restricts to an isomorphism of schemes \( \gamma^{-1}_X \Omega_X \cong \Omega_X \).

**Proof.** (i) First, let us notice the following

**Claim 15.6.4.** \( \mathcal{O}_X(V) \) is integrally closed in \( \mathcal{O}_X(\beta^{-1}_X V) \), for every open subset \( V \subset X^+ \).

**Proof of the claim.** Suppose first that \( V = \text{Spec} \ A^+_X[f^{-1}] \) for some \( f \in A^+_X \); since \( \beta_X, \mathcal{O}_X \) is a quasi-coherent \( \mathcal{O}_X^+ \)-module, we have \( \mathcal{O}_X(\beta^{-1}_X V) = A^+_X[f^{-1}] \), and since \( A^+_X \) is integrally closed in \( A_X \), the assertion holds in this case. For a general open subset \( V \), we may find an affine open covering \( V = \bigcup_{i \in I} V_i \) where each \( V_i \) is of the form \( \text{Spec} \ A^+_X[f_{ij}^{-1}] \) for some \( f_{ij} \in A^+_X \), and we get a commutative diagram of rings

\[
\begin{array}{ccc}
\mathcal{O}_X(V) & \rightarrow & R := \prod_{i \in I} \mathcal{O}_X(V_i) \\
\downarrow & & \downarrow \\
\mathcal{O}_X(\beta^{-1}_X V) & \rightarrow & R' := \prod_{i \in I} \mathcal{O}_X(\beta^{-1}_X V_i) \\
\end{array}
\]

Now, if \( h \in \mathcal{O}_X(\beta^{-1}_X V) \) is integral over \( \mathcal{O}_X(V) \), obviously the image \( h' \) of \( h \) in \( R' \) is integral over \( R \); but from the foregoing case, it is easily seen that \( R \) is integrally closed in \( R' \), so \( h' \in R \), and since the vertical arrows are injective maps, we deduce easily that \( \rho_1(h') = \rho_2(h') \), whence \( h' \in \mathcal{O}_X(V) \), and the assertion follows.

Now, by assumption, \( \beta_X(W) \) is an open subset of \( X^+ \), and \( \beta_X \) restricts to a separated morphism \( \beta^{-1}_X \beta_X(W) \rightarrow \beta_X(W) \); the latter admits a section whose image is the open subset \( W \subset \beta^{-1}_X \beta_X(W) \). Taking into account \( \ref{44} \) Ch.I, Cor.5.4.6], we see that \( W \) is an open and closed subset of \( \beta^{-1}_X \beta_X(W) \). There follow ring homomorphisms

\[
\mathcal{O}_X(\beta_{X}(W)) \rightarrow \mathcal{O}_X(\beta^{-1}_X \beta_{X}(W)) \rightarrow \mathcal{O}_X(W)
\]

whose composition is an isomorphism, and the kernel of \( \rho \) is generated by an idempotent element \( e \in \mathcal{O}_X(\beta^{-1}_X \beta_{X}(W)) \). However, claim \( \ref{15.6.4} \) implies that \( e \) lies in the image of \( \mathcal{O}_X(\beta_X(W)) \) , so \( e = 0 \), hence \( W = \beta^{-1}_X \beta_X(W) \), and the assertion follows immediately.

**Claim 15.6.5.** Let \( f : X \rightarrow Y \) and \( g : Y \rightarrow Z \) be two morphisms of schemes, such that \( h := g \circ f \) is an open immersion and the image of \( f \) is schematically dense. Then we have :

(i) \( f \) is an open immersion.

(ii) If \( g \) is separated, then \( g^{-1}h(X) = f(X) \).

**Proof of the claim.** (i) We know from \( \ref{44} \) Ch.I, Cor.5.3.13] that the morphism \( f \) is an immersion, and since its image is schematically dense, it must be an open immersion.
(ii): Since \( h \) is an open immersion, we may replace \( Z \) by \( h(X) \) and \( Y \) by \( g^{-1}h(X) \), after which we have \( h = 1_X \), and \( f \) is a section of \( g \). Since \( g \) is separated, \(^{[44]}\) Ch.I, Cor.5.4.6 then tells us that \( f \) is a closed immersion in this case, and combining with (i), the claim follows. 

(ii): Consider now the commutative diagram of schemes

\[
\begin{array}{ccc}
\beta_X^{-1}\Omega_X & \xrightarrow{f} & \gamma_X^{-1}\Omega_X \\
\downarrow h & & \downarrow g \\
\Omega_X & & \\
\end{array}
\]

where \( f \) is the restriction of \( \beta_X \) and \( g \) is the restriction of \( \gamma_X \). Thus, \( h \) is the restriction of \( \beta_X \), and it is an isomorphism, by definition of \( \Omega_X \); moreover, clearly \( f \) has schematically dense image. By claim \(^{[15.6.5]}\) it follows that \( f \) is a surjective open immersion, \( i.e. \) it is an isomorphism, and then the same holds for \( g \) as well. □

**Proposition 15.6.6.** In the situation of definition \(^{[15.6.1]}\) suppose that \( X \) spreads over \( V \). Then:

(i) The topological localization \( j_X^+: X^+ \rightarrow X \), the topological henselization \( j_X: X^h \rightarrow X \), and the completion \( j_X^\wedge : X^\wedge \rightarrow X \) of \( X \) spread over \( V \).

(ii) Let also \( f_0, \ldots, f_n \) be a sequence of elements of \( A_X \) that generate an ideal \( I \) such that \( (\beta_X^{-1}I) \cap \spec A_X/I = \emptyset \), and set \( B := \Gamma (X/(f_0, \ldots, f_n)) \) (notation of \(^{[15.5.1]}\)). The induced morphism \( Y := \spec B \rightarrow X \) spread over \( V \).

(iii) Let \( Y' \rightarrow X \) and \( Y'' \rightarrow X \) be two \( f \)-adic morphisms of quasi-affinoid schemes that spread over \( V \). The fibre product \( Y' \times_X Y'' \rightarrow X \) spreads over \( V \) (see example \(^{[15.4.8]}\)).

(iv) Let \( U \subset \beta_X^{-1}V \) be a quasi-compact open subset containing the analytic subset of \( X \).

The induced morphism \( \varphi : U \times_X X \rightarrow X \) spreads over \( V \) (see example \(^{[15.4.4]}\)).

**Proof.** (i): Say that \( X_{\text{loc}} = (X', \mathcal{T}', A^+_X) \), and let \( j_X^+: X'^+ \rightarrow X^+ \) be the morphism induced by the topological localization \( A^+_X \rightarrow A^+_X \). By inspecting \(^{[8.4.8]}\), and taking into account the natural identifications \(^{[15.4.11]}\), we get a cartesian diagram of schemes :

\[
\begin{array}{ccc}
X' & \xrightarrow{j_X} & X \\
\downarrow \beta_{X_{\text{loc}}} & & \downarrow \beta_X \\
X'^+ & \xrightarrow{j_X^+} & X^+. \\
\end{array}
\]

The assertion for \( j_X \) is an immediate consequence. The same argument applies to \( j_X^+ \). Next, say that \( X^\wedge = (X^\wedge, \mathcal{T}_X^\wedge, A^+_X) \), and \( \Gamma (X)^\wedge = (A^+_X, A^+_X, X') \). According to corollary \(^{[15.4.28]}\), the kernel \( \mathcal{J} \) of the surjective map \( A^+_X \rightarrow A^+_X := \mathcal{O}_X(X^\wedge) \) lies in \( A^+_X \), and we set \( Y := \spec A^+_X/\mathcal{J} \); there follows a commutative diagram of schemes

\[
\begin{array}{ccc}
X^\wedge & \xrightarrow{\varphi} & X \\
\downarrow \beta_X^\wedge & & \downarrow \beta_X \\
X'^{\wedge} & \xrightarrow{\nu} & Y \rightarrow X^+. \\
\end{array}
\]

whose square subdiagram is cartesian. With this notation, \( \varphi_*\mathcal{O}_X \) is a quasi-coherent \( \mathcal{O}_Y \)-algebra, and \( A^+_X = \mathcal{A}(Y) \), where \( \mathcal{A} \) is the integral closure of the image of \( \mathcal{O}_Y \) in \( \varphi_*\mathcal{O}_X \). Let \( V'' \subset Y \) and \( V'' \subset X'^{\wedge} \) be the preimages of \( V \); under our assumptions, the morphism \( \varphi : \mathcal{O}_Y \rightarrow \varphi_*\mathcal{O}_X^\wedge \) restricts to an isomorphism \( \mathcal{O}_Y|_V \cong (\varphi_*\mathcal{O}_X^\wedge)|_V \), so that \( \mathcal{A}|_V = (\varphi_*\mathcal{O}_X^\wedge)|_V \). The latter implies that the morphism \( \gamma_X^\wedge \) restricts to an isomorphism \( \gamma_X^{-1}V'' \cong V'' \), and \( \nu \) restricts to an isomorphism \( V'' \cong V'' \); lastly, since the image of \( X \) in \( X^+ \) contains \( V \), it is clear
