Abstract. We study collections of additive categories $\mathcal{M}(G)$, indexed by finite groups $G$ and related by induction and restriction, in a way that categorifies usual Mackey functors. We call them ‘Mackey 2-functors’ and provide a large collection of examples. We then isolate the initial such structure, leading to what we call ‘Mackey 2-motives’. We also exhibit a convenient calculus of morphisms in Mackey 2-motives, by means of string diagrams.

CHAPTER 1

Introduction and results

1.1. Motivation and quick outline

In algebraic geometry, Grothendieck’s motives encapsulate the common themes recurring throughout a broad range of cohomology theories. These (Weil) cohomology theories can be described axiomatically and depend on a chosen class of algebraic varieties of interest, for instance smooth projective varieties for pure motives, or all quasi-projective varieties for mixed motives.

In modern representation theory of finite groups, we propose a similar motivic unification of a widely used type of structure, that we identify under the name of Mackey 2-functor. We emphasize that examples of such structures have been studied for a long time. We only give them a convenient name.

Instead of Grothendieck’s class of algebraic varieties, we consider here a class of finite groups of interest, typically all finite groups. Instead of Weil cohomology theories, we consider additive categories, often triangulated categories, depending on the groups in question.

To apprehend the notion of Mackey 2-functor the reader should first recall the 1-version, namely ordinary Mackey functors. An ordinary Mackey functor \( M \) involves the data of abelian groups \( M(G) \) indexed by the groups \( G \) in our class of interest. These \( M(G) \) come with restriction homomorphisms \( R^G_H : M(G) \to M(H) \), induction or transfer homomorphisms \( I^G_H : M(H) \to M(G) \), and conjugation homomorphisms \( c_x : M(H) \to M(xH) \), for \( H \leq G \) and \( x \in G \). These homomorphisms are subject to a certain number of rules, most of them rather intuitive. The critical rule is the Mackey double-coset formula, which says that for all \( H, K \leq G \) the following two homomorphisms \( M(H) \to M(K) \) are equal:

\[
R^G_K \circ I^G_H = \sum_{[x] \in K \backslash G / H} I^G_{K \cap xH} \circ c_x \circ R^H_{K \cap xH}.
\]

See details in Webb’s survey [Web00] or in Appendix B.

In this work, we dial categorical complexity up one notch – we ‘categorify’ – in that we replace abelian groups by additive categories.

So, in first approximation, a Mackey 2-functor \( \mathcal{M} \) consists of the data of an additive category \( \mathcal{M}(G) \) for each group \( G \) of interest, together with further structure like restriction and induction functors, and subject to a Mackey formula at the categorical level. By definition, \( \mathcal{M} \) satisfies ambidexterity, namely each restriction functor \( \mathcal{M}(G) \to \mathcal{M}(H) \) has a two-sided adjoint. In other words, induction and coinduction coincide in \( \mathcal{M} \). As we shall recall, these structures appear in many situations, from categories of \( kG \)-modules \( \mathcal{M}(G) = \text{Mod}(kG) \) in classical linear...
representation theory (Example 4.1.4), to stable categories of $G$-spectra $\mathcal{M}(G) = \text{SH}(G)$ in $G$-equivariant homotopy theory (Example 4.3.8).

By considering adjunctions between the categories $\mathcal{M}(G)$, we have entered a 2-categorical world, as we not only have categories (0-cells) and functors (1-cells) to take into account but also natural transformations of functors (2-cells). In particular our version of the Mackey formula will not involve an equality between homomorphisms as in (1.1.1) but an isomorphism between functors. In fact, not only are 2-categories the natural framework for the output of a Mackey 2-functor $G \mapsto \mathcal{M}(G)$, the input of $\mathcal{M}$ is truly 2-categorical as well. Indeed, the class of finite groups ‘of interest’ is advantageously replaced by a class of finite groupoids ‘of interest’, for instance all finite groupoids. This apparently modest generalization not only harmonizes the input and output of our Mackey 2-functor $G \mapsto \mathcal{M}(G)$ but also allows for much cleaner Mackey formulas, in the form of Beck-Chevalley base-change formulas. Furthermore, the 2-categorical approach distinguishes the two roles played by conjugation with respect to an element $x$ of a group $G$, either as a plain group homomorphism $^x(-): H \rightarrow H$ (at the 1-level) or as a relation $^xf_1 = f_2$ between parallel group homomorphisms $f_1, f_2: H \rightarrow G$ (at the 2-level).

The motivic philosophy led Grothendieck to the plain 1-category of motives in algebraic geometry. Because of our added 2-categorical layer, the same philosophy will naturally lead us to a 2-category of Mackey 2-motives. And very much as geometric motives depend on the chosen class of varieties, so will our Mackey 2-motives depend on the chosen 2-category of groupoids we start from.

This outlines the topic we want to investigate. Our treatment is divided into seven main chapters and two appendices, as we now quickly explain.

After this brief ouverture, Chapter 1 expands into a longer introduction to Mackey 2-functors $G \mapsto \mathcal{M}(G)$. The precise definition will be found in Section 1.2, at least for $\mathcal{M}$ defined on all groupoids. (The general definition will come in Section 2.3.) We then survey the highlights of the work in more details: the Rectification Theorem in Section 1.3, the connection with derivators in Section 1.4, the construction of Mackey 2-motives and motivic decompositions in Section 1.5.

Chapter 2 begins with a detailed discussion of iso-comma squares and Mackey squares of groupoids (Sections 2.1 and 2.2). These special squares allow for canonical Mackey formulas, without choices of representatives in double cosets. In Section 2.3, we analyze which classes of finite groupoids are suitable input for (generalized) Mackey 2-functors. The second half of Chapter 2 is dedicated to two simple results about Mackey 2-functors. First we prove in the very short Section 2.4 that, for any subgroup(oid) $H \leq G$, the category $\mathcal{M}(H)$ is a separable extension of $\mathcal{M}(G)$. This result is a unification of the string of examples brought to light in [Bal15] and [BDS15], where we proved separability by providing an ad hoc argument in each instantiation of the phenomenon. Here we give a uniform proof that all examples of Mackey 2-functors automatically satisfy this separability property. Secondly, in the equally short and reassuring Section 2.5, we explain how Mackey 2-functors provide ordinary Mackey 1-functors under decategorification.

Chapter 3 is dedicated to technical preparations for the crucial Ambidexterity Theorem 4.1.1, which itself appears in the next chapter. The critical technical point is the comparison between induction and coinduction, without assuming ambidexterity a priori. See an expanded introduction to ‘rectification’ in Section 1.3.
We will then be ready to address in Chapter 4 one of our main goals, namely the proof that widely used additive categories $\mathcal{M}(G)$, depending on finite groups $G$, are indeed part of suitable Mackey 2-functors. The basic source of such examples is the Ambidexterity Theorem 4.1.1 for additive derivators. This result explains the ubiquity of Mackey 2-functors. In particular, any stable model category $\mathcal{Q}$ provides a Mackey 2-functor $G \mapsto \text{Ho}(\mathcal{Q}^G)$, via the restriction of diagram categories $\text{Ho}(\mathcal{Q}^I)$ to groupoid shapes $I = G$. In Sections 4.2 and 4.3, we provide further methods to handle more involved examples which cannot be obtained directly from a derivator, like stable module categories (Proposition 4.2.5) and genuine $G$-equivariant stable homotopy categories (Example 4.3.8).

In Chapters 5 to 7, we approach Mackey 2-functors from the motivic perspective, i.e. we prove the existence of an initial such structure. We call this universal construction the 2-category (or bicategory) of Mackey 2-motives. Our construction of Mackey 2-motives involves two layers of spans, first for 1-cells and then for 2-cells. Although very explicit, there is no denying that these constructions and the proof of their universal properties are computation-heavy. As a counterweight, we establish a calculus of string diagrams in Mackey 2-motives which removes a great deal of the technicalities of the above double-span construction. Again, we defer to Section 1.5 for an expanded introduction to Mackey 2-motives.

Finally, Appendix A collects all categorical prerequisites whereas Appendix B is dedicated to ordinary Mackey functors.

Acknowledgements: We thank Serge Bouc, Yonatan Harpaz, Ioannis Lagkas, Akhil Mathew, Hiroyuki Nakaoka, Beren Sanders, Stefan Schwede and Alexis Virelizier, for many motivating discussions and for technical assistance.

1.2. The definition of Mackey 2-functors

We are embarking on a journey in the land of 2-categories. If the latter appear dangerously exotic to some readers’ immune system, we administer vaccinations in Appendix A.1. Note however that until Chapter 5, the only 2-categories we use are obtained from the well-known 2-category $\text{CAT}$ of categories, functors and natural transformations, by restricting attention to some categories or some functors, and typically using all natural transformations. A minimal knowledge of ordinary Mackey functors could also help; see a quick review in Appendix B.

The classical Mackey formula in the form of the ‘double-coset formula’ (1.1.1) involves non-canonical choices of representatives in double-cosets. Such a non-natural concept cannot hold up very long in 2-categories, where equalities are replaced by isomorphisms which would then also depend on these choices. Just from the authors’ personal experience, the reader may want to consult [Del14] and [Bal15] for a glimpse of the difficulties that quickly arise when trying to keep track of such choices. This motivates us to use the cleaner approach via groupoids.

1.2.1. Notation. Of central use in this work is the 2-category

$$\text{gpd} = \{\text{finite groupoids, functors, natural transformations}\}$$

of finite groupoids, i.e. categories with finitely many objects and morphisms, in which all morphisms are invertible. The 2-category $\text{gpd}$ is a 1-full and 2-full 2-subcategory of the 2-category of small categories $\text{Cat}$. Note that every 2-morphism in $\text{gpd}$ is invertible, that is, $\text{gpd}$ is a $(2,1)$-category (Definition A.1.7).
We denote the objects of \(\text{gpd}\) by the same letters we typically use for groups, namely \(G, H,\) etc. The role of subgroups \(H \leq G\) is now played by faithful functors \(H \to G\) in \(\text{gpd}\). Given its importance, we fix a notation \((\rightarrow)\) for faithfulness.

**1.2.2. Remark.** There is essentially no difference between a group and a groupoid with one object. Therefore we identify each finite group \(G\) with the associated one-object groupoid with morphism group \(G\) and still denote it by \(G\) in \(\text{gpd}\). Accordingly, there is no difference between group homomorphisms \(f: G \to G'\) and the associated 1-morphisms of one-object groupoids, and we denote them by the same symbol \(f: G \to G'\). Of course, the functor \(f: G \to G'\) is faithful if and only if the group homomorphism \(f\) is injective. The 2-morphisms \(f_1 \Rightarrow f_2\) between such functors \(f_1, f_2: G \to G'\) in \(\text{gpd}\) are given at the group level by elements \(x \in G'\) of the target group which conjugate one homomorphism into the other, \(^g f_1 = f_2\), that is, \(x f_1(g)x^{-1} = f_2(g)\) for all \(g \in G\).

A groupoid is equivalent to a group if and only if it is connected, meaning that every two of its objects are isomorphic.

**1.2.3. Remark.** Given two morphisms of groupoids \(i: H \to G\) and \(u: K \to G\), with same target, we have the iso-comma groupoid \((i/u)\) whose objects are

\[
\text{Obj}(i/u) = \{ (x, y, g) \mid x \in \text{Obj}(H), y \in \text{Obj}(K), g: i(x) \sim u(y) \text{ in } G \}
\]

with component-wise morphisms on the \(x\) and \(y\) parts (in \(H\) and \(K\)) compatible with the isomorphisms \(g\) (in \(G\)). See Section 2.1. This groupoid \((i/u)\) fits in a 2-cell

\[
\begin{array}{ccc}
H & \xrightarrow{i} & G \\
\downarrow{p} & & \downarrow{u} \\
I & \xrightarrow{\gamma} & K \\
\end{array}
\]

where \(p: (i/u) \to H\) and \(q: (i/u) \to K\) are the obvious projections and \(\gamma: i p \sim q u\) is the isomorphism given at each object \((x, y, g)\) of \((i/u)\) by the third component \(g\). It is easy to check that if \(i: H \to G\) is faithful then so is \(q: (i/u) \to K\).

Iso-comma squares like (1.2.4), and those equivalent to them, provide a refined version of pullbacks in the world of groupoids and will play a critical role throughout the work. Section 2.1 is dedicated to their study. For instance, when \(G\) is a group and \(H\) and \(K\) are subgroups then the groupoid \((i/u)\) is equivalent to a coproduct of groups \(H^\circ \cap K\), as in the double-coset formula. See details in Remark 2.2.2.

We are going to consider 2-functors \(M: \text{gpd}^{\text{op}} \to \text{ADD}\), contravariant on 1-cells (hence the 'op'), defined on finite groupoids and taking values in the 2-category \(\text{ADD}\) of additive categories and additive functors. Details about additivity are provided in Appendix A.5 and A.6. For simplicity we apply the following customary rule:

**1.2.5. Convention.** Unless explicitly stated, every functor between additive categories is assumed to be additive (Definition A.5.6).

**1.2.6. Remark.** A 2-functor \(M: \text{gpd}^{\text{op}} \to \text{ADD}\) is here always understood in the strict sense (see Terminology A.1.11) although we will occasionally repeat 'strict' 2-functor as a reminder to the reader and in contrast to pseudo-functors; so it consists of the following data:

(a) for every finite groupoid \(G\), an additive category \(\mathcal{M}(G)\),
(b) for every functor $u : H \to G$ in $\mathbf{gpd}$, a ‘restriction’ functor $u^* : \mathcal{M}(G) \to \mathcal{M}(H)$,

(c) for every natural transformation $\alpha : u \Rightarrow u'$ between two parallel functors $u, u' : H \to G$, a natural transformation $^1 \alpha^* : u^* \Rightarrow (u')^*$, subject to the obvious compatibilities with identities and compositions on the nose (hence the word ‘strict’). In particular $(uv)^* = v^*u^*$ and $(\alpha\beta)^* = \alpha^*\beta^*$.

With this preparation, we can give our central definition.

1.2.7. Definition. A (global) Mackey 2-functor is a strict 2-functor (Remark 1.2.6) $\mathcal{M} : \mathbf{gpd}^{op} \to \mathbf{ADD}$ from finite groupoids to additive categories which satisfies the following axioms:

(Mack 1) Additivity: For every finite family $\{G_c\}_{c \in C}$ in $\mathbf{gpd}$, the natural functor

$$\left( \text{incl}_c^* \right)_{c \in C} : \mathcal{M}\left( \coprod_{c \in C} G_c \right) \to \prod_{c \in C} \mathcal{M}(G_c)$$

is an equivalence, where $\text{incl}_c : G_c \to \coprod_{c \in C} G_c$ is the inclusion.

(Mack 2) Induction and coinduction: For every faithful functor $i : H \to G$, the restriction functor $i^* : \mathcal{M}(G) \to \mathcal{M}(H)$ admits a left adjoint $i_!$ and a right adjoint $i^* : \mathcal{M}(G) \to \mathcal{M}(H)$

\[
\begin{array}{c}
\mathcal{M}(G) \\
\uparrow \downarrow \quad \downarrow \uparrow \\
\mathcal{M}(H)
\end{array}
\]

(Mack 3) Base-change formulas: For every iso-comma square of finite groupoids as in (1.2.4) in which $i$ and (therefore) $q$ are faithful

\[
\begin{array}{cc}
H & \sim \Rightarrow & K \\
\downarrow i & & \downarrow q \\
G & \sim \Rightarrow & \sim \Rightarrow & u \\
\uparrow p & & \uparrow \gamma & & \uparrow \gamma^{-1}
\end{array}
\]

we have isomorphisms

$q_! \circ p^* \sim \Rightarrow u^* \circ i_!$ and $u^* \circ i_* \sim \Rightarrow q_* \circ p^*$

given by the left mate $\gamma_!$ of $\gamma^*$ and the right mate $(\gamma^{-1})_*$ of $(\gamma^{-1})^*$. See Appendix A.2 for details about mates.

(Mack 4) Ambidexterity: For every faithful $i$, there exists an isomorphism

$$i_! \simeq i_*$$

between (some, and therefore any, choices of) the left and right adjoints of $i^*$ given in (Mack 2).

\[\text{Like in the theory of (pre)derivators, the variance of } \mathcal{M} \text{ on 2-morphisms is a matter of convention and could be chosen opposite since } \mathbf{gpd}^{co} \cong \mathbf{gpd} \text{ via } G \mapsto G^{op}. \text{ (The superscript ‘co’ on a 2-category denotes the formal reversal of 2-cells.)}\]
1.2.8. **Example.** The axioms are self-dual in the sense that, if $\mathcal{M}$ is a Mackey 2-functor, then there is a Mackey 2-functor $\mathcal{M}^{\text{op}}$ defined by $\mathcal{M}^{\text{op}}(G) := \mathcal{M}(G)^{\text{op}}$. This has the effect of exchanging the roles of the left and right adjunctions $i_! \dashv i^*$ and $i^* \dashv i_*$.

1.2.9. **Examples.** Mackey 2-functors abound in nature. They include:

(a) Usual $\mathbb{k}$-linear representations $\mathcal{M}(G) = \text{Mod}(\mathbb{k}G)$. See Example 4.1.4.

(b) Their derived categories $\mathcal{M}(G) = \text{D}(\mathbb{k}G)$. See Example 4.1.5.

(c) Stable module categories $\mathcal{M}(G) = \text{Stab}(\mathbb{k}G)$. See Example 4.2.6. (In this case, we shall restrict our ‘interest’ to a sub-2-category of groupoids by allowing only faithful functors as 1-cells.)

(d) Equivariant stable homotopy categories $\mathcal{M}(G) = \text{SH}(G)$. See Example 4.3.8.

(e) Equivariant Kasparov categories $\mathcal{M}(G) = \text{KK}(G)$. See Example 4.3.9.

(f) Abelian categories of ordinary Mackey functors $\mathcal{M}(G) = \text{Mack}_k(G)$. See Corollary 7.3.9.

1.2.10. **Remark.** Let us comment on Definition 1.2.7.

(a) As already announced, we shall generalize the above definition by allowing the input of $\mathcal{M}$ to consist only of a specified 2-subcategory of groupoids (Definition 2.3.5) and later we will even consider more abstract 2-categories (Hypotheses 5.1.1). The above is the ‘global’ version where $\mathcal{M}(G)$ is defined for all groupoids $G$, and $u^*$ for all functors $u$.

(b) The first axiom (Mack 1) is straightforward. Every finite groupoid is equivalent to the finite coproduct of its connected components, themselves equivalent to one-object groupoids (i.e. groups). Thus (Mack 1) allows us to think of Mackey 2-functors $\mathcal{M}$ as essentially defined on finite groups. More on this in Section 4.3.

(c) Just like the other axioms, the second and fourth ones are properties of the 2-functor $\mathcal{M}$. The adjoints $i_!$ and $i_*$, and later the isomorphism $i_! \simeq i_*$, are not part of the structure of a Mackey 2-functor. In particular all the units and counits involved in the adjunctions $i_! \dashv i^* \dashv i_*$ could be rather wild, at least in the above primeval formulation. All four axioms are stated in a way that is independent of the actual choices of left and right adjoints and associated units and counits: If the axioms hold for one such choice, they will hold for all choices. We shall spend some energy on making better choices than others, in order to establish civilized formulas; see Section 1.3.

(d) The third axiom is a standard Base-Change condition of Beck-Chevalley type (referred to as ‘BC-property’ in any case). In the iso-comma square (1.2.4)

\[
\begin{array}{ccc}
H & \xrightarrow{p} & i \downarrow \gamma \xrightarrow{q} & K \\
\downarrow i & & & \downarrow u \\
G & \xrightarrow{\gamma} & u
\end{array}
\]

induction along $i$ followed by restriction along $u$ can equivalently be computed as first doing restriction along $p$ followed by induction along $q$. The latter composition passes via the groupoid $(i/u)$ which is typically a disjoint union of ‘smaller’ groupoids, as in the double-coset formula (see Remark 2.2.7). Of course the dual axiom $u^* i_* \Rightarrow q_* p^*$ should more naturally involve the dual
iso-comma \((i'\backslash u)\). However, in groupoids we have a canonical isomorphism \((i'\backslash u) \cong (i/ u)\) when the latter is equipped with the 2-cell \(\gamma^{-1}\). This explains our simplified formulation with \((\gamma^{-1})_*: u^* i_* \cong q_* p^*\) and no mention of \((i'\backslash u)\).

(e) The fourth axiom is a standard property of many 2-functors from groups to additive categories: induction and co-induction coincide. Any ambidexterity isomorphism \(i_! \cong i_*\) can be used to equip \(i_!\) with the units and counits of \(i^* \dashv i_*\), thus making the left adjoint \(i_!\) a right adjoint as well. So we can equivalently assume the existence of a single two-sided adjoint \(i_! = i_*\) of \(i^*\). This simplification will be useful eventually but at first it can also be confusing. In most examples, Nature provides us with canonical left adjoints \(i_!\) and canonical right adjoints \(i_*\), for instance by means of (derived) Kan extensions. Such adjoints are built differently on the two sides and happen to be isomorphic in the equivariant setting. We shall give in Chapter 3 a mathematical explanation of why this phenomenon is so common.

### 1.3. Rectification

Following up on Remark 1.2.10 (c), we emphasize the slightly naive nature of the ambidexterity axiom (Mack 4). As stated, this axiom is easy to verify in examples as it only requires some completely ad hoc isomorphism \(i_! \cong i_*\) for each given \(i\), with no reference to the fact that \(i \mapsto i_!\) and \(i \mapsto i_*\) are canonically pseudo-functorial. Standard adjunction theory (Remark A.2.10) tells us that every \(\alpha: i \Rightarrow i'\) will yield \(\alpha_! = i_! \Rightarrow i'_!\) and \(\alpha_* = i_* \Rightarrow i'_*\) and every composable \(j: K \rightarrow H, i: H \rightarrow G\) will yield isomorphisms \((ij)_! \cong i_! j_!\) and \((ij)_* \cong i_* j_*\). It is then legitimate to ask whether the isomorphism \(i_! \cong i_*\) can be ‘rectified’ so as to be compatible with all of the above.

Similarly, following up on Remark 1.2.10 (c), let us say we choose a single two-sided adjoint \(i_! = i_*\) for all faithful \(i: H \rightarrow G\), in particular also \(q! = q_*\) in the iso-comma (1.2.4). Then the BC-formulas (Mack 3) provide two ways of comparing the ‘bottom’ composition \(u^* i_! = u^* i_*\) with the ‘top’ composition \(q_! p^* = q_* p^*\), one via \(\gamma_i\) and one via \((\gamma^{-1})_!\). It is again legitimate to wonder whether they agree.

The solution to these questions appears in Chapter 3, where we reach two goals. First, we show that ambidexterity can be proved by induction on the order of the finite groupoids (Proposition 3.4.1), which will be an essential part of the Ambidexterity Theorem 4.1.1. Second, assuming that ambidexterity holds even only in the weak sense of Definition 1.2.7, we show that it must then hold for a good reason: There exists a canonical isomorphism between induction and coinduction satisfying several extra properties (e.g. it is a pseudo-natural transformation as in Terminology A.1.14). This Rectification Theorem 3.4.3 yields several improvements to the notion of Mackey 2-functor, like a ‘strict’ Mackey formula (Mack 7), the agreement of the pseudo-functorialities of induction and coinduction as discussed above, a ‘special Frobenius’ property, etc. Here is the full statement:

**1.3.1. Theorem** (Rectification Theorem; see Theorem 3.4.3). Consider a Mackey 2-functor \(\mathcal{M}: \text{gpd}^{\text{op}} \rightarrow \text{ADD}\) as in Definition 1.2.7. Then we can choose for each faithful \(i: H \rightarrow G\) in \(\text{gpd}\) a two-sided adjoint

\[
i_! = i_*: \mathcal{M}(H) \rightarrow \mathcal{M}(G)
\]
of restriction $i^*: \mathcal{M}(G) \to \mathcal{M}(H)$ and units and counits
\[
\begin{align*}
\ell \eta: \text{Id} & \Rightarrow i^* i_! & \ell \varepsilon: i i^* & \Rightarrow \text{Id} \\
\varepsilon \eta: \text{Id} & \Rightarrow i_* i^* & \varepsilon \varepsilon: i^* i_* & \Rightarrow \text{Id}
\end{align*}
\]
for $i_! \dashv i^*$ and $i^* \dashv i_*$ respectively, such that all the following properties hold:

(Mack 5) Additivity of adjoints: Whenever $i = i_1 \sqcup i_2: H_1 \sqcup H_2 \to G$, under the identification $\mathcal{M}(H_1 \sqcup H_2) \cong \mathcal{M}(H_1) \oplus \mathcal{M}(H_2)$ of (Mack 1) we have
\[
(i_1 \sqcup i_1)! = (i_1)! \circ (i_2)! \quad \text{and} \quad (i_1 \sqcup i_1)_* = ((i_1)_* \circ (i_2)_*)
\]
with the obvious ‘diagonal’ units and counits. (See Remark A.6.8.)

(Mack 6) Two-sided adjoint equivalences: Whenever $i^*$ is an equivalence, the units and counits are isomorphisms and $(\ell \eta)^{-1} = \varepsilon \varepsilon$ and $(\ell \varepsilon)^{-1} = \eta \eta$. Furthermore when $i = \text{Id}$ we have $i_! = i_* = \text{Id}$ with identity units and counits.

(Mack 7) Strict Mackey Formula: For every iso-comma as in (1.2.4), the two isomorphisms $\gamma_! \colon qp^* \Rightarrow u^* i_!$ and $(\gamma^{-1})_* \colon u^* i_* \Rightarrow q_* p^*$ of (Mack 3) are moreover inverse to one another
\[
(\gamma^{-1})_* \circ \gamma_! = \text{id} \quad \text{and} \quad (\gamma^{-1})_* \circ (\gamma_!)_* = \text{id}
\]
under the equality $u^* i_! = u^* i_*$ and $q_* p^* = q_* p^*$ of their sources and targets.

(Mack 8) The pseudo-functors $i \mapsto i_!$ and $i \mapsto i_*$ coincide, namely: For every 2-cell $\alpha : i \Rightarrow i'$ between faithful $i, i' : H \to G$ we have $\alpha_! = \alpha_*$ as morphisms between the functors $i_! = i_*$ and $i'_! = i'_*$; and for every composable faithful morphisms $j: K \to H$ and $i: H \to G$ the isomorphisms $(ij)_! \cong i_! j_!$ and $(ij)_* \cong i_* j_*$ coincide.

(Mack 9) Special Frobenius Property: For every faithful $i : H \to G$, the composite
\[
\text{Id}_{\mathcal{M}(H)} \xrightarrow{\ell \eta} i^* i_! = i^* i_* \xrightarrow{\varepsilon \varepsilon} \text{Id}_{\mathcal{M}(H)}
\]
of the left unit and the right counit is the identity.

1.3.2. Remark. Most notable in the list of properties of Theorem 1.3.1 is perhaps the ‘Strict Mackey Formula’ (Mack 7). The base-change formula that we give in (Mack 3) is substantially nicer than ordinary BC-formulas encountered in the literature, which just say that $\gamma_!$ is an isomorphism without providing an actual inverse. Here an explicit inverse appears as part of the rectified structure:
\[
(\gamma^{-1})_* = (\gamma^{-1})_!.
\]
This formula is a purely 2-categorical property which has no counterpart in the world of ordinary Mackey functors. The authors did not anticipate its existence when first embarking on this project.

1.4. Mackey 2-functors and Grothendieck derivators

One of our main goals is to support our definition of Mackey 2-functor with a robust catalogue of examples which are in common use in ‘equivariant mathematics’. In order to do so, we prove theorems showing that some standard structures can be used to construct Mackey 2-functors. In particular, we prove that every additive Grothendieck derivator [Gro13] provides a Mackey 2-functor when its domain is restricted to finite groupoids (Theorem 4.1.1). This result specializes to say that a Mackey 2-functor can be associated to any ‘stable homotopy theory’, in the broad
modern sense of ‘stable homotopy’ that is customary to prismatic algebra and includes usual derived categories for instance. See also [Fra96] or [Hel88].

Recall that the prototype of a derivator

\[ D : \text{Cat}^{op} \to \text{CAT} \]

is given by \( J \mapsto \text{Ho}(Q^J) \), the homotopy category of diagrams associated to a Quillen model category \( Q \), where \( J \in \text{Cat} \) runs among small categories. In other words, every homotopy theory provides a derivator which encapsulates its 2-categorical information in terms of homotopy categories and homotopy limits and colimits (homotopy Kan extensions). In this way, every stable model category \( Q \) gives an additive derivator, i.e. one taking values in additive categories.

The analogies between Grothendieck’s notion of derivators and our Mackey 2-functors are apparent. First of all, the axioms (Mack1), (Mack2) and (Mack3) are strongly inspired by the derivators’ axioms (Der1), (Der3) and (Der4): We start from a strict 2-functor and require existence of adjoints and Beck-Chevalley properties for base-change along comma squares. For this very reason, additive derivators are a great source of Mackey 2-functors once we prove the Ambidexterity Theorem 4.1.1, which gives us (Mack4) for free in this case.

On the other hand, there are also important differences between the theory of derivators and that of Mackey 2-functors, beyond the obvious fact that Mackey 2-functors are only defined on finite groupoids and are required to take values in additive categories. Let us say a word about those differences.

The critical point is the lack of (Der2) for Mackey 2-functors. Indeed, for a derivator \( D \), the various values \( D(J) \) at small categories \( J \) (e.g. finite groupoids) are to be thought of as ‘coherent’ versions of diagrams with shape \( J \) in the base \( D(1) \) over the trivial category 1 which is often denoted \( e \) in derivator theory, or \([0]\). (In the prototype of \( D(J) = \text{Ho}(Q^J) \), this is the well-known distinction \( \text{Ho}(Q^J) \neq \text{Ho}(Q)^J \) between the homotopy category of diagrams and diagrams in the homotopy category.) Axiom (Der2) then says that the canonical functor \( D(J) \to D(1)^J \) is conservative, i.e. isomorphisms in \( D(J) \) can be detected pointwise, by restricting along the functors \( x : 1 \to J \) for all objects \( x \) of \( J \). We do not have such an axiom for Mackey 2-functors \( M \). Morphisms in \( M(G) \) which are pointwise isomorphisms are not necessarily isomorphisms. This is already illustrated with \( M(G) = \text{SH}(G) \), the stable equivariant homotopy category, in which \( \text{Res}_1^G : \text{SH}(G) \to \text{SH} \) is not conservative. Hence proving that \( \text{SH}(G) \) forms a Mackey 2-functor requires a little more care; see Example 4.3.8. Yet, the most striking example of a Mackey 2-functor which is not the restriction of a derivator because it fails (Der2) is certainly \( M(G) = \text{Stab}(kG) \), the stable module category of \( kG \)-modules modulo projectives.

Indeed, in this extreme case the category \( M(1) = 0 \) is trivial and thus cannot detect much of anything.

Another difference between Mackey functors and derivators comes from ambidexterity (Mack4), which is clearly a feature specific to Mackey 2-functors. Ambidexterity is also essential to our construction of the bicategory of Mackey 2-motives, discussed in the second part of this work (see Section 1.5 below). Of course, it is conceivable that one could construct an analogous 2-motivic version of derivators, resembling what we do here with Mackey 2-motives. In broad strokes, these derivator 2-motives could consist of a span-flavored construction in which two separate forward functors \( u_l \) and \( u_r \) have to be introduced, one left adjoint and one right adjoint to the given \( u^* \). Composition of such \( u_l \) and \( u_r \) is however rather
mysterious, and inverses to the BC-maps would have to be introduced artificially (cf. Remark 1.3.2). If feasible, such a construction seems messy. It is a major simplification of the Mackey setting that we only need one covariant functor $i! = i_*$ and thus obtain a relatively simple motivic construction, as we explain next.

1.5. Mackey 2-motives

Chapters 5 to 7 are dedicated to the motivic approach to Mackey 2-functors. They culminate with Theorem 6.1.13 in which we prove the universal property of (semi-additive) Mackey 2-motives. As announced, this part requires a little more of the theory of 2-categories and bicategories, the generalizations of 2-categories in which horizontal composition of 1-morphisms works only up to coherent isomorphisms.

Instead of producing a possibly mysterious universal construction via generators and relations, we follow a more down-to-earth approach. We propose a rather explicit construction and then pay the price in proving the universal property. Arguably, we in fact provide two explicit descriptions, one by means of spans of spans (sic) and one by means of string diagrams. Our 2-smart readers will identify the former as a bicategory and the latter as a biequivalent 2-category, i.e. a ‘strictification’; see Section 6.2.

The voluminous Chapter 5 is mostly a preparation for the central Chapter 6, whereas Chapter 7 provides $\mathbb{Z}$-linearizations of the semi-additive results obtained in Chapter 6. In more details, we construct the bicategory of additive Mackey 2-motives $\mathbb{Z}\hat{\text{Span}}(\text{gpd})$ through two layers of ‘span constructions’ and one layer of ‘block-completion’:

$$
\text{gpd}^\text{op} \xrightarrow{\text{Chapter 5}} \text{Span}(\text{gpd}) \xrightarrow{\text{Chapter 6}} \hat{\text{Span}}(\text{gpd}) \xrightarrow{\text{Chapter 7}} \mathbb{Z}\hat{\text{Span}}(\text{gpd}).
$$

The first step (Chapter 5) happens mainly at the level of 1-cells and creates left adjoints to every faithful $i: H \to G$ but does not necessarily create right adjoints. The second span construction (Chapter 6) takes place at the level of 2-cells and creates ambidexterity. The last step (Chapter 7) in the pursuit of the universal Mackey 2-functor out of $\text{gpd}$ appears for a minor reason: With $\hat{\text{Span}}(\text{gpd})$, we have only achieved semi-additivity of the target, not plain additivity. Explicitly, the 2-cells in the bicategory $\hat{\text{Span}}(\text{gpd})$ can be added but they do not admit opposites. We solve this issue in Chapter 7 by formally group-completing the 2-cells. While at it, we also locally idempotent-complete our bicategory in order to be able to split 1-cells according to idempotent 2-cells, and we do the same to 0-cells one level down, which is the meaning of ‘block-completion’. The latter construction works as expected but might not be entirely familiar, so it is discussed in some detail in Appendix A.6. Such idempotent-completions are hallmarks of every theory of motives and they make sense in our 2-categorical setting at two different levels. The ultimate bicategory $\mathbb{Z}\hat{\text{Span}}(\text{gpd})$ of truly additive Mackey 2-motives satisfies a universal property (Section 7.1), which is easily deduced from the significantly harder universal properties of $\hat{\text{Span}}(\text{gpd})$ and $\text{Span}(\text{gpd})$ that we establish first (in Sections 5.2 and 6.1 respectively).

We put the additive enrichment of $\mathbb{Z}\hat{\text{Span}}(\text{gpd})$ to task in Section 7.2, showing that the represented 2-functor $\mathbb{Z}\hat{\text{Span}}(\text{gpd})(G_0, -)$ is a Mackey 2-functor (in the
variable “−”) for every fixed groupoid \(G_0\). For instance even the trivial group \(G_0 = 1\) produces an interesting Mackey 2-functor in this way (Theorem 7.2.3).

The Burnside ring \(A(G)\) enters Mackey 2-motives in Section 7.4, in the form of an endomorphism ring of a particular 1-cell, namely the one given by the (horizontal) span \(1 \leftarrow G = G\), see (7.4.1). This endomorphism ring embeds into the endomorphism ring of the identity 1-cell, namely \(G = G = G\), as we then explain. As a consequence of this connection, every ring decomposition of the Burnside ring \(A(G)\) induces a block-decomposition of the Mackey 2-motive of \(G\) and consequently, by universality, of the category \(\mathcal{M}(G)\) for every Mackey 2-functor \(\mathcal{M}\). The latter is explained in the final Section 7.5.

***

Bicategories of spans have been considered by many authors in several variants and settings, starting already with [Bén67]. We shall in particular rely on [Hof11] to avoid tedious verifications. The interested reader can also consult [BHW10] for the relevance of spans of groupoids to physics. There is no shortage of Mackey-related publications and the use of spans in this context is well-known and widespread. For instance, an approach via \((\infty,1)\)-categories can be found in the interesting work of Barwick [Bar17]. In this context, Harpaz [Har17] has proved that the \((\infty,1)\)-category of spans of finite \(n\)-truncated spaces is the universal way of turning \(n\)-truncated spaces into an \(n\)-\(\text{-(semi-)additive}\) \(\infty\)-category, in the sense of Hopkins-Lurie [HL14]. Our theory can be seen as an extension or refinement of the \(n = 1\) case (groupoids being 1-truncated spaces) of his result. Indeed, although our 2-level approach obviously fails to capture higher equivalences, it does allow for non-invertible 2-cells and therefore provides a direct grip on adjunctions and their properties, without any need to climb further up the higher-categorical ladder. Formally, a simultaneous common generalization of the Barwick-Harpaz-Hopkins-Lurie theory and ours would require the framework of \((\infty,2)\)-categories, for which we refer to the book-in-progress of Gaitsgory and Rozenblyum [GR16, Chap. V]. It was pointed out to us by Harpaz that Hopkins and Lurie do hint at something resembling our construction of Mackey 2-motives in terms of an \((\infty,2)\)-category of spans of spans; see [HL14, Remark 4.2.5]. Since we are ultimately only interested here in finite groups, we stick with 2-categories and the stricter, and more down-to-earth, statements we can obtain at this level.
CHAPTER 2

Mackey 2-functors

We discuss Mackey 2-functors beyond the survey of Section 1.2, beginning with details on iso-commas and Mackey squares (Sections 2.1 and 2.2). In Section 2.3, we clarify what a class \( G \) of groupoids ‘of interest’ should consist of (Hypotheses 2.3.1) and we define Mackey 2-functors in that generality. We conclude the chapter by discussing the separability of restriction \( \mathcal{M}(G) \to \mathcal{M}(H) \) to subgroupoids (Section 2.4) and the decategorification of Mackey 2-functors down to ordinary Mackey functors (Section 2.5).

2.1. Comma and iso-comma squares

In any 2-category (or even bicategory), one can define a strict notion of pullback square, which will usually not be invariant under equivalence. The correct notion, at least in the case of groupoids, will consist of those squares equivalent to iso-commas. We call these Mackey squares. We begin by recalling the general notion of comma square, which plays a role in the theory of derivators, and we then specialize to the case of groupoids.

2.1.1. Definition. Let \( B \) be a 2-category. A comma square over a given cospan \( A \xrightarrow{a} C \xleftarrow{b} B \) of 1-cells of \( B \) is a 2-cell

\[
\begin{array}{ccc}
A & \xrightarrow{a/b} & B \\
\downarrow^p & & \downarrow^q \\
\downarrow^a & & \downarrow^b \\
C & \xleftarrow{b} & B
\end{array}
\]

(2.1.2)

having the following two properties, jointly expressing the fact that the 2-cell \( \gamma \) is 2-universal among those sitting over the given cospan:

(a) For every pair of 1-cells \( f: T \to A \) and \( g: T \to B \) and for every 2-cell \( \delta: af \Rightarrow bg \), there is a unique 1-cell \( h: T \to a/b \) such that \( ph = f \), \( qh = g \) and \( \gamma h = \delta \).
We will write \( \langle f, g, \delta \rangle \) for the unique 1-cell \( h \) as above

\[
\langle f, g, \delta \rangle : T \to a/b
\]
determined by these three components.

(b) For every pair of 1-cells \( h, h' : T \to a/b \) and every pair of 2-cells \( \tau_A : ph \Rightarrow ph' \) and \( \tau_B : qh \Rightarrow qh' \) such that \( (\gamma h')(a\tau_A) = (b\tau_B)(\gamma h) \)

\[
\overset{\gamma}{\downarrow}
\]

there exists a unique \( \tau : h \Rightarrow h' \) such that \( pr = \tau_A \) and \( qr = \tau_B \).

If the 2-cell \( \gamma \) is moreover invertible, and if \( (a) \) holds (only) for those \( \delta \) which are invertible, then the comma square is called an iso-comma square. Note that if a comma square is such that \( \gamma \) is invertible, then it is also an iso-comma square.

It is sometimes convenient to denote the comma object by \( A \xleftarrow{\gamma} B \) rather than \( a/b \).

2.1.3. Example. In any \((2,1)\)-category, comma and iso-comma squares coincide.

If \( B \) is furthermore locally discrete, i.e. is just a 1-category, then comma squares and iso-comma squares are precisely the same as ordinary pullback squares.

2.1.4. Example. Given an iso-comma square \((2.1.2)\), we can invert its 2-cell to obtain a new square:

\[
\overset{\gamma^{-1}}{\downarrow}
\]

It is easy to see that this is an iso-comma square for \( b : B \to C \leftarrow A : a \).

The following example is the essential prototype:

2.1.5. Example. If \( B = \text{Cat} \) is the 2-category of (small) categories, then the comma square over \( a : A \to C \leftarrow B : b \) has a well-known and transparent construction, where the objects of \( a/b \) are triples \((x, y, \gamma)\) with \( x \) an object of \( A \), with \( y \) an object of \( B \) and with \( \gamma : a(x) \to b(y) \) an arrow of \( C \), and where a morphism \((x, y, \gamma) \to (x', y', \gamma')\) is a pair \((\alpha, \beta)\) of an arrow \( \alpha : x \to x' \) of \( A \) and an arrow \( \beta : y \to y' \) of \( B \) such that the evident square commutes in \( C \), namely \( \gamma' a(\alpha) = b(\beta) \gamma \).

Then \( p : a/b \to A \) and \( q : a/b \to B \) are the obvious projections \((x, y, \gamma) \to x \) and \((x, y, \gamma) \to y \), and the two properties of Definition 2.1.1 are immediately verified.

Iso-comma squares are constructed similarly, by only considering triples \((x, y, \gamma)\) with \( \gamma \) invertible.

The construction of (iso-)comma squares in the 2-category of categories provides the (iso-)comma squares in the sub-2-category of groupoids, see Remark 1.2.3.

Example 2.1.5 allows us to characterize comma squares in general \(2\)-categories.
2.1.6. **Remark.** In a 2-category $\mathcal{B}$, a 2-cell as in (2.1.2) is a comma square if and only if composition with $p$, $q$ and $\gamma$ induces an *isomorphism* of categories

\[(2.1.7)\]

\[\mathcal{B}(T, a/b) \xrightarrow{\cong} \mathcal{B}(T, a)/\mathcal{B}(T, b)\]

for every $T \in \mathcal{B}$, where the category on the right-hand side is the comma category over $\mathcal{B}(T, A) \xrightarrow{B(T,a)} \mathcal{B}(T, C)$ in $\text{Cat}$, as described in Example 2.1.5. Indeed, parts (a) and (b) of Definition 2.1.1 are equivalent to this functor inducing a bijection on objects and on arrows, respectively. In particular, it follows that the defining property of a comma square is a universal property, characterizing it up to a unique canonical isomorphism in $\mathcal{B}$. For the same reasons, the output comma object $a/b$ is natural in the input cospan $a \rightarrow\leftarrow b$.

2.1.8. **Remark.** By the usual arguments, the universal property of comma objects yields unique associativity isomorphisms compatible with the structure 2-cells:

\[
\begin{array}{ccc}
A \rightarrow\leftarrow B & \cong & (A \rightarrow\leftarrow B) \rightarrow\leftarrow C \\
\downarrow & & \downarrow \\
A \rightarrow\leftarrow B & \rightarrow\leftarrow & C \\
\end{array}
\]

Here “compatible” means that the above diagram of 2-cells commutes, with the two slanted triangles being identities. All details of this construction will be spelled out in the course of a proof, see (5.2.12).

2.1.9. **Remark.** Building the comma square on a cospan of the form $A \xrightarrow{\text{Id}} A \leftarrow\leftarrow B$, we obtain the diagram

\[
\begin{array}{ccc}
& B \downarrow \text{id} & \\
i_b & & \text{id} \\
& A \xrightarrow{\text{id}} & \\
\end{array}
\]

\[
\begin{array}{ccc}
A \rightarrow\leftarrow B \\
\downarrow \gamma \downarrow b \\
A \rightarrow\leftarrow B \\
\end{array}
\]

where $i_b : B \rightarrow \text{Id}/b$ is the 1-cell $\langle b, \text{Id}_B, \text{id}_b : b \Rightarrow b \rangle$ in the notation of Definition 2.1.1 (a). In particular $i_b$ is a canonical right inverse of $q_b : \text{Id}/b \rightarrow B$, the comma base-change of $\text{Id}_A$ along $b$. Typically, $q_b$ and $i_b$ are not strictly invertible. But if the comma square is an iso-comma square (e.g. if we are working in a (2,1)-category), they will always be mutually quasi-inverse equivalences. Indeed, by the universal property on arrows there is a unique invertible 2-cell $\tau : i_b q_b \Rightarrow \text{Id}_{(\text{Id}/b)}$ with components $\tau_A := \gamma^{-1}$ and $\tau_B := \text{id}_{q_b}$.

A similar remark holds for cospans of the form $A \rightarrow\leftarrow B$.\[\text{id} \]
In view of Remarks 2.1.6 and 2.1.9, it is natural to relax the evil property that the functor (2.1.7) be an isomorphism into the more convenient property that it be an equivalence. Similarly, we would like to accept squares like the outside one in (2.1.10) when \(i_b\) is an equivalence. This relaxing of the definition will yield the correct class of squares for our treatment of Mackey 2-functors.

2.1.11. Proposition. Consider a 2-cell in a 2-category \(\mathcal{B}\)

\[
\begin{array}{ccc}
D & \xrightarrow{\tilde{p}} & A \\
\downarrow{\tilde{q}} & & \downarrow{a} \\
B & \xleftarrow{\gamma} & C
\end{array}
\]

(2.1.12)

and assume the comma square on \(\alpha \rightarrow b\) exists in \(\mathcal{B}\). The following are equivalent:

(i) The induced 1-cell \(\langle \tilde{p}, \tilde{q}, \tilde{\gamma} \rangle : D \rightarrow (a/b)\) of Definition 2.1.1 is an equivalence.

(ii) For every \(T \in \mathcal{B}_0\), the following induced functor is an equivalence in \(\text{Cat}\):

\[
\mathcal{B}(T, D) \to \mathcal{B}(T, a)/\mathcal{B}(T, b)
\]

\[h \mapsto \langle \tilde{p}h, \tilde{q}h, \tilde{\gamma}h \rangle.\]

Compare with (2.1.7).

Proof. Let \(k := \langle \tilde{p}, \tilde{q}, \tilde{\gamma} \rangle : D \rightarrow (a/b)\) denote the 1-cell in (i). For every object \(T \in \mathcal{B}_0\), we have a commutative diagram in \(\text{Cat}\) as follows:

\[
\begin{array}{ccc}
\mathcal{B}(T, D) & \xrightarrow{(\text{ii})} & \mathcal{B}(T, a)/\mathcal{B}(T, b) \\
\downarrow{\mathcal{B}(T, k)} & & \downarrow{\mathcal{B}(T, a/b)} \\
\mathcal{B}(T, a/b) & \xrightarrow{(2.1.7)}
\end{array}
\]

As the right-hand functor (2.1.7) is an isomorphism by Remark 2.1.6, the other two functors are simultaneously equivalences. Finally, \(\mathcal{B}(T, k)\) is an equivalence in \(\text{Cat}\) for all \(T \in \mathcal{B}_0\) if and only if \(k\) is an equivalence in \(\mathcal{B}\), by Corollary A.1.18.

2.1.13. Remark. One can unpack property (ii) in the above statement in the spirit of Definition 2.1.1 (a) and (b). Indeed, part (b) remains unchanged (it expresses full-faithfulness) but (a), which expressed surjectivity on the nose, is replaced by essential surjectivity, i.e. the existence for every 2-cell \(\delta : af \Rightarrow bg\) of a (non necessarily unique) 1-cell \(h : T \rightarrow D\) together with isomorphisms \(\varphi : f \Rightarrow \tilde{p}h\) and \(\psi : \tilde{q}h \Rightarrow g\) such that \(\delta = (b\psi)(\tilde{\gamma}h)(a\varphi)\). Such an \(h\) is then unique up to isomorphism.

2.2. Mackey squares

We now specialize our discussion of comma squares to the case of (2,1)-categories, keeping in mind our main example \(\text{gpd}\) of finite groupoids. As already mentioned in Example 2.1.3, since every 2-cell is invertible there is no distinction between comma and iso-comma squares. As is often the case, both the strict and the pseudo-version will be useful. To define spans of groupoids and their composition, we shall rely on the explicit nature of the iso-comma squares. On the other hand,
to define our Mackey 2-functors \( M : \text{gpd}^{\text{op}} \to \text{ADD} \) any square which is equivalent to an iso-comma square can be considered. We give the latter a simple name:

2.2.1. Definition. A 2-cell in a \((2,1)\)-category \( \mathcal{B} \) (e.g. in the 2-category \( \text{gpd} \))

\[
\begin{array}{c}
\text{L} \\
\Downarrow \gamma \\
\text{K} \\
\end{array}
\quad
\begin{array}{c}
\text{H} \\
\Downarrow \gamma \\
\text{G} \\
\end{array}
\quad
\begin{array}{c}
\text{j} \\
\Downarrow \gamma \\
\text{i} \\
\end{array}
\]

(2.2.2)

is called a Mackey square if the induced functor \( \langle v, j, \gamma \rangle : L \to (i/u) \) is an equivalence. See Proposition 2.1.11 and Remark 2.1.13 for equivalent formulations. (The latter could be used to define Mackey squares directly, bypassing comma squares.)

2.2.3. Remark. Any square equivalent to a Mackey square is a Mackey square.

2.2.4. Remark. Using Remark 2.1.13, it is straightforward to check that any bi-equivalence \( \mathcal{B} \cong \mathcal{B}' \) (see A.1.14) preserves Mackey squares. However there is no reason in general for it to preserve iso-comma squares, even when it happens to be a 2-functor between 2-categories.

2.2.5. Example. It is an easy exercise to verify that, if in (2.2.2) we choose \( v \) and \( u \) to be identity 1-cells and \( \gamma : i \Rightarrow j \) to be any (invertible) 2-cell, then the resulting square is a Mackey square. The special case \( \gamma = \text{id} \) yields the (outer) Mackey squares discussed in Remark 2.1.9.

2.2.6. Remark. Alternatively, Mackey squares could be called ‘homotopy cartesian’, following for instance Strickland [Str00b, Def.6.9]. Indeed, consider the 1-category \( \mathcal{G} \) of all groupoids, with functors as morphism, ignoring 2-morphisms. Then \( \mathcal{G} \) admits the structure of a Quillen model category in which weak equivalences are the (categorical) equivalences and in which our Mackey squares coincide with homotopy cartesian ones. See details in [Str00b, §6]. We avoid this terminology for several reasons. First, calling equivalences of groupoids ‘weak-equivalences’ could be judged pedantic in our setting. Second, there are many other forms of homotopy at play in the theory of Mackey 2-functors, typically in connections to the derivators appearing in examples (as the homotopy categories of Quillen model categories). Finally, it is conceptually useful to understand iso-comma squares of groupoids as a special case of comma squares of small categories, for the latter are the ones which yield base-change formulas for derivators; and (non-iso) comma squares are not homotopy pullbacks in any obvious way.

Of course, the ancestral example of Mackey square is the one which motivates the whole discussion:

2.2.7. Remark. Consider a finite group \( G \), two subgroups \( H, K \leq G \) and the corresponding inclusions \( i : H \to G \) and \( u : K \to G \) of one-object groupoids. Even in this case, the groupoid \( (i/u) \) usually has more than one connected component. In fact, it has one connected component for each double-coset \([x] = HxK\) in \( H\setminus G/K \) and the canonical groupoid \( (i/u) \) becomes non-canonically equivalent to a coproduct of one-object groupoids:

\[
\prod_{[x] \in H\setminus G/K} H^x \cap K \xrightarrow{\sim} (i/u).
\]

(2.2.8)
This decomposition depends on the choice of the representatives $x$ in the double-coset $[x] \in H \setminus G/K$. When such choices become overwhelming, as they eventually always do, the canonical construction $(i/u)$ is preferable. For instance, compare associativity as in Remark 2.1.8 to the homologous mess with double-cosets. And things only get worse with more involved diagrams.

In any case, replacing $(i/u)$ by $\coprod_{[x] \in H \setminus G/K} H^x \cap K$ via the equivalence (2.2.8) shows that the following square is a Mackey square:

$\begin{array}{ccc}
H & \xrightarrow{\gamma} & K \\
\downarrow{v} & & \downarrow{u} \\
\coprod_{[x] \in H \setminus G/K} H^x \cap K & \xrightarrow{j} & K
\end{array}$

where the $x$-component of $v$ is a conjugation-inclusion $v_x = x(-) : H^x \cap K \hookrightarrow H$ whereas each component of $j$ is the mere inclusion $j_x = \text{incl}: H^x \cap K \hookrightarrow K$; the $x$-component of $\gamma$ is the 2-cell $(-)^x : i v_x \Rightarrow u j_x : H^x \cap K \rightarrow G$. We see here conjugation playing its two roles, at the 1-cell and at the 2-cell levels.

2.2.10. Remark. Requiring a strict 2-functor $M : B \rightarrow B'$ to satisfy base-change with respect to every iso-comma square is equivalent to the (stronger) condition that $M$ satisfies base-change with respect to every Mackey square, each time assuming the relevant faithfulness to guarantee existence of adjoint. Indeed, this comes from a more general fact about mates: Suppose given two 2-cells which are equivalent, then the mate of the first one is an isomorphism if and only if the mate of the other is. See Proposition A.2.8 and Remark A.2.9 if necessary.

2.3. General Mackey 2-functors

The Mackey 2-functors $G \mapsto \mathcal{M}(G)$ discussed in Section 1.2 were the ‘global’ type, i.e. those defined on all finite group(oid)s $G$ and all functors $u : H \rightarrow G$. However, we already saw in Examples 1.2.9(c) that it is sometimes necessary to restrict to some class of groupoids, or some class of morphisms. We isolate below the conditions such a choice must satisfy.

2.3.1. Hypotheses. We consider a 2-category

$\mathcal{G} \subseteq \text{gpd}$

of finite groupoids of interest. We assume that $\mathcal{G}$ is a 2-full 2-subcategory of the 2-category $\text{gpd}$ of all finite groupoids, which is closed under finite coproducts, faithful inclusions and iso-commas along faithful morphisms. More precisely, this means that for every $G$ in $\mathcal{G}$ and every faithful functor $i : H \rightarrow G$, the groupoid $H$ and the functor $i$ belong to the 2-category $\mathcal{G}$ and furthermore for any $u : K \rightarrow G$ in $\mathcal{G}$ the iso-comma $(i/u)$ and the two functors $p : (i/u) \rightarrow H$ and $q : (i/u) \rightarrow K$ as in (1.2.4) belong to $\mathcal{G}$ as well. (Note that only $p$ comes in question here, given the stability-under-faithful-inclusion assumption; and even this is only a question if $\mathcal{G}$ is not 1-full in $\text{gpd}$.) In other words, if the bottom cospan $H \rightarrow G \leftarrow K$ of a Mackey square (2.2.2) belongs to $\mathcal{G}$ then so does the top span $H \leftrightarrow L \rightarrow K$. 
Finally, in this setting we denote by 
\[ \mathcal{J} = \mathcal{J}(G) := \{ i \in G_1(H, G) \mid i \text{ is faithful} \} \]
the class of faithful morphisms in \( G \).

2.3.2. Example. In a first reading, the reader can safely assume \( G = \text{gpd} \) everywhere, unless specifically mentioned otherwise.

2.3.3. Example. There is a gain in allowing more general \( G \) than the main example \( G = \text{gpd} \). For instance, the general formalism covers Mackey 2-functors like the stable module category, \( G \mapsto \text{Stab}(kG) \) in Example 4.2.6, which are only defined on the (2,1)-category \( \text{gpd}^f \) of finite groupoids with faithful morphisms.

2.3.4. Remark. It is legitimate to wonder whether \( G \) and \( J \) need to consist of groupoids or whether more general 2-categories \( G \) and classes \( J \) can be considered. Such an extended formalism is used in Chapters 5 and 6; see Hypotheses 5.1.1.

2.3.5. Definition. Let \( G \) be a (2,1)-category of finite groupoids of interest (and the class \( J \) of faithful morphisms) as in Hypotheses 2.3.1. Alternatively, let \( (G, J) \) be an admissible pair, as in Hypotheses 5.1.1.

A Mackey 2-functor on \( G \) (or in full, an additive \(^1\) Mackey 2-functor on the (2,1)-category \( G \), with respect to the class \( J \)) is a strict 2-functor \( \mathcal{M}: G^{\text{op}} \to \text{ADD} \) satisfying the four axioms (Mack 1)–(Mack 4) below. See details as to what such a 2-functor \( \mathcal{M}: G^{\text{op}} \to \text{ADD} \) amounts to in Remark 1.2.6(a)-(c).

(Mack 1) Additivity: For every finite family \( \{ G_\alpha \}_{\alpha \in \mathbb{N}} \) in \( G \), the natural functor
\[ \mathcal{M} \left( \prod_{\alpha \in \mathbb{N}} G_\alpha \right) \longrightarrow \prod_{\alpha \in \mathbb{N}} \mathcal{M}(G_\alpha) = \bigoplus_{\alpha \in \mathbb{N}} \mathcal{M}(G_\alpha) \]
is an equivalence (see Remark A.6.8 for the right-hand side rewriting).

(Mack 2) Induction-coinduction: For every \( i: H \to G \) in the class \( J \), restriction \( i^*: \mathcal{M}(G) \to \mathcal{M}(H) \) admits a left adjoint \( !i \) and a right adjoint \( i_* \).

(Mack 3) BC-formulas: For every Mackey square as in diagram (2.2.2), the following two mates are isomorphisms:
\[ \gamma_* : j_* \circ v^* \cong u^* i_* \quad \text{and} \quad (\gamma^{-1})_! : u^* i_! \cong j_! \circ v^*. \]
(cf. Remark 2.2.10).

(Mack 4) Ambidexterity: We have isomorphisms \( i_! \simeq i_* \) for every faithful \( i: H \to G \) in \( J \).

2.3.6. Definition. A rectified Mackey 2-functor \( \mathcal{M}: G^{\text{op}} \to \text{ADD} \) is a Mackey 2-functor together with a specified choice of functors \( i_! \) for all \( i \in J \) and adjunctions \( i_! \dashv i^* \dashv i_* := i_! (i \in J) \) which in addition to (Mack 1)–(Mack 4) of Definition 2.3.5, further satisfy (Mack 5)–(Mack 9) of Theorem 1.3.1.

2.3.7. Remark. The Rectification Theorem 3.4.3 guarantees that as soon as we have verified (Mack 1)–(Mack 4), the units and counits of \( i_! \dashv i^* \dashv i_* = i_! \) can be arranged to satisfy all the extra properties in (Mack 5)–(Mack 9): Every Mackey 2-functor can be rectified. Of course, not having to prove the latter five properties greatly simplifies the verification that a specific example of \( \mathcal{M} \) is indeed a Mackey 2-functor. On the other hand, these additional properties will be extremely precious when carefully proving results about Mackey 2-functors.

\(^1\)Here in the sense of ‘ADD-valued’.
2.3.8. Remark. Virtually everything we say here about additive categories $\mathcal{M}(G)$ will make perfect sense with semi-additive categories instead, i.e. categories in which we can add objects and morphisms, without requesting additive opposites of morphisms. See Terminology A.5.1 or [ML98, VIII.2]. Furthermore, if $\mathcal{M}: \mathbb{G}^{op} \to \text{CAT}$ is any 2-functor satisfying Additivity (Mack1) and Ambidexterity (Mack4), then each category $\mathcal{M}(G)$ is automatically semi-additive. In other words, the only thing $\mathcal{M}(G)$ is missing to be additive are the additive inverses of maps.

To see why $\mathcal{M}(G)$ is semi-additive, let $\{G_\alpha\}_{\alpha \in \mathbb{N}}$ be a finite set of copies of $G$. The folding functor $\nabla: \coprod_{\alpha} G_\alpha \to G$, which is the identity on each component, induces the diagonal functor $\text{diag}: \mathcal{M}(G) \to \prod_{\alpha} \mathcal{M}(G)$ after an application of Additivity:

Now recall that the left and right adjoint of diag are precisely the functors $\coprod_{\mathbb{N}}$ and $\prod_{\mathbb{N}}$ assigning to a family $\{X_\alpha\}_{\alpha \in \mathbb{N}}$ its coproduct and product in $\mathcal{M}(G)$, respectively. These adjoints exist and are isomorphic by the Ambidexterity of $\mathcal{M}$.

The interested reader can therefore replace accordingly

$$\text{ADD} \rightsquigarrow \text{SAD}.$$ 

However, we are human and so are most of our readers. Discussing at length semi-additive Mackey 2-functors would be somewhat misleading given that almost all examples we use are additive. We therefore require enrichment over abelian groups (not just abelian monoids) out of habit, convenience and social awareness.

2.3.9. Remark. It is easy to deduce from Additivity (Mack1) that $\mathcal{M}(\emptyset) \cong 0$, by inspecting the image of the equivalence $\nabla = (\text{Id Id}): \emptyset \sqcup \emptyset \to \emptyset$ under $\mathcal{M}$.

Recall from Remark 2.3.8 that, given a strict 2-functor $\mathcal{M}: \mathbb{G}^{op} \to \text{CAT}$ taking values in arbitrary categories and satisfying (Mack1)-(Mack4) as in Definition 2.3.5, each category $\mathcal{M}(G)$ must be semi-additive. Similarly, restriction $i^!$ and (co)induction $i_* \cong i^!$ are additive functors for every $i \in \mathbb{J}$ but the same is not necessarily true of $u^*$ for 1-cells $u$ not in $\mathbb{J}$. Including the latter gives:

2.3.10. Definition. A semi-additive Mackey 2-functor on $\mathbb{G}$ is a strict 2-functor $\mathcal{M}: \mathbb{G}^{op} \to \text{SAD}$, taking values in semi-additive categories and additive functors, and satisfying (Mack1)-(Mack4) as in Definition 2.3.5.

2.4. Separable monadicity

To give an early simple application of Mackey 2-functors, we illustrate how the knowledge that $\mathcal{M}(H)$ and $\mathcal{M}(G)$ are part of the same Mackey 2-functor $\mathcal{M}$ for a group(oid) $G$ and a subgroup(oid) $H$ bear some consequence on so-called ‘separable monadicity’. Let us remind the reader.
In [BDS15], we proved with Sanders that many examples of ‘equivariant’ categories \( \mathcal{M}(G) \) had the property that the category \( \mathcal{M}(H) \) associated to a subgroup \( H \leq G \) could be described in terms of modules over a monad defined over the category \( \mathcal{M}(G) \). In technical terms, this means that the adjunction \( \text{Res}_G^H : \mathcal{M}(G) \cong \mathcal{M}(H) : \text{CoInd}_H^G \) satisfies monadicity. This property allows us to use descent techniques to analyze the extension of objects of \( \mathcal{M}(H) \) to \( \mathcal{M}(G) \), i.e., extension of objects from the subgroup to the big group. In the case of tensor-triangulated categories, monadicity also yields a better understanding of the connections between the triangular spectra of \( \mathcal{M}(G) \) and \( \mathcal{M}(H) \). See [Bal16].

### 2.4.1. Theorem.

Let \( \mathcal{M} : \text{gpd}^{\text{op}} \to \text{ADD} \) be any (rectified) Mackey 2-functor (Definition 2.3.5) and \( i : H \rightarrow G \) be a faithful functor in \( \text{gpd} \). Then the adjunction \( i^* \dashv i_* \) is monadic, i.e., the Eilenberg-Moore comparison functor

\[
E : \mathcal{M}(H) \longrightarrow A^G_H \cdot \text{Mod}_{\mathcal{M}(G)}
\]

between \( \mathcal{M}(H) \) and the Eilenberg-Moore category of modules in \( \mathcal{M}(G) \) over the monad \( A^G_H = i_* i^* : \mathcal{M}(G) \rightarrow \mathcal{M}(G) \) induces an equivalence on idempotent-completions (Remark A.5.10)

\[
\mathcal{M}(H)^\mathbb{I} \xrightarrow{\sim} (A^G_H \cdot \text{Mod}_{\mathcal{M}(G)})^\mathbb{I} = A^G_H \cdot \text{Mod}_{\mathcal{M}(G)^\mathbb{I}}.
\]

In particular, \( E \) is an equivalence if \( \mathcal{M} : \text{gpd}^{\text{op}} \to \text{ADD} \) takes values in idempotent-complete categories. Moreover, the monad \( A^G_H : \mathcal{M}(G) \rightarrow \mathcal{M}(G) \) is separable.

**Proof.** This is a standard consequence of the existence of a natural section of the counit \( \varepsilon : i^* i_* \Rightarrow \text{Id} \), which follows from (Mack 9). Indeed, the multiplication \( A^G_H \circ A^G_H \Rightarrow A^G_H \) is induced by \( \varepsilon \) and the section of the latter tells us that \( A^G_H \) is separable. It follows that every \( A^G_H \)-module is a direct summand of a free one, and therefore both \( \mathcal{M}(H) \) and \( A^G_H \cdot \text{Mod}_{\mathcal{M}(G)} \) receive the Kleisli category of free \( A^G_H \)-modules as a ‘dense’ subcategory, in a compatible way. (Here a subcategory of an additive category is called ‘dense’ if every object of the big category is a direct summand of an object of the subcategory.) It follows that both categories \( \mathcal{M}(H) \) and \( A^G_H \cdot \text{Mod}_{\mathcal{M}(G)} \) have the same idempotent-completion as the Kleisli category. See details in [BDS15, Lemma 2.2].

### 2.5. Decategorification

It is natural to discuss ‘decategorification’ from Mackey 2-functors down to ordinary Mackey (1-)functors at this stage of the exposition, in order to facilitate understanding of our new definition. However, the treatment we present here will become clearer after the reader becomes familiar with the bicategories of (double) spans that will only appear in Chapters 5 and 6. In particular, we are going to use the universal property of \( \text{SpSpan}(G; J) \) as a black box (whose proof does not rely on the present section, of course).

In Appendix B, we describe ordinary Mackey 1-functors on a fixed finite group \( G \) as additive functors on a suitable 1-category of spans, \( \text{gpd}^1_G \), built out of the 2-category \( \text{gpd}^1_G \) of groupoids faithful over \( G \) (Definition B.0.6). Inspired by Theorem B.0.12, we replace the 2-category \( \text{gpd}^1_G \) by other (2,1)-categories \( G \) and consider proper classes \( J \) of 1-cells in \( G \). For simplicity, the reader can assume that \((G, J)\)
satisfies Hypotheses 2.3.1 but this section makes sense in the greater generality of Hypotheses 5.1.1.

2.5.1. Definition. The category of spans over the (2,1)-category $\mathbb{G}$ (with respect to the class $\mathcal{J} \subseteq \mathbb{G}_1$) is the 1-category

$$\tau_1 \text{Span}(\mathbb{G}; \mathcal{J})$$

whose objects are the same as those of $\mathbb{G}$ and whose morphisms are equivalence classes of spans $\xymatrix{G \ar@{~>}[r]^a & P \ar@{~>}[r]_b & H}$ with $b \in \mathcal{J}$, where two such pairs are declared equivalent if there exists an equivalence between the two middle objects making the triangles commute up to isomorphism:

$$\begin{array}{ccc} G & \cong & H \\ \ar^{a'} \downarrow & \cong & \downarrow \ar^{b'} \\ P & \cong & P' \end{array}$$

Composition is done in the usual way: Choose representatives for the fractions, construct the comma squares (compare Definition 5.1.6), and then retake equivalence classes. When $\mathcal{J}$ is not mentioned, we mean $\mathcal{J} = \text{all}$ as always: $\tau_1 \text{Span}(\mathbb{G}) := \tau_1 \text{Span}(\mathbb{G}; \text{all})$.

2.5.2. Remark. The advanced readers who are already familiar with Chapters 5 and 6 will observe that $\tau_1 \text{Span}(\mathbb{G}; \mathcal{J})$ is precisely the 1-truncation (Notation A.1.13) of the bicategory of spans $\text{Span}(\mathbb{G}; \mathcal{J})$ as in Definition 5.1.6, hence the notation. It is also the 1-truncation of the bicategory of spans of spans $\text{Span}(\mathbb{G}; \mathcal{J})$ as in Definition 6.1.1

$$\tau_1 \text{Span}(\mathbb{G}; \mathcal{J}) = \tau_1(\text{Span}(\mathbb{G}; \mathcal{J})) = \tau_1(\text{Span}(\mathbb{G}; \mathcal{J})).$$

This holds simply because $\text{Span}(\mathbb{G}; \mathcal{J})$ and $\text{Span}(\mathbb{G}; \mathcal{J})$ have the same 0-cells and the same 1-cells and because the only invertible 2-cells of $\text{Span}(\mathbb{G}; \mathcal{J})$ are already in $\text{Span}(\mathbb{G}; \mathcal{J})$ by Lemma A.4.5. As a consequence the notion of Mackey functors for $(\mathbb{G}, \mathcal{J})$ that we are about to consider will not see the difference between the two bicategories of spans studied in Chapters 5 and 6.

2.5.3. Remark. If the category $\tau_1 \mathbb{G}$ (Notation A.1.13) has enough pullbacks, the 1-category of spans $\tau_1 \text{Span}(\mathbb{G}; \mathcal{J})$ has an alternative description where one first takes the 1-truncation $\tau_1 \mathbb{G}$ and then considers spans in this 1-category (in the spirit of Definition A.4.1, except that only morphisms in $\tau_1 \mathcal{J}$ are allowed on the right). In particular, when $\mathcal{J} = \text{all}$, the category $\tau_1 \text{Span}(\mathbb{G})$ is nothing but $\tau_1 \mathbb{G}$.

If $\tau_1 \mathbb{G}$ does not have pullbacks, it is slightly abusive to view $\tau_1 \text{Span}(\mathbb{G})$ as the ‘category $\tau_1 \mathbb{G}$ of spans in $\tau_1 \mathbb{G}$’ for composition still requires to chose representatives of spans in $\mathbb{G}$ and to work with iso-comma squares in $\mathbb{G}$. In other words, the composition of spans in $\tau_1 \text{Span}(\mathbb{G})$ still really depends on the underlying 2-category $\mathbb{G}$. (This issue did not appear with $\mathbb{G} = \text{gpd}_{\mathcal{G}}$ in Appendix B, since $\tau_1(\text{gpd}_{\mathcal{G}})$ admits pullbacks by Corollary B.0.10.) Alternatively, one should remember the relevant class of squares in $\tau_1 \mathbb{G}$, which might have an intrinsical characterization in $\tau_1 \mathbb{G}$. These are sometimes called weak pullbacks.

2.5.4. Definition. A (generalized) Mackey functor over the (2,1)-category $\mathbb{G}$, with respect to the class $\mathcal{J} \subseteq \mathbb{G}_1$, is an additive (i.e. coproduct-preserving) functor
M: \(\tau_1 \text{Span}(G; \mathcal{J}) \to \text{Ab}\). As always when we do not specify \(\mathcal{J}\), a Mackey functor over \(G\) means that we have taken \(\mathcal{J} = \text{all}\).

Explicitly, a Mackey functor for \((G, \mathcal{J})\) consists of an abelian group \(M(G)\) for every object \(G \in G_0\), a homomorphism \(a^*: M(G) \to M(H)\) for every 1-cell \(a \in G_1(H, G)\) and a homomorphism \(a_*: M(H) \to M(G)\) if furthermore \(a \in \mathcal{J}_1(H, G)\).

This data is subject to a few rules:

1. **Additivity:** The canonical morphism \(M(G_1 \sqcup G_2) \sim \to M(G_1) \oplus M(G_2)\) is an isomorphism, for all \(G_1, G_2 \in G\).
2. If two 1-cells \(a \simeq b\) are isomorphic in the category \(G(H, G)\) then \(a^* = b^*\), and furthermore \(a_* = b_*\) if \(a, b\) belong to \(\mathcal{J}\).
3. For every (iso)comma square (or Mackey square) in \(G\) with 
   \[
   \begin{array}{ccc}
   i & \sim & j \\
   v & \Rightarrow & \gamma \\
   G & \downarrow & K \\
   i & \vphantom{\sim} & u \\
   \end{array}
   \]
   we have \(u^*i_* = j_*v^*: M(H) \to M(K)\).

Once we establish the universal property of \(\check{\text{Span}}(G; \mathcal{J})\), there are obvious ways to recover ordinary Mackey 1-functors through decategorification of Mackey 2-functors. For instance, one can use the Grothendieck group \(K_0\) as follows. We shall expand these ideas in forthcoming work.

**2.5.5. Proposition.** Let \(\mathcal{M}: G^{\text{op}} \to \text{ADD}\) be a Mackey 2-functor on \((G, \mathcal{J})\) in the sense of Definition 2.3.5. Then the composite \(K_0 \circ \mathcal{M}\) factors uniquely as

\[
\begin{array}{ccc}
G^{\text{op}} & \xrightarrow{\mathcal{M}} & \text{ADD} \\
\tau_1 \text{Span}(G; \mathcal{J}) & \xrightarrow{\sim} & \text{Ab} \\
\end{array}
\]

where \(G^{\text{op}} \to \tau_1 \text{Span}(G; \mathcal{J})\) is the functor sending \(u: H \to G\) to the equivalence class of the span \(G \xleftarrow{\sim} H \xrightarrow{\text{id}} H\). This functor \(M: \tau_1 \text{Span}(G; \mathcal{J}) \to \text{Ab}\) is a generalized Mackey functor over \(G\), in the sense of Definition 2.5.4.

**Proof.** By the universal property of Theorem 6.1.13, the Mackey 2-functor \(\mathcal{M}\) factors through \(G^{\text{op}} \to \text{Span}\). As \(\text{Ab}\) is a 1-category, the composite \(K_0 \circ \mathcal{M}\) must factor through the quotient \(\text{Span} \to \tau_1 \text{Span} = \tau_1 \text{Span}\), as claimed. The resulting functor \(M: \tau_1 \text{Span} \to \text{Ab}\) is additive by the Additivity axiom for \(\mathcal{M}\), hence is a Mackey functor. \(\square\)

**2.5.6. Remark.** It is clear from the proof of Proposition 2.5.5 and the equality \(\tau_1 \text{Span} = \tau_1 \text{Span}\) that one does not really need \(\mathcal{M}\) to be a Mackey 2-functor: The left adjoints satisfying the (left) BC-formula would suffice for \(\mathcal{M}\) to factor through \(\text{Span}\), and Additivity for it to yield a Mackey functor \(M\). This was already observed in \([\text{Nak16}]\).

**2.5.7. Remark.** We shall discuss other ‘decategorifications’ in subsequent work, for instance by considering Mackey 2-functors \(\mathcal{M}\) whose values \(M(G)\) are not mere...
additive categories but richer objects, like exact or triangulated categories, in which case the Grothendieck group $K_0$ has a finer definition.
CHAPTER 3

Rectification and ambidexterity

We want to justify our definition of ‘Mackey 2-functors’ (Definition 1.2.7). There are many examples of categories depending on finite groups for which induction and co-induction coincide. Our main goal is to show that this happens systematically in various additive settings, including ‘stable homotopy’. This general ambidexterity result (Theorems 3.3.19 and 4.1.1) explains why we do not treat induction and coinduction separately in the sequel. Theorem 4.1.1 will also be the source of a large class of examples, as we shall discuss more extensively in Section 4.1.

3.1. Self iso-commas

The present section prepares for the rectification process of Section 3.4. We assemble here the ingredients which do not depend on a 2-functor $\mathcal{M} : \text{gpd}^{op} \to \text{ADD}$ but only on constructions with iso-commas of groupoids. Specifically, we study the ‘self-iso-commas’ obtained by considering (1.2.4) in the case $u = i$: We identify certain diagonal components of such self-iso-commas and record their functorial behavior with respect to $i$.

3.1.1. Notation. For every faithful $i : H \to G$ in gpd, we consider the ‘self-iso-comma’ over the cospan $\overset{i}{\rightarrow}\underset{i}{\leftarrow}$, that is, for $i$ versus itself:

\[
\begin{array}{c}
\xymatrix{ (i/i) \\
H \ar[rr]^{P_1} & & H \\
\ar[rr]^{\sim} & & \ar[rr]^{P_2} & & G \\
H \ar[rr]_{\lambda} & & H \\
G \ar[rr]_{i} & & i \\
\end{array}
\]

(3.1.2)

We start by isolating some special (‘diagonal’) connected components of $(i/i)$.

3.1.3. Proposition. There exists a functor $\Delta_i : H \to (i/i)$
characterized by $p_1\Delta_i = p_2\Delta_i = \text{Id}_H$ and $\lambda\Delta_i = \text{id}_i$, namely $\Delta_i = \langle \text{Id}_H, \text{id}_H, \text{id}_i \rangle$ in the notation of Definition 2.1.1. This functor is fully faithful, that is, $\Delta_i$ induces an equivalence between $H$ and its essential image in $(i/i)$.

**Proof.** Consider $x, y \in H$ and a morphism $(f, g): (x, x, \text{id}_{i(x)}) \to (y, y, \text{id}_{i(y)})$ between their images in $(i/i)$ under $\Delta_i$. The pair $f: x \to y$ and $g: x \to y$ in $H$ must satisfy $\text{id}_{i(y)} \circ i(f) = i(g) \circ \text{id}_{i(x)}$ in $G$, hence $f = g$ by the faithfulness of $i$. □

**3.1.4. Remark.** We need to understand the behavior of the self-iso-comma $(i/i)$ and the embedding $\Delta_i$ in two situations. First we want to relate $(i/i)$ and $(j/j)$ in the presence of a 2-cell $\gamma: iv \Rightarrow uj$, typically but not necessarily a Mackey square, as in (2.2.2). Second, we want to relate $(i/i)$, $(j/j)$ and $(ij/ij)$ when $i$ and $j$ are composable morphisms $j \circ i$.

Here is the first setting:

**3.1.5. Notation.** We consider a 2-cell $\gamma: iv \Rightarrow uj$

\[
(3.1.6) \quad \begin{array}{c}
H \xrightarrow{v} L \\
i \downarrow \downarrow \downarrow \downarrow \\
\gamma \Rightarrow K \\
i \downarrow \downarrow \downarrow \downarrow \\
G \xleftarrow{u}
\end{array}
\]

in which both $i$ and $j$ are assumed faithful. (This square may be an iso-comma but we do not assume this here.) Consider the self-iso-comma (3.1.2) associated to $j$

\[
(3.1.7) \quad \begin{array}{c}
(j/j) \xrightarrow{q_1} L \\
q_2 \Rightarrow \quad \rho \\
q_2 \downarrow \downarrow \downarrow \downarrow \\
(j/j) \xleftarrow{j} K \\
\downarrow \downarrow \downarrow \downarrow \\
L \xleftarrow{j}
\end{array}
\]

We compare the two iso-commas (3.1.2) and (3.1.7), for $i$ and for $j$ respectively:

**3.1.8. Proposition.** With notation as in 3.1.5, there exists a (unique) functor $w = w_{v, u, \gamma}: (j/j) \to (i/i)$ such that $p_1w = vq_1$, $p_2w = vq_2$ and such that the following two morphisms $ivq_1 \Rightarrow ivq_2$ are equal (see Definition 2.1.1):

\[
(3.1.9) \quad \begin{array}{c}
(j/j) \xrightarrow{w} (i/i) \\
q_1 \Rightarrow \quad \rho \\
q_2 \downarrow \downarrow \downarrow \downarrow \\
(i/i) \xleftarrow{i} H \\
\downarrow \downarrow \downarrow \downarrow \\
G \xleftarrow{i}
\end{array}
\]

and

\[
(3.1.10) \quad \begin{array}{c}
(j/j) \xrightarrow{\gamma^{-1}} (i/i) \\
q_1 \Rightarrow \quad \rho \\
q_2 \downarrow \downarrow \downarrow \downarrow \\
(i/i) \xleftarrow{i} H \\
\downarrow \downarrow \downarrow \downarrow \\
G \xleftarrow{i}
\end{array}
\]
In other words \( w = \langle vq_1, vq_2, (\gamma^{-1}q_2)(up)(\gamma q_1) \rangle \) and the following diagram of natural transformations commutes

\[
\begin{array}{ccc}
ip_1 w & \xrightarrow{\chi} & ip_2 w \\
vq_1 & \searrow & vq_2 \\
ujq_1 & \xrightarrow{\rho} & ujq_2
\end{array}
\]

Moreover, \( w: (j/j) \to (i/i) \) is compatible with the morphism \( \Delta_i \) of Proposition 3.1.3, namely we have a commutative diagram

\[
\begin{array}{ccc}
L & \xrightarrow{\Delta_i} & (j/j) \\
v & \downarrow & w \\
H & \xrightarrow{\Delta_i} & (i/i).
\end{array}
\]

**Proof.** The universal property of \((i/i)\) as in Definition 2.1.1 (a) gives us the wanted \( w \). We only need to verify (3.1.11). Let us describe the two functors 

\( w\Delta_j, \Delta_i v: L \to (i/i). \)

Since \( \Delta_i = \langle \text{Id}_H, \text{Id}_H, \text{Id}_i \rangle \), we have \( \Delta_i \circ v = \langle v, v, \text{Id}_{iv} \rangle \). On the other hand, since \( w = \langle vq_1, vq_2, (\gamma^{-1}q_2)(up)(\gamma q_1) \rangle \), we have that \( w \circ \Delta_j \) is equal to the morphism

\( \langle vq_1 \Delta_j, vq_2 \Delta_j, (\gamma^{-1}q_2 \Delta_j)(up \Delta_j)(\gamma q_1 \Delta_j) \rangle = \langle v, v, \text{Id}_{iv} \rangle. \)

The latter uses \( q_1 \Delta_j = \text{Id} \) and \( q_2 \Delta_j = \text{Id} \) and the fact that \( \rho \Delta_j = \text{Id} \) by construction of \( \Delta_j = (j, j, \text{Id}_j) \), thus allowing \( \gamma \) and \( \gamma^{-1} \) to cancel out. \( \square \)

To state the next result, we need to isolate some class of 2-cells as in (3.1.6).

**3.1.12. Definition.** We say that a 2-cell in \( \text{gpd} \)

\[
\begin{array}{ccc}
v & \downarrow^{\gamma} & j \\
L & \xrightarrow{\sim} & K \\
i & \downarrow^{\sim} & u \\
H & \xrightarrow{\sim} & G
\end{array}
\]

is a **partial Mackey square** if the induced functor \( \langle v, j, \gamma \rangle: L \to (i/u) \) is fully faithful. In other words, \( L \) is equivalent to a union of connected components of the iso-comma \((i/u)\), although perhaps not all of them. When we assume \( j \) faithful (as we did in Notation 3.1.5) then the condition simply means that \( \langle v, j, \gamma \rangle: L \to (i/u) \) is full. The latter can be stated explicitly by saying that for every objects \( x, y \in L \), every \( h: v(x) \xrightarrow{\sim} v(y) \) and \( k: j(x) \xrightarrow{\sim} j(y) \) such that \( u(k)\gamma_x = \gamma_y i(h) \), there exists a morphism \( \ell: x \xrightarrow{\sim} y \) such that \( v(\ell) = h \) and \( j(\ell) = k \).

**3.1.13. Example.** Of course, every Mackey square (Definition 2.2.1) is a partial Mackey square. In particular, for every 2-cell \( \alpha: i \xrightarrow{\sim} i' \) between faithful
3.1.14. Example. For every faithful \( i : H \rightarrow G \) the following is a partial Mackey square by Proposition 3.1.3:

One can easily generalize the above example as follows.

3.1.15. Example. Consider two composable faithful functors \( K \overset{j}{\rightarrow} H \overset{i}{\rightarrow} G \). Then the following is a partial Mackey square

as one can directly verify that \( \langle \text{Id}_K, j, \text{id} \rangle : K \rightarrow (ij/i) \) is fully faithful.

In Proposition 3.1.8 we saw that \( w = w_{v,u,\gamma} : (j/j) \rightarrow (i/i) \) sends the diagonal component \( \Delta_j(H) \) of \( (j/j) \) to the diagonal component of \( (i/i) \) whenever we have a 2-cell \( \gamma : iv \Rightarrow uj \) as in (3.1.6). We need a condition for the non-diagonal components to be sent by \( w \) to non-diagonal components as well, which is not automatic. The partial Mackey squares do the job:

3.1.16. Proposition. Consider a 2-cell in \( \text{gpd} \) as in (3.1.6)

and recall the induced 1-cell \( w = w_{v,u,\gamma} : (j/j) \rightarrow (i/i) \) of Proposition 3.1.8. Suppose that the above is a partial Mackey square (Definition 3.1.12). Then for each connected component \( D \subset (j/j) \) which does not meet the image of \( \Delta_j \) the connected component of \( w(D) \) in \( (i/i) \) does not meet the image of \( \Delta_i \).

**Proof.** This is a lengthy but straightforward exercise. Here is an outline of the contrapositive. Let \( (x,y,k) \in (j/j) \) be an object such that \( w(x,y,k) \) is isomorphic in \( (i/i) \) to \( \Delta_i(z) \) for some \( z \in H \). We want to show that \( (x,y,k) \) is isomorphic to \( \Delta_j(x) \) in \( (j/j) \). Let \( (h_1,h_2) : w(x,y,k) \overset{\sim}{\rightarrow} \Delta_i(z) \) be an isomorphism in \( (i/i) \).
Explicitly, $w(x, y, k) = (v(x), v(y), \gamma^{-1} u(k) \gamma_x)$. Consider $h := h_2^{-1} h_1 : v(x) \sim v(y)$ and the given $k : j(x) \sim j(y)$. They satisfy $u(k) \gamma_x = \gamma_j i(h)$ because $(h_1, h_2)$ is a morphism in $(i/i)$. By the explicit formulation of the square (3.1.6) being a partial Mackey square (Definition 3.1.12) there exists $\ell : x \sim y$ such that $v(\ell) = h$ and $j(\ell) = k$. We can then verify that $(\id_x, \ell) : \Delta_j(x) \sim (x, y, k)$ is an isomorphism in $(j/j)$, as wanted.

We now turn to the second behavior of $(i/i)$ announced in Remark 3.1.4. Here is the precise setting:

3.1.17. Notation. Let $K \xrightarrow{j} H \xrightarrow{i} G$ be two composable faithful functors, and consider the three associated iso-comma squares:

\[
\begin{array}{ccc}
H & \xrightarrow{\sim} & H \\
p_1 & \xleftarrow{\sim} & p_2 \\
i & \xrightarrow{\lambda} & i
\end{array}
\quad
\begin{array}{ccc}
K & \xrightarrow{\sim} & K \\
r_1 & \xleftarrow{\sim} & r_2 \\
ij & \xrightarrow{\sigma} & ij
\end{array}
\quad
\begin{array}{ccc}
K \xrightarrow{\sim} & K \\
q_1 & \xleftarrow{\sim} & q_2 \\
ij & \xrightarrow{\rho} & ij
\end{array}
\]

Consider also the two functors

\[
(i/i) \xleftarrow{w'} \ (ij/ij) \xleftarrow{w''} (j/j)
\]

induced by the universal property of iso-comma squares and defined by their components $w = (q_1, q_2, i\rho)$ and $w' = (jr_1, jr_2, \sigma)$, see Definition 2.1.1 (a). One can readily verify that $w'' = w_{\id_K, i, \id}$ and $w' = w_{j, \id_G, \id}$ in the notation of Proposition 3.1.8 applied to the following two squares, respectively:

\[
\begin{array}{ccc}
K & \xrightarrow{j} & H \\
ij & \xrightarrow{\id} & i
\end{array}
\quad
\begin{array}{ccc}
K & \xrightarrow{i} & G \\
ij & \xrightarrow{\id} & i
\end{array}
\]

(The ‘conjugation’ by $\gamma$ in Proposition 3.1.8 disappears here since $\gamma = \id$.)

Then the connected components of $(ij/ij)$ are organized as follows:

3.1.19. Proposition. Retain Notation 3.1.17. Each connected component $C \subseteq (ij/ij)$ falls in exactly one of the following three cases:

1. $C$ belongs to the (essential) image of the diagonal $\Delta_{ij}(K)$ and the inclusion $C \hookrightarrow (ij/ij)$ lifts uniquely along $w''$ to an equivalence between $C$ and a connected component $D$ of the diagonal $\Delta_j(K) \subseteq (j/j)$.

2. $C$ is disjoint from $\Delta_{ij}(K)$ and $w'(C)$ is disjoint from $\Delta_i(H)$ in $(i/i)$.

3. $C$ is disjoint from $\Delta_{ij}(K)$ and the inclusion $C \hookrightarrow (ij/ij)$ lifts uniquely along $w''$ to an equivalence between $C$ and a connected component $D$ of $(j/j)$ which is disjoint from the diagonal $\Delta_j(K)$. 

Proof. By (3.1.11) applied to the two squares in (3.1.18), we have a commutative diagram

\[
\begin{array}{ccc}
K & \xrightarrow{\Delta_j} & (j/j) \\
\downarrow{w''} & & \downarrow{w''} \\
K & \xrightarrow{\Delta_{ij}} & (ij/ij) \\
\downarrow{j} & & \downarrow{j} \\
H & \xrightarrow{\Delta,} & (i/i) \\
\end{array}
\]

We may apply Proposition 3.1.16 to the left square in (3.1.18), which is a partial Mackey square by Example 3.1.15, and conclude the following: If a connected component \(D\) of \((j/j)\) does not meet the diagonal \(\Delta_j\) then \(w''D\) does not meet \(\Delta_{ij}\).

Now the right square in (3.1.18) is not partial Mackey in general, so we cannot apply Proposition 3.1.16 to it. Instead, we can prove:

3.1.21. Lemma. If a component \(C \subseteq (ij/ij)\) is such that \(w'C\) meets \(\Delta_i\) in \((i/i)\), then the inclusion \(C \hookrightarrow (ij/ij)\) lifts uniquely along \(w''\) to an equivalence between \(C\) and a component of \((j/j)\).

Proof. The facts that the lifting, if it exists, is unique and induces an equivalence of components, are both easy consequences of \(w''\) being fully faithful and injective on objects. The latter are seen by direct inspection: On objects, \(w''\) sends \((x,y,h)\) to \((x,y,i(h))\) hence is injective by the faithfulness of \(i\); On maps, \(w''\) sends \((k_1,k_2)\) to \((k_1,k_2)\), and the commutativity conditions for a pair \((k_1,k_2)\) \(\in (\text{Mor } K)^2\) to define a morphism in \((j/j)\) or \((ij/ij)\) are identical, again by the faithfulness of \(i\).

To prove the existence of the lifting, let \((x,y,g: ij(x) \to ij(y)) \in D\) be such that \(w''(x,y,g)\) is isomorphic to an object in the image of \(\Delta_i\), say \((h_1,h_2): w''(x,y,g) \simeq \Delta_i(z)\). Thus we have isomorphisms \(h_1: j(x) \to z\) and \(h_2: j(y) \to z\) such that \(i(h_2)g = i(h_1)\). As \(w''\) is so nice, to construct the lifting of \(D \hookrightarrow (ij/ij)\) it suffices to lift the object \((x,y,g)\). Setting \(h := h_2^{-1}h_1: j(x) \to j(y)\), we see that \((x,y,h)\) is an object of \((j/j)\) such that \(w''(x,y,h) = (x,y,g)\).

Now the trichotomy claimed in the proposition follows immediately from the commutativity of (3.1.20) and the above properties of \(w''\) and \(w'\) with respect to components.

3.2. Comparing the legs of a self iso-comma

We proceed with our gentle build up towards rectification (Section 3.4) by assuming the existence of a strict 2-functor \(M: \text{gpd}^{op} \to \text{ADD}\) which satisfies additivity, without requesting any of the further properties of Mackey 2-functors. Using only this and the self-iso-commas \((i/i)\) of Section 3.1 we can already compare some of the functors. For the sake of generality we replace the 2-category \(\text{gpd}\) by any 2-subcategory \(\mathcal{G}\) as in Hypotheses 2.3.1. Note that all constructions performed in Section 3.1 remain inside \(\mathcal{G}\) since the latter is assume closed under iso-commas (etc). We begin with a very simple natural transformation:
3.2.1. Proposition. Let \( i: H \to G \) in \( \mathcal{G} \) be faithful and let \( \mathcal{M}: \mathcal{G}^{\text{op}} \to \text{ADD} \) be a strict 2-functor satisfying additivity (Mack). Consider the self-iso-comma of Notation 3.1.1

\[
\begin{array}{c}
\xymatrix{
P_1 \ar[r]^{(i/i)} & H \ar[r]^\sim & C \ar[r] & G \\
& H \ar[ru]^\lambda_i \ar[d]_i & & \\
& i \ar[u]_i & & }
\end{array}
\]

and the ‘diagonal’ embedding \( \Delta_i: H \to (i/i) \) of Proposition 3.1.3. Then there exists a unique natural transformation \( \delta_i: p_1^* \Rightarrow p_2^* \) of functors \( \mathcal{M}(H) \to \mathcal{M}(i/i) \) with the following properties:

1. The natural transformation \( \Delta_i^*(\delta_i) \) from \( \Delta_i^* p_1^* = \text{Id}_{\mathcal{M}(H)} \) to \( \Delta_i^* p_2^* = \text{Id}_{\mathcal{M}(H)} \) equals the identity (of the functor \( \text{Id}_{\mathcal{M}(H)} \)).
2. For every connected component \( \text{incl}_C: C \to (i/i) \) disjoint from \( \Delta_i(H) \), the natural transformation \( \text{incl}^*_C(\delta_i) \) from \( \text{incl}^*_C p_1^* \) to \( \text{incl}^*_C p_2^* \) equals zero.

**Proof.** By additivity and Proposition 3.1.3, we have an equivalence

\[
\mathcal{M}(i/i) \xrightarrow{(\Delta_i^*_\text{incl}_C)(\text{incl}^*_C)} \mathcal{M}(H) \oplus \bigoplus_{C \cap \Delta_i(H)} = \mathcal{M}(C)
\]

where \( C \) runs among the connected components of \( (i/i) \) disjoint from \( \Delta_i(H) \), since the union of the other components is precisely the essential image of \( \Delta_i \). As in the statement, we denote by \( \text{incl}_C: C \to (i/i) \) the inclusions. Therefore, we can uniquely describe the morphism \( \delta_i: p_1^* \Rightarrow p_2^* \) by its image under this equivalence. \( \square \)

3.2.2. Remark. In analogy with Remark 3.1.4, we now want to discuss the behavior of \( \delta_i: p_1^* \Rightarrow p_2^* \) when \( i \) moves as in Notation 3.1.5.

3.2.3. Proposition. Let \( \mathcal{M}: \mathcal{G}^{\text{op}} \to \text{ADD} \) be a strict 2-functor satisfying additivity (Mack). Consider a 2-cell in \( \mathcal{G} \) with \( i \) and \( j \) faithful as in Notation 3.1.5

\[
\begin{array}{c}
\xymatrix{
L \ar[r]^u & \ar[r]^j & K \\
H \ar[r]^\sim & H \ar[u]^v \\
G \ar[u]^i & & \ar[r]^j &}
\end{array}
\]

and the self-iso-commas (3.1.2) and (3.1.7) for \( i \) and \( j \) respectively:

\[
\begin{array}{c}
\xymatrix{
H \ar[r]^{p_1} & C \ar[r] & H \\
& i \ar[u]^i & & \\
G \ar[u]^{p_2} & & & }
\end{array}
\quad \text{and} \quad
\begin{array}{c}
\xymatrix{
L \ar[r]^{q_1} & C \ar[r] & L \\
& j \ar[u]_j & & \\
K \ar[u]^{q_2} & & & }
\end{array}
\]

The two natural transformations \( \delta_i: p_1^* \Rightarrow p_2^* \) and \( \delta_j: q_1^* \Rightarrow q_2^* \) of Proposition 3.2.1 and the functor \( w = w_{v,u,\gamma}: (j/j) \to (i/i) \) of Proposition 3.1.8 satisfy the following relations. The functors \( w^* p_1^* = q_1^* v^* \) and \( w^* p_2^* = q_2^* v^* \) relate the following
categories: \( \mathcal{M}(H) \to \mathcal{M}(j/j) \) and we can compare the morphisms \( w^* \delta_i \) and \( \delta_j v^* \)

\[
\begin{array}{c}
\begin{tikzpicture}[baseline=(current  bounding  box.center)]
  \node (a) at (0,0) {w^* p_1^*};
  \node (b) at (2,0) {w^* p_2^*};
  \node (c) at (0,-1) {q_1^* v^*};
  \node (d) at (2,-1) {q_2^* v^*};
  \draw[->] (a) -- (b);
  \draw[->] (c) -- (d);
  \node at (1,-0.5) {?};
\end{tikzpicture}
\end{array}
\]

one connected component of \((j/j)\) at a time, by additivity.

(a) Let \( \Delta_j: L \to (j/j) \) be the ‘diagonal’ embedding of Proposition 3.1.3. Then \( \Delta_j^*(w^* \delta_i) = \Delta_j^*(\delta_j v^*) \).

(b) Let \( \text{incl}_D: D \to (j/j) \) be a connected component of \((j/j)\) such that \( w(D) \) is disconnected from \( \Delta_i(H) \), that is, no connected component of \((i/i)\) meets both \( w(D) \) and \( \Delta_i(H) \). Then \( \text{incl}_D^*(w^* \delta_i) = \text{incl}_D^*(\delta_j v^*) \) as well.

(c) If the square (3.2.4) is partial Mackey (Definition 3.1.12) then \( w^* \delta_i = \delta_j v^* \).

**Proof.** Recall from Proposition 3.1.8 that \( p_1 w = v q_1 \) and \( p_2 w = v q_2 \) and therefore the above statement makes sense. The target category, \( \mathcal{M}(j/j) \), decomposes as a product over the connected components of \((j/j)\). The latter components are of two sorts, those meeting the image of \( \Delta_j: L \to (j/j) \), discussed in (a), and those \( D \subset (j/j) \) which do not meet the image of \( \Delta_j \). For (a), applying \( \Delta_j^*: \mathcal{M}(j/j) \to \mathcal{M}(L) \), our two morphisms become the two morphisms in the third square from the top in the following diagram, which we want to show is commutative

\[
\begin{array}{c}
\begin{tikzpicture}[baseline=(current  bounding  box.center)]
  \node (a) at (0,0) {v^*};
  \node (b) at (2,0) {v^*};
  \node (c) at (0,-1) {v^* \Delta_j p_1^*};
  \node (d) at (2,-1) {v^* \Delta_j p_2^*};
  \node (e) at (0,-2) {\Delta_j^* w^* p_1^*};
  \node (f) at (2,-2) {\Delta_j^* w^* p_2^*};
  \node (g) at (0,-3) {\Delta_j^* q_1^* v^*};
  \node (h) at (2,-3) {\Delta_j^* q_2^* v^*};
  \draw[->] (a) -- (b);
  \draw[->] (a) -- (c);
  \draw[->] (a) -- (e);
  \draw[->] (a) -- (g);
  \draw[->] (b) -- (d);
  \draw[->] (b) -- (f);
  \draw[->] (b) -- (h);
  \draw[->] (c) -- (e);
  \draw[->] (c) -- (g);
  \draw[->] (d) -- (f);
  \draw[->] (d) -- (h);
\end{tikzpicture}
\end{array}
\]

The ‘outer’ square clearly commutes. The bottom square commutes by \( q_1 \Delta_j = \text{Id} = q_2 \Delta_j \) and the characterization of \( \delta_j \) on the components corresponding to \( \Delta_j \) given in Proposition 3.2.1 (1) for the faithful functor \( j \) (instead of \( i \)). The second square from the top commutes by \( w \Delta_j = \Delta_j v \), see (3.1.11). The top square commutes by \( p_1 \Delta_i = \text{Id} = p_2 \Delta_i \) and the characterization of \( \delta_i \) on the components corresponding to \( \Delta_i \) given in Proposition 3.2.1 (1) for \( i \). So the third square must commute as well, hence (a).

A connected components \( D \subset (j/j) \) as in (b) is necessarily disjoint from \( \Delta_j(L) \) for \( w \Delta_j = \Delta_j v \) and we assume \( w(D) \) disjoint from \( \Delta_i(H) \). So we can apply Proposition 3.2.1 (2) for \( \delta_i \) and for \( \delta_j \) to see that the restriction of both \( w^* \delta_i \) and \( \delta_j v^* \) are zero. Hence they agree there as well.

For (c) the assumption that we start with a partial Mackey square and Proposition 3.1.16 tell us that every connected component \( D \subset (j/j) \) which is disjoint from \( \Delta_j(L) \) satisfies the hypothesis of (b). So combining (a) and (b) we see that all components of \( w^* \delta_i \) and \( \delta_j v^* \) coincide, hence the two morphisms are equal. \( \Box \)
3.2.5. Remark. The 2-functors $\mathcal{M} : \mathbb{G}^{\text{op}} \rightarrow \text{ADD}$ which appeared in this section were only assumed to satisfy additivity. We did not use induction or coinduction, and \textit{a fortiori} we did not invoke base-change formulas. This will change in the next section.

3.3. The canonical morphism $\Theta$ from left to right adjoint

In this section, we discuss the fundamental connection between the left and the right adjoint of restriction in the presence of additivity and of BC-formulas on both sides, without assuming ambidexterity. The main result, Theorem 3.3.19, sets the stage for our Rectification Theorem 3.4.3 and for Theorem 4.1.1 where we show that every additive derivator yields a Mackey 2-functor.

Let us begin with some easy restrictions.

3.3.1. Remark. Let $\mathcal{M} : \mathbb{G}^{\text{op}} \rightarrow \text{ADD}$ be a strict 2-functor which satisfies additivity (Mack 1) and existence of induction and coinduction (Mack 2).

Additivity allows us to reduce choices of units-counits to the case of connected groupoids. Indeed, suppose we have chosen the units and counits for the adjunctions $i_1 \dashv i_1^* \dashv i_1_*$ whenever $i : H \rightarrow G$ is faithful and $H$ and $G$ are connected, then for $i = i_1 \sqcup i_2 : H_1 \sqcup H_2 \rightarrow G$, under the identification $\mathcal{M}(H_1 \sqcup H_2) \cong \mathcal{M}(H_1) \oplus \mathcal{M}(H_2)$, we can set

$$(i_1 \sqcup i_1)_! = ((i_1)_! \circ (i_2)_!) \quad \text{and} \quad (i_1 \sqcup i_1)_* = ((i_1)_* \circ (i_2)_*)$$

with the obvious ‘diagonal’ units and counits as explained in Remark A.6.8. In other words, we can easily arrange Additivity of adjoints as in (Mack 5) of Theorem 1.3.1 (without assuming necessarily $i_! \cong i_*$, just one side at a time).

Similarly, for every $i$ (between connected groupoids) such that $i^*$ is an equivalence, we can choose $i_! = i_*$ to be any inverse equivalence $(i^*)^{-1}$ and the units and counits to be the chosen isomorphisms $(i^*)^{-1} i_* \cong \text{Id}$, $\text{Id} \cong (i^*)^{-1} i_*$ and their inverses. When $i$ is an identity, we can even pick $i_! = i_* = \text{Id}$ and all units identities. Combined with (Mack 5) for non-connected $i$, we can assume without loss of generality that (Mack 6) holds true.

So the first two rectifications of Theorem 1.3.1 are easy to obtain.

3.3.2. Convention. When using explicit units and counits for $i_! \dashv i^* \dashv i_*$ we tacitly assume that they satisfy (Mack 5) and (Mack 6).

So, let us gather all hypotheses in one place:

3.3.3. Hypotheses. Let $\mathcal{M} : \mathbb{G}^{\text{op}} \rightarrow \text{ADD}$ be a strict 2-functor satisfying additivity (Mack 1), existence of adjoints on both sides (Mack 2) for restriction along faithful morphisms and the BC-formulas on both sides (Mack 3). We apply Convention 3.3.2.

3.3.4. Theorem. Let $\mathcal{M} : \mathbb{G}^{\text{op}} \rightarrow \text{ADD}$ satisfy all the properties of a Mackey 2-functor, except perhaps ambidexterity, as in Hypotheses 3.3.3. Let $i : H \rightarrow G$ be
faithful and consider the following self-iso-comma as in Notation 3.1.1:

\[ (i/i) \]

(3.3.5)

Then, there exists a unique morphism

\[ \Theta_i : i \Rightarrow i^* \]

such that the following morphism \( p_1^* \Rightarrow p_2^* \)

(3.3.6)

\[ \delta_i : p_1^* \Rightarrow p_2^* \]

is the canonical morphism \( \delta_i : p_1^* \Rightarrow p_2^* \) of Proposition 3.2.1.

The idea of the proof is to show that the construction \( \theta \mapsto \varepsilon \circ (\lambda^* \theta) \circ \eta \) of the statement is an isomorphism between suitable sets of natural transformations, so that we can define \( \Theta_i \) by deciding its image under this construction to be whatever we wish, for instance our dear \( \delta_i \). We need some preparation.

3.3.7. Notation. For the sake of completeness, we recall the formulas for the mates. Given a 2-cell

\[ \begin{array}{c}
\begin{array}{c}
L \\
\sim \end{array}
\end{array} \xymatrix{H \ar[r]^{i} & K \ar[l]_{j} } \]

iso-comma or not, but with \( i \) and \( j \) faithful, we have

\[ \gamma_! = \left( j_i^* v^* \xRightarrow{\eta} j_i^* i^* i_! \xRightarrow{\sim} j_i^* j_* u^* i_! \xRightarrow{\varepsilon} u^* i_! \right) \]

\[ (\gamma^{-1})_* = \left( u^* i_* \xRightarrow{\eta} j_* j_* u^* i_* \xRightarrow{\sim} j_* v^* i_* \xRightarrow{\varepsilon} j_* v_* \right). \]

Base-change (Mack 3) tells us that these are isomorphisms when \( (3.3.8) \) is an iso-comma. If \( u \) and \( v \) are also faithful, as will happen for self-iso-commas, we have by symmetry (Example 2.1.4):

(3.3.9) \( (\gamma^{-1})_! : v_! j_* \Rightarrow i_* u! \) and \( \gamma_* : i_* u_* \Rightarrow v_* j_* \).
In the case of the self-iso-commas (3.1.2) and (3.1.7), these base-change isomorphisms specialize to the following isomorphisms:

\begin{align}
(3.3.10) & \quad \lambda_!: p_2p_1^* \xrightarrow{\sim} i^*i! & \text{and} & \quad \lambda_*: i^*i_* \xrightarrow{\sim} p_1p_2^* \\
(3.3.11) & \quad \rho_!: q_2q_1^* \xrightarrow{\sim} j^*j! & \text{and} & \quad \rho_*: j^*j_* \xrightarrow{\sim} q_1q_2^*.
\end{align}

The critical point is the following result:

**3.3.12. Proposition.** Consider a faithful $i: H \to G$ and the corresponding self-iso-comma square as in (3.1.2). Then for any category $C$ and any pair of parallel functors $F,F': C \to \mathcal{M}(H)$, we have a natural isomorphism

$$\nabla_i: [i_1F, i_* F'] \xrightarrow{\sim} [p_1^*F, p_2^* F']$$

where we denote $[-,-]$ the sets of natural transformations (in $\mathcal{M}(G)^C$ and $\mathcal{M}(i/i)^C$ respectively). More precisely, using the isomorphisms $\lambda!: p_2p_1^* \xrightarrow{\sim} i^*i!$ and $\lambda_*: i^*i_* \xrightarrow{\sim} p_1p_2^*$ of (3.3.10), the following diagram commutes and defines $\nabla_i$:

\begin{align}
(3.3.13) & \quad [F, i^*i_* F'] \\ & \cong \cong \\ & \cong \cong \\ & \cong \cong \\ & \cong \cong \\ & \cong \cong 
\end{align}

Explicitly, the isomorphism $\nabla_i$ maps a morphism $(i_1F \xrightarrow{\theta} i_* F')$ to

\begin{align}
(3.3.14) & \quad \left( p_1^*F \xrightarrow{\eta_{i^*i_*}} (p_1^*i^*)(i_1F) \xrightarrow{\lambda_*\theta} (p_2^*i^*)(i_*F') \xrightarrow{\varepsilon_{i^*i_*}} p_2^*F' \right).
\end{align}

**Proof.** It suffices to unpack $\lambda_i$ and $\lambda_*$. The left (respectively right) composite in (3.3.13) reduces to (3.3.14) thanks to naturality and the unit-counit relation for $p_1^* \dashv p_1$ (respectively for $p_2^* \dashv p_2$). For instance, given a natural transformation $\theta: i_1F \Rightarrow i_* F'$, the left composite yields

\[ \begin{array}{c}
\begin{array}{ccc}
F & \xrightarrow{\theta} & F' \\
i_1 & \Rightarrow & i_* \\
i & \Rightarrow & i^*
\end{array}
\end{array} \]
With notation as above, we have a natural isomorphism

\[ 3.3.16 \text{ Corollary.} \]

For the isomorphism

\[ \text{If } \theta \text{ is the unique morphism} \]

\[ \text{plug } F = F' = \text{Id}_{M(H)} \text{ in Proposition 3.3.12.} \]

\[ \text{Proof.} \]

\[ \text{Proof of Theorem 3.3.4.} \]

By Corollary 3.3.16 we can uniquely define a morphism \( \Theta_i: i_1 \Rightarrow i_\ast \) by deciding the corresponding \( \nabla_i(\Theta_i) = \varepsilon \circ (\lambda^* \Theta_i) \circ \eta \) from \( p_1^* \) to \( p_2^* \). We define \( \Theta_i \) to be the one corresponding to \( \delta_i: p_1^* \Rightarrow p_2^* \) as in Proposition 3.2.1.

\[ \text{3.3.18. Remark.} \]

Unpacking the above construction, \( \Theta_i \) is the unique morphism \( i_1 \Rightarrow i_\ast \) such that the following morphism

\[ \left( p_1^* \xrightarrow{\eta} (p_1^* i^*)(i_1) \xrightarrow{\lambda^* \Theta_i} (p_2^* i^*)(i_\ast) \xrightarrow{\varepsilon} p_2^* \right) \]

of functors \( M(H) \rightarrow M(i/i) \cong M(H) \times \prod_{C \cap \Delta_i(H) = \emptyset} M(C) \) is the identity on the component \( M(H) \rightarrow M(H) \) and zero on the other components \( M(H) \rightarrow M(C) \) for \( C \subset (i/i) \) disjoint from the image of \( \Delta_i: H \rightarrow (i/i) \).

We are now ready for the main result of this section, which describes the fundamental properties of the comparison morphism \( \Theta_i: i_1 \Rightarrow i_\ast \).

\[ \text{3.3.19. Theorem.} \]

Let \( \mathcal{M}: G^{op} \rightarrow \text{ADD} \) satisfying all properties of a Mackey 2-functor, except perhaps ambidexterity, as in Hypotheses 3.3.3. Then the morphisms \( \Theta_i: i_1 \Rightarrow i_\ast \) of Theorem 3.3.4 satisfy the following:

(a) If \( H = H_1 \sqcup H_2 \) is disconnected and \( i = (i_1, i_2): H_1 \sqcup H_2 \rightarrow G \) then, under the canonical identifications \( i_1 \cong i_{11} \oplus i_{12} \) and \( i_\ast \cong i_{1\ast} \oplus i_{2\ast} \) (Convention 3.3.2), we have \( \Theta_i = \Theta_{i_1} \oplus \Theta_{i_2} \) diagonally.
(b) If $i^* : \mathcal{M}(G) \to \mathcal{M}(H)$ is an equivalence (for instance if $i : H \xrightarrow{\sim} G$ is an equivalence in $G$) then $\Theta_i$ is an isomorphism. In the special case of $i = \text{Id}$ then $\Theta_i$ is the identity.

(c) For every partial Mackey square (Definition 3.1.12)

\[
\begin{array}{ccc}
L & \xrightarrow{v} & \gamma \xrightarrow{\gamma^{-1}} K \\
\downarrow{i'} & & \downarrow{j}
\end{array}
\]

with $i$ and $j$ faithful, we have a commutative diagram

\[
\begin{array}{ccc}
u^* i & \xrightarrow{u^* \Theta_i} & u^* i_* \\
\downarrow{\gamma} & & \downarrow{(\gamma^{-1})_*} \\
\Theta_j v^* & \xrightarrow{j_* v^*} & j_* v^* \\
\end{array}
\]

In particular, the above holds if (3.3.20) is a Mackey square (Definition 2.2.1) or, even stronger, an iso-comma square. In those cases, the vertical morphisms $\gamma_!$ and $(\gamma^{-1})_*$ in (3.3.21) are isomorphisms by base-change (Mack 3).

(d) For every 2-cell $\alpha : i \xRightarrow{\sim} i'$ between faithful functors $i,i' : H \rightarrow G$, the following diagram commutes:

\[
\begin{array}{ccc}
i_! & \xrightarrow{\Theta_i} & i_* \\
\downarrow{\alpha} & & \downarrow{\alpha_*} \\
i'_! & \xrightarrow{\Theta_{i'}} & i'_* \\
\end{array}
\]

(e) For every composable faithful $K \xrightarrow{j} H \xrightarrow{i} G$ the following diagram commutes

\[
\begin{array}{ccc}
(ij)_! & \xrightarrow{(ij)_*} & (ij)_* \\
\downarrow{\Theta_{ij}} & & \downarrow{\Theta_{ij}} \\
(i)_! \Theta_j & = & i_* j_* \\
\end{array}
\]

where the vertical identifications $(ij)_! \cong i_! j_!$ and $(ij)_* \cong i_* j_*$ are the canonical isomorphisms between compositions of adjoints.

(f) For every faithful $i : H \rightarrow G$ the following composite is the identity:

\[
\begin{array}{ccc}
\text{Id} & \xrightarrow{\eta} & i^* i! \\
\downarrow{i^* \Theta_i} & & \downarrow{i^* \Theta_i} \\
i^* i_* & \xrightarrow{\epsilon} & i^* i_* \\
\end{array}
\]

We need again some preparation. Specifically we want to show that the isomorphism $\nabla_i : [i_!, i_*] \xrightarrow{\sim} [p_1^*, p_2^*]$ of Corollary 3.3.16 behaves nicely in $i$, very much in the spirit of what we did in Section 3.1.
3.3.24. Notation. Consider a 2-cell as usual (not necessarily partial Mackey)

\[ \begin{array}{c}
  v \downarrow \\
  L \downarrow j \quad \\
  H \Rightarrow K \\
  i \downarrow \\
  j \downarrow u \\
  G
\end{array} \]

and the self-iso-commas (3.1.2) and (3.1.7) for \( i \) and \( j \), together with the comparison functor \( w = w_{v,u,\gamma} : (j/j) \to (i/i) \) of Proposition 3.1.8:

\[ \begin{array}{c}
  q_2 \downarrow \\
  L \downarrow \rho \\
  j \downarrow \\
  K \Rightarrow H \\
  u \downarrow \\
  i \downarrow \lambda \\
  G
\end{array} \]

3.3.25. Proposition. Under Hypotheses 3.3.3 and the above Notation 3.3.24, the two isomorphisms \( \nabla_i \) and \( \nabla_j \) of Corollary 3.3.16 for \( i \) and \( j \) are compatible; namely for every parallel functors \( F, F' : C \to \mathcal{M}(H) \) (e.g. \( F = F' = \text{Id} \)) the following diagram of abelian groups commutes:

\[ (3.3.26) \begin{array}{ccc}
  [u^*iF, u^* i_* F'] & \overset{\nabla_i}{\Rightarrow} & [p_1^* F, p_2^* F'] \\
  v^* \downarrow & \cong & \downarrow \omega^{-} \\
  w \downarrow & \nabla_j & \\
  [j_* v^* F, j_* v^* F'] & \overset{\nabla_j}{\Rightarrow} & [q_1^* v^* F, q_2^* v^* F']
\end{array} \]

where \([-,-]\) stands everywhere for the suitable set of natural transformations.

PROOF. For completeness, let us make the morphism \( \nabla_j : [j_* v^* F, j_* v^* F'] \to [q_1^* v^* F, q_2^* v^* F'] \) of (3.3.13) more explicit. It uses (3.3.14) with \( v^* F \) and \( v^* F' \) (instead of \( F \) and \( F' \)) and with the faithful functor \( j \) (instead of \( i \)), and therefore with the self-iso-comma (3.1.7) instead of (3.1.2). Unpacking (3.3.14) gives us

\[ (j_* v^* F \xrightarrow{\omega} j_* v^* F) \xrightarrow{\nabla_j} (q_1^* v^* F \xrightarrow{\eta} j_* v^* F') \xrightarrow{\theta^* \omega} (q_2^* j_* j^*) (j_* v^* F') \xrightarrow{\varepsilon} q_2^* v^* F'). \]

Now, by starting with a \( \theta \in [iF, i_* F'] \) and successively pasting on 2-cells according to the definitions, we see that the down-then-right route in (3.3.26) produces the cell on the left-hand side below, while the right-then-down route in (3.3.26)
yields the one on the right-hand side:

We see that they are both equal to the middle one. Indeed, the left-hand equality holds by the unit-counit relations for $j_1 \vdash j^*$ and for $j^* \vdash j_*$. The second equality is direct from (3.1.10) by applying $(-)^* = \mathcal{M}(-)$, which is covariant on 2-cells. □

**Proof of Theorem 3.3.19.** We leave the isomorphism and additivity statements (a) and (b) to the reader, using Convention 3.3.2. We focus on the critical property (c), namely we want to show that the following diagram commutes:

\[(3.3.27)\]

when the initial 2-cell $\gamma: iv \Rightarrow uj$ is partial Mackey. For this, let us follow $\Theta_i \in [i_1, i_*]$ and $\Theta_j \in [j_1, j_*]$ in the following commutative diagram:

\[
\begin{array}{c}
\Theta_i \in [i_1, i_*] & \cong (3.3.17) & [p_1^*, p_2^*] \ni \delta_i \\
\Theta_j \in [j_1, j_*] & \cong (3.3.17) & [q_1^*, q_2^*] \ni \delta_j \\
\end{array}
\]

Commutativity of the top square comes from Proposition 3.3.25; that of the bottom is straightforward. The claim of the statement is that $\Theta_i$ and $\Theta_j$ map to one another under the left-hand vertical morphisms, i.e. that they have the same image in the middle, say, in $[j_1v^*, j_*v^*]$, which is still isomorphic under $\nabla_j$ to the right-hand $[q_1^*, q_2^*v^*]$. By construction in Theorem 3.3.4, under $\nabla_i$ and $\nabla_j$, our
morphisms $\Theta_i$ and $\Theta_j$ correspond, on the right-hand side of the above diagram, to $\delta_i$ and $\delta_j$ respectively. Therefore, it suffices to observe that $\delta_j u^* = w^* \delta_i$ as we proved in Proposition 3.2.3(c). This is the place where we use that (3.3.20) is partial Mackey, not just any square. This finishes the proof of the crucial part (c) of Theorem 3.3.19.

Part (d) follows from (c) applied to the (partial) Mackey square of Example 3.1.13, which gives the commutativity of

$$\begin{array}{ccc}
i_1 & \xrightarrow{\alpha} & i_s \\
\uparrow & & \uparrow \\
\alpha' & \xrightarrow{\Theta_j} & (\alpha^{-1})_*
\end{array}$$

In this case, $\alpha_1$ and $(\alpha^{-1})_*$ are isomorphisms by base change (since the square in Example 3.1.13 is actually a Mackey square). By compatibility of mates with pasting, we have $(\alpha^{-1})_* = (\alpha_*)^{-1}$ which gives the commutative square (3.3.22) of the statement. (See Remark A.2.6 if necessary.)

Similarly, part (f) follows from (c) applied to the partial Mackey square of Example 3.1.14 and the fact that $\id: \Id \Rightarrow i^* i_1$ and $\id_*: i^* i_* \Rightarrow \Id$ are nothing but the unit of $i \dashv i^*$ and the counit of $i^* \dashv i_*$ respectively. See Example A.2.5.

Finally, for part (e), consider two composable morphisms $K \xrightarrow{j} H \xrightarrow{i} G$ in $\mathcal{G}$ and recall the discussion in Section 3.1. In particular, consider as in Notation 3.1.17 the self-iso-commas

$$\begin{array}{ccc}
H & \xrightarrow{p_1} & (i/i) \\
\downarrow & \Rightarrow & \downarrow \\
G & \xrightarrow{i} & i
\end{array} \quad \begin{array}{ccc}
K & \xrightarrow{r_1} & (ij/ij) \\
\downarrow & \Rightarrow & \downarrow \\
G & \xrightarrow{ij} & i
\end{array} \quad \begin{array}{ccc}
K & \xrightarrow{q_1} & (j/j) \\
\downarrow & \Rightarrow & \downarrow \\
H & \xrightarrow{j} & j
\end{array}$$

and the two comparison functors $w'' = w_{\Id_{K^j}, \Id}$ and $w' = w_{j, \Id_G, \Id}$

$$(i/i) \xleftarrow{w'} (ij/ij) \xleftrightarrow{w''} (j/j)$$

induced by Proposition 3.1.8 applied to the obvious squares, see (3.1.18). To prove $\Theta_{ij} = \Theta_i \Theta_j$, we use the definition of $\Theta_{ij}$ from Theorem 3.3.4, namely we trace $\Theta_i \Theta_j$ along the morphisms

$$\Theta_i \Theta_j \in [i j, i*, j_*] \cong [(ij)_!, (ij)_*] \xrightarrow{\nabla_{ij}} [r_1^*, r_2^*] \xrightarrow{\incl^*_C} [\incl^*_C r_1^*, \incl^*_C r_2^*]$$

associated to each connected component $\incl_C: C \hookrightarrow (ij/ij)$ of $(ij/ij)$. Recall from Proposition 3.1.19 that these connected components come in three distinct sorts; the proof will be slightly different in each case. We need to show that the image of $\Theta_i \Theta_j$ under the above map is zero when $C \subset (ij/ij)$ is disjoint from the diagonal $\Delta_{ij}(K)$, which are cases (2) and (3) of Proposition 3.1.19; and we need to show that the image of $\Theta_i \Theta_j$ on the diagonal components is the identity, which by Proposition 3.1.3 amounts to show that its image under

$$(3.3.28) \quad \Theta_i \Theta_j \in [i j, i*, j_*] \cong [(ij)_!, (ij)_*] \xrightarrow{\nabla_{ij}} [r_1^*, r_2^*] \xrightarrow{\Delta_{ij}^*} [\Id_{\Id_K}, \Id_{\Id_K}]$$
3.3. THE CANONICAL MORPHISM Θ FROM LEFT TO RIGHT ADJUNCT

is the identity (of $\text{Id}_{\mathcal{M}(K)}$). These are the components of type (1) in Proposition 3.1.19.

Let us apply Proposition 3.3.25 to the first square of (3.18), namely

$$(3.3.29)$$

whose associated $w_{\text{Id},i,i}: (j/j) \rightarrow (ij/ij)$ is our $w''$ above. The commutative diagram (3.3.26) for $F = F' = \text{Id}$ becomes here

$$
\begin{array}{ccc}
(ij)_* & \xrightarrow{\nabla_{ij}} & [r^*_1, r^*_2] \\
\downarrow^{i^*} & & \downarrow^{w^*} \\
[i^*(ij)_*, i^*(ij)_*] & & [w^* r^*_1, w^* r^*_2] \\
\downarrow^{[\text{id},(\text{id}^{-1})_*]} & & \downarrow^{(r_1w = q_1, r_2w = q_2)} \\
[j_*, j_2] & \xrightarrow{\nabla_j} & [q^*_1, q^*_2].
\end{array}
$$

The mates $\text{id}_*$ and $(\text{id}^{-1})_*$ on the left-hand side are the ones associated to $(3.3.29)$. We now verify that the image of $\Theta_i \Theta_j$ under the above left-hand vertical composite (after the identifications $i, j \cong (ij)$; and $i_*, j_* \cong (ij)_*$) is precisely $\Theta_j$:

$$
\begin{array}{c}
\Theta_i \Theta_j \\
\downarrow \cong \\
(ij)_* \xrightarrow{\nabla_{ij}} [i^*(ij)_*, (ij)_*] \\
\downarrow^{i^*} \\
[i^*(ij)_*, i^*(ij)_*] \xrightarrow{\nabla_j} [j_*, j_*] \\
\downarrow^{[\text{id},(\text{id}^{-1})_*]} \\
\Theta_j \cong [j_*, j_*]
\end{array}
$$

Indeed, the image of $\Theta_i \Theta_j$ is defined by the following pasting:
To see why this reduces to $\Theta_j$, we first use that the canonical isomorphisms $(ij)_! \cong i_{ij}$ and $(ij)^* \cong i^*_j$ identify the units and counits of the adjunctions. Then we apply the triangle identities and conclude with the already proved property (f) for $i$.

The commutative diagram (3.3.30) and the above verification allow us to compute the projections of $\nabla_{ij}(\Theta_i\Theta_j)$ along $\text{incl}_C^*$ for two-thirds of the connected components $C \subset (ij/ij)$, namely those of type (1) and (3). First for the diagonal ones, following (3.3.28), we obtain the commutative diagram

$$
\begin{array}{c}
\Theta_i\Theta_j \in [i/j, i*_j] \\
\Theta_j \in [j, j^*] \\
\n\end{array}
$$

$$
\begin{array}{c}
\approx \quad [((ij)_!, (ij)^*)] \\

\end{array}
$$

$$
\begin{array}{c}
\nabla_{ij} \quad [r^*_1, r^*_2] \quad \Delta_{ij}^* \quad [\text{Id}_{\mathcal{M}(K)}, \text{Id}_{\mathcal{M}(K)}] \\
\n\end{array}
$$

The triangle to the right commutes because $w'' \Delta_j = \Delta_{ij}$, see (3.1.20). We then use that $\Delta_{ij}^* \nabla_{ij}(\Theta_j)$ is the identity by definition (apply Corollary 3.3.16, Theorem 3.3.4 and Proposition 3.2.1 with $j$ instead of $i$) to conclude in this case.

Consider now a connected component $C \subset (ij/ij)$ of type (3) in Proposition 3.1.19, namely such $C$ is disjoint from $\Delta_{ij}(K)$ and such that there exists a commutative diagram

$$
\begin{array}{c}
D \xrightarrow{\text{incl}_D} (j/j) \\
\approx \\
C \xrightarrow{\text{incl}_C} (ij/ij) \\
\end{array}
$$

for a connected component $D \subset (j/j)$ disjoint from $\Delta_j(K)$. We compute similarly as above

$$
\begin{array}{c}
\Theta_i\Theta_j \in [i/j, i*_j] \\
\Theta_j \in [j, j^*] \\
\n\end{array}
$$

$$
\begin{array}{c}
\approx \quad [((ij)_!, (ij)^*)] \\

\end{array}
$$

$$
\begin{array}{c}
\nabla_{ij} \quad [r^*_1, r^*_2] \quad \Delta_{ij}^* \quad [\text{incl}_D^*] \\
\n\end{array}
$$

Since $D$ is disjoint from $\Delta_j(K)$, we have by definition of $\Theta_j$ (Theorem 3.3.4 etc.) that $\text{incl}_D^* \nabla_{ij}(\Theta_j) = 0$ and therefore $\text{incl}_C^* \nabla_{ij}(\Theta_i\Theta_j) = 0$; this finishes case (3).

We are left to prove the same relation $\text{incl}_C^* \nabla_{ij}(\Theta_i\Theta_j) = 0$ but now for the connected components $C \subset (ij/ij)$ of type (2), i.e. such that $w'(C) \subset (i/i)$ is disjoint from $\Delta_i(H)$. In that case, we want to use that $\Theta_i$ vanishes on a suitable component of $(i/i)$. This requires another little preparation. For this, consider the second square of Equation (3.1.18), namely

$$
\begin{array}{c}
H \xrightarrow{\sim} G \\
\xrightarrow{id} \\
\end{array}
$$

(3.3.31)
to which we also apply Proposition 3.3.25. In this case, the commutative diagram (3.3.26) for \( F = j_i \) and \( F' = j_s \) provides the following commutative diagram:

\[
\begin{array}{c}
\begin{tikzcd}
\{i, j_i; i_s, j_s\} \arrow{rr}{\nabla_i} \arrow{d}{[\text{id}, (\text{id}^{-1})_s]} \& \& \{p_1^* j_i, p_2^* j_s\} \\
\{ijj, j^* j_{ij}, (ij)_s j^* j_{is}\} \arrow{r}{w^*} & \{w^* p_1^* j_i, w^* p_2^* j_s\} \arrow{d}{(p_1 w = j r_1, p_2 w = j r_2)}
\end{tikzcd}
\end{array}
\]

The mates \( \text{id}_i \) and \( (\text{id}^{-1})_s \) on the left-hand column are the ones associated to \( \text{id}_{ij} \) in (3.3.31). Note that \( j_i \) and \( j_s \) are not touched by the left bottom morphism, since they appear as \( F = j_i \) and \( F' = j_s \) in (3.3.26). Similarly, the bottom isomorphism is “\( \nabla_{ij} \) on \( F = j^* j_i \) and \( F' = j^* j_s \).” Finally, the functor \( \nu_{ij, \text{id}, \text{id}^*} : (ij/ij) \to (i/i) \) is here our \( \nu \), hence the \( \nu \) on the right-hand column. We paste to the above diagram the obvious diagram obtained by collapsing \( j^* j_i \) and \( j^* j_s \) thanks to the unit \( \eta : \text{Id} \Rightarrow j^* j_i \) and counit \( \varepsilon : j^* j_s \Rightarrow \text{Id} \) of \( i \vdash i^* \) and \( i^* \vdash i \) respectively. This provides the following commutative diagram:

\[
\begin{array}{c}
\begin{tikzcd}
\{i, j_i; i_s, j_s\} \arrow{rr}{\nabla_i} \arrow{d}{[\text{id}, (\text{id}^{-1})_s]} \& \& \{p_1^* j_i, p_2^* j_s\} \\
\{ijj, j^* j_{ij}, (ij)_s j^* j_{is}\} \arrow{r}{w^*} & \{w^* p_1^* j_i, w^* p_2^* j_s\} \arrow{d}{(p_1 w = j r_1, p_2 w = j r_2)}
\end{tikzcd}
\end{array}
\]

Let us verify that the left vertical composite is equal to the map induced by the canonical isomorphisms \( i_{ij} \cong (ij)_i \) and \( i_{j*} \cong (ij)_s \). Equivalently, we can check that by precomposing the vertical composite with the inverse of said induced map we get the identity; indeed, this sends every \( \alpha \in [(ij)_i, (ij)_s] \) to

\[
\begin{array}{c}
\begin{tikzcd}
\eta \rightarrow \alpha \rightarrow \xi \\
\eta \rightarrow \alpha \rightarrow \xi
\end{tikzcd}
\end{array}
\]

Now we can compute \( \text{incl}_C^* \nabla_{ij}(\Theta_i \Theta_j) \) by following \( \Theta_i \Theta_j \) from the upper-left corner, down to the lower-right one and then applying \( \text{incl}_C^* \). Let us do that. We obtain
the following commutative diagram

\[
\begin{array}{ccc}
\Theta_i \Theta_j & \in & [i_1 j_1, i_2 j_2] \\
\downarrow \cong & & \downarrow \cong \\
\nabla_i & \cong & [p_{i_1}^1 j_1, p_{i_2}^2 j_2] \\
\downarrow w'^* & & \downarrow (w'|C)^* \\
[r_{i_1}^1 j_1 ^*, r_{i_2}^2 j_2 ^*] & \cong & [\eta, \epsilon] \\
\downarrow [\eta, \epsilon] & & \downarrow [\eta, \epsilon] \\
\nabla_{ij} & \cong & [r_{i_1}^1, r_{i_2}^2] \\
\downarrow \cong & & \downarrow \cong \\
[i(j), (i j)_s] & \Rightarrow & [(i j)_1, (i j)_s] \\
\end{array}
\]

in which the left-hand half is the fruit of the above discussion whereas the right-hand part is simply obtained from the commutative diagram

\[
\begin{array}{ccc}
C & \xrightarrow{\text{incl}_C} & (ij/ij) \\
\downarrow w'|C & & \downarrow w' \\
D' & \xrightarrow{\text{incl}_{D'}} & (i/i) \\
\end{array}
\]

coming from the fact that \( C \subset (ij/ij) \) is of type (2), that is, so that the component \( D' \) of the image \( w'(C) \) is disjoint from \( \Delta_i(H) \). This property guarantees that \( \text{incl}_{D'} \circ \nabla_i(\Theta_i) = 0 \) by definition of \( \Theta_i \) (Theorem 3.3.4). Following \( \Theta_i \Theta_j \) in the above diagram, along the top horizontal arrow, we see that its image in the upper-right corner is simply \( \text{incl}_{D'} \circ \nabla_i(\Theta_i) \circ \Theta_j \) which is zero by what we just discussed.

To summarize, the image of \( \Theta_i \Theta_j \in [i_1 j_1, i_2 j_2] \) in the canonically isomorphic \([[(ij)_1, (ij)_s]]\) has the property that its image under \( \nabla_{ij} \) projects to the identity on the diagonal components of \((ij/ij)\) and to zero on all other components (if for two separate sets of reasons). So \( \nabla_{ij}(\Theta_i \Theta_j) = \delta_{ij} = \nabla_{ij}(\Theta_{ij}) \) and therefore \( \Theta_i \Theta_j = \Theta_{ij} \). This concludes the proof of Theorem 3.3.19. \( \square \)

3.3.32. Remark. It is perhaps surprising to some readers that we could prove commutativity of (3.3.21) independently of the choice of the units and counits for \( i_1 \vdash i^*_1 \vdash i_2 \) and \( j_1 \vdash j^*_1 \vdash j_2 \). However, the same units and counits appear in the construction of \( \Theta_i \) and \( \Theta_j \) and in the construction of \( \gamma_i \) and \( (\gamma^{-1})_i \). Changing one of these units or counits (up to an automorphism of the corresponding adjoint) would have no impact on the commutativity of (3.3.21), as two occurrences of the automorphism would cancel out.

We conclude this section by explaining how \( \Theta_i : i_1 \Rightarrow i_2 \) is natural in \( \mathcal{M} \).

3.3.33. Proposition. Let \( \mathcal{M}, \mathcal{N} : \mathbb{G}^{op} \rightarrow \text{ADD} \) be two strict 2-functors satisfying all properties of a Mackey 2-functor, except perhaps ambidexterity, as in Hypotheses 3.3.3. Let \( t : \mathcal{M} \rightarrow \mathcal{N} \) be a pseudo-natural transformation, with components \( t_G : \mathcal{M}(G) \rightarrow \mathcal{N}(G) \) for all \( G \in \mathbb{G}_0 \) and \( t_u : u^* t_G \Rightarrow t_H u^* \) for all \( u : H \rightarrow G \) in \( \mathbb{G}_1 \) (see Terminology A.1.14). Let \( i : H \rightarrow G \) be in \( \mathbb{I} \) and write \( \Theta_i^\mathcal{M} : i^\mathcal{M} \Rightarrow i^\mathcal{M} \) and \( \Theta_i^\mathcal{N} : i^\mathcal{N} \Rightarrow i^\mathcal{N} \) for the two natural transformations constructed in Theorem 3.3.4, for \( \mathcal{M} \) and \( \mathcal{N} \) respectively. Then the following square of natural transformations
between functors $\mathcal{M}(H) \to \mathcal{N}(G)$ commutes:

\[
\begin{array}{c}
t_{G}i_{i}^{M} \\
\mapright{(t_{i}^{-1})_{*}} \\
i_{i}^{N}t_{H} \Rightarrow \Theta_{i}^{N}t_{H} \\
\end{array}
\]

\[
\begin{array}{c}
t_{G}i_{i}^{M} \\
\mapright{(t_{i})_{*}} \\
i_{i}^{N}t_{H} \Rightarrow \Theta_{i}^{N}t_{H} \\
\end{array}
\]

**Proof.** By construction of $\Theta_{i}^{N}$, it suffices to verify that the composition around the top $(t_{i})_{*} \circ (t_{G}\Theta_{i}^{M}) \circ (t_{i}^{-1})$ has the defining property of $\Theta_{i}^{N}$, namely that under the isomorphism $\nabla_{i}: [it_{H}, i_{*}t_{H}] \sim \{(p_{1}^{*}t_{H}, p_{2}^{*}t_{H})\}$ of Proposition 3.3.12 (for $F = F' = t_{H}$), our around-the-top composite should map to $\delta_{i}^{N}t_{H}$. We repeat the notation of Theorem 3.3.4, for the reader’s convenience: $p_{1}$ and $p_{2}$ are the two projections $(i/i) \to H$ in the self-comma for $i$, as in (3.1.2), and $\delta_{i}^{N}: p_{1}^{*} = \mathcal{N}(p_{1}) \Rightarrow p_{2}^{*} = \mathcal{N}(p_{2})$ is the distinguished morphism of Proposition 3.2.1 for $\mathcal{N}$. Unsurprisingly, we must first establish the compatibility of $\delta_{i}$ for $\mathcal{M}$ and for $\mathcal{N}$, which is expressed as follows:

**3.3.35. Lemma.** There is a commutative square

\[
\begin{array}{c}
p_{1}t_{H} \\
\mapright{\delta_{i}^{N}t_{H}} \\
p_{2}t_{H} \\
\end{array}
\]

\[
\begin{array}{c}
t_{p_{1}} \simeq \ \\
\mapright{t_{(i/i)}\delta_{i}^{M}} \simeq \\
t_{p_{2}} \ \\
\end{array}
\]

of natural transformations between functors $\mathcal{M}(H) \to \mathcal{N}(i/i)$.

**Proof.** Let $C$ be either of the subgroupoids $\Delta_{i}(H)$ or $C = (i/i) \times \Delta_{i}(H)$ of the comma groupoid $(i/i)$, and let $\text{incl}_{C}: C \to (i/i)$ be the inclusion functor. Recall that $\delta_{i}^{M}$ and $\delta_{i}^{N}$ are characterized in Proposition 3.2.1 by the property that if we apply $\text{incl}_{C}^{*}: \mathcal{M}(i/i) \to \mathcal{M}(C)$ (respectively $\text{incl}_{C}^{*}: \mathcal{N}(i/i) \to \mathcal{N}(C)$) to it, we obtain the identity or zero according as to whether $C = \Delta_{i}(H)$ or $C = (i/i) \times \Delta_{i}(H)$.

Let us apply $\text{incl}_{C}^{*}$ to (3.3.36). The key to showing that it commutes in both cases is to ‘conjugate’ with the components of $t$ at all the relevant 1-cells:

This also makes use of other 2-cell components of $t$ (not depicted above) as well as of its functoriality property (Terminology A.1.14). The details are left as an exercise for the reader, easily done with string diagrams (see Appendix A.3).

Let us now turn to the announced property of the ‘around-the-top’ composition $(t_{i})_{*} \circ (t_{G}\Theta_{i}^{M}) \circ (t_{i}^{-1})$ in (3.3.34). Unpacking the definitions of the mates $(t_{i}^{-1})_{*}$ and $(t_{i})_{*}$, applying $p_{1}^{*}$ and $p_{2}^{*}$ and using $\lambda^{*}: p_{1}^{*}\lambda^{*} = p_{2}^{*}\lambda^{*}$ for $\lambda$ as in (3.1.2), we
need to show the commutativity of the central region (marked (?) of the following diagram:

![Diagram](image-url)

All seven squares commute by naturality (the top one by ‘naturality’ of \( t \), as in Terminology A.1.14, applied to \( \lambda: i/i \Rightarrow ip_2: (i/i) \to G \). The two triangles commute by the unit-counit relation of the adjunctions \( i \dashv i^* \) and \( i^* \dashv i_* \). The bottom curvy area commutes by the compatibility of the \( \delta_i \) as indicated by the reference to (3.3.36). The two ‘shoulders’ (pentagons) commute by the ‘functoriality’ of \( t \) (Terminology A.1.14). Finally, the outer diagram (hexagon) commutes by the construction of \( \Theta_i^M \) as in Theorem 3.4.1, postwhiskered by \( t_{i/i} \). This proves that the central area marked (?) does indeed commute, as announced.

\[ \square \]

3.4. Rectification of Mackey 2-functors

In this section, we want to show that ambidexterity \( i_i \simeq i_* \) can only happen if the preferred \( \Theta_i: i_i \Rightarrow i_* \) of Theorem 3.3.4 is an isomorphism. This then allows us to prove the Rectification Theorem 3.4.3. We begin by isolating an ‘induction on the order of \( G \)’ that reduces the proof of \( \Theta_i: i_i \Rightarrow i_* \) being an isomorphism to the following test: Does \( i^* \Theta_i \) being an isomorphism imply that \( \Theta_i \) is an isomorphism?

3.4.1. Proposition. Let \( \mathcal{M}: G^{op} \to \text{ADD} \) satisfy all properties of a Mackey 2-functor except perhaps ambidexterity, as in Hypotheses 3.3.3. Consider \( \Theta_i: i_i \Rightarrow i_* \) as in Theorem 3.3.4. Suppose \( \mathcal{M} \) further satisfies the following property:

(A) If \( i: H \to G \) is faithful, with \( H \) and \( G \) connected and non-empty, and if \( i^* \Theta_i \) is an isomorphism, then \( \Theta_i \) is an isomorphism.

Then \( \Theta_i \) is an isomorphism for all faithful \( i: H \to G \).

**Proof.** As said, we proceed by induction on the ‘order’ of \( G \), that is, the maximum of the orders of the finite groups \( \text{Aut}_G(x) \) over all \( x \in G \). Note that \( i_i = 0 = i_* \) when \( H \) is empty, in which case the result is trivial. By Theorem 3.3.19(b) we
know that \(\Theta_i\) is an isomorphism whenever \(i\) is an equivalence. In particular, \(\Theta_i\) is an isomorphism when \(G\) is trivial. So we can assume the result known for every \(i' : H' \to G'\) with \(G'\) of order less than that of \(G\). By additivity, Theorem 3.3.19(a), we can also assume that \(H\) and \(G\) are connected, and we can still assume \(H\) non-empty. Then if \(i : H \to G\) is full it is an equivalence and we are done. So we are reduced to the situation where \(i : H \to G\) is not full and \(H\) and \(G\) are connected, with \(H\) non-empty. (Thinking ‘groups’, this is \(H\) being a proper subgroup of \(G\).) In particular, \(H\) has order strictly less than \(G\) and we can apply the induction hypothesis to the faithful \(p_2 : (i/i) \to H\) which appears in the self-iso-comma of (3.1.2):

\[
\begin{array}{ccc}
H & \xleftarrow{i} & G \\
p_1 & \sim & \lambda & p_2 \\
\end{array}
\]

in which the vertical morphisms are isomorphism by the BC-property (Mack3).

This proves that \(i^*\Theta_i\) is an isomorphism and we are reduced to property (A). \(\square\)

3.4.2. Theorem. Let \(M : G^{\text{op}} \to \text{ADD}\) be a Mackey 2-functor (Definition 2.3.5). Then we can choose for each faithful \(i : H \to G\) in \(G\) a single two-sided adjoint \(i_! = i_*\) of \(M(H) \to M(G)\).
of restriction $i^*: \mathcal{M}(G) \to \mathcal{M}(H)$ and units and counits

\[ \ell \eta: \text{Id} \Rightarrow i^* i \quad \ell \varepsilon: i i^* \Rightarrow \text{Id} \quad \text{and} \quad \varepsilon \eta: \text{Id} \Rightarrow i_* i^* \quad \varepsilon \varepsilon: i^* i_* \Rightarrow \text{Id} \]

for $i_! \dashv i^*$ and $i^* \dashv i_*$ respectively, such that all the following properties hold:

(Mack 5) *Additivity of adjoints:* Whenever $i = i_! \sqcup i_2: H_1 \sqcup H_2 \Rightarrow G$, under the identification $\mathcal{M}(H_1 \sqcup H_2) \cong \mathcal{M}(H_1) \oplus \mathcal{M}(H_2)$, we have

\[ (i_1 \cup i_1)! = ((i_1)! (i_2)!), \quad \text{and} \quad (i_1 \cup i_1)_* = ((i_1)_* (i_2)_*) \]

with the obvious ‘diagonal’ units and counits. (See Remark A.6.8.)

(Mack 6) *Two-sided adjoint equivalences:* Whenever $i^*$ is an equivalence, the units and counits are isomorphisms and $(\ell \eta)^{-1} \sim \varepsilon$ and $(\varepsilon \varepsilon)^{-1} = \eta$. Furthermore when $i = \text{Id}$ we have $i_1 = i_* = \text{Id}$ with identity units and counits.

(Mack 7) *Strict Mackey Formula:* For every Mackey square (Definition 2.2.1) with $i$ and $j$ faithful

\[ \begin{array}{ccc}
	 H & \xleftarrow{\sim} & K \\
\downarrow^v & & \downarrow^w \\
\downarrow^L & \Rightarrow & \downarrow^R \\
 i & & j \\
\end{array} \]

the two isomorphisms $\gamma: j \circ v^* \Rightarrow u^* i_!$ and $(\gamma^{-1})_*: u^* i_* \Rightarrow j^* v^*$ of (Mack 3) are in fact inverse to one another

\[ \gamma \circ (\gamma^{-1})_* = \text{id} \quad \text{and} \quad (\gamma^{-1})_* \circ \gamma = \text{id} \]

via the identification of their source and target $u^* i_! = u^* i_*$ and $j^* v^* = j^* v^*$. (If the above square is only assumed to be a partial Mackey square (Definition 3.1.12) then $(\gamma^{-1})_* \circ \gamma = \text{id}$ still holds true.)

(Mack 8) *The two pseudo-functors $i \mapsto i_!$ and $i \mapsto i_*$ (Remark A.2.10) coincide:* For every 2-cell $\alpha: i \Rightarrow i'$ between faithful $i, i': H \Rightarrow G$ we have $\alpha = \alpha_*$ as morphisms between the functors $i_! = i_*$ and $i'_! = i'_*$. For every composable faithful morphisms $j: K \Rightarrow H$ and $i: H \Rightarrow G$ the isomorphisms $(ij)_! \cong i j_!$ and $(ij)_* \cong i_* j_*$ coincide.

(Mack 9) *Special Frobenius:* For every faithful $i: H \Rightarrow G$, the composite of the left unit and right counit $\text{Id} \xleftarrow{i \eta} i^* i_! = i^* i_* \xrightarrow{\varepsilon \varepsilon} \text{Id}$ is the identity of $\text{Id}_H$.

**Proof.** Choose left and right adjoints $i_! \dashv i^* \dashv i_*$ for every faithful $i: H \Rightarrow G$ following Convention 3.3.2 as usual. Then Theorem 3.3.4 gives us natural transformations $\Theta_i : i_! \Rightarrow i_*$ for all faithful $i$, which satisfy all the nice properties listed in Theorem 3.3.19. By Theorem 3.4.2, ambidexterity forces this $\Theta_i$ to be an isomorphism and therefore we can carry the units and counits of the right adjunction $i^* \dashv i_*$ over to $i_!$ via $\Theta_i$ to make $i_!$ a two-sided adjoint. With this new set of adjoints $i_! \dashv i^* \dashv i_*$ one can verify directly from the construction in Theorem 3.3.4 that the new $\Theta_i^{\text{new}} : i_! \Rightarrow i_*$ is nothing but the identity, see (3.3.6) in which $\Theta_i$ is absorbed into $\varepsilon \varepsilon^{\text{new}}$. Now the five properties (a)–(f) of Theorem 3.3.19 give us the five announced properties (Mack 5)–(Mack 9).

**3.4.5. Corollary.** Let $\mathcal{M}: \mathcal{G}^{\text{op}} \to \text{ADD}$ be a Mackey 2-functor. Then there exists a pseudo-functor $(-)_! : (\text{gpfd})^{\text{co}} \to \text{ADD}$ on faithful morphisms, which agrees with $\mathcal{M}$.
on 0-cells, such that each \( i_! \) is a two-sided adjoint of \( i^* \) and such that for every Mackey square (2.2.2) in which \( i \) and \( j \) are faithful, we have

\[
(\gamma_!)^{-1} = (\gamma^{-1})^*.
\]

as in (1.3.3). \qed
CHAPTER 4

Examples

We assemble here a number of examples, and some non-examples, of Mackey 2-functors $G \mapsto \mathcal{M}(G)$ as in Definition 2.3.5, defined on all finite groupoids, or sometimes only defined on a 2-subcategory $\mathcal{G}$ of $\text{gpd}$ as in Hypotheses 2.3.1. These examples are essentially all well-known.

4.1. Ambidexterity for additive derivators

As announced, the most straightforward source of Mackey 2-functors comes via stable homotopy theories. We now explain this in some detail. We refer to Groth [Gro13] for further details on derivators. We consider an additive derivator, that is, a (strict) 2-functor $\mathcal{D} : \text{Cat}^{\text{op}} \too \text{ADD}$ from the 2-category $\text{Cat}$ of small categories (or any suitable diagram category $\text{Dia} \subseteq \text{Cat}$ containing finite groupoids) to the 2-category $\text{ADD}$ of additive categories and additive functors (Appendix A.5), satisfying the axioms (Der 1)-(Der 4) of derivators; see [Gro13, Def. 1.5]. In telegraphic style, they are:

(Der 1) Additivity: $\mathcal{D}(\amalg_{\alpha \in \aleph} I_\alpha) \cong \prod_{\alpha \in \aleph} \mathcal{D}(I_\alpha)$.

(Der 2) Pointwise detection of isomorphisms: For each small category $I$, the functor $\prod_{x \in I_0} x^* : \mathcal{D}(I) \too \prod_{x \in I_0} \mathcal{D}(1)$ is conservative ($1$ is the final category).

(Der 3) For every functor $u : I \too J$, the functor $u^* : \mathcal{D}(J) \too \mathcal{D}(I)$ has a left adjoint $u_!$ and a right adjoint $u_*$. 

(Der 4) $\mathcal{D}$ satisfies base-change (or Beck-Chevalley) with respect to any comma square (Definition 2.1.1) of small categories. See [Gro13, Prop. 1.26]. (The left and right BC are here equivalent because every $u^*$ has adjoints.)

$$
\begin{array}{c}
\begin{array}{ccc}
I & \overset{s}{\longrightarrow} & J \\
\downarrow & \rightleftharpoons & \downarrow \\
K & \overset{r}{\longrightarrow} & q
\end{array} \\
\begin{array}{c}
p \\
\gamma \\
\gamma_1 \colon s p^* \sim q^* p_! \quad \text{and} \quad \gamma_* \colon p^* q_* \sim r_* s^*.
\end{array}
\end{array}
$$

Recall from [Gro13, Cor. 4.14] that if $\mathcal{D} : \text{Cat}^{\text{op}} \too \text{CAT}$ is a stable derivator, for instance the one associated to any stable homotopy theory, then $\mathcal{D}$ is automatically additive.

Given a derivator $\mathcal{D}$, one can restrict the input diagrams to finite groupoids. For every faithful morphism $i : H \too G$, restriction $i^* : \mathcal{D}(G) \too \mathcal{D}(H)$ therefore admits adjoints on both sides. We claim that doing so for an additive derivator forces
those adjoints, induction $i!$ and coinduction $i_*$, to coincide. This is the content of ambidexterity (Mack 4). We have prepared the stage for this result in Section 3.3.

4.1.1. Theorem (Ambidexterity). Let $\mathcal{D}$ be an additive derivator. Then there exists for every faithful morphism $i : H \to G$ of finite groupoids an isomorphism

$$\Theta_i : i_! \cong i_*$$

of functors $\mathcal{D}(H) \to \mathcal{D}(G)$. In other words, the restriction of $\mathcal{D}$ to finite groupoids $\mathcal{M} = \mathcal{D}_{\text{gpd}} : \text{gpd}^{\text{op}} \to \text{ADD}$ is a Mackey 2-functor.

Proof. Consider $\mathcal{M} = \mathcal{D}_{\text{gpd}}$, the restriction of the 2-functor $\mathcal{D}$ to finite groupoids, and apply Theorem 3.3.4. Its hypotheses are satisfied, namely $\mathcal{M}$ has all properties of a Mackey 2-functor except perhaps ambidexterity: indeed (Mack 1), (Mack 2) and (Mack 3) are special cases of (Der 1), (Der 3) and (Der 4), respectively. So Theorem 3.3.4 gives us $\Theta_i : i_! \cong i_*$ and it only remains to prove it is invertible. We already know that $\Theta_i$ satisfies the properties of Theorem 3.3.19, most notably (c). We use Proposition 3.4.1, or `induction on the order of $G'$, which reduces the problem to proving that $\mathcal{M}$ has property (A). So, let $i : H \to G$ be faithful, with $H$ and $G$ connected and non-empty, such that $i^* \Theta_i$ is an isomorphism and let us show that $\Theta_i$ is an isomorphism in this case. (Here we cannot use Corollary A.2.12 anymore, as we did in the proof of Theorem 3.4.2, since we do not know that $i_!$ is a right adjoint of $i^*$ – we are actually proving exactly that.) We want to use (Der 2). Let $x : 1 \to G$ be an object of $G$. Since $G$ is connected and $H$ is non-empty, $i : H \to G$ is essentially surjective and thus there exists $y : 1 \to H$ and an isomorphism $i \circ y \cong x$. Therefore $x^* \Theta_i \cong y^* i^* \Theta_i$ is an isomorphism since we assume $i^* \Theta_i$ is. This holds for every object $x$ of $G$. In short, $\Theta_i : i_! \cong i_* : \mathcal{M}(H) \to \mathcal{M}(G)$ is pointwise an isomorphism and therefore an isomorphism by (Der 2).

4.1.2. Remark. The educated practitioner of derivators will easily extend the above result to any additive derivator $\mathcal{D} : \text{Dia}^{\text{op}} \to \text{ADD}$ defined on any smaller class of diagrams $\text{Dia} \subset \text{Cat}$, as long as $\text{Dia}$ contains all finite groupoids. This extension can be relevant when dealing with `small' derivators, like the one of compact objects $\mathcal{D}^c$ in a `big' derivator $\mathcal{D}$.

4.1.3. Example (Model categories with additive homotopy category). Let $\mathcal{C}$ be a (sufficiently complete and cocomplete) model category with class of weak equivalences $W$, then by a powerful theorem of Cisinski [Cis03] it gives rise by pointwise localization to a derivator $\mathcal{D} : J \mapsto \mathcal{C}^J[W^{-1}]$. Here of course we denote by

$$W_J := \{ f \in \text{Mor}(\mathcal{C}^J) \mid x^*(f) \text{ belongs to } W \subseteq \mathcal{C}, \forall x \in \text{Obj}(J) \}$$

the class of pointwise weak equivalences in the diagram category $\mathcal{C}^J$. By [Gro13, Prop. 5.2], the derivator is additive as soon as the homotopy category $\mathcal{C}[W^{-1}]$ of $\mathcal{C}$ happens to be additive (e.g. $\mathcal{C}$ could be a model category, or an exact model category as in [Što13]). By Theorem 4.1.1, we obtain in this situation a Mackey 2-functor

$$G \mapsto \mathcal{M}(G) = \mathcal{M}_{(\mathcal{C}, W)}(G) := \mathcal{C}^G[W_G^{-1}]$$

which really only depends on the relative category $(\mathcal{C}, W)$, that is, on the underlying category and the weak equivalences of the model category $\mathcal{C}$.

Of the many examples arising this way, let us mention three notable ones, starting with the minimal way (with weak equivalences being isomorphisms):
4.1.4. Example (Linear representations). Let $k$ be any commutative ring. Then the representable additive derivator $J \mapsto (\text{Mod } k)^J$ restricts to a Mackey 2-functor $\mathcal{M}: G \mapsto (\text{Mod } k)^G$; its value at a finite group $G$ is the category $\text{Mod}(kG)$ of $k$-linear representations of $G$. As any Grothendieck category, $\mathcal{A} = \text{Mod } k$ represents an additive derivator $J \mapsto \mathcal{A}^J$, in which the adjoints $u_*$ and $u^!$ are Kan extensions (without need to derive them).

4.1.5. Example (Derived categories). Let $k$ be any commutative ring. Then the category $\text{Ch}(k)$ of chain complexes of $k$-modules admits model structures where the weak equivalences $W$ are the quasi-isomorphisms, so it fits Example 4.1.3. The value of the resulting Mackey 2-functor $\mathcal{M}$ at a finite group $G$ is the derived category $D(kG)$ of the group algebra of $G$ with coefficients in $k$.

4.1.6. Example (Spectra). Let $\text{Sp}$ be any of the nice model categories of spectra where the weak equivalences $W$ are the (stable) weak homotopy equivalences. Then Example 4.1.3 specializes to yield a Mackey 2-functor $\mathcal{M}$. Its value $\mathcal{M}(G)$ at a group $G$ is the homotopy category of '$G$-shaped diagrams' of spectra. Beware: these are neither the genuine nor the naive $G$-spectra of topologists; see Example 4.3.8.

Finally, let us mention a basic non-example.

4.1.7. Example. The category $\text{Set}$ of sets gives rise to the representable derivator $J \mapsto \text{Set}^J$, whose restriction $\mathcal{M}: G \mapsto \text{Set}^G$ to finite groupoids does not define a Mackey 2-functor for the trivial reason that $\text{Set}^G$ is not additive. We may be tempted to drop the additivity requirement in order to save this example (which can be made pointed too) but there is a less trivial failure showing that this will not work: The left and right adjoints to a restriction functor $i^*$ are (almost) never isomorphic, even when working with pointed sets instead. This follows e.g. from elementary size considerations on finite sets: Already for a subgroup $H \leq G$ and an $H$-set $X$, the natural map of $G$-sets $G \times_H X \to \text{Map}_H(G, X)$ is not a bijection in general.

4.2. Mackey sub-2-functors and quotients

4.2.1. Definition. Let $\mathcal{M}: G^{\text{op}} \to \text{ADD}$ be a Mackey 2-functor. A Mackey sub-2-functor $\mathcal{N} \subseteq \mathcal{M}$ consists of a collection of (full and replete) additive subcategories $\mathcal{N}(G) \subseteq \mathcal{M}(G)$ for $G \in \mathcal{G}$ closed under restriction and (co)induction:

$$u^*(\mathcal{N}(G)) \subseteq \mathcal{N}(H) \quad \text{and} \quad i_!(\mathcal{N}(H)) \subseteq \mathcal{N}(G)$$

for all functors $u: H \to G$ and all faithful functors $i: H \to G$ in $\mathcal{G}$.

More generally:

4.2.2. Definition. A pre-morphism of Mackey 2-functors $F: \mathcal{M} \to \mathcal{N}$ is simply a (strong pseudo-natural) transformation, as in Terminology A.1.14. A morphism $F: \mathcal{M} \to \mathcal{N}$ is a pre-morphism which interacts nicely with the two adjunctions $i_i \dashv i^* \dashv i_*$, in the sense that the mates $(F_i)_*: F_i_* \Rightarrow i_* F$ and $(F_i^{-1})!: i_! F \Rightarrow F i_!$ of $F_!$: $i^* F \Rightarrow F i^*$ are isomorphisms for all $i \in \Xi$. Actually it suffices that all the $(F_i)_*$ are invertible, or equivalently that all the $(F_i^{-1})!$ are invertible, because of Proposition 3.3.33 and because $\Theta$ is invertible for Mackey 2-functors.

We will say more on morphisms in Section 6.3.
4.2.3. Example. Let \( F : \mathcal{M} \to \mathcal{M}' \) be a morphism of Mackey 2-functors (Definition 4.2.2). Then we have a Mackey sub-2-functor \( \text{Ker } F \subseteq \mathcal{M} \) defined at each \( G \), to be the full subcategory \( (\text{Ker } F)(G) = \{ X \in \mathcal{M}(G) \mid F_G(X) \cong 0 \text{ in } \mathcal{M}(G) \} \).

Amusing examples occur when \( \mathcal{M} \) takes values in abelian categories, like for instance the one of Example 4.1.4.

4.2.4. Proposition. Let \( \mathcal{M} : \mathbb{G}^{\text{op}} \to \text{ADD} \) be a (rectified) Mackey 2-functor such that every \( \mathcal{M}(G) \) is an abelian category. Then for every faithful \( i : H \to G \) the functors \( i^* \) and \( i_* = i_\ast \) are exact and they preserve injective and projective objects. Consequently, the assignments

\[
G \mapsto \text{Inj}(\mathcal{M}(G)) \quad \text{and} \quad G \mapsto \text{Proj}(\mathcal{M}(G))
\]

define Mackey 2-functors on the sub-2-category \( \mathbb{G}^{\text{faith}} \) of \( \mathbb{G} \) with only faithful 1-cells; these are Mackey sub-2-functors of \( \mathcal{M} \) restricted to \( \mathbb{G}^{\text{faith}} \).

**Proof.** Since \( i^* \) is a left and a right adjoint it is both right and left exact. Similarly for \( i_* = i_\ast \). Then the last statements follow because left (resp. right) adjoints of exact functors preserve projectives (resp. injectives). \( \square \)

Another way to produce examples is by taking additive quotients.

4.2.5. Proposition. Let \( \mathcal{M} : \mathbb{G}^{\text{op}} \longrightarrow \text{ADD} \) be any Mackey 2-functor and \( \mathcal{N} \subseteq \mathcal{M} \) a Mackey sub-2-functor. Then the additive quotient categories \( \mathcal{M}(G)/\mathcal{N}(G) \) inherit a canonical structure of a Mackey 2-functor \( \mathcal{M}/\mathcal{N} : \mathbb{G}^{\text{op}} \to \text{ADD} \) such that the quotient \( \mathcal{M} \to \mathcal{M}/\mathcal{N} \) is a (strict) morphism of Mackey 2-functors.

**Proof.** Recall that the additive quotient \( \mathcal{M}(G)/\mathcal{N}(G) \) is, by definition, the category with the same objects as \( \mathcal{M}(G) \) and where morphisms are taken modulo the additive ideal of maps that factor through some object of \( \mathcal{N}(G) \). Thus its Hom groups are given by the following quotient of abelian groups, for all objects \( X, Y \):

\[
(\mathcal{M}(G)/\mathcal{N}(G))(X,Y) := \mathcal{M}(G)(X,Y)/\{f : X \to Y \mid \exists Z \in \mathcal{N}(G) \text{ and } X \xrightarrow{f} Y \downarrow Z \}
\]

There is an evident quotient functor \( \mathcal{M}(G) \to \mathcal{M}(G)/\mathcal{N}(G) \) which is the identity on objects and the projection on Hom groups. As a 2-functor on \( \mathbb{G}^{\text{op}} \)

\[
\begin{array}{ccc}
G & \xrightarrow{\mathbb{M}(G)/\mathcal{N}(G)} & \mathbb{M}(G) \\
\xleftarrow{u} & & \xleftarrow{u} \\
H & \xleftarrow{G} & \mathbb{M}(H)/\mathcal{N}(H) \\
& & \mathcal{N}(H)
\end{array}
\]

\( \mathcal{M}/\mathcal{N} \) consists simply of the 1-cell and 2-cells induced between the quotient categories, which exist by the hypothesis that \( u^* (\mathcal{N}(G)) \subseteq \mathcal{N}(H) \) for all \( u \). Similarly, we obtain induction functors \( i_* \) because \( i_* (\mathcal{N}(H)) \subseteq \mathcal{N}(G) \). We also verify immediately that the units and counits of the adjunctions \( i_* \dashv i^* \dashv i_* \), as well as all the existing relations between 2-cells, also descend to the quotients, so that indeed \( \mathcal{M}/\mathcal{N} : G \mapsto \mathcal{M}(G)/\mathcal{N}(G) \) inherits the structure of a Mackey 2-functor. \( \square \)

We can now consider the case of an important example which is not globally defined in the sense that not all morphisms of groupoids can be allowed.
4.3. FURTHER EXAMPLES

4.2.6. Example (Stable module categories). Fix a base field $\mathbb{k}$, and consider the Mackey 2-functor $\mathcal{M} : G \mapsto (\text{Mod}\mathbb{k})^G$ of $\mathbb{k}$-linear representations as in Example 4.1.4. We define the stable module category of a groupoid $G$ to be the additive quotient

$$\text{Stab}(\mathbb{k}G) := (\text{Mod}\mathbb{k})^G / \mathcal{N}(G)$$

where $\mathcal{N}(G) := \text{Proj}((\text{Mod}\mathbb{k})^G)$ is the full subcategory of projective objects. We would like to show that $\mathcal{M}$ induces on $G \mapsto \text{Stab}(G)$ the structure of a Mackey 2-functor by applying Proposition 4.2.5. However, in order for the subcategories $\mathcal{N}(G)$ to form a Mackey sub-2-functor we cannot allow all functors $u : H \mapsto G$ between groupoids. For instance, if $u : G \mapsto 1$ is the projection from a non-trivial group to the trivial one, then $u^* : \text{Mod}\mathbb{k} \mapsto \text{Mod}(\mathbb{k}G)$ sends $\mathbb{k}$ to the trivial $G$-representation $\mathbb{k}^{\text{triv}}$. So if $u^*$ descends to an additive functor $u^* : 0 \cong \text{Stab}(\mathbb{k}1) \mapsto \text{Stab}(\mathbb{k}G)$ we conclude that $\mathbb{k}^{\text{triv}}$ is projective, but this is only possible in the semi-simple case, i.e. if $\text{Stab}(\mathbb{k}G) \cong \{0\}$. Still, if $i : H \mapsto G$ isfaithful then $i^*(\mathcal{N}(G)) \subseteq \mathcal{N}(H)$ and $i_* (\mathcal{N}(H)) \subseteq \mathcal{N}(G)$ by Proposition 4.2.4. Hence we may apply Proposition 4.2.5 and conclude that $G \mapsto \text{Stab}(G)$ is a Mackey 2-functor defined on $\mathbb{G} = \text{gpd}^d$, the 2-full 2-subcategory of finite groupoids and faithful functors, rather than the whole $\text{gpd}$.

4.2.7. Remark. In the previous example, projective and injective objects coincide in the abelian category $(\text{Mod}\mathbb{k})^G$, hence the stable module category is triangulated (see [Hap88] [Hel60]). However, $G \mapsto \text{Stab}(G)$ cannot come from restricting a (stable or otherwise) derivator, since such a derivator would have trivial base category $\text{Stab}(\mathbb{k}1) \cong \{0\}$ and thus it would have be the zero derivator $J \mapsto \{0\}$ by (Der 2). Therefore we could not have used Theorem 4.1.1 directly.

4.3. Further examples

Following up on Remark 1.2.10 (a), let us see how one can reduce a Mackey 2-functor $\mathcal{M} : \text{gpd}^{\text{op}} \mapsto \text{ADD}$ to the values $\mathcal{M}(G)$ for $G$ actual groups, i.e. one-object groupoids (Remark 1.2.2). For simplicity, we only treat $\mathbb{G} = \text{gpd}$ but the reader can adapt to general 2-categories $\mathbb{G}$ as in Hypotheses 2.3.1.

4.3.1. Notation. Let $\mathcal{B}$ be a full sub-2-category of $\text{gpd}$, for instance $\mathbb{B} = \text{gpd}$ itself, or $\mathcal{B} = \text{gpd}_{\text{conn}} \subseteq \text{gpd}$ the sub-2-category of connected groupoids, or $\mathcal{B} = \text{group} \subseteq \text{gpd}_{\text{conn}}$ the full sub-2-category of one-objects groupoids (Remark 1.2.2). (In this section ‘full’ means ‘1-full and 2-full’.) We emphasize that here group does not stand for the ordinary 1-category of finite groups but for its enhancement obtained by adding 2-cells $\gamma_g : f_1 \Rightarrow f_2$ between homomorphisms $f_1, f_2 : H \mapsto G$ for every $g \in G$ such that $\gamma_g f_1 = f_2$. We write

$$\text{2Fun}(\mathbb{B}^{\text{op}}, \text{ADD})$$

for the 2-category of 2-functors from $\mathbb{B}^{\text{op}}$ to $\text{ADD}$, with pseudo-natural transformations as 1-cells and modifications as 2-cells (Terminology A.1.14). When $\mathcal{B}$ is closed under coproducts in $\text{gpd}$, we write

$$\text{2Fun}_{\text{full}}(\mathbb{B}^{\text{op}}, \text{ADD}) \subseteq \text{2Fun}(\mathbb{B}^{\text{op}}, \text{ADD})$$

for the full 2-category of additive 2-functors in the sense of (Mack 1), i.e. sending the coproducts of $\text{gpd}$ to products in $\text{ADD}$.
4.3.2. Lemma. With Notation 4.3.1, the restrictions

\[ 2\text{Fun}_H(\text{gpd}^{\text{pp}}, \text{ADD}) \rightarrow 2\text{Fun}(\text{gpd}^{\text{conn}}, \text{ADD}) \rightarrow 2\text{Fun}(\text{group}^{\text{pp}}, \text{ADD}) \]

are biequivalences.

PROOF. Additivity gives the first biequivalence and the biequivalence \( \text{group} \subseteq \text{gpd} \) gives the second. \(\square\)

4.3.3. Remark. Consider a 2-functor \( \mathcal{M} : \text{group}^{\text{pp}} \to \text{ADD} \). Explicitly, we have:

1. For every finite group \( G \), an additive category \( \mathcal{M}(G) \in \text{ADD} \).
2. For every homomorphism \( f : H \to G \), a functor \( f^* : \mathcal{M}(G) \to \mathcal{M}(H) \), with the obvious (strict) functoriality \( \text{Id}_{\mathcal{M}(G)} = \text{Id}_{\mathcal{M}(H)} \) and \( (f_1 f_2)^* = f_2^* f_1^* \).
3. For every two homomorphisms \( f_1, f_2 : H \to G \) and every \( g \in G \) such that \( g f_1 = f_2 \), an (invertible) natural transformation \( \gamma_g : f_1^* \Rightarrow f_2^* : \mathcal{M}(G) \to \mathcal{M}(H) \), with the obvious functoriality \( \gamma_{g_1 g_2} = \gamma_g \gamma_{g_2} \).

As particular cases of (2), we have the functors associated to inclusions \( H \leq G \):

\[ \text{Res}_H^G := (\text{inc}_H^G)^* : \mathcal{M}(G) \to \mathcal{M}(H) \]

As another case, for every subgroup \( L \leq G \) and every element \( g \in G \) the homomorphism \( c_g : L \xrightarrow{\sim} ^gL, x \mapsto gxg^{-1} \) induces a functor

\[ c_g^* : \mathcal{M}((^gL) \xrightarrow{\sim} M(L) \).

(There should not be confused with the 2-cell \( \gamma_g^* \) of (3).) Note that \( c_{g_1 g_2} = c_{g_1} c_{g_2} \), hence \( c_{g_1 g_2} = c_g^* c_g^* \). Composing with the above, we get the ‘twisted restriction’

\[ g \text{Res}_L^H := c_g^* \circ \text{Res}_L^H : \mathcal{M}(H) \to \mathcal{M}(^gL) \xrightarrow{\sim} \mathcal{M}(L) \]

for all subgroups \( H, L \leq G \) and element \( g \in G \) such that \( gL \leq H \).

As an instance of (3), for \( f_1 = \text{Id}_G \) and \( f_2 = c_g : G \xrightarrow{\sim} G \), we have an isomorphism of functors

\[ \gamma_g^* : \text{Ind}^G_H \xrightarrow{\sim} c_g^* : \mathcal{M}(G) \to \mathcal{M}(G) \]

We can now explicitly translate along the biequivalence of Lemma 4.3.2 what it means for some additive \( \mathcal{M} : \text{gpd}^{\text{pp}} \to \text{ADD} \) to be a Mackey 2-functor, in terms of its restriction to groups.

4.3.7. Proposition. Let \( \mathcal{M} : \text{gpd}^{\text{pp}} \to \text{ADD} \) be a 2-functor satisfying \((\text{Mack 1})\) and consider its restriction \( \mathcal{M} : \text{group}^{\text{pp}} \to \text{ADD} \) to the 2-category of groups with conjugations as 2-cells. Retaining Notation 4.3.1 and Remark 4.3.3, we have:

(a) The 2-functor \( \mathcal{M} \) satisfies \((\text{Mack 2})\) if and only if for all subgroup \( H \leq G \) the restriction \( \text{Res}_H^G : \mathcal{M}(G) \to \mathcal{M}(H) \) has both a left and a right adjoint, say \( \text{Ind}_H^G \) and \( \text{CoInd}_H^G \) respectively.

For the remaining statements, we assume \((\text{Mack 2})\) for \( \mathcal{M} \).

(b) The 2-functor \( \mathcal{M} \) satisfies the left \( \text{BC}\) formula \((\text{Mack 3})\) if and only if for every subgroup \( H \leq G \), every homomorphism \( f : K \to G \) and every choice of representatives \( g \in [g] \in H \setminus G / f(K) \) (where \( K \) acts on \( G \) via \( f \)) the following natural transformation is an isomorphism

\[ \bigoplus_{[g] \in H \setminus G / f(K)} \text{Ind}_f^K \circ (g^*) \xrightarrow{(\delta_g)_f} f^* \circ \text{Ind}_H^G \]
where \( \gamma f \colon f^{-1}(H^g) \to H \) is \( c_g \circ f \) and \( \beta_g \colon \text{Ind}_H^G \circ (\gamma f)^* \to f^* \circ \text{Ind}_H^G \) is the composite

\[
\begin{array}{ccc}
\text{Ind}_H^G \circ (\gamma f)^* & \xrightarrow{\beta_g} & f^* \text{Ind}_H^G \\
\downarrow \quad \eta & & \quad \downarrow \varepsilon \\
\text{Ind}_H^G \circ (\gamma f)^* \text{Res}_H^G \text{Ind}_H^G & \xrightarrow{\gamma^*} & \text{Ind}_H^G \circ (\gamma f)^* \text{Res}_H^G \text{Ind}_H^G \end{array}
\]

where \( \gamma^* : (\gamma f)^* \text{Res}_H^G \cong \text{Res}_H^G f^* : \mathcal{M}(G) \to \mathcal{M}(f^{-1}(H^g)) \) is the natural transformation associated to conjugation \( \gamma_g : \gamma f \cong f \) between the two 1-cells \( f^{-1}(H^g) \to G \) in group obtained as the composites \( f^{-1}(H^g) \xrightarrow{\gamma_f} H \xrightarrow{f} G \) and \( f^{-1}(H^g) \xrightarrow{f^{-1}(H^g)} K \xrightarrow{f} G \).

Dually, the right BC-formula reduces to a dual formula for \( f^* \circ \text{CoInd}_H^G \).

(c) The 2-functor \( \mathcal{M} \) satisfies (Mack 4) if and only if for every subgroup \( H \leq G \) there exists some isomorphism \( \text{Ind}_H^G \simeq \text{CoInd}_H^G \).

**Proof.** This is a lengthy exercise. By additivity, we reduce all problems to the case of connected finite groupoids. In that case, everything like existence of adjoints or ambidexterity reduces up to equivalence to the one-object situation. This pattern can be followed to prove (a) and (c). Let us say a few more words about (b). Again, we can reduce everything to one-object groupoids but in that case we also need to understand the resulting iso-commas. Similarly to what happened in Remark 2.2.7, if \( i : H \to G \) is the inclusion, there is an equivalence

\[
\prod_{[g] \in H \setminus G/f(K)} f^{-1}(H^g) \xrightarrow{\sim} (i/f)
\]

mapping the unique object \( \bullet \) of \( f^{-1}(H^g) \) to the object \((\bullet, \bullet, g^{-1})\) of \((i/f)\). In more 2-categorical terms, this equivalence is \( w := (\prod_g \gamma_f, \prod_g \text{incl}_H^G f^{-1}(H^g), \prod_g \gamma_g) \)

\[
\begin{array}{ccc}
H & \xrightarrow{\prod_g \gamma_f} & \prod_g \gamma_g \\
\downarrow \quad \text{incl} & & \quad \downarrow \text{incl} \\
G & \xrightarrow{f} & K \\
\end{array}
\]

with notations as in Definition 2.1.1 and the statement. It remains to explicitly trace the construction of the mate \( \gamma \) which is exactly the one announced in (b). \( \square \)

**4.3.8. Example (Genuine equivariant spectra).** Let \( \mathcal{M}(G) = \text{SH}(G) \) be the stable homotopy category of genuine \( G \)-equivariant spectra, in the sense of topology, for every finite group \( G \). By the well-known functoriality properties of equivariant stable homotopy, we obtain a Mackey 2-functor on \( G = \text{gpd} \). This can be verified via Proposition 4.3.7, by inspecting one of the available constructions of a model for \( \text{SH}(G) \), such as can be found in [LMSM86], [MM02] or [Sch16]. We leave the details to the interested topologists, limiting ourselves to the observation that the axiom (Mack 4) holds by the so-called Wirthmüller isomorphism (see e.g. [Sch16],
Cor. 5.25]), which also exists, with an extra twist, when \( G \) and \( H \) are compact Lie groups.

### 4.3.9. Example (Equivariant Kasparov theory)

Let \( \mathcal{M}(G) = KK(G) \) be the \( G \)-equivariant Kasparov category, in the sense of operator algebraists, for every finite group \( G \). By the well-known properties of equivariant Kasparov theory, we obtain a Mackey 2-functor on \( \mathcal{G} = \text{gpd} \). Again, this can be verified via Proposition 4.3.7 by inspecting the available explicit constructions of \( KK(G) \) and its functoriality at the level of algebras, see e.g. [MN06] or [Mey08]. We leave the details to the interested operator algebraists, and simply note that in this example there is a concrete construction of an ‘induction’ functor \( KK(H) \rightarrow KK(G) \) for closed subgroups of quite general topological group \( G \), which is known to be right adjoint to restriction when \( G/H \) is compact and left adjoint to it when \( G/H \) is discrete – whence (Mack4) when the groups are finite.

### 4.3.10. Remark

Unlike our ambidexterity results, e.g. Theorem 4.1.1, the above Proposition 4.3.7 does not really provide any deep reason why some data \( G \mapsto \mathcal{M}(G) \) is a Mackey 2-functor. All it does is reduce the verification to the more ordinary data of \( \mathcal{M}(G) \) for actual finite groups \( G \), as the examples are typically presented in the literature in such terms. This is mildly unsatisfying but, at least in cases such as Example 4.3.8 and Example 4.3.9, perhaps unavoidable at this point in time because of the lack of something like a theory of ‘equivariant derivators’, and of results on how to produce them from model-level constructions. Indeed, unlike all the examples of Mackey 2-functors in Section 4.1, in the above two cases the variance \( G \mapsto \mathcal{M}(G) \) cannot be obtained by a simple-minded restriction of an additive derivator to finite groupoids. This is because of the failure of (Der 2) in the variable \( G \): A map \( f : X \rightarrow X' \) between ‘\( G \)-objects’ \( X, X' \in \mathcal{M}(G) \) is not an isomorphism merely because the underlying (non-equivariant) morphism in the base category is an isomorphism.

### 4.3.11. Remark

Most of the examples we have encountered so far carry an additional structure on the additive categories of values \( \mathcal{M}(G) \), typically that of a triangulated category, of a symmetric monoidal category, or both. We will elaborate on this interesting topic in a sequel.

### 4.3.12. Remark

One can use the techniques of this chapter to discuss further examples, for instance equivariant objects in suitable categories with \( G \)-actions, like equivariant sheaves over a \( G \)-scheme. We leave such extensions to interested readers. Note however that such examples of Mackey 2-functors are typically defined on more sophisticated 2-categories of groupoids \( \mathcal{G} \), not merely sub-2-categories of \( \text{gpd} \) as we considered so far (based on Hypotheses 2.3.1). Those more general 2-categories \( \mathcal{G} \) will be considered in Chapters 5 and 6, starting with Hypotheses 5.1.1. For instance, for the Mackey 2-functor of equivariant sheaves over a given ‘base’ \( G \)-scheme \( X \), one can take as \( \mathcal{G} \) the 2-category of groupoids with a chosen embedding into the fixed ‘ambient’ group \( G \) which acts on \( X \). In other words, the natural 2-category of definition \( \mathcal{G} \) appears to be a comma 2-category in \( \text{gpd} \) (see Definition B.0.6).
CHAPTER 5

Bicategories of spans

Our next goal is to construct the universal Mackey 2-functor: a Mackey 2-functor through which all the others factor. By definition, its target will be the 2-category (or rather, at first, the bicategory) of Mackey 2-motives. This goal will only be achieved in Chapter 6. In the present chapter we provide a detailed study of an auxiliary construction, the bicategory of spans (Definition 5.1.6), which in some sense only captures ‘half’ the properties of a universal Mackey 2-functor (see Theorem 5.2.1).

Of course spans – also known as ‘correspondences’ – have been studied for a long time; they are after all one of the basic categorical tools of symmetrization. More specifically, the bicategory of spans $\text{Span}(\mathcal{E})$ on a given category with pullbacks $\mathcal{E}$ already appeared in Bénabou [Bén67], alongside the axioms of a bicategory. What we need to do here, however, is to apply the span construction to our 2-subcategory $G$ of finite groupoids of interest with distinguished class of faithful functors $J$, so we must generalize Bénabou’s construction in several directions. First, we must allow nontrivial (yet invertible) 2-cells in the input $\mathcal{E}$. Second, we must replace strict pullbacks by iso-comma squares. And finally, we must allow some asymmetry in the picture, by only allowing wrong-way 1-cells to go in one of the two directions (only the faithful $i \in J$ give rise to induction functors). Each of these generalizations has been explored before in some contexts, but we could not find any reference for all the basic properties that we will need, hence the present chapter. For future reference, we prove all results in somewhat greater generality by allowing $G$ to be any suitable (2,1)-category, not necessarily of groupoids, as we explain next.

5.1. Spans in a (2,1)-category

5.1.1. Hypotheses. We fix an essentially small (2,1)-category $G$, that is, a (strict) 2-category where every 2-cell is invertible and where the equivalence classes of objects form a set. We also fix a class $J \subseteq G_1$ of 1-cells of $G$. We say that the pair $(G, J)$ is admissible if it has the following rather mild properties:

(a) The class $J$ contains all equivalences and is closed under horizontal composition and isomorphism of 1-cells. Moreover, if $ij \in J$ then $j \in J$. 

63
(b) For every cospan \( H \xrightarrow{i} G \xleftarrow{v} K \) of 1-cells with \( i \in J \), the comma square
\[
\begin{array}{ccc}
H & \xrightarrow{(i/v)} & K \\
\downarrow{i} & & \downarrow{v} \\
G & \xrightarrow{} & \\
\end{array}
\]
exists in \( G \) (Definition 2.1.1) and moreover \( \tilde{v} \) still belongs to \( J \).

(c) Every 1-cell \( i : H \to G \) in \( J \) is faithful, see Terminology A.1.6(4).

(d) The 2-category \( G \) admits (strict) coproducts and \( J \) is closed under coproducts. We will occasionally use \( J \) to denote also the corresponding 2-full subcategory of \( G \).

5.1.2. Remark. The faithfulness assumption (c) is only needed from Section 5.4 onwards. In particular, it is not required in order to construct the span bicategory \( \text{Span}(G; J) \) nor to prove its universal property in Section 5.2. Moreover, it is probably not really needed for the later construction of the bicategory \( \text{Span}^*(G; J) \) either, but because it is so convenient and still nicely covers all our examples, we renounce generalizing in this direction.

5.1.3. Remark. Similarly, Hypothesis (d) is not needed for the construction of \( \text{Span}(G; J) \) or its universal property. However when we return to Mackey 2-functors, additivity is a basic property and, to express it, we need Hypothesis (d). See Section 6.3.

5.1.4. Example. The example to keep in mind is of course \( G = \text{gpd} \), the \((2,1)\)-category of all finite groupoids, functors between them and natural transformations. In this case we may let \( J \) be the collection of all faithful functors. More generally, any 2-category \( G \) of finite groupoids as we used in previous chapters will do (see Hypotheses 2.3.1).

5.1.5. Remark. We are relaxing some of the assumptions made about \( G \) in Chapter 2. Indeed, we do not assume anymore that \( G \) is a sub-2-category of \( \text{gpd} \). Furthermore, even for \( G \) a sub-2-category of \( \text{gpd} \), we do not require that it be closed under faithful \( H \to G \) (i.e. \( G \in G \) and \( H \to G \) faithful does not necessarily imply \( H \in G \)). There is a gain in using a general \((2,1)\)-category \( G \) instead of our main example \( \text{gpd} \) and its sub-2-categories. First, it will be convenient at one point below to use \( G^{\text{co}} \), the \((2,1)\)-category with the same 0-cells and 1-cells but with reversed 2-cells. Secondly, and more importantly, we can use comma 2-categories of groupoids. Although related to groupoids, the objects of such 2-categories contain additional information. For instance, we would like to consider for a fixed \( G \) the \((2,1)\)-category \( \text{gpd}_{G} \) of groupoids \( H \) together with a chosen faithful functor \( H \to G \) and such information is lost when one only focuses on \( H \).

Given a pair \((G, J)\) as in Hypotheses 5.1.1, we now give the first fundamental construction of this chapter in a formal way. For a more gentle approach, the reader is invited to consult the heuristic Section 5.5.

5.1.6. Definition. The bicategory of spans in the \((2,1)\)-category \( G \) with respect to the class of 1-cells \( J \), denoted
\[
\text{Span} := \text{Span}(G; J)
\]
is given by the following data:

- The objects are the same as those of \( G \), that is, \( \text{Span}_0 = G_0 \).
- A 1-cell from \( G \) to \( H \) is a span

\[
G \xleftarrow{u} P \xrightarrow{i} H
\]

of 1-cells of \( G \), with the second leg \( i \) belonging to \( \mathcal{J} \).

- A 2-cell with domain \( G \xleftarrow{u} P \xrightarrow{i} H \) and codomain \( G \xleftarrow{v} Q \xrightarrow{j} H \) is an isomorphism class \([a, \alpha_1, \alpha_2] \) of diagrams

\[
\begin{array}{c}
G \xleftarrow{u} P \xrightarrow{i} H \\
\uparrow \downarrow \alpha_1 \downarrow \downarrow \alpha_2 \\
G \xleftarrow{v} Q \xrightarrow{j} H
\end{array}
\]

in \( G \) with \( a \) in \( \mathcal{J} \); we call \( a \) the 1-cell component and \( \alpha_1 \) and \( \alpha_2 \) the 2-cell components (in \( G \)) of the 2-cell \([a, \alpha_1, \alpha_2] \) (in \( \text{Span} \)); two such diagrams \([a, \alpha_1, \alpha_2] \) and \([b, \beta_1, \beta_2] \) (with the same domain and codomain) are isomorphic, i.e. define the same 2-cell \([a, \alpha_1, \alpha_2] = [b, \beta_1, \beta_2] \), if there exists a 2-cell of \( G \) making the 1-cell components isomorphic, that is, \( \varphi: a \xrightarrow{i} b \), in a way that identifies the 2-cell components, that is, such that \((v \varphi)\alpha_1 = \beta_1 \) and \( \alpha_2 = \beta_2(j \varphi) \). Vertical composition of 2-cells is induced by pasting in \( G \) in the evident way. The identity 2-cell of \( G \xleftarrow{u} P \xrightarrow{i} H \) is \([\text{Id}_P, \text{id}_u, \text{id}_i] \).

- The horizontal composition functors

\[
\circ = \circ_{G, H, K}: \text{Span}(H, K) \times \text{Span}(G, H) \to \text{Span}(G, K)
\]

are induced by iso-comma squares in \( G \). Explicitly, on objects this sends the pair

\[
( H \xleftarrow{u} Q \xrightarrow{j} K, G \xleftarrow{u} P \xrightarrow{i} H )
\]

to the span \( G \xleftarrow{u\tilde{v}} (i/v) \xrightarrow{j\tilde{i}} K \) obtained from the following comma square:

\[
\begin{array}{c}
G \xleftarrow{u} P \xrightarrow{i} H \\
\xleftarrow{\sim} \downarrow \uparrow (i/v) \xrightarrow{j\tilde{i}} Q \xrightarrow{j} K
\end{array}
\]

This is a well-defined 1-cell by the closure properties of \( \mathcal{J} \) detailed in Hypotheses 5.1.1 (a) and (b). On arrows, the functor \( \circ_{G, H, K} \) maps \([b, \beta_1, \beta_2, [a, \alpha_1, \alpha_2]] \)
to the 2-cell \([c, \alpha_1 \tilde{v}, \beta_2 \tilde{i}]\) defined by the following diagram:

Here \(c\) is the unique 1-cell \((i/v) \to (i'/v')\) such that \(\tilde{v}'c = a \tilde{v}\), \(\tilde{i}'c = b \tilde{i}\) and \(\gamma'c = (\beta_1 \tilde{i})\gamma(\alpha_2 \tilde{v})\), given by the universal property of \((i'/v')\). (Note that the two slanted squares are strictly commutative). In the notation of Definition 2.1.1, we have \(c = \langle a \tilde{v}, b \tilde{i}, (\beta_1 \tilde{i})\gamma(\alpha_2 \tilde{v}) \rangle\).

- The associators are induced by the associativity isomorphisms of Remark 2.1.8.
- The left and right unitors are provided by the equivalences of Remark 2.1.9.

These will be invertible 2-cells, as required, because of Lemma 5.1.12 below.

5.1.9. Convention. When drawing diagrams involving 2-cells \([a, \alpha_1, \alpha_2]\) in \(\text{Span}\) (and later in \(\hat{\text{Span}}\)), we shall not display the 2-cell components \(\alpha_1\) or \(\alpha_2\) when they are equal to the identity, i.e. when they appear in a square which commutes strictly. Conversely, when not displayed, we do mean that they are equal to the relevant identity.

5.1.10. Remark. Apart from the variation involving the class \(\mathbb{J}\), the construction in Definition 5.1.6 has been studied in details by [Hof11]. In particular, the verification that the above data forms a bicategory can be deduced from [Hof11, Theorem 3.0.3]. To be precise, here we are only considering the bicategorical truncation of a natural tricategory structure, in the sense that what we call a 2-cell is actually an isomorphism class of a 2-cell with respect to certain naturally occurring 3-cells. In the present work, we do not need to consider this higher information.

5.1.11. Remark. It is legitimate to wonder whether one could also define a bicategory of spans in a 2-category with non-invertible 2-cell (other than by forgetting them to get down to a (2,1)-category). Indeed, in that setting the Beck-Chevalley condition should involve comma squares rather than iso-comma squares, like in the (Der 4) axiom for derivators. One would therefore want to compose spans via comma squares. This creates a new problem: we would not have any identity 1-cells in such a bicategory of spans, for the analogue of Remark 2.1.9 fails for comma squares. See [Hof11, Rem. 3.1.5].

An alternative approach is suggested in the proof of [Hör16, Prop. 4.9] (under some 'multicategorical' layers). One can define a bicategory of spans using only spans in which the two legs are already Grothendieck (op)fibrations. In that case, composition can be defined via iso-comma squares for one expects them to satisfy Beck-Chevalley anyway – this is where having (op)fibrations helps. The price to pay is that the 'motivic' embedding, say contravariantly from \(G\) to spans, would
not send a 1-cell \( u \) to the obvious span \( u \) anymore. Instead, \( u \) would be sent to the span \( p \leftarrow q \) where \( p \) and \( q \) are the Grothendieck (op)fibrations which appear in the following comma square, associated to \( u \):

\[
\begin{array}{c}
\text{(Id/} u) \\
p \downarrow \quad \Rightarrow \quad q \\
\text{Id} \\
\end{array}
\]

We leave such generalizations to the interested reader.

5.1.12. Lemma. A 2-cell \([a, \alpha_1, \alpha_2]\) of \( \text{Span} \) as in (5.1.7) is invertible if and only if the 1-cell \( a: P \to Q \) of \( \mathcal{G} \) is an equivalence.

Proof. Clearly if \([a, \alpha_1, \alpha_2]\) is an invertible arrow of the category \( \text{Span}(G, H) \) then the 1-cell \( a \) is invertible in \( G \) up to isomorphism, i.e. is an equivalence. Conversely, assume that \( a \) is an equivalence in \( G \), so that we find a 1-cell \( b: Q \to P \) and isomorphisms \( \varepsilon : ab \sim \text{Id}_Q \) and \( \eta : \text{Id}_P \sim ba \). Define a 2-cell as follows:

\[
\begin{array}{c}
G \overset{v}{\to} Q \overset{\text{Id}}{\to} Q \overset{i_1}{\to} H \\
\downarrow \quad \quad \quad \quad \quad \quad \downarrow \quad \quad \quad \quad \quad \quad \downarrow \\
G \overset{a}{\to} P \overset{\varepsilon^{-1} \alpha_1}{\to} H \\
\end{array}
\]

Composing vertically, we get

\[
\begin{array}{c}
G \overset{v}{\to} Q \overset{\text{Id}}{\to} Q \overset{j}{\to} H \\
\downarrow \quad \quad \quad \quad \quad \quad \downarrow \quad \quad \quad \quad \quad \quad \downarrow \\
G \overset{u}{\to} P \overset{\varepsilon^{-1} \alpha_1}{\to} H \\
\end{array}
\]

which is isomorphic to \((\text{Id}_Q, \text{Id}_v, \text{Id}_v)\) via \( \varepsilon : ab \sim \text{Id}_Q \). Therefore (5.1.13) is a right inverse of \([a, \alpha_1, \alpha_2]\). But (5.1.13) is also a 2-cell whose middle 1-cell component is an equivalence, therefore by the same argument it admits itself a right inverse. It follows formally that \([a, \alpha_1, \alpha_2]\) and (5.1.13) are mutually inverse 2-cells. \( \Box \)

5.1.14. Notation. Given 1-cells \( u, i \in \mathcal{G}_1 \) with \( i \in \mathcal{J} \), we will use the notation

\[
i i u^* := ( G \xleftarrow{u} P \xrightarrow{i} H ) \in \text{Span}(G, H)
\]

for the associated 1-cell of \( \text{Span} \), as well as the short-hand

\[
i i := i_1 \text{Id}^* = ( P \xleftarrow{\text{Id}} P \xrightarrow{i} H ) \quad \text{and} \quad u^* := \text{Id}_1 u^* = ( G \xleftarrow{u} P \xrightarrow{\text{Id}} P ) .
\]
5.1.15. Remark. With this notation, for an arbitrary 1-cell \( i_! u^* \) of \( \text{Span} \) there is a canonical isomorphism \( i_! u^* \cong i_! \circ u^* \) given by the following diagram

\[
\begin{array}{ccc}
G & \xleftarrow{u} & P \\
\downarrow & & \downarrow \Delta_P \\
G & \xleftarrow{u} & \text{Id/Id} \xrightarrow{\text{pr}_1} P \xrightarrow{\text{pr}_2} P \\
\downarrow & & \downarrow \\
\text{Id} & \xrightarrow{\text{id}} & \text{Id} \xleftarrow{\text{id}} P \\
\downarrow & & \downarrow \\
G & \xleftarrow{u} & P \\
\end{array}
\]

where \( \Delta_P = (\text{Id}_P, \text{Id}_P, \text{id}_{\text{Id}_P}) \). Indeed \( \Delta_P \) is an equivalence by Remark 2.1.9, hence by Lemma 5.1.12 the above 2-cell \([\Delta_P, \text{id}, \text{id}]\) is invertible. Explicitly, either

\[
\begin{array}{ccc}
G & \xleftarrow{u} & P \xrightarrow{\text{pr}_1} (\text{Id}/\text{Id}) \xrightarrow{\text{pr}_2} P \\
\downarrow & & \downarrow \\
G & \xleftarrow{u} & P \\
\end{array}
\]

or

\[
\begin{array}{ccc}
G & \xleftarrow{u} & P \xrightarrow{\text{pr}_1} (\text{Id}/\text{Id}) \xrightarrow{\text{pr}_2} P \\
\downarrow & & \downarrow \\
G & \xleftarrow{u} & P \\
\end{array}
\]

provide diagrams representing its inverse.

5.1.17. Remark. We have defined horizontal composition in \( \text{Span}(G; J) \) by means of iso-commas; see (5.1.8). In view of our discussion of Mackey squares in Section 2.2, the reader might wonder whether one can get away with filling-in any Mackey square instead of the iso-comma in (5.1.8). As long as we want a well-defined horizontal composition, it is necessary to choose an actual composite. (\(^1\)) However, in practice, a Mackey square often comes to mind more easily than the precise iso-comma. A good example is of course the one discussed in Remark 2.1.9. Thanks to the above Lemma 5.1.12, we know that horizontal composition with the iso-comma is isomorphic to the result of ‘composing’ by means of a Mackey square. We shall return to this idea in the next chapter, see specifically Remark 6.1.4.

5.1.18. Construction. Following Notation 5.1.14, we define two pseudo-functors

\[
(-)^* : G^{\text{op}} \rightarrow \text{Span}(G; J) \quad \text{and} \quad (-)! : J^{\text{co}} \rightarrow \text{Span}(G; J)
\]

where \( J \) is seen as a 2-full subcategory of \( G \) for the latter. Both constructions are the identity on 0-cells. The first pseudo-functor \((-)^* \) sends a 1-cell \( u : H \rightarrow G \) to \( u^* : G \rightarrow H \) and sends a 2-cell \( \alpha : u \Rightarrow v \) to the 2-cell \( \alpha^* : u^* \Rightarrow v^* \) represented by

\[
\begin{array}{ccc}
G & \xleftarrow{u} & H \\
\downarrow & & \downarrow \text{id} \\
G & \xleftarrow{v} & H \\
\end{array}
\]

\[
\begin{array}{ccc}
H & \xrightarrow{\text{Id}} & H \\
\downarrow & & \downarrow \text{id} \\
H & \xrightarrow{\text{Id}} & H \\
\end{array}
\]

\[(-)! : J^{\text{co}} \rightarrow \text{Span}(G; J)
\]

\[
\begin{array}{ccc}
G & \xleftarrow{i} & H \\
\downarrow & & \downarrow \text{id} \\
G & \xleftarrow{i} & H \\
\end{array}
\]

\[
\begin{array}{ccc}
H & \xrightarrow{\text{Id}} & H \\
\downarrow & & \downarrow \text{id} \\
H & \xrightarrow{\text{Id}} & H \\
\end{array}
\]

\[(-)! : J^{\text{co}} \rightarrow \text{Span}(G; J)
\]

\[
\begin{array}{ccc}
G & \xleftarrow{i} & H \\
\downarrow & & \downarrow \text{id} \\
G & \xleftarrow{i} & H \\
\end{array}
\]

\[
\begin{array}{ccc}
H & \xrightarrow{\text{Id}} & H \\
\downarrow & & \downarrow \text{id} \\
H & \xrightarrow{\text{Id}} & H \\
\end{array}
\]

\[(-)^* : G^{\text{op}} \rightarrow \text{Span}(G; J) \quad \text{and} \quad (-)! : J^{\text{co}} \rightarrow \text{Span}(G; J)
\]

\[\text{where } J \text{ is seen as a 2-full subcategory of } G \text{ for the latter. Both constructions are the identity on 0-cells. The first pseudo-functor } (-)^* \text{ sends a 1-cell } u : H \rightarrow G \text{ to } u^* : G \rightarrow H \text{ and sends a 2-cell } \alpha : u \Rightarrow v \text{ to the 2-cell } \alpha^* : u^* \Rightarrow v^* \text{ represented by}
\]

\[\begin{array}{ccc}
G & \xleftarrow{u} & H \\
\downarrow & & \downarrow \text{id} \\
G & \xleftarrow{v} & H \\
\end{array}
\]

\[\begin{array}{ccc}
H & \xrightarrow{\text{Id}} & H \\
\downarrow & & \downarrow \text{id} \\
H & \xrightarrow{\text{Id}} & H \\
\end{array}
\]

\[\text{This is of course a place where a post-modernist reader would be equally satisfied with a contractible space of choices. But we follow a more patriarchal definition of bicategory.}\]
5.1. SPANS IN A (2,1)-CATEGORY

The second pseudo-functor \((-)!\) sends a 1-cell \(i: H \to G\) (in \(\mathcal{J}\)) to \(i_!: H \to G\) and sends a 2-cell \(\alpha: i \Rightarrow j\) to the 2-cell \(\alpha_!: j \Rightarrow i_!\) represented by

\[
\begin{array}{ccc}
G & \xrightarrow{\text{Id}} & G \\
\downarrow \scriptstyle{\text{Id}} & & \downarrow \scriptstyle{\text{Id}} \\
G & \xrightarrow{i} & H
\end{array}
\]

\[
\begin{array}{ccc}
G & \xleftarrow{\text{Id}} & G \\
\downarrow \scriptstyle{\text{Id}} & & \downarrow \scriptstyle{\text{Id}} \\
G & \xleftarrow{i} & H
\end{array}
\]

5.1.19. Remark. Both \((-)^*\) and \((-)!\) in Construction 5.1.18 are pseudo-functors, not strict 2-functors. Indeed, for composable 1-cells \(K \xrightarrow{u} H \xrightarrow{v} G\) the canonical equivalence \(\langle \text{Id}_K, j, \text{Id}_v \rangle: K \xrightarrow{\sim} (\text{Id}_H/v)\)

\[
\begin{array}{ccc}
G & \xleftarrow{u} & H \\
\downarrow \scriptstyle{\text{pr}_1} & & \downarrow \scriptstyle{\text{pr}_2} \\
K & \xrightarrow{v} & K
\end{array}
\]

\[
\begin{array}{ccc}
G & \xrightarrow{\text{Id}} & K \\
\downarrow \scriptstyle{\text{Id}} & & \downarrow \scriptstyle{\text{Id}} \\
K & \xrightarrow{v} & H
\end{array}
\]

constructed as in Remark 2.1.9 only yields canonical isomorphisms \((uv)^* \xrightarrow{\sim} v^* \circ u^*\) rather than equalities. Similarly, for \(K \xrightarrow{i} H \xrightarrow{j} G\) in \(\mathcal{J}\), the canonical equivalence \(\langle \text{Id}_K, j, \text{id}_v \rangle: K \xrightarrow{\sim} (j/\text{Id}_H)\) yields the canonical isomorphisms \((ij)_! \xrightarrow{\sim} i_! \circ j\)!. One verifies immediately that these pseudo-functors are 2-fully faithful, i.e. are bijective on each set of parallel 2-cells. We will thus consider them as embeddings of our 2-categories \(\mathcal{G}\) and \(\mathcal{J}\) into the bicategory \(\text{Span}(\mathcal{G}; \mathcal{J})\).

5.1.20. Remark. The 2-contravariance of \((-)!\) in the above Construction 5.1.18 is opposite to the 2-covariance of \((-)^*\). We are going to prove in Proposition 5.1.21 that \(i_!\) is left adjoint to \(i^*\) in the bicategory \(\text{Span}(\mathcal{G}; \mathcal{J})\). Therefore, given a 2-cell \(\alpha: i \Rightarrow j\) in \(\mathcal{J}\), the 2-cell \(\alpha^*: i^* \Rightarrow j^*\) of \(\text{Span}\) admits a mate \(\alpha_!: j^! \Rightarrow i^!\) (compare Remark A.2.10) which will be shown to agree with the homonymous 2-cell constructed above (Remark 5.1.24).

Recall the internal definition of adjunctions in a bicategory from Terminology A.1.6 (2). The essential advantage that \(\text{Span}(\mathcal{G}; \mathcal{J})\) has over \(\mathcal{G}\) is that 1-cells in \(\mathcal{J}\) get a left adjoint in \(\text{Span}(\mathcal{G}; \mathcal{J})\) under the embedding discussed above.

5.1.21. Proposition. Let \(i: H \to G\) be any element of the distinguished class \(\mathcal{J} \subset \mathcal{G}_1\). Then there exists in \(\text{Span}(\mathcal{G}; \mathcal{J})\) a canonical adjunction \(i_! \dashv i^*\), with explicit units and counits respectively given in (5.1.22) and (5.1.23) below.
Proof. The unit $\eta: \text{Id}_H \Rightarrow i^* \circ i_*$ of the adjunction is given by the 2-cell $[\Delta_i, \text{id}, \text{id}]$ where $\Delta_i : H \rightarrow (i/i)$ is given by $\Delta_i = \langle \text{id}_H, \text{id}_H, \text{id} \rangle$:

$$
\begin{align*}
\Delta_i & : H \\
\downarrow & \\
(i/i) & \downarrow \gamma_i & \Rightarrow \\
\text{id} & \Rightarrow \\
G & \\
\end{align*}
$$

The counit $\varepsilon : i_* \circ i^* \Rightarrow \text{Id}_G$ is the following composite $[i, \text{id}, \text{id}] \circ [\Delta_H, \text{id}, \text{id}]^{-1}$, where $\Delta_H = \langle \text{id}_H, \text{id}_H, \text{id}_{iH} \rangle : H \Rightarrow (\text{Id}_H/\text{Id}_H)$:

$$
\begin{align*}
\Delta_H & : H \\
\downarrow & \\
(i/i) & \downarrow \gamma_H & \Rightarrow \\
\text{id} & \Rightarrow \\
G & \\
\end{align*}
$$

(In the above two diagrams, we sloppily denote by the same symbols $\text{pr}_1$ and $\text{pr}_2$ the two projections of each comma square, although we take care to distinguish their 2-cells.) Note that $[\Delta_H, \text{id}, \text{id}]$ is an instance of the isomorphism of Remark 5.1.15, namely $i_* \circ i^* \cong i_i$.* Thus there are two canonical diagrams representing $[\Delta_H, \text{id}, \text{id}]^{-1}$, and therefore $\varepsilon = [i, \text{id}, \text{id}] \circ [\Delta_H, \text{id}, \text{id}]^{-1} = [i \text{pr}_1, \text{id}, i\gamma_H] = [i \text{pr}_2, i\gamma_H, \text{id}]$.

We must verify the two triangle identities $(\varepsilon i_*)(i\eta) = \text{id}_i$, and $(i^*\varepsilon)(\eta i^*) = \text{id}_i*$, which involve the associators and unitors of the bicategory $\text{Span}$. For the first identity, we compute the whiskerings $i\eta$ and $\varepsilon i_*$ as follows:
Now we combine them with the appropriate associator and unitors, and we claim that the resulting composite 2-cell

\[
\eta \circ_{1} \Delta \Rightarrow \Lambda \circ_{1} \Delta
\]

is the identity of \(i_{!}\). To prove this, it suffices to verify that by composing down the middle column except for the last step \(\text{pr}_{1}\), we obtain the 1-cell \(\langle \text{Id}_{H_{i}}, i, \text{id}_{i} \rangle : H \rightarrow \langle H_{i}, G \rangle\), because this would imply that the corresponding 2-cell of \(\text{Span}\) is the inverse of the left unitor \(\text{lun} : \text{Id}_{G} \circ i_{!} \Rightarrow i_{!}\).

The only non-evident part of this is to correctly identify the 2-cell components. One way to compute it efficiently is to precompose the above composite \(H \rightarrow \langle H_{i}, G \rangle\) with an arbitrary 1-cell \(t : T \rightarrow H\) and then exploit the element-wise description of comma squares in the 2-category of categories as detailed in Remark 2.1.6. In this way it is easy to see that by composing any \(t : T \rightarrow H\) down to \(\langle H_{i}, G \rangle\) we obtain the 1-cell \(\langle t, i_{!}, \text{id}_{i} \rangle\), which is the required result, and then we conclude with Corollary A.1.18.

The verification of the second triangle identity is completely similar and is left to the reader. \(\Box\)

5.1.24. Remark. As announced in Remark 5.1.20, for a 2-cell \(\alpha : i \Rightarrow j\) in \(J\), the corresponding 2-cell \(\alpha_{!}\) in \(\text{Span}(G; J)\) given in Construction 5.1.18 is in fact the mate
of the 2-cell \(\alpha^* : i^* \Rightarrow j^*\) under the adjunctions \(i_i \dashv i^*\) and \(j_j \dashv j^*\) of Lemma 5.1.25. This verification is left to the reader but it justifies the chosen 2-contravariance of the pseudo-functor \((-) : \mathcal{J} \rightarrow \text{Span}(\mathcal{G}; \mathcal{J})\).

By Construction 5.1.18 and Proposition 5.1.21, we see that \(\text{Span}(\mathcal{G}; \mathcal{J})\) is an enlargement of \(\mathcal{G}\) which accommodates a left adjoint \(i_i \dashv i^*\) for every 1-cell \(i \in \mathcal{J}\). These adjoints are not freely added to \(\mathcal{G}\) though, but instead automatically satisfy the following Beck-Chevalley or base-change condition:

**5.1.25. Lemma.** The canonical pseudo-functor \(\mathcal{G}^{op} \rightarrow \text{Span}(\mathcal{G}; \mathcal{J})\) of Construction 5.1.18 has the following property: For any comma square in \(\mathcal{G}\)

\[
\begin{array}{ccc}
P & \xrightarrow{(i/v)} & Q \\
\downarrow \gamma & & \downarrow \eta \\
H & \xrightarrow{v} & \end{array}
\]

with \(i \in \mathcal{J}\), the mate \(\gamma_i\) of the image \(\gamma^*\) of \(\gamma\) in \(\text{Span}(\mathcal{G}; \mathcal{J})\), with respect to the adjunctions \(i_i \dashv i^*\) and \(\tilde{i}_i \dashv i^*\) of Proposition 5.1.21

\[
\begin{array}{ccc}
P & \xrightarrow{(i/v)} & Q \\
\downarrow \gamma & & \downarrow \eta \\
H & \xrightarrow{v^*} & \end{array}
\]

is invertible in \(\text{Span}(\mathcal{G}; \mathcal{J})\). (\(^2\))

**Proof.** By definition, the mate \(\gamma_i\) in question is the 2-cell of \(\text{Span}(\mathcal{G}; \mathcal{J})\) defined by the following pasting, where \(\eta\) and \(\varepsilon\) are the unit and counit of the adjunction:

\[
\begin{array}{ccc}
P & \xrightarrow{\gamma_i^*} & Q \\
\downarrow \gamma & & \downarrow \gamma \\
\end{array}
\]

Making the unitors and associators explicit, \(\gamma_i\) is the following composite:

\[
\begin{align*}
\tilde{i}_i \circ \tilde{v}^* & \xrightarrow{\eta} (\tilde{i}_i \circ \tilde{v}^*) \circ \text{Id}_P \\
& \xrightarrow{\gamma} \tilde{i}_i \circ (\tilde{v}^* \circ i_l) \circ \text{Id}_i \\
& \xrightarrow{\gamma} \tilde{i}_i \circ v^* \\
& \xrightarrow{\gamma} v^* \circ i_l
\end{align*}
\]

\(^2\)The meaning of the notation \(\gamma_i\) appearing here is not the meaning of \((-) : \mathcal{J}\) in Construction 5.1.18. Note that the latter does not necessarily make sense on the 2-cell \(\gamma : i \tilde{v} \Rightarrow v \tilde{i}\) since neither \(i \tilde{v}\) nor \(v \tilde{i}\) are assumed to belong to \(\mathcal{J}\). Compare Remark 5.1.24.
Note that by the definition of horizontal composition the target span is \( v^* \circ i_t = \tilde{v}^* \).

We must show that \( \gamma \) is invertible. We claim that \( \gamma \) is in fact the inverse of the canonical isomorphism \( \tilde{i}_t \tilde{v}^* \Rightarrow \tilde{i}_t \circ \tilde{v}^* \) of Remark 5.1.15. In order to prove our claim, we explicitly compute the composite morphism of spans

\[
\tilde{i}_t \tilde{v}^* \Rightarrow \tilde{i}_t \circ \tilde{v}^* \Rightarrow \tilde{i}_t \tilde{v}^*
\]

and show it is equal to \( \text{id}_{\tilde{i}_t \tilde{v}^*} \). This can be done as follows.

As a first step, we compute the composite \( \gamma_! \) of the first four maps. This is straightforward, as the 2-cell components of these maps are all identities, so this amounts to determining the composite 1-cell component. The target span is

\[
(i/(P/\tilde{v}))/(i/v) \rightarrow (i/(Q/\tilde{i}))/(i/v)
\]

(5.1.27)

For the second step we take a closer look at the next map, \( \gamma^* \). Note that this \( \gamma^* \) is actually defined by the commutative square

\[
\begin{array}{ccc}
(i/(P/\tilde{v}))/(i/v) & \rightarrow & (i/(Q/\tilde{i}))/(i/v) \\
\gamma^* & \rightarrow & \gamma^*
\end{array}
\]

where the bottom \( \gamma^* \) is, properly speaking, the image of \( \gamma \) under the pseudo-functor \( \mathbb{C}^{op} \rightarrow \text{Span} \) and the vertical maps are induced by the structure isomorphisms of the latter (see Construction 5.1.18). By computing this composite, the top \( \gamma^* \) turns out to be the morphism of spans with identity 2-cell components and the 1-cell component

\[
\langle \langle \tilde{v}, (\tilde{v}, \text{id}_{i/v}, \text{id}_{\tilde{v}} \cdot (\gamma \!_! \circ \gamma^* \circ i_t)), \text{id}_{\tilde{v}} \rangle \rangle : (i/(i/v)) \rightarrow (i/(Q/\tilde{i}))/(i/v) ,
\]

(5.1.28)
where \(pr_1\) and \(pr_2\) denote, respectively, the left and right projections of the uniquely relevant comma squares, and the target span looks as follows:

\[
\frac{(i/(Q/\tilde{i}))}{(i/v)} \\
\frac{i/(Q/\tilde{i})}{Q/\tilde{i}} \Rightarrow \frac{i/v}{Q}
\]

It is now straightforward to compose (5.1.27) and (5.1.28) and to see that the resulting 1-cell component is

\[
\langle \langle \tilde{v}, \tilde{i}, \text{id}_{i/v}, \text{id}_{i/v} \rangle, \text{id}_{i/v} \rangle : (i/v) \rightarrow (i/(Q/\tilde{i}))/((i/v)/(i/v))
\]

(5.1.29)

and to still have trivial 2-cell components. (Note that \(\gamma\) has now vanished. This is because \(\langle \tilde{v}, \tilde{i}, \gamma \rangle = \text{id}_{i/v}\) by the definition of the original comma square.)

For the final step, consider the last two maps. We have a whiskered counit followed by a left unitor:

\[
\frac{\tilde{i}_t \circ \tilde{i}^* \circ (v^* \circ \tilde{i}_t)}{\text{id}_{i/v} \circ (v^* \circ \tilde{i}_t) \circ \text{lum} \circ v^* \circ \tilde{i}_t}
\]

If we choose the appropriate representative for \(\varepsilon\) of the two available ones, both are given by morphisms of spans with trivial left 2-cell component but nontrivial right 2-cell component. To wit, their composite (5.1.30) computes as follows (writing
5.1. SPANS IN A (2,1)-CATEGORY

\[ X := (i/v)/(i/v)/(i/v) \] to save space:

Here \( \tau \) denotes the following comma square:

Now we hit \( X \) with (5.1.29), which we denote \( g: i/v \to X \) for short. First, it is clear that the composite 1-cell \( \text{pr}_1 \xi g \) down the middle is equal to \( \text{Id}_{i/v} \). The left 2-cell of the resulting morphism of spans is obviously trivial. It remains to show that the right 2-cell is also trivial. It is as follows:

By the very definitions of \( \Delta_{i/v} \), \( f \) and \( g \), we have in \( G \) whiskerings

\[ \theta \Delta_{i/v} = \text{id}_{\text{Id}_{i/v}} \quad \tau f = \xi \quad \xi g = \text{id}_i \]

from which it immediately follows that the above 2-cell is indeed the identity of \( \tilde{i} \), as claimed.
After having checked as in Remark 5.1.24 that, for 2-cells \( \alpha : i \Rightarrow j \) with \( i, j \in \mathcal{J} \), the two meanings of the notation \( \alpha \) coincide, Lemma 5.1.25 has the following immediate corollary:

**5.1.31. Corollary.** The pseudo-functors \((-)^* : \mathcal{G}^{\text{op}} \to \text{Span}(\mathcal{G}; \mathcal{J}) \leftarrow \mathcal{J}^{\text{co}} : (-)_! \) of Construction 5.1.18 have the property that for every \( i \in \mathcal{J} \) there is a canonical adjunction \( i_! \dashv i^* \text{ Span}(\mathcal{G}; \mathcal{J}) \).

The following result explains how the 2-cells of \text{Span} are generated by the 2-cells coming from \( \mathcal{G} \hookrightarrow \text{Span} \), by the counits of the adjunctions \( a_! \dashv a^* \) for all \( a \in \mathcal{J} \) and by the structural isomorphisms.

**5.1.32. Proposition.** Let \( \alpha = [a, \alpha_1, \alpha_2] : i_! u^* \Rightarrow j_! v^* \) be an arbitrary 2-cell in \text{Span} as displayed in (5.1.7). Then, modulo the canonical isomorphisms \( i_! u^* \simeq i_! \circ u^* \) and \( j_! v^* \simeq j_! \circ v^* \) of Remark 5.1.15, the following pasting in \text{Span} is equal to \( \alpha \):

\[
\begin{array}{ccc}
G & \xrightarrow{u^*} & P \\
\downarrow \cong \downarrow \alpha_1^* & & \downarrow \cong (\alpha_2)_! \\
G & \cong (\epsilon a)_* & \xrightarrow{(\epsilon a)_!} & H \\
\downarrow \cong & & \downarrow \cong \\
G & \xrightarrow{v^*} Q & \xrightarrow{a^*} P & \xrightarrow{a_!} Q & \xrightarrow{j_!} H \\
\downarrow \varepsilon & & \downarrow \cong & & \downarrow \cong \\
G & \xrightarrow{v^*} Q & \xrightarrow{\text{Id}} Q & \xrightarrow{j_!} H \\
\end{array}
\]

in which we use the 2-functoriality of \((-)^* \) and of \((-)_! \) as in Construction 5.1.18.

**Proof.** Exercise. \( \square \)

### 5.2. The universal property of spans

We are now going to prove a universal property of the canonical 2-functor \((-)^* : \mathcal{G}^{\text{op}} \to \text{Span}(\mathcal{G}; \mathcal{J}) \). Our result is a significant generalization and strengthening of [DPP04, Prop. 1.10]. A similar result had appeared without proof in [Her00, Theorem A2]. The first version of our universal property (Theorem 5.2.1 below) only considers pseudo-functors, and is formulated as ‘strictly’ as possible. The second version (see Theorem 5.3.7) will also consider transformations between them.

**5.2.1. Theorem.** Let \( \mathcal{G} \) and \( \mathcal{J} \) be as in Hypotheses 5.1.1. Let \( \mathcal{C} \) be any 2-category, and let \( \mathcal{F} : \mathcal{G}^{\text{op}} \to \mathcal{C} \) be a pseudo-functor such that

(a) for every \( i \in \mathcal{J} \), there exists in \( \mathcal{C} \) a left adjoint \( (\mathcal{F} i)_! \) to \( \mathcal{F} i \), and

(b) the adjunctions \( (\mathcal{F} i)_! \dashv \mathcal{F} i \) satisfy base-change with respect to all Mackey squares with two parallel sides in \( \mathcal{J} \).

Then there exists a pseudo-functor \( \mathcal{G} : \text{Span}(\mathcal{G}; \mathcal{J}) \to \mathcal{C} \) such that the diagram

\[
\begin{array}{ccc}
\mathcal{G}^{\text{op}} & \xrightarrow{\mathcal{F}} & \mathcal{C} \\
\downarrow (-)^* \downarrow & & \downarrow \mathcal{G} \\
\text{Span}(\mathcal{G}; \mathcal{J}) & &
\end{array}
\]
is strictly commutative. This extension $\mathcal{G}$ is unique up to a unique isomorphism restricting to the identity of $\mathcal{F}$, and is entirely determined by the choice of the left adjoints, with units and counits, for all $\mathcal{F} i$ (see details in Remark 5.2.2 below). Conversely, any pseudo-functor $\mathcal{F}: \mathcal{G}^{op} \to \mathcal{C}$ factoring as above must enjoy the above two properties.

The extension $\mathcal{G}$ is given in Construction 5.2.3 below.

5.2.2. **Remark.** In order to obtain Theorem 5.2.1 precisely as formulated, we must make certain choices of adjoints, in the spirit of (Mack 6). Whenever $i \in \mathcal{J}$ is a strictly invertible 1-cell, we assume that the left adjoint of $\mathcal{F} i$ is $\mathcal{F}(i^{-1})$, with counit given by the composite $\mathcal{F}(i^{-1}) \circ \mathcal{F}(i) \cong \mathcal{F}(i i^{-1}) = \mathcal{F}(\text{Id}) \cong \text{Id}$ of structure morphisms of $\mathcal{F}$, and similarly for the unit. Similarly, whenever $i = \text{Id}_H$ is an identity we take care to choose $(\mathcal{F}\text{Id}_H) := \text{Id}_F H$ as the left adjoint of $\mathcal{F}(\text{Id}_H)$, with the coherent isomorphism $\text{un}_H: \text{Id}_F H \Rightarrow \mathcal{F}(\text{Id}_H)$ and its inverse as our choice for the unit and counit of adjunction. This is so as to obtain strict commutativity $\mathcal{G} \circ (-)^* = \mathcal{F}$ in the theorem, rather than just up to an isomorphism $\mathcal{G} \circ (-)^* \simeq \mathcal{F}$, and in order to simplify formulas a little. (Compare the Rectification Theorem 1.3.1.)

**Proof of Theorem 5.2.1.** The last claim is clear: Any pseudo-functor of the form $\mathcal{F} = \mathcal{G} \circ (-)^*: \mathcal{G}^{op} \to \mathcal{C}$ must satisfy properties (a) and (b), since the required adjunctions and base-change properties take place in $\text{Span}(\mathcal{G}; \mathcal{J})$, by Proposition 5.1.21 and Lemma 5.1.25, and are preserved by the pseudo-functor $\mathcal{G}$.

Uniqueness of $\mathcal{G}$ is forced by its agreement with $\mathcal{F}$ on 0-cells, by the property that every 1-cell in $\text{Span}$ is of the form $i i \circ u^*$ (Remark 5.1.15) and that every 2-cell in $\text{Span}$ is also controlled by data coming via the embeddings of $\mathcal{G}$ and $\mathcal{J}$ into $\text{Span}$ (Proposition 5.1.32). To be more precise, assume we have two pseudo-functors $\mathcal{G}, \mathcal{G}': \text{Span} \to \mathcal{C}$ such that $\mathcal{G} \circ (-)^* = \mathcal{F} = \mathcal{G}' \circ (-)^*$. They obviously agree on objects. Moreover, we can construct a strictly invertible pseudo-natural transformation $t: \mathcal{G} \rightarrow \mathcal{G}'$ (see Terminology A.1.14) as follows. The component $t_G: \mathcal{G} G \to \mathcal{G}' G$ at an object $G$ is just the identity $\text{Id}_{\mathcal{F} G}$. For $i \in \mathcal{J}$, we obtain two adjunctions $\mathcal{G}(i) \dashv \mathcal{G}'(i^*) = \mathcal{F} i$ and $\mathcal{G}'(i^*) \dashv \mathcal{G}'(i^*) = \mathcal{F} i$ and therefore a unique invertible 2-cell $t_i: \mathcal{G}'(i) \Rightarrow \mathcal{G} (i)$ identifying their units and counts. Then we define the component $t_i u^*$ of $t$ at each 1-cell $i u^*: G \to H$ of $\text{Span}$ by the pasting

which makes use of the coherent structural isomorphisms of the pseudo-functors $\mathcal{G}$ and $\mathcal{G}'$. (Here we have omitted the canonical isomorphisms $i i u^* \cong i i \circ u^*$. ) The verification that $t = (t_G, t_i u^*)$ is a pseudo-natural transformation is left as an exercise; it follows from Proposition 5.1.32 together with the uniqueness of the $t_i$ and their compatibility with units and counits. The uniqueness of the $t_i$ also implies the claimed uniqueness of such an isomorphism $t: \mathcal{G} \rightarrow \mathcal{G}'$ (More details on such extended transformations will be given in the proof of Theorem 5.3.7.)
We now turn to the existence of $\mathcal{G}$, given a pseudo-functor $\mathcal{F}: \mathcal{G}^{\text{op}} \to \mathcal{C}$ satisfying (a) and (b). As observed in Remark A.2.10, the adjunctions $(\mathcal{F} i)_! : F i$ provided in (a) assemble into a pseudo-functor $\mathcal{F}^i: \mathcal{J} \to \mathcal{C}$ which has the same values as $\mathcal{F}$ on 0-cells, is given by the chosen adjoints $(\mathcal{F} i)_!$ on 1-cells $i$ and by the mates $\alpha_1$ on 2-cells $\alpha$ (which involve the chosen units and counits).

It remains to show that the base-change property (b) allows us to ‘glue’ $\mathcal{F}$ and $\mathcal{F}^i$ into a pseudo-functor $\mathcal{G}: \text{Span}(\mathcal{G}; \mathcal{J}) \to \mathcal{C}$ defined as follows.

5.2.3. Construction. On objects, $\mathcal{G}$ must be the same as $\mathcal{F}$. On 1-cells, we set

$$\mathcal{G}(i u^*):= \mathcal{F}_i(i) \circ \mathcal{F}(u) = (\mathcal{F} i)_! \circ (\mathcal{F} u) ,$$

with the choices of Remark 5.2.2 when $i$ happens to be invertible.

For a 2-cell $[a, \alpha_1, \alpha_2]$ of $\text{Span}(\mathcal{G}; \mathcal{J})$ represented by a diagram

we define its image to be the following pasting in $\mathcal{C}$ (compare Proposition 5.1.32):

The latter uses the counit $\varepsilon$ of the adjunction $(\mathcal{F} a)_! + \mathcal{F} a$ as well as the coherent isomorphisms $\text{fun}^{-1}: \mathcal{F}(v a) \Rightarrow (\mathcal{F} a)(\mathcal{F} v)$ and $\text{fun}^{-1}: \mathcal{F}(j a)_! \Rightarrow (\mathcal{F} j)^!(\mathcal{F} a)_!$ — the latter obtained from those of $\mathcal{F}$ by taking mates. Given a composite of two spans

The latter uses the counit $\varepsilon$ of the adjunction $(\mathcal{F} a)_! : F a$ as well as the coherent isomorphisms $\text{fun}^{-1}: \mathcal{F}(v a) \Rightarrow (\mathcal{F} a)(\mathcal{F} v)$ and $\text{fun}^{-1}: \mathcal{F}(j a)_! \Rightarrow (\mathcal{F} j)^!(\mathcal{F} a)_!$ — the latter obtained from those of $\mathcal{F}$ by taking mates. Given a composite of two spans

$$j_! v^* \circ u^* = (j_! i_!)(u \tilde v)^*$$

(5.2.5)
we define the structure isomorphism \( \func{G}((j \circ v^*) \circ (i \circ u^*)) \rightarrow \func{G}(j \circ v^* \circ i \circ u^*) \) by

\[
\begin{align*}
\func{G}(j \circ v^*) & \rightarrow \func{G}(i \circ u^*) \\
\func{F} & \rightarrow \func{F}^u \\
\func{F}_u & \rightarrow \func{F}^i \\
\func{F}^i/ & \rightarrow \func{F}^i/v \\
\func{F}^i/v & \rightarrow \func{F}^F \\
\func{F}^F & \rightarrow \func{F}^F_i \\
\func{F}^F_i & \rightarrow \func{F}^F_{i/v} \\
\func{F}^F_{i/v} & \rightarrow \func{F}^F_K \\
\func{F}^F_K & \rightarrow \func{F}^F_H \\
\func{F}^F_H & \rightarrow \func{F}^F \\
\end{align*}
\]

(5.2.6)

which is well-defined because \( \func{F} \) satisfies base-change with respect to the square \( \gamma \). As for the unitors \( \func{un}_G : \func{Id}_{G \circ G} \rightarrow \func{G}(\func{Id}_G) \), since \( \func{G}(\func{Id}_G) = \func{F}(\func{Id}_G) \circ \func{G}(\func{Id}_G) = \func{F}(\func{Id}_G) \) we may simply take them to be identical to the unitors of \( \func{F} \).

In order to prove the theorem it remains to verify that \( \func{G} \) is a well-defined pseudo-functor and that it extends \( \func{F} \). The former is precisely Lemma 5.2.7 below. For the latter, it is immediate from the construction that \( \func{G} \circ (-)^* \) agrees with \( \func{F} \) on 0-cells and 1-cells, and that for a 2-cell \( \alpha : u \Rightarrow v : H \rightarrow G \) the image \( \func{G}(\alpha^*) = \func{G}((\func{Id}_H, \alpha, \func{id}_u \circ \func{id}_v)) \) is equal to the composite

\[
\func{F}_u \xrightarrow{\func{F}\alpha} \func{F}_v = \func{F}(v \circ \func{Id}) \xrightarrow{\func{un}^{-1}(\func{F}_v)} \func{F}(\func{Id}_H) \circ \func{F}_v \xrightarrow{\func{un}^{-1} \circ \func{F}_v} \func{Id}_{\func{F}H} \circ \func{F}_v = \func{F}_v
\]

(just read it off (5.2.4), using our careful choice of adjunctions for the identity 1-cells). But this composite is equal to \( \func{F}\alpha \), as one sees by a direct application of one of the three pseudo-functor axioms. Hence \( \func{G} \circ (-)^* = \func{F} \). \( \square \)

5.2.7. Lemma. Construction 5.2.3 yields a pseudo-functor \( \func{G} : \func{Span}(\mathbb{G}; \mathbb{I}) \rightarrow \func{C} \).

Proof. The proof is rather straightforward but lengthy and not so easy to write down explicitly, hence it is included here for completeness. It will also be a good occasion for introducing string diagrams. See Appendix A.3 for a quick tutorial, and let us recall here that in our string diagrams 1-cells are always oriented left-to-right whereas 2-cells are always oriented top-to-bottom:

\[
\begin{align*}
\| & \rightarrow \\
\| & \\
\downarrow & \\
\end{align*}
\]

To begin, we need to show that \( \func{G} \) is well-defined on 2-cells. Suppose we have two diagrams in the 2-category \( \func{G} \)

\[
\begin{align*}
\func{G} & \xleftarrow{u} \func{P} \xrightarrow{i} \func{H} \\
\func{G} & \xleftarrow{v} \func{Q} \xrightarrow{j} \func{H} \\
\end{align*}
\]

representing the same 2-cell of \( \func{Span} \), as testified by the existence of an isomorphism \( \varphi : a \Rightarrow b \) satisfying \( (v \varphi)\alpha_1 = \beta_1 \) and \( \alpha_2(j \varphi^{-1}) = \beta_2 \). In string diagrams, the
latter yield the following equations in $C$ after applying the (1-contravariant and 2-covariant!) $\mathcal{F}$:

\[(5.2.8)\]

\[
\begin{align*}
\mathcal{F}_u \mathcal{F}_\beta_1 \mathcal{F}_v & = \mathcal{F}_a \mathcal{F}_{\phi} \\
\mathcal{F}_\beta_2 \mathcal{F}_b & = \mathcal{F}_\alpha_2 \mathcal{F}_a
\end{align*}
\]

Here we have also used the naturality of fun, see Example A.3.9.

We must show that $\mathcal{G}([a, \alpha_1, \alpha_2])$ and $\mathcal{G}([b, \beta_1, \beta_2])$ are equal. In strings, the construction (5.2.4) of these 2-cells of $C$ takes the following form:

\[
\begin{align*}
\mathcal{G}([a, \alpha_1, \alpha_2]) &= \mathcal{F}_u \mathcal{F}_{\phi_1} \mathcal{F}_a \\
\mathcal{G}([b, \beta_1, \beta_2]) &= \mathcal{F}_j \mathcal{F}_{\phi_2} \mathcal{F}_b
\end{align*}
\]

For clarity, in this proof the strings corresponding to the chosen left adjoints $(\mathcal{F}_i)_!$ of all $i \in J$ appear as dotted. Here $\varepsilon$ denotes the counit of one of these adjunctions. Zooming in, we see the other units and counits hiding within the mates $(\mathcal{F}_{\alpha_2})_!$ and $(\text{fun}_\mathcal{F})^{-1} = (\text{fun}_\mathcal{F})_!$, which are defined as

and similarly for the other ones.
We can now calculate as follows, using the definitions and the adjunctions (and, tacitly, the exchange law to slide blocks up and down – see (A.3.2)):

\[ G([a, \alpha_1, \alpha_2]) = F_u \circ (F_i) \circ F_j \circ F_a \circ (F_j) \circ F_\alpha_1 \circ F_\alpha_2 = F_u \circ (F_i) \circ F_j \circ F_b \circ (F_j) \circ (F_i) \circ F_\beta_1 \circ F_\beta_2 = G([b, \beta_1, \beta_2]). \]

Thus \( G \) is well-defined on 2-cells. Here, we began highlighting parts of the strings to help the reader focus on the parts that is being changed at the given step in the series of equalities. This visual aide has no further mathematical meaning.

Now it remains to verify that the structure maps \( u_\mathcal{G} \) and \( \text{fun}_\mathcal{G} \) satisfy the axioms of a pseudo-functor, whose string form is recalled in Example A.3.5. Recall that while the target \( \mathcal{C} \) is a strict 2-category the source \( \text{Span} \) is not, hence to be precise we may want to write its unitors and associators explicitly.

Given two composable spans \( G \overset{u}{\leftarrow} P \overset{i}{\rightarrow} H \) and \( H \overset{v}{\leftarrow} Q \overset{j}{\rightarrow} K \) and their composite \( G \overset{(i/v)}{\leftarrow} (i/v) \overset{j}{\rightarrow} K \) as in (5.2.5), the map \( \text{fun}_\mathcal{G} \) of (5.2.6) takes the following
stringy form. Actually, it is more convenient to write \( \text{fun}_G^{-1} \):

\[
\text{fun}_G^{-1} = F_u F_{\tilde{v}} F_{(u \tilde{v})} (F_i) \Rightarrow (F_{(i \tilde{u})} \circ \text{un}^{-1})
\]

(5.2.10)

Let us begin with checking the left unit identity, namely:

\[
\text{fun}_G^{-1} \circ \text{fun}_{\tilde{u}^{-1}} = \text{fun}_{\tilde{u}^{-1}} \circ \text{fun}_G^{-1}
\]

(5.2.11)

To compute this, we need to specialize (5.2.10) to the case \( v = j = \text{Id}_H \) in order to describe \( \text{fun}_G^{-1} : G(\text{Id}_H \circ i u^*) \Rightarrow G(\text{Id}_H) \circ G(i u^*) \). We also need the (inverted) left unitor \( \text{un}^{-1} : i u^* \Rightarrow \text{Id}_H \circ (i u^*) = i_i (u \tilde{\text{Id}})^* \) in \text{Span}, which is constructed as follows, where \( \ell := \langle \text{Id}_P, i, \text{Id}_i \rangle :
5.2. THE UNIVERSAL PROPERTY OF SPANS

Note for later use that, by definition of \( \ell = \langle \cdots, \cdots, \text{id}_i \rangle \), we have \( \gamma \ell = \text{id}_i \).

Applying \( G \) to this \( \text{lun}^{-1} \) we obtain

\[
G(\text{lun}^{-1}) = G([\ell, \text{id}_u, \text{id}_i]) =
\]

We can now verify the left unit identity (5.2.11) as follows, first plugging the above partial computations:
The next passage uses the equation $\gamma \circ \ell = \text{id}_i$ as well as the associativity of $\text{fun}_\mathcal{F}$:

The proof of the other unit identity is similar and left to the reader.

In order to check the associativity axiom, we must first make explicit the associator in $\text{Span}$. Given three composable spans, one first constructs the following four iso-commas:
Then the universal property of iso-comma squares yields strictly invertible 1-cells 
\( f : i/(j/w) \rightarrow (i/v)/w : f^{-1} \) of \( G \), uniquely determined by the following 
relations:

\[
\begin{align*}
(5.2.13) \quad & f : \begin{cases} 
xf = \langle y, \tilde{w}, \beta \rangle, \\
\delta f = \alpha t
\end{cases}, \\
& \tilde{v}xf = y, \tilde{ixf} = \tilde{w}, \gamma xf = \beta 
\end{align*}
\]

\[
(5.2.14) \quad f^{-1} : \begin{cases} 
xf^{-1} = \langle \tilde{v}x, t, \delta \rangle, \\
\beta f^{-1} = \gamma x
\end{cases},
\]

The associator and its inverse are then simply the 2-cells \([f^{-1}, id, id]\) and \([f, id, id]\).

Now, the associativity axiom for \( G \) looks as follows (where once again we write 
the inverse 2-cells out of convenience):

\[
(5.2.15)
\]

Unfurling all mates and introducing \( F(ff^{-1}) = F(Id) \cong Id \), the left-hand-side 
expands as follows:
For the next step we use the equations (5.2.13) and (5.2.14) to replace the 2-cells in the two shaded areas. We repeatedly use the associativity and unitality of \(\text{fun}_F\), leaving some straightforward details to the reader:

For the last passage, we used (5.2.13) and (5.2.14) again to rewrite several 1-cells, and we used our choice of adjunction \(\mathcal{F}(f^{-1}) \dashv \mathcal{F}(f)\) for the strictly invertible \(f \in \mathbb{J}\).

The next step uses the naturality of \(\text{fun}_F\) to merge the three strands of \(\mathcal{F}x\):

Finally, we conclude by introducing three adjunction zig-zags; the result is precisely the right-hand side of (5.2.15); for this, we use at the top layer that \((\mathcal{F}f)_! = \mathcal{F}f^{-1}\) by construction.
This completes the verification that $G$ is a pseudo-functor as claimed. □

### 5.3. Bicategorical upgrades of the universal property

Let $G$ and $J$ be as in Hypotheses 5.1.1 and let $B$ be any bicategory. The universal property given in Theorem 5.2.1 determines when a pseudo-functor $F: G^{op} \to B$ factors via the bicategory $\text{Span} = \text{Span}(G; J)$. We now want to understand what happens with 1-cells (pseudo-natural transformations) and 2-cells (modifications); see Terminology A.1.14. To facilitate the discussion we baptize the pseudo-functors in question.

#### 5.3.1. Definition

A pseudo-functor $F: G^{op} \to B$ is called a $J_1$-pseudo-functor if it satisfies conditions (a) and (b) of Theorem 5.2.1, namely:

(a) For every 1-cell $i \in J$, the 1-cell $Fi$ admits a left adjoint $(Fi)_!$ in $B$.\(^3\)

(b) For any comma square $\gamma$ along an $i \in J$, its mate $\gamma_i$ is invertible:

\[
\begin{array}{ccc}
X & \xrightarrow{i/v} & Y \\
\downarrow \gamma & & \downarrow \gamma_i \\
\quad & \quad & \quad \\
\quad & \quad & \quad \\
\quad & \quad & \quad \\
\end{array}
\]

The short name “$J_1$-pseudo-functor” certainly conveys the idea of (a). We stress that the BC-property (b) is an integral part of the definition.

Consider two pseudo-functors $G_1, G_2: \text{Span} \to B$, or equivalently by Theorem 5.2.1 the associated $J_1$-pseudo-functors $G_1 \circ (-)^*$ and $G_2 \circ (-)^*: G^{op} \to B$. Starting with a pseudo-natural transformation $G_1 \Rightarrow G_2$, we can wonder what kind of transformation $t: G_1 \circ (-)^* \Rightarrow G_2 \circ (-)^*$ we get by restriction. As we shall prove, the answer is the following class of transformations.

#### 5.3.2. Definition

Let $t: F_1 \Rightarrow F_2$ be a (strong) pseudo-natural transformation between two $J_1$-pseudo-functors $G^{op} \to B$ (Definition 5.3.1). We say that $t$ is $J_1$-strong if for every $i \in J$ the following mate $(t_i^{-1})_!$ is invertible:

\[
\begin{array}{ccc}
F_1X & \xrightarrow{tx} & F_2X \\
\downarrow \text{(F_1)i} & & \downarrow \text{(F_2)i} \\
\quad & \quad & \quad \\
\quad & \quad & \quad \\
\quad & \quad & \quad \\
\quad & \quad & \quad \\
\quad & \quad & \quad \\
\quad & \quad & \quad \\
\quad & \quad & \quad \\
\end{array}
\]

\[
\begin{array}{ccc}
F_1Y & \xrightarrow{ty} & F_2Y \\
\downarrow \text{(F_1)i} & & \downarrow \text{(F_2)i} \\
\quad & \quad & \quad \\
\quad & \quad & \quad \\
\quad & \quad & \quad \\
\quad & \quad & \quad \\
\quad & \quad & \quad \\
\quad & \quad & \quad \\
\quad & \quad & \quad \\
\quad & \quad & \quad \\
\quad & \quad & \quad \\
\quad & \quad & \quad \\
\quad & \quad & \quad \\
\end{array}
\]

is invertible: $(t_i^{-1})! : (F_2i)_! \circ t_X \cong ty \circ (F_1i)_!$.

#### 5.3.4. Remark

In the spirit of Remark A.2.10, suppose that $F_1, F_2: G^{op} \to B$ are two $J_1$-pseudo-functors and assemble the left adjoints $(F_1)i$: and $(F_2)i$: into pseudo-functors $(F_1i): J^{co} \to B$ and $(F_2i): J^{co} \to B$. Consider now a transformation $t: F_1 \Rightarrow F_2$. One hopes that $t$ induces a transformation $t_i: (F_1)i \Rightarrow (F_2)i$. Since $(F_1)i$ and $(F_2)i$ coincide with $F_1$ and $F_2$ on 0-cells, we can use $tx$ to define $t_X$ on 0-cells. Now for every $i \in J$, we define the 1-cell component $(t_i)_! := (t_i^{-1})_!$ of the transformation $t_i$ via the above recipe (5.3.3). Note that $a$ priori there is no

\(^3\)Adapting [DPP04], we could say that such $F$ are $J$-dexter.
possibility of forming a mate with \( t \) itself. It is therefore important that \( t \) is an actual strong pseudo-natural transformation not merely an (op)lax one, at least on the 1-cells in \( \mathcal{J} \).

Now the punchline is that the above definition of \( t_1 : (\mathcal{F}_1)_t \Rightarrow (\mathcal{F}_2)_t \) does not yield a strong pseudo-natural transformation but only an oplax one (Terminology A.1.14(2)), i.e. its value \((t_1)_i\) on 1-cells \( i \) is not invertible a priori. The transformation \( t : \mathcal{F}_1 \Rightarrow \mathcal{F}_2 \) is \( \mathcal{J}_t \)-strong in the sense of Definition 5.3.2 precisely when \( t_1 \) is a strong transformation \((\mathcal{F}_1)_t \Rightarrow (\mathcal{F}_2)_t : \mathcal{J}_t \Rightarrow \mathcal{B} \). This characterization should clarify the terminology “\( \mathcal{J}_t \)-strong”. We emphasize that all \( \mathcal{J}_t \)-strong transformations are assumed strong in the usual sense to begin with (for \( t \) itself on \( \mathcal{G} \)), and that the \( \mathcal{J}_t \)-strength pertains to \( t_1 \) on \( \mathcal{J} \).

5.3.5. Remark. We leave to the reader the verification that the vertical and horizontal compositions of \( \mathcal{J}_t \)-transformations remain \( \mathcal{J}_t \)-strong.

5.3.6. Notation. We denote by

\[
\text{PsFun}_{\mathcal{J}_t}(\mathcal{G}^{\text{op}}, \mathcal{B}),
\]

the sub-bicategory of \( \text{PsFun}(\mathcal{G}^{\text{op}}, \mathcal{B}) \) with \( \mathcal{J}_t \)-pseudo-functors (Definition 5.3.1) as 0-cells, with \( \mathcal{J}_t \)-strong (Definition 5.3.2) pseudo-natural transformations as 1-cells and all modifications between them as 2-cells (Terminology A.1.14).

5.3.7. Theorem. Precomposition with the pseudo-functor \((-)^* : \mathcal{G}^{\text{op}} \rightarrow \text{Span}(\mathcal{G}; \mathcal{J}) \)
induces a biequivalence of bicategories

\[
\text{PsFun}(\text{Span}(\mathcal{G}; \mathcal{J}), \mathcal{B}) \overset{\sim}{\longrightarrow} \text{PsFun}_{\mathcal{J}_t}(\mathcal{G}^{\text{op}}, \mathcal{B}).
\]

If \( \mathcal{B} \) happens to be a 2-category, then the above is a strict 2-functor between two 2-categories, and said 2-functor is furthermore locally strict, i.e. it gives isomorphisms (rather than just equivalences) between all Hom categories.

PROOF. Let us begin by assuming that the target \( \mathcal{C} := \mathcal{B} \) is a 2-category, so both ends of (5.3.8) are 2-categories. Let us also forget modifications for the moment, and consider these two pseudo-functor 2-categories simply as 1-categories.

By Theorem 5.2.1, we know that precomposition with \((-)^* : \mathcal{G}^{\text{op}} \rightarrow \text{Span}(\mathcal{G}; \mathcal{J}) \)
induces a well-defined functor

\[
\text{PsFun}(\text{Span}(\mathcal{G}; \mathcal{J}), \mathcal{C}) \rightarrow \text{PsFun}_{\mathcal{J}_t}(\mathcal{G}^{\text{op}}, \mathcal{C})
\]

that is surjective on objects. Let us now discuss morphisms.

For clarity, to avoid entire discussions happening ‘in indices’, we write \( t(u) \) instead of \( t_u \) everywhere in this proof for the 1-cell component of a transformation \( t \).

Let us explain how, for every \( \mathcal{G}_1, \mathcal{G}_2 \in \text{PsFun}(\text{Span}, \mathcal{C}) \), each \( \mathcal{J}_t \)-strong transformation \( \mathcal{G}_1 \circ (-)^* \Rightarrow \mathcal{G}_2 \circ (-)^* \) extends uniquely to a transformation \( \mathcal{G}_1 \Rightarrow \mathcal{G}_2 \).

Clearly such a \( t \) is determined on objects and on 1-cells of the form \( u^* \) by \( s = t|_{\mathcal{G}_i} \).

By Lemma A.3.11, the component \( t(i)_i \) has to be the left mate \( s(i^{-1})_i \) of \( t(i^*)^{-1} = s(i)^{-1} \) for each \( i \in \mathcal{J} \). Furthermore, the functoriality axiom of transformations (with respect to the composite \( i \circ u^* \) and the naturality axiom (with respect to the isomorphism \( \zeta : i_1 u^* \Rightarrow i_1 \circ u^* \) of Remark 5.1.15) uniquely determine
the component \( t(i_1 u^*) \) at every 1-cell \( i_1 u^* \) of \( \text{Span} \) by the following pasting:

(5.3.10)

Hence the extension \( t: G_1 \Rightarrow G_2 \) is uniquely determined by \( G_1, G_2 \) and \( s \). Straightforward but lengthy calculations (which we defer until Lemma 5.3.12) show that \( t \) is indeed a transformation, as claimed. Clearly \( t \) is strong precisely because \( s = t|_G \) is \( J_i \)-strong. Direct verification shows that the above construction \( s \mapsto t \) is the inverse of \( t \mapsto t \circ (-)^* \). So (5.3.9) is indeed an isomorphism of (1-)categories.

Let us now consider modifications. Every modification \( M: t \Rightarrow t' \) of transformations \( t, t': G_1 \Rightarrow G_2 \) of pseudo-functors \( G_1, G_2: \text{Span}(G; J) \to C \) restricts to a modifications of the restricted transformations \( t, t': G_1 \circ (-)^* \Rightarrow G_2 \circ (-)^* \). In fact, the data for \( M \) or for its restriction is the same: a family \( \{M_G: t_G \Rightarrow t'_G\} \) of 2-cells of \( C \) indexed by \( G_0 = \text{Span}(G; J)_0 \). Suppose we are given such a family \( M \).

We now claim that if \( M \) satisfies the modification axiom

(5.3.11)

for all spans of the form \( u^*: G \to P \) (i.e. if it defines a modification of the restricted transformations), then it also satisfies

for general spans \( i u^*: G \leftarrow P \to H \) (i.e. \( M \) automatically defines a modification of the original transformations of pseudo-functors on \( \text{Span}(G; J) \)). Indeed, by (5.3.10)
we may reduce the verification to spans of the form $i_t$. Now recall that the components $t(i_t), t'(i_t)$ at $i_t$ can be recovered as the left mates of $t(i^*)^{-1}, t'(i^*)^{-1}$. The diagram

```
\begin{tikzpicture}
  \node (P1) at (0,0) {$G_1 P$};
  \node (H1) at (2,0) {$G_1 H$};
  \node (P2) at (4,0) {$G_2 P$};
  \node (H2) at (6,0) {$G_2 H$};
  \node (Q1) at (0,2) {$G_1 i^*$};
  \node (Q2) at (6,2) {$G_2 i^*$};
  \draw[->] (P1) to node [midway, above] {$\varepsilon$} (H1);
  \draw[->] (H1) to node [midway, above] {$t_H$} (P2);
  \draw[->] (P2) to node [midway, below] {$\eta_p$} (H2);
  \draw[->] (H2) to node [midway, below] {$t'_P$} (P1);
  \draw[->, dotted] (P1) to node [midway, left] {$\varepsilon M_{G_1}$} (Q1);
  \draw[->, dotted] (P2) to node [midway, right] {$\varepsilon M_{G_2}$} (Q2);
  \draw[->] (Q1) to node [midway, left] {$G_1 i^*$} (P1);
  \draw[->] (Q2) to node [midway, right] {$G_2 i^*$} (P2);
\end{tikzpicture}
```

computes both mates in parallel and shows that in order to derive the axiom for $i_t$ it suffices to apply (5.3.11) with $u = i$. This shows that (5.3.9) upgrades to a 2-functor which, as we have seen, must be a locally strict bi-equivalence. This proves the theorem in the case the target is a strict 2-category.

Finally if $B$ is any bicategory, choose a bi-equivalence $B \xrightarrow{\sim} C$ to some 2-category $C$ (Remark A.1.16). It induces a commutative square of pseudo-functors

$$
\begin{array}{ccc}
\text{PsFun} \left( \text{Span}(G; I), B \right) & \xrightarrow{\sim} & \text{PsFun}_{B^\text{op}} \left( G^\text{op}, B \right) \\
\downarrow & & \downarrow \\
\text{PsFun} \left( \text{Span}(G; I), C \right) & \xrightarrow{\sim} & \text{PsFun}_{B^\text{op}} \left( G^\text{op}, C \right)
\end{array}
$$

where the bottom one is a bi-equivalence by the special case of the theorem we have already proved, and the vertical ones are bi-equivalences by Remark A.1.15. We deduce that the top pseudo-functor is also a bi-equivalence (note however there is no reason for it to be locally strict).

The proof of the theorem is almost complete. We still owe the reader the following:

**5.3.12. Lemma.** With notation as above, the 2-cells in (5.3.10) define an oplax transformation $t : G_1 \Rightarrow G_2$.

**Proof.** Let $F_1 := G_1 \circ (-)^*$ and $F_2 := G_2 \circ (-)^* : G^\text{op} \to C$ be the restrictions to $G^\text{op}$ of our two pseudo-functors $G_1, G_2 : \text{Span} \to C$. We are also given a transformation $t = (t_G, t(u))_{G \in G_0, u \in G_1} : F_1 \Rightarrow F_2$ (or actually just an oplax transformation $t$ with the property that $t(i)$ is invertible for all $i \in I$) and we must show that the 2-cells in (5.3.10) extend $t$ to a transformation $t = (t_G, t(i_t u^*)) : G_1 \Rightarrow G_2$. For this, we may as well assume that $G_1$ and $G_2$ are equal to the extensions on $\text{Span}$ of $F_1$ and $F_2$ as in Construction 5.2.3, since they are isomorphic as pseudo-functors. We will also omit the canonical isomorphisms $i_t u^* \cong i_t \circ u^*$ from the computations, as they immediately cancel out anyway.

We compute with string diagrams, as before using dotted strings to denote the images in $C$ under $G_1, G_2$ of the 1-cells in $\text{Span}(G; I)$ of the form $i_t$ for $i \in I$ (i.e. the adjoint 1-cells $(F_1 i)_t$ and $(F_2 i)_t$). The string forms of the transformation axioms can be found in Example A.3.10.
Thus (5.3.10) becomes

\[
\begin{aligned}
t(\eta_{1u^*}) &= \\
&= G_2(i_{1u^*}) = id \\
&= (t(i)\nu_1)^{-1} = id \\
&= \eta_{1u^*}
\end{aligned}
\]

where necessarily \( t(\eta_1) = (t(i)\nu_1)^{-1} \) is the left mate of the inverse of \( t(i) \), as we have seen. (Cf. Lemma A.3.11.)

Let \( \alpha = [a, \alpha_1, \alpha_2] : i_{1u^*} \Rightarrow j_{1v^*} \) be any 2-cell of \( \text{Span} \) as in (5.1.7). The naturality axiom is verified by the following computation:
The proofs of the compatibility with fun and un are quite similar and are left as an exercise for the reader. □

This completes the proof of Theorem 5.3.7. □

5.3.13. Remark. The above proof yields a more general biequivalence on bicategories of pseudo-functors and oplax transformations, which actually restricts to the one of the statement.

To explain this, let $G_1, G_2 : \text{Span}(G; J) \rightarrow B$ be two pseudo-functors. Let $F_1 = G_1 \circ (-)^*$ and $F_2 = G_2 \circ (-)^*$ be the corresponding $J$-pseudo-functors $G^{\text{op}} \rightarrow B$.

As we saw in Remark 5.3.4, our focus on $J$-strong transformations $t : F_1 \Rightarrow F_2$ is related to the desire of $t_i : (F_1)_i \Rightarrow (F_2)_i$ to be an actual strong transformation, not only an op-lax one, and the proof of Theorem 5.3.7 used this property to extend $t$ to a strong transformation $t : G_1 \Rightarrow G_2$; see (5.3.10).

Relaxing both sides, if we consider an oplax transformation $G_1 \Rightarrow G_2$ and restrict it along $(-)^*$ we evidently obtain an oplax transformation $t : F_1 \Rightarrow F_2$ but not any oplax transformation! Because of Lemma A.3.11, $t : F_1 \Rightarrow F_2$ must have the property that the component $t_i$ is invertible for every $i \in J$, because $F_1$ and $F_2$ factor as $G_1^{\text{op}} \xrightarrow{\sim} \text{Span} \rightarrow B$ and $i^*$ has a left adjoint in the intermediate bicategory $\text{Span}(G; J)$. Conversely, if we start with an oplax transformation $t : F_1 \Rightarrow F_2$ which has the property that its component $t_i$ is invertible, then we can consider its left mate to define $t(i)_i : G_1(i)_i \Rightarrow G_2(i)_i$ as in the proof of Theorem 5.3.7. The very same proof then gives the following oplax version.

5.3.14. Scholium. Precomposition with $(-)^* : G^{\text{op}} \rightarrow \text{Span}(G; J)$ induces a biequivalence

$$\text{PsFun}^{\text{oplax}}(\text{Span}(G; J), B) \xrightarrow{\sim} \text{PsFun}_{J-\text{oplax}}^{\text{J-\text{oplax}}}(G^{\text{op}}, B)$$

where the left-hand side is the bicategory of pseudo-functors, oplax transformations and modifications, and the right-hand side is the bicategory of $J$-pseudo-functors (Definition 5.3.1), oplax transformations $t$ with the property that $t_i$ is invertible for all $i \in J$ (4), and modifications between them.

---

4 One could call these ‘$J$-strong’, not to be confused with the $J_1$-strong of Definition 5.3.2.
5.3.15. Remark. We can recover [DPP04, Prop. 1.10] as a very special case of our Theorem 5.3.7. First note that if we set $\mathcal{J} = \mathcal{G}_1$ and take $\mathcal{G}$ to be a 1-category (i.e. a (2,1)-category where the only 2-arrows are the identities), then the situation is completely symmetric with respect to span transposition. In this case, there is a dual statement, with a dual proof, for the covariant embedding $\mathcal{G} \to \text{Span}(\mathcal{G}; \mathcal{J})$ (Construction 5.1.18). By forgetting modifications in the latter, it becomes precisely the result of loc. cit.

5.4. Pullback of 2-cells in the bicategory of spans

For the whole section, we abbreviate

$$\text{Span} := \text{Span}(\mathcal{G}; \mathcal{J}) .$$

So for instance $\text{Span}(G, H)$ means $\text{Span}(\mathcal{G}; \mathcal{J})(G, H)$ for every $G, H \in \mathcal{G}_0$. Recall Hypotheses 5.1.1, including part (c), i.e. the faithfulness of every $i \in \mathcal{J}$. One reason for requiring this is the following very convenient consequence.

5.4.1. Proposition. For all $G, H \in \mathcal{G}_0$, the category $\text{Span}(G, H)$ admits arbitrary pullbacks (in the usual strict sense). They are induced by the comma squares in $\mathcal{G}$.

Proof. It is well-known that iso-comma squares provide the homotopy pullbacks in the homotopy category of small groupoids, where the ordinary equivalences are inverted (cf. Remark 2.2.6). Here we need something stronger, because we claim extra compatibility and unicity properties for the map induced by the usual weak pullback property of homotopy pullbacks.

Consider the following (left-hand) cospan of maps of $\text{Span}(G, H)$, represented in $\mathcal{G}$ by the diagram on the right-hand side:

\[
\begin{array}{ccc}
G & \rightarrow & P \\
\downarrow_{\alpha_1} & & \downarrow_{\alpha_2} \\
\downarrow_{w} & & \downarrow_{k} \\
G & \rightarrow & H \\
\end{array}
\]

\[
\begin{array}{ccc}
P & \rightarrow & H \\
\downarrow_{\beta_1} & & \downarrow_{\beta_2} \\
\downarrow_{b} & & \downarrow_{j} \\
Q & \rightarrow & H \\
\end{array}
\]

\[
\begin{array}{ccc}
iu & \rightarrow & u \\
\downarrow_{[a]} & & \downarrow_{[b]} \\
\downarrow_{[a, \alpha_1, \alpha_2]} & & \downarrow_{[b, \beta_1, \beta_2]} \\
\downarrow_{k_v u^*} & & \downarrow_{j_v^*} \\
\end{array}
\]

Construct in $\mathcal{G}$ an iso-comma square over the cospan appearing in the middle column:
We can now complete the span \( P \xleftarrow{\tilde{b}} (a/b) \xrightarrow{\tilde{a}} Q \) to represent a pair of 2-cells in \( \text{Span} \):

\[
(5.4.3)
\]

\[
\begin{tikzpicture}
  \node (G) at (0,0) {G};
  \node (P) at (2,2) {P};
  \node (H) at (4,0) {H};
  \node (Q) at (2,-2) {Q};
  \draw[->] (G) -- (P) node[midway,above] {\(u\)};
  \draw[->] (P) -- (H) node[midway,above] {\(i\)};
  \draw[->] (Q) -- (G) node[midway,below] {\(i^*\)};
  \draw[->] (Q) -- (P) node[midway,below] {\(u^*\)};
  \draw[->] (Q) -- (H) node[midway,below] {\(j^*\)};
  \draw[->] (G) -- (Q) node[midway,above] {\(\beta_1^{-1}\)};
  \draw[->] (G) -- (H) node[midway,above] {\(\alpha_1^{-1}\)};
  \draw[->] (P) -- (Q) node[midway,below] {\(\alpha_2^{-1}\)};
  \draw[->] (H) -- (P) node[midway,above] {\(\beta_2^{-1}\)};
  \draw[->] (P) -- (Q) node[midway,below] {\(\gamma\)};
\end{tikzpicture}
\]

Note that there is also another possible, isomorphic, choice for such a diagram, where the \(\gamma\)'s appear in the top half, i.e. as part of the 2-cell \([\tilde{b}]\). We are going to test the universal property of a pullback in \( \text{Span}(G,H) \) for the resulting square:

\[
(5.4.4)
\]

Suppose we are given a pair of 2-cells

\[
\begin{tikzpicture}
  \node (G) at (0,0) {G};
  \node (T) at (2,2) {T};
  \node (H) at (4,0) {H};
  \node (P) at (2,-2) {P};
  \node (Q) at (4,-2) {Q};
  \draw[->] (G) -- (T) node[midway,above] {\(u\)};
  \draw[->] (T) -- (H) node[midway,above] {\(\ell\)};
  \draw[->] (G) -- (P) node[midway,below] {\(r\)};
  \draw[->] (P) -- (H) node[midway,below] {\(s\)};
  \draw[->] (G) -- (Q) node[midway,above] {\(s\)};
  \draw[->] (Q) -- (H) node[midway,above] {\(\ell\)};
\end{tikzpicture}
\]

such that \([a,\alpha_1,\alpha_2][r,\rho_1,\rho_2] = [b,\beta_1,\beta_2][s,\sigma_1,\sigma_2]\) as 2-cells from \(\ell_1x^*\) to \(k_1w^*\). The latter equation means that there exists an isomorphisms \(\varphi: a\tilde{r} \Rightarrow b\tilde{s}\) identifying its left and right 2-cell components as in Definition 5.1.6:

\[
(5.4.5)
\]

In particular, by the universal property of the comma object \(a/b\) there is a unique 1-cell \(t = (r,s,\varphi): T \to (a/b)\) of \(\mathbb{G}\), i.e. such that

\[
(5.4.6)
\]

\(\tilde{b}t = r, \quad \tilde{a}t = s\) and \(\gamma t = \varphi\).
Complete \( t \) to a 2-cell \( [t] := [t, \ldots] \in \text{Span}_a \) as follows:

\[
\begin{array}{c}
G \xleftarrow{x} T \xrightarrow{\ell} H \\
\downarrow \alpha_1 \quad \downarrow \rho_1 \quad \downarrow t \quad \downarrow r \quad \downarrow \rho_2 \quad \downarrow i \quad \downarrow \alpha_2 \\
G \xleftarrow{w} R \xleftarrow{a} P \xrightarrow{a/b} P \xrightarrow{a} R \xrightarrow{k} H.
\end{array}
\]

We must verify that \( [\tilde{b}[t] = [r] \) and \( [\tilde{a}[t] = [s] \) as 2-cells of \( \text{Span} \). In fact, these are even \textit{strict} equalities of diagrams in \( G \), because we evidently have

\[
\begin{array}{c}
G \xleftarrow{x} T \xrightarrow{\ell} H \\
\downarrow \alpha_1^{-1} \quad \downarrow \rho_1^{-1} \quad \downarrow t \quad \downarrow r \quad \downarrow \rho_2^{-1} \quad \downarrow i \quad \downarrow \alpha_2^{-1} \\
G \xleftarrow{u} P \xrightarrow{i} H
\end{array}
\]

and also, slightly less obviously,

\[
\begin{array}{c}
G \xleftarrow{x} T \xrightarrow{\ell} H \\
\downarrow \alpha_1^{-1} \quad \downarrow \rho_1^{-1} \quad \downarrow t \quad \downarrow r \quad \downarrow \rho_2^{-1} \quad \downarrow i \quad \downarrow \alpha_2^{-1} \\
G \xleftarrow{v} Q \xrightarrow{j} H
\end{array}
\]
Let us also note, for future reference, that the right-hand side of the latter identification amounts to the following identity of 2-cells in $G$:

\[
\ell \rightarrow \rightarrow s = \tilde{t} \downarrow \downarrow \tilde{a} \quad \sigma_2 \leftarrow \leftarrow \sigma_1
\]

(5.4.7)

Now it only remains for us to verify the uniqueness of the induced 2-cell $[t]$ in $\text{Span}$. Suppose we are given another 2-cell $[t']$ such that

\[
[\tilde{b}] [t'] = [r] \quad \text{and} \quad [\tilde{a}] [t'] = [s].
\]

(5.4.8)

We must show that $[t'] = [t]$, and for this we will use the morphism part of the universal property of $a/b$ to construct a suitable isomorphism $\theta: t' \cong t$. 
The 2-cell $[t']$ is represented by a diagram

$$
\begin{gathered}
  \xymatrix{
    G & x & T & \ell \\
    G & w & R & a & P & a/b & P & a & R & H \\
    G & \ar[r]_{w} & R & \ar[r]_{a} & P & \ar[r]_{a/b} & P & \ar[r]_{a} & R & \ar[r]_{k} & H
  }
  \end{gathered}
$$

and the two equations (5.4.8) are realized by isomorphisms $\zeta : \tilde{b}t' \Rightarrow r$ and $\xi : \tilde{a}t' \Rightarrow s$ as follows:

$$
\begin{gathered}
  \xymatrix{
    G & x & T & \ell & H \\
    G & w & R & a & P & a/b & P & a & R & H \\
    G & \ar[r]_{w} & R & \ar[r]_{a} & P & \ar[r]_{a/b} & P & \ar[r]_{a} & R & \ar[r]_{k} & H
  }
  \end{gathered}
\quad \begin{array}{c}
  \zeta \\
  \rho_1 \quad \beta_1^{-1} \quad \beta_2^{-1} \quad \xi \\
  \sigma_1 \quad \sigma_2
\end{array}
$$

which read

\begin{align*}
(5.4.9) & \quad (u \zeta)(\alpha_1^{-1}\tilde{b}t')\tau_1 = \rho_1 \\
(5.4.10) & \quad \tau_2(\alpha_2^{-1}\tilde{b}t') = \rho_2(i \zeta) \quad \text{hence} \quad \rho_2^{-1}\tau_2 = (i \zeta)(\alpha_2\tilde{b}t') \\
(5.4.11) & \quad \tau_2(\gamma^{-1}t')(\beta_2^{-1}\tilde{a}t') = \sigma_2(j \xi) \\
(5.4.12) & \quad \tau_2(\gamma^{-1}t')(\beta_2^{-1}\tilde{a}t') = \sigma_2(j \xi) \quad \text{hence} \quad \sigma_2^{-1}\tau_2 = (j \xi)(\beta_2\tilde{a}t')(k \gamma t')
\end{align*}

Thus we have in $G$ two parallel 1-cells $t', t : T \rightarrow a/b$ and two 2-cells $\zeta : \tilde{b}t' \Rightarrow r = \tilde{b}t$ and $\xi : \tilde{a}t' \Rightarrow s = \tilde{a}t$. From the following computation

$$
\begin{aligned}
  \xymatrix{
    & t' & \ar@{=>}[d]^s & t \\
  \ar[ru]^{\gamma} & a & \ar@{=>}[ru]^\bar{b} & b \\
  \ar[ru]^{\bar{a}} & b & \ar@{=>}[ru]^{\bar{a}} & a \\
  & k & \ar[ru]_{\bar{b}} & a
  } & = & \begin{aligned}
    \xymatrix{
      & t' & \ar@{=>}[d]^s & t \\
      \ar[ru]^{\gamma} & a & \ar@{=>}[ru]^\bar{b} & b \\
      \ar[ru]^{\bar{a}} & b & \ar@{=>}[ru]^{\bar{a}} & a \\
      & k & \ar[ru]_{\bar{b}} & a
      
    } & \quad (5.4.12)
  \end{aligned}
\end{aligned}
$$
and the faithfulness of \( k \in \mathfrak{J} \), we deduce:

\[
\begin{array}{c}
\begin{array}{c}
\xymatrix@C=2pc@R=2pc{ & A 
\ar[dr]^{\gamma} & \\
\ar[r]_{\alpha_2} & b 
\ar[ru]_{\alpha_2} & \\
& C 
\ar[ur]_{\gamma} & \\
\ar[rr]_{k} & & \\
\end{array}
\end{array}
\end{array}
\]

Hence by the universal property of \( a/b \) in Definition 2.1.1 (b) there exists a (unique) 2-cell \( \theta : t' \Rightarrow t \) in \( G \) such that

\[
(5.4.13) \quad \tilde{b}\theta = \zeta \quad \text{and} \quad \tilde{a}\theta = \xi.
\]

Finally, we claim that \( \theta \) provides an isomorphism \([t'] = [t]\) (see (5.4.6) for \([t]\)):
Indeed, the two required identities hold as follow:

\[
\begin{array}{c}
\begin{array}{c}
\xymatrix{ x \ar[r]_{g} & t' \\
\ar[u]^\tau_1 & a \ar[ru]^u \ar[ld]^w & \\
& w & \\
\end{array} \\
(5.4.13) \\
\end{array}
\end{array}
\]

\[
\begin{array}{c}
\begin{array}{c}
\xymatrix{ \tau_1 & a \ar[u]^u \ar[ld]^w & \\
\ar[ru]^a & \ar[l]^w & \\
& a & \\
\end{array} \\
(5.4.9) \\
\end{array}
\end{array}
\]

\[
\begin{array}{c}
\begin{array}{c}
\xymatrix{ \rho_1 & a \ar[u]^u \ar[ld]^w & \\
\ar[ru]^a & \ar[l]^w & \\
& a & \\
\end{array} \\
(5.4.10) \\
\end{array}
\end{array}
\]

\[
\begin{array}{c}
\begin{array}{c}
\xymatrix{ \tau_2 & a \ar[u]^u \ar[ld]^w & \\
\ar[ru]^a & \ar[l]^w & \\
& a & \\
\end{array} \\
\end{array}
\end{array}
\]

for the left-hand components. The right-hand ones hold as follows:

\[
\begin{array}{c}
\begin{array}{c}
\xymatrix{ t' \ar[r]_{g} & r \\
\ar[u]^\tau_1 & a \ar[ru]^u \ar[ld]^w & \\
& w & \\
\end{array} \\
(5.4.13) \\
\end{array}
\end{array}
\]

\[
\begin{array}{c}
\begin{array}{c}
\xymatrix{ \zeta & a \ar[u]^u \ar[ld]^w & \\
\ar[ru]^a & \ar[l]^w & \\
& a & \\
\end{array} \\
(5.4.13) \\
\end{array}
\end{array}
\]

\[
\begin{array}{c}
\begin{array}{c}
\xymatrix{ \rho_2 & a \ar[u]^u \ar[ld]^w & \\
\ar[ru]^a & \ar[l]^w & \\
& a & \\
\end{array} \\
(5.4.10) \\
\end{array}
\end{array}
\]

This proves our last remaining claim, namely \([t'] = [t]\) via the isomorphism \(\theta\). □

**5.4.14. Lemma.** The horizontal composition functors \(- \circ -\) of \(\text{Span}\) preserve the pullbacks of Proposition 5.4.1 in both variables.

**Proof.** This is essentially just a commutativity property for iso-comma squares, but we still sketch an explicit proof. Let \(\circ = \circ_{G,H,K} : \text{Span}(H,K) \times \text{Span}(G,H) \to \text{Span}(G,K)\) be one of the composition functors, and let \(\ell \chi x^* = (G \xleftarrow{\ell} S \to H) \in \text{Span}(G,H)\). It suffices to check that \(- \circ (\ell \chi x^*)\) preserves pullbacks, as the proof for the other variable is the same.

Consider a cospan \(\bullet \xleftarrow{\alpha} \bullet \xrightarrow{\beta} \bullet\) of maps in \(\text{Span}(H,K)\)
and construct its pullback by the following diagram, as in (5.4.3):

![Diagram]

The verification that $- o (f; x^*)$ preserves this pullback diagram boils down to checking that the induced 1-cell $f$ in the diagram below is an equivalence:

![Diagram](the unlabeled arrows are the canonical projections). This can be checked in CAT after applying $\text{Span}(T, -)$ and identifying $\text{Span}(T, ??)$ with $\text{Span}(T, ?)/\text{Span}(T, ??)$, as in Remark 2.1.6 (compare the proof of Proposition 5.1.21). In CAT, the functor $\Phi := \text{Span}(T, f)$ sends

$$(s, (p, q, ap \xrightarrow{\varphi} b q), \ell s \xrightarrow{\delta} w a p)$$

in $\text{Span}(T, (S/\mathcal{H} P) /_{S/\mathcal{H} R} (S/\mathcal{H} Q))$. We can define a functor in the opposite direction

$$\Psi : \text{Span}(T, (S/\mathcal{H} P) /_{S/\mathcal{H} R} (S/\mathcal{H} Q)) \to \text{Span}(T, S/\mathcal{H} (P/\mathcal{R} Q))$$
by mapping
\[
\left( s_1, (p, q, \ell s_1 \xrightarrow{\xi} bq), (s_2, q, \ell s_2 \xrightarrow{\beta_1} wq) \right),
\]
to
\[
\left( s_1, (p, q, \ell \xi \xrightarrow{\xi} bq), \ell s_1 \xrightarrow{(\alpha^{-1}p)\xi} wap \right),
\]
and one checks immediately that \( \Psi \Phi = \text{Id} \) and \( \Phi \Psi \cong \text{Id} \). \qed

5.5. Heuristic account and the 2-dual version

Of course, instead of creating left adjoints in the construction of \( \text{Span}(G; \mathcal{J}) \) in Section 5.1, we could equally well create a universal bicategory with right adjoints. In this short section, we explain the dual story by staying as close as possible to the 'left' \( \text{Span}(G; \mathcal{J}) \) studied so far. This approach will help us understand the ambidextrous bicategory of 2-motives that comes in Section 6.1. But first, we review the original construction of \( \text{Span}(G; \mathcal{J}) \) from a slightly less formal perspective.

Suppose we know nothing and want to construct a universal left-adjoint-creating bicategory \( \text{Span}(G; \mathcal{J}) \), that receives \( G \) contravariantly on 1-cells. This bicategory has to contain a 1-cell \( v^*: G \to H \) for every \( v: H \to G \) in \( G \) and a 1-cell \( i^*: G \to H \) left adjoint to \( i^* \) for every \( i: G \to H \) in \( \mathcal{J} \). Just from these basic 1-cells, and before even invoking 2-cells, we must also already expect zig-zags of 1-cells of the type \( \epsilon / \alpha \) and \( i \). The Mackey formula allows us to reduce such arbitrary zig-zags to a single short zig-zag, or span, of the form \( ii' \). The 'horizontal' composition of two such 1-cells \( G \xLeftarrow{p} P \xrightarrow{v} H \xLeftarrow{q} Q \xrightarrow{j} K \) is circumvented by flipping the middle cospan

\[
\begin{align*}
\begin{array}{c}
P \\
\xLeftarrow{p} \xrightarrow{v} \xLeftarrow{q} \\
\xrightarrow{i} \xLeftarrow{i'} \\
G \xrightarrow{u} H \xLeftarrow{\gamma} Q \xrightarrow{j} K
\end{array}
\end{align*}
\]

into \( ji \circ (v^* \circ ii') \circ u^* \cong ji \circ (i'_i \circ v'^*) \circ u^* \cong (ji'_{ii'})^{-1}(uv')^* \); the result is again a single span with the \((-)-\)-part in \( \mathcal{J} \), as wanted. Then, with \( i_i = [{\xi \xrightarrow{p} \beta_1}] \) and \( u^* = [{\epsilon \xrightarrow{\alpha^{-1}p} \beta_1}] \), we proved (using suitable 2-cells) that \( ii' \circ u^* \cong ii'u^* \) in the reassuring Remark 5.1.15. Thus we have a fair understanding of what 1-cells in \( \text{Span}(G; \mathcal{J}) \) ought to be.

Of course, ignoring 2-cells is not possible, and not only because of the many canonical isomorphisms \( \cong \) of 1-cells involved in horizontal composition, as in the previous paragraph. More importantly, \( ii \) cannot be a left adjoint to \( i^* \) unless we have adequate 2-cells to serve as unit \( \text{Id} \Rightarrow ii \) and counit \( ii^* \Rightarrow \text{Id} \). Note that the counit 2-cell \( ii^* \Rightarrow \text{Id} \) only involves our chosen short zig-zags but the unit \( \text{Id} \Rightarrow ii^* \) involves a zig-zag \( i^* \circ ii \). The latter aside, let us focus on 2-cells which are reasonably straightforward to express in terms of short zig-zags \( \alpha^* \circ i = [{\xi \xrightarrow{\alpha^{-1}p} \beta_1}] \) that needs to be circumvented via Mackey.

Leaving the latter aside, let us focus on 2-cells which are reasonably straightforward to express in terms of short zig-zags \( \alpha^* \circ i = [{\xi \xrightarrow{\alpha^{-1}p} \beta_1}] \).

(1) The 2-cells \( \alpha^* : u^* \Rightarrow v^* \) associated to every 2-cell \( \alpha : u \Rightarrow v \) in \( G \).
The mates of the above when left adjoints exist, i.e. for each \( \alpha : i \Rightarrow j \) in \( \mathcal{J} \) there should be a 2-cell \( \alpha_1 : j_1 \Rightarrow i_1 \) in our bicategory, mate of \( \alpha^* : i^* \Rightarrow j^* \).

The counit \( \varepsilon : a_0 a^* \Rightarrow \text{Id} \) for every 1-cell \( a \in \mathcal{J} \). These can also be ‘squeezed’ in the middle of a 2-cell \( ji^* \) (when it make sense) to give new 2-cells

\[
(ja)i_1(va)^* \cong j_1 a_1 a^* v^* \Rightarrow j^* v^*.
\]

Assembling those three building blocks, we can see how a 2-cell from \( i u^* \) to \( j v^* \) in \( \text{Span}(\mathcal{G};\mathcal{J}) \) should indeed contain those three types of information, as in Definition 5.1.32, or pictorially:

\[
\begin{array}{c}
\begin{array}{c}
G \\
\end{array}
\end{array}
\xymatrix{ & \ar@/_/[r]^{u} \ar@{=>}[d]_{a_1} \ar@{=>}[l] & \ar@{=>}[l]_{a_2} \ar@/^/[d]^{i} P \\
\ar@{=>}[d]_{v} \ar@{=>}[l]_{\varepsilon} \ar@{=>}[r] & H \ar@{=>}[d]_{j} \\
\begin{array}{c}
G \\
\end{array}
\end{array}
\]

The \( \alpha_1 \) goes “from \( u \) towards \( v \)” as in (1) but the \( \alpha_2 \) goes backwards, “from \( j \) towards \( i^* \)” as in (2). More precisely, using \( a = \text{Id} \), we have \( \alpha^* = [\text{Id}, \alpha, \text{id}] : u^* \Rightarrow v^* \) for any \( \alpha : u \Rightarrow v \) in \( \mathcal{G} \) and \( \alpha_1 = [\text{Id}, \text{id}, \alpha] : i_1 \Rightarrow j_1 \) for \( \alpha : j \Rightarrow i \) in \( \mathcal{J} \). These are the definitions of \( \alpha^* \) and \( \alpha_1 \) that appear in Construction 5.1.18. Finally, the 1-cell \( a \in \mathcal{J} \) goes “from \( i u^* \cong (ja)(va)^* \) towards \( j v^* \)” as in (3). Specifically, \( \varepsilon = [a, \text{id}, \text{id}] : a a^* \Rightarrow \text{id} \) is the counit of \( \alpha_1 \circ a^* \) as we saw in (5.1.23).

Similarly to what happened with 1-cells (namely \( i \circ u^* \cong i t u^* \)), we saw in Proposition 5.1.32 that all 2-cells of \( \text{Span}(\mathcal{G};\mathcal{J}) \) are generated by these three basic 2-cells (1)-(2)-(3), together with the structure isomorphisms for the pseudo-functors \( (-)^* : \mathcal{G}^{op} \to \text{Span}(\mathcal{G};\mathcal{J}) \) and \( (-)_! : \mathcal{J}^{co} \to \text{Span}(\mathcal{G};\mathcal{J}) \) given in Remark 5.1.19.

At the level of 2-cells of \( \text{Span}(\mathcal{G};\mathcal{J}) \), let us return to one peculiarity of the left construction. In the list (1)-(2)-(3), the third one features the counit \( a_0 a^* \Rightarrow \text{id} \) but not the unit. (The emotive reader should not worry about the fate of this unit. It still survives via the mates of (2).) Therefore we should expect the right-adjoint-creating construction to involve a ‘dual’ version of (3), with only the unit of the \( i^* \to i \) adjunction playing a role, not the counit anymore.

The universal property of \( \text{Span}(\mathcal{G};\mathcal{J}) \) is proven by verifying that the now ‘obvious’ construction works. If \( \mathcal{F} : \mathcal{G}^{op} \to \mathcal{C} \) satisfies the ‘left Mackey conditions’ (a) and (b) of Theorem 5.2.1 then its extension \( \mathcal{G} : \text{Span}(\mathcal{G};\mathcal{J}) \to \mathcal{C} \) is \( \mathcal{F} \) on 0-cells, maps a 1-cell \( i u^* \to \mathcal{F}(i) : \mathcal{F}(u) \) and maps a 2-cells \( [a, \alpha_1, \alpha_2] \) to the pasting (5.2.4) in \( \mathcal{C} \), corresponding under \( \mathcal{F} \) to the description of \( \alpha \) as a pasting in \( \text{Span}(\mathcal{G};\mathcal{J}) \), in the already mentioned Proposition 5.1.32.

This concludes our heuristic review of \( \text{Span}(\mathcal{G};\mathcal{J}) \); see details in Section 5.1.

* * *

In view of the above discussion, we can see how to modify our bicategory in order to have the universal construction of right adjoints. We again keep the same 0-cells as \( \mathcal{G} \). On top of the ‘old’ 1-cells \( u^* \) from \( \mathcal{G} \), we introduce for each \( i \in \mathcal{J} \) a new ‘forward’ 1-cell \( i_* \) meant to become right adjoint to \( i^* \). Using the Mackey formula carefully, we reduce every zig-zag of \( u^* \)'s and \( i_* \)'s to just one \( i_* u^* = \left[ \frac{i}{i_*} \right] \), which strongly resembles what we had before. And at the 2-cell level, adapting (1)-(2)-(3) above, we expect a similar story, namely:

(1\textsuperscript{co}) A 2-cell \( \beta^* : u^* \Rightarrow v^* \) for every 2-cell \( \beta : u \Rightarrow v \) in \( \mathcal{G} \).

(2\textsuperscript{co}) A 2-cell \( \beta_* : j_* \Rightarrow i_* \) for each \( \beta : i \Rightarrow j \) in \( \mathcal{J} \).
5.5. HEURISTIC ACCOUNT AND THE 2-DUAL VERSION

(3°) A unit \( \text{Id} \Rightarrow b^*b_* \) for every 1-cell \( b \in J \), which can also be ‘squeezed’ in the middle of suitable 2-cells \( j_*v^* \), as follows: \( j_*v^* \Rightarrow j_*b_*b^*v^* \cong (jb)_*(vb)^* \).

Assembling them pictorially, we get the following 2-cells from \( i_*u^* \) to \( j_*v^* \):

\[
\begin{array}{c}
G \\
\beta_1 \downarrow \text{see (1°)} \\
\downarrow b \\
\beta_2 \downarrow \text{see (3°)} \\
Q \\
\beta_2 \downarrow \text{see (2°)} \\
\downarrow j \\
H.
\end{array}
\]

(5.5.2) \( [b, \beta_1, \beta_2] = \)

Note in particular the reversal of \( b \) in the middle. This leads to the following auxiliary definition, 2-dual to Definition 5.1.6:

5.5.3. Notation. We denote by \( \text{Span}'(G; J) \) the following bicategory:

- The 0-cells of \( \text{Span}'(G; J) \) are those of \( G \), i.e. the same as those of \( \text{Span}(G; J) \).
- The 1-cells of \( \text{Span}'(G; J) \) are spans \( i_*u^* := [\xymatrix@C=1pc{u \ar[r] & i} \] with \( i \in J \), i.e. again the same as those of \( \text{Span}(G; J) \), up to renaming \( i_!u^* \) into \( i_*u^* \).
- The 2-cells of \( \text{Span}'(G; J) \), between \( i_*u^* \) and \( j_*v^* \) are isomorphism classes \( [b, \beta_1, \beta_2] \) of double 2-cells as in (5.5.2), under the essentially obvious notion of isomorphism, completely analogous to that of Definition 5.1.6.
- Horizontal composition uses iso-commas as in Definition 5.1.6.
- Vertical composition of 2-cells is the obvious pasting.

This bicategory \( \text{Span}'(G; J) \) receives \( G \) and \( J \) via

\[
(-)^* : G^{\text{op}} \hookrightarrow \text{Span}'(G; J) \quad \text{and} \quad (-)_* : J^{\text{co}} \hookrightarrow \text{Span}'(G; J)
\]

defined naturally by the identity on 0-cells, by \( u^* = [\xymatrix@C=1pc{u} \) and \( i_* = [\xymatrix@C=1pc{i} \) on 1-cells and by \( \beta^* = [\text{Id}, \beta, \text{id}] \) and \( \beta_1 = [\text{Id}, \text{id}, \beta] \) on 2-cells, as in Construction 5.1.18.

A hurried reader might think that \( \text{Span}'(G; J) \) is nothing but \( \text{Span}(G; J)^{\text{co}} \). This is essentially true up to a small subtlety in (5.5.2). The direction of \( b \) is indeed opposite to that of \( a \) in (5.5.1) but the \( \beta \)'s go in the same direction as the \( \alpha \)'s. In other words, if one simply reverted the \( b \)'s to try to identify \( \text{Span}'(G; J) \) with \( \text{Span}(G; J)^{\text{co}} \), that is, if we flip (5.5.2) upside down, we get

\[
\begin{array}{c}
G \\
\beta_1 \downarrow \text{see (3°)} \\
\downarrow b \\
\beta_2 \downarrow \text{see (1°)} \\
Q \\
\beta_2 \downarrow \text{see (2°)} \\
\downarrow j \\
H.
\end{array}
\]

with the \( \beta \)'s in the wrong direction. In the (2,1)-category \( G \), this can be fixed very easily by inverting the 2-cells of \( G \). In other words, the canonical isomorphism

\[
\text{Span}'(G; J) \cong \text{Span}(G; J)^{\text{co}}
\]
is the identity on 0-cells, is the renaming (identity) on 1-cells \( i \circ u^* \mapsto i \circ u^* \) but on 2-cells it involves inverting the 2-cells of \( G \):

\[
\begin{align*}
[b, \beta_1, \beta_2]: i \circ u^* & \Rightarrow j \circ v^* \quad \text{in } \text{Span}(G; J) \\
[b, \beta_1^{-1}, \beta_2^{-1}]: j \circ v^* & \Rightarrow i \circ u^* \quad \text{in } \text{Span}(G; J)
\end{align*}
\]

(5.5.5)

5.5.6. Construction. Under the isomorphism of bicategories (5.5.5), the canonical embeddings of (5.5.4) become the following:

\[
\begin{align*}
(-)^* &: G^\text{op} \to \text{Span}(G; J)^\text{co} \\
(-)^* &: J^\text{co} \to \text{Span}(G; J)^\text{co}
\end{align*}
\]

where the first one maps \( u: H \to G \) to \( u^* = [G \xleftarrow{u} H = H] \) and \( \beta: u \Rightarrow v \) to \([\text{Id}, \beta^{-1}, \text{id}]\), and the second one maps \( i: H \to G \) to \( i^* = [H = H \xrightarrow{i} G] \) and \( \beta: i \Rightarrow j \) to \([\text{Id}, \text{id}, \beta^{-1}]\). We draw the reader’s attention to the inverses appearing on 2-cells.

A last devilish detail is hidden in the left-vs-right Mackey formulas. A priori, for a functor \( F: G^\text{op} \to C \) to a bicategory in which each \( F_i \) admits a right adjoint \( (F_i)^* \), the Mackey condition (b) in Theorem 5.2.1 should say the following: For every (co) iso-comma with \( i \in J \)

\[
\begin{array}{ccc}
& v & j \\
H & \xleftarrow{i} & K \\
& \downarrow & \downarrow \\
i & \downarrow & u \\
G & \xleftarrow{u} & \end{array}
\]

(5.5.7)

the mate \( \delta*: u^*i^* \Rightarrow j^*v^* \) of \( \delta^*: j^*u^* \Rightarrow v^*i^* \) is an isomorphism. Note the co-comma \( (i/u) \) instead of \( (i/u) \) and the direction of the 2-cell, which is not anodyne since the position of \( i \) is imposed upon us in order to make sense in composition of spans (reduction of zig-zags). However, since we work with iso-comma, the above trick of inverting 2-cells yields a 1-to-1 correspondence between iso-commas and co-iso-commas. Whenever we state the right-adjoint versions by using ‘left’ iso-commas \( (i/u) \) we should expect an inverse \( \gamma^{-1} \) to enter the game.

In summary, we have the following dual to Theorem 5.2.1:

5.5.8. Theorem. Let \( G \) and \( J \) be as in Hypotheses 5.1.1. Let \( C \) be any 2-category, and let \( F: G^\text{op} \to C \) be a pseudo-functor such that

(a) for every \( i \in J \), there exists in \( C \) a right adjoint \( (F_i)^* \) to \( F_i \);
(b) the adjunctions \( F_i \dashv (F_i)^* \) satisfy base-change with respect to all Mackey squares with two parallel sides in \( J \), in the following sense: Given an iso-comma
square in $G$ with $i \in J$

\[
\begin{array}{c}
H \xleftarrow{(i/u)} \xrightarrow{j} K \\
\text{mate } (\gamma^{-1})_*: F \mu(F_i)_* \Rightarrow (F_j)_* \text{ of } (\gamma^{-1})^*: F_j F \mu \Rightarrow F \mu F_i \text{ with respect to the adjunctions } F_i \dashv (F_i)_*, \text{ and } F_j \dashv (F_j)_* \text{ is an isomorphism in } C(FH, FK).
\end{array}
\]

Then there exists a unique pseudo-functor $G: \text{Span}(G; J)^{co} \to C$ such that

\[
\begin{array}{ccc}
\text{Span}(G; J)^{co} & \xrightarrow{(-)^{**}} & C \\
\downarrow \text{id} & & \downarrow \text{id} \\
\end{array}
\]

is commutative, where $(-)^{**}: G \to \text{Span}(G; J)^{co}$ is the pseudo-functor of Construction 5.5.6. This extension $G$ is unique up to a unique isomorphism restricting to the identity of $F$, and is entirely determined by the choice of the left adjoints, with units and counits, for all $Fi$. Conversely, any pseudofunctor $F: G^{op} \to C$ factoring as above must enjoy the above two properties.

5.5.10. Construction. (Compare Construction 5.2.3.) Explicitly, $G$ is defined as follows. Assemble as in Remark A.2.10 all $(Fi)_*$ into a pseudo-functor $F_*: J^{co} \to C$. On 0-cells, the pseudo-functor $G: \text{Span}(G; J)^{co} \to C$ agrees with $F$. On 1-cells, set

\[
G(i_i^*) := F_*(i) \circ F(u) = (F_i)_* \circ (F_u).
\]

For a 2-cell $[b, \beta_1, \beta_2]: i_i^* \Rightarrow j_j^*$ of $\text{Span}(G; J)$ represented by a diagram

\[
\begin{array}{ccc}
G & \xrightarrow{u} & P \\
\downarrow \beta_1 & & \downarrow \beta_2 \\
G & \xrightarrow{v} & Q \\
\end{array}
\]

define its image $G([b, \beta_1, \beta_2]): G(j_j^*) \Rightarrow G(i_i^*)$ to be the following pasting in $C$:

\[
(5.5.11) \quad G([b, \beta_1, \beta_2]) =
\]
Note the presence of the inverses, which will compensate for the inverses involved in \((-)^{**}: \mathcal{G}^{\text{op}} \to \text{Span}(\mathcal{G}; \mathcal{J})^{\text{co}}\) of Construction 5.5.6, so that \(\mathcal{G} \circ (-)^{**} = \mathcal{F}\).

Let us finish with the ‘bicategorical upgrade’ (see Section 5.3) of the universal property of \(\text{Span}(\mathcal{G}; \mathcal{J})^{\text{co}},\) dual to the bicategorical upgrade for \(\text{Span}(\mathcal{G}; \mathcal{J})\) discussed in Theorem 5.3.7. In other words, let us add pseudo-natural transformations and modifications to Theorem 5.5.8. As in Definition 5.3.1 and Definition 5.3.2, we give a name to the relevant properties. We fix a target bicategory \(\mathcal{B}\).

5.5.12. Definition. A pseudo-functor \(\mathcal{F}: \mathcal{G}^{\text{op}} \to \mathcal{B}\) is called a \(\mathcal{J}_{*}-\text{pseudo-functor}\) if it satisfies conditions (a) and (b) of Theorem 5.5.8, namely:

(a) For every 1-cell \(i \in \mathcal{J}\), the 1-cell \(\mathcal{F}i\) admits a right adjoint \((\mathcal{F}i)_{*}\) in \(\mathcal{B}\).

(b) For every comma square \(\gamma\) along an \(i \in \mathcal{J}\), its mate \((\gamma^{-1})_{*}\) is invertible:

\[
\begin{array}{ccc}
X & \xleftarrow{v} & Y \\
\downarrow \gamma & & \downarrow \gamma^{-1} \\
Z & \xrightarrow{v} & W
\end{array}
\]

\[
\begin{array}{ccc}
\mathcal{F}X & \xleftarrow{(\mathcal{F}\gamma)_{*}} & \mathcal{F}Y \\
\downarrow \mathcal{F}v & & \downarrow \mathcal{F}v^{-1} \\
\mathcal{F}Z & \xrightarrow{\mathcal{F}v^{-1}} & \mathcal{F}W
\end{array}
\]

A (strong) pseudo-natural transformation \(t: \mathcal{F}_1 \to \mathcal{F}_2\) between two \(\mathcal{J}_{*}\)-strong pseudo-functors \(\mathcal{G}^{\text{op}} \to \mathcal{B}\) is \(\mathcal{J}_{*}\)-strong if for every \(i \in \mathcal{J}\) the following mate \((t_i)_{*}\)

\[
\begin{array}{ccc}
\mathcal{F}_1 X & \xrightarrow{\mathcal{F}_1 i} & \mathcal{F}_2 X \\
\downarrow t_{X} & & \downarrow t_{X}^{-1} \\
\mathcal{F}_1 Y & \xrightarrow{t_{Y}} & \mathcal{F}_2 Y
\end{array}
\]

\[
\begin{array}{ccc}
\mathcal{F}_1 X & \xrightarrow{(\mathcal{F}_1 i)^*} & \mathcal{F}_2 X \\
\downarrow \mathcal{F}_1 i & & \downarrow \mathcal{F}_1 i \\
\mathcal{F}_1 Y & \xrightarrow{t_{Y}} & \mathcal{F}_2 Y
\end{array}
\]

is invertible: \((t_i)_{*}: (\mathcal{F}_2 i)_{*} t_X \cong t_Y (\mathcal{F}_1 i)_{*}\). (Note that, this time, it is \((t_i^{-1})_{*}\) which would not make sense!)

5.5.14. Theorem. Let \(\mathcal{B}\) be a bicategory. Precomposition with the pseudo-functor \((-)^{**}: \mathcal{G}^{\text{op}} \to \text{Span}(\mathcal{G}; \mathcal{J})^{\text{co}}\) of Construction 5.5.6 induces a biequivalence

\[
\text{PsFun}(\text{Span}(\mathcal{G}; \mathcal{J})^{\text{co}}, \mathcal{B}) \xrightarrow{\sim} \text{PsFun}_{\mathcal{J}}(\mathcal{G}^{\text{op}}, \mathcal{B})
\]

where the right-hand bicategory has \(\mathcal{J}_{*}\)-pseudo-functors as 0-cells, \(\mathcal{J}_{*}\)-strong pseudo-natural transformations as 1-cells and all modifications as 2-cells.

If \(\mathcal{B}\) happens to be a 2-category, then the above is a strict 2-functor between two 2-categories, and said 2-functor is furthermore locally strict.

Proof. The proof of this result is dual to the one of Theorem 5.3.7. Concretely, in terms of string diagrams the two proofs are upside-down mirrors of each other.

More precisely, and more generally for two bicategories \(\mathcal{A}\) and \(\mathcal{B}\), there is an isomorphism of pseudo-functor bicategories

\[
(-)^{\text{co}}: \text{PsFun}(\mathcal{A}, \mathcal{B})^{\text{co}} \xrightarrow{\sim} \text{PsFun}(\mathcal{A}^{\text{co}}, \mathcal{B}^{\text{co}})
\]

which is defined as follows (see also Notation A.1.4). A pseudo-functor \(\mathcal{F}: \mathcal{A} \to \mathcal{B}\) is sent to the pseudo-functor \(\mathcal{F}^{\text{co}}: \mathcal{A}^{\text{co}} \to \mathcal{B}^{\text{co}}\) defined by \(\mathcal{F}^{\text{co}} = \mathcal{F}\) on 0- and 1-cells and by \(\mathcal{F}^{\text{co}}(\alpha^{\text{co}}) := (\mathcal{F}\alpha)^{\text{co}}\) on 2-cells; the structural isomorphisms of \(\mathcal{F}^{\text{co}}\) require taking inverses: \(\text{fun}_{\mathcal{F}^{\text{co}}} := (\text{fun}_{\mathcal{F}})^{-1}\) and \(\text{un}_{\mathcal{F}^{\text{co}}} := (\text{un}_{\mathcal{F}})^{-1}\). A (strong, oplax-oriented) pseudo-natural transformation \(t = \{t_X, t_u\}: \mathcal{F}_1 \to \mathcal{F}_2\) maps to
the (strong, oplax-oriented) transformation $t^{co}$ with the same 0-cell components $t^{co}_X = t_X$ and 1-cell components $(t^{co})_u := (t_u^{-1})^{co}$ defined, again, by taking inverses. Finally, a modification $M = \{ M_X : t_X \Rightarrow s_X \}$ gives rise to a modification $M^{co}$ with components $(M^{co})_X := (M_X)^{co} : s_X^{co} \Rightarrow t^{co}_X$ going in the opposite direction.

Now we can combine Theorem 5.3.7 and the above formula with $\text{Span}(G; J)$ and $G^{op}$ instead of $\mathcal{A}$ and with $B^{co}$ instead of $\mathcal{B}$. If we moreover pre-compose with the isomorphism $\alpha \mapsto \alpha^{-1}$ (so that pseudo-functors again start at $G^{op}$ rather than $G^{op, co}$), this has the total effect of replacing $(-)^*$ with $(-)^{**}$, left mates $(-)^!$, in $\mathcal{B}$ with right mates $(-)^*$, Construction 5.2.3 with Construction 5.5.10, and $J_!$-strength with $J^*$-strength, so that we obtain the claims of Theorem 5.5.14.

\[
\begin{array}{ccc}
\text{PsFun}(\text{Span}, B^{co}) & \xrightarrow{\text{Thm. 5.3.7}} & \text{PsFun}_{J!}(G^{op, co}, B^{co}) \\
\downarrow^{(5.5.16)} & & \downarrow^{(5.5.16)} \text{PsFun}_{J!}((G^{op, co}, B^{co})^{co}) \\
\text{PsFun}(\text{Span}^{co}, B)^{co} & \xrightarrow{(-)^*} & \text{PsFun}_{J!}(G^{op, co}, B)^{co} \\
\downarrow & & \downarrow \text{PsFun}_{J!}(G^{op}, B)^{co} \end{array}
\]

There is still an extra ‘co’ on the outside of the bottom $\text{PsFun}$’s, meaning that modifications go in the other direction, but of course the result follows by 2-dualizing the biequivalence obtained at the bottom. \hfill \square

5.5.17. Remark. Note that in the definition of (5.5.16) we could completely avoid taking inverses, thus obtaining a more natural-looking isomorphism $(-)^{co}$. But the new isomorphism would then map an oplax-oriented transformation (the convention we have fixed throughout) to a lax-oriented one, and similarly it would require reverting the direction of the structural isomorphisms fun and un of pseudo-functors; cf. A.1.11 and A.1.14. Thus the new formula would require the simultaneous use of both sets of conventions, both for pseudo-functors and for transformations.

5.5.18. Remark. The various co’s and op’s and inverses of the proof may be confusing, so we should spell out in detail how to perform the extension of transformations implicit in Theorem 5.5.14. Suppose for simplicity that $\mathcal{B} = \mathcal{C}$ is an actual 2-category and let $G_1, G_2 : \text{Span}(G; J)^{co} \rightarrow \mathcal{C}$ be two pseudo-functors, with the corresponding $J_*$-pseudo-functors $F_1 = G_1 \circ (-)^*$ and $F_2 = G_2 \circ (-)^{**} : G^{op} \rightarrow \mathcal{C}$. Let $t : F_1 \Rightarrow F_2$ be a transformation and let us analyze its unique extension $t : G_1 \Rightarrow G_2$ given by the above theorem. In the proof of Theorem 5.3.7, we gave an explicit formula (5.3.10) for the extension in the case of $\text{Span}$. The analogous formula for the present case of $\text{Span}^{co}$ differs slightly. Namely, we still keep $t_X$ on 0-cells $X \in G_0 = \text{Span}_0^{co}$ and we still have $t(u^*) = t(u)$ for every $u \in G_1 = \text{Span}_1^{co}$. However, for $i \in J$, we now set

\[ t(i_*) := (t(i)_*)^{-1} \]

where we take the inverse after forming the mate rather than before. Note that there is no other choice. The $J_*$-strength of $t : F_1 \Rightarrow F_2$ precisely guarantees that the above inverse makes sense and consequently that the extended transformation $t : G_1 \Rightarrow G_2$ remains strong. In other words, here the correct analogue
of (5.3.10) is given by the formula

\[(5.5.19) \quad t(i_u^*) := G_1(i_{ou^*}) \]

(modulo the canonical isomorphisms \(i_u^* \cong i_1 \circ u^*\), of course).
CHAPTER 6

Mackey 2-motives

6.1. Mackey 2-motives and their universal property

We are now ready to construct the universal Mackey 2-functor in its semi-additive incarnation (see Appendix A.5). As in Chapter 5, we allow ourselves to work with a slightly more general setting. Thus let \( G \) be an essentially small strict \( (2,1) \)-category equipped with an admissible class \( J \) of faithful 1-cells, as in Hypotheses 5.1.1, and let \( \text{Span} = \text{Span}(G; J) \) denote the bicategory of spans of Definition 5.1.6.

6.1.1. Definition. The bicategory of (semi-additive) Mackey 2-motives

\[
\text{Span} = \text{Span}(G; J)
\]

is the bicategory obtained from \( \text{Span} \) by forming the ordinary category of spans on each Hom category \( \text{Span}(G,H) \). Thus, in more details, \( \text{Span} \) consists of the following:

- The same objects \( \text{Span}(0) = \text{Span}_0 = G_0 \).
- The same 1-cells \( \text{Span}(1) = \text{Span}_1 \), i.e. spans whose right leg belongs to \( J \).
- For two objects \( G, H \in \text{Span}_0 \), the Hom category \( \text{Span}(G,H) \) is defined to be the 1-category of isomorphism classes of spans in \( \text{Span}(G,H) \). In the notation of Definition A.4.1:

\[
\]

This makes sense, because by Proposition 5.4.1 the category \( \text{Span}(G,H) \) admits pullbacks. Thus now both the vertical and horizontal compositions are computed by taking iso-comma squares in \( G \).

- The horizontal composition functors are the unique extensions

\[
\text{Span}(H,K) \times \text{Span}(G,H) \xrightarrow{\circ} \text{Span}(G,K)
\]

of the composition functors of \( \text{Span} \) along the canonical covariant and contravariant embeddings of \( \text{Span}(A,B) \) in \( \text{Span}(A,B) \). Since horizontal composition of \( \text{Span} \) preserves pullbacks (Lemma 5.4.14), these extensions exist by the functoriality and product-compatibility of ordinary spans (Lemma A.4.4).
The unitor and associator 2-cells of $\text{Span}$ are simply the canonical covariant images under $(-)_*$ of those of $\text{Span}$.

It is immediate to verify that this data forms a well-defined bicategory.

**6.1.2. Remark.** We shall of course try to avoid expanding the multiple layers of construction as much as possible. Still, the reader might want to take a quick look down the barrel at least once. Objects of $\text{Span}(G;J)$ are very easy, just $G \in G_0$. The 1-cells $G \to H$ are given by spans $(G \xrightarrow{u} P \xrightarrow{i} H)$ with $i \in J$. These 1-cells will be denoted $i_!u^*$ (by choice) but they are also $i_*u^*$. In particular, in $\text{Span}$ we have

$$i_* = \{\text{id} \to i\} = \text{id}.$$ 

This agreement is in line with the discussion of Section 5.5. Indeed, in Theorem 5.5.8, we saw that the right-adjoint-creating bicategory $\text{Span}(G;J)^\circ$ only differs from the left one, $\text{Span}(G;J)$, at the level of 2-cells. Our ambidexter $\text{Span}$ will contain both sorts of 2-cells, those of $\text{Span}$ and those of $\text{Span}^\circ$. Explicitly, a 2-cell from $i_!u^*$ to $j_!v^*$ consists of a diagram

$$i_!u^* \xrightarrow{[\beta_1, \beta_2]} G \xrightarrow{u} P \xrightarrow{i} H \xrightarrow{[\beta_1, \beta_2]} j_!v^*$$

up to isomorphism. A priori, there are two layers of ‘isomorphism’ here, namely both $[a, \alpha_1, \alpha_2]$ and $[b, \beta_1, \beta_2]$ are already isomorphism classes but, moreover, the above (vertical) span $[b_1, \ldots, b_{\alpha_2}]$ is only considered up to isomorphism in the category $\text{Span}(G, H)$. In other words, an isomorphism between two such spans of spans

consists of commutative diagrams of 2-cells in $\text{Span}$

$$\begin{array}{ccc}
G & \xrightarrow{u} & P \\
\downarrow \alpha_1 & \downarrow \beta_2 & \downarrow \beta_1 \\
\downarrow w & \downarrow k & \downarrow v \\
\downarrow \alpha_1 & \downarrow \beta_2 & \downarrow \beta_1 \\
\downarrow & \downarrow & \downarrow \\
\downarrow j & \downarrow & \downarrow \\
Q & \xrightarrow{v} & J \\
\end{array} \quad \simeq \quad \begin{array}{ccc}
G & \xrightarrow{u} & P \\
\downarrow \pi_1 & \downarrow \pi_2 & \downarrow \pi_2 \\
\downarrow \pi_1 & \downarrow \pi_2 & \downarrow \pi_2 \\
\downarrow & \downarrow & \downarrow \\
\downarrow & \downarrow & \downarrow \\
\downarrow j & \downarrow & \downarrow \\
Q & \xrightarrow{v} & J \\
\end{array}$$

such that $[f] \circ [g] = \text{Id}_{k_!w^*}$ and $[g] \circ [f] = \text{Id}_{k_!w^*}$. In particular, $f$ and $g$ are equivalences of $G$ (Lemma 5.1.12). Expanding further and writing $[f] = [f, \varphi_1, \varphi_2]$,
the commutativity of the two triangles on the left means that there are 2-cells \( \tau : b \Rightarrow b \) and \( \sigma : a \Rightarrow a \) of \( G \) providing two isomorphisms of maps of spans:

\[
\begin{array}{c}
\downarrow \beta_1 \\
\uparrow \varphi_1 \\
\downarrow \varphi_2 \\
\uparrow \pi_1 \\
\downarrow \pi_2 \\
\downarrow \gamma \\
\uparrow \delta_1 \\
\end{array}
\Rightarrow
\begin{array}{c}
\downarrow \beta_2 \\
\uparrow \varphi_2 \\
\downarrow \varphi_1 \\
\uparrow \pi_2 \\
\downarrow \pi_1 \\
\downarrow \gamma \\
\uparrow \delta_1 \\
\end{array}
\]

and

\[
\begin{array}{c}
\downarrow \alpha_1 \\
\uparrow \varphi_2 \\
\downarrow \varphi_1 \\
\uparrow \pi_2 \\
\downarrow \pi_1 \\
\downarrow \gamma \\
\uparrow \delta_1 \\
\end{array}
\Rightarrow
\begin{array}{c}
\downarrow \alpha_2 \\
\uparrow \varphi_2 \\
\downarrow \varphi_1 \\
\uparrow \pi_2 \\
\downarrow \pi_1 \\
\downarrow \gamma \\
\uparrow \delta_1 \\
\end{array}
\]

There are similar diagrams for \( g \).

**6.1.4. Remark.** We discussed in Remark 5.1.17 the effect of replacing iso-commas by arbitrary Mackey squares in the horizontal composition in \( \text{Span}(G; J) \). Essentially the same remark holds for \( \hat{\text{Span}}(G; J) \). However there is now another direction where the same concern can be expressed. Indeed, the vertical composition, which was a mere juxtaposition in \( \text{Span}(G; J) \) now involves taking pull-backs (Proposition 5.4.1). Since the 2-cells of \( \hat{\text{Span}} \) are isomorphism classes of vertical spans, we can replace the middle object up to equivalence without changing a 2-cell. This flexibility allows us to compose vertically by taking any Mackey square.

Let us investigate a little further the notion of isomorphism involved in the 2-cells of \( \hat{\text{Span}} \).

**6.1.5. Proposition.** Consider a 2-cell in \( \hat{\text{Span}} \) between \( i; u^* \) and \( j; v^* \) as in (6.1.3)

\[
\begin{array}{c}
i; u^* \\
\downarrow [b, \beta_1, \beta_2] \\
\downarrow [a, \alpha_1, \alpha_2] \\
j; v^* \\
\end{array}
\Rightarrow
\begin{array}{c}
G \xleftarrow{u} P \xrightarrow{i} H \\
G \xleftarrow{w} R \xrightarrow{k} H \\
G \xleftarrow{v} Q \xrightarrow{j} H \\
\end{array}
\]

Then we have the following basic isomorphisms of 2-cells:
(1) Whiskering by an equivalence: For every equivalence \( g: \check{R} \to R \) of the middle 0-cell in \( \mathcal{G} \), the above 2-cell is equal to the 2-cell

\[
\begin{array}{c}
G \\
\uparrow w \\
\downarrow \alpha_1 g \\
\end{array}
\begin{array}{c}
P \\
\uparrow b g \\
\downarrow \beta_1 g \\
\end{array}
\begin{array}{c}
H \\
\downarrow \alpha_2 g \\
\downarrow \beta_2 g \\
\end{array}
\]

\begin{array}{c}
\begin{array}{c}
G \\
\uparrow v \\
\downarrow \sigma_1 \\
\end{array}
\begin{array}{c}
Q \\
\downarrow \tau_1 \\
\downarrow \tau_2 \\
\end{array}
\begin{array}{c}
\downarrow \pi_1 \\
\downarrow \pi_2 \\
\end{array}
\end{array}
\]

(2) Isomorphism on branches: For any invertible 2-cell \( \alpha: a \Rightarrow \bar{a}: R \to Q \), we can replace only the ‘a-branch’ and the neighboring 2-cells of our representative to obtain another representative of the same 2-cell in \( \text{Span} \)

\[
\begin{array}{c}
G \\
\uparrow w \\
\downarrow \alpha_1 G \\
\end{array}
\begin{array}{c}
P \\
\uparrow b G \\
\downarrow \beta_1 G \\
\end{array}
\begin{array}{c}
H \\
\downarrow \alpha_2 G \\
\downarrow \beta_2 G \\
\end{array}
\]

\begin{array}{c}
\begin{array}{c}
G \\
\uparrow v \\
\downarrow \sigma_1 \\
\end{array}
\begin{array}{c}
Q \\
\downarrow \tau_1 \\
\downarrow \tau_2 \\
\end{array}
\begin{array}{c}
\downarrow \pi_1 \\
\downarrow \pi_2 \\
\end{array}
\end{array}
\]

where \( \bar{\alpha}_1 = (v \sigma) \alpha_1 \) and \( \bar{\alpha}_2 = \alpha_2 (j \sigma)^{-1} \) are simply \( \alpha_1 \) and \( \alpha_2 \) suitably transported by the isomorphism \( \sigma \). Similarly of course, if \( \tau: b \Rightarrow \bar{b} \), or \( \psi_1: w \Rightarrow \bar{w} \), or \( \psi_2: k \Rightarrow \bar{k} \), are invertible 2-cells in \( \mathcal{G} \), then our 2-cell in \( \text{Span} \) is equal to the class of any of the following representatives:

\[
\begin{array}{c}
G \\
\uparrow w \\
\downarrow \alpha_1 G \\
\end{array}
\begin{array}{c}
P \\
\uparrow b G \\
\downarrow \beta_1 G \\
\end{array}
\begin{array}{c}
H \\
\downarrow \alpha_2 G \\
\downarrow \beta_2 G \\
\end{array}
\]

\begin{array}{c}
\begin{array}{c}
G \\
\uparrow v \\
\downarrow \sigma_1 \\
\end{array}
\begin{array}{c}
Q \\
\downarrow \tau_1 \\
\downarrow \tau_2 \\
\end{array}
\begin{array}{c}
\downarrow \pi_1 \\
\downarrow \pi_2 \\
\end{array}
\end{array}
\]

where \( \bar{\beta}_1 = (u \tau) \beta_1 \) and \( \bar{\beta}_2 = \beta_2 (i \tau)^{-1} \), where \( \bar{\alpha}_1 = \alpha_1 \psi_1^{-1} \) and \( \bar{\beta}_1 = \beta_1 \psi_1^{-1} \), and where \( \bar{\alpha}_2 = \psi_2 \alpha_2 \) and \( \bar{\beta}_2 = \psi_2 \beta_2 \).

**Proof.** It is clear that (1) and (2) define isomorphisms of spans of spans. Conversely, the general isomorphism of spans of spans expanded in Remark 6.1.2 is composed of (1) and (2), as the reader can easily verify. \( \square \)

**6.1.6. Remark.** There is an obvious (1-contravariant) pseudo-functor

\[
\mathbb{G}^{op} \xrightarrow{(-)^*} \text{Span}(\mathbb{G}; J) \xrightarrow{(-)_*} \text{Span}(\mathbb{G}; J)
\]

composed of the embedding \((-)^*: \mathbb{G}^{op} \to \text{Span}(\mathbb{G}; J)\) of Construction 5.1.18 followed by the canonical embedding still denoted \((-)_*: \text{Span} \to \text{Span}\). The latter consists of the identity on 0-cells (and 1-cells) and the standard functor \((-)_*\), on Hom categories, as in Definition A.4.1. (We make it more explicit below.)
In view of Section 5.5, there is a priori another embedding of $G$ into $\text{Span}$ which composes the two 2-contravariant ones

$$G^{op} \xhookrightarrow{(-)^*} \text{Span}(G; J)^{co} \xhookrightarrow{(-)^*} \text{Span}(G; J).$$

Here the embedding $\alpha \mapsto [\text{id}, \alpha^{-1}, \text{id}]$ of Theorem 5.5.8 is followed by the canonical embedding of $(-)^*$: $\text{Span}^{co} \hookrightarrow \text{Span}$ which is the identity on 0-cells (and 1-cells) and the contravariant functor $(-)^*$ on Hom categories, as in Definition A.4.1.

Luckily the above two embeddings agree, i.e. the following commutes:

$$\begin{array}{ccc}
\text{Span}(G; J) & \xrightarrow{(-)^*} & \text{Span}(G; J)^{co} \\
\downarrow & & \downarrow \\
G^{op} & \xrightarrow{(-)^*} & \text{Span}(G; J) \\
\end{array}$$

(6.1.7)

The reason is that, for every $u, v: H \to G$ and every $\alpha: u \Rightarrow v$ in $G$, the classes of the following two (vertical) spans are equal in the category $\text{Span}(G; J)(G, H)$, i.e. the following spans are isomorphic

$$\begin{array}{ccc}
(\alpha^*)_* & = & \begin{array}{ccc}
\uparrow u & \overset{\text{id}}{\Rightarrow} & \downarrow u \\
\text{id} & \overset{\text{id}}{\Rightarrow} & \text{id} \\
\alpha & \overset{\text{id}}{\Rightarrow} & \text{id} \\
\downarrow v & \overset{\text{id}}{\Rightarrow} & \downarrow v \\
\end{array} & \cong & \begin{array}{ccc}
\uparrow u & \overset{\text{id}}{\Rightarrow} & \downarrow u \\
\alpha^{-1} & \overset{\text{id}}{\Rightarrow} & \text{id} \\
\downarrow v & \overset{\text{id}}{\Rightarrow} & \downarrow v \\
\end{array} & = & (\alpha^{**})^*
\end{array}$$

(6.1.8)

by Proposition 6.1.5 (2).

We have therefore reached the 2-motivic construction we were aiming for:

**6.1.9. Notation.** We denote the 1-contravariant embedding (6.1.7) by

$$(-)^*: G^{op} \hookrightarrow \text{Span}(G; J).$$

It is the identity on 0-cells, maps a 1-cell $u: H \to G$ to $u^* = [u^*=]: G \to H$ and maps $\alpha: u \Rightarrow v$ to the 2-cell $\alpha^*: u^* \Rightarrow v^*$ described in (6.1.8) above.

**6.1.10. Remark.** Similarly on the 2-category $J$, the two ways to (2-contravariantly) embed $J$ into $\text{Span}(G; J)$ coincide. The resulting embedding

$$(-)^*: J^{co} \hookrightarrow \text{Span}(G; J)$$

is the identity on 0-cells, as usual. It maps a 1-cell $i: H \to G$ to $i^* = [i^{-1}]: H \to G$ and a 2-cell $\beta: i \Rightarrow j$ to the 2-cell $\beta^*: i^* \Rightarrow j^*$ represented by any of the following isomorphic spans (by Proposition 6.1.5 (2) again):

$$\begin{array}{ccc}
\beta^* & = & \begin{array}{ccc}
\uparrow \text{id} & \overset{\text{id}}{\Rightarrow} & \downarrow \text{id} \\
\text{id} & \overset{\text{id}}{\Rightarrow} & \text{id} \\
\beta & \overset{\text{id}}{\Rightarrow} & \text{id} \\
\downarrow i & \overset{\text{id}}{\Rightarrow} & \downarrow i \\
\end{array} & \cong & \begin{array}{ccc}
\uparrow \text{id} & \overset{\text{id}}{\Rightarrow} & \downarrow \text{id} \\
\beta^{-1} & \overset{\text{id}}{\Rightarrow} & \text{id} \\
\downarrow i & \overset{\text{id}}{\Rightarrow} & \downarrow i \\
\end{array} & = \beta^*
\end{array}$$
Let us prove the first properties of the bicategory of Mackey 2-motives. The alert reader will surely recognize in (6.1.12) the strict Mackey formula of the Rectification Theorem 3.4.3(7).

6.1.11. Proposition. In the bicategory \( \widehat{\text{Span}} = \widehat{\text{Span}}(G; J) \), the image \( i^* \) of every 1-cell \( i \in J \) has a two-sided adjoint \( i_* \). They satisfy the following properties:

(a) Transposition of 2-cells (i.e. ordinary transposition applied to the Hom categories \( \text{Span}(G, H) \), as in Remark A.4.2) defines an involution

\[
\widehat{\text{Span}}^\text{co} \hookrightarrow \widehat{\text{Span}}
\]

which fixes 0-cells and 1-cells and maps the unit (resp. the counit) of the adjunction \( i_* \vdash i^* \), as described in Proposition 5.1.21, into the counit (resp. the unit) of the new adjunction \( i^* \vdash i_* \), and vice-versa.

(b) For every \( i : H \to G \) in \( J \), the ambidextrous adjunction \( i^* \dashv i_* \dashv i^* = i! \) is special Frobenius, meaning that the composite \( \text{id}_H \overset{\gamma}{\Rightarrow} i^* i = i^* i_* \overset{\gamma}{\Rightarrow} \text{id}_H \) of the counit and unit for the two adjunctions is the identity.

(c) For any comma square in \( G \)

\[
\begin{array}{ccc}
\Delta_i & \Rightarrow & \Delta_i \\
\pr_1 & & \pr_2 \\
H & \Rightarrow & H \\
\end{array}
\]

with \( i \in J \), the mate \( (\gamma^{-1})_* : v^* i_* \Rightarrow \tilde{v} \tilde{i}^* \) of \( (\gamma^{-1})^* : \tilde{i}^* v^* \Rightarrow \tilde{v}^* i^* \) with respect to the new adjunction \( i^* \vdash i_* \) is the inverse of the mate \( \gamma_! \) of Lemma 5.1.25:

\[
(\gamma^{-1})_* = (\gamma)_!^{-1}.
\]

**Proof.** Part (a) is clear since transposition on each Hom category

\[
\widehat{\text{Span}}^\text{co}(G, H) = \widehat{\text{Span}}(G, H)^\text{op} = (\widehat{\text{Span}}(G, H))^\text{op} \overset{(-)^t}{\Rightarrow} \widehat{\text{Span}}(G, H) = \widehat{\text{Span}}(G, H)
\]

is a contravariant isomorphism. Part (b) is a direct computation based on the following fact: If \( i : H \to G \) is a faithful 1-cell then the iso-comma \( \Delta_i/\Delta_i \) for the 1-morphism \( \Delta_i : H \to (i/i) \) (against itself) is equivalent to \( H \) itself as follows:

\[
\begin{array}{ccc}
\Delta_i & \Rightarrow & \Delta_i \\
\pr_1 & & \pr_2 \\
H & \Rightarrow & H \\
\text{id}_{\Delta_i} & \Rightarrow & \text{id}_{\Delta_i} \\
\end{array}
\]

A more detailed proof will be provided in Example 6.2.8 using string diagrams. To see why the comparison 1-cell \( (\text{Id}_H, \text{Id}_H, \text{id}_{\Delta_i}) : H \to \Delta_i/\Delta_i \) is an equivalence, as claimed, we may apply \( G(T, -) \) to easily compute in \( \text{Cat} \) and conclude with Corollary A.1.18.

Part (c) is direct from part (a) and Lemma A.4.5. Indeed, if we apply transposition \((-)^t \) to the isomorphism \( \gamma_! \) as in (5.1.26) we obtain precisely \( (\gamma^{-1})_* \). \( \square \)
The next theorem says that the canonical embedding $\mathbb{G}^{op} \hookrightarrow \text{Span}(\mathbb{G}; \mathbb{J})$ of Remark 6.1.6 is the universal pseudo-functor defined on $\mathbb{G}^{op}$ which sends the 1-cells of $\mathbb{J}$ to ambidextrous adjunctions satisfying base change and the strict Mackey formula, as in Proposition 6.1.11. More precisely:

6.1.13. Theorem (Universal property of Mackey 2-motives). Let $\mathbb{G}$ be our chosen $(2,1)$-category with a distinguished class $\mathbb{J}$ of faithful 1-cells, as in Hypotheses 5.1.1. Let $\mathcal{C}$ be any 2-category, and consider a pseudo-functor $F: \mathbb{G}^{op} \rightarrow \mathcal{C}$ such that

(a) for every $i \in \mathbb{J}$, there exists in $\mathcal{C}$ a right-and-left adjoint to $i^* = F_i$;
(b) both the left and the right adjunctions satisfy base-change with respect to all comma squares with two parallel sides in $\mathbb{J}$; and
(c) for every such comma square, the left and right adjunctions satisfy the strict Mackey formula (6.1.12).

Then there exists a pseudo-functor $\hat{F}: \text{Span}(\mathbb{G}; \mathbb{J}) \rightarrow \mathcal{C}$ such that $\mathbb{G}^{op} \xrightarrow{\hat{F}} \mathcal{C}$ is commutative. This extension $\hat{F}$ is unique up to a unique isomorphism whose restriction to $F$ is the identity, and is entirely determined by the choice of the adjoints of all $i^*$, together with units and counits. Conversely, any pseudofunctor $F$ factoring as above must enjoy the above three properties.

For identities and invertible 1-cells, we make here the same choices of adjoints as in Remark 5.2.2. This makes the triangle in the theorem strictly commute, and overall simplifies proofs a little.

We begin with the following observation.

6.1.14. Lemma. Denote by $F_! : \mathbb{J}^{co} \rightarrow \mathcal{C}$ and $F_* : \mathbb{J}^{co} \rightarrow \mathcal{C}$ the pseudo-functors induced by $F$, as explained in Remark A.2.10, by taking mates with respect to a choice of adjunctions $(Fi)_! \vdash Fi$ and $Fi \vdash (Fi)_*$ (including units and counits) satisfying all the hypotheses of Theorem 6.1.13. Then $F_i = F_*$ as pseudo-functors.

Proof. By definition we have an equality $F_i = F_*$ on objects, and clearly on 1-cells too by our choice of a left-and-right adjoint $(Fi)_! \vdash Fi$ and $Fi \vdash (Fi)_*$, for each $i \in \mathbb{J}$, as in hypothesis (a). The images of any 2-cell also coincide, and this follows from hypothesis (c). Indeed, every 2-cell $\alpha: i \Rightarrow j$ in $\mathbb{J}$ gives rise to the following Mackey squares in $\mathbb{G}$:

By taking mates of their images under $F$ (i.e. apply $F$ and insert the units and counits of one of the four adjunctions $(Fi)_! \vdash Fi \vdash (Fi)_*$, and $(Fj)_! \vdash Fj \vdash (Fj)_*$, in the only way that makes sense), we obtain respectively:
• The image $\mathcal{F}_!(\alpha)$ under $\mathcal{F}_!$;
• The image $\mathcal{F}_*(\alpha)$ under $\mathcal{F}_*$, which is also the left-hand side of the strict Mackey formula (6.1.12) for $\gamma := \alpha^{-1}$ as above;
• The map $\gamma = (\mathcal{F}_!\alpha^{-1})$ in the right-hand side of (6.1.12) for $\gamma = \alpha^{-1}$.

Then we compute

$$\mathcal{F}_*\alpha = \mathcal{F}_*((\alpha^{-1})^{-1}) = ((\mathcal{F}_*\alpha)^{-1})^{-1} \overset{(6.1.12)}{=} ((\mathcal{F}_\alpha)^{-1})^{-1} = \mathcal{F}_!\alpha$$

as claimed. For this we also use that $\mathcal{F}_!$ and $\mathcal{F}_*$ preserve inverses of 2-cells, like any pseudo-functor (this also follows from hypothesis (b), which however is not needed).

It remains to see that the coherent structure isomorphisms $\text{fun}$ and $\text{un}$ of $\mathcal{F}_!$ and $\mathcal{F}_*$ also coincide. As they arise as mates of those of $\mathcal{F}$, this follows in a similar straightforward way from the strict Mackey formula. □

**Proof of Theorem 6.1.13.** By Theorem 5.2.1 and Theorem 5.5.8 we have two extensions of $\mathcal{F}$, one to $\text{Span}(G; J)$ and one to $\text{Span}(G; J)^\text{co}$. To distinguish them and to match the universal property of spans in 1-categories, we denote them by $\mathcal{F}_*$ and $\mathcal{F}^*$ respectively. These pseudo-functors make the left-hand diagram below commute:

The theorem claims the existence of a pseudo-functor $\tilde{\mathcal{F}}$ as on the right-hand side above, whose composite with $G^{\text{op}} \rightarrow \text{Span}$ of (6.1.7) is the original $\mathcal{F}$. Since $\text{Span}$ is constructed by applying on each Hom category the span construction (for 1-categories) of Appendix A.4, we need to show that the two functors given on Hom categories by $\mathcal{F}_*$ and $\mathcal{F}^*$ assemble to a functor on $\text{Span}$. In other words, for every pair of 0-cells $G$ and $H$, we consider the functors $\mathcal{F}_*$ and $\mathcal{F}^*$ as follows

$$\text{Span}(G; J)(G, H) \xrightarrow{(\cdot)^*} \mathcal{F}_* \xrightarrow{(\cdot)^*} \text{Span}(G; J)^\text{co}(G, H)^\text{op}$$

and want to check they assemble into $\tilde{\mathcal{F}}$. We need to check the hypotheses of Proposition A.4.3, by recalling the definitions of $\mathcal{F}_*$ and $\mathcal{F}^*$ on Hom categories, which are the 1-cell and 2-cell parts of Construction 5.2.3 and Construction 5.5.10, respectively. On objects of $\text{Span}(G; J)(G, H)$, i.e. on 1-cells $i u^* = i^* u^*$ of $\text{Span}$, both functors $\mathcal{F}_*$ and $\mathcal{F}^*$ agree since

$$\mathcal{F}_*(i u^*) = (\mathcal{F}i)_!\mathcal{F}u = (\mathcal{F}i)_*\mathcal{F}u = \mathcal{F}^*(i^* u^*).$$
This gives the easy condition (a) of Proposition A.4.3. Let us check (b), which says that for any pullback square in the category $\text{Span}(G; J)(G, H)$

![Pullback Square Diagram]

the following equality holds in the category $C(\mathcal{F}G, \mathcal{F}H)$:

$$(6.1.16) \quad \mathcal{F}^*([b]) \circ \mathcal{F}_*(\{a\}) \sim \mathcal{F}_*(\{\hat{a}\}) \circ \mathcal{F}^*([\hat{b}]) .$$

Here we temporarily used the short form $\{a\}$ for $\{a, \alpha_1, \alpha_2\}$, etc, as we did in Section 5.4, where we explicitly constructed the above pullbacks in the category $\text{Span}(G; J)(G, H)$. Expanding the notation as in Proposition 5.4.1, if we start with the cospan in the category $\text{Span}(G; J)(G, H)$ as in $(5.4.2)$

![Cospan Diagram]

the above pullback square is the following left-hand square

![Pullback Square Diagram]

where the 1-cells $\hat{a}$ and $\hat{b}$ of $G$ come from the above right-hand iso-commas and the 2-cell components $\hat{\alpha}_1, \hat{\alpha}_2, \hat{\beta}_1, \hat{\beta}_2$ are given in (5.4.3). Armed with those explicit formulas for these 2-cells, we can compute the images of $\{a, ...\}$ and $\{\hat{a}, ...\}$ under $\mathcal{F}_*: \text{Span}(G; J)(G, H) \rightarrow C(\mathcal{F}G, \mathcal{F}H)$ and those of $\{b, ...\}$ and $\{\hat{b}, ...\}$ under $\mathcal{F}^*: \text{Span}(G; J)(G, H) \rightarrow C(\mathcal{F}G, \mathcal{F}H)$, by following the recipes given in (5.2.4) and (5.5.11), respectively.

For legibility, we will write with string diagrams (see Appendix A.3 if necessary). As in Section 5.2, we depict the chosen left-and-right adjoints $(\mathcal{F}_i)_i$ in $C (i \in \mathcal{I})$ with dotted lines. The required equality (6.1.16) now becomes as follows
(ignore the shaded area on the left for now):

Note the use, on the right-hand sides of each diagram, of the pseudo-functoriality of $F_!$ and $F^*$. We know from Lemma 6.1.14 that they actually agree. All the unnamed 2-cells above denote some instance of the structure isomorphisms fun of $F$ or $F_! = F^*$, or their composites and inverses (see Example A.3.5).

By the associativity of fun and the interchange law (Example A.3.2), we can rewrite the right-hand side as follows:

Thus it suffices to show the equality of the two shaded areas above, since outside of them the two diagrams already agree. Starting with the latter (right-hand side) shaded area, and making now all the mates explicit, we compute as follows using Lemma 6.1.14, the interchange law, the triangular equalities of various adjunctions,
and the strict Mackey formula:

\[
\begin{align*}
\eta \circ (F_{\gamma})_* &= \eta \circ (F_{\gamma})_* \\
(F_{\gamma})_* \circ \eta &= \eta \circ (F_{\gamma})_* \\
\end{align*}
\]

For the last equality we use the identity \((F_{\gamma}^{-1})_*(F_{\gamma})_* = \text{id}_{(F_{\alpha})_*(F_{\beta})_*}\), which is one half of the strict Mackey formula applied to the inverse Mackey square \(\gamma^{-1}\) (see Example 2.1.4). By a routine application of the interchange law, the latter diagram is then nothing but

\[
\begin{align*}
\eta \circ (F_{\gamma})_* &= \eta \circ (F_{\gamma})_* \\
(F_{\gamma})_* \circ \eta &= \eta \circ (F_{\gamma})_* \\
\end{align*}
\]

as desired.

This concludes the proof of (6.1.16), and thus that the functor

\[
\tilde{F} : \text{Span}(G; H)(G, H) \to C(FG, FH)
\]
is well-defined. To show that these functors \( \hat{F} \) on the Hom categories (for varying \( G \) and \( H \)) assemble into a pseudo-functor on \( \text{Span} \) as required, we need only to find the coherent natural isomorphisms \( \hat{F}_{G} \)

\[
\begin{array}{ccc}
\text{Span}(G; J)(G, G) & \xrightarrow{\downarrow \hat{F}} & C(FG, FG) \\
\downarrow & & \downarrow \hat{F} \\
1 & \xrightarrow{\phi} & \text{Span}(G; J)(G, G) \\
\end{array}
\]

for each object \( G \) and functors \( \hat{F}_{G,H,K} \)

\[
\begin{array}{ccc}
\text{Span}(G; J)(H, K) \times \text{Span}(G; J)(G, H) & \xrightarrow{\hat{F} \times \hat{F}} & \text{Span}(G; J)(G, K) \\
\downarrow & & \downarrow \hat{F} \\
C(FH, FK) \times C(FG, FH) & \xrightarrow{\circ} & C(FG, FK) \\
\end{array}
\]

for each triple \( G, H, K \). For this we take the same isomorphisms as for \( F \), and we verify that they are natural also as transformations of functors extended to the span categories. Since they are invertible natural transformations, this is automatic by Lemma A.4.4 (b).

6.2. A strict presentation and a calculus of string diagrams

In view of the universal property of Theorem 6.1.13, it is now straightforward to give a presentation of 2-Mackey motives in terms of the given \((2,1)\)-category \( \mathcal{G} \), some extra 1-cells and 2-cells corresponding to the ‘wrong way’ adjoint 1-cells associated to the distinguished 1-cells \( i \in \mathcal{J} \), and the necessary relations. The result is a strict 2-category \( \text{Span}^{\text{str}}(\mathcal{G}; \mathcal{J}) \) biequivalent to the double-span \( \text{Span}(\mathcal{G}; \mathcal{J}) \). We also describe a string diagram version of this strict presentation, in Construction 6.2.3 below, in order to infuse it with some helpful visual intuition.

Note that, in principle, a similar presentation could also be constructed for the intermediary bicategory \( \text{Span}(\mathcal{G}; \mathcal{J}) \) since it enjoys a similar universal property. This is left to the interested reader, keeping Remark 1.3.2 in mind.

6.2.1. Corollary (The strict 2-category of Mackey 2-motives). The bicategory of Mackey 2-motives \( \text{Span}^{\text{str}}(\mathcal{G}; \mathcal{J}) \) is canonically biequivalent to the strict 2-category \( \text{Span}^{\text{str}}(\mathcal{G}; \mathcal{J}) \) generated by:

(a) the same 0-cells as those of \( \mathcal{G} \);
(b) the two families of 1-cells

\[ u^* : G \to P \quad \text{and} \quad i_* : P \to H \]

where \((u : P \to G) \in \mathcal{G}_1\) is an arbitrary 1-cell and \((i : P \to H) \in \mathcal{J}\) a distinguished faithful 1-cell;
(c) the five families of 2-cells

\[ \alpha^* : u^* \Rightarrow v^*, \quad \ell \eta : \text{Id} \Rightarrow i^* i_* \Rightarrow \text{Id}, \quad r \eta : \text{Id} \Rightarrow i_* i^* \Rightarrow \text{Id}, \quad r \varepsilon : i^* i_* \Rightarrow \text{Id} \]

where \((\alpha : u \Rightarrow v) \in \mathcal{G}_2\) is an arbitrary 2-cell and \((i : P \to H) \in \mathcal{J}\); subject to the following relations:

(1) the images under \((-)^*\) of all the relations in \( \mathcal{G} \);
the triangle equalities which turn the two families of quadruplets
\[(i_*, i^*, \eta, \varepsilon) \quad \text{and} \quad (i^*, i_*, \eta, \varepsilon) \quad (i \in J)\]
into adjunctions; and

(3) the strict Mackey formula, as in (6.1.12), namely:
\[(\gamma_!)^{-1} := ((j_* v^* \varepsilon)(j_* \gamma^* i_*)(\varepsilon u^* i_*)^{-1} = (\varepsilon u^* i_*)(j_* (\gamma^{-1})^* i_*)(j_* v^* \eta) =: (\gamma^{-1})_*\]
for every Mackey square
\[
\begin{array}{ccc}
H & \xrightarrow{\varepsilon} & J \\
\downarrow & & \downarrow \gamma \\
G & \xrightarrow{\eta} & K
\end{array}
\]
in \(G\) with \(i\), and thus \(j\), in \(J\) (see Definition 2.2.1);
in addition, of course, to the necessary relations of a 2-category.

PROOF. Note that, by the first family of relations, there is a well-defined 2-functor \((-)^* : \mathcal{G}^{\text{op}} \to \text{Span}(G;J)^{str}\) sending \(u\) and \(\alpha\) to the generators \(u^*\) and \(\alpha^*\). By Theorem 6.1.13, the two remaining families of relations allow us to extend this 2-functor through the (homonimous) canonical pseudo-functor \((-)^* : \mathcal{G}^{\text{op}} \to \text{Span}(G;J)^{str}\):
\[
\begin{array}{ccc}
\mathcal{G}^{\text{op}} & \xrightarrow{F := (\cdot)^*} & \text{Span}(G;J)^{str} \\
\downarrow \scriptstyle{(-)^*} & & \downarrow \scriptstyle{\text{Span}(G;J)^{str}} \\
\text{Span}(G;J) & \xrightarrow{\hat{F}} & \text{Span}(G;J)
\end{array}
\]
Indeed, we choose here the unique extension \(\hat{F}\) which is determined by the adjunctions \((i_*, i^*, \eta, \varepsilon)\) and \((i^*, i_*, \eta, \varepsilon)\). Let us define a pseudo-functor \(F'\) in the opposite direction: It send the generators \(u^*, i_*, \alpha^*\) of \(\text{Span}(G;J)^{str}\) to the homonimous 1- or 2-cells of \(\text{Span}(G;J)\), and it sends the remaining generating 2-cells \(\varepsilon, \eta, \varepsilon, \eta, \varepsilon\) to the corresponding canonical units and counits of adjunction as previously constructed in \(\text{Span}(G;J)\).

It is now a straightforward observation that \(F'\) can be endowed with the structure of a pseudo-functor, quasi-inverse to \(\hat{F}\): use Proposition 6.1.11 and the evident candidates for \(\text{fun}_{F'}\) and \(\text{un}_{F'}\). Alternatively, one can verify that the above 2-functor \((-)^* : \mathcal{G}^{\text{op}} \to \text{Span}(G;J)^{str}\) satisfies the same universal property as \(\text{Span}(G;J)\), but limited to (strict) 2-functors to (strict) 2-categories \(\mathcal{C}\). (This ‘strict’ verification is much easier!) As a consequence, \(\hat{F}\) must be isomorphic to the strictification of \(\text{Span}(G;J)\), as in Remark A.1.16, and in particular \(\hat{F}\) is a biequivalence. We leave the remaining details to the reader. \(\square\)

The above presentation of \(\text{Span}(G;J)^{str}\) may look a little unwieldy. We will now rephrase it using string diagrams (see Appendix A.3), which will provide a visually suggestive string calculus for computing with Mackey 2-motives. This is strongly reminiscent of the Penrose and Reidemeister graphical calculus for (braided) pivotal monoidal categories; see [TV17, §§2.2-2.3]. Contrary to loc. cit., though, we will not attempt to rigorously prove a topological invariance theorem for our diagrams,
because of the extra labelling and orientability issues which would make the result somewhat complicated.

6.2.3. Construction. We can (re)define $\text{Span}(G; J)^\text{op}$ as the 2-category generated by the following basic string diagrams:

(a) The plane regions (0-cells), which are labelled by the 0-cells of $G$:

(b) Two families of basic oriented strings, namely

\[ \text{for every 1-cell } u: P \to G \text{ of } G \text{ and every } (i: P \to H) \text{ in } J. \text{ The orientation, upwards or downwards, is indicated by the arrow-head placed on the string. As before, such a string corresponds to a 1-cell from the left-hand region to the right-hand one. The orientation allows us to have two possible strings decorated with the label } i, \text{ for } i: P \to H \text{ in } J: \text{ one string pointing downward corresponding to } i^* \text{ (from } H \text{ to } P) \text{ and one string pointing upward corresponding to } i! = i_* \text{ (from } P \text{ to } H). \]

(c) A 2-cell (dot) as follows

\[ \text{for every 2-cell } \alpha: u \Rightarrow v: P \to G \text{ of } G, \text{ as well as four additional 2-cells} \]

\[ \text{for every 1-cell } i: P \to H \text{ in } J. \text{ We leave the latter unlabeled and undotted because the orientation and shape of the string suffices for distinguishing them.} \]

These basic 2-cells can be combined vertically and horizontally according to the usual rules, taking care to also preserve the orientations on all strings. The resulting combined string diagrams are subject to the usual relations of a 2-category (the insertion and deletion of identities as in Example A.3.1, the interchange law as in Example A.3.2, etc.), as well as the additional three families of relations:

1. All the relations coming from the 2-category $G$.
2. The following ‘zig-zag’ relations

\[ (6.2.4) \quad \begin{array}{c} \begin{array}{c} \text{P} \\ \text{H} \end{array} \end{array} = \begin{array}{c} \begin{array}{c} \text{H} \\ \text{P} \end{array} \end{array} \]

and

\[ (6.2.5) \quad \begin{array}{c} \begin{array}{c} \text{H} \\ \text{P} \end{array} \end{array} = \begin{array}{c} \begin{array}{c} \text{P} \\ \text{H} \end{array} \end{array} \]
for every \( (i : P \to H) \in J \).

(3) And for every Mackey square (6.2.2), the two ‘pull-over’ relations

\[
\begin{align*}
\gamma & : \begin{array}{c}
\begin{array}{c}
\bullet \downarrow \alpha \\
\bullet \downarrow \beta
\end{array}
\end{array} \\
\begin{array}{c}
\begin{array}{c}
\bullet \downarrow \alpha \\
\bullet \downarrow \beta
\end{array}
\end{array} \\
\end{align*}
\]

where we have depicted the ‘exchange’ 2-cell \( \gamma \) of the Mackey square with a crossing \( \times \) and its inverse \( \gamma^{-1} \) with the corresponding uncrossing \( \times \). (Beware that each crossing still indicates a 2-cell, so that in general the string labels change when going past it—although the orientation of each strand is preserved.)

6.2.7. Remark. The argument in Lemma 6.1.14, on the agreement of the pseudo-functors \( F_! \) and \( F_* \), implies that the equation

\[
\alpha : \begin{array}{c}
\begin{array}{c}
\bullet \downarrow \alpha \\
\bullet \downarrow \beta
\end{array}
\end{array} = \begin{array}{c}
\begin{array}{c}
\bullet \downarrow \alpha \\
\bullet \downarrow \beta
\end{array}
\end{array}
\]

holds in \( \text{Span}(\mathbb{G}; J) \) for every 2-cell \( \alpha : i \Rightarrow j : P \to H \) between 1-cells \( i, j \) in \( J \). We invite the reader to (re)check this by themselves, by noticing how it immediately follows from the pull-over relations (6.2.6) for either of the Mackey squares

\[
\begin{array}{c}
\begin{array}{c}
\bullet \downarrow \alpha \\
\bullet \downarrow \beta
\end{array}
\end{array} \quad \text{or} \quad \begin{array}{c}
\begin{array}{c}
\bullet \downarrow \alpha \\
\bullet \downarrow \beta
\end{array}
\end{array}
\]

together with the fact that, on such squares, taking mates \((-)_!\) and \((-)_*\) commute with taking inverses. By viewing the above equation as a generalization of (6.2.5), it makes sense to introduce the simple notation

\[
\begin{array}{c}
\begin{array}{c}
\bullet \downarrow \alpha \\
\bullet \downarrow \beta
\end{array}
\end{array}
\]

for the 2-cell \( \alpha_! = \alpha_* \), suggesting that we may twist an oriented string upside down (provided it lives in \( J \)) while preserving the labeled dots it carries.

We end this section with an example of a nontrivial computation by means of the above string calculus.

6.2.8. Example (Special Frobenius via strings). Let us provide a complete proof of the special Frobenius property of the ambidextrous adjunction \( i \dashv i^* \dashv i \) in \( \text{Span} \) for any \( i : H \to G \) in \( J \), which we had only sketched in Proposition 6.1.11 (b). Thus
we claim that \( \varepsilon \ell \eta = \text{id}_{\text{id}_G} \), or equivalently, in string diagrams:

\[
H \circ \eta = H.
\]

In order to prove this, we recall from \textit{loc. cit.} that in any \((2,1)\)-category \(G\) the square

\[
\begin{array}{ccc}
H & \xrightarrow{\text{id}_{\Delta}} & H \\
\downarrow & & \downarrow \\
(i/i) & \xrightarrow{\Delta} & \Delta
\end{array}
\]

(6.2.9)

is a Mackey square whenever \( i \) is faithful, where \( \Delta = \langle \text{Id}, \text{Id}, \text{id}_i \rangle \) is the unique 1-cell \( H \to (i/i) \) such that \( \text{pr}_1 \Delta = \text{Id}_H \), \( \text{pr}_2 \Delta = \text{Id}_H \) and \( \gamma \Delta = \text{id}_i \):

\[
\begin{array}{ccc}
H & \xrightarrow{\gamma} & H \\
\downarrow & & \downarrow \\
G & \xrightarrow{i} & i
\end{array}
\]

(6.2.10)

The point here is not to redo the latter computation, which already happens in \( G \), but to show that string diagrams allow us to rigorously keep track of \textit{all} the information in the 2-cells of \( \text{Span} \), which can otherwise be quite overwhelming if written out in full using cell diagrams. Now we compute as follows, where as usual we highlight at each step the areas where the action is about to happen:
6.3. The bicategory of Mackey 2-functors

Let us investigate morphisms of Mackey 2-functors, which only made a brief appearance in Section 4.2 (see Definition 4.2.2). The following proposition characterizes morphisms in four equivalent ways.

6.3.1. Proposition. Let \( t: \mathcal{M} \Rightarrow \mathcal{N} \) be a pre-morphism of (rectified) Mackey 2-functors \( \mathcal{M}, \mathcal{N} : \mathbb{G}^{\text{op}} \rightarrow \text{ADD} \) (i.e. \( t \) is a pseudo-natural transformation of the underlying 2-functors). The following are equivalent:

(i) \( t \) extends (in a unique way) to a pseudo-natural transformation \( \hat{t}: \hat{\mathcal{M}} \Rightarrow \hat{\mathcal{N}} \) between the two extended pseudo-functors \( \hat{\mathcal{M}}, \hat{\mathcal{N}} : \text{Span}(\mathbb{G}; \mathbb{J}) \rightarrow \text{ADD} \) obtained as in Theorem 6.1.13.

(ii) For each \((i: H \rightarrow G) \in \mathbb{J}\), the two mates

\[
\begin{align*}
\mathcal{M}(G) & \xrightarrow{t_G} \mathcal{N}(G) \\
\mathcal{M}(H) & \xrightarrow{t_H} \mathcal{N}(H)
\end{align*}
\]

obtained from the component \( t_i: t_H \circ i^* = i^* \circ t_G \) are each other’s inverses.

(iii) For each \((i: H \rightarrow G) \in \mathbb{J}\), the left mate \((t_i)^{-1}\) of (ii) is invertible.

(iv) For each \((i: H \rightarrow G) \in \mathbb{J}\), the right mate \((t_i)_*\) of (ii) is invertible.

Then we conclude with the relations \( \text{pr}_1 \Delta = \text{Id}_H = \text{pr}_2 \Delta \) of (6.2.10).
PROOF. As was already mentioned in Section 4.2, the equivalence between (ii) and the weaker (iii) or (iv) is immediate because of the commutative square

\[
\begin{array}{ccc}
t_G i^* & \cong & t_G \Theta^M \\
\downarrow (t_i^{-1}) & & \downarrow (t_i)_* \\
i^*_H t_H & \cong & \Theta^M i^*_H \\
i^*_N t_H & \cong & \Theta^N i^*_H \\
\end{array}
\]

of Proposition 3.3.33, which already gives us (in the rectified setting where \( \Theta = \text{Id} \)) that one composition is the identity:

\[
(t_i)_* \circ (t_i^{-1}) = \text{id}.
\]

Now assume (i), i.e. that we are given a (strong, oplax-oriented) pseudo-natural transformation \( \hat{t} : \hat{\mathcal{M}} \Rightarrow \hat{\mathcal{N}} \), and let \( \mathcal{M} := \hat{\mathcal{M}} \circ (-)^* \), \( \mathcal{N} := \hat{\mathcal{N}} \circ (-)^* \) and \( t := \hat{t} \circ (-)^* : \mathcal{M} \to \mathcal{N} \) be the restrictions to \( G \). Lemma A.3.11 (applied to the adjunction \((\ell, r) := (i^*_H, i^*_N) \in \text{Span}\)) shows that the components \( \hat{t}(i^!i^*) \) at each \( i \in J \) are uniquely determined by the components \( t(i^*i) = \hat{t}(i^*i) \) and the adjunctions \( i^*i \dashv i^*i^* \), as the mates

\[\hat{t}(i^!) = (\hat{t}(i^*)^{-1})! = (t(i^!)^{-1})!\]

for all \( i \in J \). Similarly, we may use Lemma A.3.11 with the other adjunctions \( i^*i \dashv i^*i^* \), which yields

\[\hat{t}(i^*) = (\hat{t}(i^*)^{-1})_! = (t(i^!)^{-1})_!\]

Of course in \( \text{Span} \) we have the equality \( i^*_! = i^*_i \) of 1-cells, hence (6.3.2) and (6.3.3) together imply that

\[\hat{t}(i^!)^{-1}_! = (t(i^!)^{-1})_*\]

for all \( i \in J \). Thus (i) implies (ii).

It remains only to show that (ii) implies (i). Thus assume that \( t : \mathcal{M} \Rightarrow \mathcal{N} \) satisfies (ii). Recall that, as in the proof of Theorem 5.3.7, the naturality and functoriality axioms of \( \hat{t} \) and the decomposition

\[
\begin{array}{ccc}
\hat{\mathcal{M}}(i^!u^*) & \cong & \hat{\mathcal{N}}(i^!u^*) \\
\downarrow \cong & \downarrow \cong \\
\mathcal{M} & \cong & \mathcal{N} \\
\downarrow \cong & \downarrow \cong \\
i & \cong & i
\end{array}
\]

show that all components \( \hat{t}(i^!u^*) \) of \( \hat{t} \) are dictated by \( t \), so we must only show that these components satisfy the axioms of a pseudo-natural transformation \( \hat{\mathcal{M}} \Rightarrow \hat{\mathcal{N}} \).
Recall that \( \tilde{\mathcal{M}} \) is (re)constructed by gluing together two extensions of \( \mathcal{M} \), namely \( \mathcal{M}_* \) and \( \mathcal{M}^* \), given by Construction 5.2.3 and Construction 5.5.10 respectively:

\[
\begin{array}{ccc}
\text{Span}(G; J) & \xrightarrow{(-)^*} & \mathcal{M}_* \\
\xRightarrow{(-)_*} & & \xRightarrow{(\sim)_*} \\
\mathcal{M}^* & \xrightarrow{(-)^{**}} & \text{Span}(G; J)^{\text{co}}
\end{array}
\]

Indeed, by definition (see (6.1.15)) \( \tilde{\mathcal{M}} \) is given by \( \tilde{\mathcal{M}}([\beta, \alpha]) = \mathcal{M}_*(\alpha)\mathcal{M}^*(\beta) \) on arbitrary 2-cells \([\beta, \alpha]\) of \( \text{Span} \) as in (6.1.3). The composite diagonal on the left is the canonical ‘motivic’ pseudo-functor \((-)^*: \mathcal{G}^{\text{op}} \to \text{Span} \) of Notation 6.1.9. Similar remarks hold for \( \mathcal{N} \).

As we have observed above, the equality (6.3.4) is necessary if we want to extend \( t \) to a pseudo-natural \( \hat{t}: \tilde{\mathcal{M}} \Rightarrow \tilde{\mathcal{N}} \), and the data of the latter is then uniquely determined by setting \( t(i) : = \tilde{t}(i_*) := (t(i)^{-1}) = (t(i_*))^{-1} \).

Note that (ii) implies in particular that \( t: \mathcal{M} \Rightarrow \mathcal{N} \) is a \( \mathbb{J}_1 \)-strong transformation (Definition 5.3.2). Hence by Theorem 5.3.7 we already know that \( \hat{t} \) is a transformation \( \mathcal{M}_* \Rightarrow \mathcal{N}_* \). Similarly, (ii) also implies that \( t \) is \( \mathbb{J}_1 \)-strong and thus, by the dual Theorem 5.5.14, extends to a transformation \( \hat{t}: \mathcal{M}^* \Rightarrow \mathcal{N}^* \) (see also Remark 5.5.18).

Since \( \tilde{\mathcal{M}} \) and \( \tilde{\mathcal{N}} \) coincide with \( \mathcal{M}_* \) and \( \mathcal{N}_* \) on 0- and 1-cells and have the same structural isomorphisms fun and un, this already implies that \( \hat{t} \) satisfies the functoriality axioms of a transformation \( \tilde{\mathcal{M}} \Rightarrow \tilde{\mathcal{N}} \), so it only remains to check that it satisfies the naturality axiom. Consider again any 2-cell of \( \text{Span} \)

\[
\begin{array}{ccc}
\mathcal{M}(i_*, u^*) & \xrightarrow{\beta} & \mathcal{M}(i_*, w^*) \\
\xRightarrow{\alpha} & & \xRightarrow{\gamma} \\
\mathcal{N}(i_*, v^*) & \xrightarrow{\beta} & \mathcal{N}(i_*, v^*)
\end{array}
\]

with \( \alpha = [a, \alpha_1, \alpha_2] \) and \( \beta = [b, \beta_1, \beta_2] \) as in (6.1.3). The following computation

\[
\begin{array}{ccc}
\tilde{\mathcal{M}}(i_*, u^*) & \xrightarrow{(\hat{t})_*} & \tilde{\mathcal{M}}(i_*, w^*) \\
\xRightarrow{\hat{t}(i_*)} & & \xRightarrow{\hat{t}(i_*)} \\
\tilde{\mathcal{N}}(i_*, v^*) & \xrightarrow{\hat{t}(i_*)} & \tilde{\mathcal{N}}(i_*, v^*)
\end{array}
\]

shows that the naturality of \( \hat{t} \) reduces to the naturality (\( \hat{\circ} \)) as a transformation \( \mathcal{M}_* \Rightarrow \mathcal{N}_* \) and the naturality (\( \hat{\triangleright} \)) as a transformation \( \mathcal{M}^* \Rightarrow \mathcal{N}^* \), which we know hold true.

\[\square\]

6.3.5. Notation. We denote by

\[
\text{Mack}(G; J)
\]

the (2-full) sub-2-category of \( \text{PsFun}(G^{\text{op}}, \text{ADD}) \) consisting of Mackey 2-functors, morphisms between them (i.e. transformations satisfying the equivalent conditions
of Proposition 6.3.1) and modifications. From the perspective of additive decompositions coming up in Chapter 7, it is natural to also consider the 1-full and 2-full sub-2-category

\[ \text{Mack}_{ic}(G; J) \]

of \( \text{Mack}(G; J) \) consisting of those Mackey functors \( \mathcal{M}: G^{op} \to \text{ADD}_{ic} \) taking values in idempotent-complete additive categories.

**6.3.6. Theorem.** By precomposing with the embedding \((\cdot)^*: G^{op} \hookrightarrow \text{Span}(G; J)\), we obtain a biequivalence

\[ \text{PsFun}_{11}(\text{Span}(G; J), \text{ADD}) \simeq \text{Mack}(G; J) \]

where on the left we have the bicategory of additive pseudo-functors on \( \text{Span}(G; J) \), all strong pseudo-natural transformations between them, and modifications. Similarly, with idempotent-complete values we have a biequivalence

\[ \text{PsFun}_{11}(\text{Span}(G; J), \text{ADD}_{ic}) \simeq \text{Mack}_{ic}(G; J) . \]

**Proof.** This is now an immediate consequence of Proposition 6.3.1 and the universal property of Mackey 2-motives, once we have checked that modifications also correspond. But the latter was already proved as part of Theorem 5.3.7. Indeed, as was observed above, the data of a transformation \( t: \tilde{M} \Rightarrow \tilde{N}: \text{Span} \to C \) is the same as that of its restriction to \( \text{Span} \), and moreover is uniquely determined by its further restriction \( t = \tilde{t} \circ (-)^* \) on \( G^{op} \) by taking mates. Similarly, the data of a modification at the levels of \( G^{op} \), \( \text{Span} \) or \( \text{Span} \) are all the same, hence it is only a question of verifying the modification axiom with respect to the various classes of 1-cells. Hence the verification done in the proof of Theorem 5.3.7 (for \( \text{Span} \)) works here as well (for \( \text{Span} \)) and yields the required bijections. \( \square \)

**6.3.7. Remark.** The above is analogous to the situation with ordinary Mackey 1-functors. Indeed, the category of Mackey functors (over \( \mathbb{Z} \)) for a finite group \( G \) can be defined as \( \text{Mack}(G) := \text{Fun}_+(\widehat{G\text{-set}}, \text{Ab}) \), the category of additive functors on the ordinary span category of \( G \)-sets; see Appendix A.4. The canonical embedding \((\cdot)^*: (G\text{-set})^{op} \to \widehat{G\text{-set}}\) induces a forgetful functor \( \text{Mack}(G) \to \text{Fun}_+(G\text{-set}, \text{Ab}) \), that is, any natural transformation \( t: M \Rightarrow N \) of Mackey functors also defines a natural transformation \( s = t \circ (-)^*: M^* = M \circ (-)^* \Rightarrow N \circ (-)^* = N^* \) (a ‘pre-morphism’). But conversely, not every natural transformation \( s: M^* \Rightarrow N^* \) is a natural transformation \( M \Rightarrow N \): We are still missing the commutativity of the squares involving the induction maps.

**6.3.8. Example.** Let \( D \) and \( E \) be additive derivators \( \text{Cat}^{op} \to \text{ADD} \) (Section 4.1) and let \( F: D \to E \) be a morphism of additive derivators, that is, a pseudo-natural transformation where the functors \( F_J: D(J) \to E(J) \) are additive for all \( J \in \text{Cat} \). Then the restricted 2-functors \( \mathcal{M} := D|_{\text{gpd}} \) and \( \mathcal{N} := E|_{\text{gpd}} \) are Mackey 2-functors (Theorem 4.1.1), and the restricted pseudo-natural transformation \( t := F|_{\text{gpd}}: \mathcal{M} \Rightarrow \mathcal{N} \) is obviously a pre-morphism between them. If \( F \) moreover preserves (homotopy) limits and colimits then \( t \) is even a morphism of Mackey 2-functors. Indeed, for a morphism of derivators the preservation of limits and colimits is equivalent to the \textit{a priori} stronger preservation of all homotopy Kan extensions (see [Gro13, §2.2]), which for \( t = F|_{\text{gpd}} \) specializes to the preservation of \( i_i \) and \( i_\ast \) in the sense of Proposition 6.3.1 (iii) and (iv).
Thus restriction along the inclusion $\text{gpd} \hookrightarrow \text{Cat}$ induces a pseudo-functor from the bicategory of additive derivators with continuous and co-continuous morphisms to the bicategory of Mackey 2-functors $\text{Mack}(\text{gpd}; \text{faithful})$. 

CHAPTER 7

Additive Mackey 2-motives and decompositions

In this chapter we take a closer look at the additivity properties of Mackey 2-functors. With an eye on decomposition results, we introduce the bicategory $\mathbb{Z}\text{Span}^\text{add}$ of additive Mackey 2-motives (Definition 7.1.7), where it is possible to take differences of 2-cells and to use idempotent 2-cells in order to split 1-cells and 0-cells into direct sums. We refer the reader to Appendix A.5 and A.6 for recollections on additivity and semi-additivity in categories and bicategories.

7.1. Additive Mackey 2-motives

7.1.1. Hypotheses. For simplicity, we revert to the simplest set of hypotheses, as stated in Hypotheses 2.3.1, namely $\mathbb{G}$ is a sub-2-category of the (2,1)-category $\text{gpd}$ of finite groupoids, and $\mathbb{J}$ consists of all faithful 1-cells of $\mathbb{G}$. Furthermore, we assume that $\mathbb{G}$ is closed under finite coproducts $\sqcup$ in $\text{gpd}$.

7.1.2. Remark. The interested reader will replace Hypotheses 7.1.1 by Hypotheses 5.1.1 plus a requirement that coproducts in $\mathbb{G}$ be sufficiently ‘disjoint’; cf. Example A.5.13 and (the proof of) Lemma 7.1.4. We avoid this generalization, since it does not yet present a good ratio of ‘new examples per added abstract nonsense’.

Let $\text{Span}(\mathbb{G};\mathbb{J})$ be the associated bicategory of Mackey 2-motives, as in Definition 6.1.1. We begin with the following observation.

7.1.3. Proposition. The finite coproducts of $\mathbb{G}$ make $\text{Span}(\mathbb{G};\mathbb{J})$ into a locally semi-additive bicategory in the sense of Definition A.6.1. Thus each Hom category $\text{Span}(\mathbb{G};\mathbb{J})(G,H)$ is semi-additive: It admits direct sums

$$(i_!u^*) \oplus (j_!v^*) = ((i \sqcup j)_!(u \sqcup v)^*)$$

of its objects, as well as a zero object $0 = (G \leftarrow \emptyset \rightarrow H)$, and therefore inherits a (unique) sum operation for parallel morphisms which makes each Hom-set into an abelian monoid, and composition bilinear. And the composition functors $- \circ -$ are additive in both variables.

Moreover, the finite coproducts of objects in $\mathbb{G}$ become in $\text{Span}(\mathbb{G};\mathbb{J})$ direct sums in the sense of Definition A.6.6.

Proof. This is all rather straightforward from the definitions. See Example A.5.13 for details on the sum of 1-cells and 2-cells. Let us just say a word on the direct sum of objects in $\text{Span}(\mathbb{G};\mathbb{J})$, concretely. The empty groupoid $\emptyset \in \mathbb{G}$ clearly becomes a zero object. Given two groupoids $X_1, X_2 \in \mathbb{G}_0$ with coproduct
\( i_1 : X_1 \to X_1 \sqcup X_2 \leftarrow X_2 : i_2 \) in \( G \), the resulting direct sum in \( \text{Span} \) has structure 1-cells given by the following spans:

\[
  \begin{array}{ccc}
  X_1 & \overset{(i_1)_*}{\longrightarrow} & X_1 \sqcup X_2 \overset{(i_2)_*}{\longrightarrow} X_2 .
  \end{array}
\]

These diagrams remain direct sums in the double-span bicategory \( \text{Span} \). Half of this claim follows from Lemma 7.1.4 below. The other verifications are similar and left to the reader.

**7.1.4. Lemma.** If \( j_1 : H_1 \to H_1 \sqcup H_2 \leftarrow H_2 : j_2 \) is a coproduct of finite groupoids contained in \( G \subseteq \text{gpd} \), then \( j_1^* : H_1 \leftarrow H_1 \sqcup H_2 \to H_2 : j_2^* \) is a product in \( \text{Span}(G; \mathcal{J}) \).

**Proof.** Let \( G \in \mathcal{G}_0 \) be a finite groupoid. We must show that the functor

\[
  \text{Span}(G; \mathcal{J})(G, H_1 \sqcup H_2) \xrightarrow{\Phi} \text{Span}(G; \mathcal{J})(G, H_1) \times \text{Span}(G; \mathcal{J})(G, H_2)
\]

induced by composition with \( j_1^* \) and \( j_2^* \) is an equivalence. On objects, \( \Phi \) sends a span \( G \xrightarrow{\mu} P \xrightarrow{i} H_1 \sqcup H_2 \) to the pair

\[
  \begin{array}{ccc}
  (i/j_1) & \Rightarrow & H_1 \\
  P & \xleftarrow{\mu} & G \xrightarrow{j_1} H_1 \sqcup H_2 \\
  \end{array}
\]

of composite spans. On maps, it is similarly induced by whiskering with \( j_\ell^* \) for \( \ell \in \{1, 2\} \). Write \( P = P_1 \sqcup P_2 \) for the decomposition of \( P \) induced by that of its image \( i(P) \subseteq H_1 \sqcup H_2 \), that is \( P_\ell := i^{-1}(i(P) \cap H_\ell) \). It is easy to check that the comparison functor \( P_\ell \to (i/j_\ell) \)

\[
  \begin{array}{ccc}
  P_\ell & \xrightarrow{i} & H_\ell \\
  \xleftarrow{\mu} & G \xrightarrow{j_\ell} H_1 \sqcup H_2 \\
  \end{array}
\]

is an equivalence for \( \ell \in \{1, 2\} \), from which we deduce an isomorphism

\[
  (7.1.5) \quad \Phi(G \xrightarrow{\mu} P \xrightarrow{i} H_1 \sqcup H_2) \cong \left( (G \xrightarrow{\mu_1} P_1 \xrightarrow{i_1} H_1), (G \xrightarrow{\mu_2} P_2 \xrightarrow{i_2} H_2) \right).
\]

There is also a ‘summation’ functor

\[
  \text{Span}(G; \mathcal{J})(G, H_1) \times \text{Span}(G; \mathcal{J})(G, H_2) \xrightarrow{\Psi} \text{Span}(G; \mathcal{J})(G, H_1 \sqcup H_2)
\]

which sends a pair \( ((G \xrightarrow{\nu_1} Q_1 \xrightarrow{i_1} H_1), (G \xrightarrow{\nu_2} Q_2 \xrightarrow{i_2} H_2)) \) to the span

\[
  (G \xrightarrow{(\nu_1, \nu_2)} Q_1 \sqcup Q_2 \xrightarrow{i_1 \sqcup i_2} H_1 \sqcup H_2)
\]

and similarly on morphisms. Using (7.1.5), it is now straightforward to check that \( \Psi \) and \( \Phi \) are mutually inverse equivalences.

\( \square \)
7.1.6. Remark. The 2-cells in the bicategory $\text{Span}$ of Mackey 2-motives do not have additive inverses, though, which can be inconvenient. For instance, if $e = e^2: \text{Id}_X \Rightarrow \text{Id}_X$ is an idempotent 2-cell, we may wish to form the complementary idempotent $1_X - e$ (here we write $1_X := \text{id}_{\text{Id}_X}$ for short). Moreover, we may be tempted to use the decomposition $1_X = e + (1_X - e)$ in order to split the 1-cell $\text{Id}_X$ or even the object $X$ itself. Unfortunately, none of this can be done in the bicategory $\text{Span}$. Fortunately, it is not too hard to enlarge such a bicategory so as to accommodate negatives and splittings. Indeed, in Appendix A.6 we construct the block-completion $\mathcal{B}^\text{♭}$ of any locally semi-additive bicategory $\mathcal{B}$ with direct sums. The bicategory $\mathcal{B}^\text{♭}$ is block-complete, that is: (1) it is locally idempotent-complete, i.e. its idempotent 2-cells split 1-cells into direct sums, and (2) its idempotent 2-cells similarly give rise to direct sum decompositions of 0-cells (see Remark A.6.15 and Definition A.6.17). Moreover, there is an embedding $\mathcal{B} \rightarrow \mathcal{B}^\text{♭}$ which is the universal pseudo-functor to a block-complete bicategory (Theorem A.6.23).

By Proposition 7.1.3 this construction can be applied to $\text{Span}$, leading to:

7.1.7. Definition (Additive and $k$-linear Mackey 2-motives). We define the bicategory of additive Mackey 2-motives to be

$$\mathbb{Z}\text{Span}(G; J) := \text{Span}(G; J)^{\text{♭}},$$

the block-completion (as in Construction A.6.22 and Remark A.6.24) of the locally semi-additive bicategory $\text{Span}(G; J)$. For contrast, we refer to the unadorned $\text{Span}(G; J)$ as the bicategory of semi-additive Mackey 2-motives. Concretely, the bicategory $\mathbb{Z}\text{Span}(G; J)$ consists of:

- As objects, all pairs $(G, e)$ where $G \in \mathcal{G}_0$ is a finite groupoid and $e = e^2: \text{Id}_G \Rightarrow \text{Id}_G$ is an idempotent element of the (group-completed) commutative ring

$$\text{Span}(G; J)(\text{Id}_G, \text{Id}_G).$$

- For Hom categories, the subcategories

$$\mathbb{Z}\text{Span}(G; J)((G, e), (G', e')) \subseteq ((\text{Span}(G; J)(G, G'))^{\text{♭}})$$

of the idempotent-completion $(\cdot)^{\text{♭}}$ of the group completion $(\cdot)^{\text{♭}}$ of the semi-additive category $\text{Span}(G; J)(G, G')$, consisting of those 1-cells $u$ and 2-cells $\alpha$ which absorb the idempotents $e$ and $e'$, in the sense that $e \circ u \circ e' \cong u$ and $e \circ \alpha \circ e' \cong \alpha$ (see (A.6.20) for more details).

More generally, if $k$ is any commutative ring we define the bicategory of $k$-linear Mackey 2-motives

$$k\text{Span}(G; J) := (k \otimes \mathbb{Z}\text{Span}(G; J))^{\text{♭}},$$

to be the block-completion of the $k$-linearization of (the group completion of) semi-additive Mackey 2-motives. The latter is obtained simply by tensoring all Hom-groups of 2-cells with $k$ and extending the structural functors $k$-linearly.

7.1.8. Remark. Additive 2-motives inherit from their semi-additive progenitors the property of classifying all Mackey 2-functors whose values are idempotent-complete additive categories. In other words, precomposition with the canonical pseudo-functor $\mathcal{G}^{\text{op}} \rightarrow \mathbb{Z}\text{Span}(G; J)$ induces a biequivalence

$$(7.1.9) \quad \text{PsFun}_{\text{II}}(\mathbb{Z}\text{Span}(G; J), \text{ADD}_{k}) \simeq \text{Mack}_{k}(G; J).$$
In order to see this, it suffices to break the canonical embedding down to its composition factors (see Remark A.6.24):

\[
\begin{align*}
G^{\text{op}} & \downarrow \downarrow \downarrow \downarrow \downarrow \\
\text{Span} & \downarrow \downarrow \downarrow \downarrow \\
\text{Span}_+ & \downarrow \downarrow \downarrow \\
(\text{Span}_+)^2 & \downarrow \downarrow \\
\mathbb{Z}\text{Span} = ((\text{Span}_+)^2)^b & \text{def.} \\
\text{PsFun}_{\text{II}}(G^{\text{op}}, \text{ADD}_{\text{ic}}) & \supseteq \text{Mack}_{\text{ic}} \\
\text{PsFun}_{\text{II}}(\text{Span}, \text{ADD}_{\text{ic}}) & \simeq \text{by Theorem 6.3.6} \\
\text{PsFun}_{\text{II}}(\text{Span}_+, \text{ADD}_{\text{ic}}) & \simeq \text{by Remark A.6.4(1)} \\
\text{PsFun}_{\text{II}}((\text{Span}_+)^2, \text{ADD}_{\text{ic}}) & \simeq \text{by Remark A.6.4(2)} \\
\text{PsFun}_{\text{II}}(\text{Span}_+^b, \text{ADD}_{\text{ic}}) & \simeq \text{by Theorem A.6.23} \\
\text{PsFun}_{\text{II}}(\text{Span}_+^b, \text{ADD}_{\text{ic}}) & \simeq \text{by Remark A.6.4(2)} \\
\text{PsFun}_{\text{II}}(\text{Span}_+^b, \text{ADD}_{\text{ic}}) & \simeq \text{by Theorem A.6.23} \\
\end{align*}
\]

Besides the universal properties of the various constructions, this also uses the convenient fact that additive pseudo-functors are automatically \textit{locally} additive (Proposition A.6.14), as well as the fact that the target 2-category \ADD_{\text{ic}} is itself block-complete (Example A.6.18).

7.1.10. Remark. We note that each of the canonical pseudo-functors on the left-hand side of the above picture (and hence their composite \( G^{\text{op}} \rightarrow \mathbb{Z}\text{Span}(G; J) \)) does deserve the name ‘embedding’, because it is injective on 0-, 1- and 2-cells. Injectivity may fail in general on 2-cells for the group completion \( B \rightarrow B_{+} \), but holds in this particular case where the Hom monoids of 2-cells in \( \text{Span}(G; J) \) with \( G \subseteq \text{gpd} \) are all free; see Example A.5.13 for details.

7.1.11. Definition. If \( \mathcal{M} : G^{\text{op}} \rightarrow \text{ADD}_{\text{ic}} \) is any Mackey 2-functor with idempotent-complete values, its essentially unique extension to an additive functor

\[ \mathcal{M} : \mathbb{Z}\text{Span}(G; J) \longrightarrow \text{ADD}_{\text{ic}} \]

will be referred to as the \textit{realization} of additive 2-motives via \( \mathcal{M} \).

7.1.12. Remark. If so wished, there is a way to obtain realizations as \textit{strict} 2-functors rather than mere pseudo-functors, just like Mackey 2-functors are 2-functors. Indeed, recall that we may replace \( \text{Span}(G; J) \) with a biequivalent strict version \( \text{Span}(G; J)^{\text{str}} \), for instance the one explicitly presented in Corollary 6.2.1, which is an essentially small strict 2-category. Then we obtain biequivalences

\[
\text{2Fun}_{\text{II}} (\mathbb{Z}\text{Span}(G; J)^{\text{str}}, \text{ADD}_{\text{ic}}) \simeq \text{PsFun}_{\text{II}} (\mathbb{Z}\text{Span}(G; J)^{\text{str}}, \text{ADD}_{\text{ic}}) \Rightarrow \text{Mack}_{\text{ic}}(G; J)
\]

where \( \mathbb{Z}\text{Span}(G; J)^{\text{str}} \) is defined as in Definition 7.1.7, and \( \text{2Fun}_{\text{II}} (\mathcal{C}, \mathcal{C}') \) denotes the 2-category of additive 2-functors between 2-categories \( \mathcal{C} \) and \( \mathcal{C}' \), pseudo-natural transformations between them and modifications (\textit{cf.} Notation 4.3.1). The first biequivalence holds by Power’s strictification theorem for pseudo-functors, recalled in Remark A.1.17, and the second one is induced by the biequivalence (7.1.9) and the strictification \( \text{Span}(G; J) \Rightarrow \text{Span}(G; J)^{\text{str}} \) (see also Remark A.1.15).
7.2. The Yoneda embedding

Our next theorem shows that Mackey 2-motives could be simply thought of as representable Mackey 2-functors:

**7.2.1. Theorem.** There is a ‘Yoneda’ pseudo-functor

\[ \mathbb{Z}
\text{Span}(G; J)^{\text{op}} \rightarrow \text{Mack}(G; J), \quad (G, e) \mapsto \mathbb{Z}
\text{Span}((G, e), -)|_{G^{\text{op}}} \]

which is a biequivalence on its 1- and 2-full image.

**Proof.** Since \(\mathbb{Z}
\text{Span}\) is block-complete by construction, as explained in Remark A.6.25 we have a contravariant Yoneda embedding

\[ \mathbb{Z}
\text{Span}(G; J)^{\text{op}} \rightarrow \text{PsFun}(\mathbb{Z}
\text{Span}(G; J), \text{Addic}) \]

into the category of additive pseudo-functors. In full generality, this is a biequivalence onto its 1- and 2-full image. We may also replace \(\text{Addic}\) with \(\text{ADDic}\) without changing the conclusion. In order to prove the theorem, it now suffices to compose the above with the biequivalence of (7.1.9). □

Thanks to this result, we may now add a new large family to our list of Mackey 2-functors in Examples 1.2.9:

**7.2.2. Notation.** For every finite groupoid \(G_0 \in \mathbb{G}\) and every idempotent 2-cell \(e_0 = e_0^G : \text{Id}_G \Rightarrow \text{Id}_G\) in \(\mathbb{Z}
\text{Span}(G; J)\) (for instance \(e_0 = 1_G\)), we obtain from Theorem 7.2.1 a canonical Mackey 2-functor

\[ \mathcal{M}^{(G_0, e_0)}_{\text{univ}} := \mathbb{Z}
\text{Span}(G; J)((G_0, e_0), -) \]

on \(G\).

The simplest case of this construction, where we set \(G_0 = 1\) the trivial group and \(e_0 = 1_{G_0}\) the identity, is already quite interesting because it recovers ordinary spans of \(G\)-sets, repackaged into a single Mackey 2-functor:

**7.2.3. Theorem.** Let \(\mathbb{G} = \text{gpd}\) and \(\mathbb{J} = \text{faithful}\). Then the Mackey 2-functor \(\mathcal{M}^{1}_{\text{univ}}\) associated to the trivial group \(1 = (1, 1, 1)\) is canonically given by

\[ (\mathbb{G}
\text{set})^\bullet_0 \cong \mathcal{M}^{1}_{\text{univ}}(G) \]

for every finite group \(G\), and if \(u : H \rightarrow G\) is any group homomorphism then \(u^*\) is induced by the restriction functor \(u^* : \mathbb{G}
\text{set} \rightarrow \mathbb{H}
\text{set}\). In other words, the (group-completed and idempotent-completed) ordinary span categories of \(G\)-sets extend, by varying \(G\), to a Mackey 2-functor.

**Proof.** Fix a finite group \(G\). As explained in Appendix B, the category of \(G\)-sets can be viewed as a comma category of groupoids over \(G\). More precisely, we prove in Corollary B.0.10 that the transport groupoid functor \(G \ltimes (-) : \mathbb{G}
\text{set} \rightarrow \text{gpd}\) lifts to an equivalence

\[ \mathbb{G}
\text{set} \xrightarrow{\sim} \tau_1(\text{gpd}^{G}) \]

between the category of \(G\)-sets and the truncated comma 2-category of faithful functors in \(\mathbb{G} = \text{gpd}\) over \(G\). There is also an evident forgetful functor

\[ \text{Span}(G; J)(1, G) \rightarrow \tau_1(\text{gpd}^{G}) \]
defined as follows (on 1-cells)

\[
\begin{array}{ccc}
H & \xrightarrow{i} & G \\
\downarrow & \Downarrow & \downarrow \\
H' & \xrightarrow{j} & G'.
\end{array}
\]

This functor is clearly an isomorphism, since there is always exactly one way to complete any object \((H, i)\) and morphism \([a, \alpha]\) of \(\tau_1 (\text{gpd}_{G})\) to an object or a morphism of \(\text{Span}(G; J)(1, G)\). By combining the above two equivalences, taking 1-categories of spans, and group- and idempotent-completing, we get a canonical equivalence

\[
(\hat{G} \text{-set})_+ \cong \text{Fun}_+ ((G \text{-set})_+, \text{Ab})
\]

as claimed. It is now straightforward to determine the restrictions \(u^*\).

---

### 7.3. Presheaves over a Mackey 2-functor

We recall (Remark B.0.3) that there is an equivalence

\[(7.3.1)\]

\[\text{Mack}_2(G) \cong \text{Fun}_+ ((\hat{G} \text{-set})_+, \text{Ab})\]

between the category of ordinary Mackey functors for the group \(G\) and the additive functor category over spans of \(G\)-sets. Thus \((\hat{G} \text{-set})_+\) can be identified with the category of representable Mackey functors for \(G\).

Our next goal is to extend the result of Theorem 7.2.3 to show that we can also form a Mackey 2-functor by assembling the abelian categories of all Mackey functors (not just the representable ones). For this we can use the following general construction:

**7.3.2. Proposition.** Let \(S\) be a Mackey 2-functor on \((G; J)\) such that each additive category \(S(G)\) is essentially small, and let \(\mathcal{A}\) be a cocomplete abelian category. Then \(G \mapsto \mathcal{M}(G) := \text{Fun}_+ (S(G)^{\text{op}}, \mathcal{A})\) defines a Mackey 2-functor \(\mathcal{M} : \mathcal{G}^{\text{op}} \to \text{ADD}_{\text{lc}}\) on \((G; J)\), with 1- and 2-functoriality extended from that of \(S\) along the additive Yoneda embeddings \(y_G : S(G) \hookrightarrow \mathcal{M}(G), X \mapsto S(-, X)\).

**Proof.** Let us describe the structure of \(\mathcal{M}\) in some details. Given a 1-cell \(u : H \to G\) of \(\mathcal{G}\), we can extend \(u^* : S(G) \to S(H)\) to the functor categories by forming the left Kan extension of \(y_H \circ u^*\) along \(y_G:\)

\[
\begin{array}{ccc}
S(G) & \xrightarrow{y_G} & \mathcal{M}(G) \\
\downarrow & \not\equiv & \downarrow \\
S(H) & \xrightarrow{y_H \circ u^*} & \mathcal{M}(H).
\end{array}
\]

Since \(y_G\) is fully faithful, the canonical natural transformation \(u^* y_G \Rightarrow y_H u^*\) is an isomorphism. In fact, the extension is given by the formula

\[(7.3.4)\]

\[(u^* M)(Y) = \colim_{(X, y_G X \to M)} y_H u^* X\]
where $M \in \mathcal{M}(G)$, $Y \in \mathcal{S}(H)$, and the colimit is taken over the comma category of $y_G$ over $M$. (We may even define the extension $u^*$ so that the square (7.3.3) commutes strictly.)

The extended functor $u^* : \mathcal{M}(G) \to \mathcal{M}(H)$ has a right adjoint $u_*$ given by restriction along $u^* : \mathcal{S}(G)^{\text{op}} \to \mathcal{S}(H)^{\text{op}}$, that is:

$$u_*N = N \circ u^* \quad \text{for all } N \in \mathcal{M}(H).$$

It follows also from the standard properties of Kan extensions that for every 2-cell $\alpha : u \Rightarrow v$ of $G$, the natural transformation $\alpha^* : u^* \Rightarrow v^*$ given by the 2-functoriality of $\mathcal{S}$ extends uniquely between the extended functors $u^*$ and $v^*$ on $\mathcal{M}(G)$. This makes $\mathcal{M}(\cdot)$ into a 2-functor $\mathcal{G}^{\text{op}} \to ADD^e$. Let us verify that it satisfies the axioms of a Mackey 2-functor as given in Definition 1.2.7.

Clearly $\mathcal{M}$ satisfies the additivity axiom (Mack 1) because $\mathcal{S}$ does:

$$\mathcal{M}(G_1 \sqcup G_2) = \text{Fun}(G_1 \sqcup G_2)^{\text{op}}, A) \\
\cong \text{Fun}(S(G_1)^{\text{op}} \oplus S(G_2)^{\text{op}}, A) \\
\cong \text{Fun}(S(G_1)^{\text{op}}, A) \oplus \text{Fun}(S(G_2)^{\text{op}}, A) \\
= \mathcal{M}(G_1) \oplus \mathcal{M}(G_2).$$

For the existence of the adjoints (Mack 2), let $i \in J$. We have already seen that a right adjoint $i_*$ exists. We claim that in this case it is also left adjoint to restriction $i^*$. In order to see this, we first prove the remarkably simple formula

$$i^* M \cong M \circ i_* \quad (M \in \mathcal{M}(G))$$

for the restriction functor. Indeed, for all $Y \in \mathcal{S}(H)$ we have:

$$(i^* M)(Y) = \colim_{(X,gX \to M)} (y_Hi^* X)(Y) \quad \text{by (7.3.4)}$$

$$\cong \colim_{(X,gX \to M)} \mathcal{S}(H)(Y, i^* X)$$

$$\cong \colim_{(X,gX \to M)} \mathcal{S}(G)(i_* Y, X) \quad \text{by } i_* = i_1 \cdot i^* \text{ for } \mathcal{S}$$

$$= \colim_{(X,gX \to M)} (y_G X)(i_* Y)$$

$$= \left( \colim_{(X,gX \to M)} y_G X \right)(i_* Y)$$

$$\cong M(i_* Y)$$

which proves (7.3.6). We will also need the isomorphism

$$i_* \circ y_H \cong y_G \circ i_*$$

which follows from the computation (for $Y \in \mathcal{S}(H)$)

$$i_*(y_H(Y)) = y_H(Y) \circ i^* \quad \text{by (7.3.5)}$$

$$= \mathcal{S}(H)(i^*(-), Y)$$

$$\cong \mathcal{S}(G)(- , i_* Y) \quad \text{by } i^* \dashv i_* \text{ for } \mathcal{S}$$

$$= y_G(i_*(Y))$$

where we have now used the other adjunction, $i^* \dashv i_*$, for the Mackey 2-functor $\mathcal{S}$.

To find the claimed natural isomorphism

$$\mathcal{M}(G)(i_* N, M) \cong \mathcal{M}(H)(N, i^* M)$$
consider first the case where \( M \in \mathcal{M}(G) \) is arbitrary and \( N = y_H Y \in \mathcal{M}(H) \) is representable. We compute:
\[
\begin{align*}
\mathcal{M}(G)(i_* y_H(Y), M) &\cong \mathcal{M}(G)(y_H i_*(Y), M) \quad \text{by (7.3.7)} \\
&\cong M(i_* Y) \quad \text{by Yoneda} \\
&\cong (i^* M)(Y) \quad \text{by (7.3.6)} \\
&\cong \mathcal{M}(H)(y_H Y, i^* M) \quad \text{by Yoneda}.
\end{align*}
\]

This extends to arbitrary \( N \), because we can rewrite \( N \) as a colimit of representable objects and because \( i_* \) commutes with colimits, the latter being an immediate consequence of (7.3.5). This concludes the proof of (Mack 2) and, incidentally, also of the ambidexterity axiom (Mack 4).

To verify the Base-Change formulas (Mack 3), consider the mates
\[
q_l \circ p^* \Rightarrow u^* \circ i_! \quad \text{and} \quad u^* \circ i_* \Rightarrow q_! \circ p^*
\]

of the natural transformation \( \mathcal{M}(\gamma) = \gamma^* : p^* i^* \Rightarrow q^* u^* \) induced by a suitable isocomma square of \( G \). By (7.3.3) and (7.3.6), the restriction and induction functors of \( \mathcal{M} \) — and therefore also the adjunctions \( i_* \dashv i^* \dashv i_* \) — restrict to those of \( S \) via the Yoneda embeddings. Since \( S \) is a Mackey 2-functor, it follows that the components of the two mates at all representable objects are invertible. By writing an arbitrary object as a colimit of representables, and because the source and target functors commute with colimits, we deduce that the component at an arbitrary object is also invertible. This ends the proof that \( \mathcal{M} \) is a Mackey 2-functor. \( \square \)

**7.3.8. Remark.** The above proof illustrates the advantage of defining Mackey 2-functors (Definition 2.3.5) without requiring the Strict Mackey Formula (Mack 7). The latter could be difficult to verify when the adjoints are provided up to a series of natural isomorphisms. However, the Rectification Theorem 3.4.3 still guarantees that one can modify units and counits, if necessary, to guarantee (Mack 7) as well.

**7.3.9. Corollary.** The assignment \( G \mapsto \text{Mack}_2(G) \) extends to a Mackey 2-functor defined on \( G = \text{gpd} \) and \( J = \text{faithful} \). The result also holds over any base ring \( k \) instead of the integers.

**Proof.** Apply Proposition 7.3.2 to \( \mathcal{S} := (G \mapsto (\hat{G} - \text{set})^{\text{op}}_+) \), the dual (as in Example 1.2.8) of the Mackey 2-functor of Theorem 7.2.3, and combine the result with (7.3.1). By replacing \( \text{Ab} \) with \( k \text{-}\text{Mod} \) in the latter equation, we obtain the more general result for \( k \)-linear Mackey functors. \( \square \)

**7.4. The Burnside ring in Mackey 2-motives**

Recall that the Burnside ring \( A(G) \) of a finite group \( G \) is the Grothendieck ring of finite \( G \)-sets, \( A(G) := K_0(G - \text{set}, \Pi, \times) \). It is also the endomorphism ring of \( G/G \) in the additive category of ordinary spans (see [Bou97] and [Lew80]):
\[
A(G) \cong \text{End}_{(\hat{G} - \text{set})^+_+}(G/G) = \text{End}_{(\hat{G} - \text{set})^+_+}(G/G).
\]

By tracing the \( G \)-set \( G/G \) through the equivalence of Theorem 7.2.3, we see that it maps to the span \( 1 \leftarrow G = G \), as an object in \( \text{Hom}_{\text{Sp}_{\text{fin}}(G;\mathbb{Z})}(1, G) \). Therefore we
can identify $A(G)$ inside of additive Mackey 2-motives $\mathbf{Z\text{Span}} = \mathbf{Z\text{Span}}(G; J)$ as the following 2-cell endomorphism ring of the 1-cell $1 \leftarrow G = G$:

$A(G) \cong \text{End}_{\mathbf{Z\text{Span}}(1, G)}(1 \leftarrow G = G)$. 

**7.4.2. Proposition.** For every group $G$, whiskering with $(1 \leftarrow G = G)$ induces a ring epimorphism

$\phi: \text{End}_{\mathbf{Z\text{Span}}(G, G)}(1 \leftarrow G = G) \to A(G)$

which admits a canonical section $\psi: A(G) \to \text{End}_{\mathbf{Z\text{Span}}(G, G)}(1 \leftarrow G = G)$ which is also a ring homomorphism. The analogous result holds over any commutative ring $k$, with $k$-algebra homomorphisms

$\phi_k: \text{End}_{\mathbf{Z\text{Span}}(G, G)}(1 \leftarrow G = G) \to kA(G)$

and $\psi_k$, where $kA(G) := k \otimes \mathbb{Z} A(G)$ and where similarly $k\mathbf{Span}(G; J)$ is the $k$-linear bicategory of Mackey 2-motives.

**Proof.** The $k$-linear generalization is obtained by tensoring everything in sight with $k$, so let us concentrate on $k = \mathbb{Z}$. Moreover, we use (7.4.1) to work entirely within $\mathbf{Z\text{Span}}$. The horizontal composition of $\mathbf{Z\text{Span}}$ induces a whiskering functor

$\phi = (-) \circ (1 \leftarrow G = G): \mathbf{Z\text{Span}}(G, G) \longrightarrow \mathbf{Z\text{Span}}(1, G)$

which further specializes to a ring homomorphism

$\phi: \text{End}_{\mathbf{Z\text{Span}}(G, G)}(1 \leftarrow G = G) \longrightarrow \text{End}_{\mathbf{Z\text{Span}}(1, G)}(1 \leftarrow G = G)$,

where in the target we have tacitly used the canonical isomorphism of Remark 2.1.9 to replace the 1-cell $1 \leftarrow G = G$ by $1 \leftarrow G = G$.

Unpacking the construction, we see by a lengthy but straightforward computation that $\phi$ simply maps a 2-cell (represented by a diagram) as on the left-hand side below, see (6.1.3), to the 2-cell (represented by the diagram) on the right-hand side:

\[
\begin{array}{ccc}
G & \xrightarrow{\beta_1} & G \\
\downarrow w & & \downarrow \beta_2 \\
R & \xrightarrow{k} & G \\
\downarrow \alpha_1 & & \downarrow \alpha_2 \\
G & & G \\
\end{array}
\]  
\[
\begin{array}{ccc}
1 & \xrightarrow{\beta_1} & G \\
\downarrow \beta_2 & & \downarrow \beta_2 \\
R & \xrightarrow{k} & G \\
\downarrow \alpha_1 & & \downarrow \alpha_2 \\
1 & & G \\
\end{array}
\]

In the opposite direction, we define a section

$\psi: \text{End}_{\mathbf{Z\text{Span}}(1, G)}(1 \leftarrow G = G) \longrightarrow \text{End}_{\mathbf{Z\text{Span}}(G, G)}(1 \leftarrow G = G)$

of $\phi$ by extending $\mathbb{Z}$-linearly the following assignment:

\[
\begin{array}{ccc}
G & \xrightarrow{\beta} & G \\
\downarrow \beta & & \downarrow \beta \\
R & \xrightarrow{k} & G \\
\downarrow a & & \downarrow a \\
1 & & 1 \\
\end{array}
\]  
\[
\begin{array}{ccc}
G & \xrightarrow{\beta^{-1}} & G \\
\downarrow \beta & & \downarrow \beta \\
R & \xrightarrow{k} & G \\
\downarrow a & & \downarrow a \\
G & & G \\
\end{array}
\]
It is not hard to see that this construction is well-defined. Indeed, the data of an equivalence between two diagrams as on the left-hand side (see (6.1.2) or Proposition 6.1.5) is immediately seen to satisfy also the conditions for being an equivalence between their images under (7.4.4). We also obviously have $\phi \circ \psi = \text{id}$.

To see that $\psi$ (or $\phi$, as made explicit in (7.4.3)) is a ring homomorphism, recall that in these endomorphism rings of 2-cells the addition is induced by coproducts of $G$ taken at the middle object $R$, and the multiplication is induced by taking iso-comma squares vertically, with the identity being the diagram containing only identity 2-cells of $G$. These are all preserved by both $\phi$ and $\psi$. □

7.4.5. Remark. Following up on the above proof, one can similarly use Proposition 6.1.5 to represent any 2-cell in $\text{End}_{Z\text{Sp}\hat{\alpha}}(G,G)(\text{Id}_G)$ of the form

$$
\begin{array}{c}
G \\
\beta_1 & b & \beta_2 \\
G & w & k \\
\alpha_1 & a & \alpha_2 \\
G & G & G
\end{array}
$$

(7.4.6)

by replacing every 1-cell $a, b, k, w$ by our favorite one, say $k$. However, one needs to decide which 2-cell to use to apply Proposition 6.1.5 (2). Each of the three replacements (say of $a, b$ and $w$) allows us to replace one 2-cell among $\alpha_1, \alpha_2, \beta_1, \beta_2$ by an identity. However, the fourth one would survive. For instance, in the 2-cell (7.4.6), if we replace ‘anti-clockwise’ the three 1-cells $b, w, a$ by $k$ using $\beta_2: b \Rightarrow k, \beta_2\beta_1: w \Rightarrow k$, and $\beta_2\beta_1\alpha_1^{-1}: a \Rightarrow k$ respectively, we obtain the isomorphic 2-cell

$$
\begin{array}{c}
G \\
\beta \text{id} & k & \beta \text{id} \\
G & k & k \\
\beta \text{id} & k & \gamma \\
G & G & G
\end{array}
$$

where the automorphism $\gamma := \alpha_2\alpha_1\beta_1^{-1}\beta_2^{-1}: k \Rightarrow k$ is not necessarily the identity. The latter is in fact the obstruction for belonging to the image of the homomorphism $\psi$ of (7.4.4). Therefore we do not expect $\phi$ to be an isomorphism in general. These questions will be further investigated elsewhere.

7.5. Motivic decompositions of Mackey 2-functors

We conclude by explaining how the Burnside ring $A(G)$ of a finite group(oid) $G$ acts on the additive category $\mathcal{M}(G)$, for any Mackey 2-functor $\mathcal{M}$. As a consequence, ring decompositions of $A(G)$ induce decomposition of the category $\mathcal{M}(G)$.

7.5.1. Proposition. Let $\mathcal{M}: G^{\text{op}} \to \text{ADD}_e$ be a Mackey 2-functor and consider $\hat{\mathcal{M}}: Z\text{Sp}\hat{\alpha} \to \text{ADD}_e$ the associated realization of Mackey 2-motives via $\mathcal{M}$ (Definition 7.1.11). Then $\hat{\mathcal{M}}$ induces ring homomorphisms for every groupoid $G \in G_0$

$$
\text{End}_{Z\text{Sp}\hat{\alpha}}(G,G)(\text{Id}_G) \xrightarrow{\hat{\mathcal{M}}} \text{End}_{\text{Fun}_+(\mathcal{M}(G),\mathcal{M}(G))}(\text{Id}_{\mathcal{M}(G)})
$$
between rings of endomorphisms of the identity 1-cells. In particular, precomposition with the homomorphism \( \psi: A(G) \to \text{End}_{\mathbb{Z}\text{span}}(G,G)(\text{Id}_G) \) of Proposition 7.4.2 yields a ring homomorphism

\[
A(G) \xrightarrow{\mathcal{M}\psi} \text{End}_{\text{Fun}(\mathcal{M}(G),\mathcal{M}(G))}(\text{Id}_{\mathcal{M}(G)}).
\]

Proof. This is simply the 2-functoriality of \( \mathcal{M} \) on the endomorphism ring of the 1-cell \( \text{Id}_G: G \to G \) in \( \mathbb{Z}\text{span} \), whose image is \( \mathcal{M}(\text{Id}_G) = \text{Id}_{\mathcal{M}(G)} \).

7.5.3. Remark. We can think of the ring homomorphism \( \rho := \mathcal{M}\psi \) of (7.5.2) as an action of the ring \( A(G) \) on the category \( \mathcal{M}(G) \), since every \( a \in A(G) \) yields a natural transformation \( \rho(a) = \mathcal{M}(\psi(a)): \text{Id}_{\mathcal{M}(G)} \to \text{Id}_{\mathcal{M}(G)} \) and therefore an actual endomorphism \( \rho(a)_x : x \to x \) for every object \( x \in \mathcal{M}(G) \). In fact, in this way \( \mathcal{M}(G) \) becomes an \( A(G) \)-linear category, a.k.a. a category enriched in \( A(G) \)-modules: the Hom sets are \( A(G) \)-modules and composition is \( A(G) \)-bilinear.

This is a very general fact: If \( A \) is any commutative ring and \( \mathcal{M} \) is any additive category, to give an \( A \)-enrichment on \( \mathcal{M} \) is the same thing as to give a ring homomorphism \( \rho: A \to \text{End}_{\text{Fun}((\mathcal{M},\mathcal{M}))}(\text{Id}_{\mathcal{M}}) \). Given \( \rho \), we obtain the actions by \( a \cdot f := \rho(a)_y \circ f = f \circ \rho(a)_x \) (for \( a \in A \) and \( f \in \mathcal{M}(x,y) \)). Conversely, given the \( A \)-enrichment we recover the ring homomorphism \( \rho \) by letting \( \rho(a)(a) := r \cdot \text{id}_x \) for all \( x \in \text{Obj} \mathcal{M} \).

7.5.4. Corollary. With notation as in Proposition 7.5.1, any ring decomposition \( A(G) \cong B_1 \times B_2 \) yields a corresponding decomposition of the additive category \( \mathcal{M}(G) \) as \( \mathcal{M}(G) \cong \mathcal{N}_1 \oplus \mathcal{N}_2 \) in such a way that for every \( \{i,j\} = \{1,2\} \), the ring \( B_i \) acts as zero on \( \mathcal{N}_j \) and acts on \( \mathcal{N}_i \) via the homomorphism \( \mathcal{M}\psi \) of (7.5.2).

Proof. The decomposition \( 1 = e_1 + e_2 \) in idempotents associated to the isomorphism \( A(G) \cong B_1 \times B_2 \) yields under \( \mathcal{M}\psi \) a similar decomposition of \( \text{id}_{\text{Id}_{\mathcal{M}(G)}} = f_1 + f_2 \) by Proposition 7.5.1. Since \( \mathcal{M}(G) \) is idempotent-complete, the idempotents \( (f_1)_m \) and \( (f_2)_m \) yield decompositions of every object \( m \in \mathcal{M}(G) \), and consequently a decomposition of the category \( \mathcal{M}(G) \) as announced. Compare Example A.6.5 for \( \mathcal{A} = \mathcal{B} = \mathcal{M}(G) \) and \( F = \text{Id}_{\mathcal{M}(G)} \).

Equivalently (and more abstractly), use that \( \mathcal{M} \) is additive, i.e. it sends biproducts of objects in the block-complete bicategory \( \mathbb{Z}\text{span} \) to biproducts in \( \text{ADD}_{\text{de}} \).

7.5.5. Example. The decompositions of Burnside rings \( kA(G) \) have been variously described in the literature, so it is possible to apply Corollary 7.5.4 concretely. The primordial result is due to Dress [Dre69] and says that the primitive idempotents of the integral Burnside ring \( A(G) \) are in bijection with the conjugacy classes of perfect subgroups of \( G \). See also [Yos83] for a different approach.
A.1. Bicategories and 2-categories

As some excellent sources on bicategories and 2-categories are readily available, we do not provide a full discussion but limit ourselves to fixing ideas and notations. The original reference is Bénabou [Bén67] and popular sources include Kelly-Street [KS74]. In more recent literature, the reader can find a very short treatment in Leinster [Lei98] or in Street [Str00a], a textbook chapter in [Bor94, §7.7], and a longer discussion in Lack [Lac10].

A.1.1. Terminology. We will use the following standard terminology:

(1) A \textit{bicategory} $\mathcal{B}$ is a weak 2-category, i.e. a category ‘weakly enriched in categories’ in the precise sense of Bénabou [Bén67]. It consists of a class of object $\mathcal{B}_0$, categories $\mathcal{B}(X,Y)$ for all pairs $X,Y \in \mathcal{B}_0$, composition and unit functors $\circ = \circ_{X,Y,Z} : \mathcal{B}(Y,Z) \times \mathcal{B}(X,Y) \to \mathcal{B}(X,Z)$ $\text{1}_X$ or $\text{Id}_X : 1 \to \mathcal{B}(X,X)$ as well as natural isomorphisms (called \textit{associators} and \textit{left and right unitors}) expressing the up-to-isomorphism associativity and unitality of composition, which are required to satisfy two commutativity conditions (see Remark A.1.16):

\[
\begin{align*}
\begin{array}{c}
\mathcal{B}(Z,W) \times \mathcal{B}(Y,Z) \times \mathcal{B}(X,Y) \xrightarrow{\text{Id} \times \circ} \mathcal{B}(Z,W) \times \mathcal{B}(X,Z) \\
\mathcal{B}(Y,W) \times \mathcal{B}(X,Y) \xrightarrow{\circ} \mathcal{B}(X,W)
\end{array}
\end{align*}
\]

\[
\begin{align*}
\begin{array}{c}
1 \times \mathcal{B}(X,Y) \xrightarrow{1_Y \times \text{Id}} \mathcal{B}(Y,Y) \times \mathcal{B}(X,Y) \\
\mathcal{B}(X,Y) \times 1 \xrightarrow{\text{Id} \times 1_X} \mathcal{B}(X,Y) \times \mathcal{B}(X,X) \xrightarrow{\circ} \mathcal{B}(X,Y)
\end{array}
\end{align*}
\]
A 2-category $\mathcal{B}$ is a bicategory whose associators and unitors are all identities. It is the same as a category enriched over categories in the strict sense of [Kel05].

(3) The objects of a bicategory $\mathcal{B}$ are also called 0-cells, the objects of each $\mathcal{B}(X,Y)$ (sometimes denoted $\mathcal{B}_1(X,Y)$) are called 1-cells and the arrows of each $\mathcal{B}(X,Y)$ are called 2-cells. The effect of the composition functors on 1-cells is horizontal composition and on 2-cells vertical composition, as suggested by the following picture where a $k$-cell appears with dimension $k \in \{0,1,2\}$:

$$\begin{array}{c}
\begin{tikzpicture}[baseline=-20pt]
\node (A) at (0,0) {$X$};
\node (B) at (2,0) {$Y$};
\node (C) at (4,0) {$Z$};
\draw[->] (A) to node[auto] {$f_1$} (B);
\draw[->] (B) to node[auto] {$f_2$} (C);
\draw[->] (A) to node[auto] {$\beta_1$} (C);
\draw[->] (A) to node[auto,swap] {$\alpha_1$} (B);
\draw[->] (B) to node[auto] {$\alpha_2$} (C);
\end{tikzpicture}
\end{array}$$

Both compositions will often be denoted simply by juxtaposition. For example the exchange law

$$(\beta_2 \alpha_2)(\beta_1 \alpha_1) = (\beta_2 \beta_1)(\alpha_2 \alpha_1)$$

equals two linear notations for the same 2-cell $g_1 f_1 \Rightarrow g_3 f_3$ obtained by composing the four ones in the above diagram.

(4) With notation as above, the composition functors $\circ$ restrict e.g. to functors

$$g_1 \circ - : \mathcal{B}(X,Y) \to \mathcal{B}(X,Z) \quad - \circ f_1 : \mathcal{B}(Y,Z) \to \mathcal{B}(X,Z)$$

sending $\alpha_1 \mapsto g_1 \alpha_1$ and $\beta_1 \mapsto \beta_1 f_1$. Such operations on 2-cells are referred to as whiskering (and were already used in (A.1.2) above).

A.1.4. Notation. Given a bicategory $\mathcal{B}$, the bicategories $\mathcal{B}^{\text{op}}$ and $\mathcal{B}^{\text{co}}$ are obtained by reverting 1-cells and 2-cells respectively. Reverting both gives $\mathcal{B}^{\text{op,co}}$. We write $f^{\text{op}} : Y \to X$ for the 1-cell of $\mathcal{B}^{\text{op}}$ corresponding to the 1-cell $f : X \to Y$ of $\mathcal{B}$, and $\alpha^{\text{co}} : v^{\text{(op)}} \Rightarrow u^{\text{(op)}}$ for the 2-cell of $\mathcal{B}^{(\text{op,co})}$ corresponding to $\alpha : u \Rightarrow v$ in $\mathcal{B}$.

A.1.5. Example. We denote by $\text{CAT}$ the 2-category of categories, whose objects are typically denoted $\mathcal{A}, \mathcal{B}, \mathcal{C}$, etc. We denote by $\text{Cat}$ the 2-subcategory of (essentially) small categories, whose objects are typically denoted $I, J$, etc.

A.1.6. Terminology. Recall that many categorical notions, familiar from the 2-category $\text{CAT}$ of categories, can be internalized into any bicategory $\mathcal{B}$.

(1) An equivalence $X \simeq Y$ between two objects of $\mathcal{B}$ is a 1-cell $f \in \mathcal{B}(X,Y)$ such that there exists a 1-cell $g \in \mathcal{B}(Y,X)$ together with isomorphisms (invertible 2-cells) $1_X \equiv g \circ f$ in $\mathcal{B}(X,X)$ and $1_Y \equiv f \circ g$ in $\mathcal{B}(Y,Y)$.

(2) Similarly, an adjunction in $\mathcal{B}$, often written $f \dashv g$, consists of 1-cells $f \in \mathcal{B}(X,Y)$ and $g \in \mathcal{B}(Y,X)$ together with 2-cells (the unit and counit of adjunction) $\eta : 1_X \Rightarrow g \circ f$ and $\varepsilon : f \circ g \Rightarrow 1_Y$ satisfying the usual triangle equalities $(f \varepsilon)(\eta f) = 1_f$ and $(\varepsilon g)(g \eta) = 1_g$.

(3) An adjoint equivalence is an adjunction where the unit and counit are invertible.

(4) A 1-cell $i : X \to Y$ is faithful if whiskering with $i$ on the left is injective, i.e. for every $Z \in \mathcal{B}_0$ the induced functor $i_* : \mathcal{B}(Z,X) \to \mathcal{B}(Z,Y)$ is faithful in $\text{Cat}$. 

A.1.7. **Definition.** A 2-category in which every 2-cell is invertible, *i.e.* whose Hom categories $\mathcal{B}(X,Y)$ are all groupoids, will be called a $(2,1)$-category.

For instance, $\text{gpd}$ is a $(2,1)$-category, see Notation 1.2.1.

A.1.8. **Remark.** When speaking of bicategories, we use the adverb ‘locally’ to mean ‘Hom-wise’, in an enriched sense. So, we say that a bicategory $\mathcal{B}$ is ‘locally P’, where P is some property or type of category, if every Hom-category $\mathcal{B}(X,Y)$ is P and if the composition functors are P-compatible.

A.1.9. **Example.** Every ordinary category, or 1-category, can be considered the same as a locally discrete 2-category, i.e. one whose only 2-cells are identities. Locally discrete 2-categories are in particular $(2,1)$-categories.

A.1.10. **Example.** Some bicategories playing a central role in this work are locally additive: their Hom categories are additive and the composition functors are additive in both variables. See Definition A.6.1 for this and closely related notions.

A.1.11. **Terminology.** In order to compare bicategories, we use:

1. A pseudo-functor (in Bénabou’s terminology, homomorphism) $\mathcal{F}: \mathcal{B} \to \mathcal{B}'$ between two bicategories $\mathcal{B}$ and $\mathcal{B}'$ consists of a map on objects $\mathcal{F} = \mathcal{F}_0: \mathcal{B}_0 \to \mathcal{B}'_0$ together with functors $\mathcal{F} = \mathcal{F}_{XY}: \mathcal{B}(X,Y) \to \mathcal{B}'(\mathcal{F}X,\mathcal{F}Y)$ on the Hom categories and natural isomorphisms expressing the up-to-isomorphism, or pseudo-, functoriality of $\mathcal{F}$; the latter are required to make the following diagrams commute (see Remark A.1.17 below):

\[
\begin{array}{ccc}
B(Y,Z) \times B(X,Y) & \xrightarrow{\circ} & B(X,Z) \\
\mathcal{F} \times \mathcal{F} & \beta & \mathcal{F} \\
\mathcal{B}(\mathcal{F}Y,\mathcal{F}Z) \times \mathcal{B}(\mathcal{F}X,\mathcal{F}Y) & \xrightarrow{\circ} & \mathcal{B}(\mathcal{F}X,\mathcal{F}Z)
\end{array}
\]

\[
\begin{array}{ccc}
& & \\
\mathcal{F}_{XYZ} & \xrightarrow{\text{un}_X} & \\
\mathcal{F} & \xrightarrow{\text{un}_X} & \mathcal{B}(\mathcal{F}X,\mathcal{F}Y)
\end{array}
\]

2. A (strict) 2-functor will always refer to a strict pseudo-functor, i.e. one where $\text{fun}_{XYZ}$ and $\text{un}_X$ are all identities.

A.1.12. **Example.** A pseudo-functor whose target is locally discrete is necessarily strict; we will simply call it a functor, the prime examples being (ordinary) functors between (ordinary) categories. Note however that a pseudo-functor $\mathcal{F}: \mathcal{B} \to \mathcal{B}'$
whose source $B$ is locally discrete need not be strict if $B'$ is not locally discrete, even, say, when $B$ is a group.

A.1.13. Notation. Every bicategory $B$ has an associated 1-truncation $\tau_1 B$, defined to be the 1-category obtained from $B$ by identifying any two isomorphic 1-cells and then discarding the 2-cells. There is an obvious functor $B \to \tau_1 B$, which is initial among functors from $B$ to 1-categories.

A.1.14. Terminology. Pseudo-functors among bicategories can be naturally assembled into bicategories, as follows. Fix two bicategories $B$ and $B'$.

(1) If $F_1, F_2 : B \to B'$ are parallel pseudo-functors, a (pseudo-natural) transformation $t : F_1 \Rightarrow F_2$ between them consists of a 1-cell $t_X : F_1 X \to F_2 X$ for every object $X$ of $B$ and of an invertible 2-cell

\[
\begin{array}{ccc}
F_1 X & \xrightarrow{t_X} & F_2 X \\
F_1 u & \not\xRightarrow{t_u} & F_2 u \\
F_1 Y & \xrightarrow{t_Y} & F_2 Y
\end{array}
\]

for every 1-cell $u : X \to Y$ of $B$, subject to reasonable compatibility conditions with the vertical and horizontal composition of $B$ which are detailed in [Lei98]. In pasting diagrams (thus omitting associators), the latter require that

\[
\begin{array}{ccc}
F_1 X & \xrightarrow{t_X} & F_2 X \\
\text{Id} & \xrightarrow{\mu^{-1}} & \text{Id} \\
F_1 X & \xrightarrow{t_X} & F_2 X \\
\end{array} = \begin{array}{ccc}
F_1 X & \xrightarrow{t_X} & F_2 X \\
\text{Id} & \xrightarrow{\mu} & \text{Id} \\
F_1 X & \xrightarrow{t_X} & F_2 X \\
\end{array}
\]

and

\[
\begin{array}{ccc}
F_1 X & \xrightarrow{t_X} & F_2 X \\
F_1 u & \not\xRightarrow{t_u} & F_2 u \\
F_1 Y & \xrightarrow{t_Y} & F_2 Y \\
F_1 Z & \xrightarrow{t_Z} & F_2 Z \\
\end{array} = \begin{array}{ccc}
F_1 X & \xrightarrow{t_X} & F_2 X \\
F_1 vu & \not\xRightarrow{t_{vu}} & F_2 vu \\
F_1 Z & \xrightarrow{t_Z} & F_2 Z \\
\end{array}
\]

commute for all composable pair of 1-cells $\xrightarrow{u} (functoriality)$ as well as

\[
\begin{array}{ccc}
F_1 X & \xrightarrow{t_X} & F_2 X \\
F_1 u & \not\xRightarrow{t_u} & F_2 u \\
F_1 Y & \xrightarrow{t_Y} & F_2 Y \\
\end{array} = \begin{array}{ccc}
F_1 X & \xrightarrow{t_X} & F_2 X \\
F_1 u \xRightarrow{\alpha} & F_2 u' \xRightarrow{\alpha} & F_2 Y \\
\end{array}
\]

for every 2-cell $\alpha : u' \Rightarrow u$ (naturality). Note that the orientation of the 2-cells $t_u$ is a matter of convention, since they are invertible.
(2) If the 2-cells $t_u$ in the definition of a pseudo-natural transformation are not required to be invertible, one speaks of an oplax transformation. If they are oriented in the opposite direction (i.e. $t_u : t_Y (F_1u) \Rightarrow (F_2u)t_X$), one obtains the notion of a lax transformation. (1) For contrast, a pseudo-natural transformation as in (1) above is also referred to as a strong transformation. It is a strict transformation if the 2-cells $t_u$ are actually all identities.

(3) If $t, s : F_1 \Rightarrow F_2$ are two parallel (oplax or strong) transformations of pseudo-functors, a modification $M : t \Rightarrow s$ between them consists of a 2-cell $M_X : t_X \Rightarrow s_X$ of $B'$ for every object $X$ of $B$, such that the square

$$
\begin{array}{ccc}
(F_2u)t_X & \Rightarrow & (F_2u)s_X \\
\downarrow t_\gamma & & \downarrow s_\gamma \\
(F_1u)t_Y & \Rightarrow & (F_1u)s_Y
\end{array}
$$

is commutative for every 1-cell $u : X \to Y$ in $B$.

(4) We will denote by $\text{PsFun}(B, B')$ the bicategory with pseudo-functors $B \to B'$ as 0-cells, pseudo-natural transformations between them as 1-cells and modifications as 2-cells. The horizontal composition of transformations and the vertical composition of modifications is performed in the evident way by composing 1- and 2-cells of $B'$. In particular, if $B'$ is a 2-category then so is $\text{PsFun}(B, B')$.

(5) A biequivalence between bicategories is a pseudo-functor $F : B \to B'$ such that there exists a pseudo-functor $G : B' \to B$ and equivalences $1_B \simeq GF$ in $\text{PsFun}(B, B)$ and $FG \simeq 1_{B'}$ in $\text{PsFun}(B', B')$. Similarly to ordinary equivalences of categories, a pseudo-functor $F : B \to B'$ is a biequivalence if and only if each functor $\mathcal{F} : B(X, Y) \to B'(FX, FY)$ is an equivalence of categories (expressing ‘essential full-faithfulness’) and such that $\mathcal{F}$ is ‘essentially surjective’ meaning that for every $Y \in B'$ there exists $X \in B$ and an equivalence $\mathcal{F}X \simeq Y$ in $B'$. This uses the axiom of choice for proper classes and the possibility of correcting any equivalence to an adjoint equivalence (see [Lei04, Prop. 1.5.13]).

A.1.15. Remark. The previous terminology makes clear what it means for two pseudo-functors to be equivalent or isomorphic. Pseudo-functors can be composed in the evident way ([Bén67, Thm. 4.3.1]), and indeed by allowing their source and target to vary we get a tricategory of bicategories, pseudofunctors, transformations and modifications – but we will not need to go into that. Note nonetheless that $\text{PsFun}(-, -)$ preserves biequivalences on each variable.

A.1.16. Remark. The coherence axioms (A.1.2) satisfied by the associators and unitors of a bicategory $B$ generalize those for a monoidal category. They guarantee that the analogue of Mac Lane’s coherence theorem holds: There exists a (canonical) biequivalence $\mathcal{F} : B \ll B'$ where $B'$ is a 2-category (see e.g. [Lei04, Thm. 1.5.15]). An elegant way to view this result is as a bicategorical Yoneda lemma: By the coherence axioms, the assignment $X \mapsto B(-, X)$ induces a well-defined pseudo-functor $B \to \text{PsFun}(B'^{op}, \text{Cat})$ which restricts to a biequivalence $B \ll B'$ onto its 1- and 2-full image $B'$ which, like its ambient bicategory $\text{PsFun}(B'^{op}, \text{Cat})$, is strict since $\text{Cat}$ is. An important consequence of this is that 2-cells of $B$ can be unambiguously presented by a pasting diagram ([KS74]), that is, by a 2-dimensional

---

1 Some authors prefer to swap the use of ‘lax’ and ‘oplax’.
display of composable 2-cells, without having to worry about choosing a sequence of evaluation moves of the diagram by vertical and horizontal composition, since all choices will yield the same 2-cell as end result.

**A.1.17. Remark.** The coherence axioms satisfied by the structural isomorphisms fun and un of a pseudo-functor $F: B \rightarrow B'$ (detailed in [Bén67, §4] [Lei98]) are again reminiscent of those of a (strong) monoidal functor between monoidal categories. These axioms guarantee that the internal notions of Terminology A.1.6, among many others, are preserved by pseudo-functors, hence in particular that they are invariant under biequivalence. Similarly to bicategories, pseudo-functors can often be strictified (though not always, cf. [Lac07, Lemma 2]). E.g. if $C$ is any small 2-category, every pseudo-functor $C \rightarrow \text{Cat}$ is equivalent in $\text{PsFun}(C, \text{Cat})$ to some 2-functor; see [Pow89, §4.2].

**A.1.18. Corollary.** A 1-cell $f: X \rightarrow Y$ in a bicategory $B$ is an equivalence if and only if $B(T, f): B(T, X) \rightarrow B(T, Y)$ is an equivalence of categories for every $T \in B_0$.

**Proof.** Since biequivalences preserve internal equivalences (Remark A.1.15), by replacing $B$ with its image in $\text{PsFun}(B^{op}, \text{Cat})$ under the bicategorical Yoneda embedding $u \mapsto \triangleright B(-, u)$ (Remark A.1.16) it suffices to prove the following: a 1-cell $\alpha: F \rightarrow G$ in $\text{PsFun}(B, \text{Cat})$ is an equivalence if and only if each component $\alpha_T: FT \rightarrow GT$ is an equivalence of categories. One implication is immediate; for the other, assume that each $\alpha_T$ is an equivalence. Choose an adjoint equivalence $\beta_T \dashv \alpha_T$ for each $T$, with unit $\eta_T: \text{Id}_{FX} \cong \alpha_X \beta_X$ and counit $\varepsilon_T: \beta_T \alpha_T \cong \text{Id}_{GX}$, and use them to define (invertible) natural transformations $\beta_u$ as follows

\[
\begin{array}{ccc}
GX & \xrightarrow{\beta_X} & FX \\
\downarrow\gamma_X & \Leftarrow \downarrow\beta_u & \downarrow\gamma_u \\
GY & \xrightarrow{\beta_Y} & FY
\end{array}
\quad
\begin{array}{ccc}
GX & \xleftarrow{\alpha_X} & FX \\
\downarrow\alpha_{-1} & \Leftarrow \downarrow\alpha_{-1} & \downarrow\alpha_{-1} \\
FY & \xleftarrow{\beta_Y} & FY
\end{array}
\]

for all $u: X \rightarrow Y$. It follows from the triangle equalities of the adjunctions that $\beta := \{ \beta_T, \beta_u \}$ is a pseudo-natural transformation $G \Rightarrow F$ and that the units and counits form mutually inverse modifications $\beta \alpha \cong \text{Id}_F$ and $\text{Id}_G \cong \beta \alpha$, showing in particular that $F$ is an equivalence in $\text{PsFun}(B^{op}, \text{Cat})$. □

**A.1.19. Remark.** Specifically for 2-categories there is another form of the Yoneda lemma, which comes from viewing 2-categories as categories (strictly) enriched over the cartesian closed category $\text{Cat}$ and by specializing the results of [Kel05, §2]. This result however will not be so useful for us, because for any given 2-categories $C$ and $D$ it only concerns the 2-category $\text{Cat-Fun}(C, D)$ of 2-functors $F: C \rightarrow D$, strict natural transformations, and modifications (i.e. the ‘functor category’ of [Kel05]); hence it says nothing about non-strict pseudo-natural transformations.

We shall encounter the following 2-categorical variant of usual comma (or ‘slice’) categories:
A.1.20. Definition. Let \( \mathcal{B} \) be a 2-category and \( B \in \mathcal{B}_0 \) be a 0-cell. We denote by \( \mathcal{B}/B \) the following comma 2-category over \( \mathcal{B} \). By definition, its objects are pairs \( (X, i_X) \) where \( X \in \mathcal{B}_0 \) is a 0-cell and \( i_X : X \to B \) is a 1-cell of \( \mathcal{B} \). A 1-cell \( (X, i_X) \to (X', i_{X'}) \) consists of a pair \( (f, \alpha_f) \) where \( f : X \to X' \) is a 1-cell and \( \alpha_f : i_{X'} \circ f \Rightarrow i_X \) a 2-cell \(^2\) in \( \mathcal{B} \). A 2-cell \( (f, \alpha_f) \Rightarrow (g, \alpha_g) \) in \( \mathcal{B}/B \) is a 2-cell \( \alpha : f \Rightarrow g \) of \( \mathcal{B} \) such that \( \alpha_g \circ (i_{X'} \circ \alpha_f) = \alpha_f \):

\[
\begin{array}{ccc}
X & \xrightarrow{i_X} & \mathcal{B} \\
\downarrow f & \Downarrow \alpha_f & \downarrow \Rightarrow \\
X' & \xrightarrow{i_{X'}} & \mathcal{B}.
\end{array}
\]

The vertical and horizontal compositions of \( \mathcal{B}/B \) are induced by those of \( \mathcal{B} \) in the evident way. There is an obvious forgetful 2-functor \( \mathcal{B}/B \to \mathcal{B} \) which sends \( (X, i_X) \to X \) and \( (f, \alpha_f) \to f \).

A.2. Mates

Most familiar results on adjunctions generalize to general bicategories \( \mathcal{B} \). Let us in particular recall some basic facts about mates, that is, about the 2-cell correspondences which are induced (in various ways) by adjunctions. Consider an adjunction \( \ell \dashv r \) in \( \mathcal{B} \), for instance in \( \mathcal{B} = \text{CAT} \), with unit \( \eta : 1 \Rightarrow r \ell \) and counit \( \varepsilon : \ell r \Rightarrow 1 \). Then, for any two 1-cells \( f_1 \) and \( f_2 \) (with suitable source and target), there are natural bijections between sets of 2-cells (here all simply denoted \([-,-]\))

\[
[f_1, rf_2] \sim [\ell f_1, f_2] \quad \text{and} \quad [f_1 r, f_2] \sim [f_1, f_2 \ell]
\]

given by

\[
\begin{array}{ccc}
& f_1 & \xrightarrow{\alpha} & f_2 \\
\downarrow \alpha_f & \Downarrow & \downarrow \Rightarrow \\
\ & f_1 & \xrightarrow{\beta} & f_2
\end{array}
\quad \text{and} \quad
\begin{array}{ccc}
& f_1 & \xrightarrow{\eta} & f_2 \\
\downarrow \beta_f & \Downarrow & \downarrow \Rightarrow \\
\ & f_1 & \xrightarrow{\varepsilon} & f_2
\end{array}
\]

respectively.

A.2.1. Remark. Throughout the work, we use mates for functors of the form \( u^*, v^*, i^*, j^* \) in \( \text{CAT} \) appearing through various 2-functors \( \mathcal{M} \) from (2-subcategories of) \( \text{Cat} \) with values in \( \text{CAT} \), that is, with \( u^* = \mathcal{M}(u) \), etc. Let us phrase the results we need about mates in this setting.

Suppose given four 1-cells and their image under such a 2-functor \( \mathcal{M} \)

\[
\begin{array}{ccc}
v & \xrightarrow{j} & u \\
\downarrow & \Downarrow & \downarrow \\
i & \xrightarrow{u^*} & i^*
\end{array}
\xrightarrow{\mathcal{M}}
\begin{array}{ccc}
v^* & \xrightarrow{j^*} & u^* \\
\downarrow & \Downarrow & \downarrow \\
i^* & \xrightarrow{u^*} & i^*
\end{array}
\]

\(^2\) One can also consider a version in which \( \alpha_f \) is requested to be invertible. When we apply this construction to a \((2,1)\)-category, like \( \mathcal{B} = \text{gpd} \), this choice will be irrelevant.
(the squares are not assumed to commute). Playing the above construction on both sides in the presence of adjunctions \( i \vdash i^* \vdash i_* \) and \( j \vdash j^* \vdash j_* \) yields bijections
\[
[v^* i^*, j^* u^*] \overset{\sim}{\to} [j_i v^*, u^* i^*] \quad \text{and} \quad [j^* u^*, v^* i^*] \overset{\sim}{\to} [u^* i^*, j_* v^*].
\]

On 2-cells \( \alpha^* \) and \( \beta^* \) coming via \( \mathcal{M} \), we use the standard notation
\[
[i v, u j] \xrightarrow{\mathcal{M}} [v^* i^*, j^* u^*] \overset{\sim}{\to} [j_i v^*, u^* i^*]
\]
and
\[
[u j, i v] \xrightarrow{\mathcal{M}} [j^* u^*, v^* i^*] \overset{\sim}{\to} [u^* i^*, j_* v^*]
\]
which matches the usual one for derivators. Explicitly, these mates of \( \alpha^* \) are:

\[
(A.2.3) \quad \alpha_1 = \left( j_i v^* \xrightarrow{\eta} j_i j^* u^* \xrightarrow{\alpha^*} j_i j^* u^* \xrightarrow{\epsilon} j_i v^* \right)
\]

\[
(A.2.4) \quad \beta_* = \left( u^* i_* \xrightarrow{\eta} j_* j_i v^* \xrightarrow{\beta^*} j_* j_i v^* \xrightarrow{\epsilon} j_* j_i v^* \right)
\]

For the details of the so-called calculus of mates, the reader is invited to consult [Gro13, §1.2] or [KS74]. We shall in particular invoke compatibility of mates with pasting, which can be found in [Gro13, Lem. 1.14].

**A.2.5. Example.** For any 1-cell \( i \), consider the commutative squares

\[
\begin{array}{ccc}
\xymatrix{ & i \ar[dr]_{\text{id}_i} & \\
& & \\
i \ar[ur]_{\text{id}_i} & \ar[ru]_{i} & \\
}
\end{array}
\quad \text{and} \quad
\begin{array}{ccc}
\xymatrix{ & i \ar[dr]_{\text{id}_i} & \\
& & \\
i \ar[ur]_{\text{id}_i} & \ar[ru]_{i} & \\
}
\end{array}
\]

then, using the left-hand diagram, the left mate \( (\text{id}_i)_! = \epsilon : i_i i^* \Rightarrow \text{Id} \) is the counit of \( i \vdash i^* \). Similarly, in the right-hand diagram, the right mate \( (\text{id}_i)_* = \eta : \text{Id} \Rightarrow i_* i^* \) is the unit of \( i^* \vdash i_* \). This is tacitly using the identity as adjoint to the identity, with identity units and counits.

**A.2.6. Remark.** Given a morphism \( \alpha : k \Rightarrow \ell \) between 1-cells with left adjoints \( k_i \vdash k \) and \( \ell_i \vdash \ell \), we obtain (e.g. by Yoneda) a canonical morphism \( \alpha_! : \ell_! \Rightarrow k_! \).
This is nothing but the mate of
\[
\begin{array}{c}
\alpha \\
\downarrow \\
\beta
\end{array}
\]
which we also denote \(\alpha_1\) anyway. Compatibility of mates with pasting becomes the 2-contravariant functoriality of \((-)_!\), namely
\[
(\beta_\alpha)_! = \alpha_! \beta_! \quad \text{and} \quad \text{id}_! = \text{id}.
\]

**A.2.7. Remark.** There are situations where the notation \((-)_!\) can be slightly ambiguous, particularly if the ‘ambient square’ is not made explicit. For instance, if we are given a 2-cell \(\gamma: k\ell' \Rightarrow \ell k'\) in a 2-category it might happen that both \(\ell\) and \(\ell'\) have left adjoints \(\ell_!\) and \(\ell'_!\), in which case the mate of \(\gamma\) would be \((\gamma_!)_!\). But it can simultaneously happen that \((k\ell')_!\) and \((\ell k')_!\) have left adjoints, in which case the mate of \(\gamma\) can be understood as the 2-cell also denoted \((\gamma_!)_!\), as in Remark A.2.6. This issue is purely notational and context should usually make clear what is meant. Note that providing the source and target 1-cells avoids any confusion and we shall try to do so.

Compatibility of mates with pasting gives in particular:

**A.2.8. Proposition.** Consider the left-hand diagram and its whiskered 2-cell
\[
\begin{array}{c}
\gamma \\
\downarrow \\
\gamma_!
\end{array}
\]
Suppose that \(d^*\) has a left adjoint \(d!\). Then \((\gamma d)_! = \gamma_! \varepsilon\), or more precisely the following diagram commutes
\[
\begin{array}{c}
jvd\downarrow \\
j!v^* \quad \sim \quad (jd)_!(vd)^* \\
\downarrow \\
j!v^* \gamma \quad \sim \quad \gamma_d !
\end{array}
\]
where \(\varepsilon: d!d^* \Rightarrow \text{id}\) is the counit of \(d_! \dashv d^*\). Dually, for right mates.

**Proof.** The 2-cell on the right is the result of the pasting of the 2-cell on the left with the 2-cells of Example A.2.5.

**A.2.9. Remark.** The above proposition applies in particular when \(d\) is an equivalence, allowing us to replace the top object of a square up to equivalence. The reader can furthermore verify that the mating isomorphisms \([v^*i^*, j^*u^*] \cong [j^*v^*, u^*i^*]\) and \([j^*u^*, i^*v^*] \cong [u^*i^*, j^*v^*]\) of (A.2.2) are natural in \(i, u, j, k\), with respect to 2-cells \(i \Rightarrow i', u \Rightarrow u', j \Rightarrow j', v \Rightarrow v'\).

**A.2.10. Remark.** Suppose we have a pseudo-functor \(F: \mathcal{B} \to \mathcal{B}'\) with the property that every 1-cell \(Fu\) admits in \(\mathcal{B}'\) a left adjoint \((Fu)_!\). Then a choice of adjunctions
(Fu)_! ⊣ Fu for every u defines a pseudo-functor \( F_1 : B^{op, co} \to B' \) which agrees with \( F \) on objects, sends a 1-cell \( u \) to \((Fu)_!\) and a 2-cell \( \alpha \) to the mate \((F\alpha)_!\) defined as in Remark A.2.6. The coherent structure isomorphisms fun and un of \( F_1 \) are provided by the mates (for the adjunctions \((Fu)_! ⊣ Fu\)) of the images in \( B' \) of those of \( F \), together with the unique invertible 2-cells induced by the uniqueness property of adjunctions. The latter also implies that different choices of adjunctions would yield canonically isomorphic pseudo-functors. Note that, even if we start out with a strict 2-functor \( F \), there is no reason in general for \( F_1 \) to be strict.

Similarly, a choice of right adjoints \( Fu ⊣ (Fu)_\ast \) for all 1-cells \( u \) of \( B \) defines a pseudo-functor \( F_\ast : B^{op, co} \to B' \).

Finally, if the 2-functor \( F : B \to B' \) is such that every 1-cell \( Fu \) admits an ambidextrous adjoint \( (Fu)_! = (Fu)_\ast \), we obtain from the above discussion two pseudo-functors \( F_1 \) and \( F_\ast : B^{op, co} \to B' \) which agree on 0-cells and 1-cells but a priori are different on 2-cells. What happens on 2-cells depends on the choices of the units and counits for the left adjunctions \((Fu)_! \) versus the choices of the units and counits for the right adjunctions \((Fu)_\ast \). This is the situation we encounter with our Mackey 2-functors \( M : gpd^{op} \to \text{CAT} \). The requirement that those units and counits can be chosen so that \( F_1 = F_\ast \) on 2-cells is property (Mack 8), which itself rests on the Strict Mackey Formula (Mack 7), in the Rectification Theorem 1.3.1.

The next facts can be established ‘one object at a time’ or in the following more functorial form.

**A.2.11. Lemma.** Let \( \ell \Rightarrow r \) be an adjunction (in a bicategory, see A.1.6).

(a) Horizontal composition \( \ell \circ - \) induces an injection on 2-cells \([s, r] \to [\ell s, \ell r]\).

(b) If \( \theta : r \Rightarrow r \) is such that \( \ell \theta : \ell r \Rightarrow \ell r \) is the identity then \( \theta = id_r \) as well.

(c) If \( \theta : r \Rightarrow r \) is such that \( \ell \theta : \ell r \Rightarrow \ell r \) admits a left inverse then so does \( \theta \).

(d) If \( \theta : r \Rightarrow r \) is such that \( \ell \theta : \ell r \Rightarrow \ell r \) is an isomorphism then so is \( \theta \).

**Proof.** The mating isomorphism \([s, r] \sim [\ell s, \ell r] \) decomposes as

\[
\begin{array}{c}
[s, r] \xrightarrow{\ell} [\ell s, \ell r] \xrightarrow{\ell \circ -} [\ell s, \ell r]
\end{array}
\]

hence the first map is a split monomorphism. This proves (a), from which (b) immediately follows by taking \( s = r \) and considering \( id_r, \theta \in [r, r] \). Let us prove (c). Let \( \varphi : \ell r \Rightarrow \ell r \) be a left inverse of \( \ell \theta \), meaning \( \varphi \circ (\ell \theta) = id_{\ell r} \). Define \( \phi : r \Rightarrow r \) as the following mate of \( \varphi \)

\[
\phi : r \xrightarrow{\varphi r} r\ell r \xrightarrow{r\varphi} r\ell r \xrightarrow{\varphi r} r .
\]

Then consider \( \phi \theta : r \Rightarrow r \) and compute \( \ell(\phi \theta) \)

\[
\begin{array}{c}
\ell r \xrightarrow{\ell \theta} \ell r \xrightarrow{\ell \varphi} \ell r \xrightarrow{\ell \varphi} \ell r
\end{array}
\]

by unpacking the definition of \( \phi \) (right-hand square) and using naturality for the left-hand square. The bottom composes to the identity by choice of \( \varphi \) and therefore...
the top composite is the identity as well by the unit-counit relation $(r ε)(η r) = id_r$. Hence $ℓ(φθ) = id_r$, and we obtain (c) thanks to (b). Now for (d), we can apply (c) to find $φ: r ⇒ r$ such that $φθ = id_r$. Hence $ℓ(φθ) = (ℓθ)^{-1}$ and therefore $ℓ(θφ) = id_r$, and (b) gives us again $θφ = id_r$. So $φ$ is the inverse of $θ$. □

A.2.12. Corollary. Let $r$ and $r'$ be two right adjoints (in a bicategory) of the same $ℓ$ and let $θ: r ⇒ r'$ be a 2-cell such that $ℓθ$ is an isomorphism $ℓr ⇓ ⇒ ℓr'$. Then $θ: r ⇒ r'$ is an isomorphism.

Proof. Let $χ: r ⇓ ⇒ r'$ be any isomorphism and apply Lemma A.2.11(d) to the 2-cell $χ^{-1}θ: r ⇒ r$. □

A.3. String diagrams

Instead of the usual cellular or globular pasting diagrams (Remark A.1.16), where a $k$-cell is depicted by an oriented ‘arrow’ of dimension $k$ ($k = 0, 1, 2$), one can compute in a bicategory $B$ by using their planar duals, string diagrams. References for string diagrams include [Str96], [JS91], [TV17].

They are dual diagrams, in that they represent 0-cells as regions of the plane, 1-cells as lines separating regions, and 2-cells as dots (or boxes) separating lines. So for instance the pasting diagram on the left

\[ \begin{array}{ccc}
X & \xrightarrow{f} & Y \\
\downarrow{g} & & \downarrow{h} \\
U & \xrightarrow{k} & V
\end{array} \]

\[ \begin{array}{ccc}
\downarrow{\alpha} & & \downarrow{\beta} \\
\downarrow{\beta} & & \downarrow{\alpha}
\end{array} \]

\[ \begin{array}{ccc}
\downarrow{\ell} & & \downarrow{m} \\
\uparrow{\ell} & & \uparrow{m}
\end{array} \]

\[ \begin{array}{ccc}
f & & g \\
\downarrow{h} & & \downarrow{h} \\
V & \xrightarrow{m} & Z
\end{array} \]

\[ \begin{array}{ccc}
f & & g \\
\downarrow{h} & & \downarrow{h} \\
V & \xrightarrow{m} & Z
\end{array} \]

can be replaced by the string diagram on the right to represent the same composite 2-cell of $B$. Instead of indicating sources and targets by orienting cells ($→$, $⇒$), string diagrams typically rely on the left-right and top-down directions of the page. As above, we choose to orient 1-cells left-to-right and 2-cells top-to-bottom. Just as for pasting diagrams, the consistency in general bicategories of the calculus of string diagrams — in which horizontal composition necessarily appears to be strictly associative and unital — relies on the coherence theorem (Remark A.1.16).

An advantage of computing with string diagrams is that identity 1-cells can be safely omitted most of the time. Moreover, with strings, many compatibility and coherence axioms simply say that certain dots may slide along past certain others. Thus relations between string diagrams often take an intuitive geometric form.

A.3.1. Example. An identity 2-cell $id_f$ (for $f: X ⇒ Y$) and an identity 1-cell $Id_X$ may take any of the following successively more inconspicuous string forms:
A.3.2. Example (Exchange law). A special case of (A.1.3) yields the relation

\[ f_1 g_1 f_2 g_2 = f_1 g_1 f_2 g_2 \alpha \beta \]

which suggests that parallel blocks may slide past each other.

A.3.3. Example (Adjoint functors). For instance, the unit \( \eta : \text{Id}_X \Rightarrow \ell r \) and counit \( \varepsilon : \ell r \Rightarrow \text{Id}_Y \) of an adjunction \( \ell : Y \simeq X : r \) may be depicted by either of these successively simpler diagrams:

The two triangular equations for this adjunction become

\[ \begin{align*}
\ell &\quad \eta \\
\varepsilon &\quad r
\end{align*} \]

which suggest that unit-counit pairs may be straightened by pulling the string.

A.3.4. Example (Mates). The calculus of mates recalled in Appendix A.2 has a nice formulation in terms of string diagrams. For a 2-cell

\[ \begin{align*}
\alpha &\Rightarrow \\
v^* &\Rightarrow j^*
\end{align*} \]

and adjunctions \( i_! \dashv i_* \) and \( j_! \dashv j_* \), as typically appear in this work, the mates \( \alpha! \) and \( \alpha^* \) are depicted as

\[ \begin{align*}
\alpha! &\Rightarrow \\
\alpha &\Rightarrow
\end{align*} \]

In particular, the special case with \( u = \text{Id} \) and \( v = \text{Id} \) (which gives rise for instance to the pseudo-functoriality of \((-)!\) and \((-)'\), as in Remark A.2.10) becomes simply:

\[ \begin{align*}
\eta &\Rightarrow \\
\alpha &\Rightarrow
\end{align*} \]
It is an instructive exercise to verify all the claims in Appendix A.2 using string notation.

**A.3.5. Example** (Pseudo-functors). The strings for the two structural isomorphisms of a pseudo-functor $\mathcal{F} : \mathcal{B} \to \mathcal{B}'$ (see Terminology A.1.11) take the following form:

Of the coherence axioms, the unital relations for a 1-cell $f : X \to Y$ of $\mathcal{B}$ become

and the associativity relation for three composable 1-cells $f_1 \circ \ldots \circ f_n = g_1 \circ \ldots \circ g_m$ between composite 1-cells of $\mathcal{B}$ there is only one way to go from $\mathcal{F}(f_1) \circ \ldots \circ \mathcal{F}(f_n)$...
to $F(g_1) \circ \ldots \circ F(g_m)$ by combining instances of fun and un, so we may as well represent this canonical 2-cell by a single dot:

$$\begin{array}{c}
Ff_1 \ldots Ff_n \\
\vdots \\
Fg_1 \ldots Fg_m
\end{array}$$

(A.3.8)

A.3.9. Example. Consider again a pseudo-functor $F = (F, \text{fun}, \text{un}): B \to B'$. The fact that fun is a natural transformation translates into the string equation

$$F(\psi \phi) Ff Fg F(gf) = F(\psi Ff' Fg')$$

for any pair of 2-cells $\varphi: f \Rightarrow f'$ and $\psi: g \Rightarrow g'$ in $B$.

$$F^X \overset{t_X}{\longrightarrow} G^X \quad \text{and} \quad F^u \overset{t(u)}{\longrightarrow} G^v \qquad \text{for each 0-cell } X \text{ and for each 1-cell } u: X \to Y.$$  

The functoriality axioms say that we may slide un and fun past $t$

$$F^X t = F^{t(X)} = G^{t(u)} t^X \quad \text{for all composable } X \overset{u}{\to} Y \overset{v}{\to} Z,$$

and the naturality axiom says that we may do the same with the image of every 2-cell $\alpha: u' \Rightarrow u$:

$$F^X t \overset{\alpha}{\Rightarrow} G^X \quad \text{and} \quad F^u t \overset{\alpha}{\Rightarrow} G^v \quad \text{for all composable } X \overset{u}{\to} Y \overset{v}{\to} Z.$$  

A.3.11. Lemma. Consider an oplax transformation $t: F \Rightarrow G$ between pseudo-functors $F, G: B \to B'$, and let $\ell \dashv r$ be an adjunction in $B$. Then the component $t_r$ is invertible, with inverse the right mate of $t_{\ell}$ with respect to (the images under $F$ and $G$) of the given adjunction. Equivalently, $t_{\ell}$ is the left mate of $t_r^{-1}$.

Proof. This is [DPP04, Lemma 1.9]. (To be precise, our statement follows by applying loc. cit. to the 2-dual adjunction $f := r^{co} \dashv \ell^{co} =: u$ and the lax
transformation $t^\mathsf{co}: \mathcal{F}^\mathsf{co}, \mathcal{G}^\mathsf{co}: \mathcal{B}^\mathsf{co} \to \mathcal{C}^\mathsf{co}$. Beware that in loc. cit. the use of ‘lax’ and ‘oplax’ is inverted with respect to ours). We provide here a transparent proof with strings.

The equivalence of the two conclusions is the mate correspondence and is immediately verified. Writing $\eta$ and $\varepsilon$ for the unit and counit of the adjunction $\ell \dashv r$, recall that the unit and counit of the adjunction $\mathcal{F}\ell \dashv \mathcal{F}r$ are given by

$$\eta = \text{Id}_{\mathcal{F}\ell} \mathcal{G}\ell \mathcal{F}\varepsilon \mathcal{F}r \mathcal{G}r \varepsilon$$

$$\varepsilon = \text{Id}_{\mathcal{F}r} \mathcal{G}r \mathcal{F}\eta \mathcal{F}\ell \eta$$

respectively, and similarly for $\mathcal{G}$. Now compute using exchange (Example A.3.2) followed by the functoriality and naturality of $t$ (Example A.3.10):

$$t(r) \circ t(\ell) = t(r) \mathcal{G}\ell \mathcal{F}\eta \mathcal{F}r \mathcal{G}r \varepsilon$$

The verification of $(t_\ell)_* \circ t_r = \text{id}$ is symmetrical and is left to the reader. □

A.3.12. Remark. The statement of Lemma A.3.11 is asymmetric: $t$ is oplax and the conclusion does not guarantee invertibility of $t_\ell$. The dual statement says that if $t$ is a lax transformation then $t_\ell$ is indeed invertible, with inverse $(t_r)_!$.

***
A prominent feature of string diagrams over cellular pasting diagrams is that it is actually possible to prove that their ‘evaluation’ into 2-cells is invariant under deformation of diagrams, in a suitable sense (ambient isotopy, sequences of moves, etc.; see [Str96, §4] [BMS13, §2] [TV17, §2]). This incorporates the strictification theorem but is stronger, and it allows to give presentations of certain (structured) monoidal categories or bicategories in terms of equivalences classes of string diagrams modulo deformation. This use of strings will be taken up in Section 6.2, where we will present a strictification of the bicategory of Mackey 2-motives. Nonetheless, in this work we will mostly use strings more informally, starting in Chapter 5, as a conveniently compact notation for complicated 2-cells which, in usual cellular notation, would take up too much space on the page and would be hard to read.

In practice, and again in order to save space, we will slightly cheat and present our diagrams in a compressed form by suppressing some of the white space. We conclude this section with an explanation of how to translate such diagrams, with the help of an example taken from the proof of Lemma 5.2.7.

**A.3.13. Example.** Say we encounter a string diagram like the one on the left:

![String Diagram Example]

It stands for a 2-cell $\alpha$ of some bicategory $\mathcal{B}$. Concretely, how do we determine this 2-cell? For a start, context should allow us to add labels to all the dots and boxes (representing specified 2-cells) and all strings (1-cells) that make it up, as in the right-hand side above. (We omit the labels for the planar regions – i.e. objects – but it could also be done.) Then we add some white space in the vertical and horizontal directions (by an ‘ambient isotopy’) until we are able to cut up the diagram into horizontal stripes, each of which consists of a horizontal juxtaposition (i.e. an horizontal composition in $\mathcal{B}$) of recognizable dots/boxes/identities. While doing this, we take care not to change the up-down orientation of each piece of string.
We obtain something like this:

\[
\begin{align*}
\sigma_1 &= \text{id}(\mathcal{F}_i) \circ \eta \circ \text{id}\mathcal{F}_u \\
\sigma_2 &= \text{id}(\mathcal{F}_i) \circ \mathcal{F}_\alpha \circ \text{id}(\mathcal{F}_ja) \circ \mathcal{F}_\alpha \\
\sigma_3 &= \varepsilon \circ \text{id}(\mathcal{F}_ja) \circ \eta \circ \text{id}\mathcal{F}_va \\
\sigma_4 &= \text{id}(\mathcal{F}_ja) \circ \text{id}\mathcal{F}_a \circ \eta \circ \text{id}(\mathcal{F}_a) \circ \text{fun}^{-1} \\
\sigma_5 &= \text{id}(\mathcal{F}_ja) \circ \text{fun} \circ (\mathcal{F}_j) \circ \varepsilon \circ \text{id}\mathcal{F}_v \\
\sigma_6 &= \varepsilon \circ \text{id}(\mathcal{F}_j) \circ \text{id}\mathcal{F}_v
\end{align*}
\]

If \( \mathcal{B} \) happens to be a strict 2-category, we can already evaluate each stripe separately into a 2-cell \( \sigma_i \), by horizontally composing the 2-cells we encounter when scanning the stripe from left to right. The results are depicted on the right-hand side. Note that, by scanning each line from left to right, we can read off the source and target 1-cells of each \( \sigma_i \). They are composable by construction, and their (vertical) composite in \( \mathcal{B} \) is the final result: \( \alpha = \sigma_6 \sigma_5 \sigma_4 \sigma_3 \sigma_2 \sigma_1 \).

If \( \mathcal{B} \) is not strict, then we must first insert some identity 1-cells so that every dot/box has an explicit domain and codomain in the diagram:

\[(A.3.14)\]

Here we have also drawn, within each stripe, vertical boundaries separating the dot/boxes. If the diagram happens to contain dot/boxes such as \((A.3.8)\) having more then two strings in either its domain or codomain, then they must all be broken down into more elementary components (this can create new stripes).

Then we choose, for each stripe, a bracketing of the dotted boxes within the stripe, and use it to horizontally compose the 2-cells corresponding to the dot/boxes in the stripe so as to form a 2-cell \( \sigma_i \). For instance, for \( i = 3 \) we may choose \( \sigma_i = (((\varepsilon \circ \text{id}(\mathcal{F}_ja)) \circ \eta) \circ \text{id}\mathcal{F}_va) \). Indeed, we may choose the canonical left bracketing for all \( i \). Note that each boundary line between stripes inherits now two bracketed lists of 1-cells, corresponding to the codomain of the stripe above it and the domain of the one below it. These two bracketed lists may differ in general, by some missing or extra identity 1-cells and in the bracketing itself. Fortunately
we can connect the two associated 1-cells by inserting instances of the associativity and unitality isomorphisms of $B$, in order to vertically compose the $\sigma_i$'s. By the strictification theorem for bicategories, this is always possible and the resulting composite $\alpha$ does not depend on the choice of bracketing or of connecting isomorphisms. More generally, as mentioned above, the axioms of bicategories guarantee that this procedure (suitably formalized) evaluates to a unique $\alpha$ even under a wide class of deformations of the diagram.

If we want to translate the original string diagram into a cellular pasting diagram, this can be done in a straightforward way by forming the planar dual diagram of (A.3.14) with respect to the dotted boxes:

\[
\begin{array}{c}
\begin{array}{c}
F_u \\
\downarrow \eta \quad F_{ja} \quad (F_i) \quad \downarrow \\
\end{array}
\end{array}
\begin{array}{c}
\begin{array}{c}
F_u \\
\downarrow \eta \quad F_{ja} \quad (F_i) \quad \downarrow \\
\end{array}
\end{array}
\begin{array}{c}
\begin{array}{c}
F_{\alpha_1} \\
\downarrow \eta \quad F_{a} \quad (F_{ja}) \quad \downarrow \\
\end{array}
\end{array}
\begin{array}{c}
\begin{array}{c}
F_{\alpha_2} \\
\downarrow \eta \quad F_{a} \quad (F_{ja}) \quad \downarrow \\
\end{array}
\end{array}
\begin{array}{c}
\begin{array}{c}
F_i \\
\downarrow \eta \quad F_{ja} \quad (F_i) \quad \downarrow \\
\end{array}
\end{array}
\begin{array}{c}
\begin{array}{c}
F_{\alpha_2} \\
\downarrow \eta \quad F_{a} \quad (F_{ja}) \quad \downarrow \\
\end{array}
\end{array}
\begin{array}{c}
\begin{array}{c}
F_{\alpha_1} \\
\downarrow \eta \quad F_{a} \quad (F_{ja}) \quad \downarrow \\
\end{array}
\end{array}
\begin{array}{c}
\begin{array}{c}
F_i \\
\downarrow \eta \quad F_{ja} \quad (F_i) \quad \downarrow \\
\end{array}
\end{array}
\begin{array}{c}
\begin{array}{c}
F_{\alpha_1} \\
\downarrow \eta \quad F_{a} \quad (F_{ja}) \quad \downarrow \\
\end{array}
\end{array}
\begin{array}{c}
\begin{array}{c}
F_i \\
\downarrow \eta \quad F_{ja} \quad (F_i) \quad \downarrow \\
\end{array}
\end{array}
\begin{array}{c}
\begin{array}{c}
F_{\alpha_2} \\
\downarrow \eta \quad F_{a} \quad (F_{ja}) \quad \downarrow \\
\end{array}
\end{array}
\begin{array}{c}
\begin{array}{c}
F_i \\
\downarrow \eta \quad F_{ja} \quad (F_i) \quad \downarrow \\
\end{array}
\end{array}
\begin{array}{c}
\begin{array}{c}
F_{\alpha_1} \\
\downarrow \eta \quad F_{a} \quad (F_{ja}) \quad \downarrow \\
\end{array}
\end{array}
\begin{array}{c}
\begin{array}{c}
F_i \\
\downarrow \eta \quad F_{ja} \quad (F_i) \quad \downarrow \\
\end{array}
\end{array}
\begin{array}{c}
\begin{array}{c}
F_{\alpha_2} \\
\downarrow \eta \quad F_{a} \quad (F_{ja}) \quad \downarrow \\
\end{array}
\end{array}
\begin{array}{c}
\begin{array}{c}
F_i \\
\downarrow \eta \quad F_{ja} \quad (F_i) \quad \downarrow \\
\end{array}
\end{array}
\begin{array}{c}
\begin{array}{c}
F_{\alpha_1} \\
\downarrow \eta \quad F_{a} \quad (F_{ja}) \quad \downarrow \\
\end{array}
\end{array}
\begin{array}{c}
\begin{array}{c}
F_i \\
\downarrow \eta \quad F_{ja} \quad (F_i) \quad \downarrow \\
\end{array}
\end{array}
\begin{array}{c}
\begin{array}{c}
F_{\alpha_2} \\
\downarrow \eta \quad F_{a} \quad (F_{ja}) \quad \downarrow \\
\end{array}
\end{array}
\begin{array}{c}
\begin{array}{c}
F_i \\
\downarrow \eta \quad F_{ja} \quad (F_i) \quad \downarrow \\
\end{array}
\end{array}
\begin{array}{c}
\begin{array}{c}
F_{\alpha_1} \\
\downarrow \eta \quad F_{a} \quad (F_{ja}) \quad \downarrow \\
\end{array}
\end{array}
\begin{array}{c}
\begin{array}{c}
F_i \\
\downarrow \eta \quad F_{ja} \quad (F_i) \quad \downarrow \\
\end{array}
\end{array}
\begin{array}{c}
\begin{array}{c}
F_{\alpha_2} \\
\downarrow \eta \quad F_{a} \quad (F_{ja}) \quad \downarrow \\
\end{array}
\end{array}
\begin{array}{c}
\begin{array}{c}
F_i \\
\downarrow \eta \quad F_{ja} \quad (F_i) \quad \downarrow \\
\end{array}
\end{array}
\begin{array}{c}
\begin{array}{c}
F_{\alpha_1} \\
\downarrow \eta \quad F_{a} \quad (F_{ja}) \quad \downarrow \\
\end{array}
\end{array}
\begin{array}{c}
\begin{array}{c}
F_i \\
\downarrow \eta \quad F_{ja} \quad (F_i) \quad \downarrow \\
\end{array}
\end{array}
\begin{array}{c}
\begin{array}{c}
F_{\alpha_2} \\
\downarrow \eta \quad F_{a} \quad (F_{ja}) \quad \downarrow \\
\end{array}
\end{array}
\begin{array}{c}
\begin{array}{c}
F_i \\
\downarrow \eta \quad F_{ja} \quad (F_i) \quad \downarrow \\
\end{array}
\end{array}
\begin{array}{c}
\begin{array}{c}
F_{\alpha_1} \\
\downarrow \eta \quad F_{a} \quad (F_{ja}) \quad \downarrow \\
\end{array}
\end{array}
\begin{array}{c}
\begin{array}{c}
F_i \\
\downarrow \eta \quad F_{ja} \quad (F_i) \quad \downarrow \\
\end{array}
\end{array}
\begin{array}{c}
\begin{array}{c}
F_{\alpha_2} \\
\downarrow \eta \quad F_{a} \quad (F_{ja}) \quad \downarrow \\
\end{array}
\end{array}
\begin{array}{c}
\begin{array}{c}
F_i \\
\downarrow \eta \quad F_{ja} \quad (F_i) \quad \downarrow \\
\end{array}
\end{array}
\end{array}
\end{array}
\]

It is also straightforward to produce a string diagram by dualizing such a grid-like cellular pasting.

Note that in order to evaluate a cellular diagram as above in a non-strict bicategory we are equally obliged to insert coherence isomorphisms and make choices.

### A.4. The ordinary category of spans

**A.4.1. Definition.** Let $C$ be an essentially small category with pullbacks. We write

\[ \tilde{C} \]

for the *ordinary category of spans*, where the objects are the same as those of $C$, a morphism $X \to Y$ is an isomorphism class of spans $X \leftarrow S \to Y$ and composition is induced by taking pullbacks in the standard way of correspondences (or calculus of fraction). See Remark A.4.6. If a morphism $\varphi: X \to Y$ of $\tilde{C}$ is represented by

\[
\begin{array}{c}
\begin{array}{c}
X \\
\nearrow f \\
S \\
\searrow g \\
Y \\
\end{array}
\end{array}
\]

we will also write $\varphi = [f, g]$. We will use the notation

\[
(-)_*: C \to \tilde{C} \quad \text{and} \quad (-)^*: \text{C}^{\text{op}} \to \tilde{C}
\]
A.4. THE ORDINARY CATEGORY OF SPANS

for the two canonical functors given on morphisms by
\[ f \mapsto f_* := [\text{id}, f] \quad \text{and} \quad f \mapsto f^* := [f, \text{id}]. \]

We record a few basic properties of the construction \( \hat{C} \).

A.4.2. Remark. The operation \( \varphi = [f, g] \mapsto \varphi^t := [g, f] \) of switching the two legs of a span provides an involutive isomorphism of categories
\[ (-)^t : \hat{C}^{\text{op}} \xrightarrow{\cong} \hat{C} \]
which is the identity on objects. We will call it transposition.

A.4.3. Proposition. The embeddings \((-)_* \) and \((-)^* \) are fully faithful and jointly satisfy the following property: To give a functor \( F : \hat{C} \to D \) to any other category \( D \) is the same as to give a pair of functors \( F_* : C \to D \) and \( F^* : C^{\text{op}} \to D \) such that
(a) \( F_* \) and \( F^* \) take the same values on objects, and
(b) for any pullback square in \( C \)
\[
\begin{array}{ccc}
  a & \xrightarrow{\varphi} & b \\
  \downarrow & & \downarrow \\
  c & \xleftarrow{\varphi} & d
\end{array}
\]
the equation \( F_* (b) F^* (a) = F^* (d) F_* (c) \) holds in \( D \).

The functor \( F \) is the unique one such that \( F \circ (-)_* = F_* \) and \( F \circ (-)^* = F^* \):

\[
\begin{array}{ccc}
  (-)_* & \xrightarrow{F_*} & D \\
  \downarrow & & \downarrow \\
  (-)^* & \xleftarrow{F^*} & C^{\text{op}}
\end{array}
\]

Proof. This is ultimately a (well-known) special case of the universal property in Theorem 5.3.7, which is also quite easy to verify directly. \( \square \)

A.4.4. Lemma. The construction \( C \mapsto \hat{C} \) satisfies the following properties:
(a) Every pullback-preserving functor \( F : C_1 \to C_2 \) extends uniquely to a functor \( \hat{F} : \hat{C}_1 \to \hat{C}_2 \) commuting with the canonical embeddings \((-)_*\) and \((-)^*\), and given by the formula \( \hat{F} ([f, g]) = [F f, F g] \).
(b) Each isomorphism \( \alpha : F \Rightarrow G \) of pullback-preserving functors \( F, G : C_1 \to C_2 \)
yields an isomorphism \( \hat{\alpha} : \hat{F} \Rightarrow \hat{G} \) defined by \( \hat{\alpha}_X = (\alpha_X)_* \).
(c) Taking \((-)\) commutes with products of categories: \( \hat{C}_1 \times \hat{C}_2 = \hat{C}_1 \times \hat{C}_2 \).

Proof. Part (a) follows from the universal property of Proposition A.4.3, and the rest is equally straightforward. Note that there is no reason for (b) to be true in general if \( \alpha \) is not invertible, because \( (\alpha_X)_* \) in \( \hat{C}_2 \) may not be natural in \( X \). \( \square \)

A.4.5. Lemma. Let \( C \) be a category with pullbacks. The only isomorphisms \( \varphi \) in \( \hat{C} \)
are those coming from \( C \), that is, those of the form \( \varphi = f_\circ \) for an isomorphism \( f \) in \( C \). It follows that every isomorphism \( \varphi \) in \( \hat{C} \) satisfies \( \varphi^{-1} = \varphi^t \) in the notation of Remark A.4.2.
PROOF. Let \( \varphi = [a, b] \) and \( \psi = [c, d] \) be mutually inverse spans. Then \( \psi \varphi = \text{id} \) implies that \( a \) and \( d \) are split epis and the pullback maps \( \bar{a} \) and \( \bar{b} \) are split monos.

\[
\begin{array}{c}
\begin{tikzcd}
\circ & a \ar{r}{b} & c \ar{r}{d} & b \ar{lu}{\circ} \ar{ru}{}
\end{tikzcd}
\end{array}
\]

Similarly, \( \varphi \psi = \text{id} \) implies that \( c \) and \( b \) are split epis and the pullback maps \( \bar{a} \) and \( \bar{d} \) are split monos. Since pullbacks preserve split epis, we see that each of the maps \( \bar{a}, \bar{b}, \bar{c} \) and \( \bar{d} \) is both a split mono and a split epi, hence is invertible. Then the maps \( a, b, c \) and \( d \), being their right or left inverses, are also isomorphisms. It follows that \( \varphi = [a, b] = [\text{id, } ba^{-1}] = f_* \) for \( f := ba^{-1} \).

The second part follows immediately since \( (f_*)^{-1} = f^* = (f_*)^t \).

We conclude with a few words relating the 1-category of spans \( \hat{\mathcal{C}} \) to bicategories.

A.4.6. Remark. We expand details about spans and their composition in Chapter 6, even at the bicategorical level. In particular, the above \( \hat{\mathcal{C}} \) is nothing but the 1-truncation \( \tau_1 \) (Notation A.1.13) of the bicategory \( \text{Span}(\mathcal{C}, \text{Mor}\mathcal{C}) \):

\[
\hat{\mathcal{C}} = \tau_1 \text{Span}(\mathcal{C}, \text{Mor}\mathcal{C}).
\]

Indeed, every ordinary category \( \mathcal{C} \) can be viewed as a 'locally discrete' 2-category, i.e. one whose only 2-cells are the identities. In such a (2,1)-category, iso-comma squares and weak pullbacks coincide with ordinary pullbacks. Moreover, every 1-cell (morphism of \( \mathcal{C} \)) is trivially faithful. Thus if \( \mathcal{C} \) is an essentially small category admitting arbitrary pullbacks, viewed as a (2,1)-category \( \mathcal{G} := \hat{\mathcal{C}} \) equipped with \( \mathcal{J} = \text{Mor}\mathcal{C} \) the class of all morphisms, we may construct the bicategory of spans \( \text{Span}(\mathcal{C}, \text{Mor}\mathcal{C}) = \text{Span}(\mathcal{G}; \mathcal{J}) \) as in Definition 5.1.6. This is the special case originally considered by Bénabou [Bén67].

A.5. Additivity for categories

The purpose of this section is to fix our terminology in relation to additivity, semi-additivity and idempotent-completion. All the results mentioned are standard.

A.5.1. Terminology. We consider the following additive notions for categories:

1. A pointed category \( \mathcal{A} \), with zero object 0 (both initial and final), is called \textit{semi-additive} if for any two objects \( X, Y \in \mathcal{A} \), the coproduct \( X \sqcup Y \) and the product \( X \times Y \) exist and coincide, i.e. are isomorphic via the canonical map \( X \sqcup Y \to X \times Y \) with components \( (\text{id}_X, 0_{X,Y}, 0_{Y,X}, \text{id}_Y) \), where \( 0_{U,V} : U \to 0 \to V \) denotes the unique map factoring through 0. We denote by \( X \oplus Y \) this \textit{biproduct}. In that case every set \( \mathcal{A}(X,Y) \) canonically becomes an abelian monoid with neutral element \( 0 := 0_{X,Y} \) and with addition defined for all \( f, g \in \mathcal{A}(X,Y) \) by

\[
(A.5.2) \quad f + g = \left( X \begin{array}{c}
\begin{tikzcd}
\circ & 1 \ar{r}{1} & X \ar{r}{1} & X \oplus X \ar{r}{f \oplus g} & Y \oplus Y = Y \sqcup Y \ar{r}{1 \oplus 1} & Y
\end{tikzcd}
\end{array} \right).
\]

Consequently \( \mathcal{A} \) is a category \textit{enriched over abelian monoids}, in the strict sense of [Kel05], meaning that composition is bilinear: \( h(f + g) = hg + hf, (f + g)h = fh + gh, 0f = 0 \) and \( g0 = 0 \). Compare [ML98, VIII.2].
(2) In a category enriched over abelian monoids, a \textit{direct sum} of two objects $X_1$ and $X_2$ is a diagram

\begin{equation}
X_1 \xrightarrow{i_1} X_1 \oplus X_2 \xrightarrow{i_2} X_2
\end{equation}

such that $p_{\alpha}i_{\alpha} = \text{id}_{X_{\alpha}}$, $p_{\alpha}i_{\beta} = 0$ (for $\{\alpha, \beta\} = \{1, 2\}$) and $i_1p_1 + i_2p_2 = \text{id}_{X_1 \oplus X_2}$. Then $(X_1 \oplus X_2, p_1, p_2)$ is the product $X_1 \times X_2$ and $(X_1 \oplus X_2, i_1, i_2)$ is the coproduct $X_1 \sqcup X_2$. Thus direct sums are the same as biproducts.

(3) An \textit{additive} category $\mathcal{A}$ is a semi-additive category such that every morphism $f: X \to Y$ has an opposite $-f: X \to Y$, i.e. the abelian monoids $\mathcal{A}(X,Y)$ are abelian groups.

A.5.4. Remark. One can equivalently define a semi-additive (resp. additive) category as a category enriched over abelian monoids (resp. abelian groups) that admits all finite direct sums, including the empty sum which is 0.

A.5.5. Remark. In a semi-additive category $\mathcal{A}$, if $X = X_1 \oplus \ldots \oplus X_m$ and $Y = Y_1 \oplus \ldots \oplus Y_n$ are two direct sums, we obtain an isomorphism of abelian monoids

$$\mathcal{A}(X,Y) \cong \bigoplus_{\alpha,\beta} \mathcal{A}(X_{\beta}, Y_{\alpha}) \quad f \mapsto (p_{\alpha}f_{\beta})_{\alpha,\beta}$$

with inverse $(g_{\alpha,\beta})_{\alpha,\beta} \mapsto \sum_{\alpha,\beta} i_{\alpha}g_{\alpha,\beta}p_\beta$, which turns composition of maps into matrix multiplication. In particular, (A.5.2) reads $f + g = (1\ 1)((0 \ 0)(1\ 1))$.

There is only one relevant notion of additivity for functors:

A.5.6. Definition. Let $\mathcal{A}$ and $\mathcal{B}$ be semi-additive (e.g. additive) categories. A functor $F: \mathcal{A} \to \mathcal{B}$ is called \textit{additive} if it preserves sums of morphisms, $F(f + g) = F(f) + F(g)$, and zero maps, $F(0_{X,Y}) = 0_{F(X,Y)}$. That is, $F$ is a functor of categories enriched over abelian monoids, in the sense of [Kel05].

A.5.7. Remark. An additive functor automatically preserves direct sums, up to a unique canonical isomorphism, by Terminology A.5.1 (2). Conversely, if $F: \mathcal{A} \to \mathcal{B}$ sends the direct sums of $\mathcal{A}$ to direct sums of $\mathcal{B}$ (e.g. if $F$ is an equivalence) then $F$ must be additive because of (A.5.2).

A.5.8. Notation. Together with all natural transformations between them, the additive functors $\mathcal{A} \to \mathcal{B}$ form a category

$$\text{Fun}_+(\mathcal{A}, \mathcal{B})$$

Let $\text{Sad}$ be the 2-category of all small categories which are semi-additive and whose Hom categories are the above $\text{Fun}_+(\mathcal{A}, \mathcal{B})$. Let $\text{Add}$ be the full sub-2-category of $\text{Sad}$ consisting of additive categories. Compositions are the obvious restrictions of those of $\text{Cat}$ in both cases.

It will also be useful to allow all large semi-additive and all large additive categories, which gives rise to the (‘very large’) 2-categories $\text{SAD}$ and $\text{ADD}$, respectively, with all additive functors as 1-cells and all their natural transformations as 2-cells.

A.5.9. Definition. One says that an additive category $\mathcal{A}$ is \textit{idempotent-complete} if every idempotent endomorphism $e = e^2: X \to X$ in $\mathcal{A}$ splits, i.e. if it yields a decomposition $X \simeq X_1 \oplus X_2$ under which $e$ becomes the projection $\left(\begin{smallmatrix} 1 & 0 \\ 0 & 0 \end{smallmatrix}\right)$ on $X_1$. This decomposition yields $X = \text{im}(e) \oplus \text{im}(1-e)$, that is, both $e$ and $1-e$ have an image even if $\mathcal{A}$ is not abelian. In particular, the direct summand $\text{im}(e)$ is unique.
up to unique isomorphism, and is functorial in $e$. We denote by $\text{Add}_{ic}$ the full sub-2-category of $\text{Add}$ consisting of idempotent-complete additive categories, and similarly for $\text{ADD}_{ic} \subset \text{ADD}$.

**A.5.10. Remark.** The fully faithful 2-functors $\text{Add}_{ic} \hookrightarrow \text{Add} \hookrightarrow \text{Sad}$ are reflexive inclusions in the 2-categorical sense:

\[
\begin{array}{ccc}
\text{Sad} & \xrightarrow{\sim} & \text{Add} \\
\downarrow & & \downarrow \\
\text{Add}_{ic} & \xrightarrow{\sim} & \text{Add}
\end{array}
\]

In other words, for every semi-additive category $\mathcal{A}$, there exists an additive functor $\mathcal{A} \to \mathcal{A}_+$, with $\mathcal{A}_+$ additive, that induces by pre-composition an equivalence

(A.5.11)  
\[\text{Fun}_+(\mathcal{A}_+, \mathcal{B}) \xrightarrow{\sim} \text{Fun}_+(\mathcal{A}, \mathcal{B})\]

for every additive category $\mathcal{B}$. This construction $\mathcal{A} \to \mathcal{A}_+$ uniquely extends to a 2-functor $(-)_+: \text{Sad} \to \text{Add}$. Similarly, for every additive category $\mathcal{C}$, there exists an additive functor $\mathcal{C} \to \mathcal{C}_+$, with $\mathcal{C}$ idempotent-complete, that induces by pre-composition an equivalence

(A.5.12)  
\[\text{Fun}_+(\mathcal{C}_+, \mathcal{D}) \xrightarrow{\sim} \text{Fun}_+(\mathcal{C}, \mathcal{D})\]

for every idempotent-complete additive category $\mathcal{D}$. This construction $\mathcal{C} \to \mathcal{C}_+$ uniquely extends to a 2-functor $(-)^+: \text{Add} \to \text{Add}_{ic}$.

We recall the details for the reader’s convenience:

1. **Group-completion $\mathcal{A}_+$**: This is a purely ‘enriched-category’ construction. Recall that every abelian monoid $M$ maps to the associated (Grothendieck) group $M_+$ obtained by formally adding opposites $-m$ for every $m \in M$ and declaring $m - n = m' - n'$ in $M_+$ if $m + n' + \ell = m' + n + \ell$ in $M$ for some $\ell \in M$. This functor $M \mapsto M_+$ provides a left adjoint to the inclusion of abelian groups into abelian monoids, which is moreover monoidal (i.e. $(M \times M')_+ \cong M_+ \times M'_+$).

We can then group-complete any category $\mathcal{A}$ enriched over abelian monoids by declaring $\mathcal{A}_+(X, Y) := (\mathcal{A}(X, Y))_+$. By the universal property, there is an additive functor $\mathcal{A} \to \mathcal{A}_+$ inducing the required equivalence (A.5.11), which in this case is in fact an isomorphism of categories.

2. **Idempotent-completion $\mathcal{C}^\sharp$**: Let $\mathcal{C}$ be an additive category. Its idempotent-completion (a.k.a. Karoubi envelope) $\mathcal{C}^\sharp$ has objects given by pairs $(X, e)$, where $X$ is an object of $\mathcal{C}$ and $e = e^2: X \to X$ is an idempotent, and morphisms $f: (X, e) \to (X', e')$ given by morphisms $f: X \to X'$ in $\mathcal{C}$ such that $f = e'fe$. The embedding $\mathcal{C} \to \mathcal{C}^\sharp$ maps an object $X$ to $(X, \text{id})$ and a morphism $f$ to $f$. For every idempotent $e = e^2: X \to X$, we have $(X, e) \oplus (X, 1 - e) \cong (X, \text{id})$ in $\mathcal{C}^\sharp$. To prove the equivalence (A.5.12), note that every additive $F: \mathcal{C} \to \mathcal{D}$ extends uniquely to $\mathcal{C}^\sharp$ by mapping $(X, e)$ to the summand $\text{im}(F(e))$ of $F(X)$.

**A.5.13. Example** (Span categories). Let $\mathcal{C}$ be a category with pull-backs and consider the category $\hat{\mathcal{C}}$ of spans in $\mathcal{C}$ (see Definition A.4.1). Assume moreover that $\mathcal{C}$ is lextensive, i.e. it admits all finite limits and finite coproducts and the functor

$\mathcal{C}/X \times \mathcal{C}/Y \xrightarrow{\sim} \mathcal{C}/X \sqcup Y$ \quad \quad $(f: S \to X, g: T \to Y) \mapsto (f \sqcup g: S \sqcup T \to X \sqcup Y)$
comparing comma categories is an equivalence for all objects $X, Y$. Lextensive categories include finite sets, finite $G$-sets for a group $G$, the (1-)category of finite groupoids, or indeed any (elementary) topos. Then its category of spans $\hat{C}$ is semi-additive, as explained in [PS07, §3]. Concretely, the empty coproduct (initial object) $\emptyset$ of $C$ is a zero object in $\hat{C}$ and a coproduct $i_1 : X_1 \to X_1 \sqcup X_2 \leftarrow X_2 : i_2$ provides the following direct sum:

$$X_1 \xrightarrow{(i_1)_*} X_1 \sqcup X_2 \xleftarrow{(i_2)_*} X_2.$$ 

The resulting addition (A.5.2) of two spans $[X \leftarrow S_1 \to Y]$ and $[X \leftarrow S_2 \to Y]$ is simply given by $[X \leftarrow S_1 \sqcup S_2 \to Y]$, and the zero map $0_{X,Y}$ is $[X \leftarrow \emptyset \to Y]$. If $F : C \to C'$ is a pullback- and coproduct-preserving functor, the induced functor $\hat{F} : \hat{C} \to \hat{C}'$ (Lemma A.4.4) is clearly additive. It is also common to consider the additive category of spans $\hat{C}_+$, obtained by group-completion as in Remark A.5.10 (1). Note that the canonical functor $\hat{C} \to \hat{C}_+$ is faithful, at least if $C$ has the property that each object decomposes into a (up to isomorphism) unique finite coproduct of II-indecomposable objects (as happens with finite $G$-sets, groupoids etc.). Indeed, the latter property is inherited by the comma categories $C//U$ and implies that each Hom abelian monoid $\hat{C}(X,Y) = \text{Obj}(C/(X \times Y))/\sim$ is free and therefore cancellable, so that the canonical homomorphism $\hat{C}(X,Y) \to \hat{C}(X,Y)_+$ is injective.

A.5.14. Example. The most common example of idempotent-completion $C^\flat$ might be the category of projective $R$-modules $R\text{-Proj} \cong (R\text{-Free})^\Delta$ which is the idempotent-completion of the additive category of free $R$-modules, for every ring $R$.

A.6. Additivity for bicategories

We now extend the 1-categorical ideas of Appendix A.5 to the realm of bicategories, insofar as needed in this work. Most notably, we introduce the notion of ‘block-completion’ (Definition A.6.17 and Construction A.6.22) which reflects the possibility of decomposing 0-cells and 1-cells by way of idempotents. But we first apply the definitions and constructions of Appendix A.5 locally, i.e. ‘Hom-wise’.

A.6.1. Definition. We say that a bicategory $B$ is locally semi-additive (resp. locally additive, resp. locally idempotent-complete), if all its Hom categories $B(X,Y)$ are semi-additive (resp. additive, resp. idempotent-complete) and all its horizontal composition functors are additive functors. A pseudo-functor $F : B \to B'$ between locally semi-additive bicategories is locally additive if each component $F : B(X,Y) \to B'(FX,FY)$ is an additive functor (Definition A.5.6).

A.6.2. Remark. The coherent structure maps of any locally semi-additive bicategory are compatible with direct sums of 1-cells, that is, we have $\text{run}_{f_1 \oplus f_2} = \text{run}_{f_1} \oplus \text{run}_{f_2}$ for the right unitors, and similarly for left unitors and associators. This follows from naturality, and is a completely general fact. The components of any natural transformation $\alpha : F \Rightarrow G : A \to A'$ of additive functors between semi-additive categories decompose diagonally on direct sums: $\alpha_{x_1 \oplus x_2} = \alpha_{x_1} \oplus \alpha_{x_2}$.

A.6.3. Remark. If $B$ is a locally additive bicategory, then for each object $X$ we have a 2-cell endomorphism ring $\text{End}_{B(X,X)}(\text{Id}_X)$. For short, we will simply denote
by \(1_X\) its multiplicative unit \(\text{id}_{\text{Id}_X}\). This ring is commutative by the standard commutative diagram:

\[
\begin{array}{ccc}
\text{Id}_X & \xrightarrow{\alpha} & \text{Id}_X \\
\downarrow \beta & & \downarrow \beta \\
\text{Id}_X \circ \text{Id}_X & \xrightarrow{\text{id} \circ \beta} & \text{Id}_X \circ \text{Id}_X \\
\downarrow \alpha & & \downarrow \alpha \\
\text{Id}_X \circ \text{Id}_X & \xrightarrow{\text{id} \circ \beta} & \text{Id}_X \circ \text{Id}_X \\
\end{array}
\]

This is a form of Eckmann-Hilton argument: The two operations given by horizontal and vertical composition must coincide on \(\text{End}(\text{Id}_X)\).

**A.6.4. Remark.** By locally applying the constructions of Remark A.5.10, we obtain canonical forgetful and completion pseudo-functors comparing the three kinds of enriched bicategories of Definition A.6.1. Let us be specific.

1. If the bicategory \(\mathcal{B}\) is locally semi-additive there is a canonical pseudo-functor \(\mathcal{B} \to \mathcal{B}^+\), where \(\mathcal{B}^+\) is locally additive and through which every other pseudo-functor \(\mathcal{B} \to \mathcal{B}'\) to some locally semi-additive bicategory \(\mathcal{B}'\) must factor (essentially) uniquely. The 0-cells of \(\mathcal{B}\) and \(\mathcal{B}^+\) are the same and the Hom categories of \(\mathcal{B}^+\) are simply the group completions \(\mathcal{B}^+(X,Y) := \mathcal{B}(X,Y)^+\). The pseudo-functor \(\mathcal{B} \to \mathcal{B}^+\) has components given by the canonical functors \(\mathcal{B}(X,Y) \to \mathcal{B}(X,Y)^+\); see Remark A.5.10(1). Note that \(\mathcal{B}^+\) has the same 0-cells and 1-cells as \(\mathcal{B}\) and that 2-cells of \(\mathcal{B}^+\) are (formal) differences of 2-cells of \(\mathcal{B}\). It is immediate to see that the canonical embedding \(\mathcal{B} \to \mathcal{B}^+\) induces, for any locally additive category \(\mathcal{C}\), a bi-equivalence (actually an isomorphism)

\[
\text{PsFun}^+(\mathcal{B}^+, \mathcal{C}) \xrightarrow{\sim} \text{PsFun}^+(\mathcal{B}, \mathcal{C})
\]

of bicategories of **locally additive** pseudo-functors, pseudo-natural transformations and modifications.

2. Similarly, if \(\mathcal{C}\) is a locally additive bicategory there is a canonical pseudo-functor \(\mathcal{C} \to \mathcal{C}^\delta\), where \(\mathcal{C}^\delta\) is locally idempotent-complete and through which every other pseudo-functor \(\mathcal{C} \to \mathcal{C}'\) to some locally idempotent-complete bicategory \(\mathcal{C}'\) must factor (essentially) uniquely. The 0-cells of \(\mathcal{C}\) and \(\mathcal{C}^\delta\) are the same and the Hom categories of \(\mathcal{C}^\delta\) are simply the idempotent-completions \(\mathcal{C}^\delta(X,Y) := \mathcal{C}(X,Y)^\delta\). The pseudo-functor \(\mathcal{C} \to \mathcal{C}^\delta\) has components given by the canonical functors \(\mathcal{C}(X,Y) \to \mathcal{C}(X,Y)^\delta\); see Remark A.5.10(2). Note that the 0-cells of \(\mathcal{C}^\delta\) are the same as those of \(\mathcal{C}\), that 1-cells of \(\mathcal{C}^\delta\) are direct summands of 1-cells of \(\mathcal{C}\) (i.e. 1-cells together with an idempotent 2-cell), and that 2-cells of \(\mathcal{C}^\delta\) are 2-cells of \(\mathcal{C}\) which are compatible with the relevant idempotents. For every locally idempotent-complete bicategory \(\mathcal{C}\), the embedding \(\mathcal{B} \to \mathcal{B}^\delta\) induces a biequivalence

\[
\text{PsFun}^+(\mathcal{B}^\delta, \mathcal{C}) \xrightarrow{\sim} \text{PsFun}^+(\mathcal{B}, \mathcal{C})
\]

of bicategories of locally additive pseudo-functors. (We leave this as an easy exercise. The existence and uniqueness of the extension of pseudo-natural transformations \(t\) uses that their 2-cell components \(t_f\) decompose diagonally for
A.6. ADDITIVITY FOR BICATEGORIES

167

direct sums of 1-cells: \( t_f = t_{f_1} \oplus t_{f_2} \) if \( f = f_1 \oplus f_2 \). This is a consequence of the naturality axiom similarly to Remark A.6.2.

A.6.5. Example. The 2-category \( \text{ADD}_{ic} \) of idempotent-complete additive categories is itself locally idempotent-complete as a bicategory. In other words, we have \( \text{ADD}_{ic} \Rightarrow (\text{ADD}_{ic})^3 \). Indeed, for additive categories \( \mathcal{A} \) and \( \mathcal{B} \) with \( \mathcal{A} \) and \( \mathcal{B} \) idempotent-complete, the category \( \text{Fun}_{ic}(\mathcal{A}, \mathcal{B}) \) of additive functors from \( \mathcal{A} \) to \( \mathcal{B} \) is idempotent-complete. To see this, observe that if \( e = e^2: F \Rightarrow F \) is an idempotent natural transformation of \( F: \mathcal{A} \to \mathcal{B} \) then for every \( x \in \text{Obj} \mathcal{A} \) the idempotent \( e_x: F(x) \to F(x) \) yields a decomposition \( F(A) \cong \text{im}(e_x) \oplus \text{im}(1 - e_x) \) in \( \mathcal{B} \); we can then decompose \( F \cong F_1 \oplus F_2 \) where one defines \( F_1: \mathcal{A} \to \mathcal{B} \) by mapping an object \( A \) to \( \text{im}(e_x) \) and a morphism \( f: x \to x' \) to \( F(f)e_x = e_{x'}F(f) \), which restricts to \( \text{im}(e_x) \to \text{im}(e_{x'}) \), and similarly for \( F_2 \) with \( 1 - e_x \) instead of \( e_x \).

After the above discussion of Hom categories in bicategories \( \mathcal{B} \), we now turn to constructions involving 0-cells:

A.6.6. Definition. Let \( \mathcal{B} \) be a bicategory.

1. A final object of \( \mathcal{B} \) is an object \( * \) with the property that \( \mathcal{B}(X,*) \to 1 \) is an equivalence for all \( X \in \text{B_0} \), where the (final) category 1 has one object and one morphism. Dually, an initial object of \( \mathcal{B} \) is a \( \emptyset \in \mathcal{B}_0 \) such that \( \mathcal{B}(*,Y) \to 1 \) is an equivalence, and a zero object 0 is one which is both initial and final.

2. A product of 0-cells \( X_1 \) and \( X_2 \) is a pair of 1-cells \( p_1: X_1 \leftarrow X_1 \times X_2 \to X_2 \) \( p_2 \) inducing an equivalence

\[
(p_{1*}, p_{2*}): \mathcal{B}(Y, X_1 \times X_2) \to \mathcal{B}(Y, X_1) \times \mathcal{B}(Y, X_2)
\]

of Hom categories for all \( Y \). Dually, a diagram \( X_1 \to X_1 \sqcup X_2 \leftarrow X_2 \) is a coproduct if it induces equivalences \( \mathcal{B}(X_1 \sqcup X_2, Y) \to \mathcal{B}(X_1, Y) \times \mathcal{B}(X_2, Y) \).

3. Assume that the Hom categories of \( \mathcal{B} \) admit zero objects \( 0 = 0_{X,Y} \in \mathcal{B}(X,Y) \) and that they are preserved by horizontal composition. Then if \( \mathcal{B} \) has a product \( X_1 \times X_2 \) and a coproduct \( X_1 \sqcup X_2 \) we may define a (unique up to isomorphism) comparison 1-cell \( X_1 \sqcup X_2 \to X_1 \times X_2 \) determined by the four components \( (\text{Id}_{X_2}, 0_{X_1,x_2}, 0_{X_2,x_1}, \text{Id}_{X_1}) \). If the latter is an equivalence, we may equip \( X_1 \sqcup X_2 \) (or equivalently \( X_1 \times X_2 \)) with the structure both of a product and of a coproduct and will call it a biproduct of \( X_1 \) and \( X_2 \).

4. Assume that \( \mathcal{B} \) is locally semi-additive (Definition A.6.1). A direct sum in \( \mathcal{B} \) is a diagram of 1-cells as in (A.5.3) for which there exist isomorphisms

\[
p_1 \circ i_1 \simeq \text{Id}_{X_1}, \quad p_2 \circ i_2 \simeq \text{Id}_{X_2}, \quad p_2 \circ i_1 \simeq 0_{X_2,x_1}, \quad p_1 \circ i_2 \simeq 0_{X_1,x_2}, \quad i_1 p_1 \oplus i_2 p_2 \simeq \text{Id}_{X_1 \oplus X_2}
\]

where the latter uses the direct sum in the category \( \mathcal{B}(X_1 \oplus X_2, X_1 \oplus X_2) \). Each of the above notions is called strict if the equivalences are actually isomorphisms (in the latter, if the isomorphisms are equalities). We extend the definitions as usual to finite products, coproducts, biproducts and direct sums, the empty case being defined to be an initial, final, and both initial and final (i.e. zero) object.

The next lemma provides a strong link between (co)products of 0-cells and (co)products of 1-cells in each Hom category (cf. Terminology A.5.12).
A.6.7. Lemma. In any locally semi-additive bicategory $\mathcal{B}$, biproducts and direct sum are equivalent notions.

Proof. We leave this as a straightforward exercise for the reader, which makes crucial use of the fact that the horizontal composition functors of $\mathcal{B}$ preserve direct sums (i.e. biproducts) of 1-cells in both variables. □

A.6.8. Remark. As in ordinary categories, we can use the standard matrix notation (Remark A.5.5) for 1-cells into, or out of, a direct sum in a bicategory, as well as 2-cells between such 1-cells. For instance in ADD, if the components $F_1$ and $F_2$ of a functor $F = (F_i) : \mathcal{A} \to B_1 \oplus B_2$ admit left adjoints $F_1 \dashv F_1$ and $F_2 \dashv F_2$ then these are the components of the left adjoint of $F$, that is, $F_1 = (F_1 \circ F_2) \dashv F$ with compatible units and counits:

$$\eta : \text{Id}_{B_1 \oplus B_2} = \begin{pmatrix} 1_{B_1} & 0 \\ 0 & 1_{B_2} \end{pmatrix} \begin{pmatrix} \eta_1 & 0 \\ 0 & \eta_2 \end{pmatrix} \begin{pmatrix} F_1 F_1 & F_1 F_2 \\ F_2 F_1 & F_2 F_2 \end{pmatrix} = \begin{pmatrix} (F_1) & (F_1, F_2) \end{pmatrix} = F F_1$$

$$\varepsilon : F_1 F = (F_1, F_2) \begin{pmatrix} F_1 \\ F_2 \end{pmatrix} = F_1 F_1 \oplus F_2 F_2 \xrightarrow{\varepsilon_1 \oplus \varepsilon_2} \text{Id}_\mathcal{A}.$$

A.6.9. Example. The 2-category $\text{gpd}$ of all finite groupoids admits all finite (strict) coproducts, provided by the usual disjoint unions of categories, and $\text{gpd}$ also admits (strict) finite products provided by the usual product of categories.

A.6.10. Example. The bicategories $\text{SAD}$ and $\text{ADD}$ of semi-additive, respectively additive, categories admit all finite direct sums. Indeed, the usual (strict) product $\mathcal{A}_1 \oplus \mathcal{A}_2 := \mathcal{A}_1 \times \mathcal{A}_2$ of two (semi-)additive categories is again so, with objectwise direct sums $(A_1, A_2) \oplus (B_1, B_2) = (A_1 \oplus B_1, A_2 \oplus B_2)$ and zero object $0 = (0, 0)$, and in this case is also a (non strict) coproduct, with structural 1-cells given by the embedding functors $\mathcal{A}_1 \embed \mathcal{A}_1 \oplus \mathcal{A}_2$, $\mathcal{X}_1 \mapsto (A_1, 0)$ and $\mathcal{A}_2 \embed \mathcal{A}_1 \oplus \mathcal{A}_2$, $\mathcal{A}_2 \mapsto (0, \mathcal{X}_2)$. If $\mathcal{A}_1$ and $\mathcal{A}_2$ happen to be idempotent-complete then so is $\mathcal{A}_1 \oplus \mathcal{A}_2$, hence $\text{ADD}_{ic}$ also admits direct sums.

A.6.11. Definition. In this work, we say that a pseudo-functor $\mathcal{F} : \mathcal{B} \to \mathcal{B}'$ between bicategories with products is additive if it preserves products, i.e. if the canonical comparison 1-cells

$$\mathcal{F}(\bullet) \xrightarrow{\sim} \bullet \quad \text{and} \quad \mathcal{F}(X_1 \times X_2) \xrightarrow{\sim} \mathcal{F}(X_1) \times \mathcal{F}(X_2)$$

are equivalences for all objects $^3$. Typically, we consider functors $\mathcal{M} : \mathcal{G}^{\text{op}} \to \text{ADD}$ where $\mathcal{B} = \mathcal{G}^{\text{op}}$ for $\mathcal{G}$ a bicategory of finite groupoids closed under finite coproducts in $\text{gpd}$, which then become products in the opposite bicategory $\mathcal{B}$. Thus additivity for $\mathcal{M}$ translates into the by now familiar axiom (Mack 1) for Mackey 2-functors or (Der 1) for derivators. Because of this context, we will use the notation

$$\text{PsFun}_{\Pi}(\mathcal{B}, \mathcal{B}') \subseteq \text{PsFun}(\mathcal{B}, \mathcal{B}')$$

for the the 1- and 2-full sub-bicategory of additive pseudo-functors, decorated with ‘$\Pi$’ rather than the more logical ‘$\Pi$’.

$^3$One can check that the latter implies the former provided there exists a 1-cell $\bullet \to \mathcal{F}(\bullet)$, which must be the case for instance when the target bicategory is pointed (e.g. $\mathcal{B}' = \text{ADD}$).
A.6.12. Lemma. Let $\mathcal{B}$ be a locally semi-additive bicategory and assume that the direct sums $X \oplus X$ and $Y \oplus Y$ exist for some $X, Y \in \mathcal{B}_0$. Then the direct sums in the Hom category $\mathcal{B}(X, Y)$ are given by the composite functor
\[
\mathcal{B}(X, Y) \times \mathcal{B}(X, Y) \xrightarrow{-\oplus-} \mathcal{B}(X \oplus X, Y \oplus Y) \xrightarrow{(\Delta^\ast, \nabla^\ast)} \mathcal{B}(X, Y),
\]
where $\Delta : X \to X \oplus X$ and $\nabla : X \oplus Y \to X$ are the diagonal and co-diagonal 1-cells, and $- \oplus -$ is induced by the direct sums of 0-cells.

Proof. The definition of direct sums of 0-cells gives us an equivalence
\[
\mathcal{B}(X \oplus X, Y \oplus Y) \cong \mathcal{B}(X, X) \oplus \mathcal{B}(X, Y) \oplus \mathcal{B}(Y, X) \oplus \mathcal{B}(Y, Y).
\]
In particular, any pair of 1-cells $f_1 : X \to X$ and $f_2 : Y \to Y$ gives rise to the 1-cell
\[
\begin{pmatrix}
  f_1 & 0 \\
  0 & f_2
\end{pmatrix} : X \otimes Y \to X \otimes Y
\]
corresponding to the four components $(f_1, 0_{X,Y}, 0_{Y,X}, f_2)$, and similarly for 2-cells. This is what the first functor $- \oplus -$ in (A.6.13) does. Note that
\[
\begin{pmatrix}
  f_1 & 0 \\
  0 & f_2
\end{pmatrix}
\]
is nothing but the 1-cell direct sum $f_1 \oplus f_2 = (f_1 \oplus 0) \oplus (0 \oplus f_2)$ in $\mathcal{B}(X \oplus X, Y \oplus Y)$, since the two have the same 2-cell Hom groups
\[
\text{Hom}(f_1, g) \oplus \text{Hom}(f_2, g) \quad \text{and} \quad \text{Hom}(g, f_1) \oplus \text{Hom}(g, f_2)
\]
to and from any other 1-cell $g : X \oplus Y \to Y \oplus Y$ (as they are calculated component-wise). Since the horizontal pre- and post-composition functors $- \circ \Delta$ and $\nabla \circ -$ are additive, we see that the second functor in (A.6.13) must send
\[
\begin{pmatrix}
  f_1 & 0 \\
  0 & f_2
\end{pmatrix}
\]
to the direct sum $f_1 \oplus f_2$ in $\mathcal{B}(X, Y)$. \hfill \Box

The next result is as amusing as it is useful:

A.6.14. Proposition. Let $\mathcal{F}$ be any pseudo-functor between locally additive bicategories with finite direct sums. Then $\mathcal{F}$ is additive (Definition A.6.11) if and only if it is locally additive (Definition A.6.1). In other words: $\mathcal{F}$ preserves direct sums of 0-cells iff it preserves direct sums of 1-cells iff it preserves sums of 2-cells.

Proof. The last claimed equivalence follows by applying Remark A.5.7 to all the functors $\mathcal{F}_{X,Y} : \mathcal{B}(X,Y) \to \mathcal{B}'(FX, FY)$. If $\mathcal{F}$ is locally additive then it preserves all direct sum diagrams, which are expressed in terms of isomorphisms between composites and direct sums of 1-cells. Since direct sums are (bi)products by Lemma A.6.7, $\mathcal{F}$ is additive. Conversely, an additive pseudo-functor must preserve the direct sums in each Hom category by Lemma A.6.12. \hfill \Box

Next, we consider the link between direct sum decompositions and idempotents. The local idempotent-completion $\mathcal{C} \mapsto \mathcal{C}^\ast$ of Remark A.6.4 is somewhat unsatisfactory, because it does not account for decompositions of 0-cells:

A.6.15. Remark. Let $\mathcal{B}$ be a locally additive bicategory, and suppose we have an equivalence $X \simeq X_1 \oplus X_2$ decomposing an object $X$ into a direct sum of two objects. We obtain an induced equivalence of additive categories
\[
\mathcal{B}(X, X) \simeq \mathcal{B}(X_1, X_1) \oplus \mathcal{B}(X_1, X_2) \oplus \mathcal{B}(X_2, X_1) \oplus \mathcal{B}(X_2, X_2)
\]
which allows us to write 1-cells $X \to X$ and their morphisms in matrix notation (cf. Remark A.6.8). In particular, the identity 1-cell $\text{Id}_X$ has components
(\text{Id}_{X_1},0,0,\text{Id}_{X_2}) \text{ and its (by Remark A.6.3, commutative) endomorphism ring decomposes into a product as follows:}

\[
\text{End}_{B(X,Y)}(\text{Id}_X) \cong \text{End} \left( \begin{array}{cc} \text{Id}_{X_1} & 0 \\ 0 & \text{Id}_{X_2} \end{array} \right) \cong \text{End}_{B(X_1,X_1)}(\text{Id}_{X_1}) \times \text{End}_{B(X_2,X_2)}(\text{Id}_{X_2}).
\]

Moreover, such a ring decomposition corresponds to a decomposition of its unit \(1_X := \text{id}_{id,X}\) as a sum of two orthogonal idempotents:

\[
(\text{A.6.16}) \quad 1_X = e_1 + e_2 \quad \text{with} \quad e_1^2 = e_1, \quad e_2^2 = e_2 \quad \text{and} \quad e_1 e_2 = 0.
\]

In the opposite direction, however, if we are given a sum decomposition \(1_X = e_1 + e_2\) in orthogonal idempotents, nothing guarantees the existence of a direct sum decomposition \(X \simeq X_1 \oplus X_2\) in \(B\) giving rise to it. This leads us to the following definition.

**A.6.17. Definition.** A locally idempotent-complete bicategory \(B\) (Definition A.6.1) is block-complete if

1. it admits all finite direct sums (Definition A.6.6), and
2. it admits block-decompositions. By the latter we simply mean that, whenever the identity 2-cell \(1_X = \text{id}_{id,X}\) of an object \(X\) decomposes as a sum of two orthogonal idempotents as in (A.6.16), then there exist objects \(X_1, X_2\) and an equivalence \(X \simeq X_1 \oplus X_2\) identifying the idempotent \(e_1\) and \(e_2\) with the 2-cells \((\begin{smallmatrix} 1 & 0 \\ 0 & 0 \end{smallmatrix})\) and \((\begin{smallmatrix} 0 & 0 \\ 0 & 1 \end{smallmatrix})\), respectively.

The second condition is of course equivalent to its analogue with \(n\) rather than two summands, for \(n \geq 2\) arbitrary.

**A.6.18. Example.** The 2-category \(\text{Add}_{\mathcal{C}}\) of idempotent-complete additive categories, and its very large version \(\text{ADD}_{\mathcal{C}}\), are block-complete. Indeed, they are locally idempotent-complete by Example A.6.5 and admit finite direct sums by Example A.6.10. As for block-decompositions, consider a sum decomposition \(1_A = e_1 + e_2\) in orthogonal idempotent natural transformations of the identity \(1_A = \text{id}_{id,A}\) of some idempotent-complete category \(\mathcal{A}\). For each \(i = 1, 2\) and each object \(x \in \mathcal{A}\), the component \(e_{i,x} : A \to A\) is an idempotent in \(\mathcal{A}\). We therefore obtain a splitting \(x \simeq \text{im}(e_{1,x}) \oplus \text{im}(e_{2,x})\) in \(\mathcal{A}\) identifying \(e_{1,x}\) and \(e_{2,x}\) with \((\begin{smallmatrix} 1 & 0 \\ 0 & 0 \end{smallmatrix})\) and \((\begin{smallmatrix} 0 & 0 \\ 0 & 1 \end{smallmatrix})\), respectively (cf. Definition A.5.9). By the functoriality of images, this defines two endofunctors (for \(i = 1, 2\))

\[
E_i : \mathcal{A} \to \mathcal{A}, \quad A \mapsto E_i(x) := \text{im}(e_{i,x})
\]

with the property that the identity functor \(\text{Id}_\mathcal{A}\) is isomorphic to the direct sum \(E_1 \oplus E_2\) in \(\text{ADD}(\mathcal{A}, \mathcal{A})\). We now define (for \(i = 1, 2\))

\[
\mathcal{A}_i := \text{Im}(E_i) \subseteq \mathcal{A}
\]

to be the full replete image of \(E_i\) in \(\mathcal{A}\). Using the orthogonality of \(\mathcal{A}_1\) and \(\mathcal{A}_2\) within \(\mathcal{A}\), which follows from that of \(e_1\) and \(e_2\), it is now straightforward to verify that the two functors

\[
\mathcal{A} \to \mathcal{A}_1 \oplus \mathcal{A}_2, \quad x \mapsto (E_1 x, E_2 x)
\]

and

\[
\mathcal{A}_1 \oplus \mathcal{A}_2 \to \mathcal{A}, \quad (x_1, x_2) \mapsto x_1 \oplus x_2
\]

are mutually inverse equivalences. This shows that \(1_\mathcal{A} = e_1 + e_2\) is realized by the block-decomposition \(\mathcal{A} \simeq \mathcal{A}_1 \oplus \mathcal{A}_2\), as wished.
Now we take a closer look at the image 1-cells $E$ of idempotent 2-cells $e$.

A.6.19. Notation. Let $e = e^2 : \text{Id}_X \Rightarrow \text{Id}_X$ be an idempotent 2-cell in a locally additive bicategory $\mathcal{B}$ such that $\mathcal{B}(X, X) = \mathcal{B}(X, X)^2$ is idempotent-complete. Then $e$ splits: There exists a 1-cell $E = \text{id}(e) : X \to X$ together with 2-cells $r_e : \text{Id}_X \Rightarrow E$ and $i_e : E \Rightarrow \text{Id}_X$ such that $i_e r_e = e$ and $r_e i_e = \text{id}_E$, this data being unique up to a unique isomorphism. For any 1-cell $F : X \to Y$, we can define two 2-cells $\rho_{e,F} : F \circ E \Rightarrow F$ and $\overline{\rho}_{e,F} : F \Rightarrow F \circ E$ by the following two pastings:

\[
\begin{array}{c}
\begin{array}{c}
\begin{array}{c}
E \xrightarrow{i_e} X \xrightarrow{r_e} \text{Id}_X \xrightarrow{\downarrow} Y \\
X \xrightarrow{\downarrow} \text{Id}_X \xrightarrow{\downarrow} \text{Id}_X \xrightarrow{\downarrow} Y \\
F \xrightarrow{\downarrow} F \xrightarrow{\downarrow} F
\end{array}
\end{array}
\end{array}
\]

\[
\begin{array}{c}
\begin{array}{c}
\begin{array}{c}
F \xrightarrow{\downarrow} F \xrightarrow{\downarrow} F \xrightarrow{\downarrow} F \\
X \xrightarrow{\downarrow} \text{Id}_X \xrightarrow{\downarrow} \text{Id}_X \xrightarrow{\downarrow} Y \\
Y \xrightarrow{\downarrow} Y \xrightarrow{\downarrow} Y \\
Y \xrightarrow{\downarrow} Y \xrightarrow{\downarrow} Y
\end{array}
\end{array}
\end{array}
\]

Similarly, for any 1-cell $G : Z \to X$ we define $\lambda_{e,G} : E \circ G \Rightarrow G$ and $\overline{\lambda}_{e,G} : G \Rightarrow E \circ G$ by the following two pastings:

\[
\begin{array}{c}
\begin{array}{c}
\begin{array}{c}
G \xrightarrow{\downarrow} G \xrightarrow{\downarrow} G \\
Z \xrightarrow{\downarrow} Z \xrightarrow{\downarrow} Z \\
Z \xrightarrow{\downarrow} Z \xrightarrow{\downarrow} Z
\end{array}
\end{array}
\end{array}
\]

\[
\begin{array}{c}
\begin{array}{c}
\begin{array}{c}
G \xrightarrow{\downarrow} G \xrightarrow{\downarrow} G \\
X \xrightarrow{\downarrow} X \xrightarrow{\downarrow} X \\
X \xrightarrow{\downarrow} X \xrightarrow{\downarrow} X
\end{array}
\end{array}
\end{array}
\]

A.6.20. Lemma. Retaining Notation A.6.19, we have:

(a) For every $F : X \to Y$, the 2-cell $\rho_{e,F} : F \circ \text{id}(e) \Rightarrow F$ is invertible if and only if $F$ absorbs $e$, in the sense that $F e = \text{id}_F$, i.e. modulo right unitors we can identify the 2-cells

\[
\text{id}_F \cong \begin{pmatrix}
\text{id}_X \\
X \\
\text{id}_X
\end{pmatrix}.
\]

The latter is further equivalent to the condition $F \circ (1_X - e) \cong 0$.

(b) For every $G : Z \to X$, the 2-cell $\lambda_{e,G} : \text{id}(e) \circ G \Rightarrow G$ is invertible if and only if $G$ absorbs $e$, in the sense that $e G = \text{id}_G$, i.e. modulo left unitors we can identify the 2-cells

\[
\text{id}_G \cong \begin{pmatrix}
\text{id}_X \\
Z \\
\text{id}_X
\end{pmatrix}.
\]

The latter is further equivalent to the condition $(1_X - e) \circ G \cong 0$.

Proof. By the equation $r_e i_e = \text{id}_E$, it is always the case that $\overline{\rho}_{e,F} \rho_{e,F} = \text{id}_{F \circ E}$ and $\overline{\lambda}_{e,G} \lambda_{e,G} = \text{id}_{E \circ G}$. Moreover, we see by the equation $i_e r_e = e$ that $\rho_{e,F} \overline{\rho}_{e,F} = \text{id}_F$ precisely when $F$ absorbs $e$; and similarly for $G$. The equivalence with the vanishing statements is trivial since $1_X = e + (1_X - e)$. □
A.6.21. Remark. Note that \( E = \text{im}(e) : X \to X \) itself absorbs \( e \) on both sides. This follows from the vanishing conditions for absorption in Lemma A.6.20, the vanishing of the vertical composite \( (1_X - e)e \), and the fact that the unitors identify the vertical and horizontal compositions of 2-cells \( \text{Id}_X \Rightarrow \text{Id}_X \) (cf. Remark A.6.3).

We are now ready for the main construction of this section.

A.6.22. Construction (Block completion). Let \( \mathcal{B} \) be a locally idempotent-complete additive bicategory with all finite direct sums of 0-cells (Definition A.6.6). Let us construct a new bicategory \( \mathcal{B}^p \) called the block-completion of \( \mathcal{B} \), as follows.

- The 0-cells of \( \mathcal{B}^p \) consist of pairs \((X, e)\) where \( X \) is a 0-cell of \( \mathcal{B} \) and \( e = e^2 : \text{Id}_X \to \text{Id}_X \) is an idempotent 2-cell of the identity 1-cell of \( X \) in the category \( \mathcal{B}(X, X) \). (Since we assume \( \mathcal{B}(X, X) \) idempotent-complete, this idempotent \( e \) corresponds to a decomposition \( \text{Id}_X \cong E_1 \oplus E_2 \) where \( E_1 = \text{im}(e) \) and \( E_2 = \text{im}(1 - e) \).)

- The Hom-category \( \mathcal{B}^p((X, e), (X', e')) \) is the full subcategory of \( \mathcal{B}(X, X') \) of those 1-cells \( F : X \to X' \) which absorb the idempotents \( e \) and \( e' \) in the equivalent senses of Lemma A.6.20 (for instance: \( e' \circ F \cong \text{id}_F \cong F \circ e \)).

- The composition functors of \( \mathcal{B}^p \) are simply restricted from those of \( \mathcal{B} \). The identity 1-cell \( \text{Id}_{(X,e)} \) is given by the direct summand \( E = \text{im}(e) \leq \text{Id}_X \), which exists because \( \mathcal{B}(X, X) \) is idempotent-complete and which belongs to \( \mathcal{B}^p \) by Remark A.6.21.

- The associators \( \text{ass}_{X,Y,Z} \) of \( \mathcal{B}^p \) are those of \( \mathcal{B} \). For any 1-cell \( F : (X, e) \to (X', e') \), we define the right and left unitors \( \text{run}_F : F \circ \text{Id}_{(X,e)} \Rightarrow F \) and \( \text{lun}_F : \text{Id}_{(X',e')} \circ F \Rightarrow F \) to be the 2-cells \( \rho_{e,F} \) and \( \lambda_{e',F} \) of Notation A.6.19. They are invertible by Lemma A.6.20 since \( F \) absorbs \( e \) and \( e' \).

It is straightforward to verify that the above data defines a bicategory. The only possible issue concerns the unitor coherence axioms, which follow from the idempotency of \( e \) and an identification of vertical and horizontal compositions as in Remark A.6.21.

We have a (rather strict) pseudo-functor \( \mathcal{B} \to \mathcal{B}^p \) mapping 0-cells \( X \) to \( (X,1) \) and which is the identity on 1-cells and 2-cells. (Here we use the canonical identification \( \text{im}(1_X) = \text{Id}_X \) in \( \mathcal{B}(X, X) \).)

A.6.23. Theorem (Universal property of block-completion). Let \( \mathcal{B} \) be a locally idempotent-complete additive bicategory, with all finite direct sums of 0-cells (Definition A.6.6). The bicategory \( \mathcal{B}^p \) of Construction A.6.22 is block-complete and the 2-functor \( \mathcal{B} \to \mathcal{B}^p \) induces by pre-composition a biequivalence

\[
\text{PsFun}_{\mathcal{U}}(\mathcal{B}^p, \mathcal{C}) \cong \text{PsFun}_{\mathcal{U}}(\mathcal{B}, \mathcal{C})
\]

of bicategories of additive pseudo-functors, for every block-complete bicategory \( \mathcal{C} \).

Proof. The pattern of proof is similar to the universal property of the idempotent-completion of additive 1-categories. All unproved claims below are straightforward verifications, most easily done after strictifying \( \mathcal{B} \) and \( \mathcal{C} \).

Given two idempotents \( (X, e : \text{Id}_X \to \text{Id}_X) \) and \((X', e' : \text{Id}_{X'} \to \text{Id}_{X'})\), one needs to verify that the subcategory \( \mathcal{B}^p((X, e), (X', e')) \subseteq \mathcal{B}(X, X') \) is idempotent complete, for which it suffices to see that it is closed under taking direct sums. This follows easily from the compatibility of the unitors with direct sums (Remark A.6.2) and guarantees that \( \mathcal{B}^p \) remains locally idempotent-complete.
The direct sums of objects in $\mathcal{B}^p$ are directly inherited from those of $\mathcal{B}$ as expected: $(X, e) \oplus (X', e') = (X \oplus X', \left( \begin{smallmatrix} 0 & 0 \\ e & e' \end{smallmatrix} \right))$ and $\mathcal{B}^p$ admits block-decompositions because we have equivalences

$$(X, e) \oplus (X, 1 - e) \cong (X, 1)$$

(see Lemma A.6.20). More generally, for an object $(X, e)$ of $\mathcal{B}^p$ and an idempotent $f = f^2: \text{Id}_X \to \text{Id}_X$ of its identity 1-cell, which itself is the summand $\text{im}(e) \leq \text{Id}_X$, we have $(X, e) \cong (X, f) \oplus (X, e - f)$ in $\mathcal{B}^p$, with the equivalence similarly given by the 1-cells of $\mathcal{B}$ consisting of $\text{im}(e)$, $\text{im}(f)$ and $\text{im}(e - f)$. Thus $\mathcal{B}^p$ is block-complete, as claimed.

Now let $\mathcal{C}$ be another block-complete bicategory. Given a pseudo-functor $F: \mathcal{B} \to \mathcal{C}$ and an idempotent $e = e^2: X \to X$ in $\mathcal{B}$, we obtain under the isomorphism $F(\text{Id}_X) \cong \text{Id}_{F(X)}$ an idempotent $F(e): \text{Id}_{F(X)} \to \text{Id}_{F(X)}$. Since $\mathcal{C}$ is block-complete, $F(X) = Y_1 \oplus Y_2$ such that the constructed idempotent is the projection onto $Y_1$ (on the identity) and one simply sends $(X, e)$ to that 0-cell $Y_1$. This construction extends to a pseudo-functor $\hat{F}: \mathcal{B}^p \to \mathcal{C}$ which agrees with $F$ on $\mathcal{B}$. It is easy to verify that, up to a unique isomorphism, this is the only way to extend $F: B \to C$ into an additive functor $\hat{F}: \mathcal{B}^p \to \mathcal{C}$.

Consider now two such extensions $\hat{F}, \hat{G}: \mathcal{B}^p \to \mathcal{C}$ of pseudo-functors $F, G: \mathcal{B} \to \mathcal{C}$, and let $t: F \Rightarrow G$ be a pseudo-natural transformation. We claim that $t$ extends in a unique way to a pseudo-natural transformation $\hat{t}: \hat{F} \Rightarrow \hat{G}$.

To see the uniqueness of such a $\hat{t}$, we can reason similarly to Remark A.6.2. Let $X = X_1 \oplus X_2$ be a 0-cell direct sum in $\mathcal{B}^p$. Then the structure 1-cells $i_k$ and $p_\ell$ (for $k, \ell \in \{1, 2\}$) of the direct sum $X_1 \oplus X_2$ give rise to diagrams

where the vertical composites are either (isomorphic to) identity or zero 1-cells. Together with the naturality and functoriality of $\hat{t}$, these diagrams show that $\hat{t} = \left( \begin{smallmatrix} i_{X_1} & 0 \\ 0 & i_{X_2} \end{smallmatrix} \right)$. A similar reasoning shows that the 2-cell components $\hat{t}_f$ for $f: X_1 \oplus X_2 \to Y_1 \oplus Y_2$ decompose according to the matrix coordinates of $f$. In particular, since all objects and 1-cells of $\mathcal{B}^p$ arise as direct summands of objects and 1-cells of $\mathcal{B}$, it follows that the 1- and 2-cell components of $\hat{t}$ are determined by those of $t$ (together with the chosen direct sum decompositions of the target objects $F(X)$ and $G(X)$ for every idempotent $e$ on $X$). Thus indeed $t$ determines $\hat{t}$.
For the construction of the extension $\hat{t}$ from $t$, we just reason backwards. Namely, for every object $(X, e)$ of $B^\flat$, we set $\hat{t}_{(X, e)}$ to be the 1-cell

$$\hat{t}_{(X, e)} := G(\text{im}(e)) \circ t_X \circ F(\text{im}(e))$$

of $C$ (i.e. the $\mathcal{F}(X, e) \Rightarrow \mathcal{G}(X, e)$-component of $t_X$ with respect to the direct sum decompositions of source and target). For every 1-cell $f: (X, e) \to (X', e')$ of $B^\flat$ we define $\hat{t}_f$ by the pasting

$$\hat{F}(X, e) \xrightarrow{\hat{t}_{(X, e)}} \hat{G}(X, e)$$

$$\xrightarrow{\hat{F} \text{im}(e)} \xrightarrow{\hat{G} \text{im}(e)}$$

$$\xrightarrow{\hat{F} t_X \hat{G} f} \xrightarrow{\hat{G} f}$$

$$\hat{F}(X, e) \xrightarrow{\hat{t}_{(X, e)}} \hat{G}(X, e)$$

where the left and right outmost invertible 2-cells are by the absorbency of $f$.

Finally, consider a modification $M = (M_X)_{X \in B_0}: t \Rightarrow s$, where $t$, $s: \mathcal{F} \Rightarrow \mathcal{G}$ are any two parallel transformations. For every idempotent $e = e^2: \text{Id}_X \to \text{Id}_X$ on $X$, we define a 2-cell $\hat{M}_{(X, e)}$ by the following pasting:

$$\hat{F}(X, e) \xrightarrow{\hat{t}_{(X, e)}} \hat{G}(X, e)$$

$$\xrightarrow{\hat{F} \text{im}(e)} \xrightarrow{\hat{G} \text{im}(e)}$$

$$\xrightarrow{\hat{F} M_X \hat{G} s_X} \xrightarrow{\hat{G} s_X}$$

The resulting collection $\hat{M} := (\hat{M}_{(X, e)}: \hat{t}_{(X, e)} \Rightarrow \hat{s}_{(X, e)})_{(X, e) \in B_0}$ defines a modification $\hat{M}: \hat{t} \Rightarrow \hat{s}$ extending $M$ in the unique possible way. □

**A.6.24. Remark.** One can of course combine the Hom-wise group completion and idempotent-completion of Remark A.6.4 and the block-completion of Construction A.6.22: If $B$ is a locally semi-additive bicategory with all finite sums, it can first be made into a locally additive bicategory $B^+$, which can be made into a locally idempotent-complete one $(B^+)^\natural$, which can then be block-completed into $((B^+)^\natural)^\flat$. We still get a universal pseudo-functor

$$B \to B^+ \hookrightarrow (B^+)^\natural \hookrightarrow ((B^+)^\natural)^\flat = B^\flat$$

into a block-complete bicategory, and we can still denote the latter by $B^\flat$ and call it the *block-completion* of $B$. 
We end by recording an additive version of the bicategorical Yoneda lemma:

**A.6.25. Remark.** Let \( B \) be any locally additive bicategory with all finite direct sums of objects. Then there are covariant and contravariant Yoneda pseudo-functors

\[
B \to \text{PsFun}_{\text{Hilb}}(B^{\text{op}}, \text{Add}), \quad X \mapsto B(-, X)
\]

and

\[
B^{\text{op}} \to \text{PsFun}_{\text{Hilb}}(B, \text{Add}), \quad X \mapsto B(X, -)
\]

which are biequivalences on their 1- and 2-full images. If \( B \) is locally idempotent-complete, we may of course replace \( \text{Add} \) with \( \text{Add}_{\text{ic}} \). The non-additive version is well-known and is essentially equivalent to the strictification theorem (see Remark A.1.16). The additive version is then an easy consequence: Each pseudo-functor \( B(-, X): B^{\text{op}} \to \text{Cat} \) takes values in \( \text{Add} \) because \( B \) is locally additive, and preserves direct sums simply because they are, in particular, coproducts; and similarly for the dual embedding.

Since in Section 7.1 we use the latter version, let us be more explicit on the construction of the contravariant Yoneda pseudo-functor. It sends an object \( X \in B_0 \) to the pseudo-functor \( B(X, -): B \to \text{Add} \); a 1-cell \( u: X \to Y \) to the pseudo-natural transformation \( u^*: B(u, -): B(Y, -) \to B(X, -) \) with components \( u^*_T = B(u, T): B(Y, T) \to B(X, T), v \mapsto vu \) (for \( T \in B_0 \)) and \( u^*_T = \text{ass}_{XYT}^{-1}: w(vu) \Rightarrow (wu) \) (for \( T \to S \)); and a 2-cell \( \alpha: u \Rightarrow u' \) to the modification \( u^* \Rightarrow u'^* \) with components \( B(\alpha, T) = (-) \circ \alpha: B(u, T) \Rightarrow B(u', T) \) (for \( T \in B_0 \)). Note that this is still covariant on 2-cells \( \alpha \)!
APPENDIX B

Ordinary Mackey functors on a given group

In this section, we fix an ‘ambient group’ $G$. We recall the classical definitions of Mackey functors on $G$. The first one is the original definition, due to Green [Gre71].

**B.0.1. Definition.** A Mackey functor $M$ on the finite group $G$ consists of the data of an abelian group $M(H)$ for each subgroup $H \leq G$, together with restriction homomorphisms $R^H_H : M(H) \to M(K)$ and induction (or transfer) homomorphisms $I^K_H : M(K) \to M(H)$ for all $K \leq H$, and conjugation homomorphisms $c_g : M(H) \to M(g^H)$ for all $g \in G$; this data must satisfy a series of rather obvious compatibilities (with obvious quantifiers):

(a) $R^H_H = \text{id}$, $I^K_K = \text{id}$ and $c_h = \text{id}_{M(H)}$ when $h \in H$;
(b) $c_g h = c_g c_h$ and whenever $J \leq K \leq H$ then $R^H_J = R^K_K R^H_J$ and $I^K_J = I^K_K I^K_J$;
(c) $c_g R^K_K = R^K_{gK} c_g$ and $c_g I^K_K = I^K_K c_g$;

as well as the following non-trivial Mackey (double-coset) formula for all $K, J \leq H$:

\[
R^H_J \circ I^K_K = \sum_{[x] \in J \cap K \cap K} I^K_{[x] K} \circ c_x \circ R^K_{[x] K}.
\]

See details in Lewis [Lew80], Thévenaz-Webb [TW95], Bouc [Bou97], or Webb’s survey [Web00] whose notation we adopted above. A morphism of Mackey functors $F : M \to M'$ consists of homomorphisms $F(H) : M(H) \to M'(H)$ for all $H \leq G$, commuting with restriction, induction and conjugation maps.

**B.0.3. Remark.** There is a well-known ‘motivic’ approach, due to Dress [Dre73] and Lindner [Lin76], to the above ordinary Mackey functors through the Burnside category $\mathcal{A}(G)$. The objects of the additive category $\mathcal{A}(G)$ are finite $G$-sets $X$ and the morphism group $\text{Hom}_{\mathcal{A}(G)}(X, Y)$ is the group-completion of the abelian monoid of isomorphism classes of spans $X \leftarrow Z \to Y$ of $G$-maps. Every subgroup $H \leq G$ defines a $G$-set $G/H$ and this assignment $H \mapsto G/H$ satisfies the same two variances and compatibilities as a Mackey functor (it defines a Mackey functor with values in $\mathcal{A}(G)$). The Burnside category $\mathcal{A}(G)$ is ‘motivic’ in that every Mackey functor factors uniquely through an additive functor from $\mathcal{A}(G)$ to Ab.

Note that the above assignment $H \mapsto G/H$, from subgroups of $G$ to objects in $\mathcal{A}(G)$, factors via the category $G$-set. Each conjugation $c_g : H \to g^H$ yields a map of $G$-sets $G/H \to G/\langle g \rangle H$ given by $[x]_H \mapsto [xg^{-1}]_{\langle g \rangle H}$. In particular $c_h : H \to H$ becomes the identity $G/H \to G/H$. This explains $c_h = \text{id}_{M(H)}$ in Definition B.0.1.

In the language of Appendix A.4, we can consider $\overline{G}$-set, the span category for the 1-category $G$-set of finite $G$-sets. The above Burnside category $\mathcal{A}(G)$ is obtained

\footnote{The latter condition $c_h = \text{id}_{M(H)}$ is not really ‘obvious’; it is a defining feature related to the fact that $M(H)$ should really only depend on the $G$-set $G/H$. See Remark B.0.3.}

177
from $\hat{\text{set}}$ by group-completing the (abelian monoids of) morphisms. Hence there is no difference between additive functors $A(G) \to \text{Ab}$ and additive functors $\hat{\text{set}} \to \text{Ab}$ where additivity of $F$ simply means that $F(X \sqcup Y) \cong F(X) \oplus F(Y)$ via the natural map (which implies $F(\emptyset) = 0$ as usual).

Consequently, we have an equivalence of categories

$$\text{(B.0.4)} \quad \left\{ \text{Mackey functors on } G \right\} \xrightarrow{\sim} \left\{ \text{additive functors } \hat{\text{set}} \to \text{Ab} \right\}. \quad (\text{Definition B.0.1})$$

Since $\hat{\text{set}}$ is a semi-additive category (Example A.5.13) and $\text{Ab}$ is idempotent complete, in the above equivalence we may also replace the former with its idempotent complete additive envelope $(\hat{\text{set}})_{\text{idem}}$ (Remark A.5.10). When we wish to emphasize the above description as additive functors on $\hat{\text{set}}$, or $(\hat{\text{set}})_{\text{idem}}$, we shall refer to the latter as Mackey functors for $G$ in the sense of Dress-Lindner.

We now want to rephrase the above with groupoids instead of $G$-sets. This involves a well-known construction:

**B.0.5. Remark.** Recall that the transport groupoid, or translation groupoid, of a $G$-set $X$ is the groupoid $G \ltimes X$ having $X$ as object-set and with an arrow $(g,x): x \to x'$ (also written $g: x \to gx$ for simplicity) for every $g \in G$ such that $gx = x'$. If $f: X \to Y$ is a $G$-equivariant map, there is an evident (faithful!) functor $G \ltimes f: G \ltimes X \to G \ltimes Y$ defined as $x \mapsto f(x)$ on objects and $(g,x) \mapsto (g,f(x))$ on maps. This defines a faithful strict 2-functor

$$G \ltimes -: G\text{-}\text{set} \to \text{gpd}^f$$

from finite $G$-sets to the 2-category of finite groupoids and faithful functors. An explicit computation (see e.g. Ganter [Gan13, Prop. 2.9]) shows that $G \ltimes -$ preserves weak pullbacks, i.e. sends pullbacks of $G$-sets to what we call Mackey squares in Section 2.1 (i.e. squares equivalent to iso-comma squares of groupoids).

We now want to refine the target of the above $G \ltimes -$ construction.

**B.0.6. Definition.** For our fixed finite group $G$, we will denote by

$$\text{gpd}^f_G$$

the 2-category of finite groupoids and faithful functors, $\text{gpd}^f$, over $G$. By Definition A.1.20, its objects are pairs $(H, i_H)$ where $H \in \text{gpd}_0$ is a finite groupoid and $i_H: H \to G$ is a faithful functor in $\text{gpd}$. A 1-cell $(H, i_H) \to (H', i_{H'})$ consists of a pair $(u, \alpha_u)$ where $u: H \to H'$ is a (necessarily faithful) functor and $\alpha_u: i_H \circ u \Rightarrow i_{H'}$ a natural isomorphism. A 2-cell $(u, \alpha_u) \Rightarrow (v, \alpha_v)$ is a 2-cell $u \Rightarrow v$ of $\text{gpd}$ compatible with $\alpha_u$ and $\alpha_v$ in that $\alpha_v(i_{H'} \circ u) = \alpha_u$:

$$u \begin{array}{c} \circ \end{array} \begin{array}{c} \alpha \end{array} \begin{array}{c} \Rightarrow \end{array} \begin{array}{c} \alpha_v \end{array} \begin{array}{c} \Rightarrow \end{array} \begin{array}{c} \alpha_u \end{array} \begin{array}{c} \Rightarrow \end{array} v \quad G \quad H \quad H'$$

$$u \begin{array}{c} \alpha_u \end{array} \begin{array}{c} \Rightarrow \end{array} \begin{array}{c} \alpha_v \end{array} \begin{array}{c} \Rightarrow \end{array} \begin{array}{c} \alpha_u \end{array} \begin{array}{c} \Rightarrow \end{array} v \quad G \quad H \quad H'$$

The vertical and horizontal compositions of $\text{gpd}^f_G$ are induced by those of $\text{gpd}$ in the evident way. There is an obvious forgetful 2-functor $\text{gpd}^f_G \to \text{gpd}^f \subset \text{gpd}$ which sends $(H, i_H)$ to $H$ and $(u, \alpha_u)$ to $u$. We call $\text{gpd}^f_G$, the 2-category of finite groupoids embedded into $G$.  

B.0.7. Remark. The transport groupoid $X \mapsto G \ltimes X$ canonically lifts to $\mathfrak{gpd}^f_G$ if we endow the groupoid $G \ltimes X$ of a $G$-set $X$ with the structure functor

$$\pi_X : G \ltimes X \to G, \quad x \mapsto *, \quad (g, x) \mapsto g$$

and if we send a $G$-map $f : X \to Y$ to the pair $(G \ltimes f, \text{id})$; this is well-defined because $\pi_X$ is faithful and because $\pi_Y \circ (G \ltimes f)$ and $\pi_X$ are equal functors.

B.0.8. Proposition. The canonical lift $X \mapsto (G \ltimes X, \pi_X)$ of the transport groupoid (as in Remark B.0.7) is a bi-equivalence $G$-set $\sim \mathfrak{gpd}^f_G$

where the $1$-category $G$-set is viewed as a discrete $2$-category. In particular, the Hom categories of $\mathfrak{gpd}^f_G$ are all equivalent to sets.

Proof. We must verify that the $2$-functor $G \ltimes - : G\text{-set} \to \mathfrak{gpd}^f_G$, is surjective on objects up to equivalence, and that for every pair of $G$-sets $X, Y$ the functor $G\text{-set}(X, Y) \to \mathfrak{gpd}^f_G(G \ltimes X, G \ltimes Y)$ is an equivalence of $1$-categories.

For the first point, let $i_H : H \to G$ be a faithful functor in $\mathfrak{gpd}$. Note that $G \ltimes -$ commutes with coproducts, so that we may easily reduce to the case where $H$ is a group, and up to equivalence in $\mathfrak{gpd}^f_G$, we can even assume that $i_H : H \to G$ corresponds to the inclusion of a subgroup. We then obtain a commutative triangle

$$\xymatrix{ H \ar[rr]^{i_H} \ar[dr]_u & & G \ar[dl]_{\pi_{G/H}} \ar@{=}[dl] \\
& G \ltimes (G/H) & }$$

where $u$ is the equivalence of groupoids which sends $* \mapsto eH$ on objects and $h \mapsto (h, eH)$ on maps. Therefore $H$ is equivalent in $\mathfrak{gpd}^f_G$ to a transport groupoid, as claimed.

For the second point, fix two $G$-sets $X$ and $Y$. Since the category $G\text{-set}(X, Y)$ is discrete, what we must show is that for every $1$-cell $(u, \alpha_u) : (G \ltimes X, \pi_X) \to (G \ltimes Y, \pi_Y)$ in $\mathfrak{gpd}^f_G$, there exist exactly one $G$-map $f : X \to Y$ and one (invertible) $2$-cell $\alpha : u \Rightarrow G \ltimes f$. To see why this is the case, unfold the definitions: A $1$-cell $(u, \alpha_u)$ consists precisely of a functor $u : G \ltimes X \to G \ltimes Y$, whose components on objects $x \in X$ and maps $(g, x)$ we will denote respectively by

$$x \mapsto u(x) \quad \text{and} \quad (g, x) : x \mapsto gx \mapsto u(g, x) : u(x) \mapsto u(gx) = u(g, x)u(x)$$

and a natural transformation $\alpha_u : \pi_Y \circ u \Rightarrow \pi_X$, which is precisely the same as a collection $(\alpha_{u, x})_{x \in X}$ of elements $\alpha_{u, x} \in G$ such that

$$(B.0.9) \quad g \cdot \alpha_{u, x} = \alpha_{u, gx} \cdot u(g, x)$$

in $G$ for all $g \in G$ and $x \in X$. Now define a map $f : X \to Y$ by setting $f(x) := \alpha_{u, x} \cdot u(x)$. It is $G$-equivariant by (B.0.9):

$$f(gx) = \alpha_{u, gx} \cdot u(gx) = \alpha_{u, gx} \cdot u(g, x) \cdot u(x) = g \cdot \alpha_{u, x} \cdot u(x) = g \cdot f(x).$$
Moreover the collection $\alpha := (\alpha_{u,x})_{x \in X}$ forms a natural transformation $\alpha: u \Rightarrow G \ltimes f$ (again by (B.0.9)) such that $\pi_Y \alpha = \alpha_u$ (so it defines a 2-cell in $\mathbf{gpd}^f_G$), and it is immediate to see that these are the unique possible choices for such $f$ and $\alpha$. □

Recall 1-truncation $\tau_1(\mathbf{-})$ from Notation A.1.13, which produces a 1-category out of a 2-category by identifying isomorphic 1-cells (and then dropping 2-cells).

**B.0.10. Corollary.** The functor $X \mapsto (G \ltimes X, \pi_X)$ of Definition B.0.6 induces an equivalence of categories $G\mathbf{-set} \stackrel{\sim}{\to} \tau_1(\mathbf{gpd}^f_G)$.

In particular, the 1-truncated category $\tau_1(\mathbf{gpd}^f_G)$ admits pullbacks.

**Proof.** Apply 1-truncation $\tau_1(\mathbf{-})$ to the biequivalence $G\mathbf{-set} \stackrel{\sim}{\to} \mathbf{gpd}^f_G$ of Proposition B.0.8. Here $G\mathbf{-set}$ is a discrete bicategory so $\tau_1(G\mathbf{-set}) = G\mathbf{-set}$. □

**B.0.11. Definition.** Since the category $\mathcal{C} := \tau_1(\mathbf{gpd}^f_G)$ admits pullbacks, let

$$\widehat{\mathbf{gpd}}^f_G := \mathcal{C} = (\tau_1(\mathbf{gpd}^f_G))$$

be the corresponding category of spans in the sense of Appendix A.4. We call $\widehat{\mathbf{gpd}}^f_G$ the category of spans of groupoids faithful over $G$.

Explicitly, an object of $\widehat{\mathbf{gpd}}^f_G$ consists of a finite groupoid $H$ with a chosen faithful functor $i_H: H \rightarrow G$ to $G$ and morphisms are equivalence classes of ‘spans’

$$
\begin{array}{ccc}
H & \xrightarrow{u} & S & \xrightarrow{v} & K \\
\downarrow{i_H} \sim \searrow{i_S} & & \swarrow{i_S} \sim \downarrow{i_K} \\
\searrow{i_H} & & \downarrow{i_K}
\end{array}
$$

(in which the triangles commute up to isomorphisms), where two such spans are equivalent if there exists an equivalence between the middle objects making everything commute up to isomorphism.

This 1-category of spans $\widehat{\mathbf{gpd}}^f_G$ is also the 1-truncation $\tau_1 \mathbf{Span}(\mathbf{gpd}^f_G, \mathbf{all})$ of the bicategory of spans (Definition 5.1.6) for the 2-category $\mathbb{G} = \mathbf{gpd}^f_G$ with respect to $\mathbb{J} = \mathbf{all}$ (which are all faithful anyway). We return to this observation in Remark 2.5.2, where we explain it in a more general setting.

**B.0.12. Theorem.** The category of ordinary Mackey functors on $G$ in the sense of Definition B.0.1 is equivalent to the category of additive functors $\widehat{\mathbf{gpd}}^f_G \rightarrow \mathbf{Ab}$ on the above category $\widehat{\mathbf{gpd}}^f_G$ of spans of groupoids faithful over $G$.

**Proof.** By Corollary B.0.10, we have an equivalence of categories of spans $\widehat{G}\mathbf{-set} \stackrel{\sim}{\to} \widehat{\mathbf{gpd}}^f_G$. The result now follows from the Dress-Lindner description (B.0.4) of Mackey functors. □
