Notes
$\qquad$
－$S$ ：Polish state space of the point process（equipped with the $\qquad$ $\sigma$－algebra of Borel sets $\mathcal{B}$ ）
－A configuration of points is denoted $x=\left\{x_{1}, \ldots, x_{n}, \ldots\right\}$ ．For $B \subseteq S: x_{B}=x \cap B$.
$\qquad$
－$N_{l f}$ ：space of locally finite configurations，i．e．

$$
\left\{x, n\left(x_{B}\right)=\left|x_{B}\right|<\infty, \forall B \text { bounded } \subseteq S\right\}
$$

equipped with $\mathcal{N}_{l f}=\sigma\left(\left\{x \in \mathcal{N}_{l f}, n\left(x_{B}\right)=m\right\}, B \in \mathcal{B}, B\right.$ bounded，$\left.m \geq 1\right)$ ．

## Definition

A point process $X$ defined on $S$ is a measurable application defined on some probability space $(\Omega, \mathcal{F}, P)$ with values on $N_{\text {If }}$ ．

Measurability of $X \Leftrightarrow N(B)=\left|X_{B}\right|$ is a r．v．for any bounded $B \in \mathcal{B}$ ．

## Proposition

$\qquad$
The distribution of a point process $X$
(1) is determined by the finite dimensional distributions of its counting function, i.e. the joint distribution of $N\left(B_{1}\right), \ldots, N\left(B_{m}\right)$ for any bounded $B_{1}, \ldots, B_{m} \in \mathcal{B}$ and any $m \geq 1$.
(2) is uniquely determined by its void probabilities, i.e. by

$$
P(N(B)=0), \quad \text { for bounded } B \in \mathcal{B}
$$

- From now on, we assume that $S=\mathbb{R}^{d}$ (and even $d=2$ ) or a bounded domain of $\mathbb{R}^{2}$.
- Everything can de extended to marked spatial point processes and/or to more complex domains.

Notes
$\qquad$

- Moments play an important role in the modelling of classical inference.
- For point processes $=$ moments of counting variables.
$\qquad$

## Definition: for $n \geq 1$ we define

$\qquad$

- the $n$-th order moment measure (defined on $S^{n}$ ) by $\qquad$

$$
\mu^{(n)}=\mathrm{E} \sum_{u_{1}, \ldots, u_{n}} \mathbf{1}\left(\left\{u_{1}, \ldots, u_{n}\right\} \in D\right), \quad D \subseteq S^{n}
$$

- the $n$-th order reduced moment measure (defined on $S^{n}$ ) by

$$
\alpha^{(n)}(D)=\mathrm{E} \sum_{u_{1}, \ldots, u_{n}}^{\neq} \mathbf{1}\left(\left\{u_{1}, \ldots, u_{n}\right\} \in D\right), \quad D \subseteq S^{n}
$$

where the $\neq$ sign means that the $n$ points are pairwise distinct.

## Intensity functions

Assume $\mu^{(1)}$ and $\alpha^{(2)}$ are absolutely continuous w.r.t. Lebesgue measure, and denote by $\rho$ and $\rho^{(2)}$ the densities. $\qquad$

## Campbell Theorems

$\qquad$
(1) For any measurable function $h: S \rightarrow \mathbb{R}$ $\qquad$

$$
\mathrm{E} \sum_{u \in X} h(u)=\int_{S} h(u) \rho(u) \mathrm{d} u
$$

$\qquad$
(2) For any measurable function $h: S \times S \rightarrow \mathbb{R}$
$\qquad$

$$
\mathrm{E} \sum_{u, v \in X}^{\neq} h(u, v)=\int_{S} \int_{S} h(u, v) \rho^{(2)}(u, v) \mathrm{d} u \mathrm{~d} v .
$$

$\qquad$
$\qquad$
$\rho(u) \mathrm{d} u \simeq$ Probability of the occurence of $u$ in $B(u, \mathrm{~d} u)$ $\rho^{(2)}(u, v) \simeq$ Probability of the occurence of $u$ in $B(u, \mathrm{~d} u)$ and $v$ in $B(v, \mathrm{~d} v)$.
$\qquad$
$\qquad$

Notes
$\qquad$
Classical definition: $X \sim \operatorname{Poisson}(S, \rho)$ $\qquad$

- $\forall m \geq 1, \forall$ bounded and disjoint $B_{1}, \ldots, B_{m} \subset S$, the r.v. $X_{B_{1}}, \ldots, X_{B_{m}}$ are independent.
- $N(B) \sim \mathcal{P}\left(\int_{B} \rho(u) \mathrm{d} u\right)$ for any bounded $A \subset S$.
- $\forall B \subset S, \forall F \in N_{I f}$
$\qquad$

$$
P\left(X_{B} \in F\right)=\sum_{n \geq 0} \frac{e^{-\int_{B} \rho(u) \mathrm{d} u}}{n!} \int_{B} \ldots \int_{B} \mathbf{1}\left(\left\{x_{1}, \ldots, x_{n}\right\} \in F\right) \prod_{i=1}^{n} \rho\left(x_{i}\right) \mathrm{d} x_{i}
$$

$\qquad$

- If $\rho(\cdot)=\rho, X$ is said to be homogeneous which implies

$$
\mathrm{E} N(B)=\rho|B|, \quad \operatorname{Var} N(B)=\rho|B|
$$

- and if $S=\mathbb{R}^{d}, X$ is stationary and isotropic.

Definitions, Poisson
$\rho(u)=\beta e^{-u_{1}-u_{1}^{2}-.5 u_{1}^{3}}$
$\qquad$
$\qquad$

- $\rho=200$.
- $\rho(u)=\beta e^{2 \sin \left(4 \pi u_{1} u_{2}\right)}$.
( $\beta$ is adjusted s.t. the mean number of points in $S, \int_{S} \rho(u) \mathrm{d} u=200$.) $\qquad$

$\qquad$
$\qquad$
$\qquad$
$\qquad$
$\qquad$

Notes
$\qquad$
Proposition : if $X \sim$ Poisson $(S, \rho)$ $\qquad$

- Void probabilities : $v(B)=P(N(B)=0)=e^{-\int_{B}(\rho(u) d u)}$. $\qquad$
- For any $u, v \in S, \rho^{(2)}(u, v)=\rho(u) \rho(v)$ (also valid for $\rho^{(k)}, k \geq 1$ ) $\qquad$
- and if $|S|<\infty, X$ admits a density w.r.t. Poisson $(S, 1)$ given by

$$
f(x)=e^{|S|-\int_{s} \rho(u) \mathrm{d} u} \prod_{u \in X} \rho(u) .
$$

$\qquad$

- Slivnyak-Mecke Theorem : for any non-negative function
$\qquad$ $h: S \times N_{I f} \rightarrow \mathbb{R}^{+}$, then

$$
\mathrm{E} \sum_{u \in X} h(u, X \backslash u)=\int_{S} \mathrm{E} h(u, X) \rho(u) \mathrm{d} u
$$

$\qquad$
$\qquad$

Example : if $\rho(\cdot)=\rho, \mathrm{E} \sum_{u \in X \cap[0,1]^{2}} \mathbf{1}(d(u, X \backslash u) \leq R)=\rho\left(1-e^{-\rho \pi R^{2}}\right)$
Simulation

|  |  |
| :---: | :---: |
| $\begin{aligned} & \rho=20, R=0.1 \\ & \sum_{u \in x} \mathbf{1}(d(u, x \backslash u) \leq R)=9 \\ & \rho\left(1-\exp \left(-\rho \pi R^{2}\right)\right) \simeq 9.33 \end{aligned}$ | $\begin{aligned} & \rho=100, R=0.05 \\ & \sum_{u \in x} \mathbf{1}(d(u, x \backslash u) \leq R)=60 \\ & \rho\left(1-\exp \left(-\rho \pi R^{2}\right)\right) \simeq 54.41 \end{aligned}$ |

$\qquad$
$\qquad$
$\qquad$
$\qquad$
$\qquad$
$\qquad$
$\qquad$
$\qquad$
$\qquad$
$\qquad$

Notes
$\qquad$

- Simulation :
- homogeneous case : very simple
$\qquad$
- inhomogeneous case : a thinning procedure can be efficiently done if $\rho(u) \leq c$ : simulate Poisson( $c, W$ ) and delete a point $u$ with prob. $1-\rho(u) / c$.
- Inference :
- consists in estimating $\rho, \rho(\cdot ; \theta)$ or $\rho(u)$ depending on the context.
- All these estimates can be used even if the spatial point process is not Poisson (wait for a few slides)
- Asymptotic properties very simple to derive under the Poisson assumption.
- Goodness-of-fit tests : tests based on quadrats counting, based on the void probability,...
- We consider here the problem of estimating the parameter $\rho$ of a homogeneous Poisson point process defined on $S$ and observed on a window $W \subseteq S$.
- Since $N(W) \sim \mathcal{P}(\rho|W|)$, the natural estimator of $\rho$ is

$$
\widehat{\rho}=N(W) /|W|
$$

$\qquad$

## Properties

- (i) $\widehat{\rho}$ corresponds to the maximum likelihood estimate.
$\qquad$
- (ii) $\hat{\rho}$ is unbiased. $\qquad$
- (iii) $\operatorname{Var} \widehat{\rho}=\frac{\rho}{|W|}$. $\qquad$
Proof : (i) follows from the definition of the density (ii-iii) can be checked using the Campbell formulae.
$\qquad$

Notes
$\qquad$
Asymptotic results

- For large $N(W), \widehat{\rho}|W| \simeq \mathcal{N}(\rho|W|, \rho|W|)$ and so
$\qquad$
$\qquad$

$$
|W|^{1 / 2}(\widehat{\rho}-\rho) \simeq \mathcal{N}(0, \rho)
$$

$\qquad$
(the approximation is actually a convergence as $W \rightarrow \mathbb{R}^{d}$ ) $\qquad$

- Variance stabilizing transform :
$\qquad$

$$
2|W|^{1 / 2}(\sqrt{\hat{\rho}}-\sqrt{\rho}) \simeq \mathcal{N}(0,1)
$$

$\qquad$

- We deduce a $1-\alpha(\alpha \in(0,1))$ confidence interval for $\rho$

$$
\mathrm{IC}_{1-\alpha}(\rho)=\left(\sqrt{\hat{\rho}} \pm \frac{z_{\alpha / 2}}{2|W|^{1 / 2}}\right)^{2}
$$

Notes
$\qquad$

$\qquad$
$\qquad$
$\qquad$
$\qquad$
$\qquad$
$\qquad$
$\qquad$
$\qquad$

- We consider three unmarked datasets : japanesepines, swedishpines, finpines.
- Plot the data, estimate the intensity parameter.
- Construct a confidence interval for each of them. Which one is significantly more abundant?
- Judge the assumption of the Poisson model using a GoF test based on quadrats.
$\qquad$
$\qquad$
$\qquad$
$\qquad$
$\qquad$
$\qquad$
$\qquad$
$\qquad$

Notes
$\qquad$

- Assume that $\rho$ is parametrized by a vector $\theta \in \mathbb{R}^{p}(p \geq 1)$. The most well-known model is the log-linear one :

$$
\rho(u)=\rho(u ; \theta)=\exp \left(\theta^{\top} z(u)\right)
$$

where $z(u)=\left(z_{1}(u), z_{2}(u), \ldots, z_{p}(u)\right)$ correspond to known spatial
$\qquad$ functions or spatial covariates.

- $\theta$ can be estimated by maximizing the log-likelihood on $W$ $\qquad$

$$
\begin{aligned}
I_{W}(X, \theta) & =\sum_{u \in X_{W}} \log \rho(u ; \theta)+\int_{W}(1-\rho(u ; \theta)) \mathrm{d} u \\
& =|W|+\underbrace{\sum_{u \in X_{W}} \theta^{\top} z(u)-\int_{W} \exp \left(\theta^{\top} z(u)\right) \mathrm{d} u}_{:=\ell_{W}(X, \theta)} .
\end{aligned}
$$

$\qquad$
$\qquad$

In other words

$$
\widehat{\theta}=\operatorname{Argmax}_{\theta} \ell_{W}(X, \theta)
$$

$\qquad$

- Why would $\widehat{\theta}$ be a good estimate? $\qquad$
Compute the score function $\qquad$

$$
s_{W}(X, \theta)=\nabla \ell_{W}(X, \theta)=\sum_{u \in X_{W}} z(u)-\int_{W} z(u) \underbrace{\exp \left(\theta^{\top} z(u)\right)}_{:=\rho(u)} \mathrm{d} u
$$

$\qquad$

The true parameter $\theta_{0}$ (i.e. $X \sim P_{\theta_{0}}$ ) minimizes the expectation of the score function. Indeed from Campbell formula

$$
E s_{W}(X, \theta)=\int_{W} z(u)\left(\exp \left(\theta_{0}^{\top} z(u)\right)-\exp \left(\theta^{\top} z(u)\right)\right) \mathrm{d} u=0
$$

$$
\text { when } \theta=\theta_{0} \text {. }
$$

- Rathbun and Cressie (1994) showed the strong consistency and the asymptotic normality of $\widehat{\theta}$ as $W \rightarrow \mathbb{R}^{d}$.

Notes

A point pattern giving the locations of 3605 trees in a tropical rain forest Accompanied by covariate data giving the elevation (altitude) $\left(z_{1}\right)$ and slope of elevation $\left(z_{2}\right)$ in the study region.
elevation,21
$\qquad$

$\qquad$
$\qquad$

Assume an inhomogeneous Poisson point process (which is not true, see the next chapter) with intensity

$$
\log \rho(u)=\beta+\theta_{1} z_{1}(u)+\theta_{2} z_{2}(u)
$$

Question : how can we prove that each covariate has a significant influence?

Definitions, Poisson

## (Diggle 2003)

- Idea is to mimic the kernel density estimation to define a nonparametric estimator of the spatial function $\rho$.
- Let $k: \mathbb{R}^{d} \rightarrow \mathbb{R}^{+}$a symmetric kernel with intensity one. Examples of kernels
- Gaussian kernel : $(2 \pi)^{-d / 2} \exp \left(-\|y\|^{2} / 2\right)$.
- Cylindric kernel : $\frac{1}{\pi} \mathbf{1}(\|y\| \leq 1)$.
- Epanecnikov kernel : $\frac{3}{4} \mathbf{1}(|y|<1)\left(1-|y|^{2}\right)$.
- Let $h$ be a positive real number (which will play the role of a bandwidth window), then the nonparametric estimate (with border correction) at the location $v$ is defined as

$$
\widehat{\rho}_{h}(v)=K_{h}(v)^{-1} \sum_{u \in X_{w}} \frac{1}{h^{d}} k\left(\frac{\|v-u\|}{h}\right)
$$

$\qquad$
$\qquad$
$\qquad$
$\qquad$
$\qquad$
$\qquad$
$\qquad$
$\qquad$
$\qquad$
$\qquad$

Notes
$\qquad$
Indeed, using the Campbell formula and a change of variables we can $\qquad$ obtain

$$
\begin{aligned}
\mathrm{E} \widehat{\rho}_{h}(v) & =K_{h}(v)^{-1} \mathrm{E} \sum_{u \in X_{W}} \frac{1}{h^{d}} k\left(\frac{\|v-u\|}{h}\right) \\
& =K_{h}(v)^{-1} \int_{W} \frac{1}{h^{d}} k\left(\frac{\|v-u\|}{h}\right) \rho(u) \mathrm{d} u \\
& =K_{h}(v)^{-1} \int_{\frac{w-v}{h}} k(\|\omega\|) \rho(\omega h+v) \mathrm{d} \omega \\
& \stackrel{\text { hmall }}{\simeq} K_{h}(v)^{-1} \int_{\frac{w-v}{h}} k(\|\omega\|) \rho(v) \mathrm{d} \omega \\
& \simeq \rho(v) .
\end{aligned}
$$

$\qquad$
$\qquad$
$\qquad$
$\qquad$
$\qquad$
$\qquad$

More theoretical justifications and properties and a discussion on the bandwidth parameter and edge corrections can be found in Diggle (2003).

Summary statistics
Modelling and inference

## Objective and classification

Objective $\qquad$

- Define some descriptive statistics for s.p.p. (independently on any model so).
- Measure the abundance of points, the clustering or the repulsiveness of a spatial point pattern w.r.t. the Poisson point process.
$\qquad$
lassification :
- First-order type based on the intensity function.
- Second-order type statistics : pair correlation function, Ripley's K function.
- Statistics based on distances : empy space function $F$, nearest-neigbour $G, J$ function.
(We assume that $\rho$ and $\rho^{(2)}$ exist in the rest of the talk)
$\qquad$
$\qquad$
$\qquad$
$\qquad$
$\qquad$
$\qquad$
$\qquad$
$\qquad$

Notes
$\qquad$
Thanks to Campbell formulae, the estimates of the intensity for a Poisson point process can be used to estimate the intensity of a general spatial point process $X$. In particular
(1) if $X$ is stationary $\widehat{\rho}=N(W) /|W|$ is an estimate of $\rho$.
(2) Non-stationary, parametric estimation of the intensity : if $\rho(u)=\rho(u ; \theta)$ can be used using the "Poisson likelihood", i.e.

$$
I_{W}(X, \theta)=\sum_{u \in X_{W}} \log \rho(u ; \theta)-\int_{W} \rho(u ; \theta) \mathrm{d} u
$$

(3) Non stationary, non-parametric estimation of the intensity (see previous chapter for notation) :

$$
\widehat{\rho}_{h}(u)=K_{h}(u)^{-1} \sum_{v \in X_{w}} \frac{1}{h^{d}} k\left(\frac{\|v-u\|}{h}\right) .
$$

$\qquad$
$\qquad$
$\qquad$
$\qquad$
$\qquad$
$\qquad$
$\qquad$
$\qquad$
$\qquad$

## A simulation example in the stationary case

$\qquad$
We generated $m=10000$ replications of a stationary log-Gaussian Cox processes (Thomas process, $\kappa=50, \sigma=.005$ ) with intensity $\rho=400$. $\qquad$

|  | $W=[0,1]^{2}$ | $W=[0,2]^{2}$ |
| :--- | :--- | :--- |
| Emp. Mean of $\widehat{\rho}$ | 400.4 | 399.5 |
| Emp. Var. of $\widehat{\rho}$ | 1741.4 | 507.4 |

A survey of the estimation of the asymptotic variance of $\widehat{\rho}$ can be found in Prokesova and Heinrich (2010) and references therein.

Notes

We generated $B=1000$ replications of Thomas process with parameters $\kappa=50, \sigma=.005$ and with intensity function

$$
\rho(u)=\exp \left(\beta-\theta u_{1}^{2} u_{2}^{2}\right)
$$

with $\theta=-2$ and $\beta$ adjusted s.t. $\mathrm{EN}(W)=200$ for $W=[0,1]^{2}$ and 800 for $W=[0,2]^{2}$.

$\qquad$
$\qquad$
$\qquad$
$\qquad$
$\qquad$

Then for each replication, $\theta$ is estimated using the "Poisson likelihood"

|  | $W=[0,1]^{2}$ | $W=[0,2]^{2}$ |
| :--- | :--- | :--- |
| Emp. Mean of $\widehat{\theta}$ | -2.03 | -2.01 |
| Emp. Var. of $\widehat{\theta}$ | 0.13 | 0.03 |

[^0]- See Guan (2006), Guan and Loh (2008), Waagepetersen, Guan and Jalilian (2012) and Coeurjolly and Møller (2012) for details and refinements.

## Ripley's K function

## Notes

We assume (for simplicity) the stationarity and isotropy of $X$.

## Definition

The Ripley's $K$ function is literally defined for $r \geq 0$ by $\qquad$

$$
\begin{aligned}
K(r) & =\frac{1}{\rho} \mathrm{E}(\text { number of extra events within distance } r \text { of a randomly chosen event }) \\
& =\frac{1}{\rho} \mathrm{E}(N(B(0, r) \backslash 0) \mid 0 \in X)
\end{aligned}
$$

$\qquad$
$\qquad$

We define the $L$ function as $L(r)=(K(r) / \pi)^{1 / 2}$.
$\qquad$

## Properties

$\qquad$

- Under the Poisson case, $K(r)=\pi r^{2} ; L(r)=r$.
- If $K(r)>\pi r^{2}$ or $L(r)>r$ (resp. $K(r)<\pi r^{2}$ or $\left.L(r)<r\right)$ we suspect clustering (regularity) at distances lower than $r$.
$\qquad$

Notes
$\qquad$

## Definition

$\qquad$
If $\rho$ and $\rho^{(2)}$ exist, then the pair correlation function is defined by
$\qquad$

$$
g(u, v)=\frac{\rho^{(2)}(u, v)}{\rho(u) \rho(v)}
$$

where we set for convention $a / 0=0$ for $a \geq 0$. $\qquad$

$$
g(u, v) \begin{cases}=1 & \text { if } X \sim \operatorname{Poisson}(S, \rho) \\ >1 & \text { for attractive point pattern. } \\ <1 & \text { for repulsive point pattern. }\end{cases}
$$

$\qquad$
$\qquad$

If $S=\mathbb{R}^{d}$ and $X$ is stationary and isotropic, then

$$
g(u, v)=\frac{\rho^{(2)}(\|v-u\|)}{\rho^{2}}=\bar{g}(\|v-u\|
$$

$\qquad$
$\qquad$
$\qquad$
$\qquad$

## Theorem

For stationary and isotropic processes in $S=\mathbb{R}^{d}$

$$
g(r)=\frac{K^{\prime}(r)}{\sigma_{d} r^{d-1}}
$$

$\qquad$
$\qquad$
where $\sigma_{d}=d \omega_{d}$ is the surface area of unit sphere $\mathbb{S}^{d-1}$ in $\mathbb{R}^{d}$. $\qquad$
$\underline{\text { Proof : Using polar decomposition we obtain }}$ $\qquad$

$$
K(r)=\int_{B(0, r)} g(\|u\|) \mathrm{d} u=\int_{0}^{r} \int_{S^{d-1}} t^{d-1} g(t) \mathrm{d} t=\sigma_{d} \int_{0}^{r} t^{d-1} g(t) \mathrm{d} t
$$

$\qquad$
$\qquad$
$\qquad$

Edge corrected estimation of the $K$ function
Notes
$\qquad$
$\qquad$
$\qquad$
$\qquad$
$\qquad$
where $W_{\ominus r}=\{u \in W: B(u, r) \subseteq W\}$ is the erosion of $W$ by $r$.
$\qquad$

- the translation-corrected estimate as

$$
\widehat{K}_{T C}(r)=\frac{1}{\widehat{\rho}^{2}} \sum_{u, v \in X_{w}}^{\neq} \frac{\mathbf{1}(v-u \in B(0, r))}{\left|W \cap W_{v-u}\right|}
$$

where $W_{u}=W+u=\{u+v: v \in W\}$.
Remark : everything extends to 2nd-order reweighted stationary point processes; asymptotic properties depend on mixing conditions,. .

For convenience, we consider only stationary and isotropic point processes.

- Then, the pair correlation function $g(u, v)=g(\|u-v\|)$ can be $\qquad$ estimated using the following edge corrected kernel estimate $\qquad$

$$
\widehat{g}(r)=\frac{1}{\widehat{\rho^{2}}} \sum_{u, v \in X_{w}}^{\neq} \frac{k_{h}(\|v-u\|-r)}{\sigma_{d} r^{d-1}\left|W \cap W_{v-u}\right|}
$$

$\qquad$
where $k_{h}(t)=h^{-d} k(t / h)$.

- Alternatively, we can estimate estimate the derivative of the $K$ function (after smooting using e.g. spline techniques) and define

$$
\widehat{g}(r)=\frac{\widehat{K^{\prime}}(r)}{\sigma_{d} r^{d-1}}
$$

Assume $X$ is stationary (definitions can be extended in the general case)

## Definition

- The empty space function is defined by $\qquad$

$$
F(r)=P(d(0, X) \leq r)=P(N(B(0, r))>0), \quad r>0 .
$$

$\qquad$

- The nearest-neighbour distribution function is $\qquad$

$$
G(r)=P(d(0, X \backslash 0) \leq r \mid 0 \in X)
$$

- $J$-function : $J(r)=(1-G(r)) /(1-F(r)), \quad r>0$.
$\qquad$
- Poisson case : $\forall r>0, F(r)=G(r)=1-e^{-\pi r^{2}}, J(r)=1$.
- $F(r)<F_{\text {pois }}(r), G(r)>G_{\text {pois }}(r), J(r)<1$ : attraction at dist. $<r$.
- $F(r)>F_{\text {pois }}(r), G(r)<G_{\text {pois }}(r), J(r)>1$ : repulsion at dist. $<r$.
$\qquad$

Notes
$\qquad$
As for the $K$ and $L$ functions, several edge corrections exist. We focus here only on the $\qquad$ border correction. We assume that $X$ is observed on a bounded window $W$ with positive volume.

## Definition

- Let $I \subseteq W$ be a finite regular grid of points and $n(I)$ its cardinality. Then, the (border corrected) estimator of $F$ is $\qquad$

$$
\widehat{F}(r)=\frac{1}{n\left(l_{r}\right)} \sum_{u \in I_{r}} \mathbf{1}(d(u, X) \leq r)
$$

$\qquad$
where $I_{r}=I \cap W_{\ominus r}$.

- The (border corrected) estimator of $G$ is

$$
\widehat{G}(r)=\frac{1}{N\left(W_{\ominus r}\right)} \sum_{u \in X \cap W_{\ominus r}} \mathbf{1}(d(u, X \backslash u) \leq r)
$$

$\qquad$

Examples

Notes
$\qquad$
The main objectives of this section are $\qquad$

- to present more realistic models than the too simple Poisson point process to take into account the spatial dependence between points.
- to present statistical methodologies to infer these models.

We can distinguish several classes of models for spatial point processes
(1) point processes based on the thinning of a Poisson point processes, on the superimposition of Poisson point processes. [sometimes hard to relate the stochastic process producing the realization and the physical phenomenon producing the data]
(2) Cox point processes (which include Cluster point processes,... ).
(3) Gibbs point processes.
(9) Determinental point processes.

| Examples | Definitions, Poisson | Summary statistics | Modelling and inference |
| :--- | :--- | :--- | :--- |
| An attempt to classify these models $\ldots$ |  |  |  |
| Model | Allows to model | Are moments <br> expressible <br> in a closed form? | Pensity w.r.t. <br> Poisson? |
| Cox | attraction | yes | no |
| Gibbs | repulsion <br> but also attraction <br> Determinental | no | yes |

$\qquad$
$\qquad$
$\qquad$

This course only focuses on the two first classes of point processes, i.e. on Cox and Gibbs point processes.
$\qquad$

Notes
Definition
$\qquad$

We let $S \subseteq \mathbb{R}^{d}$ throughout this section. $B$ denotes any bounded domain $\subseteq S$. $\qquad$
Definition
Suppose that $Z=\{Z(u): u \in S\}$ is a nonnegative random field so that with probability one, $u \rightarrow Z(u)$ is a locally integrable function. If the conditional distribution of $X$ given $Z$ is a Poisson process on $S$ with intensity function $Z$, then $X$ is said to be a Cox process driven by $Z$
$\qquad$

## Remarks :

$\qquad$

- $Z$ is a random field means that $Z(u)$ is a random variable $\forall u \in S$. $\qquad$
- if $\mathrm{E} Z(u)$ exists and is locally integrable then w.p. $1, Z(u)$ is a locally integrable function

## Proposition

(1) Provided $Z(u)$ has finite expectation and variance for any $u \in S$ $\qquad$

$$
\rho(u)=\mathrm{E} Z(u), \rho^{(2)}(u, v)=\mathrm{E}[Z(u) Z(v)], g(u, v)=\frac{\mathrm{E}[Z(u) Z(v)]}{\rho(u) \rho(v)} .
$$

$\qquad$
(2) The void probabilities are given by $\qquad$

$$
v(B)=\operatorname{Eexp}\left(-\int_{B} Z(u) \mathrm{d} u\right)
$$

for bounded $B \subseteq S$.
Proof : direct consequence of the fact that $X \mid Z$ is a Poisson point process with intensity function $Z$. $\qquad$

| Examples | Definitions, Poisson | Summary statistics |
| :--- | :---: | :--- | Modelling and inference

Notes

## Proposition

Let $A, B$ bounded sets of $S$, then

$$
\operatorname{Cov}(N(A), N(B))=\int_{A} \int_{B} \operatorname{Cov}(Z(u), Z(v)) \mathrm{d} u \mathrm{~d} v+\int_{A \cap B} \mathrm{E} Z(u) \mathrm{d} u
$$

$\qquad$

Consequence :

- In particular, $\operatorname{Var} N(A) \geq \mathrm{E} N(A)$ with equality only when $X$ is a Poisson process. $\qquad$
- $\Rightarrow$ over-dispersion of the counting variables. $\qquad$
Other remarks :
- Most of models have pcf such that $g \geq 1$ (but a few exceptions $\exists$ ).
- If $S=\mathbb{R}^{d}$ and $X$ is stationary and/or isotropic then $X$ is stationary and/or isotropic.
- Explicit expressions of the $F, G$ and $J$ functions in the stationary case are in general difficult to derive.

Definitions, Poisson
Summary statistics

## Definition

A mixed Poisson process is a Cox process where $Z(u)=Z_{0}$ is given by a positive random variable for any $u \in S$, i.e. $X \mid Z_{0}$ follows a homogeneous Poisson process with intensity $Z_{0}$.

- Limited interest ...
- $X$ is stationary and (provided $Z_{0}$ has first two moments)

$$
\rho=\mathrm{E} Z_{0} \quad \text { and } \quad g(u, v)=\frac{\mathrm{E}\left[Z_{0}^{2}\right]}{\mathrm{E}\left[Z_{0}\right]^{2}} \geq 1
$$

$\qquad$
$\qquad$

- The $K$ and $L$ functions are given by

$$
K(r)=\beta \omega_{d} r^{d} \quad \text { and } \quad L(r)=\beta^{1 / d} r \geq r
$$

where $\omega_{d}=|B(0,1)|$ and $\beta=\frac{\mathrm{E}\left[Z_{z}^{2}\right]}{\mathrm{E}\left[Z_{0}\right]^{2}}$.
(recall that $K^{\prime}(r)=d \omega_{d} g(r) r^{d-1}$ ).
$\qquad$
$\qquad$
$\qquad$

Notes

Definition
Let $C$ be a stationary Poisson process on $\mathbb{R}^{d}$ with intensity $\kappa>0$.
Conditional on $C$, let $X_{c}, c \in C$ be independent Poisson processes on $\mathbb{R}^{d}$ where $X_{c}$ has intensity function
$\qquad$

$$
\rho_{c}(u)=\alpha k(u-c)
$$

where $\alpha>0$ is a parameter and $k$ is a kernel (i.e. for all $c \in \mathbb{R}^{d}$,
$u \rightarrow k(u-c)$ is a density function). Then $X=\cup_{c \in C} X_{c}$ is a
Neymann-Scott process with cluster centres $C$ and clusters $X_{c}, c \in C$.

- $X$ is also a Cox process on $\mathbb{R}^{d}$ driven by $Z(u)=\sum_{c \in C} \alpha k(u-c)$.
- Simulating a Neymann-Scott process (on $W$ ) is very simple (if $k$ has compact support $T<\infty$ )
(1) Generate $C \sim \operatorname{Poisson}(W \oplus T, k)$.

2) For each $c \in C$, generate $X_{c} \sim \operatorname{Poisson}\left(W, \rho_{c}\right)$
(3) Concatenate all the $X_{c}$ 's. $\qquad$

- If $k$ has unbounded support, an exact simulation is still possible.

We obtain specific models by choosing specific kernel densities. $\qquad$
(1) the Matérn cluster process where

$$
k(u)=\mathbf{1}(\|u\| \leq R) \frac{1}{\omega_{d} R^{d}}
$$

is the uniform density on the $B(0, R)$.
(2) the Thomas process where

$$
k(u)=\left(\frac{1}{2 \pi \sigma^{2}}\right)^{d / 2} \exp \left(-\frac{\|u\|^{2}}{2 \sigma^{2}}\right)
$$

is the density of $\mathcal{N}\left(0, \sigma^{2} I_{d}\right)$.
When $R$ is small or when $\sigma$ is small, then point pattern exhibit strong attraction.

Notes

- $\kappa$ is the mean number of cluster centres per unit square, $\alpha$ is the mean number of daughters points per cluster.
- $X$ is stationary (since $Z$ is stationary) and is isotropic if $k(u)=k(\|u\|)$.
- Intensity of $X: \rho(u)=\alpha \kappa$.
- The (stationary) pair correlation function is given by $g(u, v)=1+\frac{k * k(v-u)}{\kappa} \geq 1 \quad$ where $\quad k * k(u)=\int k(c) k(v-u+c) \mathrm{d} c$.
- The $F, G$ and $J$ functions are also expressible in terms of $k$. In particular $\qquad$

$$
J(r)=\int k(u) \exp \left(-\alpha \int_{\|v\| \leq r} k(u+v) \mathrm{d} v\right) \mathrm{d} u
$$

whereby we deduce that $\exp (-\alpha) \leq J(r) \leq 1$.

Back to the Thomas process
Recall that $k$ is the density of a $\mathcal{N}\left(0, \sigma^{2} l_{d}\right)$. Applying the previous results, we get (for the pcf)
$\qquad$
$\qquad$
$g(r)=1+\frac{1}{\left(4 \pi \sigma^{2}\right)^{d / 2}} \exp \left(-r^{2} /\left(4 \sigma^{2}\right)\right) / \kappa$

(similar developments can be done for the $K, L, J$ functions and with more work for the Matérn process).

- Inhomogeneous Neymann-Scott processes can be obtained by $\qquad$ replacing the intensity parameter $\kappa$ by a spatial function $\kappa(u)$.
- The natural extension of NS processes is given by shot-noise Cox processes which is a Cox process driven by

$$
Z(u)=\sum_{(c, \gamma) \in \Phi} \gamma k(c, u)
$$

where $k(\cdot, \cdot)$ is a kernel and $\Phi$ is a Poisson point process on $\mathbb{R}^{d} \times(0, \infty)$ with a locally integrable intensity function $\zeta$. (see e.g. Møller and Waagepetersen 2004 for complements).

Notes
$\qquad$

## Definition

Let $X$ be a Cox process on $\mathbb{R}^{d}$ driven by $Z=\exp Y$ where $Y$ is a Gaussian random field. Then, $X$ is said to be a $\log$ Gaussian Cox process (LGCP).

## Remarks :

- we could consider $Z=h(Y)$ for some non-negative function $h$, but the $\exp$ leads to tractable calculations.
- another possibility : using a $\chi^{2}$ field, i.e. $Z(u)=Y_{1}(u)^{2}+\ldots+Y_{m}(u)^{2}$ are the $Y_{i}$ 's are independent Gaussian fields with zero mean.
- LGCP are easy to simulate since the problem is transfered to generate a Gaussian field (which can be handled by several methods)
- The mean and covariance function of $Y$ determine the distribution of $X$.
- In the following we let

$$
m(u)=\mathrm{E} Y(u) \quad \text { and } c(u, v)=\operatorname{Cov}(Y(u), Y(v))
$$

and we focus on the case where $c(u, v)$ depends only on $\|v-u\|$ (covariance function invariant by translation and by rotation). $\qquad$

- Conditions on $c$ are needed to get a covariance function. Among functions satisfying these properties we find:
- the power exponential family satisfies these conditions

$$
c(u, v)=\sigma^{2} r(\|v-u\| / \alpha) \text { with } r(t)=\exp \left(-t^{\delta}\right), t \geq 0
$$

$\qquad$
with $\alpha, \sigma>0 . \delta=1$ is the exponential correlation function; $\delta=1 / 2$ is the stable correlation function ; $\delta=2$ is the $\qquad$
Gaussian correlation function.

- the cardinal sine correlation :

$$
c(u, v)=\sigma^{2} r(\|v-u\| / \alpha) \text { with } r(t)=\frac{\sin (t)}{t}, t \geq 0
$$

$\qquad$

## Proposition

Let $X$ be a LGCP then under the previous notation
(1) the intensition function of $X$ is
$\qquad$

$$
\rho(u)=\exp (m(u)+c(u, u) / 2) .
$$

(2) The pair correlation function $g$ of $X$ is

$$
g(u, v)=\exp (c(u, v))
$$

Proof : based on the fact that for $U \sim \mathcal{N}\left(\zeta, \sigma^{2}\right)$, the Laplace transform of $U$ is $E \exp (t U)=\exp \left(\zeta+\sigma^{2} t / 2\right)$.

- one to one correspondendce between ( $m, c$ ) and $(\rho, g)$.
- If $c$ is translation invariant then $X$ is second order reweighted stationary (stationary if $m$ is constant, and isotropic if in addition $c(u, v)$ depends only on $\|v-u\|)$.

Definitions, Poissor

- pcf for the power exponential family : $\log g(r)=\sigma^{2} \exp \left(-\left(\frac{r}{\alpha}\right)^{\delta}\right), \quad \alpha, \sigma, \delta>0$ $\qquad$
- pcf for the cardinal sine correlation : $\log g(r)=\sigma^{2} \frac{\sin (r / \alpha)}{r / \alpha}, \quad \alpha, \sigma>0$ $\qquad$

Summary statistic
Is likelihood available?

Assume (only here) that $S$ is a bounded domain, then the density of $X_{S}$ w.r.t a Poisson processes with unit rate is given by

$$
f(x)=\mathrm{E}\left[\exp \left(|S|-\int_{S} Z(u) \mathrm{d} u\right) \prod_{u \in x} Z(u)\right]
$$

$\qquad$
for finite point configurations $x \subset S$. Explicit expression of the expectation is usually unknown and the integral may be difficult to calculate.
$\Rightarrow$ MLE is usually impossible to calculate (approximations or Bayesian should be used)

- In most of applications, we only observe the realization of $X$. $\Rightarrow Z$ should be considered as a latent process generating the point process, which is not observed.

Notes
$\qquad$

- Assume we observe the realization of a stationary Cox point process $\qquad$ which belongs to a parametric family with parameter $\theta$ (ex : $\theta=\left(\alpha, \kappa, \sigma^{2}\right)$ for the Thomas process, $\theta=\left(\mu, \alpha, \sigma^{2}\right)$ for a LGCP with exponential correlation function).
- For most of Cox point processes, $\rho=\rho_{\theta}, K=K_{\theta}$ or $g=g_{\theta}$ functions are expressible in a closed form, for instance :
- for a planar $(d=2)$ Thomas process (NS process with Gaussian kernel) : $\rho=\alpha \kappa$ and

$$
g_{\theta}(r)=1+\frac{1}{\sqrt{4 \pi \sigma^{2}}} \exp \left(-r^{2} /\left(4 \sigma^{2}\right)\right) / \kappa \quad \text { and } \quad K_{\theta}(r)=\pi r^{2}+\left(1-\exp \left(-r^{2} /\left(4 \sigma^{2}\right)\right)\right) / \kappa
$$

- for a LGCP with exponential correlation function

$$
\rho=\exp \left(m+\sigma^{2} / 2\right) \quad \text { and } \quad \log g_{\theta}(r)=\sigma^{2} \exp (-r / a / p h a) .
$$

$\qquad$

- Then the idea is then to estimate $\theta$ using a minimum contrast
$\qquad$ approach : i.e. define $\hat{\theta}$ as the minimizer of

$$
\int_{r_{1}}^{r_{2}}\left|\widehat{K}(r)^{q}-K_{\theta}(r)^{q}\right|^{2} \mathrm{~d} r \quad \text { or } \quad \int_{r_{1}}^{r_{2}}\left|\widehat{g}(r)^{q}-g_{\theta}(r)^{q}\right|^{2} \mathrm{~d} r
$$

$\qquad$
$\qquad$
where $\qquad$

- $\widehat{K}(r)$ and $\widehat{g}(r)$ are the nonparametric estimates of $K(r)$ and $g(r)$.
$\qquad$
- where $\left[r_{1}, r_{2}\right.$ ] is a set of $r$ fixed values.
- $q$ is a power parameter (adviced in the literature to be set to $q=1 / 4$ or $1 / 2$ ).
$\qquad$
$\qquad$
$\qquad$

| Examples Definitions, Poisson | Summary statistics Modeling and inference |
| :---: | :---: |
| A short simulation |  |

Notes

- we generated 200 replications of a Thomas process with parameters
$\qquad$ $\kappa=100, \sigma^{2}=10^{-4}$ and $\alpha=5$
- we estimated the parameters $\sigma^{2}$ and $\kappa$ using the minimimum contrast estimat based on the $K$ function.
$\qquad$
$\qquad$
- Then $\alpha$ is estimated using $\widehat{\alpha}=\widehat{\rho} / \widehat{\kappa}$

|  | Parameter $\kappa$ |  |
| :--- | :--- | :--- |
|  | $W=[0,1]^{2}$ | $W=[0,2]^{2}$ |
| Emp. mean | 98.9 | 102.4 |
| Emp. var. | 251.9 | 78.1 |

|  | Parameter $\alpha$ |  |
| :--- | :--- | :--- |
|  | $W=[0,1]^{2}$ | $W=[0,2]^{2}$ |
| Emp. mean | 4.9 | 4.9 |
| Emp. var. | 40.1 | 6.1 |

$\qquad$

|  | Parameter $\sigma^{2}$ |  |
| :--- | :--- | :--- |
|  | $W=[0,1]^{2}$ | $W=[0,2]^{2}$ |
| Emp. mean | $1.01 \times 10^{-4}$ | $9.7 \times 10^{-5}$ |
| Emp. var. | $1.5 \times 10^{-5}$ | $8.2 \times 10^{-6}$ |

- the objective of this section is to introduce a new class of point processes : the class of Gibbs point processes.
- Gibbs point process:
- are mainly used to model repulsion between point (but a few models allows also to produce aggregated models ). That's why this kind of models are widely used in statistical physics to model particles systems.
- are defined (in a bounded domain) by a density w.r.t. a Poisson point process
$\Rightarrow$ very easy to interpret the model and the parameters.
$\qquad$
$\qquad$
$\qquad$
their main drawback : moments are not expressible in a closed form and density known up to a scalar $\Rightarrow$ specific inference methods are required.

Notes
$\qquad$
$\qquad$

- Throughout this chapter : we assume that the point process $X$ is defined in a bounded domain $S \subset \mathbb{R}^{d}(|S|<\infty)$.
- Gibbs point processes defined on $\mathbb{R}^{d}$ are of particular interest :
- in statistical physics because they can model phase transition
- in asymptotic statistics : if for instance we want to prove the convergence of an estimator as the window expands to $\mathbb{R}^{d}$
However, the formalism is more complicated and technical and this is not considered here.
$\Rightarrow$ from now, $X$ is a finite point process in $S$ (bounded) taking values in $N_{f}$ (space of finite configurations of points)

$$
N_{f}=\{x \subset S: n(x)<\infty\}
$$

Definitions, Poiss

## Definition

A finite point process $X$ on a bounded domain $S(0<|S|<\infty)$ is said to be a Gibbs point process if it admits a density $f$ w.r.t. a Poisson point process with unit rate, i.e. for any $F \subseteq N_{f}$
$\qquad$

$$
\begin{aligned}
P(X \in F)= & \sum_{n \geq 0} \frac{\exp (-|S|)}{n!} \times \\
& \int_{S} \ldots \int_{S} \mathbf{1}\left(\left\{x_{1}, \ldots, x_{n}\right\} \in F\right) f\left(\left\{x_{1}, \ldots, x_{n}\right\}\right) \mathrm{d} x_{1} \ldots \mathrm{~d} x_{n}
\end{aligned}
$$

$\qquad$
$\qquad$
where the term $n=0$ is read as $\exp (-|S|) \mathbf{1}(\emptyset \in F) f(\emptyset)$.

- Gpp can be viewed as a perturbation of a Poisson point process. $\qquad$
- $f$ is easily interpretable since it is in some sense a weight w.r.t. a Poisson process. $\qquad$

| Examples | Definitions, Poisson | Summary statistics |
| :--- | :--- | :--- | Modelling and inference

Notes
$\qquad$
$\qquad$
Poisson $(S, \rho)$ (such that $\mu(S)<\infty$ ), we recall that $X$ admits a density w.r.t. to a Poisson point process with unit rate given for any $x \in N_{f}$ by

$$
f(x)=\exp (|S|-\mu(S)) \prod_{u \in x} \rho(u) .
$$

In most of cases, $f$ is specified up to a proportionality $f=c^{-1} h$ where $h: N_{f} \rightarrow \mathbb{R}^{+}$is a known function.
$\Rightarrow c$ is given by

$$
c=\sum_{n \geq 0} \frac{\exp (-|S|)}{n!} \int_{S} \ldots \int_{S} h\left(\left\{x_{1}, \ldots, x_{n}\right\}\right) \mathrm{d} x_{1} \ldots \mathrm{~d} x_{n}=\mathrm{E}[h(Y)]
$$

$\qquad$
$\qquad$
where $Y \sim \operatorname{Poisson}(S, 1)$.

## Definition

The Papangelou conditional intensity for a point process $X$ with density $f$ is defined by
$\qquad$
$\qquad$
for any $x \in N_{f}$ and $u \in S(u \notin x)$, taking $a / 0=0$ for $a \geq 0$.
$\qquad$
$\qquad$

- $\lambda$ does not depend on $c$. $\qquad$
- for Poisson $(S, \rho), \lambda(u, x)=\rho(u)$ does not depend on $x$ !
- $\lambda(u, x) \mathrm{d} u$ can be interpreted as the conditional probability of observing a point in an infinitesimal region containing $u$ of size $\mathrm{d} u$
$\qquad$
$\qquad$ given the rest of $X$ is $x$.

| Examples | Definitions, Poisson | Summary statistics |
| :--- | :--- | :--- | Modelling and inference

Notes
Attraction, repulsion, heredity
$\qquad$

## Definition

We often say that $X$ (or $f$ ) is
$\qquad$

- attractive if $\qquad$
- repulsive if
$\qquad$
$\lambda(u, x) \geq \lambda(u, y)$ whenever $x \subset y$. $\qquad$
- hereditary if $\qquad$

$$
f(x)>0 \Rightarrow f(y)>0 \text { for any } y \subset x
$$

$\qquad$

- if $f$ is hereditary, then $f \Leftrightarrow \lambda$ (one-to-one correspondence).

## Existence of a Gpp in $S(|S|<\infty)$

## Proposition

Let $\phi^{\star}: S \rightarrow \mathbb{R}^{+}$be a function so that $c^{\star}=\int_{S} \phi^{\star}(u) \mathrm{d} u<\infty$. Let $h=c f$, we say that $X$ (or $f$ ) satisfies the
$\qquad$

- local stability property if for any $x \in N_{f}, u \in S$ $\qquad$

$$
h(x \cup u) \leq \phi^{\star}(u) h(x) \Leftrightarrow \lambda(u, x) \leq \phi^{\star}(u) .
$$

$\qquad$

- the Ruelle stability property if for any $x \in N_{f}$ and for $\alpha>0$ $\qquad$

$$
h(x) \leq \alpha \prod_{u \in x} \phi^{\star}(u)
$$

local stability condition $\Rightarrow$ Ruelle stability condition (and that $f$ is hereditary) $\Rightarrow$ existence of point process in $S$.

Proof : the first implication is obvious; for the last one it consists in checking that $c<\infty$.

Notes
$\qquad$
For simplicity, we focus on the isotropic case.

## Definition

A istotropic parwise interaction point process (PIPP) has a density of the
$\qquad$ form (for any $x \in N_{f}$ )
$\qquad$
$\qquad$

$$
f(x) \propto \prod_{u \in x} \phi(u) \prod_{\{u, v\} \subseteq x} \phi_{2}(\|v-u\|)
$$

$\qquad$
where $\phi: S \rightarrow \mathbb{R}^{+}$and $\phi_{2}: \mathbb{R}_{*}^{+} \rightarrow \mathbb{R}+$.

- If $\phi$ is constant (equal to $\beta$ ) then the Gpp is said to be homogeneous (note that $\prod_{u \in x} \phi(u)=\beta^{n(x)}$ ).
$\qquad$
- $\phi_{2}$ is called the interaction function.
- this class of models is hereditary
- $f$ is repulsive if $\phi_{2} \leq 1$, in which case the process is locally stable if $\int_{S} \phi(u) \mathrm{d} u$.

Strauss point process
Among the class of PIPP, the main example is the Strauss point process defined by $\qquad$

$$
f(x) \propto \beta^{n(x)} \gamma^{s_{R}(x)} \quad \lambda(u, x)=\beta \gamma^{t_{R}(u, x)}
$$

where $\beta>0, R<\infty$, where $s_{R}(x)$ is the number of $R$-close pairs of points in $x$ and $t_{R}(u, x)=s_{R}(x \cup u)-s_{R}(x)$ is the number of $R$-close neighbours of $u$ in $x$

$$
s_{R}(x)=\sum_{\{u, v\} \in x} 1(\|v-u\| \leq R) \text { and } t_{R}(u, x)=\sum_{v \in x} \mathbf{1}(\|v-u\| \leq R)
$$

$\qquad$

The parameter $\gamma$ is called the interaction parameter :

- $\gamma=1$ : homogeneous Poisson point process with intensity $\beta$.
- $0<\gamma<1$ : repulsive point process.
- $\gamma=0$ : hard-core process with hard-core $R$; the points are prohibited from being closer han $R$.
- $\gamma>1$ : the model is not well-defined (if there exists a set $A \subset S$ with $|A|>0$ and $\operatorname{diam}(A) \leq R$, then $\left.c>\sum_{n \geq 0} \frac{(\beta|A|)^{n}}{n!} \gamma^{n(n-1) / 2}=\infty\right)$.

## Definition

A Gibbs point process $X$ has a finite range $R$ if the Papangelou $\qquad$
conditional intensity satisfies
$\qquad$

$$
\lambda(u, x)=\lambda(u, x \cap B(u, R)) .
$$

$\qquad$

- the probability to insert a point $u$ into $x$ depends only on some neighborhood of $u$.
- this definition is actually more general and leads to the definition of Markov point process (omitted here to save time).
$\qquad$
$\qquad$
- interesting property when we want to deal with edge effects.
- Finite range of the Strauss point process $=R$.
$\qquad$
$\qquad$

Notes
$\qquad$

- Strauss point process : $\phi_{2}(r)=\gamma^{1(r \leq R)}$. $\qquad$
- Piecewise Strauss point process: $\qquad$

$$
\phi_{2}(r)=\gamma_{1}^{1\left(r \leq R_{1}\right)} \gamma_{2}^{1\left(R_{1}<r \leq R_{2}\right)} \ldots \gamma_{p}^{1\left(R_{p-1}<r \leq R\right)}
$$

$$
\text { with } \gamma_{i} \in[0,1] \text { and } 0 \leq R_{1}<\ldots<R_{p}=R<\infty \text { (finite range } R \text { ). }
$$

- Overlap area process:

$$
\phi_{2}(r)=\gamma^{|B(u, R / 2) \cap B(v, R / 2)|}
$$

with $r=\|v-u\|$ with $\gamma \in[0,1]$ (finite range $R$ ).

- Lennard-Jones process:

$$
\phi_{2}(r)=\exp \left(\alpha_{1}(\sigma / r)^{6}-\alpha_{2}(\sigma / r)^{12}\right)
$$

with $\alpha \geq 0, \alpha_{2}>0, \sigma>0$ (well-known example used in statistical physics, not locally stable but Ruelle stable) (infinite range).

- Geyer's triplet point process :

$$
f(x) \propto \beta^{n(x)} \gamma^{s_{R}(x)} \delta^{u_{R}(x)}
$$

$\beta>0, s_{R}(x)$ is defined as in the Strauss case and $\qquad$

$$
u_{R}(x)=\sum_{\{u, v, w\}} \mathbf{1}(\|v-u\| \leq R,\|w-v\| \leq R,\|w-u\| \leq R)
$$

$\qquad$

- (i) $\gamma \in[0,1]$ and $\delta \in[0,1]$ : locally stable, repulsive, finite range $R$.
- (ii) $\gamma>1$ and $\delta \in(0,1)$ : locally stable, neither attractive nor $\qquad$ repulsive, finite range $R$.

Notes
$\qquad$

- Area-interaction point process :

$$
f(x) \propto \beta^{n(x)} \gamma^{-\left|U_{x, R}\right|}
$$

$\qquad$
$\qquad$
where $U_{x, R}=\cup_{u \in x} B(u, R), \beta>0$ and $\gamma>0$. It is attractive $\qquad$ for $\gamma \geq 1$ and repulsive for $0<\gamma \leq 1$. In both cases, it is locally stable since

$$
\lambda(u, x)=\beta \gamma^{-\left|B(u, R) \backslash \cup_{v \in x: \| v-u \mid \leq 2 R} B(v, R)\right|}
$$

satisfies $\lambda(u, x) \leq \beta$ when $\gamma \geq 1$ and $\lambda(u, x) \leq \beta \gamma^{-\omega_{d} R^{d}}$ in the other case. (finite range $2 R$ )

The following result is also a characterization of a Gibbs point process.

## Georgii-Nguyen-Zeissin Formula

Let $X$ be a finite and hereditary Gibbs point process defined on $S$. Then,
$\qquad$
for any function $h: S \times N_{f} \rightarrow \mathbb{R}^{+}$, we have $\qquad$

$$
\mathrm{E}\left[\sum_{u \in X} h(u, X \backslash u)\right]=\int_{S} \mathrm{E}[h(u, X) \lambda(u, X)] \mathrm{d} u
$$

Proof : we know that $\mathrm{Eg}(X)=\mathrm{E}[g(Y) f(Y)]$ where $f$ is the density of a Poisson point process with unit rate $Y$. Apply this to the function $g(X)=\sum_{u \in X} h(u, X \backslash u)$

$$
\begin{aligned}
\mathrm{E}[g(X)] & =\mathrm{E}\left[\sum_{u \in Y} h(u, Y \backslash u) f(Y)\right] \\
& =\int_{S} \mathrm{E}[h(u, Y) f(Y \cup u)] \mathrm{d} u \quad \text { from the Slivnyak-Mecke Theorem } \\
& =\int_{S} \mathrm{E}[h(u, Y) f(Y) \lambda(u, Y)] \mathrm{d} u \quad \text { since } X \text { is hereditary } \\
& =\int_{S} \mathrm{E}[h(u, X) \lambda(u, X)] \mathrm{d} u .
\end{aligned}
$$

$\qquad$
$\qquad$
$\qquad$
$\qquad$
$\qquad$
$\qquad$

Notes
$\qquad$

## Proposition

(1) The intensity function is given by
$\qquad$

$$
\rho(u)=\mathrm{E}[\lambda(u, X)] .
$$

$\qquad$
(2) The second order intensity function is given by
$\qquad$
$\qquad$

$$
\rho^{(2)}(u, v)=\mathrm{E}[\lambda(u, X) \lambda(v, X)]
$$

- can be deduced from the GNZ formula.
$\qquad$
- Except for the Poissonian case, moments are not expressible in a closed form, e.g.
$\qquad$
rosed torm, e.g
$\qquad$

$$
\rho(u)=\frac{1}{c} \sum_{n \geq 0} \frac{\exp (-|S|)}{n!} \int_{S} \cdots \int_{S} \lambda\left(u,\left\{x_{1}, \ldots, x_{n}\right\}\right) h\left(\left\{x_{1}, \ldots, x_{n}\right\}\right) \mathrm{d} x_{1} \ldots \mathrm{~d} x_{n} .
$$

- Approximations can be obtained using a Monte-Carlo approach or using a saddle-point approximation (very recent).
efinitions, Pois
- we observe a realization of $X$ on $W=S(|S|<\infty$; edge effects $\qquad$ occur when $W \subset S$ ) of a parametric Gibbs point process with density which belongs to a parametric family of densities $\left(f_{\theta}=h_{\theta} / c_{\theta}\right)_{\theta \in \Theta}$ for $\Theta \subset \mathbb{R}^{p}$.
- Problem : estimate the parameter $\theta$ based on a single realization.
- MLE approach : the log-likelihood is $\ell_{W}(x ; \theta)=\log h_{\theta}-\log c_{\theta}$
$\qquad$

Pbm : Given a model $h_{\theta}$ can be computed but $c_{\theta}$ cannot be $\qquad$ evaluated even for a single value of $\theta$; asymptotic properties are only partial.
$\Rightarrow$ several solutions exist
(1) Approximate $c_{\theta}$ using a Monte-Carlo approach.
(2) Bayesian approach, importance sampling method (to estimate a ratio of normalizing constants).
(3) Combine the MLE with the Ogata-Tanemura approximation.
(9) Find another method which does not involve $c_{\theta}$.
$\qquad$
$\qquad$
$\qquad$
$\qquad$
Pseudo-likelihood

Notes
$\qquad$
$\qquad$

- To avoid the computation of the normalizing constant, the idea is to compute a likelihood based on conditional densities

$$
P L_{W}(x ; \theta)=\exp (-|W|) \lim _{i \rightarrow \infty} \prod_{j=1}^{m_{i}} f\left(x_{A_{i j}} \mid x_{W \backslash A_{i j}} ; \theta\right)
$$

where $\left\{A_{i j}: j=1, \ldots, m_{i}\right\} i=1,2, \ldots$ are nested subdivisions of $W$.
$\qquad$
$\qquad$
$\qquad$
$\qquad$

- By letting $m_{i} \rightarrow \infty$ and $m_{i} \max \left|A_{i j}\right|^{2} \rightarrow 0$ as $i \rightarrow \infty$ and taking the log, Jensen and Møller (91) obtained

$$
L P L_{W}(x ; \theta)=\sum_{u \in x_{W}} \lambda(u, x \backslash u ; \theta)-\int_{W} \lambda(u, x ; \theta) \mathrm{d} u
$$

$\qquad$
$\qquad$
$\qquad$
$\qquad$

## Comments on the Pseudo-likelihood

The MPLE is the estimate $\widehat{\theta}$ maximizing

$$
L P L_{W}(x ; \theta)=\sum_{u \in x_{W}} \log \lambda(u, x \backslash u ; \theta)-\int_{W} \lambda(u, x ; \theta) \mathrm{d} u
$$

$\qquad$
$\qquad$
(1) Independent on $c_{\theta}$, so the $L P L$ is up to an integral discretization and up to edge effects very to compute.
$\qquad$
(2) If $X$ has a finite range $R$, then since $x$ is observed in $W$, we can replace $W$ by $W_{\ominus R}$ so that for instance $\lambda(u, x ; \theta)$ can always be computed for any $u \in W_{\ominus R}$ (border correction)
(3) If $\log \lambda(u, x ; \theta)=\theta^{\top} v(u, x)$ (exponential family - class of all examples presented before), then LPL is a concave function of $\theta$.
$\qquad$
under suitable conditions $\widehat{\theta}$ is a consistent estimate and satisfies a
$\qquad$ CLT (and a fast covariance estimate is available) as the window $W$ expands to $\mathbb{R}^{d}$. [Jensen and Künsch'94, Billiot Coeurjolly and Drouilhet'08-'10, Coeurjolly and Rubak'12].
$\qquad$
$\qquad$
$\qquad$
$\qquad$

| Examples | Definitions, Poisson | Summary statistics | Modelling and inference |
| :--- | :--- | :--- | :--- |
| Simulation example |  |  |  |

Notes

We generated 100 replications of Strauss point processes (a border correction was applied) :
(1) $\bmod 1: \beta=100, \gamma=0.2, R=.05$.
(2) $\bmod 2: \beta=100, \gamma=0.5, R=.05$.

Estimates of $\beta$
$W=[0,1]^{2} \quad W=[0,2]$

 | $\bmod 2$ | 99.28 | $(20.48)$ | 98.21 | $(8.53)$ |
| :--- | :--- | :--- | :--- | :--- | $\begin{array}{lllll}\bmod 1 & 0.20 & (0.09) & 0.21 & (0.06) \\ \bmod 2 & 0.52 & (0.19) & 0.51 & (0.09)\end{array}$

$\qquad$
$\qquad$
$\qquad$
$\qquad$
$\qquad$
$\qquad$
$\qquad$
$\qquad$
$\qquad$
$\qquad$

- Denote for any function $h$ (eventually depending on $\theta$ )
$L_{W}(X, h ; \theta)=\sum_{u \in X_{W}} h(u, X \backslash u ; \theta)$ and $R_{W}(X, h ; \theta)=\int_{W} h(u, X ; \theta) \lambda(u, X ; \theta) \mathrm{d} u$
$\qquad$
- The GNZ formula states : $\mathrm{E}\left[L_{W}(X, h ; \theta)\right]=\mathrm{E}\left[R_{W}(X, h ; \theta)\right]$.
- Idea : if $\theta$ is a $p$-dimensional vector, $\qquad$
(1) choose $p$ test function $h_{i}$ and define the contrast

$$
U_{W}(X, \theta)=\sum_{i=1}^{p}\left(L_{W}(X, h ; \theta)-R_{W}(X, h ; \theta)\right)^{2}
$$

(2) Define $\widetilde{\theta}^{T F}=\operatorname{argmin}_{\theta} U_{W}(X, \theta)$.

| Examples | Definitions, Poisson |
| :--- | :--- |
| Takacs-Fiksel | (2) |

General comments :

- like the MPLE :
- independent of $c_{\theta}$, border correction possible in case of $X$ has a finite range
- consistent and asymptotically Gaussian estimate (Coeurjolly et al.'12).
- Another advantage : interesting choices of test functions cal least to a decreasing of computation time.
$\mathrm{Ex}: h_{i}(u, X)=n\left(B\left(u, r_{i}\right)\right) \lambda^{-1}(u, X ; \theta) \Rightarrow R_{W}$ independent of $\theta$.
$\qquad$
$\qquad$
- Actually : MPLE $=$ TFE with $h=\left(h_{1}, \ldots, h_{p}\right)^{\top}=\lambda^{(1)}(\cdot, \cdot ; \theta)$. Indeed (assume $\log \lambda(u, X ; \theta)=\theta^{\top} v(u, X)$ (for simplicity)

$$
\nabla L P L_{W}(X ; \theta)=\sum_{u \in X_{W}} v(u, X \backslash u)-\int_{W} v(u, X) \lambda(u, X ; \theta) \mathrm{d} u
$$

$\qquad$
$\qquad$
$\qquad$
$\qquad$
$\qquad$
$\qquad$
$\qquad$
$\qquad$

Recall that the Papangelou conditional intensity of a Strauss point process is $\qquad$

$$
\lambda(u, X)=\beta \gamma^{t_{R}(u, X)} \text { with } t_{R}(u, X)=\sum_{v \in X} 1(\|v-u\| \leq R)
$$

$\qquad$

Choose $h_{1}(u, X)=\mathbf{1}(n(B(u, R)=0))$ and
$h_{2}(u, X)=\mathbf{1}(n(B(u, R)=1))$, then
$\qquad$

- $L_{W}\left(X, h_{1}\right)=L_{1}$ and $R_{W}\left(X, h_{1}\right)=\beta \int_{W} \mathbf{1}(n(B(u, R)=0))=\beta I_{1}$.
- $L_{W}\left(X, h_{2}\right)=L_{2}$ and $R_{W}\left(X, h_{2}\right)=\beta \gamma \int_{W} \mathbf{1}(n(B(u, R)=1))=\beta I_{2}$.

Then, the contrast function rewrites $\qquad$

$$
U_{W}(X)=\left(L_{1}-\beta l_{1}\right)^{2}+\left(L_{2}-\beta \gamma I_{2}\right)^{2}
$$

$\qquad$
which leads to the explicit solution

$$
\widehat{\beta}=\frac{L_{1}}{I_{1}} \quad \text { and } \widehat{\gamma}=\frac{L_{2}}{l_{2}} \times \frac{I_{1}}{L_{1}} .
$$

$\qquad$
$\qquad$

| Examples | Definitions, Poisson | Summary statistics |
| :--- | :--- | :--- | Modelling and inference

Notes

## Other parametric approaches

- Variational approach : (Baddeley and Dereudre'12)
- Method based on a logistic regression likelihood (Baddeley, Coeurjolly, Rubak, Waagepetersen'13).

## Model fitting :

- Monte-Carlo approach : we can compare a summary statistic e.g. L with $L_{\widehat{\theta}}$.
Pbm : $L_{\theta}$ not expressible in a closed form and must be approximated.
- We can still use the GNZ formula : given a test function $h$, we can construct

$$
L_{W}(X, h ; \widehat{\theta})-R_{W}(X, h ; \widehat{\theta})=: \operatorname{Residuals}(\mathrm{X}, \mathrm{~h}) .
$$

$\qquad$
If the model is correct, then Residuals( $\mathrm{X}, \mathrm{h}$ ) should be close to $\qquad$

## General Conclusion

## Notes

## The anaysis of spatial point pattern

- very large domain of research including probability, mathematical statistics, applied statistics $\qquad$
- own specific models, methodologies and software(s) to deal with.
- is involved in more and more applied fields : economy, biology, physics, hydrology, environmetrics,...

## Still a lot of challenges

$\qquad$

- Modelling : the "true model", problems of existence, phase transition.
- Many classical statistical methodologies need to be adapted (and proved) to s.p.p. : robust methods, resampling techniques, multiple
$\qquad$ hypothesis testing.
- High-dimensional problems : $S=\mathbb{R}^{d}$ with $d$ large, selection of variables, regularization methods,... $\qquad$
- Space-time point processes.

Notes
$\qquad$
$\qquad$
$\qquad$
$\qquad$
$\qquad$
$\qquad$
$\qquad$
$\qquad$
$\qquad$
$\qquad$

[^0]:    - Asymptotic results are more awkward to derive and depend on mixing coefficients of the spatial point process $X$.
